Abstract

Background: My E-Diary for Activities and Lifestyle (MEDAL) is a web-based time-use diary developed to assess the diet and movement behaviors of Asian school children.

Objective: This study aims to determine the accuracy of MEDAL in assessing the dietary intake of Malaysian school children, using photographs of the children's meals taken by their parents as an objective reference.

Methods: A convenience sample of 46 children aged 10 to 11 years recorded their daily meals in MEDAL for 4 days (2 weekdays and 2 weekend days). Their parents took photographs of the meals and snacks of their children before and after consumption during the 4-day period and sent them along with a brief description of food and drinks consumed via an instant SMS text messaging app. The accuracy of the children's reports of the food they had consumed was determined by comparing their MEDAL reports to the photographs of the food sent by their parents.

Results: Overall, the match, omission, and intrusion rates were 62% (IQR 46%-86%), 39% (IQR 16%-55%), and 20% (IQR 6%-44%), respectively. Carbohydrate-based items from the food categories "rice and porridge"; "breads, spreads, and cereals"; and "noodles, pasta, and potatoes" were reported most accurately (total match rates: 68%-76%). "Snack and dessert" items were omitted most often (omission rate: 54%). Furthermore, side dishes from "vegetables and mushrooms," "eggs and tofu," "meat and fish," and "curry" food groups were often omitted (omission rates: 42%-46%). Items from "milk, cheese, and yogurt"; "snacks and desserts"; and "drinks" food groups intruded most often (intrusion rates: 37%-46%). Compared to the items reported by the boys, those reported by the girls had higher match rates (69% vs 53%) and lesser omission rates (31% vs 49%; *P*=.03, respectively).

Conclusions: In conclusion, children aged 10 to 11 years can self-report all their meals in MEDAL, although some items are omitted or intruded. Therefore, MEDAL is a tool that can be used to assess the dietary intake of Malaysian school children.

Introduction

Background

Healthy dietary patterns developed during childhood and adolescence may track into adulthood [1]. Understanding children's dietary patterns is crucial when guiding them to develop healthy eating habits from an early age. However, measuring the diets of school children has always been challenging, as doing so relies on the children's cognitive abilities and abilities to recall dietary intake as well as estimate and indicate portion size [2,3]. While parents can be the primary proxy reporter, they may not be aware of what their child consumes away from home [4]. When children are aged approximately 7 to 8 years, their ability to recall without assistance slowly develops but only for food consumed in the past 24 hours [5], while their ability to remember and estimate portion size is still limited [6]. A study conducted in Malaysia showed that children aged 7 to 9 years can self-report their dietary intake for lunch accurately, without proxy assistance [7]. At the age of 8 to 12 years, children can self-report food intake as reliably as their parents [8]. However, self-reporting of food intake is tedious and time-consuming, which sometimes hamper the retrieval of dietary information from children [9]. Assessment tools that are intuitive, quick and simple to use, flexible, fun, engaging, nonintrusive, and age-appropriate can elicit the cooperation of children [9]. Therefore, to encourage and motivate children to self-report dietary assessment protocol, a novel assessment method may enhance the recruitment and completion rates while maintaining an acceptable level of data accuracy [2,10].

Children may find technology-based dietary assessment methods more attractive and appealing than paper-based methods [11]. The web-based dietary assessment method has proved to be a practical way of assessing children's dietary intake [12,13]. In Singapore, a web-based time-use diary, My E-Diary for Activities and Lifestyle (MEDAL), has been developed to assess the diet and movement behaviors of school children aged ≥10 years [14]. MEDAL includes food options that are popular with the major ethnic groups in Asia and also captures information on food portions, location of activities, and concurrent activities performed by the children [14]. As Malaysia shares a border with Singapore and the Malaysian population exhibits similar food preferences and lifestyle behaviors, it is thought that MEDAL can be used by them. Therefore, MEDAL has been customized for Malaysian school children, with the addition of typical foods and beverages, as well as various activities practiced by Malaysian school children (eg, Solat [Muslim prayer], standing prayer, sitting or kneeling prayer, tuition classes and music lessons, track-and-field activities, and exercise).

The reference method in validating self-reported dietary intake is direct observation, where the agreement rates (match, omission, and intrusion rates) among direct observation, web-based food questionnaires [15,16], and web-based food records [17] are compared. This method provides precise information on the types and amount of food intake, with acceptable accuracy and good reliability [18]. However, these validation studies, which use direct observation as a reference method, only validate a single meal, while validation studies should include all meals, as the food items consumed vary with meal types, locations of consumption, and options available. The previous study conducted in Singapore [14] demonstrated that children could use MEDAL to self-report food intake for 1 meal during school recess but did not determine the accuracy of MEDAL to self-report food intake for all meals.

In addition, direct observation was usually conducted by trained researchers who had undergone extensive training in the visual estimation of food consumption [18]. Therefore, direct observation can be labor-intensive and subject to reporting errors by the observer. In addition, direct observation may not be feasible during situations such as the COVID-19 pandemic when movement restriction or physical distancing hinders researchers from directly observing the children's food intake. However, while children were restricted from attending school, their parents were able to observe their children's food intake. To minimize the parents' burden as proxy reporters through direct observation, food photography by parents was adopted in this study as an objective measure to determine the accuracy of MEDAL in assessing the dietary intake of school children.

Objective

With this background, this study aimed to determine the accuracy of MEDAL in assessing the dietary intake of Malaysian school children, using photographs of their children's meals taken by parents as objective references.

Methods

Ethical Considerations

The protocol of this study was approved by the Universiti Kebangsaan Malaysia Research Ethics Committee (JEP-2019-307). Permission to conduct the study was obtained from the Ministry of Education, Malaysia; the relevant state education departments; and the school principals. The school children participating in the study were provided with informed consent forms to obtain permission from their parents before the commencement of the study.

Study Participants

This study was conducted in April 2021 (study 1) and October to December 2021 (study 2) during the COVID-19 pandemic. A total of 53 children were recruited using convenience sampling, with 25 (47%) children from 2 primary schools for study 1 and 28 (53%) children from 3 primary schools for study 2. The study 1 students attended school in person, while the study 2 students attended classes online at home due to the implementation of movement control orders.

Primary school children aged 10 to 11 years were recruited for this study. Students were eligible if they understood Malay, English, or Chinese and had access to a computer, laptop, or tablet with internet connectivity. In addition, their parents had to own a smartphone with an internet connection to take food photos before and after meals and send them to us via an instant SMS text messaging app (eg, WhatsApp or Telegram). Information on the participants' accessibility to electronic devices with internet access at home and their parents' accessibility to a smartphone with internet access were obtained in the consent form.

Study Procedures

MEDAL Web-Based App

MEDAL (National University of Singapore) is a self-administered, web-based time-use diary that captures the diet and activities of school children aged 10 to 12 years in the Asian context [14]. MEDAL was customized for use among Malaysian school children by translating the text into the Malay and Chinese languages and adding food and drinks that were consumed and activities that were performed typically by Malaysian school children. Children were requested to record daily activities from the time they woke up until bedtime for 4 days. They could choose from 6 broad categories of activities: "wash up/brush teeth," "eat and drink," "traveling," "nap/sleep," "sitting/praying activities," and "active activities."

When children recorded an "eat and drink" activity, they could choose the food and drink items they had consumed from 14 main food and drink groups (eg, breads, spreads, and cereals; curry or curry with coconut gravy; drinks; eggs and tofu; fast food; fruits; meat and fish; milk, cheese, and yogurt; vegetables and mushrooms; noodles, pasta, and potatoes; rice and porridge; snacks and desserts; soups; and supplements). For each food and drink item selected, the children also chose the portion size from 4 pictorial options (presented simultaneously) that best matched the amount consumed [14]. The children could use the "others" textbox if the items consumed were not listed in MEDAL and reported the amount consumed from the following 4 options: 1/2 portion, 1 portion, 1.5 portions, or 2 portions [14].

Demonstration of the Use of MEDAL

In study 1, we conducted a demonstration session in the computer laboratories of the participants' schools. We demonstrated how to log in and record diet and daily activities in MEDAL. After the demonstration, the participants recorded what they consumed and did for 2 weekdays and 2 weekend days. For the second day, the participants were allowed to use school computers during recess to record their diet and activities if they had not completed the first day's recording, after which they would continue recording at home for the remaining days.

In study 2, students could not attend school physically because of a government-imposed movement control order. Thus, face-to-face demonstration sessions for the students were not possible, and web-based demonstration sessions via Google Meet (Google LLC) were conducted instead. We demonstrated how to log in and record diet and activity entries with a prerecorded video. After the demonstration, the participants continued recording their entries at home using their own tablets, laptops, or computers.

Food Photography by Parents

Before the commencement of the study, all parents from both study periods were provided with standard guidelines on how to photograph the food their children were going to consume. To ensure compliance, reminders to take food photographs were sent to the parents' SMS text messaging app twice a day before breakfast and dinner. During the 4 days of the study period, parents were required to photograph all the food and drinks consumed by their children, before and after consumption, for all meals, that is, breakfast, lunch, dinner, and snacks.

In study 1, the parents photographed all meals consumed by the children during nonschool times, while we photographed the school recess meal for the non-Muslim participants. Most Muslim participants (16 out of 25, 64% children) could not eat and drink during school recess, as study 1 was conducted during the Ramadhan fasting period.

In study 2, the parents photographed all meals consumed by the children as the children attended classes at home. Every day, parents sent photographs of the food and drinks before and after consumption, along with a brief description of what had been consumed, to us via an instant SMS text messaging app such as WhatsApp (Meta Platforms) or Telegram (Telegram FZ LLC). Figure 1 presents photographs with a description of the food and drink consumed. Figure 2 presents examples of food photographs for breakfast, lunch, dinner, and snacks taken before and after consumption.

Figure 1. Photographs of the food taken before and after consumption, with a text description of the food consumed.

Lunch 1:12 pm

Chicken rice and cucumber 1:12 pm

1:13 pm

Figure 2. Examples of food photographs taken by parents before and after consumption of breakfast, lunch, dinner, and snacks.

Anthropometric Measurements

In study 1, we recorded children's anthropometric measurements at schools. Height was measured using a portable Seca stadiometer (Seca 213, SECA, Hamburg, Germany) and weight using a Seca weighing scale (Seca 803, SECA, Hamburg, Germany). In study 2, anthropometric measurements of children were self-reported by parents due to the movement control order. Parents were asked to submit their children's height and weight. Guidelines on how to make proper measurements were provided to the parents. School records of the participants' most recent height and weight were used if home measurements were impossible.

BMI was calculated from body mass (kg) divided by the square of height (m^2). BMI for age was calculated based on the World Health Organization growth reference for individuals aged 5 to 19 years [19]. *Z* scores for BMI for age were determined using the World Health Organization AnthroPlus (version 1.0.3) [20] software. The cutoff value for BMI for age for underweight was <−2 to −3 SD, overweight was >1 SD, and obesity was >2 SD. Values within > −2 SD and <1 SD were classified as normal weight.

Data Processing

The accuracy of the child-reported food items was determined by comparing the self-reports of meal intake in MEDAL with the objective measures of food photographs taken by parents. Parents took photographs of the food before and after consumption for each meal taken by their children in the 4 days corresponding to the days of record in MEDAL. The meals included breakfast, lunch, dinner, and snacks or desserts. The food photographs taken by the parents for each meal were matched with the self-report by the children in MEDAL. The food photographs that matched the MEDAL diet entries for a meal were used for analysis. Missing food photographs or MEDAL entries were excluded from the analysis.

Food items in MEDAL include single items (eg, drinks, snacks, or desserts); composite meals consisting of staple food items with ingredients from the various food groups (eg, fried noodles); and components of mixed meals consisting of staple food items (eg, white rice) with side dishes (eg, steamed meat) [21]. Food items were classified into 14 food groups.

The accuracy of self-reported meals was determined by comparing the self-reported food items in MEDAL to the food items depicted as consumed in the photographs sent by the parents before and after consumption and classifying them as matches, omissions, and intrusion rates [17].

An “exact match” refers to a situation in which the food item self-reported by a child in MEDAL matches, to the maximum extent, the food item depicted in the reference photo provided by the parent. An “approximate match” refers to a situation in which the food item self-reported by a child in MEDAL matches with slight variations to the food item depicted in the reference photo. For example, a parent provides a reference photo of a glass of full cream milk their child had consumed. However, the child self-reported having consumed low-fat milk in MEDAL. The 2 food items are not identical but are recognized as similar, as they belong to the milk category. An “intrusion” refers to food items that are self-reported by a child in MEDAL but are not depicted in the reference photo, while an “omission” refers to food items that are depicted in reference photos but are not self-reported by the child in MEDAL. For instance, if a child self-reported consuming noodles in MEDAL, but this consumption was not observed in the reference photo provided by parents, this would be considered an intrusion. In contrast, if the reference photo showed that the child had consumed white rice, but the child did not self-report any food or drinks, this would be classified as an omission.

The formulas for calculating the match, intrusion, and omission rates are as follows [17]:

Statistical Analysis

Descriptive statistics was used to summarize the characteristics of participants. The data were not normally distributed; therefore, the Mann-Whitney *U* test was used to test the differences in age between study 1 and study 2 participants. Pearson χ^2 test and Fisher exact test were performed to compare the characteristics of study 1 and study 2 participants. The accuracy of self-reported food items was determined and expressed as median match rate (%), intrusions rate (%), and omissions rate (%). Furthermore, the Mann-Whitney *U* test was used to determine the difference in match, intrusion, and omission rates between the boys and girls. Kruskal-Wallis test was used to compare the median match, intrusion, and omission rates among different meals; then, the Bonferroni post hoc Mann-Whitney *U* test was used to identify the significant paired groups among the different meals. The match, omission, and intrusion rates by food group were presented as percentages (%). Statistical analysis was performed using the SPSS Statistics (version 25.0; IBM Corp) [22]. A significance level of $P<.05$ (95% CI) was adopted.

Results

Overview

Flowcharts of participants from both study periods are presented in Multimedia Appendix 1. A total of 53 students were recruited for both study periods, with 25 (47%) children in study 1 and 28 (53%) children in study 2. However, after excluding children who did not complete MEDAL or whose parents did not provide any food photographs, only 46 (87%) children were included in the analysis. All food photographs for all meals sent over the 4 days that corresponded to the MEDAL diet entries were included in the analysis. Only the food photographs or MEDAL diet entries of the eating occasions that were missing were excluded from the analysis.

Overall, 65% (30/46) of the participants were girls, 30% (14/46) were overweight and obese, and 82% (38/46) completed 3 to 4 days of recording in MEDAL (P=.76, P=.60, and P=.22, respectively; Table 1). However, a significant association was found among the ethnic groups between study 1 and study 2 (P=.004). A higher proportion of Malays (ethnic majority group) was found in study 1 than in study 2. This was because study 1 participants were recruited from national-type schools, while study 2 participants were recruited from national-type and Chinese schools. The median age of children in study 2 (median 10.8, IQR 10.56-11.26 years) was significantly higher than the median age of children in study 1 (median 10.2, IQR 9.9-10.4 years; $P<.001$). The higher median age of children in study 2 was due to study 2 being conducted near the end of the year. Differences in sex, weight status, and the number of days of MEDAL completion between participants in study 1 (21/46, 46%) and study 2 (25/46, 54%) were not significant (P=.76, P=.60, and P=.22, respectively).

Table 1. Characteristics of participants in study 1 and study 2 (n=46).

Characteristics	Total (n=46)	Study 1 (n=21)	Study 2 (n=25)	*P* value
Sex, n (%)				.76[a]
Boys	16 (35)	8 (38)	8 (32)	
Girls	30 (65)	13 (62)	17 (68)	
Age (y), median (IQR)	10.53 (10.2-10.95)	10.2 (9.9-10.4)	10.8 (10.56-11.26)	<.001[b]
Ethnicity, n (%)				.004[c]
Chinese	18 (39)	3 (14)	15 (60)	
Malay	25 (54)	16 (76)	9 (36)	
Others	3 (7)	2 (10)	1 (4)	
BMI status, n (%)				.60[c]
Underweight	3 (7)	2 (10)	1 (4)	
Normal weight	29 (63)	14 (67)	15 (60)	
Overweight	8 (17)	2 (10)	6 (24)	
Obese	6 (13)	3 (14)	3 (12)	
Number of days of completion of My E-Diary for Activities and Lifestyle, n (%)				.22[c]
<1	2 (4)	0 (0)	2 (8)	
1	3 (7)	2 (10)	1 (4)	
2	3 (7)	2 (10)	1 (4)	
3	7 (15)	1 (5)	6 (24)	
4	31 (67)	16 (76)	15 (60)	

[a] *P* values were assessed by the Pearson χ^2 test (categorical).

[b] *P* values were assessed by the Mann-Whitney *U* test (nonparametric).

[c] *P* values were assessed by the Fisher exact test (categorical).

Match, Omission, and Intrusion Rates

Table 2 presents the match (%), omission (%), and intrusion (%) rates observed between the food photographs received from the parents and self-reported food and drink items by the participants in MEDAL. The match, omission, and intrusion rates were 62%, 39%, and 20%, respectively. The total match rate was further broken down into exact match rate and approximate match rate, which were 60% and 1%, respectively.

The median exact match rate (*P*=.03), total match rate (*P*=.004), and omission rate (*P*=.004) were significantly different among meal types. Of all meals, snacks showed a significantly lower total match rate (53%) than breakfast (83%) and dinner (75%; *P*=.01 and *P*=.02, respectively). Furthermore, snacks consumed were omitted more often (47%) than breakfast (18%) and dinner (25%; *P*=.01 and *P*=.02, respectively). Post hoc tests failed to indicate any significant difference among the meal types for exact match rate.

Table 2. Percentage of the match, omission, and intrusion rates observed between photographed meals and self-reported individual food and drink items in My E-Diary for Activities and Lifestyle (MEDAL).

Variables	Observed items[a], n	Reported items[b], n	Approximate match rate (%)[c], median (IQR)	Exact match rate (%)[d], median (IQR)	Total match rate (%)[e], median (IQR)	Omission rate (%)[f], median (IQR)	Intrusion rate (%)[g], median (IQR)
On the basis of each meal (n=46)	1267	1004	1.4 (0-6.4)	60.3 (40.1-79.8)	61.6 (46-86.4)	39.3 (15.8-54.8)	19.5 (5.9-44.2)

[a] Number of food items depicted in photographs.

[b] Number of food items reported in MEDAL.

[c] Approximate match is defined as a similar food with a slight variation, eg, full-fat milk and low-fat milk. Approximate match = (number of food items reported in MEDAL with approximate matches/number of food items photographed by parents) × 100.

[d] Exact match is defined as a selection of the same food or drink item in both the photograph and self-report in MEDAL. Exact match rate = (number of food items reported in MEDAL with exact matches/number of food items photographed by parents) × 100.

[e] Total match rate = (number of food items reported in MEDAL with exact and approximate matches/number of food items photographed by parents) × 100.

[f] Omission is defined as a food or drink item depicted in the photograph but not reported in the self-administered MEDAL report. Omission rate = (number of food items reported in MEDAL with omissions/number of food items photographed by parents) 100 = [omissions/(omissions + matches)] × 100.

[g] Intrusion is defined as a food or drink item reported in MEDAL but not depicted in the photograph. Intrusion rate = (number of food items reported in MEDAL with intrusions/number of food items reported in MEDAL × 100 = [intrusions/(intrusions + matches)] × 100.

[h] Kruskal-Wallis test (*P*=.05) and Bonferroni post hoc Mann-Whitney *U* test indicated that “snacks” had significantly lower total match than breakfast (*P*=.01) and dinner (*P*=.02) and higher omission than breakfast (*P*=.01) and dinner (*P*=.02).

[i] N/A: not applicable.

[j] Results show the rates for all meals for all 4 days.

[k] The Mann-Whitney *U* test (*P*=.05).

Compared to boys, girls reported more total matches (69% vs 53%) and fewer omissions (31% vs 49%; *P*=.03, respectively). There was no significant difference between boys and girls in exact match, approximate match, and intrusion rates (*P*=.07, *P*=.94, and *P*=.26, respectively; Table 2).

Food Groups Reporting Accuracy

The match, omission, and intrusion rates of the food items were further analyzed by food groups (Table 3). At the food-group level, the “rice and porridge”; “breads, spreads, and cereals”; and “noodles, pasta, and potatoes” categories, the carbohydrate-based items, were reported most precisely (total match rates: 68%-76%). More than half of the “snack and dessert” items were omitted (omission rate: 54%). The side dishes that tended to be omitted by the participants were “vegetables and mushroom,” “eggs and tofu,” “meat and fish,” and “curry” (omission rates: 42%-46%). The food categories of “milk, cheese, and yogurt”; “snacks and desserts”; and “drinks” intruded most often (intrusion rates: 37%-46%).

Table 3. Percentage of matches, omissions, and intrusions observed between photographed meals and self-reported individual food and drink items in My E-Diary for Activities and Lifestyle (MEDAL) by food groups.

Food groups	Total observed items[a], n (%)	Total reported items[b], n (%)	Matches, n (%)			Omissions[c], n (%)	Intrusions[d], n (%)
			Total[e]	Approximate[f]	Exact[g]		
Rice and porridge (n=215)	195 (90.7)	168 (78.1)	148 (75.9)	10 (5.1)	138 (70.8)	48 (24.6)	20 (11.9)

[a] Number of food items depicted in photographs.

[b] Number of food items reported in MEDAL.

[c] Omission rate = (number of food items reported in MEDAL with omissions/number of food items photographed by parents) [100 = omissions/(omissions + matches)] × 100.

[d] Intrusion rate = (number of food items reported in MEDAL with intrusions/number of food items reported in MEDAL) 100 = [intrusions/(intrusions + matches)] × 100.

[e] Total match rate = (number of food items reported in MEDAL with exact and approximate matches/number of food items photographed by parents) × 100.

[f] Approximate match rate = (number of food items reported in MEDAL with approximate matches/number of food items photographed by parents) × 100.

[g] Exact match rate = (number of food items reported in MEDAL with exact matches/number of food items photographed by parents) × 100.

Discussion

Principal Findings

Overall, the match, omission, and intrusion rates in this study were 62%, 39%, and 20%, respectively. We found that girls reported more total matches and made fewer omissions than boys. At the food-group level, carbohydrate-based items such as “rice and porridge”; “breads, spreads, and cereals”; and “noodles, pasta, and potatoes” were reported most accurately. However, “snack and dessert” items and side dishes of mixed meals such as “vegetables and mushroom,” “eggs and tofu,” “meat and fish,” and “curry” were omitted most often. Furthermore, items from “milk, cheese, and yogurt”; “snacks and desserts”; and “drinks” groups intruded most often.

This study indicated that Malaysian school children aged 10 to 11 years are capable of using the customized MEDAL web-based app to self-report food and drink items, albeit with some inaccuracies. While Tugault-Lafleur et al [18] stated that an acceptable cutoff of ≥85% for match rates and ≤15% for both omission and intrusion rates, this does not mean that the results from this study indicate poor accuracy for self-reported food items. The suggested cutoff was originally developed for meals in the school context. Furthermore, as Baxter and Thompson [23] suggested, children tend to recall food consumed as part of a 24-hour period with lower accuracy than a single meal. Children in this study reported all meals consumed in 24 hours at home and school rather than a single meal in the school context. Therefore, it is reasonable that the match rates would be lower and the omission and intrusion rates would be higher than the suggested acceptable cutoff values.

Furthermore, the total match rates (62%) from this study were slightly higher (better) than the total match rates from the validity study (60%) conducted in Singapore [21], although only school meals were included in the validity study conducted in Singapore and more meals were included in this study.

However, food photography by parents was used as the reference measure, and thus there might be a possibility that the children in this study referred to the food photographs taken by their parents while self-reporting their meals in MEDAL. In addition, the match rates from this study were slightly higher than those from other studies that used web-based dietary assessment tools, for example, studies conducted in Brazil (43%) [16], Denmark (59%) [12], and the United States (42%) [24]. These studies used direct observation as the reference measure. Moreover, the slightly higher match rate in this study might be attributable to the fact that older children were recruited (aged 10 to 11 years) instead of the younger children (aged 7 to 9 years), as older children have better recall than younger children [25]. Furthermore, direct observation was used as the reference measure. In contrast, a Malaysian study [7] conducted among children aged 7 to 9 years demonstrated a higher match rate (89%) than this study, which might be attributable to the fact that the participants only needed to recall a single recess meal, whereas in this study, participants were asked to recall all their meals in a day.

The omission (39%) and intrusion rates (20%) in this study are higher than the cutoff value of ≤15% [18]. In general, children might have recorded their dietary intake in MEDAL the following day or later, instead of on the same day. According to Baxter et al [26], the accuracy of omission and intrusion rates declines significantly when the time interval between reporting and eating increases.

In addition, the omission rates (39%) were higher than the validity study conducted in Singapore (25%) [21] and other studies conducted in Malaysia (14%) [7], Brazil (28%) [16], Norway (27%) [17], and the United States (28%) [24]. These studies validated only lunches consumed in a school environment, which are fixed meals with little variation.

However, the increased omission rates in this study might be due to the inclusion of all meals consumed for validation purposes rather than a specific meal in a particular setting. This is further supported by “snacks” being the most omitted meal type in this study (47%). In conjunction with omission rates, “snacks and desserts” (54%) were food items that were omitted most often. This may also explain the higher omission rate in this study because children may be underreporting snacks and desserts, which are deemed to be unhealthy. Children may also forget to report snacks as one of their meals or they may be multitasking (eg, watching television or studying) while consuming snacks.

At the same time, carbohydrate-based items in “rice and porridge”; “breads, spreads, and cereals”; and “noodles, pasta, and potatoes” categories were reported most accurately (total match rates: 68%-76%) in this study. Carbohydrate-based items are usually consumed as main course items during each main meal in Asia, making them more recallable than side dishes or less common foods [5]. Moreover, this study found that the side dishes of mixed meals were commonly omitted, as items from the “vegetables and mushrooms,” “eggs and tofu,” “meat and fish,” and “curry” groups (omission rates: 42%-46%) were commonly consumed as side dishes, together with the carbohydrate-based items (eg, rice, porridge, or noodles) in Asia. Therefore, the results in this study are consistent with the findings of the study by Pérez-Rodrigo et al [5] that carbohydrate-based items are recalled better than side dishes. Children tend to recall salient items, such as main course foods, more easily than less salient items [27]. Side dishes of mixed meals were commonly omitted in this study because children may lack basic knowledge or familiarity with the food, food preparation, added ingredients, and components of side dishes in mixed meals [5]. Therefore, they omitted these food groups in their self-reports of dietary intake.

Furthermore, the intrusion rates in this study are slightly higher than those in the validity study conducted in Singapore (20% vs 15%) and a study conducted in Malaysia (3%) [7]. However, the intrusion rate is lower than those in studies conducted in Brazil (29%) [15,16] and the United States (30%) [24]. The food groups of “milk, cheese, and yogurt”; “snacks and desserts”; and “drinks” intruded most (intrusion rates: 37%-46%) in this study. These food groups intruded most because they are consumed along with the main meal or during snacking. These results are consistent with those of a study conducted in Brazil, where the intrusion rates are the highest for dairy products [16]. Furthermore, the results are supported by a study conducted in Norway, in which the items that intruded most were “yogurt” (56%) and “beverages and other” [17]. Despite this, the result of the intrusion is further influenced by the fact that parents might have forgotten to photograph the food items. Parents might have been unaware of their children consuming food or drink items along with their main meals or snacking and, thus, did not photograph the food.

Moreover, reporting accuracy was linked to gender differences. Girls often reported their dietary intake more accurately than boys [28]. The results in this study are consistent with the results from the study by Lyng et al [28], as the girls recalled better than the boys. The girls had a lower omission rate and a higher match rate than the boys (P=.03). This might be because boys are not as detailed as girls when selecting the food and drinks to report in MEDAL. Furthermore, a previous study demonstrated that compared to boys, girls recalled more details and provided more detailed elaborations on information content [29]. Therefore, the higher accuracy in reporting observed in girls may be attributed to their tendency to provide more detailed information. Furthermore, another study also showed that girls outperformed boys in object recall (recalling a series of pictures presented) and word selective reminding (a verbal free-recall task on word lists) than boys [30]. Consequently, it is plausible that girls exhibit better recall abilities regarding food and drink consumption, which could influence their selection of food and drink items in MEDAL.

Nevertheless, this study has several possible limitations. First, we used the parents’ photographs of the food items as the reference measure. The parents might have forgotten to photograph some food items, drinks, or snacks consumed by their children. Furthermore, parents might be unaware that their child had consumed certain food items, especially if they were working, which could lead to photographs of the food items not being taken. Thus, the intrusion rate was further affected by the forgetfulness or unawareness of parents. Another limitation was that the photographs of the food may serve as a visual-prompting tool for the children, which could increase the match rate. In addition, this study used a convenience sample, which was limited to schools in Kuala Lumpur city and students with internet access and electronic devices. Thus, the results of this study might not be extrapolated due to the limited technology skills in rural areas or other cities. Moreover, study 1 was conducted during the Ramadhan fasting period, which limited the meals reported by children during school recess. Therefore, overall, the results might not be generalizable to the non-Ramadhan fasting period.

Despite these limitations, this study has its strengths. First, it contributes to our understanding of dietary assessment among children aged 10 to 11 years in Malaysia. Furthermore, this is the first study conducted in Malaysia to determine school children's ability to report dietary intake using a web-based diary. The main strength of this study is its validation of all meals consumed by the children in various settings instead of evaluating specific meals in a particular context. This enables the results to be extrapolated to meals consumed outside the school. As a result, numerous food and drink items were reported and analyzed, which increases the generalizability of the findings to the varied eating practices of a multicultural community.

This study has some implications for future research. In order to improve accuracy, children should be encouraged to report their food items in the web-based diary as frequently as possible and preferably on the same day. Furthermore, researchers should remind the children to report on the details of such food items as side dishes and snacks or drinks that are consumed along with meals or during multitasking. Future research should be conducted in different cities or rural areas to further affirm these results.

Conclusions

In conclusion, the overall match (62%), omission (39%), and intrusion (20%) rates suggest that children are able to report their food and drink intake in MEDAL, although some items are omitted or intrude. Thus, MEDAL is a promising tool to assess the dietary intake of Malaysian school children aged 10 to 11 years. Future research should be conducted with a larger sample size and in nonurban areas to provide further insights into the accuracy of MEDAL in capturing the dietary intake of children.

Acknowledgments

This study was conducted with the aid of a research grant from the National University of Singapore Initiative to Improve Health in Asia (NIHA), coordinated by the Global Asia Institute of the National University of Singapore and supported by the Glaxo Smith Kline-Economic Development Board (Singapore) Trust Fund (grant NIHA-2018-007). The authors would like to thank the school principal, teachers, parents, and school children who participated in the study for their complete commitment. Furthermore, the authors would like to acknowledge the effort and dedication of the enumerators and all those involved in this project.

Abstract

Background: Asynchronous communication via electronic modes (e-communication), including patient portals, secure messaging services, SMS text messaging, and email, is increasingly used to supplement synchronous face-to-face medical visits; however, little is known about its quality in pediatric settings.

Objective: This review aimed to summarize contemporary literature on pediatric caregivers' experiences with and perspectives of e-communication with their child's health care team to identify how e-communication has been optimized to improve patient care.

Methods: A scoping review following the Arksey and O'Malley methodological framework searched PubMed, CINAHL, Embase, and Web of Science using terms such as "Electronic Health Records" and "Communication" from 2013 to 2023 that discussed caregiver experiences and perspectives of e-communication with their child's health care provider. Studies were excluded if they were abstracts, non-English papers, nonscientific papers, systematic reviews, or quality improvement initiatives, or pertained to synchronous telemedicine. We conducted a two-step screening process by scanning the title and abstract and reviewing the full text by two independent screeners to confirm eligibility. From an initial 903 articles identified via the database search, 23 articles fulfilled all the inclusion criteria and are included in this review.

Results: Of the 23 articles meeting the inclusion criteria, 11 used quantitative methods, 7 used qualitative methods, and 5 used mixed methods. The caregiver sample sizes ranged from 51 to 3339 in the quantitative studies and 8 to 36 in the qualitative and mixed methods studies. A majority (n=17) used the patient portal that was self-categorized by the study. Secure messaging through a portal or other mobile health app was used in 26% (n=6) of the studies, while nonsecure messaging outside of the portal was used 17% (n=4) of the time and email was used 33.3% (n=8) of the time. In 19 of the studies, parents reported positive experiences with and a desire for e-communication methods.

Conclusions: The literature overwhelmingly supported caregiver satisfaction with and desire for e-communication in health care, but no literature intentionally studied how to improve the quality of e-communication, which is a critical gap to address.

electronic communication; patient portal; provider-patient relations; parental caregiver; relational coordination theory; patient-clinician relationship; mobile phone

Introduction

In pediatric health care, effective communication between the caregiver and clinician is pivotal for enhancing illness understanding, promoting treatment adherence, and fostering improved experiences [1-4]. Asynchronous electronic communication (e-communication), through patient portals, secure messaging, email, and SMS text messaging, is increasingly used to supplement synchronous face-to-face medical visits [5]. However, little is known about the quality of e-communication in pediatric settings.

Despite the acceleration of e-communication following the COVID-19 pandemic and the 21st Century Cures Act mandating the sharing of clinical notes with patients, there is limited evidence on the best practices, and what evidence does exist may not be applicable to the specific needs of caregivers of patients with complex needs, of children, or of both [6-10]. Limited research exists on how parental caregivers (hereinafter "caregivers") perceive e-communication, particularly concerning its quality and perceived impact on care delivery [2,6].

The relational coordination theory is well-suited for exploring e-communication between caregivers and health care teams, as it emphasizes the quality of communication and relationships in coordinating complex, interdependent tasks such as caring for a child [11]. The relational coordination theory highlights seven key domains—shared goals; shared knowledge; mutual respect; and communication that is frequent, timely, and accurate, and aids in problem-solving—to support effective teamwork [11,12]. When applied in settings such as pediatric health care, strong relational coordination can improve communication and care outcomes [13]. Thus, incorporating relational coordination into the analysis of e-communication helps to conceptualize caregiver–health care team dynamics and inform improvements in practice.

This review was undertaken to determine contemporary literature on pediatric caregivers' perspectives of e-communication with their child's health care team. We aimed to (1) identify modes of caregiver–health care team e-communication; (2) assess caregiver perspectives on e-communication experiences or expectations; and (3) map findings from such studies to relational coordination domains to better understand its role in effective e-communication and how it may be leveraged to alter delivery of care systems and patient and caregiver satisfaction. The overall purpose of our study was to characterize objectives, therapeutic elements, and delivery characteristics of e-communication as a step to inform intervention development, health care practices/policies, and caregiver and health care team workflows.

Methods

We conducted a scoping review that followed the Arksey and O'Malley [14] methodological framework and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Checklist 1) [15]. We used the communication domains of the relational coordination theory to guide article synthesis [11,12].

Study Identification

The search strategy was iteratively developed in consultation with an experienced medical librarian (Supplement 1 in Multimedia Appendix 1) and conducted in February 2023. We searched PubMed, CINAHL, Embase, and Web of Science using relevant search terms and MeSH (Medical Subject Headings) terms (Supplement 2 in Multimedia Appendix 2).

We included studies within a 10-year period that discussed caregiver experiences and perspectives of e-communication with their child's health care provider. E-communication was defined as web-based technology that allows for asynchronous communication between a caregiver and provider, such as patient portals tethered to electronic health records (EHRs) with or without access to clinical notes, secure messaging, nonsecure messaging (eg, personal mobile, nonsecure SMS text messaging, and WhatsApp), and email. We defined the caregiver as the child's primary caregiver and decision maker. The health care team was defined as medical professionals from various disciplines who provide comprehensive care to children, including registered nurses, nurse practitioners, physician assistants, and physicians. We limited the children's age from 0 through 13 years due to legal, access, and privacy issues for older, adolescent patients [10,16].

Studies were excluded if they were abstracts, non-English papers, nonscientific papers, systematic reviews, or quality improvement initiatives, or if they pertained to synchronous telemedicine.

Article Selection

We used the Covidence literature review software to conduct a two-step screening process by scanning the title and abstract and reviewing the full text by two independent screeners to confirm eligibility. The reviewers applied the inclusion and exclusion criteria to articles, discussed discrepancies as a group to reach consensus, and carefully documented decisions within the software. This method ensured a consistent and thorough review process.

Study Synthesis

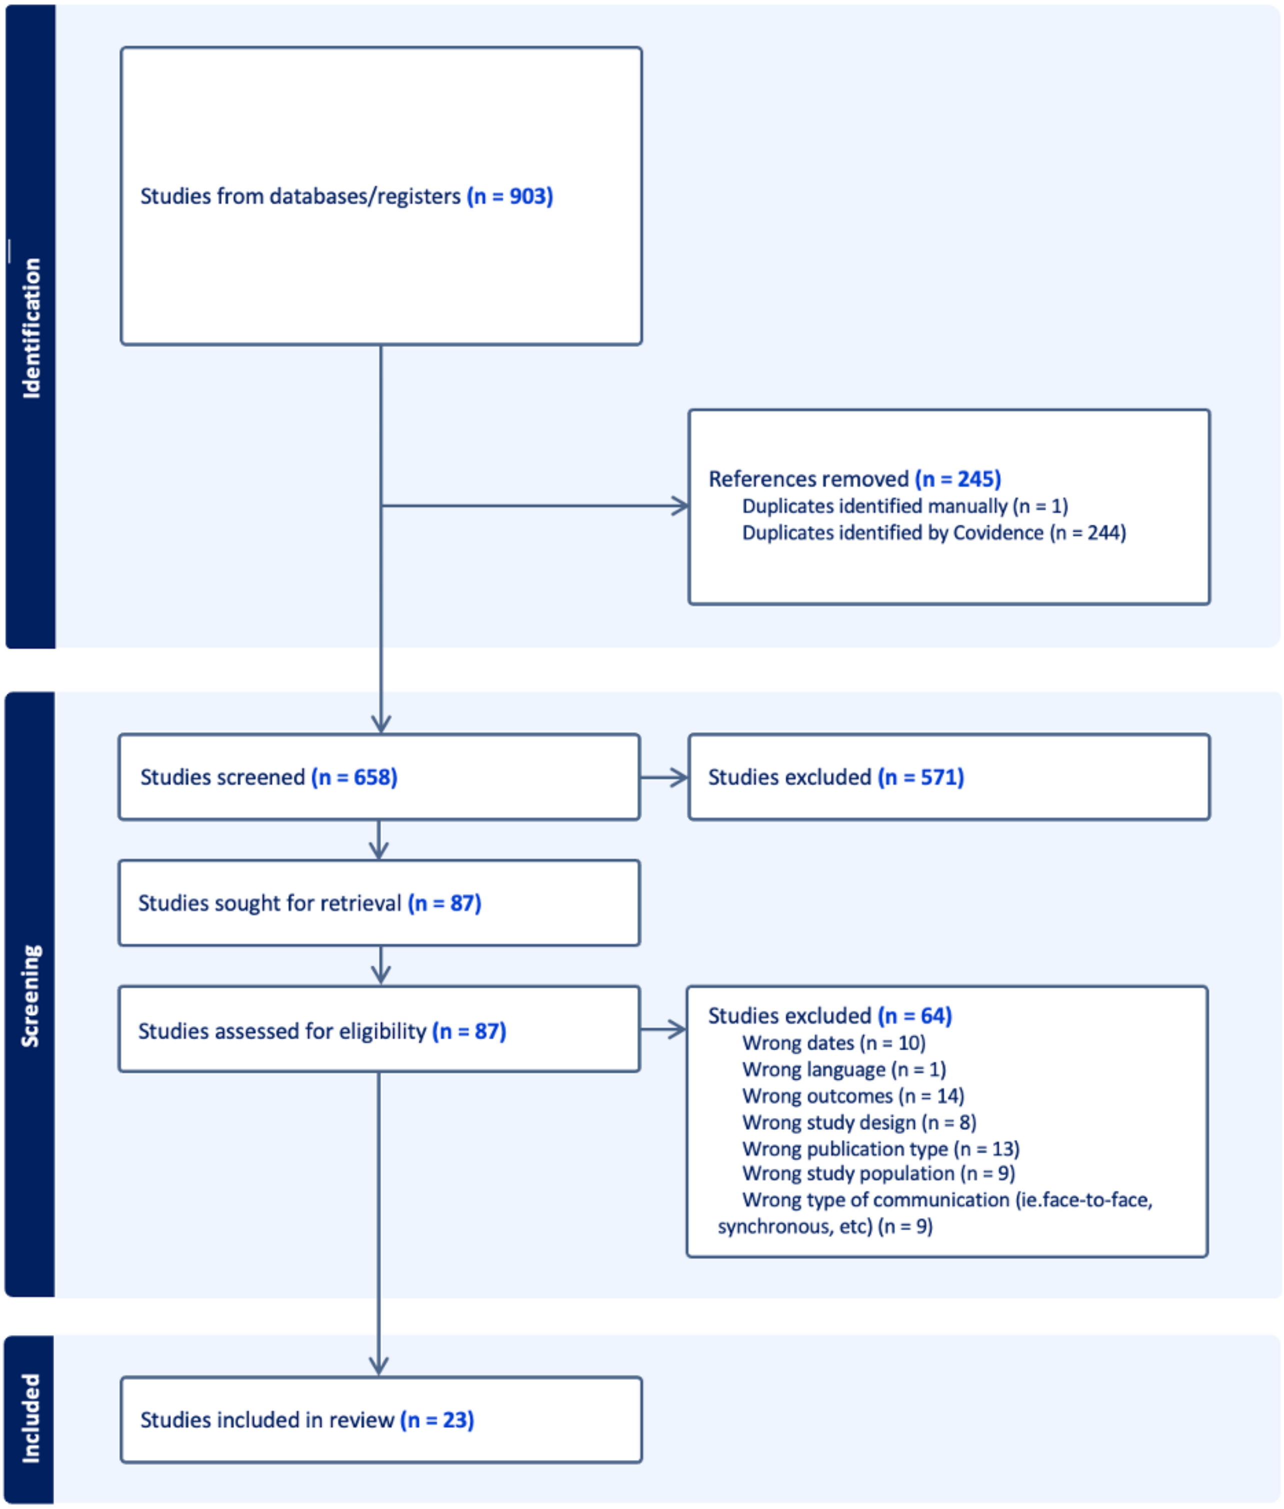
The approach to summarize and report on the findings from the identified articles varied by the research question (RQ). We first compiled articles that assessed caregiver–health care team e-communication (RQ1) by focusing on key parameters, such as the year, setting, population, and mode of e-communication [17]. We then performed a thematic analysis to synthesize information from articles that reported on caregiver satisfaction related to e-communication (RQ2) and the seven relational coordination domains (RQ3). The analysis pertaining to RQ2 and RQ3 involved mapping the findings of the mode of e-communication onto the relational coordination domains, under the hypothesis that the higher the number of relational coordination domains identified per article, the higher the caregiver satisfaction [12].

Results

Overview

In total, 903 articles were identified via the database search. After the duplicates were removed, 658 articles remained for title and abstract screening. Eighty-seven percent (571/659) of the articles were excluded, resulting in 87 full-text studies assessed for eligibility. During the full-text review, 74% (64/87) of the articles were excluded, which resulted in 23 articles included in this review. Figure 1 shows the study selection process in a PRISMA diagram [15].

Figure 1. PRISMA (Preferred Reporting Items and Systematic Reviews) flow diagram showing the literature search and study inclusion.



Basic Characteristics of the Included Studies

The characteristics of the included articles are summarized in Table 1 and individually presented in Supplement 1 in Multimedia Appendix 1. Of the 23 articles included in this review, 11 used quantitative methods, 7 used qualitative methods, and 5 used mixed methods. Sixteen studies (70%) were conducted in the United States, and one-third (n=8, 34.7%) were published after 2020. Half of the studies were conducted in an ambulatory setting (n=13, 56.5%), with the next most frequent location being an inpatient setting (n=8, 34.7%), of which 2 (8%) were in the neonatal intensive care unit. Only 4 (17.4%) were conducted in the community setting. One-third (n=7, 30.4%) of the studies involved populations with chronic illness or complex medical needs. Half (n=12, 52.2%) of the studies included participants in addition to caregivers, such as health care providers, adult patients, and teachers. The caregiver sample sizes ranged from 51 to 3339 in the quantitative studies and 8 to 36 in the qualitative and mixed methods studies. Over half of the 11 caregiver-only studies included 80% or greater female participants.

Table . Basic characteristics of the included studies.[a]

	Overall (N=23), n (%)	EHR[b]/patient portal (n=17), n (%)	Other[c] (n=13), n (%)
Year			
2013 - 2016	8 (34.8)	6 (75.0)	5 (62.5)
2017 - 2020	7 (30.4)	5 (71.4)	4 (57.1)
2021 - 2023	8 (34.8)	6 (75.0)	4 (50.0)
Study Design			
Quantitative	11 (47.8)	8 (72.7)	6 (54.5)
Qualitative	7 (30.4)	6 (85.7)	3 (42.9)
Mixed methods	5 (21.7)	3 (60.0)	4 (80.0)
Participants			
Parents	23 (100.0)	17 (73.9)	13 (56.5)
Health care worker	9 (39.1)	5 (55.6)	6 (66.7)
Adult patient	1 (4.3)	1 (100.0)	0 (0.0)
Teacher	1 (4.3)	0 (0.0)	1 (100.0)
Setting			
Ambulatory	13 (56.5)	11 (84.6)	7 (53.8)
Inpatient/ICU[d]	8 (34.8)	7 (87.5)	4 (50.0)
Community-based	4 (17.4)	2 (50.0)	4 (100.0)
Web-based	1 (4.3)	0 (0.0)	1 (100.0)
Mode of e-communication			
EHR/patient portal	17 (73.9)	—[e]	—
Secure messaging	6 (26.1)	—	—
Email	8 (34.7)	—	—
Nonsecure SMS text messaging	4 (17.4)	—	—
Phone	3 (13.0)	—	—
Other	2 (9.7)	—	—

[a] Individual studies may have more than one category of participants, setting, or mode of e-communication, so the overall percentage corresponds to 23 studies. The columns EHR/patient portal and Other (any mode that is not EHR/patient portal as described by a study) may add up to more than the number of overall studies in a row because studies may include more than one mode of e-communication. The percentage in those columns is the number of studies/number of overall studies in the corresponding row.

[b] EHR: electronic health record.

[c] Other includes secure messaging (n=6), email (n=8), SMS messaging (n=4), phone (n=3), fax (n=1), and web chat (n=1).

[d] ICU: intensive care unit.

[e] Not applicable.

Modes of Communication

The studies were assessed for the mode of e-communication utilized for caregiver–health care team communication and may include more than one mode (Table 2; Supplement 3 in Multimedia Appendix 3). A majority (n=17) used the patient portal that was self-categorized by the study. Secure messaging through a portal or other mobile health app was used in 26% (n=6) of the studies, while nonsecure messaging outside of the portal was used 17% (n=4) of the time and email was used 33% (n=8) of the time. Health care team phone messaging services and facsimiles were cited at 13% (n=3) and 4% (n=1), respectively. Notably, secure messaging was not described in studies prior to 2016; however, patient portals and email were actively referenced throughout the entire study period and could have included secure messaging. Correspondingly, SMS text messaging did not appear in studies after 2021.

[a]EHR: electronic health record.

Caregiver Experiences and Expectations for E-Communication in Pediatric Health Care

Overall, when studies are evaluated for positive versus negative caregiver experiences with e-communication use, a majority (n=20, 87%) identified positive experiences, with 3 studies finding more negative impressions of e-communication primarily due to cumbersome electronic system interface, not specifically the quality of communication [30,34,38].

Caregiver utilization of e-communication methods varied widely across studies, but common themes emerged. Particularly, 18 studies highlighted caregiver satisfaction through enhanced access to information, faster communication, and increased preparedness. For example, the ability to access patient information through portals, as noted in both national surveys [19] and qualitative studies [22], empowers caregivers by providing them with immediate, transparent access to their child's health data. The capacity to view laboratory and clinical data, request referrals, or schedule appointments through such systems reduces logistical barriers, offering convenience and a sense of control [19]. Moreover, electronic communication tools, such as portal messaging, email, and texting, reduce caregivers' anxiety by ensuring quicker, more precise interactions with health care teams. For example, mothers in neonatal intensive care unit settings were able to better understand their infant's condition and prepare for postdischarge care through improved clarity and communication speed [41]. However, even as e-communication platforms demonstrate significant benefits, nearly half of caregivers still prefer face-to-face interactions [41]. This suggests that while many caregivers value face-to-face interactions for nuanced discussions, using e-communication in conjunction helps improve access, alleviate burdens, and better equip caregivers for comprehensive conversations, contributing to overall satisfaction [22].

Other studies highlight the importance of a dynamic, two-way exchange of information in e-communication systems. For instance, a qualitative study of parents of children with chronic illnesses found that a secure messaging portal reduced barriers to getting timely answers, which in turn fostered feelings of control, independence, and reassurance [18]. A randomized controlled trial study using the MyAsthma portal demonstrated how ongoing bidirectional communication between families and clinicians supports shared decision-making by enabling real-time adjustments to treatment plans [20]. A cross-sectional survey further revealed that parents are not passive recipients but active participants, frequently initiating communication through messages or requests, emphasizing their active role in managing their child's health care [42].

Three studies focused on the caregivers' perceptions of reading their child's electronic progress notes [24-26]. One survey found that access to their child's clinical progress note positively impacted the caregivers' level of "confidence and trust" in their health care and enabled caregivers to feel like a "part of that team." [24] In qualitative focus groups, an inpatient-facing study found that caregivers believed that communication via access to clinical notes would "enhance the partnership and collaboration" between caregivers and the health care team and support higher standards for communication accuracy and accountability [25]. A survey on the impact of clinical notes being made available online to patients on the patient-physician relationship demonstrated that a parent's perception of their child's physician was generally positive with access to notes and 15% of parents used the ability to contact their provider about something they read in the note [26].

Three studies focused on the impact and satisfaction that SMS text messaging has on parental caregivers. An intervention focused on sending updates to parents via an SMS text regarding clinical updates significantly improved parental satisfaction with the medical treatment, the information provided, and the communication with their neonatal intensive care unit–admitted infants' medical staff. Parents also indicated perceived improvements in medical staff's availability, patience, approachability, and trust after the intervention. In a recent mixed methods study evaluating the use of a non–EHR-tethered secure messaging system compared to emails and phone calls, caregivers enjoyed the "laid-back, casual quick messages" of SMS text messaging; however, they felt email was the most convenient method because they were already logged into their email and they could "communicate with multiple providers at the same time" [35]. In a study involving an intervention of web-based chat consultation with resident physicians, caregivers felt their concerns and questions were "well handled" by the extra time with providers via the web chat, despite it not being face-to-face [40].

Two additional studies focused on attitudes specifically toward emailing the child's health care team. A majority (n=178, 78%) of caregivers from a 2013 cross-sectional study in an urban pediatric primary care clinic showed interest in communicating with their child's providers by this method and attitudes were favorable, with three-quarters of email users reporting that it would improve communication with their provider [33]. A mixed methods study that elicited parents' perspectives on this topic for informing medical student training found that most participants placed high value on a provider's "ability to communicate, respectfully, and empathetically in email." [36]

For the 3 studies that discussed the needs of parents of children with complex needs, the modes of e-communication involved patient portal, secure messaging, email, and SMS text messaging, which were universally believed to enhance the patient/caregiver and health care team relationship [34,35,38]. However, a theme of operational barriers emerged from each study. For example, a lack of integration and interoperability of e-communication systems within and across institutions and professions was found to add considerable effort to both the caregivers and the health care team [34].

Evidence of Relational Coordination Concepts

Of the 7 concepts of the relational coordination theory, "timely" e-communication was identified as a key characteristic in a majority of the studies (n=20) [43], followed by the relationships with "shared knowledge" (n=16; Table 2). Thematic analysis noted "accurate" communication in approximately two-thirds of the studies (n=14), and both "frequent" communication and relationships with "shared goals" were associated with half of the studies (n=11). The relationship with "mutual respect" was detected in fewer than half of the studies (n=10), and "problem-solving" communication was only identified in one-quarter of the studies (n=6). Four references, each quantitative in design, were only coded for the "timely" relational coordination domain [31,33,37,40]. One reference did not demonstrate evidence of relational coordination concepts [19]. These counts help map the prevalence of each concept in the literature and provide insight into the degree to which relational coordination principles have been explored in the context of caregivers' experiences.

Discussion

Key Findings

This scoping review included 23 articles and identified a small body of literature from the last decade focusing on parental caregiver's perspectives on e-communication with their child's health care team. Overwhelmingly parents reported positive experiences with and a desire for e-communication methods. This is particularly relevant to the times as the 21st Century

Cures Act [9] has increased the sharing of clinical notes and test results asynchronously with patients/caregivers. However, there is sparse data on how parents/caregivers perceive such new platforms of communication, given that only 5 out of 23 studies include analysis of access to clinical notes. Overall, the findings suggest positive caregiver experiences with e-communication. Negative perceptions were largely due to technological barriers, including workflow disruptions and underdeveloped communication platforms. These barriers impacted the ease of communication but were not explicitly linked to the quality of the interaction between caregivers and health care team.

The literature spans care settings and illness acuity, and includes chronic, primary, and specialty care. Female caregivers were the most prevalent among the caregiver populations studied. Most studies examined lived experiences of participants, while a small number addressed anticipated expectations [25,32,36]. Although most studies had aims centered around the theme of caregiver perceptions of communication via various modes of e-communication with their child's health care team, the lack of standardized measures for the quality of e-communication made systematically looking across studies for factors to improve the caregiver perception difficult.

Gaps in the Literature

Despite the well-documented growing use of e-communication between patients/caregivers and the health care team, little is known about the characteristics and quality of the conversations that occur and whether the quality of the conversations impacts outcomes [44,45]. In rare instances where the content of e-communication has been analyzed, differences have been identified compared to in-person communication. For example, one study of e-communication via online portals at a large medical center showed a reduction in partnership-building language and supportive talk compared to in-person conversations [46]. Although this study did not measure the effects of this shift, it is possible that such changes could negatively impact the perceived quality of communication. Since evidence exists within nonelectronic communication (ie, face-to-face communication) about how specific content affects perceived quality [6], it is important to determine if those same characteristics and quality preferences apply to e-communication.

Although different modes of communication were studied, trends in preference for mode of e-communication may have changed over time due to increased use of and advances in EHRs and patient portals in the last several years [47]. However, none of the studies necessarily explored whether EHRs and patient portals were the primary modes of communication being routinely utilized. For example, a study may have specifically been asking about patient portals, but the caregiver and health care team may actually communicate most often via nonencrypted texts. SMS text messaging a health care team member's personal cell phone, as opposed to using a secure messaging service through a portal or web-based application, was not evident in this literature search; however, the practice is commonplace [48].

Relational Coordination Theory and Its Relevance

The relational coordination theory emphasizes the importance of shared goals, shared knowledge, and mutual respect in communication. Although the 7 key domains of the theory are present in part in a majority of the studies, both quantitative and qualitative, no study explicitly used the relational coordination theory as a framework to aid in conceptualization, measures of communication, or design of tools or interventions to improve e-communication. However, given the theory's focus on the quality of relationships through communication between team members, it is highly relevant for understanding and improving e-communication between caregivers and health care teams. To strengthen the application of the relational coordination theory, future studies should integrate it into the analysis of caregiver-provider e-communication to better assess how shared goals and mutual respect are fostered or hindered through electronic means, and how these domains affect the quality of care.

Limitations of the Literature

There are limitations to our ability to generalize the findings of this review to the national landscape of patient portals, as the majority of studies were conducted at academic health care institutes. This introduces a potential bias in the sample, as academic health care institutes may have different patient populations, resources to support an EHR/portal, and communication practices compared to other types of health care settings (eg, community hospitals and private practices). There was an absence in the literature on the use of nonsecure SMS text messaging despite its widespread application. Furthermore, not restricting the studies by country enhances the diversity in the review, health care, communication, and e-communication practices that vary across countries, which may also affect generalizability.

Populations in this scoping review were not diverse in sex, with possible underrepresentation of male caregivers in a majority of the studies. The rationale for this sex difference in contemporary research was not explained in any of the studies but likely represented convenience sampling. However, fathers, particularly fathers from disadvantaged backgrounds, have historically been underrepresented in pediatric research, and their lack of recruitment may impede our understanding of paternal effects on children's health and the development of effective family interventions [49].

The participants were not diverse in origins, cultures, or native languages, which appears to be due to language-based inclusion/exclusion criteria cited in some studies, as well as racial and ethnic disparities in technology needed for patient portal offers, access, and use [50]. Workarounds to language barriers might include the use of automated translation software, such as Google Translate, by caregivers or providers to attempt to facilitate asynchronous e-communication; however, the translation is not accurate across languages and only contributes to worsening of health inequity [51,52]. As the perspectives identified in the studies reflect English language speakers, caregivers from other linguistic or cultural backgrounds might have different expectations or priorities for e-communication.

Finally, the lack of representation of the independent child voice in the review is a significant limitation. By primarily focusing on caregivers, the review may not fully capture the perspectives and preferences of the primary participant in pediatric care—the patients themselves who may have high digital literacy. Measurement of children's views in communication, particularly in adolescents and young adults, and their impact on outcomes and experiences is crucial for a comprehensive understanding of pediatric e-communication dynamics.

Conclusions

This review provides a foundation for understanding the evidence base regarding how e-communication may be used to drive improved patient outcomes, experiences, or health care system workflows. The gap in the literature regarding pediatric caregiver and health care team e-communication, specifically the lack of evaluation of the quality of the communication from the caregiver perspective, is urgent to address given the rapid proliferation of e-communication in health care [47]. Investigating this critical void can contribute valuable insights to health care policy and practice guidelines. As e-communication tools become increasingly integrated into health care delivery, understanding the needs, preferences, and experiences of caregivers is essential for optimizing communication quality and enhancing experiences.

Abstract

Background: Falls are the most common hospitalized injury mechanism in children aged ≤1 years, and currently, there are no targeted prevention interventions. The prevention of falls in children of this age requires changes in the behavior of their caregivers, and theoretically informed digital behavior change interventions (DBCIs) may provide a unique mechanism for achieving effective intervention. However, user acceptance and the ability of DBCIs to effect the required changes in behavior are critical to their likelihood of success.

Objective: This study aims to evaluate a behavior theory–informed digital intervention developed following a user-centered approach for user experience, the potential for this intervention to prevent infant falls, and its impact on behavioral drivers underpinning fall risk in young children.

Methods: Parents of infants aged <1 year were recruited and asked to use the intervention for 3 months. A pre-post longitudinal design was used to examine the change in the potential to reduce the risk of falls after a 3-month exposure to the intervention. Postintervention data on behavioral drivers for fall prevention, user acceptability, and engagement with the app were also collected. Interviews were conducted to explore user experiences and identify areas for further improvement of the intervention.

Results: A total of 62 parents participated in the study. A statistically significant effect on the potential to reduce falls was observed after the intervention. This effect was higher for new parents. Parents agreed that the intervention targeted most of the target behavior drivers. The impact of behavior drivers and intervention on the potential for fall prevention had a positive correlation. The intervention demonstrated good levels of acceptability. Feedback from participants was mostly positive, and the primary area identified for further improvement was widening the scope of the intervention.

Conclusions: This study demonstrated the promise of a newly developed digital intervention to reduce the risk of infant falls, particularly among new parents. It also showed a positive influence of the DBCI on the drivers of parental behaviors that are important for fall reduction among infants. The acceptability of the app was high, and important insights were gained from users about how to further improve the app.

Introduction

Children aged ≤1 year, that is, infants, have the highest rate of death owing to fall-related injury, and falls are the most common injury mechanism resulting in emergency department visits and hospitalizations during infancy. The head is the most commonly injured body part owing to infant falls [1-5], and in severe cases, these result in skull fractures, traumatic brain injuries, and long bone fractures [6].

Most of these fall events can be prevented by age-appropriate safe parenting practices and making changes in the child's environment [7-9], but currently, there are no targeted, proven interventions specifically for infant fall prevention [10,11], and there is also evidence that fall injuries have increased in recent years [12].

To fill this gap, the research team created a behavior theory–based digital intervention for infant fall prevention following an iterative user-centered process [13]. As detailed in the first paper, the Behavior Change Wheel (BCW) [14] combined with the person-based approach [15] was used to theoretically inform and develop a user-centered digital intervention. The resulting intervention included 4 modules targeting common fall mechanisms and events occurring within the first year of an infant's life.

The four modules consisted of (1) a safe feeding module targeting the prevention of falls related to feeding, (2) a safe furniture use module targeting infant falls related to furniture, (3) a safe use of baby products module targeting infant falls related to baby products, and (4) a safer environment module targeting stairs-related infant falls. The main features of the app include written articles (13 short articles, reading time per article approximately 3-5 min), trackable “tasks” encouraged by the articles where users can check off tasks as they complete them, a dashboard allowing users to check adherence with suggested tasks, and push notifications to remind users to engage with the app. (see the app screenshots in Multimedia Appendix 1).

The user-centered approach taken to develop this intervention inherently focused on ensuring that the target population comprehended the material provided and that the method of delivery was acceptable to users. However, as detailed in the first paper [13], this development process was undertaken iteratively with each individual module, and there is a need to ensure the acceptability of the overall app that integrates the 4 modules. Although the use of the BCW in designing the app was intended to increase the likelihood that engagement with the app would lead to the adoption of behaviors required to reduce the risk of falls among infants, this is not guaranteed, and there is also a need to evaluate whether the app is likely to have the desired impact and if this impact is consistent across all users. Finally, the app can only realize its desired effect if there is appropriate engagement by users with the app, and there remains the need to assess likely parental engagement and the scope for further improving engagement. This paper presents a 3-month longitudinal study to address these questions. The specific aims of this study were as follows:

1. To determine the overall impact of exposure to the intervention on parents' potential to reduce the risk of infant falls and determine if this is consistent across all users.
2. To examine the behavioral drivers for falls prevention (capability, opportunity, and motivation) among parents after exposure to the intervention and examine the relationship between these factors and the impact of the intervention.
3. To determine acceptability of the app as a whole and engagement with the app.
4. To explore user experience to identify factors driving user acceptability and engagement and scope for further improving the intervention.

Methods

Study Design

This study used a pre-post longitudinal design to examine the change in the potential of parents to reduce the risk of falls after a 3-month exposure to the intervention (part 1). The postexposure survey delivered at 3 months also collected data on behavioral drivers for falls prevention (part 2), user acceptability, and engagement with the app (part 3). User experience was further studied through in-depth interviews with a subset of participants to provide insight into factors driving user acceptability and engagement and to identify the scope for further improvement of the intervention (part 4). Parts 1 to 3 were quantitative and part 4 was qualitative. A mixed methods analysis approach was then used to triangulate the user experience findings from parts 3 and 4.

Ethics Approval

Ethics approval for the study was obtained from the University of New South Wales Human Research Ethics Executive Committee (HC210494).

Study Setting and Participants

Inclusion criteria for participants taking part in this study were as follows: must be aged ≥18 years, a parent of a child aged 0 to 6 months or an expectant parent within 2 months of the due date (mother or father), living in Australia, able to speak and understand English, and have access to a smartphone (iOS or Android). The study duration was 3 months. Participants needed to be in Australia with access to an iOS or Android smartphone because of the availability of the app in relevant app stores. The study duration was selected to cover the relevance of the information within the intervention.

Recruitment

Participants were recruited from an Australian market research company's existing consumer panel of parents between November and December 2021. A screening survey with questions to assess the inclusion criteria was emailed to the members of the consumer panel. Eligible participants who registered their interest in participating were electronically sent the main consent form to read and consent.

Within the main consent form, participants were invited to opt-in for the in-depth interviews, but a decision not to opt-in to this component did not preclude involvement in the main study. The first 10 consenting participants who opted in and provided separate consent for the in-depth interviews were selected.

The participants were given a gift voucher for Aus $100 (US $65) for completing both baseline and poststudy surveys. In addition, participants who took part in the poststudy in-depth interviews were given an Aus $40 (US $26) gift voucher.

Access to the App

Participants were provided with a link to download the app from the Google Play Store or Apple App Store depending on the smartphone they own.

Data Collection

Baseline and poststudy quantitative data were collected via a survey hosted on REDCap (Research Electronic Database Capture; Vanderbilt University) and distributed to participants electronically (Table 1). The baseline survey collected data on participant demographics (such as education level, income level, number of children, and marital status; Table 2) and questions designed to measure participants' potential to reduce the risk of infant falls. The latter consisted of the following four questions:

1. I know how to prevent falls among young children
2. Falls in children aged ≤1 year can be prevented
3. I am confident I can take actions to reduce the risk of my child falling
4. I have taken specific actions to reduce the risk of my child falling

The same 4 questions were also included in the poststudy survey. This set of questions was designed to demonstrate whether exposure to the app had the overall desired impact and was measured using a 5-point Likert scale (strongly disagree to strongly agree). The poststudy survey also included open-ended questions designed to (1) collect data from participants on the behavioral drivers for potential to reduce the risk of infant falls (Table 3) based on the Capability, Opportunity, Motivation–Behavior (COM-B) self-evaluation questionnaire [16] and (2) collect information on user experience. The latter user experience questions were framed in terms of user acceptance and engagement with the app.

User acceptance was measured by asking participants how much they liked the app and to rate the level of agreement (Likert scale: strongly disagree to strongly agree) with the following six statements: (1) I found the app easy to use; (2) I found the information useful; (3) the advice provided was easy to follow; (4) I could act on the advice provided; (5) I like the features of the app; (6) I found the reminders or notifications helpful.

For engagement, participants were asked about their use of the app and its features and to respond to the statements "I used the app" (not at all; once; more than once but not often; often—more than once a month; frequently—more than 4 times a month); "I read all the articles" (Likert scale: strongly disagree to strongly agree); and "I used the task list feature" (Likert scale: strongly disagree to strongly agree).

Poststudy qualitative interviews were conducted with a subgroup of 10 participants to understand parents' user experience with the app and to understand further opportunities to improve the app. In-depth interviews were conducted face-to-face using videoconferencing (Microsoft Teams). A discussion guide was used to structure interviews with each participant. The discussion guide was developed to ensure that participants understood the context of the discussion and to collect more in-depth details about the factors driving their acceptability and engagement with the app than could be collected through a quantitative survey. Similarly, it was also designed to collect more detailed insight into how the material provided in the app influenced the behaviors required to reduce the risk of falls in infants. Before conducting the interviews, the discussion guide was refined through peer-to-peer testing to optimize discussion flow and clarity. The final discussion guide used to frame the 10 in-depth interviews is provided in Multimedia Appendix 2. All the interviews were recorded and transcribed verbatim.

Table 1. Summary table of research variables.

Aim, variable, and source	Data type	Analysis conducted
Aim 1		
Factors assumed related to fall prevention (secondary outcome)		
Response to survey questions: I know how to prevent falls among young children (a)	5-point Likert scale	Difference between before and after using a paired Wilcoxon signed rank test
Falls in children under 1 can be prevented (b)	5-point Likert scale	Difference between before and after using a paired Wilcoxon signed rank test
I am confident I can take actions to reduce the risk of my child falling (c)	5-point Likert scale	Difference between before and after using a paired Wilcoxon signed rank test
I have taken specific actions to reduce the risk of my child falling (d)	5-point Likert scale	Difference between before and after using a paired Wilcoxon signed rank test
Potential to reduce falls (primary outcome)		
Sum of a to d	Continuous variable	Difference in means before and after using a 1-tailed paired *t* test
Intervention impact (“total change”—primary outcome)		
Calculated by postintervention potential to reduce falls minus preintervention potential to reduce falls	Continuous variable	Difference in means between different demographic groups using a 1-tailed paired *t* test
Demographics (independent variable)		
Various levels (Table 2) for relationship to child, age, experience, country of birth, household income, marital status, and education level	Categorical variable	Difference in means between different demographic groups using a 1-tailed paired *t* test
Aim 2		
Intervention impact (“total change”—primary outcome)		
Calculated by postintervention potential to reduce falls minus preintervention potential to reduce falls	Continuous variable	Linear regression used to examine influence of behavior scores on intervention impact while controlling for parental experience
Capability score (independent variable)		
Response to survey questions (Table 3) by Likert scales summed	Continuous variable	Linear regression used to examine influence of behavior scores on intervention impact while controlling for parental experience
Opportunity score (independent variable)		
Response to survey questions (Table 3) by Likert scales summed	Continuous variable	Linear regression used to examine influence of behavior scores on intervention impact while controlling for parental experience
Motivation score (independent variable)		
Response to survey questions (Table 3) by Likert scales summed	Continuous variable	Linear regression used to examine influence of behavior scores on intervention impact while controlling for parental experience
Overall behavior score (independent variable)		
Calculated by the aggregate of capability, opportunity, and motivation scores	Continuous variable	Linear regression used to examine influence of overall behavior score on intervention impact while controlling for parental experience
Experienced parent (confounder)		
Yes=2 or more children; no=1 child	Categorical variable	Linear regression used to examine influence of overall behavior score on intervention impact while controlling for parental experience
Aim 3		
Engagement (outcome)		
Response to survey questions	5-point Likert scale	Descriptive statistics
Likeability (outcome)		

Aim, variable, and source	Data type	Analysis conducted
Response to survey questions	5-point Likert scale	Descriptive statistics
Aim 4		
Barriers and enablers of the intervention		
Poststudy interview	Qualitative data	Qualitative descriptive method

Table 2. Participant demographics (N=60).

	Participants, n (%)	Total change, mean (SD)	*P* value
Relationship to child			.48
Mother	54 (90)	2.35 (2.17)	
Father	6 (10)	1.67 (2.80)	
Age (y)			.41
26-35	40 (67)	2.15 (2.34)

Table 3. The mean level of agreement with intervention impact on behavioral drivers.

	Values, mean (SD)
The app has improved my knowledge on (capability)	
The importance of getting rest	3.93 (0.94)
How to reduce fall risk while feeding my baby	4.15 (0.84)
How to reduce fall risk while my baby sleeps	4.12 (0.90)
How to reduce fall risk while changing my baby	4.40 (0.79)
How to reduce fall risk when using baby products like chairs and prams	4.17 (0.85)
How to reduce fall risk on stairs	4.30 (0.79)
Overall	4.18 (0.86)
After using the app, I feel (opportunity)	
I have the support I need to get enough rest	3.50 (0.98)
I have everything I need to reduce fall risk while I feed my baby	4.35 (0.60)
I have everything I need to reduce fall risk while my baby sleeps	4.38 (0.56)
I have a safe place to change my baby	4.52 (0.68)
I am able to correctly use safety straps when using baby products like chairs and prams	4.58 (0.53)
I have everything I need to reduce fall risk on stairs	4.20 (0.73)
Overall	4.26 (0.78)
After using the app (motivation)	
Remember to ask for help when feeling tired and feeding my baby	3.90 (1.00)
Have established a routine to reduce fall risk while feeding my baby	4.08 (0.81)
Intend to ensure my baby always sleeps in a cot	3.95 (1.17)
Believe changing my baby on the floor is the best option if I do not have access to a safe change table	4.53 (0.77)
Have established the habit of correctly using safety straps when using baby products like chairs and prams	4.42 (0.74)
Believe stairgates are important in areas accessed by my child	4.68 (0.50)
Overall	4.26 (0.90)

Analysis

The R programming language (R Foundation for Statistical Computing) was used for statistical analysis. In-depth interview data were transcribed and analyzed using NVivo software (Lumivero). Sample characteristics for the 60 participants in the longitudinal study were examined using descriptive statistics. The analytical approaches varied for each part (parts 1-4) of the study. The following section describes the approach adopted for each part.

Part 1: Determining the Overall Impact of Exposure to Intervention to Reduce the Risk of Falls

The primary outcomes studied in part 1 were the change in responses to the 4 questions included in both the pre- and poststudy surveys (ie, I know how to prevent falls among young children; falls in children under 1 can be prevented; I am confident I can take actions to reduce the risk of my child falling; and I have taken specific actions to reduce the risk of my child falling) and change in overall participants "potential to reduce the risk of infant falls." The latter was calculated from both pre- and poststudy responses by summing the Likert values for each of the 4 questions. An "intervention impact" score was then calculated by subtracting the total pre score from the total post score.

The pre-post difference in responses to the 4 questions was examined using paired Wilcoxon signed rank tests. The pre-post difference in the overall "potential to reduce the risk of infant falls" was examined using a 1-tailed paired *t* test.

The influence of exposure to the app on potential to reduce the risk of infant falls for different types of participants (as described by demographic variables: relationship to child, age of parent, 1 or more children, country of birth, household income, marital status, and education level) was examined by testing the difference in mean "intervention impact" between the different demographic groups. For dichotomous variables, independent 1-tailed *t* tests were used, and for variables with ≥2 category levels, ANOVA was used.

Part 2: Behavior Drivers for Fall Prevention After Exposure to the Intervention and the Relationship Between Behavior Drivers and the Impact of the Intervention

To examine the behavioral drivers for falls prevention (capability, opportunity, and motivation) among parents after exposure to the intervention, the mean level of agreement with each of the capability, opportunity, and motivation statements (Table 3) was calculated across the whole sample, together with the overall mean for each group of statements across the whole sample, that is, a mean overall capability, opportunity, and motivation score.

To examine the relationship between the behavioral drivers as self-evaluated by participants and the impact of the intervention, a capability, opportunity, and motivation score was calculated for each participant by summing the level of response provided for each question in each group (Table 3), and an overall "behavioral driver" score for each participant was calculated by summing the level of agreement with each statement listed in Table 3. The association between the behavioral component scores (ie, capability, opportunity, and motivation scores for each participant) and the impact of the intervention was examined using multivariable linear regression. A second linear regression analysis was then conducted to examine the relationship between the overall behavioral driver scores and the impact of the intervention. In both regression models, demographic variables found to be significantly associated with the impact of the intervention were also controlled for parent's experience.

Part 3: Determining Acceptability of the App as a Whole and Engagement With the App

Engagement with the app, as measured using responses to the question "I used the app," and the number of tracked tasks per participant were examined using descriptive statistics.

The acceptability of the app as a whole was determined by calculating the mean levels of agreement for each "app-like" statement across the sample, together with the mean overall level of agreement for this group of "app-like" statements across the sample.

Part 4: Explore User Experience to Identify Factors Driving or Hindering User Acceptability and Engagement and Scope for Further Improvement

The in-depth interview data were analyzed using a qualitative descriptive method to identify barriers and enablers of the intervention in terms of user experience [17].

Sample Size

A sample size of 62 was estimated to be sufficient for the quantitative components of the study based on a power calculation to see a significant change in parents' potential to reduce the risk of falls with an effect size of 0.4 and 80% power at the 5% level, allowing for up to 20% loss to follow-up and rounding up to the next full number.

For the qualitative poststudy in-depth interview, a sample size of 10 was chosen using a rule of thumb that this sample size should be sufficient to reach saturation and is double the minimum sample size recommended for digital intervention usability studies with a sample of 5 [18].

Results

Sample Characteristics

A total of 62 participants were recruited, downloaded the app, and completed the baseline survey, with 2 (3%) lost to follow-up. Therefore, 60 participants completed the poststudy survey. Table 2 presents the sample characteristics. In summary, 54 (90%) were mothers, 40 (67%) were aged 26 to 35 years, 20 (33%) were new parents, and 49 (82%) were born in Australia; 43 (72%) patients were married.

Part 1: Determining the Overall Impact of Exposure to the Intervention to Reduce the Risk of Falls

There was a significant improvement in each measure of the potential to reduce the risk of infant falls from after exposure to the intervention compared with before exposure. For each question, there was a significant increase in the level of agreement with the statements (Figures 1-4; $P<.001$).

There was also a significant improvement in the overall potential of parents to reduce the risk of falls after using the intervention. The mean overall score among participants before exposure was 15.77 (SD 2.24; range 10-20) and 18.05 (SD 1.86; range 14-20) after a 3-month exposure to the app ($P<.001$). Across the entire sample, the mean "total change" in potential to reduce the risk of falls was 2.28 (SD 2.23; range −2 to 8).

Table 2 presents the "total change" according to the different participant demographics. The only significant difference by demographics was a significantly greater "total change" in the potential to reduce the risk of infant falls among participants with only 1 child. Parents with ≥2 children had a mean "total change" of 1.85 (SD 2.08; range –2 to 5) whereas the less-experienced parents with only 1 child had a mean "total change" of 3.15 (SD 2.30; range –1 to 8; $P=.03$).

Figure 1. Level of agreement with “I know how to prevent falls among young children”: before versus after.

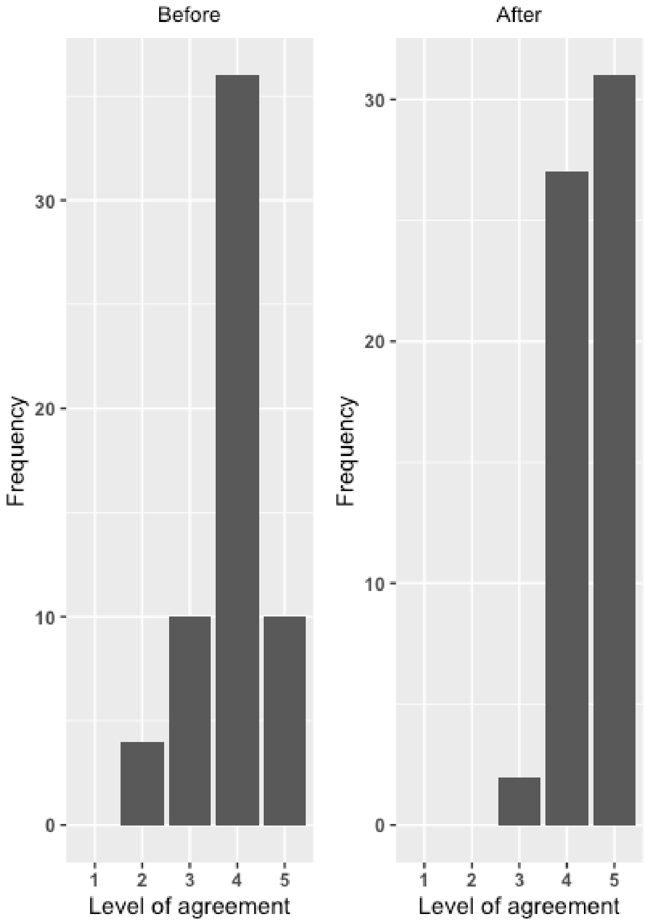

Figure 2. Level of agreement with “Falls in children under 1 can be prevented”: before versus after.

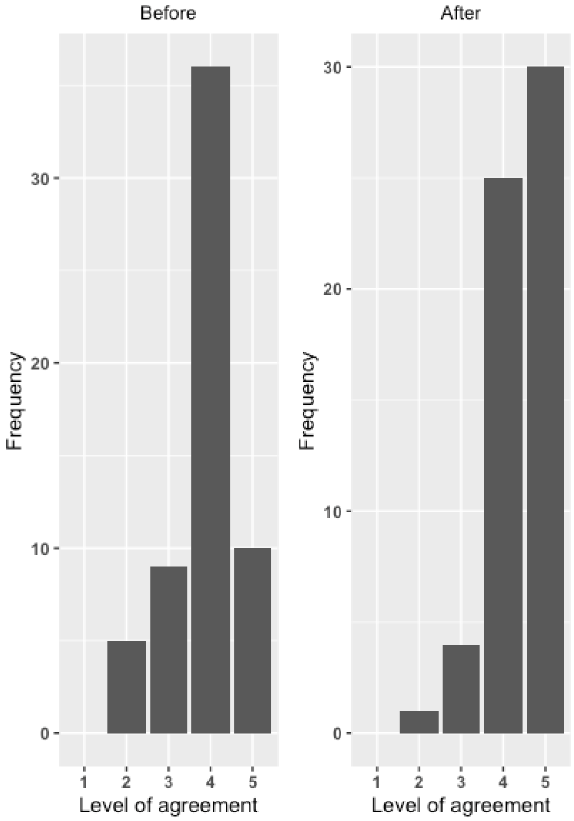

Figure 3. Level of agreement with “I am confident I can take actions to reduce the risk of my child falling”: before versus after.

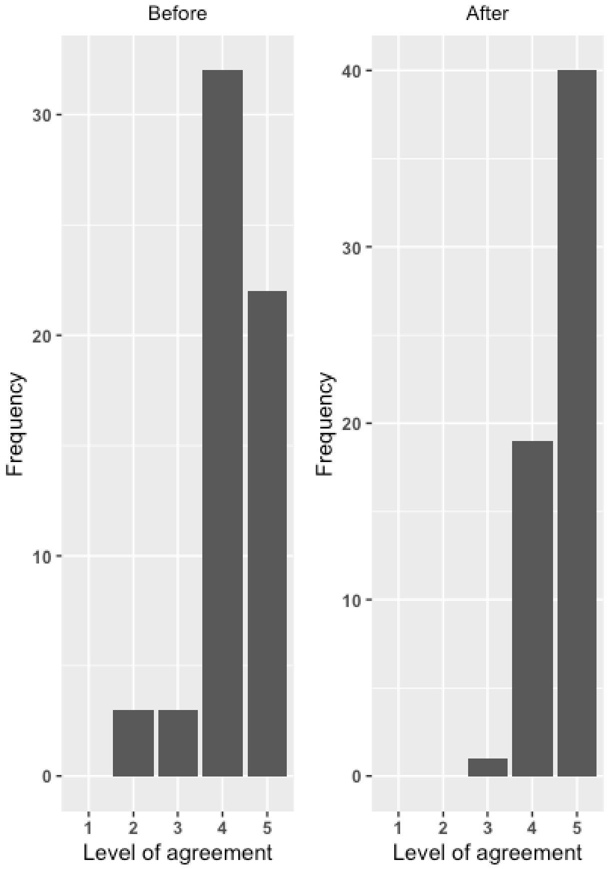

Figure 4. Level of agreement with “I have taken specific actions to reduce the risk of my child falling”: before versus after.

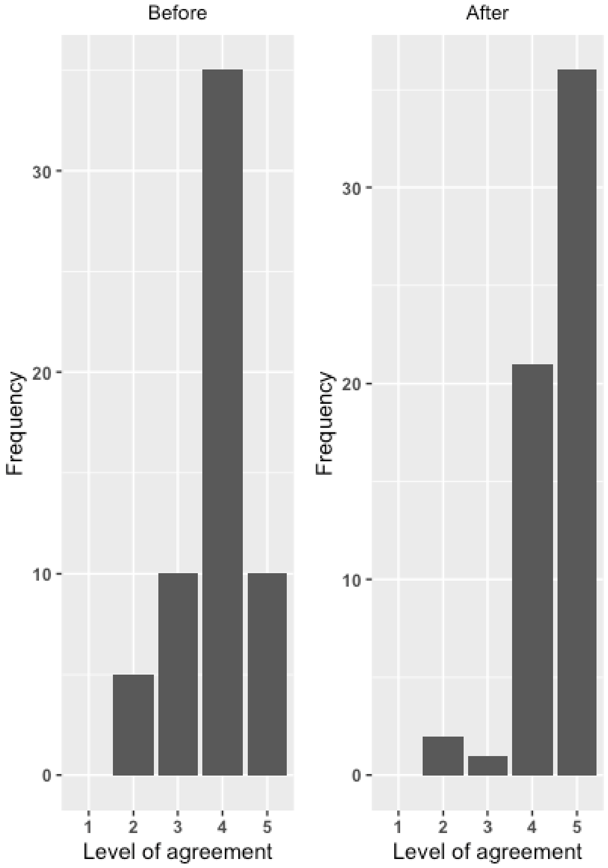

Part 2: Behavior Drivers for Fall Prevention After Exposure to the Intervention and the Relationship Between Behavior Drivers and the Impact of the Intervention

The mean level of agreement with each statement across the sample is shown in Table 3. As shown in Table 3, there was strong agreement with overall capability, motivation, and opportunity as self-evaluated by participants after using the app. The only aspect where there was inconsistent strong agreement was in questions related to getting enough rest where capability, opportunity, and motivation means across the sample remained <4.

Tables 4 and 5 present the results of the linear regression analyses. In the univariate analysis, opportunity and motivation scores were significantly associated with the impact of the interventions, with increasing behavioral component scores associated with increasing impact scores. However, in the multivariable analysis when controlling for parent experience (which was found to be significantly associated with the impact of intervention in part 1), none of the individual behavior components were significantly associated with impact (Table 4).

As shown in Table 5, the overall behavior score was significantly associated with increasing impact scores, even when controlling for parents' experience.

Table 4. Regression analysis modeling the relationship between behavior drivers and intervention impact.

	Univariate		Multivariable	
	Estimate	*P* value	Estimate	*P* value
Capability score	0.127	.07	−0.017	.86
Opportunity score	0.257	.006[a]	0.191	.12
Motivation score	0.207	.01[a]	0.926	.49
Experienced parent (yes or no)	−1.3	.03[a]	−1.196	.04[a]

[a] *P*<.05.

Table 5. Regression analysis modeling the relationship between overall behavior score and intervention impact.

	Univariate		Multivariable	
	Estimate	*P* value	Estimate	*P* value

Experienced parent (yes or no)	−1.3	.03[b]	−1.118	.04[b]

[a] BD: Behavior Drivers Score.

[b] *P*<.05.

Part 3: Determining Acceptability of the App as a Whole and Engagement With the App

Table 6 presents the mean level of agreement of app use statements across the sample of participants, including their app use, whether they read the articles, and used the task tracking feature. The mean number of completed tasks per participant was 24 (SD 24.2052).

Table 7 presents the mean levels of agreement across the whole sample for each of the "app-like" statements and the mean overall, indicating generally strong acceptability (agreement levels over 4) of the app as a whole. The lowest levels of agreement were in the response to the "I like the features of the app" and "I found the reminders/notifications helpful."

Table 6. Participant agreement with the use of the intervention.

App use	Scores, mean (SD)
I used the app	3.53 (0.68)
I read the articles	4.17 (0.98)
I used the task tracking feature	3.75 (1.31)

Table 7. Participant agreement with the acceptability of the intervention.

App-like	Scores, mean (SD)
I found the app easy to use	4.20 (0.71)
I found the information useful	4.05 (0.79)
The advice provided was easy to follow	4.52 (0.60)
I could act on the advice provided	4.22 (0.94)
I like the features of the app	3.67 (0.93)
I found the reminders or notifications helpful	3.68 (0.89)
Overall score	4.05 (0.87)

Part 4: Exploring User Experience to Identify Factors Driving or Hindering User Acceptability and Engagement and Scope for Further Improvement (Qualitative Analysis)

General Understanding of Child Injury and Feedback on the Intervention

Parents expressed that the intervention provided them with important information, which was new. The intervention seemed to be valued more by new parents. It was evident that child injury was not an area that parents gave much attention to ("Injury is not something I had put too much thought into, I guess I just considered a baby didn't move"). Some parents had a general understanding and personal fear about falls due to the experiences of other parents they knew. In addition, safe sleeping practices and safe change table practices were commonly identified as information parents received from antenatal classes ("one of the main ones that I sort of looked at when my first son was born was more pages like SIDS"). However, the consensus was that they had little knowledge of specific preventive actions for most of the common fall events:

> *I learned so much...it brought to light a lot of things that you wouldn't think of...first I was like, you know, but then every time I would read something, I'd learn something.*

Experienced parents (who had more than 1 child) also identified the importance of the intervention. Even in cases where they knew some preventive actions beforehand due to lived experiences ("it was really just some anecdotal stories of my friends babies falling off things and hurting themselves..."), they identified that the intervention was a good reminder to adhere to safe behaviors:

> *I can't remember how I learned the information with my first child, but it was definitely a great reminder and easy access to find the information all in one place.*

Parents liked the style of the articles, which they reported they found engaging and informative and liked that the length was not too long. They also identified that if articles were too long, parents may not bother reading them, particularly as during the first year of a child's life a lot of information is "thrown" at parents:

> *I thought it was really well written. I liked the style of the way that it was written. I thought it was. It was very engaging and informative and I liked the length of it as well. But it wasn't too long. It just made it easy to when you're busy as a mum, sort of dip in and out of just having a bit of a look and yeah, and like getting some information quite quickly rather than reading pages and pages out. It was also quite easy to access different topics with them.*

Parents also identified the importance of the tone of the intervention and appreciated the practical nature of the advice provided:

> *I liked it because it was really straightforward. It's not in any way condescending. I don't think it's like I think sometimes you read resources and they can be like talking down to you. But I found that it was like simple language, but not in a condescending way.*

Credible profiles were valued by parents. They requested more ways to show the credibility of the information such as embedded links below the articles from reputable organizations:

> *And I like it. It's got the...like professors on there.... So it's telling you that there's experts on this.*

The task-tracking and adherence dashboards were features liked by most participants. "Checking things off a list" was well liked. The adherence dashboard was found to be an incentive "to get it all green." Parents understood the rationale of task tracking and expressed its importance in encouraging them to adhere to what was conveyed in the articles. However, there were some issues with the user experience of this feature ("I'm not finding easy to find what the ongoing ones are"). One parent requested access to the task list directly, without going through any related article. Another expressed that they could not get "100%" due to some tasks being not relevant for them. The "if-then" tasks were somewhat disliked:

> *I think that I think that idea of it is good, like having tasks that you can go through and say, yes, we've done this, but just the way it was delivered.*
>
> *I quite like checking things off. At least you know this is quite satisfying to kind of get to the ending. Right. OK, well, you know, I have half a clue about what I'm doing in this area.*

The notifications were found to be helpful. Parents expressed that the notifications made them come back to the app, made them read the articles, and helped them adhere to suggested practices. However, 2 participants mentioned that they did not receive notifications:

> *I liked the little reminders and I do. I do like that ‘cause. I think you get busy and then you don’t think to use it. So I did like the notifications as a way from reminding to dip back in and have information.*

App esthetics was also positively received. Parents liked that the app used real photos rather than drawings. Several “typos” within the content were noticed by the parents and were negatively received (“I’m a bit of a stickler for, you know, the text, I guess so, like typos and things, you know”).

Feedback on 4 Modules

Information provided in the safe feeding module was not practical for some parents. This was because it was dependent on the amount of social support available for mothers.

In addition, some mothers identified the possibility of cosleeping occurring, although this was not suggested by the module. One mother indicated that her initial evaluation of the intervention was not positive because of this inapplicability to her situation:

> *Uhm, I think probably this one was the least effective for me. I think like I like I mean it. I thought it was very helpful for reminding, reminding you of the importance of rest in that, that there it is risky to feed while you are tired. I think like in terms of actually making changes, it was I think the app was less helpful in doing that then the other modules because it was really around like getting support and that sort of thing, which is something that the app can’t necessarily help you with because either you have social support and you have people that can help you or you don’t work down the other modules provided more practical advice which weren’t sort of dependent on social support.*
>
> *Get enough sleep, you know, have your partner or someone to support you to come and do that? Well,... I actually left my job after my first one, and my husband still works and he gets up at 4:00 AM. It’s unrealistic for me to expect that. But for me, the one who doesn’t work to say, Oh no, you need to get up. Or every second night you’re on duty to take over. It’s just not possible.*

Some advice was not practical for parents with more than one child, such as “sleeping while the baby sleeps,” where they have to take care of the other child at the same time (“to sleep when the baby sleeps, I thought, what about my toddler, he doesn’t nap”).

Despite these limitations, parents understood the reasons for the suggested practices. They also expressed that the module made them conscious when they were tired during night feeding and encouraged them to take action to reduce the chance of falling asleep while holding the baby. Some expressed the importance of acknowledging differences in individual experiences within the module to mitigate any negative feelings induced (“it’s one of those things where it’s like ideal situation, right. But the reality is just sometimes so different”).

The parents liked the safe furniture use module. The message “one day the baby is still, and next day they are rolling,” resonated well with the parents. Commonly, parents expressed that they practiced keeping the baby in the cot if they had to move away or “on the floor,” where they could not fall, but some parents still left their baby on a bed, when they are in the prerolling age, in the “middle of the bed”:

> *I really liked this one. It made me yeah, it really made me reconsider that. Uhm, you know, even if you think either in the middle of the bed they are fine, that actually like it, they made that maybe when they roll and so it may be this. So this was helpful for me in thinking actually, although you’re tempted to put them on the bed or put them on the change table, they’re actually safer on the floor like putting them on the carpet actually safer than putting them on the bed. So this one actually really did stick with me. And that’s something that I thought about continually is actually just put him on the floor and he’s safer ’n the floor 'cause he can’t. fall anywhere.*

Parents found safe nappy change practices to be acceptable when using a change table. For some, this was aligned with the information received previously in the antenatal classes, but most mentioned that there are no safety straps in their own change tables, so keeping a hand on the baby was the applicable advice (“I don’t have a change table with straps and I do. I’m not sure that that’s a standard thing”). Changing nappies on the floor “where they can’t fall” was also liked by some, but some expressed this may be not practical in instances where the mother had a cesarean birth (“but as a mom who had two caesareans, I’m not gonna be getting down on the floor with a newborn baby”).

The module for the safe use of baby products was well received. Parents reported that the module made a difference on how they used safety straps with products. Some parents previously did not think of using straps when the baby was “very small” but reported that the module had an influence on changing the practice of using safety straps. One parent found that the information also influenced how they picked secondhand baby products, which seemed to be a common practice:

> *I think it might has made me so that you always say the straps here, but I think it’s just made it. It really reinforced to me how important it is to always do it up and if they look, you know that you think are there sitting there. They look secure, already without the straps on just to make it a habit of doing them up. So that was really good reminder for me that or you always need to just do it up just to just for that safety ‘cause you never know when they’re gonna try and reach for something or rollout or slide out. I think it also made me more aware of When I was buying secondhand baby items, they saw that all of the clips and everything were usable and that and present.*

The use of a wheeled baby walker was well accepted. Parents had commonly received some information on the negatives of baby walkers before the intervention. They understood that wheeled walkers are a fall risk and might also affect a baby's natural ability to stand. One parent mentioned that they still used one, but the duration of use was reduced after the intervention:

> *No, I never did. Somewhere I read early on that they aren't safe 'cause they can get to places they shouldn't be able to get to. Uh,.... So I've never had one. I had a bouncer that didn't move. That's probably not great for their development, but in put them in it too much. But it wasn't their safety thing in terms of, yeah, getting places, they shouldn't get to.*

Parents who had stairs in their homes identified the importance of the information included in the module for creating a safe home. Parents knew about using safe gates but identified the importance of other stair safety practices, but commonly, parents who did not have stairs found this module not relevant to them. They requested relevant information, such as babyproofing the environments:

> *We already knew that we needed to get safety gates. I've got friends with children. So you're already aware of the gates. But I do find the app. Yeah. Helpful from just from the tips around stairs. So, like, sort of saying don't step over the gate. And that's really stuck out to me. Was like, hold onto the rails and like and making sure that you have a free hand because it's so easy with stairs to hold baby in one hand and then be carrying a cup of tea or something else with the other hand. That is something that has changed my behavior, like making sure that I don't have my hands full and nothing to hold onto.*

General Feedback

Most of the interviewed parents expected more from the intervention. Even those who really liked the intervention expected more. Some thought the scope was too narrow, focusing only on falls, compared with multiple injury mechanisms, and mentioned that they may not have used it if they came across it outside the study. In addition, they felt that the intervention should have more engaging features ("It need something to keep you coming back to"). Parents had several suggestions to improve the scope of the intervention, such as providing more information relevant to older children, information on other child injury types, and prevention (babyproofing the house), including first-aid information and tapping into other relevant early childhood information:

> *...And I know this is sort of more a pilot, but I just wanted to see more, but I think that's where you're going with it. I'm, I've got through the modules quite quickly and I thought there's no more. I finished it now.*

> *...but I would really love like a checklist of this is everything that you need to do, you know, to baby proof your house so, you know, draw locks, baby gates like a, you know, like a a nice little comprehensive list for you to sort of do a scan of your house and then, everything you can do to make it injury safe, your baby.*

Parents expressed the importance of receiving the app from reputable agents to find it valuable and for them to use it (eg, via an antenatal class):

> *I think if I'd been aware of it, yeah, I definitely think so. So yeah, if, yeah, if at the hospital or the midwife or if it had been in, you know, the baby bundle that you get if there'd been a little flyer. Yeah, it would be something I'd look at. And definitely if I'd known it.*

Parents reported that they liked mobile apps rather than scanning through websites to obtain relevant information. Similarly, it was evident that although they tended to use social media groups (Facebook groups) to seek childcare information, they preferred reputable sources and sources where they can find professionally backed reputable information:

> *And sometime like when you're looking at websites and stuff, it can get so confusing, whereas like having an app or just one place to look just makes things so much more straightforward.*

> *I've recently got rid of Facebook because they're or maybe within those groups, there tends to be lots of negativity and scaring and I would be, I think it's taken me three kids and this long to realize that it's probably not a space I really want to be in and without an expert moderator, I don't wanna be there 'cause you can get too much information.*

Parents felt that there is a place for digital interventions in the space of early childhood interventions. Several parents shared the opinion that the support provided by the primary health care system reduced after a while and identified the viability of digital health interventions to fill this gap. In addition, they felt that the intervention value would increase if it provided some form of opportunity to connect with a health care professional:

> *Because there is such limited access to midwife and nursing support after having baby now like anything you can access at home...make a difference.*

> *You have lot of contact with the support initially, then you don't really see anyone.*

Triangulation of Quantitative and Qualitative Data

Triangulating the quantitative and qualitative data provided insights for where key improvements could be made to the app going forward. As shown in Table 8, where these are summarized, these largely focus on improvements that would make the app more valuable to parents.

Table 8. Areas to improve and potential improvements.

Areas to improve	Potential improvement
Broadening the scope of the intervention	Intervention could be broadened by including first-aid information and other injury information, including information relevant to a broader age group of children and other early childcare information. Special consideration needs to be given to make the app more valuable for experienced parents.
More autonomy for parents and reframing some advice as "suggestions"	Within intervention content, focus will be given to ensure the advice conveys as suggestions rather than "must follow" advice.
Improving practicality of information	Special consideration will be given to palpability of advice considering a range of individual circumstances of parents.
Improvements to task tracking	The task-tracking feature will be improved by introducing a direct way to access task lists and better ways to identify task ongoing and completion states.
Improvements to if-then plans	If-then tasks will be improved with giving parents a list of options that they can select from to create if-then rules.
Connecting parents to a health care professional	A feature where parents have ≥1 sessions with a health care professional who is experienced in child injury and early childhood could be introduced. This could also be used as a reengaging moment with the intervention for parents.

Discussion

Principal Findings

The findings from this study demonstrate promising potential of the intervention in terms of the impact on reducing the risk of infant falls, particularly among new parents. They also indicate promise in terms of an influence on drivers of parental behaviors important for fall reduction among infants. Acceptability of the app was high, and important insights were gained from users about how to further improve the app.

In this study, the potential to reduce the risk of falls was measured by examining the change in responses to a set of questions asked by the participants before and after the 3-month long exposure to the app. As there was no available validated measure, this set of questions was developed on the basis that knowing falls can be prevented, feeling confident that actions can be taken to prevent falls and taking action to reduce fall risk align with what was hoped would be the desired outcomes from exposure to the app. Although this is self-reported and not a validated measure, the relationship observed between this measure and the participants' responses to questions based on the COM-B self-evaluation questionnaire provides a level of promise that the intervention may work as intended. However, confirmation of the effectiveness of the intervention requires a different methodological approach, such as randomization and use of control, and for this purpose, the use of an objective measure such as reduction in falls would be preferred. Demonstrating the promise of an intervention during the early stages is important, as this reduces the risk of unnecessarily wasting resources in a later, larger, and more resource-intensive randomized controlled trial.

For digital and mobile health interventions, acceptability, usability, and engagement are likely to be as important to effectiveness as the content. The results also demonstrate promise in this regard. Importantly, the users trialing the app appeared to like the app and found it easy to use and useful. More importantly, the feedback from the users identified some areas for further improvement that could be relatively easily actioned, such as improvements to the task-tracking and "if-then" plans, and reframing some of the advice provided to convey more autonomy. However, as identified in user testing during the development phases [13], it was clear from this longitudinal study that in the longer term, the scope of the app needs to be broadened to increase the likelihood of high levels of ongoing engagement.

Concerns raised about the practicality of advice and the relevance of all components of the intervention to all users in this longitudinal study also reflected some of the feedback received during the user testing reported in the study by Cooray et al [13]. As noted in this study [13], issues raised regarding the practicality of advice drawn from best-practice sources indicate a need for further research into practical solutions. However, it may be that it is only certain parents or parents in certain situations who have practical issues, that needs to be explored further. It is possible that the contents of the intervention could be delivered in an individually tailored manner, and this might overcome both the concern of relevance of all information to all users, as well as issues related to the practicality of some advice for certain people or situations. Digital intervention in which injury prevention information is tailored to individuals has been found to be effective in promoting the adoption of safety behaviors relevant to the use of stair gates as well as other childhood injury mechanisms [19]. The potential of this approach should be considered in conjunction with further development of the app.

The potential promise of this behavioral theory–driven app on influencing behavior relevant to falls aligns with the success of other theory-driven digital interventions targeting childhood injury in changing behavior [20-23]. However, this is the first childhood injury intervention developed using the BCW. The significant association between the "behavior score" calculated from responses to the parental COM-B self-evaluation questionnaire and the outcome measure observed in this study also appear to be the first attempt at examining the pathways through which a behavioral theory–driven childhood injury prevention intervention works. Although the approach in this study was rudimentary, consideration should be given to designing future rigorous testing of the app in such a way that the mechanistic pathways can be studied in parallel with the overall effectiveness. The quantitative process evaluation being undertaken by Brown et al [24] in conjunction with the evaluation of their user-driven intervention to reduce the misuse of child restraints is an example of how this might be achieved. This level of evidence for the behavioral underpinnings of the success of digital interventions would further strengthen the case for designing childhood injury interventions using a behavioral theory lens.

The person-based approach to app development is likely to have influenced the high levels of usability and acceptance of the app. However, user feedback indicates that more work is required to increase engagement. The importance of engagement in digital injury prevention interventions has also been identified by other researchers. For example, Ning et al [20] cited poor engagement as a factor that may have reduced the impact of their digital intervention on reducing actual rates of injury. In their study, they measured average hours of engagement and felt that the level of engagement was relatively lower in terms of average hours of engagement than had been reported in other successful digital interventions [20]. However, no attempt has been made to directly study the level of engagement and any outcome. In contrast, Burgess et al [22] examined the direct association between their measure of engagement and an increase in knowledge and found a significant association. Including objective measures of engagement in future attempts to quantitatively evaluate processes underpinning the success of digital interventions would also appear to be useful.

The lack of an objective or quantifiable measure of engagement in this study was a limitation, and tracking engagement is something that should be added to the protocols of any future studies with this app. Other important limitations of this study are as follows: the use of an unvalidated outcome measure for the performance of the app and the pre-post design, which means no causal relationship between exposure to the app and the outcome measure can be confidently claimed. Furthermore, when reviewing the results of this study, it should be noted that recruiting participants via an internet-based panel means that the sample is possibly biased toward inclusion of only those who are already digitally active and computer literate, which may affect the generalizability of the findings. Future studies should aim to assess the intervention across a broader segment of the population. Keeping these limitations in mind, a strength of the study lies in the usefulness of the work as an intermediate step between optimization through user testing and a more resource-intensive controlled trial with a larger population-representative sample.

Conclusions

The 3-month longitudinal user-testing study has demonstrated the potential promise of the behavioral theory–driven, person-based intervention and has highlighted further scope for refinement. Overall, broadening the scope of the app appears to be the most important issue to be addressed in future work.

Abstract

Background: Since 2020, parents have had increasing opportunities to use telemedicine for their children, but how parents decide whether to use telemedicine for acute pediatric care relative to alternative sites of care is not clear. One of the most common reasons parents seek acute care for their children is for acute respiratory tract infections (ARTIs).

Objective: This study aims to examine parental expectations of care via telemedicine for pediatric ARTIs, contrasting expectations of care delivered via primary care telemedicine and direct-to-consumer (DTC) telemedicine.

Methods: We performed a sequential mixed methods analysis to examine how parents assess telemedicine for their children's acute care. We used ARTIs as a case study for examining parent perceptions of telemedicine. First, we analyzed semistructured interviews focused on parent responses about the use of telemedicine. Each factor discussed by parents was coded to reflect whether parents indicated it incentivized or disincentivized their preferences for telemedicine versus in-person care. Results were organized by a 7-dimension framework of parental health care seeking that was generated previously, which included dimensions related to care sites (expected access, affordability, clinical quality, and site quality) and dimensions related to child or family factors (perceived illness severity, perceived child susceptibility, and parent self-efficacy). Second, we analyzed responses to a national survey, which inquired about parental expectations of primary care telemedicine, commercial DTC telemedicine, and 3 in-person sites of care (primary care, urgent care, and emergency department) across 21 factors identified through prior qualitative work. To assess whether parents had different expectations of different telemedicine models, we compared survey responses for primary care telemedicine and commercial DTC telemedicine using weighted logistic regression.

Results: Interview participants (n=40) described factors affecting their perceptions of telemedicine as a care modality for pediatric ARTIs. Generally, factors aligned with access and affordability (eg, decreased wait time and lower out-of-pocket cost) were discussed as potential incentives for telemedicine use, while factors aligned with perceived illness severity, child susceptibility, and clinician quality (eg, trustworthiness) were discussed as potential disincentives for telemedicine use. In survey responses (n=1206), primary care and commercial DTC telemedicine were rated similarly on items related to expected accessibility and affordability. In contrast, on items related to expected quality of care, primary care telemedicine was viewed similarly to in-person primary care, while commercial DTC telemedicine was rated lower. For example, 69.7% (weighted; 842/1197) of respondents anticipated their children would be comfortable and cooperative with primary care telemedicine versus 49.7% (weighted; 584/1193) with commercial DTC telemedicine (*P*<.001).

Conclusions: In a mixed methods analysis focused on telemedicine for ARTIs, parents expressed more concerns about telemedicine quality in commercial DTC models compared with primary care–based telemedicine. These results could help health systems better design telemedicine initiatives to support family-centered care.

Introduction

The decision to seek care for a sick child is an increasingly complex one for parents. Parents are faced with a variety of care site options, which include both in-person (ie, primary care, urgent care, and emergency department [ED]) and virtual care modalities (ie, primary care provider [PCP] telemedicine and commercial direct-to-consumer [DTC] telemedicine). In recent years, families have increased experience and opportunity to use telemedicine with both their PCP and DTC telemedicine companies [1-4]. Many studies of prior telemedicine users indicate high parent satisfaction after telemedicine use, including high satisfaction with interpersonal and technical components of these visits, while others note concerns about the quality of interpersonal interaction and concerns about misdiagnosis and privacy [5-8]. Studies of parent perceptions as they anticipate or make decisions about potential telemedicine use are fewer. Some have importantly detailed disparities in general willingness to use telemedicine by sociodemographic characteristics or technology ownership [9,10]. Beyond general willingness to use telemedicine, however, it is important to understand decision factors influencing parents toward or away from telemedicine use at the time of a specific health care need.

One common reason for problem-based visits among children is the cluster of diagnoses known as acute respiratory tract infections (ARTIs), which include viral (eg, viral upper respiratory infection and viral pharyngitis) and bacterial infections (eg, streptococcal pharyngitis and acute otitis media). Before the pandemic, ARTIs accounted for over one-third of acute pediatric primary care visits and nearly 50% of DTC telemedicine visits [4,11]. The volume of pediatric ARTI visits dropped substantially during the early pandemic but increased over time with otitis media, streptococcal sore throat, and acute upper respiratory infection remaining common acute visit diagnoses for both in-person and telemedicine care during the later pandemic period [2,12-15]. These data suggest that deciding whether to seek care for pediatric cough and cold symptoms is one of the more common care-seeking decisions faced by parents. Thus, we focus on ARTIs as an illustrative example of a reason parents may seek care for their child, providing an opportunity to examine care-seeking decision-making processes. Important prior studies uncovered factors that may influence family decision-making about ARTI care-seeking, including site accessibility (eg, timeliness and geographic) and quality (eg, interpersonal and clinical) as well as illness and family factors [16-18], but did not explore how the option of telemedicine informs these decisions. More recent qualitative studies have begun to explore ARTI care-seeking decisions in the context of the option of telemedicine [19,20]. As an example, we recently examined parents decision-making for pediatric ARTIs in the context of the option of telemedicine and identified 7 dimensions that influence parents' decisions: perceived illness severity, perceived child susceptibility, parental self-efficacy, expected accessibility of care, expected affordability of care, expected quality of clinician, and expected quality of site [19]. By applying this framework to qualitative and quantitative data focused specifically on parent perceptions of the potential values and risks of telemedicine use, we seek now to understand how families assess individual factors to decide whether to use telemedicine for a specific ARTI care need. Understanding parent perceptions of telemedicine across these 7 dimensions is important to support health care systems in incorporating telemedicine into the acute care landscape beyond the public health emergency.

Therefore, in this analysis, we investigated current parent views regarding decision factors that potentially influence their intention to use telemedicine and other sites of acute care when their children have ARTI symptoms. Specifically, we sought to better understand parent perceptions of telemedicine models compared with in-person care for pediatric ARTIs using both qualitative and quantitative data to specifically examine potential differences in expectations of telemedicine delivered via PCPs versus telemedicine delivered via commercial DTC providers.

Methods

Overview

We performed a sequential mixed methods analysis to examine how parents approach decisions about the use of telemedicine when care-seeking for commonly experienced acute illness. We first conducted a qualitative analysis of semistructured parent interviews in which we asked parents to discuss prior care-seeking when their children were experiencing ARTI symptoms. Previous analysis of specific portions of these semistructured interviews which focused broadly on the decision to seek care published previously reported on 7 broad dimensions that parents consider when deciding whether and where to seek care for their children (perceived illness severity, perceived child susceptibility, parental self-efficacy, expected accessibility of care, expected affordability of care, expected quality of clinician, and expected quality of site) [19]. In this analysis, we examined parent responses to a specific later portion of the interviews where parents were asked to reflect specifically on the option to use telemedicine, which we analyzed to elucidate factors that might incentivize or disincentivize parents to seek ARTI care through telemedicine. Building on these qualitative findings, we fielded and analyzed a national survey to examine pediatric telemedicine use. Prior analysis examined parent-reported use of primary care telemedicine [21]. In this analysis, we focus instead on parent expectations of the care their child would receive if they presented at each of 5 different sites of care: in-person primary care, in-person urgent care, in-person ED, PCP telemedicine, and commercial DTC telemedicine. We adhered to the standards for reporting quality research guidelines for reporting the qualitative portion of this research [22].

Semistructured Interviews

As described in greater detail elsewhere, we first interviewed 16 pediatric research and clinical professionals to establish a normative expert model of parent care-seeking. Insights from these interviews then informed an interview guide for subsequent semistructured interviews with parents. Prior to launching interviews with a full sample (n=40), we conducted 3 pilot interviews with parents to ensure clarity of our questions and definitions. The first portion of the open-ended interview guide inquired about perceived needs, desires, and care-seeking decisions when seeking care generally for a child's ARTI, with results reported previously [19]. This paper focuses on a portion of the interview guide that inquired about the risks and benefits of telemedicine care for a child's ARTI ("What are your thoughts on the benefits of having a provider see your child while you are in your own house?" and "When, if ever, would telemedicine feel like a good choice for a child with a cold?") and barriers to telemedicine use ("What might make a telemedicine visit difficult for your family?"). Parents of children aged 1-5 years were recruited through a research registry of parents in Western Pennsylvania and beyond. All interviews were recorded, transcribed, and analyzed using thematic content analysis. Team members (SB, KR, and TK) independently coded each sentence in the first 5 transcripts and together reviewed and then developed a preliminary codebook of a priori and emergent codes. For each code present, we noted, when relevant, whether the factor was discussed specifically as a reason to use or avoid telemedicine. Upon achieving consensus, a codebook containing definitions and rules was finalized. The remaining transcripts were coded by a primary coder (SB), and 14 of those were cocoded by a second coder (KR or TK). Dedoose (SocioCultural Research Consultants), a qualitative research software program, was used to code interviews. In this paper, we present parental perceptions of potential factors that might positively or negatively influence their interest in the use of telemedicine organized by the previously identified 7 dimensions [19] to illustrate the degree to which these dimensions influence parental decisions to seek care from telemedicine.

National Survey

As described in greater detail elsewhere [21], we then developed a survey informed by our prior qualitative findings and fielded the survey nationally through the University of Chicago's AmeriSpeak Panel [23], a nationally representative panel. The survey included items asking about parent priorities and expectations when seeking care for a child's ARTI, prior telemedicine use, and sociodemographic characteristics. The survey underwent cognitive testing with 3 parents of young children and was offered in English and Spanish. Prior analysis of survey data focused on parent-report of PCP telemedicine use relative to sociodemographic characteristics of the respondent [21]. This analysis focuses on parent expectations of 21 different factors with the potential to influence their care-seeking across 5 different sites of care: in-person primary care, in-person urgent care, in-person ED, PCP telemedicine, and commercial DTC telemedicine. The order in which care sites were presented to respondents was randomized.

In the survey, PCP telemedicine was described as "a telemedicine visit with your child's usual primary care office or clinic. This would be a virtual visit with the provider or group of providers that conduct in-person well and sick care for your child(ren) in the office or clinic." DTC commercial telemedicine was described as "a telemedicine company or group that focuses on telemedicine visits rather than in-person care (also called DTC telemedicine). Providers in these groups do not provide care in-person and are not part of your child's usual care team. In these visits, you connect online and see an available provider in a model that could be thought of as virtual urgent care. Some DTC telemedicine groups or companies are affiliated with health systems but are still separate from primary care clinics who might see their own patients through telemedicine."

The survey was fielded to members of the AmeriSpeak panel, with panel members eligible if they were caregivers of children aged ≤17 years.

This analysis focused on the percentage of respondents who anticipated that the specified care site would meet their expectations "always" or "often" for each of the 21 specific items. For each of the 21 items, we calculated the weighted percentage of respondents who indicated they "always" or "often" expect that item at each site, using weights derived from panel sampling weights along with survey response rates, such that the demographics of the weighted sample align with the US Current Population Survey [24]. Surveys with missing responses to individual items were omitted from denominator for that item. We then used *t* statistics from weighted logistic regression models to compare responses for each item for PCP telemedicine and DTC telemedicine. Finally, we averaged responses to items within each of the 7 dimensions for PCP telemedicine and DTC telemedicine to further synthesize the differences between expectations of PCP and DTC telemedicine.

Ethical Considerations

Semistructured Interviews

The qualitative interview portion of this study was determined exempt from human participants review by the University of Pittsburgh institutional review board (IRB; STUDY20040025). Participants received an IRB-approved introductory script prior to participating in the interview informing them of the goals of the interview, potential risks and benefits, plans to protect their information, and how to contact the research team if they had questions, and they then provided verbal consent to proceed. Identifiable data collected only for payment purposes were stored separately from interview data; interview data were deidentified. Participants received a US $50 gift card through the University of Pittsburgh's Vincent Payment Solutions.

National Survey

The survey portion of this study was determined exempt from human participants review by the University of Pittsburgh IRB and by the National Opinion Research Center at the University of Chicago IRB (STUDY21070080). The University of Pittsburgh research team only received deidentified data from National Opinion Research Center for analysis. Survey respondents were compensated for their time through AmeriSpeak, receiving the cash equivalent of $5 (equivalent of US $17.50/hour) for completing the survey.

Results

Qualitative Interview Results

A total of 40 parents participated in the qualitative interviews, of which 65% (n=26) of parents had more than 1 child, 65% (n=26) of parents had previous experience using telemedicine for a child, and 38% (n=15) of parents had children insured by a commercial or employer-sponsored insurer (Table 1).

Table 1. Demographic characteristics of participants in qualitative parent interviews (n=40).

Dimensions Affecting Parental Perceptions of Telemedicine

Interviewees described a range of factors that affect their perceptions of telemedicine care for their children. These factors mapped onto the 7 dimensions influencing care-seeking, including dimensions related to care sites (expected access, affordability, clinical quality, and site quality) and dimensions related to child or family factors (perceived illness severity, perceived child susceptibility, parent self-efficacy) [19].

Expected Accessibility of the Site

Interviewees expressed interest in using telemedicine due to perceived opportunities to increase temporal accessibility, mitigate geographic accessibility, and maximize convenience (Multimedia Appendix 1). In contrast, some spoke about the value of telemedicine only as a last resort option when other sites could not be accessed. One interviewee described how using telemedicine maximizes convenience as follows: "I honestly couldn't see how [using telemedicine] would make anything difficult, 'cause it's saving me time, gas, all of that stuff" (parent 24). In contrast, some interviewees expressed concerns about digital accessibility and how telemedicine might be less optimal for their family or for other families: "You might not even have access to computer. I mean I guess everybody has a cell phone, but, you know, connecting to like a video call on your cell phone isn't always ideal" (parent 06).

Expected Affordability of the Site

Interviewees favored telemedicine use if out-of-pocket costs were less than or equal to in-person options: "I mean you're not getting that one-on-one or face-to-face time necessarily, so, I kind of feel like [telemedicine] should probably be cheaper [laughter] or free" (parent 06). Parents viewed telemedicine favorably if insurance would cover the expense and less favorably if there was a likelihood of needing further in-person evaluation contributing to a possible second visit expense or when costs for telemedicine were out-of-pocket.

Expected Quality of the Site

Interviewees viewed telemedicine positively when they perceived that telemedicine increased their child's comfort level and made seeking care safer: "Well, the kids will be more comfortable [on telemedicine]. I mean, 'cause I know kids...they get anxious when they go to the doctor's office, so they're symptoms might get worse...I mean, they might also pick other stuff up when they go to the doctor's office. So it might just be an ease, so you're not exposing yourself to other things" (parent 39). Parents were split on whether they felt like telemedicine would allow for adequate assessment of ARTI symptoms, noting that evaluation of some symptoms (eg, ear pain) might be more difficult than others (eg, red eyes) over telemedicine without the availability of equipment with remote assessment capabilities. In contrast, some parents were less receptive to the idea of seeking telemedicine, and pointed out that a telemedicine appointment cannot provide comprehensive clinical care: "It's kind of hard—you can't really do immunization [on telemedicine]—I mean, 'cause you would still have to go to the office to get those" (parent 39).

Expected Quality of the Clinician

Interviewees discussed intersections between telemedicine and the expected quality of clinicians. Some interviewees indicated they would be less interested in using telemedicine if they could not visit a familiar provider: "If it was doctor that...didn't know [my child] well, I might not feel 100% comfortable. But because [pediatrician] knows him and his personality...I'd probably feel more comfortable if [telemedicine] was with her" (parent 12). Interviewees were divided on whether they perceived they would receive reassurance over telemedicine. There was a general perception among interviewees that receiving trustworthy care would be less likely over telemedicine. Additionally, parents expressed more interest in telemedicine when the provider was someone with experience in caring for children. One parent described their preference for a provider with pediatric expertise: "I don't want, you know, like, a doctor who just got their degree last week to try and diagnose what my son has, like, with his cold and everything. I would want someone looking at it who has experience with kids" (parent 31).

Perceived Severity of Illness of the Child

Parent interviewees discussed perceptions of telemedicine that mapped along the following 3 primary child and parent dimensions: perceived severity, perceived child susceptibility, and parental self-efficacy (Multimedia Appendix 2). Interviewees primarily viewed telemedicine less favorably when they perceived the high severity of a child's illness and symptom complexity. One interviewee described her care-seeking decision when her child had a cold: "I think if it's just like a normal cold...I feel like I would be pretty comfortable doing telemedicine for that. And then if they thought it was severe enough, then I would go in" (parent 30). Parent's perceptions of using telemedicine based on their child's demeanor and appearance were divided, with interviewees expressing both interest and disinterest in using telemedicine when their child appeared more ill. In contrast, interviewees generally viewed the use of telemedicine favorably when prolonged persistence of their child's symptoms was the primary driver of care seeking.

Perceived Susceptibility of the Child

Interviewees generally expressed less interest in telemedicine use for ARTI acute care when they perceived greater underlying susceptibility of the child, such as if they have a child with medical complexity or younger age. One interviewee described her preference for in-person care because of a perceived vulnerability to the illness of her child: "I need my child to be seen by somebody because I need them to listen to her lungs, and I need them to check her ears. Maybe if the child is not prone to having ear infections, and she's not asthmatic, then it would be a little different" (parent 33). In contrast, interviewees showed more interest in telemedicine use when trying to avoid community-based exposure: "I'm thinking now I probably should have done [telemedicine] instead of having to take him in, and like possibly exposing him" (parent 12).

Perceived Self-Efficacy of the Parent

Parent self-efficacy factors identified by interviewees included achieving the goal of the visit, antibiotic expectations, and easing uncertainty, all of which interviewees generally viewed as achievable through telemedicine care. For individual interviewees, however, self-efficacy factors, such as parent health literacy and worry, were discussed as individual reasons to seek and not to seek care through telemedicine. Concerns about the ability to protect their child's privacy (ie, information privacy and physical location privacy) and negotiate power differentials (ie, equity and patient-clinician power dynamics) contributed to parental worry about using telemedicine. One parent described these worries: "They [provider on telemedicine] could catch you at a really bad time whenever, you know, 'cause when a kid is sick...things in the house just kind of—everything falls into chaos, so they could be seeing a snapshot and judging your entire life by that" (parent 03).

Survey Results

Survey invitations were sent to 6015 AmeriSpeak panelists, with 1599 (26.6%) of those invited completing the screener; of the 1599 individuals screened, 1297 (81.1%) met the eligibility requirements; and of the 1297 individuals who were eligible, 1206 (93.0%) completed the survey. The majority (1136/1206; 96% weighted) of respondents took the survey in English, and 60% (weighted; 714/1206) had children insured through a private employer or purchased directly (Table 2).

Table 2. Demographic characteristics of participants (n=1206) and weighted percentages in a quantitative national survey.

Characteristics	Survey respondents, n (weighted %)[a]
Sex	
Female	786 (55.3)
Male	420 (44.7)
Age group (years)	
18-29	158 (11.8)
30-44	761 (59.2)
45-59	258 (26.3)
>60	29 (2.6)
Race and ethnicity	
Asian, non-Hispanic	34 (6.4)
Black, non-Hispanic	109 (11.3)
Hispanic	375 (22)
White, non-Hispanic	634 (56.6)
Other, non-Hispanic	54 (3.7)
Census division	
South Atlantic	233 (19.5)
Pacific	195 (16.7)
East North Central	172 (14.3)
West South Central	136 (13.2)
Mountain	129 (8)
Mid-Atlantic	103 (11.4)
West North Central	102 (6.6)
East South Central	77 (6)

Survey language	
English	1136 (96.1)
Spanish	70 (3.9)
Previous telemedicine use for a child	
Yes	516 (41)
Child insurance type	
Employer or Commercial	714 (60.2)
Medicaid or federal	460 (37)
Uninsured	32 (2.8)

[a] Percentages may sum to >100% due to rounding.

Parents were asked to indicate how often they expect to find each of the 21 specific items across 5 different care sites. For most items, respondents most commonly expected to experience that item at an in-person primary care visit compared with the 4 other sites. The 2 virtual sites of care carried higher expectations than in-person primary care for items related to accessibility and not being near other sick children (Multimedia Appendix 3). For example, out of 1200 respondents answering the item, 56.3% (weighted; n=679) expected to avoid a long wait through a primary care visit, compared with 60% (weighted; 740/1195) through commercial DTC telemedicine and 64.1% weighted (790/1200) through PCP telemedicine. The 2 virtual sites carried lower expectations than all 3 in-person sites for "being able to complete all tasks" (within the expected quality of site dimension) and "ability to care for severe symptoms" (within the perceived illness severity dimension; Table 3 and Multimedia Appendix 3).

Parents reported high expectations for PCP telemedicine across several system dimensions (Table 3), with three-quarters indicating expecting to be able to usually or always see a provider with experience caring for children (919/1195; 76.5% weighted) and to receive care in a way that protects the child's privacy (932/1198; 76.2% weighted). Parents largely had higher expectations for PCP telemedicine than commercial DTC telemedicine for items related specifically to their perception of their child's illness and susceptibility with 75.7% (weighted; 915/1198) always or often expecting the ability to receive care across the 0-17 years age range at PCP telemedicine (Table 4 and Multimedia Appendix 4).

Comparing expectations specifically for the 2 telemedicine options, responses were relatively similar for accessibility items and were the most discrepant for quality of clinician and child susceptibility items. For example, a similar percentage of parents expected to always or often receive care that does not disrupt their schedule for PCP telemedicine (723/1200; 60.2% weighted) and DTC telemedicine (696/1195; 59.1% weighted; *P*=.57), which is an item under the accessibility dimension. In contrast, parents' expectations to often or usually receive care from a "provider who they trust to make choices in their child's best interest" varied from 72.4% (weighted; 885/1199) for PCP telemedicine to 54.3% (weighted; 664/1192) for DTC telemedicine (*P*<.001). Similarly, parents' expectations to always or often receive care from a "provider with full access to their child's medical history" ranged from 71.3% (weighted; 857/1194) for PCP telemedicine to 46.5% (weighted; 541/1190) for DTC telemedicine (*P*<.001).

Survey results were averaged within each of the 7 dimensions and mapped onto the previously identified health care–seeking decision model (Figure 1), with line weight illustrating the difference in parent expectations of PCP and DTC telemedicine.

Table 3. Percentage of caregiver respondents (n=1206) who "always" or "often" expect the factors listed relating to expected accessibility, affordability, and quality at the 2 telemedicine sites (primary care provider [PCP] telemedicine and direct-to-consumer [DTC] telemedicine).

Factors[a]	PCP telemedicine, n/N (weighted %)	DTC telemedicine, n/N (weighted %)	*P* value
Expected accessibility			
Fits schedule	723/1200 (60.2)	696/1195 (59.1)	.57
Minimal hassle	892/1199 (73.9)	843/1195 (70.4)	.045
Minimal wait	790/1200 (64.1)	740/1195 (60.0)	.04
Expected affordability			
Minimal costs	676/1197 (54.5)	553/1196 (46.2)	<.001
Expected quality of the site			
Knows child	726/1198 (60.5)	416/1196 (35.9)	<.001
Pediatric experience	919/1195 (76.5)	672/1193 (55.9)	<.001
Record access	857/1194 (71.3)	541/1190 (46.5)	<.001
Can trust	885/1199 (72.4)	664/1192 (54.3)	<.001
Expected quality of the site			
Protects privacy	932/1198 (76.2)	756/1196 (61.8)	<.001
Comprehensive tasks	656/1194 (56.1)	505/1196 (42.3)	<.001
Avoid exposures	890/1197 (73.4)	856/1192 (72.4)	.54
Child comfort	842/1197 (70.3)	584/1193 (50.2)	<.001

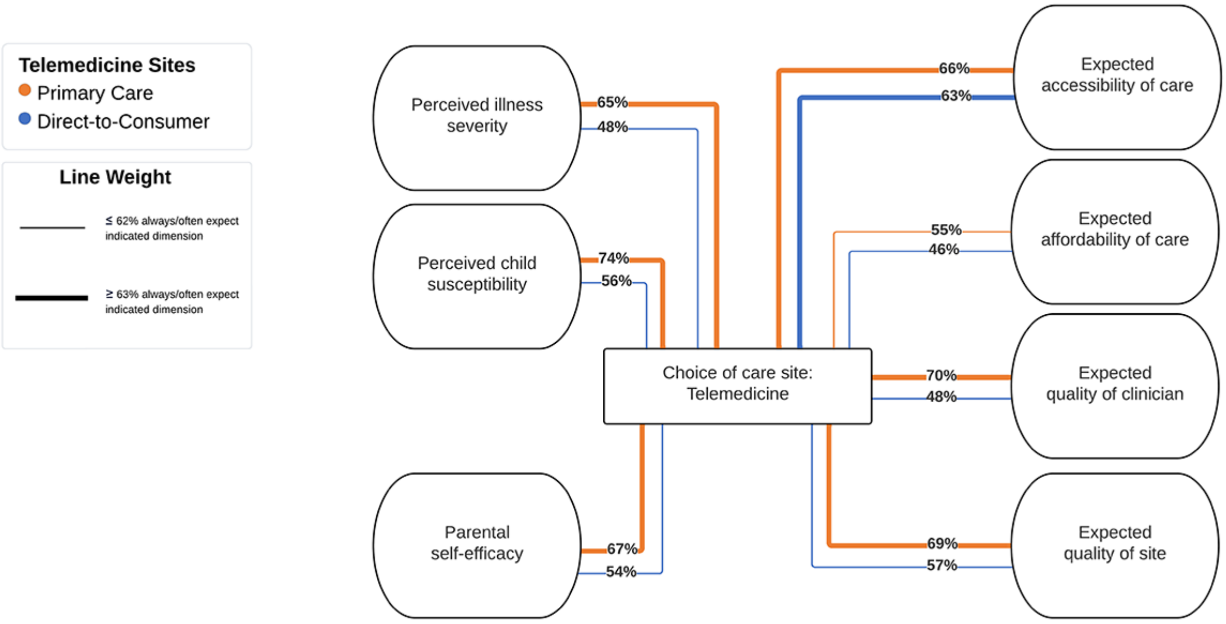
[a] For each item, we calculated the weighted percentage of nonmissing responses indicating that the item was expected "always" or "often" at the specified site. We determined statistical significance using *t* statistics from weighted logistic regression models to compare responses for each item for PCP telemedicine and DTC telemedicine.

Table 4. Percentage of caregiver respondents (n=1206) who "always" or "often" expect the factors listed relating to perceived illness severity, perceived child susceptibility and parental self-efficacy factors at the two telemedicine sites (primary care provider [PCP] telemedicine and direct-to-consumer [DTC] telemedicine).

Factors[a]	PCP telemedicine, n/N (weighted %)	DTC telemedicine, n/N (weighted %)	*P* value
Perceived illness severity			
Severity responsive	773/1199 (63.1)	585/1198 (48.3)	<.001
Duration responsive	792/1196 (65.3)	576/1194 (48.1)	<.001
Multiple symptom responsive	814/1199 (67.9)	634/1198 (51.6)	<.001
Seriousness responsive	762/1199 (63.3)	553/1196 (46.0)	<.001
Mood responsive	790/1196 (64.4)	579/1190 (47.6)	<.001
Perceived child susceptibility			
Considers history	902/1193 (73.1)	646/1195 (52.6)	<.001
Age responsive	915/1198 (75.7)	718/1193 (58.4)	<.001
Parental self-efficacy			
Will understand	892/1200 (73.1)	703/1198 (57.9)	<.001
Obtain doctor forms	754/1199 (61.8)	609/1198 (50.6)	<.001

[a] For each item, we calculated the weighted percentage of nonmissing responses indicating that the item was expected "always" or "often" at the specified site. We determined statistical significance using *t* statistics from weighted logistic regression models to compare responses for each item for PCP telemedicine and DTC telemedicine.

Figure 1. Percent of parents expecting each of 7 dimensions of the influence diagram of health care–seeking decisions when seeking care at primary care provider telemedicine and direct-to-consumer telemedicine. The center rectangle represents the decision "choice of care site." Focusing on the choice to use either of the 2 studied telemedicine models (primary care telemedicine and commercial direct-to-consumer telemedicine), this choice is surrounded by dimensions affecting this decision in ovals with averaged expectations of survey respondents of primary care telemedicine (orange) and direct-to-consumer telemedicine (blue). Line weight indicates the average percentage of respondents expecting the factors within the indicated dimension always or often at the indicated telemedicine site.



Discussion

Through semistructured interviews, parents expressed positive assessments of telemedicine accessibility but voiced concerns about telemedicine quality. In a structured survey informed by these results, we found continued positive expectations of telemedicine accessibility and less concern about quality for PCP telemedicine relative to commercial DTC telemedicine. Respondents anticipated that both models of telemedicine would minimize hassle, wait time, schedule disruption, and exposure to other ill children. However, respondents had higher expectations of clinician and site quality and the ability to treat severe illness from PCP telemedicine compared with DTC telemedicine. The strengths of this analysis include a mixed methods approach with qualitative interviews conducted until saturation was achieved followed by a large nationally representative survey, which was conducted 2 years into the COVID-19 pandemic.

These findings first provide an illustration of the applicability of our health care–seeking decision model [19], which incorporates elements represented in prior models representing both health beliefs and access to care [25,26]. By using the health care–seeking decision model as a guiding framework for the interpretation of these qualitative and quantitative data, we uncovered differences in parent perceptions of expected quality versus expected accessibility across different models of telemedicine care. The survey data further support the health care–seeking decision model, with these quantitative items showing variation across sites and dimensions.

The relatively high expectations of quality in PCP telemedicine—and the contrast to expectations in DTC telemedicine—comes at an important time for state and federal policy makers as the COVID-19 public health emergency has ended. These findings indicate that parents differentiate between primary care models of telemedicine and virtual-only telemedicine, but this is not a distinction that has made its way into all payment and policy discussions. In states and state Medicaid programs that have not adopted telehealth-supportive legislation or kept up with telemedicine policy changes in Medicare during the pandemic [27], there is a real threat to the financial sustainability of PCP telemedicine [28]. Specifically, if the majority of payers for patients within a pediatric primary care practice do not provide coverage at parity for telemedicine while the child is at home, then primary care clinicians may not be able to continue offering telemedicine to their patient panels [28]. As of June to August 2021, 63% of pediatricians reported that they were continuing to use telemedicine [29]; that number could rise or fall further depending on the ability of payers to signal and provide ongoing support for this modality of care. PCPs with concerns that patients may just as readily seek telemedicine care elsewhere may wish to take note of these results indicating that families value the continuity, pediatric expertise, and access to medical records of telemedicine through primary care practices offer.

While our data suggest that parents have the highest expectations for in-person primary care, it should be noted that parents' expectations of PCP telemedicine approach expectations of in-person primary care for items in dimensions related to quality and even surpass in-person primary care for items related to access. In terms of virtual care options, our data suggest parents may preferentially choose PCP telemedicine for their children over DTC telemedicine, which is supported by the observation that the growth in telemedicine volume for children during the pandemic occurred almost entirely through PCP telemedicine rather than telemedicine-only providers [2]. PCP telemedicine also carries more positive expectations than urgent care or ED for access, quality, and parental self-efficacy dimensions. Thus, maintaining PCP telemedicine as an option may help families choose lower-cost options of care and maintain continuity. PCPs and health systems may also wish to ensure that patients can readily recognize and electronically engage PCP telemedicine, to ensure parents are connecting with the care and the providers that they desire.

Limitations include that results from qualitative interviews may not be generalizable to the population as this sample may over- or underrepresent certain populations when seeking care, such as female caregivers. Our research focuses specifically on how parents perceive telemedicine use in the context of seeking care for ARTI symptoms, and we note that these expectations could vary for other conditions. Interviews were conducted between April and July 2021, during a time when care-seeking decisions may have been influenced by the ongoing COVID-19 pandemic. However, the survey results were fielded in February 2022, a time when COVID-19 vaccines were available and parents had potentially 2 years of experience with telemedicine. We note also that while we had high rates of completion among those screened and determined to be eligible (1206/1297, 93%), there was a sizable number of nonresponders to the initial invitation to complete the screener, which may bias results.

In conclusion, in this mixed methods analysis of parent perceptions of telemedicine when approaching ARTI care-seeking decisions, parents expressed positive assessments of telemedicine accessibility while also voicing more concerns about telemedicine quality in commercial DTC models compared with primary care–based telemedicine. Future work is needed to help support families in making care-seeking decisions when their children are sick, by both supporting family decision-making and aligning in-person and telemedicine care options with child needs and family expectations.

Abstract

Background: The COVID-19 pandemic transformed the home lives of many families in the United States, especially those with young children. Understanding the relationship between child and parent screen time and family stressors exacerbated by the pandemic may help inform interventions that aim to support early child development.

Objective: We aim to assess the changing relationship between family screen time and factors related to pandemic-induced remote work and childcare or school closures.

Methods: In the spring of 2021 we administered a survey, similar to one administered in the spring of 2019, to a national sample of parents of young children (aged 6 to 60 months). Using iterative sampling with propensity scores, we recruited participants whose sociodemographic characteristics matched the 2019 survey. Participants were aged >18 years, proficient in English or Spanish, and residing in the United States. The main outcomes were changes in child screen time (eg, mobile phone, tablet, computer, and television) and parenting technoference, defined as perceived screen-related interference with parent-child interactions. Additional survey items reported pandemic-related job loss, and changes to work hours, work location, caregiving responsibilities, day care or school access, and family health and socioeconomic status.

Results: We enrolled 280 parents, from diverse backgrounds. Parents reported pandemic-related changes in child screen time (mean increase of 1.1, SD 0.9 hours), and greater parenting technoference (3.0 to 3.4 devices interfering per day; P=.01). Increased child screen time and parenting technoference were highest for parents experiencing job loss (mean change in child screen time 1.46, SD 1.03; mean parenting technoference score 3.89, SD 2.05), second highest for working parents who did not lose their job (mean change in child screen time 1.02, SD 0.83; mean parenting technoference score 3.37, SD 1.94), and lowest for nonworking parents (mean change in child screen time 0.68, SD 0.66; mean parenting technoference score 2.66, SD 1.70), with differences significant at P<.01. School closure and job loss were most associated with increased child screen time during the pandemic after controlling for other stressors and sociodemographic characteristics (d=0.52, P<.001; d=0.31, P=.01). Increased child screen time and school closure were most associated with increased parenting technoference (d=0.78, P<.001; d=0.30, P=.01).

Conclusions: Work and school changes due to the COVID-19 pandemic were associated with increased technology interference in the lives of young children. This study adds to our understanding of the interaction between technology use at home and social factors that are necessary to support early childhood health and development. It also supports possible enhanced recommendations for primary care providers and childcare educators to guide parents in establishing home-based “screen time rules” not only for their children but also for themselves.

child health; parent-child relationship; screen time; technoference; health equity

Introduction

Use of electronic technologies use may be an important determinant of maternal and child health. Information technology, including its corollary "screen time," has intruded into the everyday lives of the youngest children and the newest parents [1]. Since they became increasingly essential tools to facilitate remote connections, learning, and entertainment during the COVID-19 pandemic, the use of screen-enabled technologies (eg, smartphones, tablets, and laptop computers) increased for both young children and their parents [2-4].

Though not all technology use is detrimental to child health [5-7], increased screen use by young children can interfere with parent-child interactions [8,9]. For infants and young children, their primary interaction partners are their adult caregivers, typically parents. Ecodevelopmental theory proposes that contextual features of a child's environment, including aspects that disrupt their caregiving experiences, are likely to influence socioemotional and cognitive development. Indeed, parents' own use of mobile and other technological devices (termed "parenting technoference") is associated with early childhood problem behaviors, delayed language acquisition, and poor healthy eating habits [10-13]. In particular, studies show that parent use of mobile devices interferes with their ability to respond to child cues and bids for attention [13-15]. This phenomenon was made even more complex during the pandemic when parent or child screen time increased for a variety of reasons [2,16,17].

Parent stress—which increased during the pandemic for multiple reasons, including job loss and related difficulties from lost income, expectations to work full-time from home while simultaneously caring for children, and managing children's schooling at home—may have further increased both child screen time [10] and parenting technoference [15,18]. Examining how the screen time of parents and their young children changed during the pandemic, especially for pandemic-related stressors, may provide useful insights into how mobile technology use by both young children and their caregivers is changing parent-child interactions and child development. This in turn is critical to informing policies, programs, and parents with meaningful guidance regarding their use [13,19].

In this study, we aimed to examine the research question, "How did child and parent screen use and home-based 'parenting technoference' in the United States change since the COVID-19 pandemic, and how were these changes moderated by pandemic-related socioeconomic stressors?" To accomplish this, we conducted a national survey of parents of young children (aged 6 months to 5 years) during the pandemic's first year, modeled on a similar survey administered before the pandemic [20]. The previous survey's parent or child screen time measurement aim overlapped with this study's surveys, while other aims (eg, the relationship between parent screen time and parent desire for help to reduce screen time) did not [20]. We hypothesized that the pandemic would be associated with increases in outcome variables measuring child or parent screen use and technoscience. We also hypothesized that increases in these screen time and technoference outcomes would be most pronounced among families that encounter more socioeconomic stressors (eg, job loss, food insecurity, and family dysfunction). To our knowledge, the unique interrelationship between parenting technoference, child screen time, and pandemic-induced remote work and reduced childcare has not been studied in a representative US sample. This is especially relevant to emerging issues regarding dual responsibilities of childcare supervision while simultaneously working for pay.

Methods

Study Design

In March and April of 2021, we conducted an observational repeated cross-sectional study by administering a population-based web-based survey of US parents of children younger than 5 years previously administered in May and June of 2019 [20]. Recruitment and administration of this open, voluntary, web-based survey were performed using CloudResearch (TurkPrime; Prime Research Solutions LLC) and Qualtrics (Qualtrics). As in the 2019 survey, participants could choose to take the survey in English or Spanish (details of translation in Glassman et al [20]). Participants were provided reminders for unanswered questions and were able to review responses via a back button before submission.

Ethical Considerations

All participants were provided an informed consent form, discussing survey length and anonymity of responses, before being taken to the first survey question. All procedures were approved by Stanford's Human Subjects Research Office (institutional review board protocol 57720).

Participants

Inclusion criteria were adults aged >18 years with primary caregiving responsibility for at least 1 child aged >6 months and <5 years in the household. Exclusion criteria were the inability to read English or Spanish or completing the survey outside of the United States. For the survey, the index child was defined as the youngest child in the household. We sought a sample of participants whose sociodemographic characteristics matched that of the 280 participants in the 2019 survey. To accomplish this, CloudResearch oversampled participants, and we used iterative, propensity score matching until we were able to create a matched sample. As noted in the Limitations section, the present study's sample therefore carried the same generalizability strengths and weaknesses as the sample obtained for the 2019 survey [20]. For example, we aimed to match how participants in the original survey were distributed across the 4 census regions of the United States (Midwest: 52/280, 19%;

Northeast: 54/280, 19%; South: 119/280, 42%; and West: 55/280, 20%).

Survey Items

We used the same survey items about parent perceptions of their own technology use, parent perceptions of their technology use in the presence of their young child (parenting technoference), and sociodemographic factors, as described in detail in the publication of the 2019 survey results [20]. Additionally, we added items that assessed parents' perceptions of changes in their child's average daily screen time, as well as items capturing pandemic-related stressors. Wording for all items and construct coding is provided in detail in the web-based supplementary material and summarized (see Multimedia Appendix 1). The survey was translated into Spanish by a trained, bilingual research associate and back-translated from Spanish to English by another independent, trained bilingual research associate; differences between the original and back-translated versions were resolved in Spanish by a third bilingual research coordinator.

Outcome Measures

The primary outcomes were (1) the extent to which parents perceived their child's screen time to have increased since the pandemic began, (2) the extent to which parents perceived their mobile device use as interfering in their interactions with their young children [21], and (3) parents' perceptions of the degree to which their own mobile device use was problematic in general (eg, reported inability to resist checking text messages) [21]. Outcome 1 (change in child screen time) was assessed by asking how many more hours per day the index child used each of the following 6 devices: television, computer, smartphone, tablet, other handheld device (eg, iPod Touch), and video game console. Response options were 0, <1, 1, 2, 3, 4+ more hours per day and were coded as 0, 0.5, 1, 2, 3 and 4, respectively. Outcome 2 was measured using the parenting technoference index, which is a count from 0 to 6 of the number of devices (eg, smartphone and tablet) that interrupted a conversation or activity between the parent and index child at least one time on a typical day [18]. Outcome 3 was assessed using the parent problem technology use scale, which is an average of responses to 3 questions such as "when my mobile electronic device alerts me to indicate new messages, I cannot resist checking them," with 6-point Likert scale response options ranging from strongly disagree to strongly agree [18].

Measures of Pandemic-Related Stressors

Independent variables representing pandemic-related stress were measured using new and previously validated items and scales assessing whether parents experienced the following potential stressors during the first year of the pandemic: job loss (yes, no, or did not have a job before the pandemic), reduction in job hours (yes, no, or not applicable [N/A]), change to remote work (yes, no, or N/A), child day care or preschool or school closure (yes, no, or N/A), change in caregiving time (decreased, increase by 1, 2, 3, 4+ hours, coded as –1 to 4), and reduced ability to meet family health and socioeconomic needs (3-point scale from less difficult to more difficult across 4 domains—health care, food, utilities, and housing). We also examined how the pandemic-related increase in child screen time outcome was related to the technoference and parent problem technology use outcomes.

Measures of Sociodemographic and Household Characteristics

The sociodemographic and household characteristics were selected because they have been hypothesized to be confounding variables in similar studies of child and parent screen time. They included self-report of age (parent and child), sex, race or ethnicity, language spoken at home, marital status, number of children, education level, and income level. A proxy measure of the geographic region in which the participant resided was derived from the longitude or latitude values of the survey respondent's computer captured by CloudResearch survey administration. Geographic region was categorized into the 4 US census regions defined by West, South, Northeast, and Midwest.

Data Analysis

We first conducted data distribution and quality assessments to identify potential missing values and outliers. We removed outliers defined as "speeders" (those who answer unreasonably fast) and "straightliners" (those who answer with identical values for each survey item in a block) as described for the 2019 survey [20,22,23]. All returned surveys were analyzed.

Propensity Score Matching Procedures

To obtain a 2021 survey sample that matched our 2019 survey sample as closely as possible on the measured covariates, we used optimal pair full matching, which attempts to pair each "treatment" unit—in our case, the observations from the 2021 survey—with one or more "control" units—the observations from the 2019 survey. To accomplish this, a propensity score was estimated for each observation in the 2019 and 2021 survey using a logistic regression of the observation's "treatment" status on the following covariates: parent age, sex, Hispanic ethnicity, language spoken in the home, number of children, education, income, geographic region, and marital status. Each observation from the 2019 survey was then paired with an observation from the 2021 survey such that the sum of the differences between propensity scores across the pairs was minimized. The 2021 survey observations satisfying this criterion were selected as the matched sample. Following this procedure, the *t* tests (2-tailed tests) and chi-square tests used to validate that the differences between the samples on each of the covariates were not significant. We used the *MatchIt* package in R (R Foundation for Statistical Computing) to accomplish the match [24].

Bivariate Analyses

To assess whether parenting technoference and parent problem technology use was higher during the pandemic than in 2019, we used 2-sample *t* tests and Wilcoxon rank sum tests, given that our sample size was only moderate [25]. We report results from the *t* tests since the results were virtually identical.

For the 2021 survey results, the bivariate association between each outcome and pandemic-related stressor or sociodemographic characteristic was assessed using *t* tests. The results of these tests were used to screen for variables to enter into multivariable regression models given the relatively small sample size. We used a stricter screening criterion (*P*.05) than in our prior study because we had a larger pool of potential independent variables and covariates to assess in this study. We did not include the job change (to remote) or job hours reduced variables in multivariable models given they were missing for all parents who were not working before the pandemic. We also elected to include the education and not income variables given their high correlation.

Multivariable Regression Analyses

To evaluate the independent association between the outcomes and pandemic-related stress and sociodemographic characteristics we estimated linear regression models. Separate models were used for each outcome. We assessed the association between a given independent variable and outcome by examining both the statistical significance (at *P*.05) of the Wald test for its regression coefficient as well as a measure of effect size. The effect size was estimated using Cohen *d* and partial η^2. All analyses were conducted using the R (version 3.5.3; R Core Team).

Results

Sample Characteristics and Propensity Score Matching

To obtain a sample of 280 parents of children aged 0-5 years matching the sociodemographic characteristics of the prepandemic sample, 517 consenting participants meeting eligibility criteria were recruited in stages between March and April of 2021. Of these, 468 participants met the data quality criteria. The *MatchIt* algorithm in R requires that there are no missing covariate values, which resulted in a pool of 443 observations for matching. Table 1 shows that the optimal pair matching algorithm was able to select 280 observations from this sample such that all covariate means or percentage distributions matched within 1 point, and there were no statistically significant differences in characteristics between the 2 groups (*P*>.70 for each characteristic). The mean age of respondents was 33 (SD 8) years, with 80% (223/280) female and 20% (57/280) male, 68% (192/280) White, 12% (33/280) Black, and 24% (67/280) Hispanic participants. Almost half (133/280, 48%) had at least a college degree, with 24% (66/280) of them reporting some college, and 29% (81/280) of them having a high school degree or lower educational attainment.

Bivariate Results: Changes in Screen Time Outcomes

Table 2 shows that while parent reports of their absolute mean level of screen time did not change, mean levels of parents' perceptions of their own parenting technoference and problem device use were higher in the spring 2021 midpandemic sample than the spring 2019 prepandemic sample (3.0, SD 2.1, vs 3.4, SD 2.0; 3.7, SD 1.3, vs 4.0, SD 1.2). Differences for each outcome were statistically significant (*P*<.05). The mean for the change in child screen time variable was 1.1 (SD 0.90) on a scale of 0 to 4, where 0 represented no change, and 4 represented an increase of 4 or more hours.

Table 2. Comparison of outcomes before and during COVID-19.

Outcome (scale)	Pre–COVID-19 pandemic (spring 2019), mean (SD)	During the COVID-19 pandemic (spring 2021), mean (SD)	*P* value[a]
Parenting technoference (0-6)	3.0 (2.1)	3.4 (2.0)	.01
Problem technology use (0-6)	3.7 (1.3)	4.0 (1.2)	.03
Change in child screen time since pandemic[b] (0-4)	Not asked	1.1 (0.90)	N/A[c]

[b] Child screen time was not asked in the pre–COVID-19 survey.
[c] N/A: not applicable.

Bivariate Results: Association Between Sociodemographic and Pandemic-Related Stressors and Outcomes

Table 3 shows the results of bivariate analyses of the relationships between the outcomes and the sociodemographic and pandemic-related stress variables. Male caregivers (eg, fathers) on average reported higher levels of increased child screen time (1.45, SD 1.07, vs 1.01, SD 0.83; *P*=.01) and higher levels of their own mobile technology use interfering with interactions with their young child (3.91, SD 1.97, vs 3.32, SD 1.97, *P*=.05) since the pandemic. Reports of parenting technoference were greater, on average, for those with a college degree or higher than for those with some college or no college (3.82, SD 2.02, vs 3.21, SD 1.83, and 3.0, SD 1.92, respectively; *P*=.01), and for those with a family income above US $75,000 than for those with an income less than US $75,000 (4.04, SD 1.92, vs 3.16, SD 1.95, *P*<.001). Reports of increase in child screen time and parenting technoference were highest for working parents who lost a job during the pandemic (1.46 and 3.89, respectively), second highest for working parents who did not report losing their job during the first year of the pandemic (1.02 and 3.37, respectively), and lowest for nonworking parents (0.68 and 2.66, respectively), with differences significant at *P*=.01. Among working parents, those whose job changed to remote reported higher levels of pandemic-related increases in child screen time (1.35 vs 1.02; *P*=.01) and parenting technoference (4.18 vs 3.19; *P*<.001) than those whose did not. Reports of increases in parenting technoference and child screen time were higher among parents of children whose day care or preschool or school closed during the pandemic than among those whose child's day care or preschool or school did not close and those whose child did not attend school (4.07 vs 3.29 and 2.65, respectively, *P*<.001; 1.40 vs 0.96 and 0.75; *P*=.002). Change in child screen time was moderately and statistically significantly correlated with parent technoference (*r*=0.44, *P*<.001).

Multivariable Regression Results

In multivariable models (Table 4), having day care, preschool, or school closed during the pandemic and losing a job during the pandemic were most strongly associated with increased child screen time, accounting for 7.23% (*P*<.001) and 3.54% (*P*=.01) of the variance in the outcome after covarying for sociodemographic characteristics. The change in child screen time outcome in turn was most strongly associated with parenting technoference during the pandemic, accounting for 13.5% of the variance (*P*<.001), followed by having day care or preschool or school closed during the pandemic (η^2=2.40%, *P*=.01) after covarying for sociodemographic characteristics. Parents with a high school education or less reported lower levels of perceived technoference than did parents with a college degree or more (η^2=2.4%, *P*=.02).

Table 4. The results of regression models[a] (post bivariate screening) by outcome.

Discussion

Principal Findings

Serial, national surveys 1 year prior and 1 year into the COVID-19 pandemic revealed increases in child screen time alongside increases in parenting technoference—that is, increases in parents’ perceptions of their own device time interfering with their interactions with their child. Parents reported that their children increased their screen time by approximately 1 hour per day (0.9 hours per day). This finding is consistent with other recent studies [27], including a national survey [3] that found screen time among school-aged children increased by an average of 50 minutes during the early months of the pandemic. The finding of increased parenting technoference is consistent with a recently published study that found an increase in maternal use of mobile devices while parenting during the pandemic lockdowns [16].

We found a strong association between technology use and changes in a child's schooling, parent work, and remote options for school or work. We also found higher rates of reported technoference among parents with higher levels of educational attainment, as well as among male (vs female) caregivers. These findings are consistent with recent evidence suggesting that increases in child screen time were directly associated with decreased childcare availability [28]. Day care or school closure—which constitutes not just a change in routine but a challenge to supervision requirements for young children, especially if the parent is expected to work while being responsible for children's needs—was related to increases in parenting technoference as well as child screen time. Another recent study suggested that there was an important interrelationship between parent stressors, the pandemic, and negative parenting techniques such as coercive parenting [29]. Further, there is now a body of literature showing that parenting technoference negatively affects child development through mechanisms such as delayed language acquisition [10,13,18]. The factor most strongly associated with the parenting technoference outcome was the change in child screen time outcome itself. Other studies have shown a strong relationship between parent screen time and child screen time [30,31].

Together these findings suggest that future research and development on interventions designed to mitigate the negative effects of technology on parent-child interactions should consider extrinsic factors and how those may affect the potential feedback loops involved in parent and child device time. These findings may also be critical to informing new consumer health interventions designed for home-based implementation [32,33].

Parent job status was an important contributor to pandemic-related increases in child screen time and technoference. In particular, working parents who experienced job loss during the first year of the pandemic were more likely to report increased child screen time and increased technoference than nonworking parents and parents who did not lose their jobs. Further, working parents (regardless of job loss) were more likely to report technoference than nonworking parents. Several mechanisms may explain these findings. A job-stressed parent may be more likely to use a mobile device as a stress-reduction tool [10,19]. It is also possible that a job-stressed parent is more likely to use a mobile device as a "babysitter" to keep their child occupied as they attend to their own needs, such as job interviews or social support [28]. Future research should explore more deeply the complex interplay between parent and child screen time for working compared to nonworking parents. Program and policy considerations to improve early child development may want to consider different strategies tailored to parent work status.

Limitations

This study has several limitations common to repeated, cross-sectional observational studies. First, no causal inferences can be made about the timing of the constructs assessed. Experimental studies may better allow for exploring the causal role of how specific contextual events (eg, remote vs in-person work; availability and types of caregivers to supervise children while parents attend to other tasks, child access to nontechnological play materials) affect patterns of parent and child device use, which may be especially relevant in an age of hybrid work policies.

Second, common limitations and biases associated with web-based surveys include social desirability bias and selection bias. Despite oversampling from traditionally underrepresented groups and the matched design to assure greater alignment with the prior survey, these biases may distort the generalizability of these findings. There were inevitably unmeasured confounders omitted from the propensity score matching model. Specifically, this study's sample included more participants who identified as female, with lower income levels, higher education levels, and a lower prevalence of speaking a language other than English, when compared with the general US population. On the other hand, the results may be generalizable to all 4 census regions of the United States since there was a reasonable representation of respondents from each.

Another limitation was that some items in the prepandemic survey were different, not allowing us to make temporal comparisons. Further, this study was limited by the fact that the measures of parent technoference and child screen time were self-reported and were not externally validated. Parent perceptions of their own technoference and child's screen time may not correspond to actual levels. Future studies in this area could overcome this limitation by including ecological momentary assessment to capture technoference in real time, or by using newly developing AI-based behavioral observation tools for research. Strategies to mitigate the negative effects of technoference and child screen time ideally should consider both actual and perceived levels of these problems. Finally, it is possible that our specific measures of pandemic stress were not sufficiently sensitive. In this context, it may also be that parent-reported measures of pandemic-related changes in child screen time are better at capturing pandemic-related stress than our direct items about childcare burden.

Conclusions

Using a national survey representative of all US parents, we found that the COVID-19 pandemic indirectly accelerated preexisting trends of increasing technology and screen use in the lives of young children. In particular, work and day care or school changes due to the COVID-19 pandemic were associated with increased technology interference in the lives of young children. In concert with a growing body of literature, our study further supports the notion that future parenting technoference research and policy making should consider the causes and context behind parenting technoference [34]. In particular, this study suggests important mechanisms through which certain external stresses on parents, especially concerning dual responsibilities of childcare supervision while simultaneously working for pay, may impact healthy child development. For researchers, it motivates the need for more robust studies examining the interrelationships among other contextual factors not examined in this study (eg, availability and types of caregivers, child access to nontechnological play materials), stress, parent screen time, child screen time, and child development. For practitioners, this study buttresses existing recommendations for primary-care providers and childcare educators to guide parents to establish home-based "screen time rules," not only for their children but also for themselves. To help support families in this effort, our findings add updated context to existing policy recommendations from the American Academy of Pediatrics and other national organizations about the safe use of screens and screen time by young children and their adult caregivers. State and federal policymakers should consider these findings to inform evolving regulations that pertain to child exposure to new media (eg, social media, apps, and virtual-reality headsets), and consider its implications for research funding to strengthen the causal evidence base on the positive and negative impact of these media on parent and child well-being.

Acknowledgments

This study was funded by the Stanford University School of Medicine Clinical Excellence Research Center (CERC). The funder provided support for survey administration and statistical analysis but had no role in the design and conduct of this study, collection, management, or decision to submit this paper for publication. The authors would like to thank Robert M Kaplan for his thorough editorial assistance and encouragement.

Authors' Contributions

JG and AJ had full access to all of the data in this study and take responsibility for the integrity of the data and the accuracy of the data analysis. JG, LS, KLH, and AM conceptualized and designed the study. Acquisition, analysis, and interpretation of data were undertaken by all authors. Further, critical revision of this paper for important intellectual content was also undertaken by all authors. JG, LS, and KLH drafted this paper. Statistical analysis was performed by AJ and JG. Administrative, technical, or material support was provided by JG, LS, and AM. JG supervised the study.

Abstract

Background: The population health burden of adverse childhood experiences (ACEs) reflects a critical need for evidence-based provider training. Rural children are also more likely than urban children to have any ACEs. A large proportion of providers are unaware of the detrimental effects of ACEs. There is a significant documented need for training providers about ACEs and trauma-informed care, in addition to a demand for that training.

Objective: The objective was to develop, implement, and evaluate an online ACEs training curriculum tailored to Missouri providers, particularly those in rural areas given the higher prevalence of ACEs.

Methods: From July 2021 to June 2022, we conducted literature reviews and environmental scans of training videos, partner organizations, clinical practice guidelines, and community-based resources to curate appropriate and tailored content for the course. We developed the ACEs training course in the Canvas learning platform (Instructure) with the assistance of an instructional designer and media designer. The course was certified for continuing medical education, as well as continuing education for licensed professional counselors, psychologists, and social workers. Recruitment occurred via key stakeholder email invitations and snowball recruitment.

Results: Overall, 135 providers across Missouri requested enrollment, with 72.6% (n=98) enrolling and accessing the training. Of the latter, 49% (n=48) completed course requirements, with 100% of respondents agreeing that the content was relevant to their work, life, or practice; they intend to apply the content to their work, life, or practice; they feel confident to do so; and they would recommend the course to others. Qualitative responses supported active intent to translate knowledge into practice.

Conclusions: This study demonstrated the feasibility, acceptability, and effectiveness of interprofessional workforce ACEs training. Robust interest statewide reflects recognition of the topic's importance and intention to translate knowledge into practice.

Introduction

A large proportion of providers are unaware of the detrimental effects of adverse childhood experiences (ACEs) [1]. ACEs are commonly defined as personal abuse that is psychological, physical, or sexual; personal neglect that is emotional or physical; or household challenges that include violence against the mother, divorce, or separation; or living with household members who were substance abusers, mentally ill or suicidal, or had ever been imprisoned [2,3]. Other studies consider additional adversities such as the death of a parent or sibling, poor housing, discrimination, bullying, and poverty, among others [4,5].

If we can reduce intergenerational transmission of ACEs, we have the potential to mitigate ACEs and theoretically make profound improvements in population health outcomes. Overall, 60.9% of US adults experience 1 or more than 1 type of ACE and 15.6% experience 4 or more than 4 types [6]. ACEs increase the risk of adult diseases including heart disease, cancer, chronic lung disease, skeletal fractures, and liver disease via chronic stress and coping behaviors [2,6]. Cumulative exposures to multiple ACEs are associated with an increased risk of substance misuse [2,7,8], including opioids [9-11] and alcohol [12], and an increased risk of suicide [2]. Suicide and other "deaths of despair," ie, deaths from suicide and drug poisoning (including opioids and alcohol) contribute significantly to rising US mortality rates [13]. A 10% reduction in the prevalence of ACEs equates to an annual savings of 3 million disability-adjusted life years or $105 billion US [14]. Illicit drug use had the highest population-attributable fractions associated with ACEs, and population-attributable fractions of causes of ill health were highest for mental illness outcomes: ACEs were attributed to about 30% of cases of anxiety and 40% of cases of depression in North America [14]. The intersection of ACEs, suicide, and overdose is a priority area for the United States Department of Agriculture [15] and the Centers for Disease Control and Prevention (CDC) [16]. Finally, an objective of the US Department of Health and Human Services' Healthy People 2030 is to reduce the number of young adults (aged 18 to 25 years) who report 3 or more than 3 ACEs; this is described as a high-priority public health issue with evidence-based interventions to address it [17].

In addition to the rising US mortality rates mentioned above, there is a place-based mortality penalty, especially for high-poverty rural areas [18]. Rural children are statistically more likely than urban children to experience economic hardship, household substance misuse, household mental illness, household incarceration, and parental separation or divorce, as well as witness neighborhood violence and household violence [19]. Rural children are also more likely than urban children to have any ACEs [19].

There is a significant documented need for training providers about ACEs and trauma-informed care, in addition to a demand for that training [1]. Practical considerations exist with the implementation of training, including time and institutional support, interactive components, practical examples, and not retraumatizing providers who have themselves experienced ACEs [1]. A commentary in 2020 by Campbell [20], suggested that there could be harm to patients from ACEs screening, despite acknowledging there is an evidence base for related clinical preventive services, such as screening for alcohol and drug use disorder and interpersonal violence. A response to this caution coauthored by the investigator of the original ACEs study Felitti stated that "ACEs screening was used as part of a comprehensive health assessment at Kaiser in more than 440,000 adult patients without ever evoking a complaint" [21] and recommended to implement ACEs screening in practice with enthusiasm. Still, the identification of ACEs is only 1 component of translating the science into practice. Providers need to be ready with a planned intervention after ACEs are identified, depending upon a primary, secondary, or tertiary prevention response. Finally, providers need to be aware of positive childhood experiences so they can recognize and encourage these behaviors in parents.

Evaluating the uptake, satisfaction, and effectiveness of ACEs trainings on provider practice is key [1]. The purpose of this project was to develop, implement, and evaluate an online workforce training curriculum tailored to Missouri providers (particularly rural) to improve their capacity to provide evidence-based care to high-needs patient populations in resource-limited settings.

Methods

Setting

Missouri ranks 34th nationwide on ACEs, with 17% of children aged 0 - 17 years having experienced 2 or more ACEs [22]. In Missouri, 99 out of the 115 (86.1%) counties (114 counties plus the city of St. Louis) are rural, and 33.2% of Missouri's population lives in rural counties [23].

Participants

This study is part of a larger project with the overall goal of training physicians who work in rural communities and providing them with the highest level of up-to-date information. Our training was tailored toward interdisciplinary Missouri providers, with the goal of reaching a significant proportion of rural providers. All provider types (including physicians, clinicians, professionals, paraprofessionals, and ancillary service staff) were eligible to enroll so the course would reflect a cross-sector approach and participants could learn from each other in the discussions. We were particularly interested in enrolling rural clinicians. A separate paper details the evaluation of the discussion posts [24].

Course Development

From July 2021 to June 2022, we conducted literature reviews and environmental scans of training videos, partner organizations, clinical practice guidelines, and community-based resources to curate appropriate and tailored content for the course. The content of the course included but was not limited to select published works from Felitti, ACEs videos developed by the CDC [25,26], a TED talk by Harris [27] on how childhood trauma affects health across the lifespan, US Preventive Services Task Force recommendations for screening, and other literature. Resources included but were not limited to Findhelp, Missouri Department of Health and Senior Services' crime victim services, home visiting programs, related partner organizations, screening, and measurement tools. We developed the ACEs training course in the Canvas learning platform with the assistance of an instructional designer and media designer. The designers played a key role in style, usability, design, and best practices for online learning. The course was designed to be asynchronous with interactive elements, such as videos, discussions, and quizzes. Given providers may themselves have experienced childhood adversity, a trigger warning was included on the home page and a mindfulness breathing exercise was included in the instructions.

We pilot-tested the course with health provider colleagues for content, gaps, length, satisfaction, and usability prior to implementation. The final course outline is described in Textbox 1.

Textbox 1. Adverse childhood experiences course outline.

Module 0: Getting started

- This module includes a welcome, introduction of the instructor, demographic survey for participants to complete, an overview of the course and expectations, and a discussion.

Module 1: What are adverse childhood experiences?

- This module includes an overview of the module and explanation of the original adverse childhood experiences (ACEs), expanded ACEs, a discussion, and a quiz.

Module 2: How do adverse childhood experiences impact health?

- This module includes an overview of the module and explanation of ACEs' impact on the developing brain, adult health, depression, substance use disorders, other impacts, increased risk of disease, and population-attributable risk. The module includes a discussion and quiz.

Module 3: How common are adverse childhood experiences?

- This module includes an overview of the module and explanation of how common ACEs are in the United States, Missouri, rural areas, and the status of Missourians' health and wellness outcomes. The module includes a discussion and quiz.

Module 4: How did the COVID-19 pandemic affect adverse childhood experiences?

- This module includes an overview of the module and explanation of the psychological impact of the COVID-19 pandemic, as well as how the COVID-19 pandemic affected ACEs. The module includes a discussion and quiz.

Module 5: What can we do to address adverse childhood experiences?

- This module includes an overview of the module and explanation of the risk factors for ACEs, what can be done at the provider level, what the evidence says about screening, positive childhood experiences and protective factors, what can be done at the organizational, community, and policy levels. The module includes a discussion and quiz.

Module: Wrap up

- This module includes links to resources, explanation of how to enroll in the ACEs listserv, and instructions for completing the course and course evaluation.

Certification

As an incentive to enroll and complete the training, we offered continuing education (CE) credits free of charge to participants. The office of Continuing Education for Health Professions (CEHP) is housed on the University of Missouri campus. CEHP's mission is to provide evidence-based, relevant, and responsive learning activities designed to narrow professional practice gaps with respect to the knowledge, competence, and performance of the health care team.

CEHP reviewed the course content for continuing medical education credits, awarding the course 3 American Medical Association Physician's Recognition Award Category 1 Credits. Upon request from enrollees, the office also reviewed the course for CE for licensed professional counselors, psychologists, and social workers with Missouri licenses. CEHP attested that this course contains 3 clock hours of instructional time. Licensed professionals measuring CE credit based on a 50-minute hour may claim up to 3.6 contact hours for full attendance at this program. Certificates of completion were also available.

To qualify for CE credit or a certificate of completion, trainees were required to complete (1) a demographic survey required by the funder and available in the introductory course pages; (2) six discussion assignments; (3) five quizzes, receiving a grade of at least 80% on each; and (4) the end-of-course evaluation. The course evaluation is linked to a separate page in Qualtrics (Qualtrics, LLC). We chose to make the course evaluation anonymous to protect the respondents' identity and to improve the integrity of the responses while recognizing we would not be able to individually validate trainees' completion of this course requirement. Some of the demographic survey questions (eg, do you consider yourself disadvantaged or the level of rurality of their hometown setting) are reflective of self-identity and self-report rather than objective indicators.

Recruitment, Enrollment, and Tracking

The course was launched via key stakeholder email invitations in late November 2022 with snowball recruitment thereafter. Email invitations included a statewide listserv focused on responding to the opioid crisis, as well as to a network of rural providers. The recruitment email included that the course is an asynchronous online course available through June 30, 2023, free of charge to participants, offers free CE credit, and a basic course outline. Interested individuals sent an email with a request to enroll in the training. The individual was then sent instructions for creating a Canvas account, with technical support available for troubleshooting challenges. Once the Canvas account was created, the individual was subsequently invited into the ACEs training. Course requests, enrollment, and completion were tracked in Microsoft Excel. Periodically throughout the course implementation period, study personnel sent email reminders to those enrolled regarding the end date for the training.

Data Analyses

The data used for analysis in this study included the course enrollment tracking data, the demographic survey data, and the course evaluation survey data. Frequencies and percentages were calculated for quantitative data; missing responses were not included in the calculations. Age was approximated by subtracting birth year collected in the sponsor demographic survey from 2023. Short-answer open-ended questions were qualitatively coded into major themes independently by 2 authors and then reviewed for divergence. Reported quotes were lightly copyedited.

Ethical Considerations

The University of Missouri Institutional Review Board reviewed and approved this project (#2096686).

Results

Enrollment and Completion

Overall, 135 individuals requested enrollment into the ACEs training. Of those, 98 (72.6%) completed the steps for enrollment and accessed the course. Among the individuals who enrolled and accessed the course, 70 (71.4%) completed the demographic survey, and 48 (49%) completed all course requirements.

Participant Characteristics

The setting in which participants worked varied (Table 1). The majority of participants worked in “other” settings (n=28, 40%), followed by clinical sites (n=12, 17.1%); academic medical centers (n=8, 11.4%); federally qualified health centers or Look-Alikes (n=6, 8.6%; Look-Alikes are community-based health center programs that meet program requirements but do not receive health center program funding); government (n=6, 8.6%); private practice or industry (n=4, 5.7%); and public community, rural, or migrant health centers (n=4, 5.7%). Responses for the employment setting location included 27.1% (n=19) rural areas, 25.7% (n=18) health professional shortage areas, 18.6% (n=13) medically underserved communities, and 12.9% (n=9) primary care settings. Most (n=30, 42.9%) participants reported their hometown setting as rural, with 34.3% (n=24) suburban and 18.6% (n=13) urban.

Regarding participant characteristics, 84.3% (n=59) reported their gender as female, with a balanced distribution across age groups 20 to 59 years. The majority of participants reported White race (n=62, 88.6%), and a minority (n=11, 15.7%) considered themselves disadvantaged (defined as growing up in an area that was medically underserved or had insufficient access to social, economic, and educational opportunities). Respondents’ professional disciplines consisted of 50% (n=35) behavioral health, 18.6% (n=13) nursing, 14.3% (n=10) other, 10% (n=7) public health, 4.3% (n=3) student, and 2.9% (n=2) medicine. Enrollee fields and degrees included bachelors (BS, BA, and BSPH), nursing (RN, FNP, BSN, DNP, and CPNP), social work (MSW, LMSW, and LCSW), licensed professional counselors (MA, MAC, MS, MEd, and PLPC), others with master’s degrees (MPH, MS, and MPA), doctorates (PhD), and physicians (MD).

Table . Characteristics of adverse childhood experiences course participants who completed the demographic survey (n=70).

Variable			Values, n (%)
Personal attributes			
	Gender

	Employment setting (check all that apply)		
		Academic medical center	8 (11.4)
		Area health education center	2 (2.9)
		Federally qualified health center or Look-Alike	6 (8.6)
		Government	6 (8.6)
		Nonacademic medical center	1 (1.4)
		Other clinical site	12 (17.1)

Variable			Values, n (%)
		Other health center	2 (2.9)
		Private practice or industry	4 (5.7)
		Public setting—community, rural, or migrant health center	4 (5.7)
		Public setting—health department	2 (2.9)
		Rural health clinic	1 (1.4)
		Other	28 (40.0)
	Employer is located in (check all that apply)		
		Health professional shortage area	18 (25.7)
		Medically underserved community	13 (18.6)
		Primary care setting	9 (12.9)
		Rural area	19 (27.1)

[a] You might consider yourself disadvantaged if you grew up in an area that was medically underserved or had insufficient access to social, economic, and educational opportunities.

Course Evaluation

Of those who completed the training, 42 (87.5%) completed the course evaluation. Quantitative responses are summarized in Table 2. Almost three-fourths of respondents live, work, or serve in rural areas of Missouri.

All respondents (100%) agreed or strongly agreed that the content is relevant to their work, life, or practice; the learning objectives are clear; the resources are helpful; they intend to apply the course content to their work, life, or practice; they feel confident implementing the knowledge gained; and they would recommend the course to others. Most respondents agreed or strongly agreed the length is appropriate (n=41, 97.6%), the videos are informative (n=41, 97.6%), the quizzes provide a helpful self-assessment (n=40, 95.2%), and the discussions are valuable (n=33, 78.6%). Most respondents rated the course overall as excellent or very good (n=39, 92.9%).

A total of 37 respondents answered the question “Please describe the strengths of the course, ie, elements you liked, things that worked well, ‘a-ha’ moments, helpful course content or features.” Responses included a breadth of course components—videos, rural or urban comparisons, statistics, discussion, quizzes, charts or graphs, resources, and online format. Eleven respondents provided suggestions to the question “Please describe opportunities to improve the course, ie, challenges with navigating the course, missing content, barriers to completing the course, etc.” Three respondents did not care for the discussion boards, 2 had technology problems, 1 did not care for the quizzes, and 1 felt the online format was limiting the interaction. The remaining suggestions included incorporating brainstorming technology such as “Jam Boards,” more videos on how to implement the research in the workplace, more emphasis on the role of social workers, and case studies asking people how they would approach a scenario.

Table . Results of adverse childhood experiences course evaluation quantitative questions (n=42).

Question name and response option		Values, n (%)
The content is relevant to my work, life, or practice		
	Strongly agree or agree	42 (100.0)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
The learning objectives are clear		
	Strongly agree or agree	42 (100.0)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
The length is appropriate		
	Strongly agree or agree	41 (97.6)
	Neutral or not sure	1 (2.4)
	Strongly disagree or disagree	0 (0.0)
The videos are informative		
	Strongly agree or agree	41 (97.6)
	Neutral or not sure	1 (2.4)
	Strongly disagree or disagree	0 (0.0)
The quizzes provided a helpful self-assessment		
	Strongly agree or agree	40 (95.2)
	Neutral or not sure	1 (2.4)
	Strongly disagree or disagree	1 (2.4)
The discussions are valuable		
	Strongly agree or agree	33 (78.6)
	Neutral or not sure	8 (19.0)
	Strongly disagree or disagree	1 (2.4)
The resources are helpful		
	Strongly agree or agree	42 (100.0)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
I intend to apply the course content in my work, life, or practice		
	Strongly agree or agree	42 (100.0)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
I feel confident that I can implement the knowledge I gained		
	Strongly agree or agree	42 (100.0)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
Please rate the course overall		
	Excellent or very good	39 (92.9)
	Good	3 (7.1)
	Fair or poor	0 (0.0)
I would recommend this course to others		
	Strongly agree or agree	42 (100.0)

Question name and response option		Values, n (%)
	Neutral or not sure	0 (0.0)
	Strongly disagree or disagree	0 (0.0)
Do you live, work in, or serve individuals in rural areas of Missouri?		
	Yes	31 (73.8)
	No	11 (26.2)

Translation to Practice

A total of 33 respondents answered the question “If you intend to apply the course content to your work, life, or practice, please describe how,” with 26 (78.8%) respondents reporting some level of active intent and 14 (42.4%) respondents suggested using the course content for active organizational planning or changing their practice toward a more advanced trauma-informed care work environment.

> *Apply to current and future practice in the health care field with children and adults.* [Example response 1]
>
> *I want to keep in mind the mother’s ACE score when working with them in parenting classes. Seeing how their own ACE scores affect them and how they can affect their children.* [Example response 2]
>
> *Moving our organization past trauma awareness and into more trauma-informed work.* [Example response 3]
>
> *I will look to implement ACEs screening in our organization and increase trauma informed care.* [Example response 4]
>
> *I work with youth in a school setting. This could be helpful to implement trauma informed care in the school setting, while also being aware of ACEs with clients.* [Example response 5]
>
> *We are currently working on ways to prevent overdose events among youth and have been considering how we can take ACEs into account in preventing overdose and long-term negative health effects related to addiction.* [Example response 6]
>
> *This information is very important to my work with people as well in life. Also, to my organization as we continue to grow towards a trauma-informed organization.* [Example response 7]
>
> *Information will help inform TIC team in evaluating policies.* [Example response 8]

A total of 8 (24.2%) respondents suggested the training will help them actively educate others.

> *Spreading the word on the existence of ACEs and how to use them for positive growth in children.* [Example response 1]
>
> *Psychoeducation in therapy.* [Example response 2]
>
> *Educating my organization and other community partners.* [Example response 3]
>
> *Educating youth and families.* [Example response 4]

Also, 4 (12.1%) respondents reported an intent to screen for ACEs.

> *Have begun utilizing ACEs scoring with incarcerated population.* [Example response 1]
>
> *I work...with clients in the mental health field, so completing the ACEs when they enroll will provide us with more history of the clients and their experiences.* [Example response 2]
>
> *I can use this as I get to know my students. I plan to start using the ACE test as I assess how best I can help my students.* [Example response 3]

Finally, 7 (21.2%) alluded to awareness, which was coded as a passive reaction to applying the course content. Example quotes included:

> *I find it important to be aware of ACEs as a counselor in learning to understand why and how people present as they do in a college setting.* [Example response 1]
>
> *I am aware of the need for more primary care providers to have training in this area.* [Example response 2]
>
> *I work with foster/adoptive families and ACEs are big part of their lives.*
>
> *[Example response 3]*
>
> *I have a new list of resources to utilize, and a better knowledge of what ACEs are and what they might look like in a school setting.* [Example response 4]
>
> *My knowledge of...COVID-19’s effects on ACEs, and [the heightened level of ACEs in rural areas] keeps me more aware of key things to look for.* [Example response 5]

Discussion

Principal Findings

A limited body of literature exists related to educating providers on ACEs and trauma-informed care, as well as evaluating their knowledge, perceived importance, and attitudes toward ACEs in practice [1]. The objective of our study was to develop, deliver, and evaluate an interprofessional, online, asynchronous ACEs training program for interdisciplinary providers across Missouri, especially in rural areas. With a large proportion of providers unaware of the detrimental effects of ACEs, significant need for training providers about ACEs and demand for that training [1], our findings add critical insight to the uptake, satisfaction, and effectiveness of ACEs provider training. Our study additionally addresses a critical gap with its focus on rural providers. Increasing the number of ACEs and trauma-aware providers is a step toward increasing trauma-informed care. The Substance Abuse and Mental Health Services Administration [28] considers being trauma-informed as having a basic realization of trauma and how it impacts families and individuals, recognizing the signs of trauma, responding by applying the principles of a trauma-informed approach, and resisting retraumatizing individuals. These four assumptions work in conjunction with their six key principles and they are (1) safety; (2) trustworthiness and transparency; (3) peer support; (4) collaboration and mutuality; (5) empowerment, voice, and choice; and (6) cultural, historical, and gender issues. The Substance Abuse and Mental Health Services Administration further includes cross-sector collaboration among its implementation practices; an additional strength of our training includes its interprofessional scope of providers.

The overall response to recruitment efforts was stronger than anticipated given we leveraged only a few key communication channels, with 135 individuals statewide requesting enrollment. Additionally, our recruitment and enrollment effort successfully reached the target demographic, with 73.8% (n=31) of participants living, working, or serving in rural areas, despite the broadband challenges. While 90% of rural Missouri counties have broadband internet, Missouri ranks 43rd among states in internet coverage speed and availability [23]. In Missouri, 41 rural counties do not have a hospital [23], making ACEs awareness efforts at the prevention level even more crucial. The course was designed as an asynchronous, online course and technology can sometimes be a barrier, particularly for age cohorts educated prior to the popularity of online courses. However, while the age group distribution for those who completed enrollment was nicely balanced across 20 to 59 years of age, it is possible a selection bias occurred with the 27.4% of individuals who requested enrollment but did not complete enrollment being less comfortable with technology, despite the available assistance. Finally, enrollment by medical providers was modest, despite the asynchronous format to accommodate busy schedules and available continuing medical education.

Among participants completing the course, the course evaluation indicated strong levels of satisfaction with the structure and content. This is particularly encouraging given the interdisciplinary nature of the content, as it was not tailored to a specific discipline by design, yet 100% of respondents agreed the content was relevant to their work, life, or practice; that they intend to apply the content to their work, life, or practice; they feel confident to do so; and would recommend the course to others. Regarding what could be improved, respondents scored the value of the discussions lowest compared to other content questions (78.6% agreed or strongly agreed the discussions are valuable). We attribute this score to the discussion requiring the most active engagement on the part of participants. Active learning is a best practice in online learning, as well as a requirement for these CE credits.

Among the respondents who reported intent to apply the course content in practice, 78.8% suggested active planning, training, or screening, naming specific examples. This is an encouraging indication of effective knowledge transfer and declaration of intention.

Conclusions

This study developed, implemented, and evaluated an online workforce training curriculum tailored to Missouri providers (particularly rural) to improve their capacity to provide evidence-based care to high-needs patient populations in resource-limited settings. This study demonstrated the feasibility, acceptability, and effectiveness of interprofessional online workforce training of ACEs, while also reaching resource-limited rural counties. Robust interest statewide reflects recognition of the topic’s importance and the potential for this training to effect change. Future research is needed to follow up with participants to inquire about knowledge retention and actual implementation in practice, as well as ultimately any benefit to the patient.

Abstract

Background: Retinopathy of prematurity (ROP) is a leading cause of visual impairment and blindness in preterm infants.

Objective: This study sought to investigate the association between red blood cell (RBC) transfusion and ROP in very preterm infants (VPIs) to inform clinical strategies for ROP prevention and treatment.

Methods: We designed a prospective multicenter cohort study that included VPIs and follow-up data from January 2017 to December 2022 at 3 neonatal clinical medicine centers. They were categorized into a transfusion group (infants who received an RBC transfusion within 4 wk) and a nontransfusion group. The relationship between RBC transfusion and ROP incidence was assessed using binary logistic regression, with subgroup analyses based on gestational age, birth weight, sex, and sepsis status. Inverse probability of treatment weighting and propensity score matching were applied to account for all potential confounding factors that could affect ROP development, followed by sensitivity analysis.

Results: The study included 832 VPIs, including 327 in the nontransfusion group and 505 in the transfusion group. The transfusion group had a lower average birth weight and gestational age and a greater incidence of ROP, ≥stage 2 ROP, and severe ROP. Logistic regression analysis revealed that the transfusion group had a significantly greater risk of ROP (adjusted odds ratio [aOR] 1.70, 95% CI 1.14‐2.53, *P*=.009) and ≥stage 2 ROP (aOR 1.68, 95% CI 1.02‐2.78, *P*=.04) but not severe ROP (aOR 1.75, 95% CI 0.61‐5.02, *P*=.30). The trend analysis also revealed an increased risk of ROP with an increasing number of transfusions and a larger volume of blood transfused (*P* for trend<.001). Subgroup analyses confirmed a consistent trend, with the transfusion group at a higher risk for ROP across all subgroups. Inverse probability of treatment weighting and propensity score matching analyses supported the initial findings.

Conclusions: For VPIs, RBC transfusion significantly increases the risk of ROP, and the risk increases with an increasing number of transfusions and volume of blood transfused.

KEYWORDS

red blood cell transfusion; retinopathy of prematurity; VPI; very preterm infants; ROP; visual impairment; blindness; RBC; red blood cell

Introduction

Retinopathy of prematurity (ROP) is a retinal vasoproliferative disease that occurs in premature and low-birth-weight infants and is the most common cause of blindness and low vision in infants [1,2]. Early detection and treatment are essential for preventing irreversible visual impairment and blindness. The main pathophysiological factor in ROP is an imbalance between proangiogenic and antiangiogenic factors released locally in the retina, resulting in abnormal neovascularization [3].

In premature infants, anemia is caused by multiple factors, including insufficient iron reserves from the mother, nutritional deficiency, a short red blood cell (RBC) lifespan, an immature hematopoietic system, and iatrogenic blood loss. RBC transfusion is one of the main treatments for anemia in premature infants. More than half of premature infants with a gestational age of less than 30 weeks and more than 80% of extremely low-birth-weight infants receive at least 1 RBC transfusion during hospitalization [4]. Although RBC transfusion can significantly improve oxygenation status and promote weight gain in anemic premature infants, the adverse reactions caused by RBC transfusion cannot be ignored. Previous studies have reported that RBC transfusion in premature infants is closely related to the development of necrotizing enterocolitis, bronchopulmonary dysplasia, and abnormal neurological outcomes [5]. However, whether RBC transfusion leads to the development of ROP remains controversial. Prospective and retrospective studies have not provided consistent results [6,7]. ROP may regress naturally or progress to stage 3 or higher, with severe cases requiring laser treatment or intravitreal anti–vascular endothelial growth factor (VEGF) injections [8]. Even for infants with ROP who receive timely treatment and those with ROP below the treatment threshold, there is still a risk of permanent visual impairment [9]. Identifying risk factors that can lead to the development and progression of ROP is crucial for its prevention.

Therefore, the purpose of this study was to determine the correlation between RBC transfusion and the occurrence of ROP, providing new insights for the prevention and treatment of ROP.

Methods

Study Participants

Inclusion and Exclusion Criteria

A multicenter cohort study of very preterm infants (VPIs) who were admitted to 3 neonatal intensive care units in Sichuan was conducted from January 1, 2017, to December 31, 2022. The exclusion criteria for infants were as follows: (1) severe lethal congenital malformations (such as central nervous system malformations, congenital facial malformations, or congenital heart malformations); (2) participation refusal by parents or guardians; (3) incomplete hospitalization and transfusion records; (4) discharge or death before ROP screening; and (5) irregular follow-up after discharge.

Definitions and Diagnostic Criteria for Related Diseases

Early-onset sepsis (≤3 d after birth) and late-onset sepsis (>3 d after birth) were classified based on the timing of onset. The clinical diagnosis of sepsis was based on clinical manifestations and positive results for ≥2 nonspecific blood tests, cerebrospinal fluid examination results consistent with bacterial meningitis, or the detection of bacterial DNA in the blood. A confirmed diagnosis required clinical manifestations and positive blood or cerebrospinal fluid (or other sterile body fluid) cultures [10,11].

Premature rupture of membranes refers to the spontaneous rupture of fetal membranes before labor or before the onset of the first stage of labor [12].

Hypertensive disorders of pregnancy are specific and common diseases in pregnant women and include gestational hypertension, preeclampsia (mild and severe), eclampsia, chronic hypertension with preeclampsia, and chronic hypertension with superimposed gestational hypertension [13].

Gestational diabetes mellitus was defined as meeting any one of the following criteria: a random blood glucose level ≥5.1 mmol/L, a postprandial 1-hour blood glucose level ≥10.0 mmol/L, or a postprandial 2-hour blood glucose level ≥8.5 mmol/L [14].

Small for gestational age (SGA) was defined as a birth weight below the 10th percentile of the average birth weight for infants of the same gestational age and sex according to the Chinese birth weight curve for different gestational ages created by Zhu et al [15,16] in 2018.

Apnea of prematurity was defined as a respiratory pause ≥20 seconds or <20 seconds accompanied by a decrease in heart rate or oxygen saturation [17].

Transfusion Criteria for Premature Infants

There is no unified transfusion guideline for anemia in premature infants. The timing and volume of transfusions are usually determined by physicians based on the clinical manifestations, laboratory parameters, and transfusion standards set by each department. Clinical manifestations include poor weight gain or slow growth, irregular breathing, and hemodynamic disturbances. The laboratory parameters include the RBC count, hematocrit level, hemoglobin content, and central and peripheral oxygen saturation. The transfusion dose is 15 - 20 mL/kg per session, and if repeated transfusions are needed, blood from the same donor should be used whenever possible.

ROP Screening, Diagnosis, and Follow-Up

The initial screening for preterm infants was scheduled between 4 and 5 weeks after birth or at a corrected gestational age of 31 to 32 weeks. The examination was conducted by an experienced ophthalmologist using a RetCam III (Natus Medical Inc), an American-made, wide-angle digital pediatric retinal camera, following a systematic order: the posterior pole, macula, temporal, superior, nasal, and inferior regions.

All the examinations were performed by the same ophthalmologist, who diagnosed and staged ROP according to the severity of the condition; ROP was categorized into stages 1 to 5 [18]. Severe ROP was defined as stage 3 to stage 5 ROP or plus disease in zone I or II [19]. Infants with immature retinal development and no ROP undergo retinal re-examinations every 3 to 4 weeks before peripheral vascularization. The follow-up interval for infants with established ROP was determined according to the severity of the condition.

Methodology

A standardized questionnaire for obtaining basic information for preterm infants was developed, and data from the infants' hospital records were documented. All the data were entered independently by 2 individuals using EpiData software (version 3.1; The EpiData Association), with discrepancies resolved by a third party. The following data were collected: (1) maternal information: mode of delivery, gestational diabetes status, hypertensive disorders of pregnancy status, chorioamnionitis status, and premature rupture of membrane status (defined as rupture occurring more than 18 h before delivery); (2) infant information: gestational age, birth weight, 5-minute Apgar score, and SGA status; (3) postnatal conditions: duration of nasal continuous positive airway pressure (nCPAP), use of invasive mechanical ventilation, highest oxygen concentration (sustained for more than 2 h), apnea status, early-onset sepsis status, late-onset sepsis status, invasive ventilation status, and duration of invasive ventilation; (4) transfusion-related indicators: transfusion status, age at first transfusion, number of transfusions, and total blood volume transfused within the first

4 weeks of hospitalization; and (5) outcomes: ROP status, ≥stage 2 ROP status, and severe ROP status.

Statistical Analysis

Statistical software was used for data description and inference. Categorical data are represented by frequencies and percentages, while continuous data are represented by the mean and SD (for normally distributed data) or median and IQR (for nonnormally distributed data). Chi-square tests were used for group comparisons of categorical data, and independent *2-tailed t* tests or Mann Whitney *U* tests were used for continuous data. Multivariate binary logistic regression was used to adjust for potential confounders and calculate the adjusted odds ratio (aOR) of RBC transfusion in premature infants with ROP. Trend tests (*P* for trend) were used to assess the association between the number of transfusions and the volume of blood transfused in infants with ROP. Subgroup analysis was performed based on gestational age, birth weight, sex, and sepsis status. Forest plots were generated to analyze the impact of RBC transfusions on the incidence of ROP in each subgroup.

To address potential baseline data bias in real-world studies, inverse probability of treatment weighting (IPTW) and 1:1 propensity score matching (PSM) methods were used to balance baseline differences between groups [20]. Sensitivity analysis was conducted using the calculated sample sizes obtained from these postrandomization methods to validate the stability of the results. All the statistical analyses were performed using open-source R packages and SPSS software (version 26.0; IBM Corp). A *P* value <.05 was considered to indicate statistical significance.

Ethical Considerations

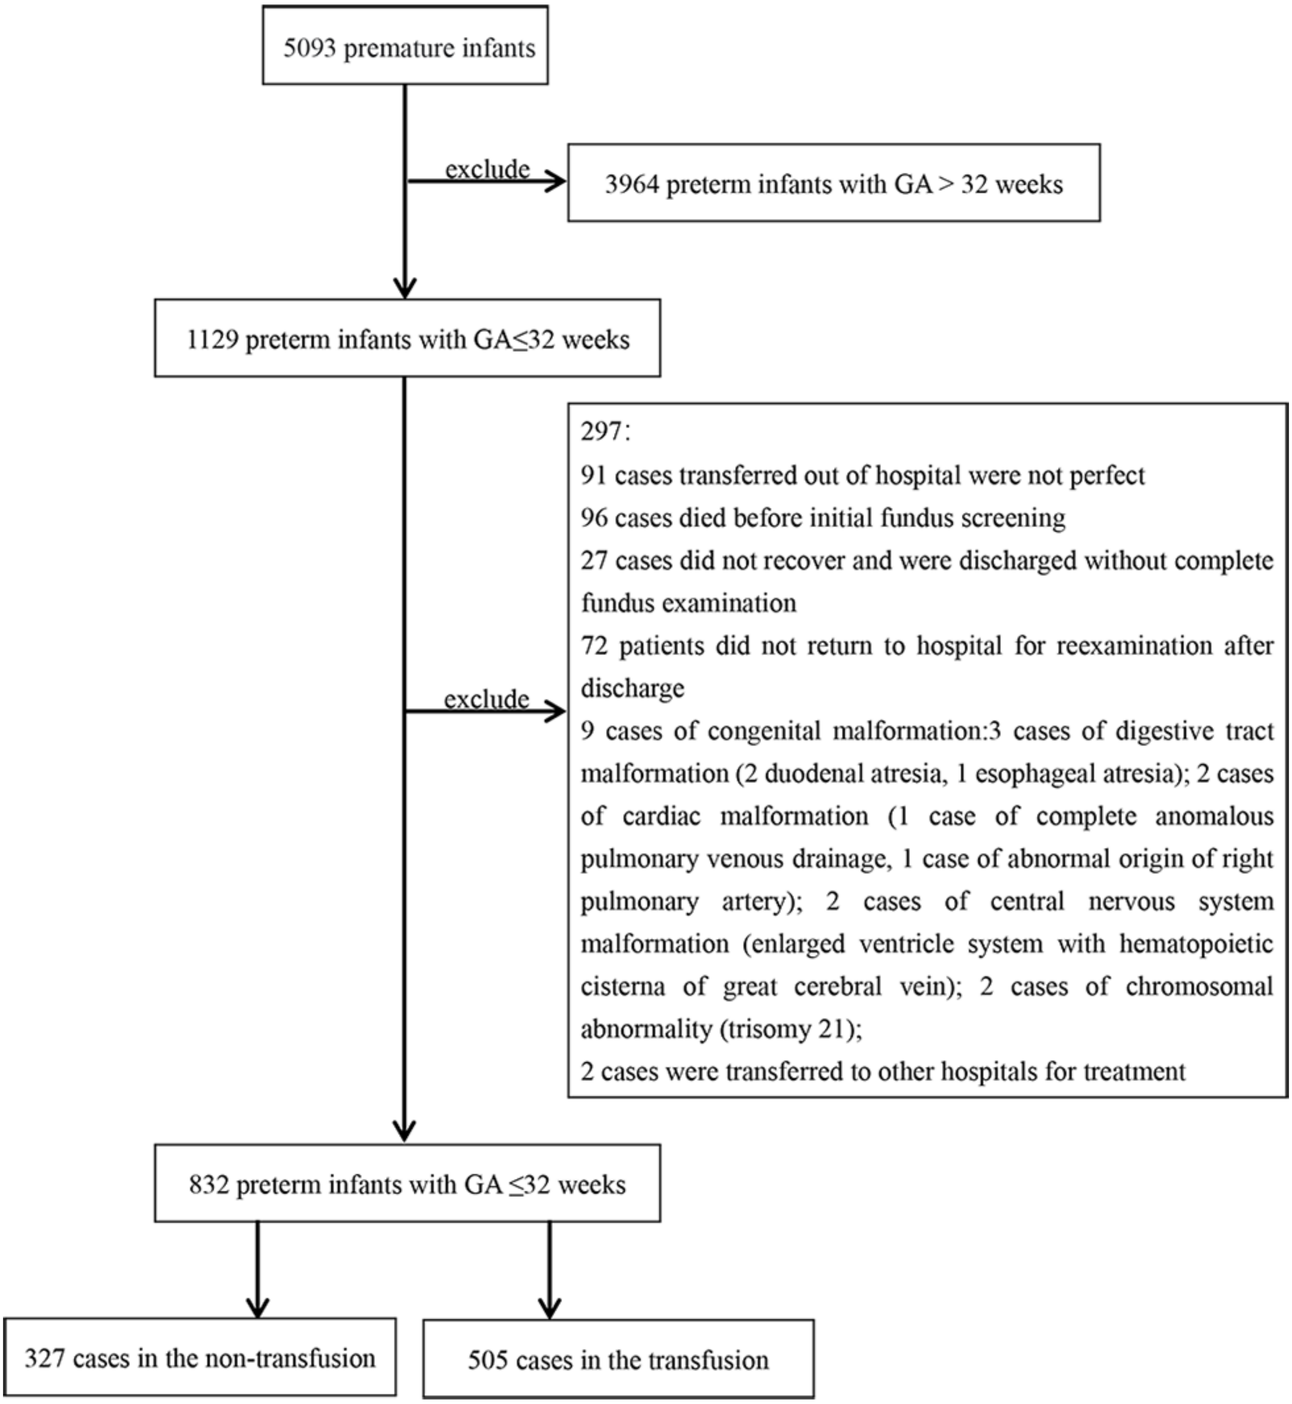
The Clinical Trial Ethics Committee of the Affiliated Hospital of Southwest Medical University approved the study (approval number Y2024124). The study was in accordance with the ethical standards of the institutional research committee and with the 1964 Helsinki Declaration and its later amendments. Informed consent was obtained from the legal guardians of all participants included in the study.

Results

Case Selection Process

During the study period, a total of 1129 VPIs were admitted to 3 neonatal intensive care units. After excluding 297 infants, 832 were ultimately included. Since the initial screening for ROP occurs between 4 and 5 weeks after birth, infants who received RBC transfusions within 4 weeks after birth were defined as the transfusion group, and those who did not receive transfusions within 4 weeks or who received transfusions after 4 weeks were defined as the nontransfusion group. The nontransfusion group consisted of 327 (39.3%) infants, and the transfusion group included 505 (60.7%) infants (Figure 1).

Figure 1. Flowchart of the selection of the research participants. GA: gestational age.



Study Results Before Random Matching

Comparison of General Information Between the 2 Groups

Table 1 shows that the preterm infants in the transfusion group had a younger gestational age (median 30.10, IQR 28.90-31.10 wk vs median 31.10, IQR 30.30-31.60 wk, z=−8.77, *P*<.001), a lower average birth weight (mean 1327, SD 251 g vs mean 1543, SD 231 g; *t*=12.50, df=830, *P*<.001), and a lower 5-minute Apgar score (median 8, IQR 7-9 points vs median 9, IQR 8-9 points, z=−6.73, *P*<.001). The highest oxygen concentrations required were greater (median 30%, IQR 28-40% vs median 28%, IQR 25-30%, z=−10.02, *P*<.001); the duration of nCPAP use was greater (median 11, IQR 6-18 d vs median 6, IQR 3-9 d, z=−12.03, *P*<.001); and the incidences of mechanical ventilation (156/505, 30.9% vs 16/327, 4.9%, $\chi^2_1=81.80$, *P*<.001), apnea (280/505, 55.5% vs 87/327, 26.6%, $\chi^2_1=66.96$, *P*<.001), early-onset sepsis (132/505, 26.1% vs 60/327, 18.4%, $\chi^2_1=6.79$, *P*=.009), late-onset sepsis (198/505, 39.2% vs 57/327, 17.4%, $\chi^2_1=44.28$, *P*<.001), and SGA (59/505, 11.7% vs 14/327, 4.3%, $\chi^2_1=13.59$, *P*<.001) were significantly greater in the transfusion group than in the nontransfusion group (Table 1).

	SGA[b], n (%)	14 (4.3)	59 (11.7)	13.59 (1)	<.001

[a] nCPAP: nasal continuous positive airway pressure.

[b] SGA: small for gestational age.

The Impact of Transfusion Within 4 Weeks on ROP Incidence

Using the results of univariate analysis as a basis, potential confounding factors were included in a multivariate binary logistic regression model. The results showed that the risk of ROP (aOR 1.70, 95% CI 1.14‑2.53; *P*=.009) and ≥stage 2 ROP (aOR 1.68, 95% CI 1.02‑2.78; *P*=.04) in the transfusion group was significantly greater than that in the nontransfusion group; however, there was no significant difference in the risk of severe ROP between the 2 groups (aOR 1.75, 95% CI 0.61‑5.02; *P*=.30) (Table 2).

Table . The impact of red blood cell (RBC) transfusion within 4 wk on retinopathy of prematurity (ROP) incidence.

	Nontransfusion group (n=327), n (%)	Transfusion group (n=505), n (%)	OR[a] (95% CI)	*P* value	aOR[b] (95% CI)	*P* value
ROP	58 (17.7)	239 (47.3)	4.17 (2.99-5.81)	<.001	1.70 (1.14-2.53)	.009
≥Stage 2 ROP	30 (9.2)	159 (31.5)	4.55 (2.99-6.92)	<.001	1.68 (1.02-2.78)	.04
Severe ROP	5 (1.5)	51 (10.1)	7.23 (2.86-18.33)	<.001	1.75 (0.61-5.02)	.30

[a] OR: odds ratio.

[b] aOR: adjusted odds ratio. Adjusted for gestational age, birth weight, 5-min Apgar score, mechanical ventilation use, maximum oxygen concentration, early-onset sepsis, late-onset sepsis, apnea, and small for gestational age.

The Impact of Different Transfusion Frequencies Within 4 Weeks on ROP Incidence

To clarify the impact of different transfusion frequencies within 4 weeks on ROP incidence, preterm infants in the transfusion group were further divided into a single transfusion group (339 infants) and a multiple transfusion group (166 infants) and compared with those in the nontransfusion group. A single transfusion within 4 weeks increased the risk of ROP (aOR 1.79, 95% CI 1.20 - 2.68; *P*=.005) but did not increase the risk of ≥stage 2 ROP or severe ROP; multiple transfusions within 4 weeks increased the risk of ROP (aOR 2.95, 95% CI 1.67 - 5.21; *P*<.001) and ≥stage 2 ROP (aOR 2.84, 95% CI 1.47 - 5.47; *P*=.002) but did not increase the risk of severe ROP (Multimedia Appendix 1). As the number of transfusions increased, the risk of ROP, ≥stage 2 ROP, and severe ROP gradually increased, with trend test results all less than 0.001, indicating that the higher the number of transfusions was, the greater the risk of ROP.

The Impact of Different Transfusion Volumes Within 4 Weeks on ROP Incidence

To clarify the impact of different transfusion volumes within 4 weeks on ROP incidence, preterm infants in the transfusion group were further divided based on the total volume of blood transfused. Due to the nonnormal distribution of the total transfusion volume within 4 weeks, the infants in the transfusion group were divided into the following 3 groups according to the IQR and compared with those in the nontransfusion group: the ≤34 mL/kg group (176 infants), 34 - 42 mL/kg group (159 infants), and ≥42 mL/kg group (170 infants). A total transfusion volume ≤34 mL/kg within 4 weeks did not increase the risk of ROP, ≥stage 2 ROP, or severe ROP; a total transfusion volume of 34 - 42 mL/kg within 4 weeks increased the risk of ROP (aOR 1.67, 95% CI 1.02 - 2.72, *P*=.04) but did not increase the risk of ≥stage 2 ROP or severe ROP; and a total transfusion volume ≥42 mL/kg within 4 weeks increased the risk of ROP (odds ratio [OR] 2.88, 95% CI 1.54 - 5.39, *P*<.001) and ≥stage 2 ROP (OR 3.08, 95% CI 1.53 - 6.23, *P=.002*) but did not increase the risk of severe ROP (Multimedia Appendix 2). As the total transfusion volume increased, the risk of ROP, ≥stage 2 ROP, and severe ROP gradually increased, with trend test results all less than 0.001, indicating that the greater the total transfusion volume was, the greater the risk of ROP.

The Impact of Transfusion on ROP Incidence in Various Subgroups of Preterm Infants

To clarify the impact of transfusion within 4 weeks on ROP incidence in different preterm infant populations, the included preterm infants were divided into 3 subgroups based on gestational age (>30 weeks ≤30 weeks), birth weight (>1500 g, ≤1500 g), sex (male, female) and sepsis status (yes, no). Although there were no significant differences in some outcome indicators between the subgroups, the overall trend was consistent, with the risk of ROP in the transfusion group being greater than that in the nontransfusion group (Figure 2, Multimedia Appendices 3, 4, and 5).

Sensitivity Analysis Results After IPTW and PSM

Given the numerous factors influencing ROP incidence and the significant imbalance in the baseline data in this real-world study, as shown in Table 2, the ROP data showed considerable changes before and after adjusting for confounding factors, suggesting potential selection bias in the study results. Therefore, the IPTW and PSM methods were applied in this study to evaluate all factors that could affect ROP incidence between the 2 groups. Sensitivity analysis was performed using the calculated sample sizes obtained after IPTW and PSM to validate the stability of the impact of RBC transfusions on ROP incidence. The balance between the groups was significantly improved after IPTW and PSM (Multimedia Appendices 6 and 7). The results obtained after IPTW and PSM were consistent with the original results (Multimedia Appendices 8 and 9).

Discussion

Principal Findings

Previous studies on the association between RBC transfusion and ROP incidence have used a retrospective case-control design to investigate risk factors for ROP development. This is the first prospective multicenter cohort study in which infants were categorized based on whether they received RBC transfusions within the first 4 weeks after birth. The study included all VPIs who were admitted to 3 centers over nearly 6 years, and the correlation between RBC transfusion and ROP incidence was explored. The results indicated that RBC transfusion within the first 4 weeks significantly increases the risk of ROP in VPIs, and this correlation remained consistent across different groups of preterm infants.

Despite various available measures to prevent anemia in preterm infants, the use of RBC transfusion remains inevitable [21]. Studies show that more than 90% of extremely low-birth-weight infants receive at least 1 RBC transfusion during their hospital stay, with the risk of transfusion increasing for infants with younger gestational ages, lower birth weights, and greater immaturity [22,23]. Puia-Dumitrescu et al’s [24] study, which included 54 preterm infants with a gestational age of 30 weeks and a birth weight less than 1000 g, revealed that the average number of RBC transfusions during a 10-week hospital stay was 8. For extremely preterm infants with a gestational age of 23 - 24 weeks, the average number of transfusions was 11, and for those with a gestational age of 27 - 28 weeks, the number could reach 6. Our study revealed that 505 (60.7%) preterm infants with a gestational age ≤32 weeks received at least 1 RBC transfusion within 28 days of hospitalization, with a greater likelihood of transfusion in infants with a younger gestational age. The proportion of transfusions decreased with increasing gestational age and birth weight, which is consistent with previous findings.

ROP is a common complication in preterm infants, and its incidence and severity decrease as gestational age and birth weight increase. In this study, the incidence of ROP in preterm infants with a gestational age ≤32 weeks was 297 (35.6%), and the incidence of severe ROP was 56 (6.7%). The incidence of ROP is greater in infants with younger gestational ages, with those born at less than 28 weeks having an incidence rate of approximately 70%, which is consistent with the reports by Dai et al [25].

The pathogenesis of ROP is multifactorial, with low gestational age, low birth weight, and prolonged exposure to oxygen therapy being the main risk factors for ROP [26]. In addition to these risk factors, RBC transfusion has been suggested to be a risk factor for ROP development in numerous case-control studies [27-29]. However, Lundgren et al [30] reported that the duration of anemia in the first week after birth was an independent risk factor for ROP, while RBC transfusion was not. Given the inconsistent results of retrospective studies, our prospective cohort study aimed to clarify the association between RBC transfusion and ROP incidence. The results indicated that after adjusting for confounding factors such as gestational age at birth, birth weight, and nCPAP use, RBC transfusion within the first 4 weeks of hospitalization significantly increased the risk of ROP and ≥stage 2 ROP in VPIs. However, there was no significant difference in the incidence of severe ROP between the 2 groups, which may have been due to the low incidence of severe ROP and the small sample size. Given that this study was observational, many factors influence ROP development, and there is potential selection bias due to the imbalance of baseline data, we applied the IPTW and PSM methods to account for all potential confounding factors that could affect ROP development. The results still suggested that RBC transfusion increases the risk of ROP in VPIs, and this association remained consistent across different groups of preterm infants.

The risk of ROP increases with an increasing number of RBC transfusions and volume of blood transfused. Ghirardello et al’s [31] study, which included 641 preterm infants with very low birth weight, showed that RBC transfusion is an independent risk factor for ROP development in very low-birth-weight infants, and the risk of complications increases with an increasing number of transfusions, with 3 or more transfusions increasing the risk of bronchopulmonary dysplasia and ROP by 4.88 times. Hengartner et al’s [32] retrospective study of 178 extremely preterm infants showed that infants with ≥stage 2 ROP received more transfusions, had larger volumes transfused, and received earlier treatment. Additionally, Uberos et al’s [19] data indicate that the relationship between the number of RBC transfusions and the risk of ROP and severe ROP is more significant than that between early RBC transfusion (within the first 7 d of life) and the risk of ROP and severe ROP. Our study revealed that the risk of ROP and ≥stage 2 ROP increases with an increasing number of RBC transfusions and volume of blood transfused, which is consistent with the findings of the aforementioned studies.

The mechanism by which RBC transfusion leads to ROP development is not yet fully understood, but it may be related to the replacement of fetal hemoglobin (HbF) with adult hemoglobin after transfusion, which leads to changes in the type and quantity of hemoglobin [33]. Since adult hemoglobin has a decreased affinity for oxygen, developing retinal tissue is exposed to high oxygen levels, leading to oxidative damage to vascular endothelial cells, downregulation of VEGF expression, and stagnation of retinal vascular development [34]. This results in retinal hypoxia, increased VEGF and erythropoietin expression, pathological proliferation of vessels in the retina and vitreous, and the development of ROP [35]. Jiramongkolchai et al’s [36] prospective cohort study showed that infants with the lowest percentage of HbF at a corrected age of 31 weeks had a 7.6-fold increased risk of mild and severe ROP, and this risk increased to 12.3 times by the corrected age of 34 weeks, indicating that a lower HbF percentage is associated with a greater risk of ROP. Prasad et al [37,38] conducted 2 prospective studies to explore the correlation between HbF concentration and ROP, and the results showed that preterm infants with lower HbF levels were at higher risk of developing ROP, and preterm infants with higher HbF concentration were more likely to have ROP spontaneously subside. HbF may play a protective role in the occurrence and development of ROP. Teofili et al investigated the relationship between transfusion-free survival and ROP [39]. The study found that preterm infants receiving RBC transfusions before 28 weeks of gestational age were associated with an increased risk of developing severe ROP, that gestational age at second transfusion was a better predictor of developing severe ROP than gestational age at first transfusion, and that maintaining higher levels of HbF may help reduce the risk of ROP [39].

Preventing anemia and reducing the risk of RBC transfusion are pressing issues for neonatologists. Delayed cord clamping [40], reduced iatrogenic blood loss, and iron supplementation are beneficial interventions for preventing anemia. Research on the RBC source, storage time, and different transfusion thresholds is currently ongoing, but there are no unified results. Kirpalani et al [41] reported that restrictive transfusion strategies did not reduce the incidence of ROP; Glaser et al’s [42] large cohort study revealed that restrictive transfusion strategies could reduce the risk of ROP, while liberal transfusion strategies increased the risk. In recent years, umbilical cord blood (UCB) transfusion has gained increasing attention. The use of UCB from healthy newborns has been proposed to prevent ROP in preterm infants. The main potential advantage of UCB is that it contains the same amount of HbF as newborns in utero. Thus, autologous UCB transfusions would maintain a physiological concentration of HbF during the first weeks of life, which has a greater affinity for oxygen and is more stable in an oxidative environment, maintaining similar oxygen transportation and tissue delivery as in the fetal stage. This fact could optimize the postnatal development of different immature tissues [43].

Limitations

This study has certain limitations. First, as a multicenter observational study spanning 6 years, there may have been changes in the treatment and transfusion strategies for preterm infants across centers, leading to potential bias in the results. Second, although the IPTW and PSM methods were used to control for known confounding factors, unknown confounding factors and other intermediate factors may still have affected the results. Therefore, considering the potential impact of unknown confounding factors, we believe that well-designed, larger-sample randomized clinical trials are needed to further validate the effects of RBC transfusion, different RBC storage times, transfusion intervals, and anemia status on the development of ROP. We also need to learn from the work of Schallmoser et al [44], integrating the medical profession with machine learning to construct a predictive model for the risk of retinopathy of ROP occurrence.

Conclusions

Based on our study results, RBC transfusion increases the risk of ROP, and this effect is consistent across different groups of preterm infants. For VPIs, RBC transfusions are strongly associated with an increased risk of ROP, which escalates alongside the number and volume of transfusions. We recommend that for VPIs with small gestational age, low birth weight, and high risk of sepsis, the indications for RBC transfusion in preterm infants should be strictly controlled and that the number of transfusions and volume of blood transfused should be limited to reduce adverse consequences.

Abstract

Background: Children (aged 0-14 years) living with HIV often experience lower rates of HIV diagnosis, treatment, and viral load suppression. In Haiti, only 63% of children living with HIV know their HIV status (compared to 85% overall), 63% are on treatment (compared to 85% overall), and 48% are virally suppressed (compared to 73% overall). Electronic medical records (EMRs) can improve HIV care and patient outcomes, but these benefits are largely dependent on providers having access to quality and nonmissing data.

Objective: We sought to understand the associations between EMR data missingness and interruption in antiretroviral therapy treatment by age group (pediatric vs adult).

Methods: We assessed associations between patient intake record data missingness and interruption in treatment (IIT) status at 6 and 12 months post antiretroviral therapy initiation using patient-level data drawn from iSanté, the most widely used EMR in Haiti. Missingness was assessed for tuberculosis diagnosis, World Health Organization HIV stage, and weight using a composite score indicator (ie, the number of indicators of interest missing). Risk ratios were estimated using marginal parameters from multilevel modified Poisson models with robust error variances and random intercepts for the facility to account for clustering.

Results: Data were drawn from 50 facilities and comprised 31,457 patient records from people living with HIV, of which 1306 (4.2%) were pediatric cases. Pediatric patients were more likely than adult patients to experience IIT (n=431, 33% vs n=7477, 23.4% at 6 months; *P*<.001). Additionally, pediatric patient records had higher data missingness, with 581 (44.5%) pediatric records missing at least 1 indicator of interest, compared to 7812 (25.9%) adult records (*P*<.001). Among pediatric patients, each additional indicator missing was associated with a 1.34 times greater likelihood of experiencing IIT at 6 months (95% CI 1.08-1.66; *P*=.008) and 1.24 times greater likelihood of experiencing IIT at 12 months (95% CI 1.05-1.46; *P*=.01). These relationships were not statistically significant for adult patients. Compared to pediatric patients with 0 missing indicators, pediatric patients with 1, 2, or 3 missing indicators were 1.59 (95% CI 1.26-2.01; *P*<.001), 1.74 (95% CI 1.02-2.97; *P*=.04), and 2.25 (95% CI 1.43-3.56; *P*=.001) times more likely to experience IIT at 6 months, respectively. Among adult patients, compared to patients with 0 indicators missing, having all 3 indicators missing was associated with being 1.32 times more likely to experience IIT at 6 months (95% CI 1.03-1.70; *P*=.03), while there was no association with IIT status for other levels of missingness.

Conclusions: These findings suggest that both EMR data quality and quality of care are lower for children living with HIV in Haiti. This underscores the need for further research into the mechanisms by which EMR data quality impacts the quality of care and patient outcomes among this population. Efforts to improve both EMR data quality and quality of care should consider prioritizing pediatric patients.

Introduction

Despite improvements in HIV testing, care, and treatment and reduced HIV incidence over the last 3 decades, Haiti has the largest population of people living with HIV in the Caribbean, with an estimated 1.8% of the population (150,000 persons) having received a positive HIV diagnosis, including nearly 6000 children (aged 0-14 years) living with HIV [1]. Children living with HIV often have lower rates of HIV diagnosis, treatment, and viral load suppression [2]. In Haiti, children living with HIV fare worse across all steps of the care cascade, with only 63% knowing their HIV status (compared to 85% overall), 63% on treatment (compared to 85% overall), and 48% virally suppressed (compared to 73% overall) [1]. Reviews of patient records in Haiti revealed that children living with HIV were significantly less likely to initiate antiretroviral therapy (ART) in a timely manner as compared to adults, and once initiated, were less likely than adults to be retained in ART treatment [3,4].

Electronic medical records (EMRs) can improve HIV patient care and outcomes in multiple ways, including (1) directly informing individual patient care, such as tracking clinical outcomes, ART adherence and retention, as well as patient follow-up; and (2) promoting provider compliance with treatment and care guidelines [5-13]. However, these benefits are largely dependent on providers having access to high-quality data (ie, reliable, timely, and nonmissing data) [14-16]. In the context of EMRs, data missingness is both an element of quality of care (vis-à-vis noncompliance with reporting guidelines) and can itself lead to lower quality of care, as missing data cannot be used to inform clinical decision-making [17]. However, despite the importance of data quality in the value proposition of EMRs, the evidence base exploring the association between data missingness and patient outcomes is limited, especially in resource-limited settings. Although many studies of EMRs include both data quality and patient outcomes as indicators of interest, a direct association between the two is rarely assessed. In addition, no studies reviewed for this paper assessed this relationship by age cohort.

We hypothesize that data missingness will be associated with greater interruption in treatment (IIT) and that this relationship may be larger among children living with HIV. We used ART patient data extracted from the iSanté EMR system to assess the association between age group, data missingness, and IIT.

Methods

Study Design

This was a retrospective longitudinal study using patient-level routine EMR data.

Data Source

We used patient-level clinical and pharmacy data extracted from iSanté—the most widely used EMR in Haiti, which covers over 1.8 million primary care patients and more than 200,000 unique records for people living with HIV [18,19]. iSanté records include data on key HIV care cascade processes (eg, clinical history) and electronic pharmacy data (eg, ART dispensing and continuation).

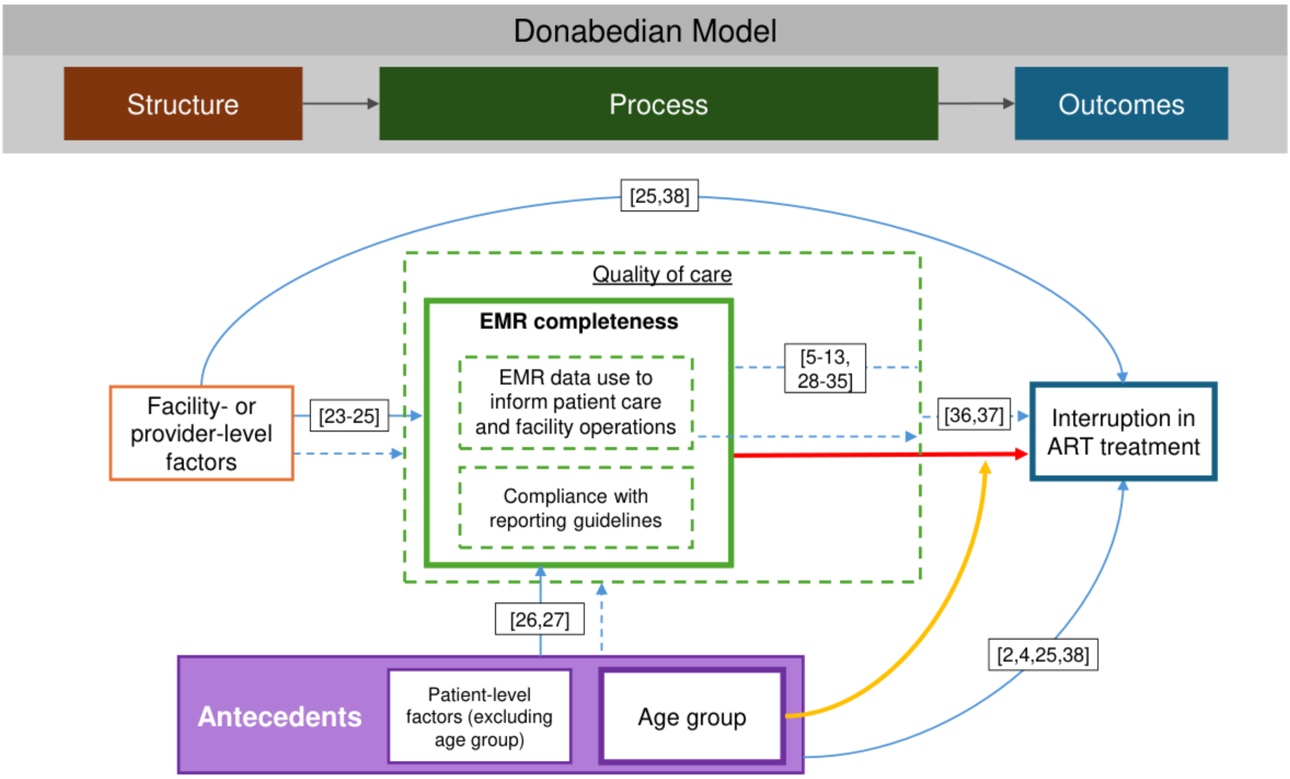
Sample

This analysis included data from 50 facilities and covered individuals who initiated ART between June 2016 and December 2021. Our analyses had a number of data exclusions. A total of 24 facilities were excluded from the analysis due to being prison-based facilities, having >20% of records entered more than 90 days after the visit date, or having a mean number of prescription records per patient less than 5 (suggesting data record input issues). Data before June 2016 were excluded to account for changes in treatment patterns following adoption of the test-and-treat approach to HIV care in mid-2016. Patient records included in the analysis were restricted to patients who initiated ART at least $n+2$ months before the data extraction date (end of July 2022) to allow for sufficient follow-up time to observe the outcome and to account for any delay in the entry of patient files, where n refers to the 6- or 12-month IIT outcome (eg, for the 6 months outcome, data were restricted to those who had initiated ART before December 2021). Individuals without date of birth data (n=1174, 3.2%) were excluded as correct age group categorization was essential for the analysis. Additionally, to better assess the relationship between data missingness at intake and IIT status 6 or 12 months after initiating ART, patients who completed their intake visit more than 3 months prior to initiating ART were excluded from the analysis (n=4083, 11.5%). A CONSORT (Consolidated Standards of Reporting Trials) flow diagram can be found in Multimedia Appendix 1 [20].

Conceptual Model

Figure 1 shows our proposed causal model, which is situated within the Donabedian framework [21] for quality of care, as modified by Coyle and Battles [22] to include medical antecedents. The Donabedian framework divides care into 3 primary components: structure (ie, the context in which care is delivered), process (ie, actual service delivery), and outcome. In the context of HIV care and EMRs, these can be understood as the facility or organizational context in which HIV care is delivered as well as the system aspects of EMRs (eg, accessibility and usability); the provision of HIV care, including the use of EMRs to both document and inform care; and HIV outcomes (eg, IIT). The various pathways in our conceptual model were justified through the published literature [2,4-13,23-38].

Figure 1. Conceptual model [2,4-13,23-38]. The blue lines indicate proposed causal pathways; the red line indicates the observed association of interest; the yellow line indicates effect modification by age; the dashed lines indicate unobserved pathways or variables. ART: antiretroviral therapy; EMR: electronic medical record.



Analysis

Outcome Variable

The primary outcomes of interest were IIT at the current facility at 6 and 12 months post ART initiation, defined as being more than 28 days late in picking up ART medication as of the dates 6 or 12 months after initiating ART. This definition for IIT status has been used in prior research in Haiti and other settings [39-41].

Covariates

Age groups were categorized as pediatric (0-14 years) and adult (>15 years) as of the time of ART initiation, following the age definition used to define pediatric care in Haiti (<15 years).

Data Missingness

Data missingness was defined as an indicator not being collected during the patient's intake visit. Assessment of missingness was restricted to indicators that were shared between both pediatric and adult intake forms, indicators that were clinically meaningful for HIV care, and where missingness could be differentiated from the absence of that issue (eg, the headache symptomology field may be missing due to a patient not presenting with a headache or due to the provider failing to document that issue, whereas the World Health Organization [WHO] HIV stage indicator is expected to be completed for all patients) [42]. Within these stipulations, we assessed missingness for weight, current WHO HIV stage, and current tuberculosis (TB) diagnosis. As the importance and impact of missingness for particular indicators may vary by age group (eg, routine documentation of weight is generally of higher importance for pediatric patients), missingness was analyzed as individual binary outcomes (defined as missing or nonmissing) as well as through a composite score indicator (the number of indicators of interest missing), which was analyzed as both a continuous and categorical outcome.

Models

Associations between data missingness (exposure) and interruption in ART treatment at a patient's current facility (outcome) were assessed through marginal parameters from multilevel modified Poisson models with robust error variances and random intercepts for the facility to account for clustering. Modified Poisson models have been shown to provide unbiased estimates of the risk ratio, important for nonrare binary outcomes where odds ratios estimated through logistic regression will overestimate the risk ratio and potentially lead to improper interpretation of the results [43,44]. Patient sex, facility type, ownership, patient volume, and duration of iSanté use were included as fixed effects to control for potential confounding. Models were stratified by age group to understand the relationship between data missingness and IIT status within each age group. Additional models were run with the age group as an interaction term with the continuous composite indicator to assess the statistical significance of the age group as an effect modifier in the association between missingness and IIT status.

Ethical Considerations

The secondary use of deidentified patient data from the iSanté EMR was approved by the University of Washington Human Subjects Division as nonengaged research (STUDY00016591 "Patient Risk Profiles for Interruption in Treatment among People Living with HIV in Haiti: Leveraging Health Information

Systems and Prediction Models to Identify Patients at High Risk"). The research was also reviewed and approved by the Haiti Ministry of Public Health and Population's National Bioethics Committee (reference number 2223-26).

Results

Primary Findings

In total, data were drawn from 50 facilities across 9 departments (of 10 total) in Haiti and comprised 31,457 patient records for people living with HIV. Of these, 30,151 (95.8%) were adult patients and 1306 (4.2%) were pediatric patients. The majority of patients (n=19,544, 62.1%) were female and received care at health centers (n=19,051, 60.6%) or hospitals (n=9883, 31.4%). The median duration of iSanté use at each health facility was 17.5 (IQR 15.8-18.3) years, and the median monthly patient volume was 348 (IQR 172-544). Table 1 further details participant and facility characteristics.

Table . Participant characteristics[a].

Characteristics		Patients		
		Overall (N=31,457)	Adult (n=30,151, 95.8%)	Pediatric (n=1306, 4.2%)
Sex, n (%)				
	Female	19,544 (62.1)	18,855 (62.5)	689 (52.8)
	Male	11,913 (37.9)	11,296 (37.5)	617 (47.2)
Age (years), median (IQR)		35 (27-44)	35 (28-44)	3 (0-9)
Facility type, n (%)				
	Health center	19,051 (60.6)	18,319 (60.8)	732 (56.0)
	Hospital	9883 (31.4)	9406 (31.2)	477 (36.5)
	Dispensary	2523 (8.0)	2426 (8.0)	97 (7.4)
Facility ownership, n (%)				
	Both public and private	7337 (23.3)	7008 (23.2)	329 (25.2)
	Private	11,466 (36.4)	11,109 (36.8)	357 (27.3)
	Public	12,654 (40.2)	12,034 (39.9)	620 (47.5)
Duration of iSanté use, median (IQR)		17.5 (15.8-18.3)	17.5 (15.3-18.3)	18.1 (17.0-18.3)
Monthly patient volume, median (IQR)		348 (172-544)	348 (172-544)	408 (200-626)

[a] Facility-related characteristics are described at the patient level (eg, the proportion of patients initiating antiretroviral therapy at a health center versus a hospital or dispensary).

IIT status and indicator missingness are detailed in Table 2. Across all age groups, the proportion of patients who experienced IIT at 6 and 12 months post ART initiation were 23.8% (n=7477) and 29.3% (n=9222), respectively. Overall, the weight indicator had the highest level of missingness, with 5365 (17.1%) patient records missing weight data, while TB diagnosis had the lowest (n=1417, 4.5%). Both IIT status and data missingness were higher among pediatric patients. Pediatric patients were more likely than adult patients to be IIT at both 6 months (n=431, 33.0% vs n=7046, 23.4%; *P*<.001) and 12 months (n=551, 42.2% vs n=8671, 28.8%; *P*<.001). Only 55.5% (n=725) of pediatric patient records had no indicators of interest missing, compared to 74.1% (n=22,339) of adult patient records. Pediatric patient records were also more likely to have at least 3 (3.1%) indicators missing compared to adult records (n=401, 1.3%; *P*<.001). Variation in missingness across age groups was greatest for the WHO HIV stage, with 32.5% (n=425) of pediatric records missing this indicator compared to 11.1% (n=3355) of adult records (*P*<.001).

Table . Interruption in treatment (IIT) status and indicator missingness.

Characteristics		Patients		*P* value[a]
		Overall (N=31,457), n (%)	Pediatric (n=1306), n (%)	
IIT status				
	6 months	7477 (23.8)	431 (33.0)	<.001
	12 months	9222 (29.3)	551 (42.2)	<.001
Indicator missingness				
	Weight	5365 (17.1)	265 (20.3)	.001
	WHO[b] HIV stage	3780 (12.0)	425 (32.5)	<.001
	TB[c] diagnosis	1417 (4.5)	79 (6.0)	.006
Composite missingness score (number of indicators missing)				
	0	23,064 (73.3)	725 (55.5)	<.001
	1	6666 (21.2)	434 (33.2)	<.001
	2	1285 (4.1)	106 (8.1)	<.001
	3	442 (1.4)	41 (3.1)	<.001

[a] Pearson χ^2 test.

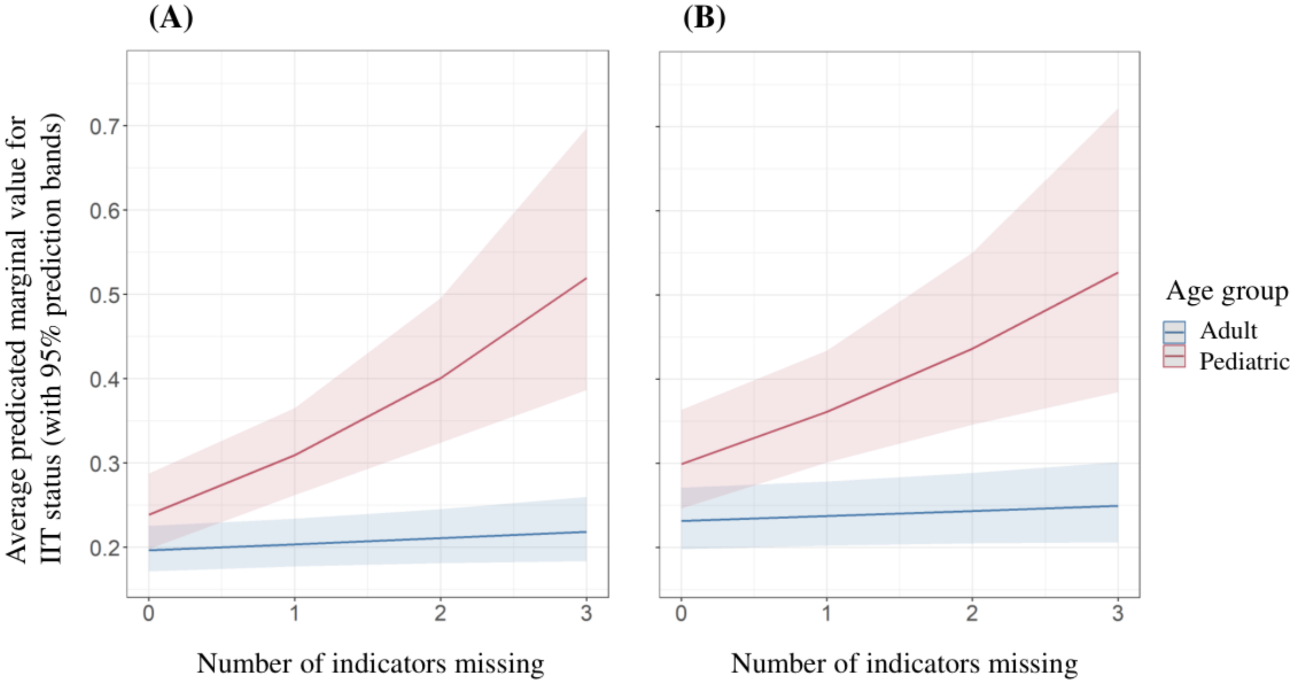
[c] TB: tuberculosis.

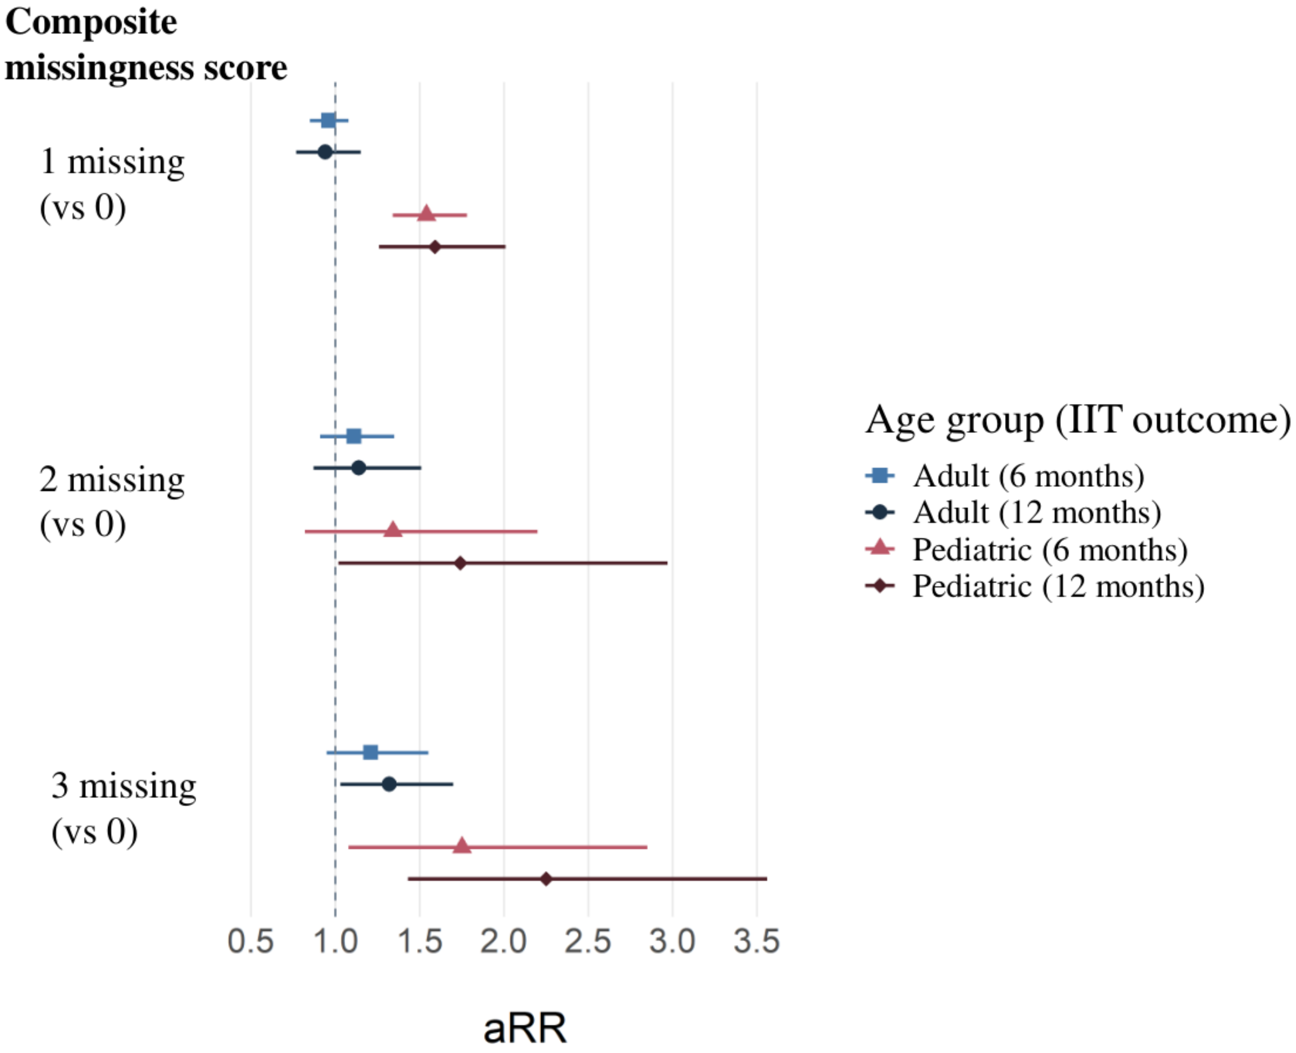
Results from models exploring the association between IIT status and the composite missingness score as a continuous variable are shown in Figure 2 (full multivariable regression results can be found in Multimedia Appendix 2). Statistically significant associations were observed between higher values of the composite missingness score and a greater likelihood of experiencing IIT at both 6 and 12 months among pediatric patients. However, no such association was observed among adult patients for either outcome. Among pediatric patients, each additional indicator missing was associated with a 1.34 times greater likelihood of experiencing IIT at 6 months post ART initiation (95% CI 1.08-1.66; *P*=.008) and 1.24 times greater likelihood of experiencing IIT at 12 months (95% CI 1.05-1.46; *P*=.01). Our interaction models (not shown) revealed that the relationship between the composite score indicator and IIT status was statistically significantly larger among pediatric patients compared to adult patients at both 6 months, where pediatric patients had a 25% greater risk of experiencing IIT for each additional missing element compared to adult patients (95% CI 1.02-1.53; *P*=.03), and 12 months, where pediatric patients had an 18% greater risk of experiencing IIT for each additional missing element compared to adult patients (95% CI 1.01-1.38; *P*=.04).

Figure 2. Multivariable regression of interruption in treatment (IIT) status at (A) 6 months post antiretroviral therapy (ART) initiation and (B) 12 months post ART initiation against composite missingness score (continuous), stratified by age group.



We also assessed the composite missingness score as a categorical variable (Figure 3) to understand the estimates of excess risk in the absence of the assumption of a linear relationship between missingness and IIT status (full multivariable regression results can be found in Multimedia Appendix 2). Compared to pediatric patients with 0 missing indicators, pediatric patients with 1, 2, or 3 missing indicators were 1.59 (95% CI 1.26-2.01; *P*<.001), 1.74 (95% CI 1.02-2.97; *P*=.04), and 2.25 (95% CI 1.43-3.56*; P*=.001) times more likely to experience IIT at 6 months, respectively. At 12 months, pediatric patients with 1, 2, or 3 missing indicators were 1.54 (95% CI 1.34-1.78; *P*<.001), 1.34 (95% CI 0.82-2.20; *P*=.24), and 1.75 (95% CI 1.08-2.85; *P*=.02) times more likely to experience IIT, respectively, although this association was no longer significant for those with 2 indicators missing. Among adult patients, compared to patients with 0 indicators missing, having all 3 indicators missing was associated with being 1.32 times more likely to experience IIT at 6 months (95% CI 1.03-1.70; *P*=.03), while having 3 indicators missing was not associated with IIT at 12 months, and having 1 or 2 indicators missing was not associated with IIT at either 6 or 12 months.

Figure 3. Multivariable regression of interruption in treatment (IIT) status at 6 and 12 months post antiretroviral therapy initiation against composite missingness score (categorical), stratified by age group. aRR: adjusted risk ratio.



For the individual missingness indicators (Multimedia Appendix 2), only the WHO HIV stage indicator was associated with IIT status among pediatric patients, where pediatric patients with missing WHO HIV stage data on their intake form were 2.17 times more likely to experience IIT at 6 months (95% CI 1.79-2.64; *P*<.001) and 1.79 times more likely to experience IIT at 12 months (95% CI 1.54-2.08; *P*<.001), as compared to pediatric patients with nonmissing WHO HIV stage data. Missingness for the WHO stage data among adult patients and missingness for weight and TB status among either age group were not associated with IIT status at either 6 or 12 months.

Sensitivity Analyses

We hypothesized that providers at facilities with a lower proportion of pediatric patients may be less familiar with pediatric care, and therefore, less compliant with treatment and reporting guidelines, which could potentially impact the relationship between data missingness and IIT. However, neither missingness nor IIT status showed a significant association with the proportion of pediatric patients at a given facility, and an interaction model did not show any difference in the relationship between data missingness and IIT status by the proportion of pediatric patients (data are not shown). We additionally explored a more granular definition for age groups 0-9, 10-14, 15-19, 20-24, and >25 years. In age group–stratified models, the association between the continuous composite data missingness score and IIT status at 6 months was only statistically significant for the 0-9 age group, which showed a positive association between greater missingness and likelihood of experiencing IIT (data are not shown).

Discussion

Principal Findings

In this retrospective longitudinal study of patient record data drawn from the iSanté EMR system in Haiti, we found that both data missingness and interruption in ART treatment were higher for pediatric patients compared to adult patients; nearly one-third of pediatric patients had IIT at 6 months compared to just over one-fifth of adults, and nearly half of pediatric patients had missing values for indicators of interest on their intake forms compared to just over one-quarter of adult patients. Data missingness showed a substantial and significant association with greater IIT, with adult patients being 30% more likely and pediatric patients more than twice as likely to have IIT at 6 months when all 3 indicators of interest were missing. The relationship between missingness and IIT status was stronger and more consistent among pediatric patients; pediatric patients showed statistically significantly greater likelihood of experiencing IIT at 6 and 12 months for the composite score indicator both overall (continuous) and across all levels of missingness (categorical), while for adult patients this relationship was only significant at 6 months and for the highest level of missingness in the categorical analysis. Individual indicator missingness showed little association with IIT status, except for the WHO HIV stage among pediatric patients. Within the modified Donabedian quality of care framework, our results show a link between the process of care provision (vis-à-vis compliance with reporting guidelines and data use for clinical decision-making) and patient outcomes (IIT status) after adjusting for structural elements (ie, facility characteristics), with the association being highly dependent on medical care antecedents (ie, patient age group) [21,22].

There is a rich evidence base showing the potential impact of EMR use on HIV service provision and quality of care by promoting adherence to care guidelines, enabling higher quality patient data, improving provider efficiency, and informing patient care, tracking, and follow-up [5-13]. The benefits of EMRs, however, are largely predicated on providers having access to quality data (ie, reliable, timely, and nonmissing) to inform their work, and there is a growing evidence base on the importance and impact of patient record quality (electronic or otherwise) on quality of care, care engagement, or health outcomes [14-16,29,30]. Particularly relevant to this analysis, one study of more than 6000 patient records collected from the National Clinical Audit for Rheumatoid and Early Inflammatory Arthritis found that missing baseline patient data was significantly associated with the odds of timely initiation of treatment being halved [29]. In a qualitative study of health care professionals in South Africa, participants reported viewing data quality as an critical element in the provision of quality health care services, including how poor EMR information integrity can lead “to errors that endanger patient safety or decrease the quality of care” [45]. A systematic review found that data missingness was a commonly cited barrier to the use of EMRs to inform population health efforts [12]. In another systematic review, Albagmi [11] found that EMRs were associated with both better documentation and higher quality of care, although a direct causal relationship between data quality and quality of care was not directly assessed. This limitation is common to much of the literature on EMR data quality; many studies of EMR implementation include both data quality and quality of care indicators as outcomes or indicators of interest, but few directly assess the relationship between data quality and quality of care or patient outcomes. Our results, therefore, contribute to this limited evidence base, providing evidence that EMR data quality is associated with interruption in ART treatment.

Although we have established a temporal sequence for the relationship between data quality and IIT status, the absence of measurements for other elements of quality of care makes it impossible to discern whether the observed association was due to poor data quality itself or data quality as a proxy for broader quality of care. Data quality could be a marker of lower provider competence, poorer supplies and infrastructure at the health facility, higher provider-patient ratio, lower contact time between providers and patients, or other phenomena associated with IIT status. Further research is necessary to understand the role data missingness plays in care provision.

Our finding that overall missingness was higher among pediatric patients and that the association between missingness and IIT status was stronger among pediatric patients supports our hypothesis that there may be differential quality of care among pediatric patients leading to poorer retention in care. Pediatric populations living with HIV have unique care needs, and poorer engagement for pediatric patients across the HIV care cascade is a multifaceted issue, involving behavioral, psychosocial, pharmacokinetic, and structural factors [17,46]. The literature has identified a number of key barriers to pediatric ART adherence, including stigma among caregivers to seek or continue care for children; lack of education or training for caregivers on caring for a child living with HIV; complexities inherent to a patient-caregiver-provider relationship; limited patient agency due to age and patient-caregiver power structures; patient-led treatment refusal, sometimes due to a lack of palatable formulations for younger patients; and lack of providers trained in pediatric HIV care or family-based service delivery [17,47,48]. Relevant to this analysis, prior research has shown direct links between quality of care, care engagement, and patient outcomes for this population. In their analysis of children living with HIV in Nigeria, Ojikutu et al [37] found that higher quality care—measured as a composite score exploring TB screening, adherence measurement and counseling, CD4 and weight documentation, and medication prescription—was significantly associated with a lower likelihood of pediatric and adolescent patients being lost to follow-up and mortality. Improving the quality of care for children living with HIV, including better patient record quality, is necessary to address the gaps in HIV testing and treatment among children living with HIV.

Limitations

At present, it is not possible to track patients between facilities within our analysis data. As such, it is not possible to distinguish patients who transferred to a new facility but remained on ART and those who interrupted or fully discontinued treatment. As a result, our ART retention outcome was defined as an IIT at a patient’s current facility rather than interruption overall. This outcome still fits within our causal model, with lower quality of care being feasibly associated with either an actual IIT or transfer to another facility for higher quality care, and it still represents a meaningful proxy indicator for clinical outcomes, as facility transfer may be associated with ART treatment gaps or discontinuation. Patient transfers are also not a limitation specific to this study; a systematic review of ART retention studies found that nearly 20% of patients classified as lost to follow-up had actually self-transferred to another facility [49].

Additionally, our results may be confounded if the missingness of the indicators is associated with the values of that indicator as well as our outcome. For example, if a higher WHO HIV stage is associated with both a greater likelihood of being missing and a greater likelihood of IIT, the observed association may be due to the latent WHO HIV stage rather than the data missingness. Of note, although integrated with iSanté, pharmacy data used to calculate the IIT outcome variables are collected through different mechanisms and staff. This includes greater data quality oversight, in part due to their inclusion in routine President's Emergency Plan for AIDS Relief (PEPFAR) monitoring, evaluation, and reporting. Therefore, we do not anticipate that misclassification of the IIT outcome due to missing pharmacy data will be highly correlated with our exposure (missingness among indicators of interest), and thus, it will not present a substantial risk of bias. Finally, we were not able to assess associations with clinical outcomes (eg, viral suppression) due to data availability limitations.

Strengths

This was an observational study, and therefore, it could not assess a causal relationship between data missingness and IIT; however, our hypothesis is strengthened by the robust sample size and analytical design; strong association observed between missingness and IIT status; a dose-response relationship wherein greater missingness was associated with greater likelihood of a patient having IIT; and established temporal sequence, as the intake data are completed prior to ART initiation and the IIT outcomes.

Conclusions

Our analysis showed that both patient record data missingness for key indicators and interruption in ART treatment were common among patients, with nearly one-quarter of patients having IIT at 6 months and more than one-quarter of patients missing at least 1 indicator of interest in their patient record. Both IIT status and data missingness were more common among pediatric patients. Greater data missingness was associated with a higher likelihood of being IIT at 6 and 12 months for both pediatric and adult patients, although the association was stronger and more consistent among pediatric patients. Our findings motivate further research into the mechanisms by which EMR data quality impacts the quality of care and patient outcomes, particularly among children living with HIV. Additionally, efforts to improve both EMR data quality and quality of care should consider prioritizing pediatric patients.

Acknowledgments

The authors would like to acknowledge the partnership of the Centre Haïtien pour le Renforcement du Système de Santé (CHARESS) and the Ministère de Santé Publique et de la Population (MSPP) as well as funding from the Centers for Disease Control and Prevention (CDC), without which this work would not have been possible.

This research was developed by the CHARESS and the International Training and Education Center for Health (I-TECH) with support from the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) through the CDC (Cooperative Agreement 5 NU2GGH002226-04-00). Abstract

Background: More than 2 out of 3 children and adolescents in the United States experience trauma by the age of 16 years. Exposure to trauma in early life is linked to a range of negative mental health outcomes throughout the lifespan, particularly co-occurring symptoms of posttraumatic stress (PTS), anxiety, and depression. There has been an increasing uptake of digital mental health interventions (DMHIs) among youths, particularly for anxiety and depression. However, little is known regarding the incidence of trauma exposure and PTS symptoms among youths participating in DMHIs and whether PTS symptoms impact anxiety and depressive symptom treatment response. Moreover, it is unclear whether participation in a DMHI for anxiety and depressive symptoms is associated with secondary effects on PTS symptoms among trauma-exposed youths.

Objective: This study aims to use retrospective data from youths participating in a DMHI to (1) characterize rates of trauma, PTS, and comorbid anxiety and depressive symptoms; (2) determine whether trauma exposure and elevated PTS symptoms impact the improvement of comorbid anxiety and depressive symptoms throughout participation in care; and (3) determine whether participation in a non–posttraumatic DMHI is linked to reductions in PTS symptoms.

Methods: This study was conducted using retrospective data from members (children ages 6 to 12 years) involved in a pediatric collaborative care DMHI. Participating caregivers reported their children's trauma exposure. PTS, anxiety, and depressive symptom severity were measured monthly using validated assessments.

Results: Among eligible participants (n=966), 30.2% (n=292) reported at least 1 traumatic event. Of those with trauma exposure and elevated symptoms of PTS (n=119), 73% (n=87) exhibited elevated anxiety symptoms and 50% (n=59) exhibited elevated depressive symptoms. Compared to children with no trauma, children with elevated PTS symptoms showed smaller reductions per month in anxiety but not depressive symptoms (anxiety: $F_{2,287}=26.11$; $P<.001$). PTS symptoms also decreased significantly throughout care, with 96% (n=79) of participants showing symptom reductions.

Conclusions: This study provides preliminary evidence for the frequency of trauma exposure and comorbid psychiatric symptoms, as well as variations in treatment response between trauma-exposed and nontrauma-exposed youths, among participants in a pediatric collaborative care DMHI. Youths with traumatic experiences may show increased psychiatric comorbidities and slower treatment responses than their peers with no history of trauma. These findings deliver compelling evidence that collaborative care DMHIs may be well-suited to address mental health symptoms in children with a history of trauma while also highlighting the critical need to assess symptoms of PTS in children seeking treatment.

Introduction

More than two-thirds of children have experienced trauma, such as abuse, neglect, natural disasters, and sudden loss of a loved one, by the age of 16 years [1,2]. These rates have been exacerbated by the recent COVID-19 pandemic and associated lockdowns, which appear to have caused a significant increase in child maltreatment globally [3-6]. During the first year of the pandemic, more than 11% of US adolescents reported physical abuse and 55% reported emotional abuse—2- and 3-fold increases compared to prepandemic rates [7,8]. The far-reaching and pervasive effects of childhood trauma are well documented. Those who experience trauma, particularly in childhood and adolescence [9], are at increased risk for a number of maladaptive mental and physical health outcomes throughout the lifespan [10,11] including posttraumatic stress disorder (PTSD). PTSD and symptoms of posttraumatic stress (PTS) develop as a result of a traumatic event and include reexperiencing (eg, flashbacks or memories of the event), avoidance of reminders and feelings related to the event, and elevated arousal and alterations in cognition and mood (eg, negative emotions and feelings, blame, and isolation [12]). Recent estimates suggest that 16% of children and adolescents who experience trauma go on to develop PTSD, although symptom severity is often dependent on age and gender, as well as type, duration, and severity of the trauma experienced [13]. Those with trauma are not only at risk for developing PTSD but also a number of mental health difficulties, particularly anxiety and depression [14]. Indeed, PTS, depression, and anxiety share common symptoms, etiologies, and effective treatment modalities such as cognitive behavioral therapy (CBT) [15,16].

Youths with traumatic experiences are significantly more likely to receive mental health care from a variety of sources, including primary care physicians, therapists, psychiatrists, school counselors, and social workers [17]. With shortages of in-person mental health providers and rates of pediatric mental health disorders increasing, traditional modalities of mental health care are becoming steadily more overburdened, expensive, and inaccessible. These issues of accessibility paired with the lockdowns of the COVID-19 pandemic catalyzed widespread uptake of digital mental health interventions (DMHIs) or those facilitated by technologies such as computers and smartphones. Although a number of DMHIs are available for the treatment of pediatric PTSD [18], these interventions and associated research are limited in significant ways. First, no research has been done to characterize the rates of trauma among youths participating in DMHIs for comorbid symptoms such as anxiety and depression, which are some of the most prevalent mental health disorders among youths. Indeed, most youths who receive mental health services do so for anxiety and depressive symptoms [19-21]. Given the etiological overlap among PTS, depression, and anxiety, there is a high likelihood that many youths with PTS symptoms would experience secondary benefits when receiving mental health care for anxiety and depression. Second, there is little understanding of how traumatic experiences and PTS symptoms impact the treatment response of anxiety and depressive symptoms for youths participating in a DMHI. By exploring these 2 lines of research, pediatric DMHIs will be better equipped to adapt their care programs and modalities to the needs of users with traumatic experiences and posttraumatic symptoms.

The collaborative care model (CoCM), in which primary care providers partner with behavioral care managers (BCMs) and psychiatrists to coordinate patient-centered and measurement-based care, is widely considered the best practice for pediatric mental health care [22]. Researchers have argued that the CoCM, with its use of regular symptom measurement and individualized care, confers better outcomes, particularly for those with trauma who are exhibiting complex and comorbid symptoms of PTS, depression, and anxiety [23,24]. Early evidence indicates that DMHIs using the CoCM are associated with improvements in pediatric mental health problems, including anxiety and depression [10,25,26]. However, no research has been done to understand the use and effectiveness of collaborative care DMHIs for anxiety and depression among trauma-exposed youths.

Therefore, the purpose of this study was to use retrospective data from youths participating in a collaborative care DMHI to (1) characterize rates of trauma, PTS, and comorbid anxiety and depressive symptoms; (2) determine whether trauma exposure and elevated PTS symptoms impact improvement of comorbid anxiety and depressive symptoms throughout participation in care; and (3) determine whether participation in a non–posttraumatic DMHI is linked to reductions in PTS symptoms.

Methods

Participants

Bend Health Inc members aged 6 to 12 years (at baseline, before care started) were eligible for inclusion in the study if they (1) had their first coaching or therapy session with Bend between January 1, 2023, and October 1, 2023 (9 months), and (2) completed the trauma assessment before beginning care (N=979). To more specifically assess symptom outcomes for members receiving care for mental health symptoms other than PTS, members who participated in the trauma care program were excluded from all analyses (n=13, 1.3%). Thus, the final sample included 966 members.

Ethical Considerations

Study procedures were approved by the Biomedical Research Alliance of New York (Study 23-12-034-1374). All participants provided informed consent to their data being used for research purposes upon enrollment, and all data were anonymized and deidentified prior to analysis. Bend Health Inc members were not compensated for their participation in this retrospective research.

Treatment

Treatment with Bend Health Inc has been described previously [25]. Bend Health Inc is a DMHI for youths that uses the CoCM to implement a whole-family approach, involving caregivers in treatment. Each member is assigned a behavioral care manager (BCM) who oversees and manages the child's individual treatment plan and works with primary care providers, psychiatrists, therapists, and coaches to determine the correct treatment plan for each member. The member then meets regularly with either a licensed therapist or a coach, depending on the type and severity of mental health symptoms the member is experiencing. To specifically target a particular symptom domain (eg, anxiety symptoms), children are assigned a care program (by their BCM) based on their symptom severity and care goals. All care programs are designed to be developmentally appropriate for the age of the member, and the primary care programs (eg, anxiety, depression, and attention-deficit/hyperactivity disorder [ADHD]) are intended to take approximately 12 weeks to complete. During sessions, coaches and therapists provide behavioral care that is informed by the components of the care program. The informational contents of all care programs are also available in a digital platform for members and their caregivers to access between sessions (asynchronously). Once a month, caregivers are asked to complete questionnaires regarding their child's symptoms, including PTS, anxiety, and depressive symptoms.

Therapy at Bend Health Inc provides diagnostic clarity, addresses complicated history of trauma and problematic behaviors, and provides clinical treatment for mental health disorders. Coaching provides behavior change tools and improvements in self-efficacy using evidence-based best practices. When appropriate, members' care can escalate to include both coaching and therapy for the treatment of more severe symptoms. Both coaching and therapy at Bend Health Inc are based on CBT, behavioral activation, motivational interviewing, caregiver training, and mindfulness-based practices. Depending on symptom needs and care plan, members may also meet with a psychiatrist at enrollment and throughout care for additional symptoms and medication management.

Assessments

At enrollment into care with Bend Health Inc, caregivers are asked to report their child's demographic information, including date of birth, sex, gender, and race or ethnicity. The response options for sex are "male," "female," and "other." The response options for gender are "male," "female," "transgender," "nonbinary," and "other." From January 1, 2023, to May 26, 2023, only 1 race or ethnicity response could be selected, and the options were "White," "Black or African American," "American Indian or Alaska Native," "Asian," "Hispanic or Latino," and "Other." From May 26, 2023, to October 1, 2023, multiple race or ethnicity responses could be selected, and the options were "White," "Black or African American," "American Indian or Alaska Native," "Chinese," "Vietnamese," "Native Hawaiian," "Filipino," "Korean," "Japanese," "Chamorro," "Other Asian," "Other Pacific Islander," "Some other race or multi-racial," "Mexican," "Mexican American," "Chicano," "Puerto Rican," "Cuban," and "Another Hispanic, Latino, or Spanish origin."

To assess children's mental health symptoms during the enrollment process, caregivers first respond to screener questions. When elevated symptoms are flagged by the responses to the screeners, caregivers are then prompted to complete fully validated assessments. To screen for PTS, caregivers are asked the question: "Has your child ever experienced a traumatic event?" If the response to this question is "Yes," caregivers are then asked to report the nature and timing of the child's most distressing event, and they also complete the entire Child PTSD Symptom Scale (for the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition; CPSS-V) validated questionnaire [27]. To assess the nature of the traumatic event, caregivers are asked to describe their child's most distressing event in a free textbox. To assess the timing of the traumatic event, caregivers are asked "How long has it been since that event occurred?" with the following response options: "1-30 days," "1-3 months," "3-6 months," "6-12 months," "1-2 years," "2-4 years," and "4+ years." The CPSS-V consists of 20 items, in which caregivers are asked to report how often their child exhibits behaviors consistent with PTS, such as "trying not to think about it [the distressing event] or have feelings about it" and "trouble having good feelings." Responses to these items are made on a 5-item Likert-type scale, with responses ranging from "not at all" (score=0) to "6 or more times a week/almost always" (score=4).

Screener questions for anxiety and depressive symptoms are taken from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) cross-cutting measure, which asks caregivers to report the frequency (in the last 2 weeks) that their child exhibits behaviors associated with anxiety and depression [28]. There are 3 anxiety symptom screener questions and 2 depressive symptom screener questions. Responses to the anxiety and depressive symptom screeners are made on a 5-item Likert-type scale with responses ranging from "not at all" (score=0) to "nearly every day" (score=4). If a caregiver responds to any anxiety or depressive screener question with "several days" (score=2) or more frequently, they are prompted to complete the PROMIS (Patient-Reported Outcomes Measurement Information System) anxiety assessment or PROMIS depressive assessment, respectively [29]. The PROMIS anxiety assessment includes 10 questions about common anxiety symptoms (eg, feeling worried). The PROMIS depression assessment includes 11 questions about common depressive symptoms (eg, feeling lonely). For both PROMIS assessments, caregivers report the frequency of their child's behaviors or feelings in the last 7 days, with responses on a 5-item Likert-type scale ranging from "never" (score=1) to "almost always" (score=5). Caregivers were prompted to complete mental health symptom screeners and assessments within the web-based portal every month after enrollment to track mental health symptom severity throughout care.

Statistical Methods

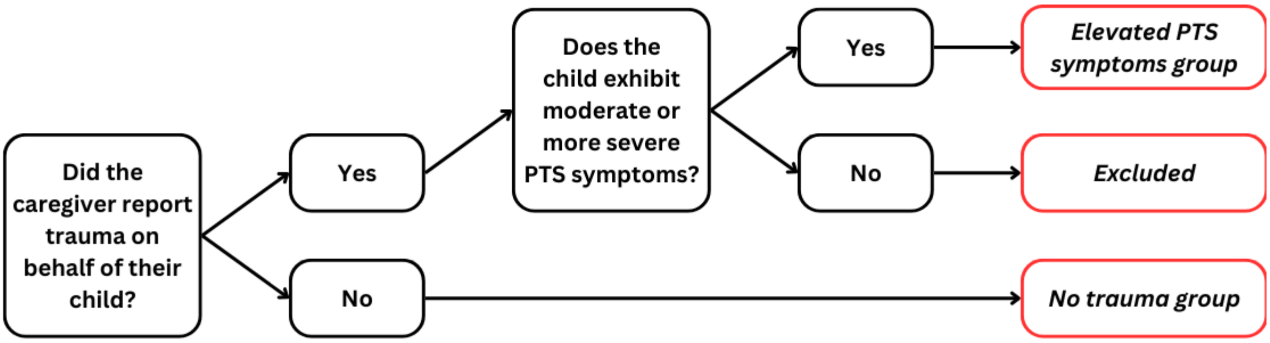
Responses to all items from the CPSS-V were aggregated for a total PTS score of 0 to 80. Using standardized criteria, PTS symptom severity was determined based on CPSS-V scoring norms [27], which are as follows: minimal (scores: 0 to 10), mild (score: 11 to 20), moderate (score: 21 to 40), severe (score: 41 to 60), and very severe (score: 61 to 80). Responses to the items from the anxiety and depression PROMIS assessments were aggregated for a total anxiety score of 10 to 50 and a total depressive symptom score of 11 to 55, respectively. Then, total PROMIS scores were converted to t-scores using standardized criteria [30]. Anxiety and depressive symptom severity were then determined based on t-scores as follows: none to slight (t-score <55), mild (t-score 55-59.9), moderate (t-score 60-69.9), and severe (t-score ≥70). For PTS, anxiety, and depressive symptoms, symptom severity of moderate, severe, or very severe was considered "elevated."

Standard descriptive statistics—including percent, mean (SD), and median (IQR)—are used throughout the "Results" section, as appropriate. For all analyses (outlined in detail below), between-group comparisons for categorical variables were performed using chi-square tests, and comparisons for continuous variables were performed using 2-tailed Wilcoxon signed rank tests or 2-tailed *t* tests, as appropriate based on data distribution (determined by Shapiro-Wilk test). Where between-group comparisons could not be performed given a small representation within a category of interest, only the descriptive statistics are reported.

PTS Symptoms

For all members included in the study (n=966), the rates of reported trauma at baseline (last assessment before care started) were described. For members that had a traumatic event, CPSS-V scores, PTS symptom severity, and the timing of the traumatic event were reported. Members with no traumatic event were included in the no trauma group. Members with both a traumatic event and CPSS-V scores indicating moderate or greater PTS symptoms were included in the elevated PTS symptoms group. Members with a traumatic event and nonelevated PTS symptoms were not included in the primary analyses, and thus all further analyses were applied only to members in the "no trauma" and "elevated PTS symptoms" groups (Figure 1).

Figure 1. Flowchart delineating study group formation and exclusion criteria. PTS: posttraumatic stress.



Member Characteristics and Care Use

Member characteristics and care use patterns were reported for each group. The following member characteristics were assessed: age in years (at baseline), sex (male, female, and nonbinary), gender conforming (conforming and nonconforming), ethnicity (Asian, Black or African American, Hispanic/Latino, White, and Other), and mental health diagnoses by type (anxiety disorder, depressive disorder, and ADHD). Date of birth was used to calculate age in years (at enrollment). If a member's sex at birth and gender identity (reported at enrollment) were not identical, they were classified as gender nonconforming. Otherwise, members were classified as gender conforming. Details on the reporting of race or ethnicity are included in the Multimedia Appendix 1. Rates of elevated mental health symptoms at baseline (moderate or greater severity) were also assessed for anxiety and depressive symptoms. For care use patterns, the duration of care (months between the first session and the last session) and participation in coaching and therapy were reported only for members with at least 1 coaching or therapy session (106 excluded). Between-group comparisons were performed for the following variables of interest: age, female sex (yes or no), gender conformity (conforming or nonconforming), ethnicity (White or non-White), elevated mental health symptom (elevated or nonelevated; all types), months in care, and participation in therapy (yes or no).

Mental Health Symptom Reduction

PTS symptom reduction was assessed for members in the "elevated PTS symptoms" group. Rates of members with symptom reduction were assessed for those with at least 1 coaching or therapy session, and who completed at least one symptom assessment after starting care (37 excluded). Symptom reduction was considered a decrease in score from baseline or screening out of the last assessment. Then, the amount of total change over the duration of care was assessed by delta CPSS-V score from baseline to the last *full* CPSS-V assessment (no screened-out assessments), and delta scores were compared to 0 using a Wilcoxon signed rank test to assess for a significant change in score. This analysis was performed on data from members with at least 1 coaching or therapy session, and at least 1 full symptom assessment after starting care (54 excluded). To determine whether PTS symptoms decreased over months in care, CPSS-V scores were assessed over months in care by a linear mixed effects model with a fixed effect of months in care and a random effect of member ID on the intercept. Potential covariates were added to this basic model, and if a potential covariate improved model fit (based on the likelihood ratio test [LRT]), it was included in the final model. Models with the addition of the following covariates were tested against the basic model: age (at baseline), sex (female vs nonfemale), and race or ethnicity (White vs non-White).

Anxiety and depressive symptoms were assessed over time in care and compared between groups. First, the rates of members with symptom reduction were assessed for members with elevated mental health symptoms at baseline, at least 1 coaching or therapy session, and at least 1 symptom assessment after starting care (anxiety symptoms: 576 excluded; depressive symptoms: 658 excluded). Symptom reduction was considered a decrease in t-score from baseline or screening-out of the last assessment. The rates of members with symptom reduction were compared between groups using chi-square tests. These analyses were performed on data from members with elevated mental health symptoms at baseline, at least 1 coaching or therapy session, and at least one full symptom assessment after starting care (anxiety symptoms: 626 excluded; depressive symptoms: 712 excluded). Then, the total change in t-score (delta t-score) from baseline to the last full assessment was compared between groups using a 2-tailed *t* test or Wilcoxon signed rank test, as determined based on sample distribution. Finally, the rate of anxiety and depressive symptom reduction was compared between groups using linear mixed effects analyses with a fixed effect of group, the interaction of the group with months (in care), and a random effect of the subject on the intercept.

For all linear mixed effects analyses, to ensure that the findings were not skewed by baseline assessments occurring very early before the start of care, members whose baseline assessment occurred greater than 1 month before the first coaching or therapy session were excluded (PTS symptoms: additional 6 excluded; anxiety symptoms: additional 10 excluded; depressive symptoms: additional 4 excluded). A single additional member (n=1) was excluded from the depressive symptom linear mixed effects analysis due to an outlier t-score. For between-group analyses of rates of symptom reduction and total change, we confirmed that each group took their last and *full* last assessments at approximately the same time in care by between-group Wilcoxon signed rank comparisons of assessment timing for each symptom domain.

Results

PTS Symptoms

Of the 966 members included in the study, 30.2% (n=292) had experienced a traumatic event and the remaining 69.8% (n=674) did not have a traumatic event. For members with a traumatic event, CPSS-V scores were a median of 18 (IQR 9-28), with scores ranging from 0 (minimal PTS symptom severity) to 61 (very severe PTS symptoms). Of members with a traumatic event, 86 (29.5%) had minimal symptoms, 87 (29.8%) had mild symptoms, 99 (33.9%) had moderate symptoms, 19 (6.5%) had severe symptoms, and 1 (0.3%) had very severe symptoms. As such, for members with a traumatic event, 59.2% (n=173) had nonelevated PTS symptoms and 40.8% (n=119) had elevated PTS symptoms.

While 63.7% (n=186) of all members with a traumatic event reported that the event occurred 1 or more years before baseline, the timing of the event varied (Table 1). Notably, the rate of children having experienced the event within the last 30 days was nearly twice as high for children with elevated PTS symptoms (n=14, 11.8%) versus nonelevated PTS symptoms (n=10, 5.8%). For all further analyses, 674 were included in the no trauma group (no trauma reported at baseline), 119 were included in the elevated PTS symptoms group (traumatic event and elevated PTS symptoms), and 173 were not included in further analyses (traumatic event and nonelevated PTS symptoms).

Table 1. Timing of trauma, respective to when it was reported at baseline, reported for members in the no trauma and elevated PTS symptoms groups.

Timing of trauma (prior to baseline)	Nonelevated PTS[a] symptoms, n (%)	Elevated PTS symptoms, n (%)
Total	173 (59.2)	119 (40.8)
1 to 30 days	10 (5.8)	14 (11.8)
1 to 3 months	14 (8.1)	11 (9.2)
3 to 6 months	15 (8.7)	10 (8.4)
6 to 12 months	19 (11)	13 (10.9)
1 to 2 years	34 (19.7)	23 (19.3)
2 to 4 years	38 (22)	23 (19.3)
4 or more years	43 (24.9)	25 (21)

[a] PTS: posttraumatic stress.

Member Characteristics

Children with elevated PTS symptoms were a median of 10 (IQR 9-11) years old, 56.3% (n=67) were female, and they were largely gender conforming (n=113, 95%; Table 2). In terms of their race or ethnicity, 44.5% (n=53) were “White” and 35.3% (n=42) were “Other” or multiracial. Compared to members with no trauma, members with elevated symptoms of PTS were older (z=–4.38; P<.001) and more predominantly female (χ^2_1=5.33; P=.02). Rates of elevated mental health symptoms at baseline were higher for children with elevated PTS symptoms compared to children with no trauma. Specifically, 72.6% (n=87) of children with elevated PTS symptoms had elevated anxiety symptoms compared to 33.9% (n=228) of children with no trauma (χ^2_1=63.55; *P*<.001). Approximately 1 in 2 children with elevated PTS symptoms also had elevated depressive symptoms (n=59, 49.6%) compared to 1 in 5 children with no trauma (n=135, 20%; χ^2_1=46.21; *P*<.001). Children with elevated symptoms of PTS had higher rates of participation in the anxiety care program (χ^2_1=7.75; *P*=.005) and depression care program (χ^2_1=3.79; *P*=.05; statistical trend) and lower rates of participation in the ADHD care program (χ^2_1=4.06; *P*=.04).

Table 2. Member characteristics reported for children in the no trauma and elevated PTS[a] symptom groups. Between-group comparisons were performed with chi-square tests unless otherwise specified.

Member characteristics	No trauma (n=674), n (%)	Elevated PTS symptoms (n=119), n (%)	Between-group comparisons	
			Chi-square (*df*=1)	*P* value

For members in the no trauma group who began coaching or therapy, they were in care for a median of 3.03 (IQR 1.63-4.50) months; 98.8% (n=479) were in coaching and 23.7% (n=115) were in therapy. For members in the elevated PTS symptoms group that began coaching or therapy, they were in care for a median of 3.03 (IQR 1.89-4.67) months, and 100% (n=102) were in coaching and 25.5% (n=26) were in therapy. The duration of care did not differ between groups (*z*=–1.08; *P*=.28), and the rates of members in therapy also did not differ between groups (χ^2_1=1.27; *P*=.26).

Mental Health Symptom Reduction

The rates of reduction in anxiety and depressive symptoms from baseline to the last assessment did not differ between groups (anxiety: $\chi^2_1=1.33$; $P=.25$ and depressive: $\chi^2_1=0.28$; $P=.59$), with 84.3% (183/217) of all members exhibiting a reduction in anxiety symptom severity and 86.7% (117/135) of all members exhibiting a reduction in depressive symptom severity (Table 3). The amount of change (delta t-score) from baseline to the last *full* assessment also did not differ significantly between groups (anxiety: $z=–0.35$; $P=.73$ and depressive: $t_{51.23}=0.19$; $P=.85$). Specifically, for all children, anxiety t-scores decreased by a median of 5 points (IQR –9 to 0) and depression t-scores decreased by a mean of 3.77 (SD 7.54) points. The number of months between baseline and the last assessment and baseline and the last full assessment did not differ between groups for anxiety and depressive symptoms (all $P>.05$).

Table 3. Change in anxiety and depressive symptoms from baseline. Rates of members with a reduction in symptom severity from baseline to their last assessment and the change in t-score from baseline to the last full assessment are reported for each group.

Mental health symptom	No trauma	Elevated PTS[a] symptoms	Between-group comparisons[b]	
			Chi-square (*df*=1)	*P* value
Percent with reduction in symptom severity (baseline to last assessment)				
Anxiety, n/N (%)	130/158 (82.3)	53/59 (89.8)	1.33	.25
Depressive, n/N (%)	80/94 (85)	37/41 (90)	0.28	.59
Delta t-score (baseline to last *full* assessment)				
Anxiety[c]			–0.35[d]	.73

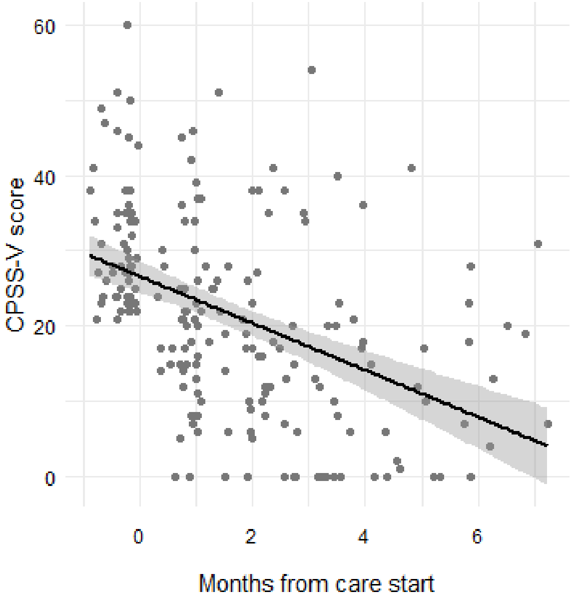
In the linear mixed effects model of anxiety symptom severity, the main effect of the group was not statistically significant ($F_{1,155}=2.52$; $P=.11$), indicating that the no trauma and elevated PTS symptoms groups did not differ in anxiety symptom severity. The interaction of the group with months (from care start) was significant ($F_{2,287}=26.11$; $P<.001$), such that children with no trauma had larger anxiety symptom reduction per month (mean –1.23, SD 0.19) than children with elevated PTS symptoms (mean –1.12, SD 0.31). For depressive symptom severity, the main effect of the group was not statistically significant ($F_{1,74}=2.39$; $P=.13$). The interaction of the group with months approached significance ($F_{2,112}=2.86$; $P=.06$), as children with elevated PTS symptoms had slightly larger depressive symptom reduction per month (mean –0.65, SD 0.44) than children with no trauma (mean –0.64, SD 0.34).

For those with elevated PTS symptoms, 96.3% (79/82) exhibited PTS symptom reduction from baseline to the last assessment, with the last assessment having a median of 2.33 (IQR 1.04-3.89) months after the start of care. For members who took the *full* CPSS-V after beginning care (n=65; median 2 months, IQR 1.03-3.50 after the start of care), CPSS-V scores decreased significantly from baseline (median change score –13 points, IQR –19 to –6; $z=–6.35$; $P<.001$). Results from the linear mixed effects model of PTS symptoms, which included a fixed effect of age (LRT: $\chi^2_1=3.97$; $P=.046$) and female sex (LRT: $\chi^2_1=4.92$, $P=.03$), showed that CPSS-V scores decreased significantly over months in care ($F_{1,140}=67.11$; $P<.001$) by an estimated mean of 3.37 (SD 0.41) points per month (Figure 2). The main effects of age ($F_{1,54}=2.07$; $P=.16$) and female sex ($F_{1,54}=1.42$; $P=.24$) were not statistically significant.

Figure 2. CPSS-V score over months in care for members with elevated PTS symptoms. CPSS: Child PTSD Symptom Scale; PTS: posttraumatic stress.



Discussion

Principal Findings

The purpose of this study was to use retrospective data from youths participating in a collaborative care DMHI to (1) characterize rates of trauma, PTS, and comorbid anxiety and depressive symptoms; (2) determine whether trauma exposure and elevated PTS symptoms impact the improvement of comorbid anxiety and depressive symptoms throughout participation in care; and (3) determine whether participation in collaborative care DMHI is linked to reductions in PTS symptoms. We found that trauma, PTS, and psychiatric comorbidity are common among youths participating in a DMHI, and comorbid PTS is associated with variations in rates of improvement for anxiety and depressive symptoms. Moreover, participation in a collaborative care DMHI is linked to improvements in PTS symptoms for most participants. These findings offer valuable preliminary insights into the clinical characteristics and sequelae among trauma-exposed youths participating in a DMHI.

Nearly 1 in 3 members participating in care for depressive, anxiety, or ADHD symptoms had experienced trauma. Many trauma-exposed youths reported symptoms of elevated PTS (n=119, 41%), and children with a traumatic event and elevated PTS had higher rates of elevated anxiety (n=87, 73%) and depressive symptoms (n=59, 50%) than children with no trauma. These observed rates of PTS, which are higher than previous estimates among trauma-exposed youths [13], paired with the high—albeit expected [31]—co-occurrence of anxiety and depression, highlight an acute need for DMHIs to provide both PTS screening and evidence-based treatment for youths with complex trauma-related symptomatology [32]. A slight majority (n=67, 56%) of those with elevated PTS were female, suggesting a limited role of sex in this sample's PTS symptoms. Recent estimates suggest that more than twice as many women develop PTSD in adulthood as men [33], a discrepancy that remains largely consistent when controlling for trauma type [34]. However, these sex-based differences in PTSD prevalence may not arise until adolescence, during which pubertal changes catalyze developments in fear-related neurocognitive processing [35]. Incidence of sexual violence in adolescence may also contribute to sex-based differences in PTS: the majority of youths who experience sexual violence are between 12 and 17 years, and 82% of all sexual assault and abuse victims younger than 18 years are female [36]. Given the relatively young age of our sample, it is understandable that we did not identify such stark sex-based differences in PTS severity. Nevertheless, DMHIs should take into account sex-based differences in trauma and PTS risk factors when providing pediatric mental health care.

PTS symptom severity significantly impacted treatment response for anxiety. Youths with elevated PTS symptoms showed smaller reductions in anxiety symptoms compared to those without PTS symptoms. This is understandable, given the particularly close symptom overlap and etiology of PTS and anxiety [37,38]. Anxiety symptoms may be particularly related to PTSD in the form of anxiety sensitivity or the fear of anxiety-related sensations [39], with previous research suggesting that anxiety sensitivity is both retrospectively and prospectively related to PTSD severity [40,41]. PTS symptoms can also interfere with mental health treatment by exacerbating anxiety and other mental health symptoms, increasing feelings of overall distress, and decreasing receptivity to treatment [42,43]. It should be noted that youths with elevated PTS symptoms showed *larger* reductions in depressive symptoms; however, this effect was small and was not statistically significant. Given the small effect size paired with the limited sample, this finding requires additional study and replication before we interpret it further. In sum, these results suggest that among youths receiving digital mental health care for anxiety and depressive symptoms, screening for and consideration of PTS symptoms are crucial, as PTS may impact the timing and magnitude of treatment response. These findings also emphasize the importance of measurement-based care models such as the CoCM, that is, early and regular screening for PTS symptoms, which is a central aspect of the CoCM, is crucial to proactive treatment and long-term symptom improvement among trauma-exposed youths [32].

Although the intervention did not directly target PTS symptoms, most participants showed significant decreases in PTS symptoms throughout care. This finding likely points to the shared treatment targets (eg, emotion regulation [44]) and evidence-based methods (eg, CBT [15]) across PTS, anxiety, and depressive symptoms. Several DMHIs exist for the treatment of pediatric PTSD [18,45]; however, a recent review found that most are of poor quality and lack evidence- and measurement-based practice in the formation and implementation of the intervention [45]. As the usage of DMHIs for child mental health continues to increase, this study indicates that collaborative care DMHIs, which include high-quality evidence- and measurement-based care, are linked to secondary improvements in PTS symptoms via behavioral health care for depression, anxiety, and other mental health concerns (eg, ADHD). Taken together, these preliminary findings suggest that collaborative DMHIs may confer improvements in symptoms that are related to but outside the scope of treatment targets. Importantly, further experimental research is necessary to compare these effects with active and nonactive controls.

Limitations and Future Directions

Although illuminating, these findings are limited by several notable factors. First, the retrospective nature of the study design limits us from drawing causal conclusions from our results. Further experimental research comparing the current DMHI with a randomized controlled group will offer more conclusive evidence for the effectiveness of the current intervention above and beyond another type of mental health treatment. Another consequence of the retrospective study design is that our results may be biased by participants self-selecting into care, given that nontreatment factors associated with mental health care use may also underlie symptom improvements (eg, family support, increased parental education, and perceived need [46]). Future studies should include a more rigorous study design with a randomized controlled group and data from long-term members.

This study did not address whether particular behavioral intervention methods—including coaching versus therapy and specific symptom target (eg, anxiety or depression)—may be more or less beneficial to mental health outcomes than other methods. Instead, we assessed outcomes associated with participation in the DMHI regardless of intervention methods. In future studies, identification of the behavioral interventions that are most beneficial to mental health outcomes in the context of DMHIs would greatly enhance the quality and efficacy of DMHIs in addressing PTS and comorbid anxiety and depression.

Given the relatively small sample size of children with trauma and elevated PTS symptoms, we were not able to gauge whether the nature of the participants' trauma exposure (eg, type and timing) may have predicted their outcomes. A large body of research suggests that the development of PTS and comorbid psychiatric symptoms following trauma exposure is heavily correlated with the nature of the trauma [11,47]; as such, our analyses are missing a potentially significant covariate. While we reported the timing of trauma for members with an event, we could not assess timing as a potential covariate in further analyses. Future research should continue to assess whether the nature of a child's exposure to a traumatic event may affect their outcomes and symptom trajectory within the context of a DMHI. Nonetheless, the high correlation between participants experiencing a traumatic event and exhibiting elevated PTS symptoms suggests that the trauma measure accurately reflected traumatic exposure.

Conclusions

This study provides preliminary evidence for the frequency of trauma exposure and comorbid psychiatric symptoms, as well as variations in treatment response between trauma-exposed and nontrauma-exposed youths, among participants in a pediatric collaborative care DMHI. Youths with traumatic experiences may show increased psychiatric comorbidities and slower treatment responses than their peers with no history of trauma. These findings deliver compelling evidence that collaborative care DMHIs may be well-suited to address mental health symptoms in children with a history of trauma while also highlighting the critical need to assess symptoms of PTS in children seeking treatment.

Authors' Contributions

LGH and DLS contributed to the conceptualization, methodology, formal analysis, writing the original draft, manuscript reviewing and editing, and visualization of this study. ABB contributed to the writing of the original draft and editing. MR edited the paper and acquired funds. AP and RG reviewed and edited the paper. JH contributed to the conceptualization, writing the original draft, manuscript reviewing and editing, and supervision of this study.

Conflicts of Interest

All authors are employed by Bend Health Inc, which delivered the treatment used in this retrospective study. However, authors' employment status and salary are not dependent upon the results of their research.

Abstract

Background: Pain assessment in the infant population is challenging owing to their inability to verbalize and hence self-report pain. Currently, there is a paucity of data on how parents identify and manage this pain at home using standardized pain assessment tools.

Objective: This study aimed to explore parents' assessment and intervention of pain in their infants at home following same-day surgery, using standardized pain assessment tools.

Methods: This prospective study initially recruited 109 infant boys undergoing circumcision (same-day surgery). To assess pain at home over 3 days after surgery, parents using iOS devices were assigned to use the PainChek Infant tool, which is a point-of-care artificial intelligence–enabled tool, while parents using Android devices were assigned to use the Observer-Administered Visual Analog Scale (ObsVAS) tool. Chi-square analysis compared the intervention undertaken and pain presence. Generalized estimating equations were used to evaluate outcomes related to construct validity and clinical utility. Receiver operating characteristic analysis assessed pain score cutoffs in relation to the intervention used.

Results: A total of 69 parents completed postsurgery pain assessments at home and returned their pain diaries. Of these 69 parents, 24 used ObsVAS and 45 used PainChek Infant. Feeding alone and feeding with medication were the most common pain interventions. Pain presence over time reduced. In the presence of pain, an intervention was likely to be administered (χ^2_2=21.4; P<.001), with a medicinal intervention being 12.6 (95% CI 4.3-37.0; P<.001) times more likely and a nonmedicinal intervention being 5.2 (95% CI 1.8-14.6; P=.002) times more likely than no intervention. In the presence of intervention, score cutoff values were ≥2 for PainChek Infant and ≥20 for ObsVAS. A significant effect between the use of the pain instrument (χ^2_1=7.2, P=.007) and intervention (χ^2_2=43.4, P<.001) was found, supporting the construct validity of both instruments. Standardized pain scores were the highest when a medicinal intervention was undertaken (estimated marginal mean [EMM]=34.2%), followed by a nonmedicinal intervention (EMM=23.5%) and no intervention (EMM=11.2%). Similar trends were seen for both pain instruments. Pain was reduced in 94.5% (224/237) of assessments where parents undertook an intervention. In 75.1% (178/237) of assessments indicative of pain, the score changed from pain to no pain, with PainChek Infant assessments more likely to report this change (odds ratio 4.1, 95% CI 1.4-12.3) compared with ObsVAS assessments.

Conclusions: The use of standardized pain assessment instruments by parents at home to assess pain in their infants can inform their decision-making regarding pain identification and management, including determining the effectiveness of the chosen intervention. In addition to the construct validity and clinical utility of PainChek Infant and ObsVAS in this setting, feeding alone and a combination of feeding with medication use were the key pain intervention strategies used by parents.

Introduction

Surgical procedures represent a well-established cause of pain in infants [1]. Good management of pain following various medical procedures, including same-day surgery, is important in infants, considering both short-term and long-term consequences that can arise as a result of a lack of neuronal pathway maturity [2-4]. Literature data suggest that early pain experiences cause activity-induced alterations in pain sensitivity, and these changes continue beyond infancy [3]. In this regard, it is worth noting that the long-lasting effects of suboptimal management of pain in children are more pronounced in comparison to the adult population [5]. Furthermore, in situations where children are exposed to repeated treatment and therefore repeated painful episodes, significant anxiety potentially leading to psychological and emotional consequences for the child and their carers can occur [6].

Despite compelling evidence suggesting the need to better recognize and manage pain in infants, pain in this population group still often remains underestimated and undertreated [4,7]. One of the key contributors to these issues is the fact that infants are unable to self-report pain due to their inability to verbally communicate, therefore making pain identification a major challenge in this population [4,8]. Eccleston et al [4] recently proposed 4 transformative aims with the view of improving pain management in children, one of which was that “pain should be made visible,” highlighting the need to adequately assess pain.

Circumcision is one of the most commonly performed same-day surgical procedures in the world [9,10]. It is estimated that the global prevalence of male circumcision is approximately 38%-39%, and depending on religious beliefs, these figures can reach over 95%, especially in countries with Muslim or Jewish majority [9]. Postoperative pain, such as that associated with circumcision surgery, is by definition acute pain, since it lasts for less than 3 months [4,11]. This pain involves nociceptive mechanisms, and its expected resolution usually occurs as a result of the healing process [4]. It has been suggested that following circumcision (same-day surgery), pain is persistent over a number of days after hospital discharge, which often makes treatment with analgesics necessary [12]. Other studies have also confirmed that children often experience moderate to severe levels of pain following same-day surgery [13-16]. Treatment of this pain generally takes place at home, considering that infants are usually discharged from the hospital on the same day the surgical procedure is performed and parents are then engaged in a number of demanding tasks, including pain assessment and treatment administration [14]. Various issues have been reported in relation to pain management by parents at home, and it has been suggested that the management of children’s postoperative pain at home, following hospital discharge, is generally poor [14,17]. The ability of parents to assess and identify pain and the need for assistance in this aspect have been reported as areas that need to be addressed [14,17,18].

When it comes to pain identification, there are a number of pain assessment scales that have been developed to assess pain in infants and young children, but there is no gold standard [19]. Most of these tools have limited evidence regarding their validity and clinical utility, and they are based on observer identification and evaluation of specific biomarkers indicative of pain [7,20,21]. None of the currently available pain assessment scales use automation to assess pain, and they are all limited by user subjectivity during pain assessment. Moreover, although these tools are used and validated in clinical practice settings, they are usually not used by parents at home. Additionally, there is limited literature reporting the pain assessment–related outcomes of tools specifically designed for use in the infant population (parents conduct pain assessments and use pain assessment tools at home).

This study aimed to explore parents’ assessments of their infants’ pain at home using standardized pain assessment instruments and investigate what pharmacological or nonpharmacological interventions they chose to manage pain following same-day surgery (ie, circumcision). The focus was on exploring the construct validity and clinical utility of 2 pain assessment scales, namely PainChek Infant and Observer-Administered Visual Analog Scale (ObsVAS). PainChek Infant has been designed specifically for use in the infant population and is an example of an automated digital pain assessment scale that uses artificial intelligence (AI) to identify facial indicators of pain [8,22]. ObsVAS is an instrument that has been commonly used to assess and quantify pain and distress [23]. In this regard, we aimed to explore the presence and improvement of pain following different interventions, evaluate how these pain assessment tools track pain levels, and assess their diagnostic accuracy across potential different cutoff points following the intervention and assessment of pain by parents at home.

Methods

Study Design

This prospective study collected data from the parents of infant boys up to 12 months of age undergoing circumcision at Kavaja Hospital in Prishtina in Kosovo from January to December 2023. Infants were excluded from the study if they had any psychiatric or developmental disorders or physical conditions that may interfere with the standard care program, or if their surgeon deemed they should not participate in the study. After undergoing same-day circumcision surgery and following hospital discharge, consenting parents were recruited to conduct pain assessments at home when pain was suspected and then at 30-minute and 60-minute intervals after intervention for a period of up to 3 days after surgery. Parents conducted pain assessments using 1 of the 2 validated pain assessment instruments provided: PainChek Infant or ObsVAS.

Postsurgery Pain Assessment

PainChek Infant

PainChek Infant is a class 1 medical device in the form of a mobile app, which has regulatory clearance for the assessment of procedural pain in Australia and Europe. Assessment takes only 3 seconds to complete [8,22]. PainChek Infant uses AI for the automated recognition and analysis of an infant's face, allowing the detection of 6 facial action units (AUs) indicative of the presence of pain: AU4 (brow lowering), AU9 (wrinkling of the nose), AU15 (lip corner depression), AU20 (horizontal mouth stretch), AU25 (parting lips), and AU43 (eye closure). These facial actions represent specific muscle movements (contractions or relaxations) as classified by the Baby Facial Action Coding System (BabyFACS) [24]. Each of the 6 AUs is scored using a binary scale (0=absent, 1=present), yielding a total potential score of 6 for comparative analysis with ObsVAS scores (standardized to a percentage). PainChek Infant's algorithm to detect the abovementioned AU codes using AI was created on trained images of infants undergoing immunization procedures and corresponding to the age group of infants recruited for this study [8]. Initially, independent coders trained in the facial action coding system analyzed labeled infant images in relation to the presence of AU codes of interest. These labeled images were then used in training the model that is integrated into the mobile app. Using separate independent training and validation datasets, 5-fold cross-validation was employed to create the AI model. The tool has been specifically designed to assess pain in infants (aged 1-12 months), taking into account the facial actions commonly associated with pain in this population. It should be emphasized that prior to assessing facial indicators of pain, the users of PainChek Infant are instructed to rule out other common causes of nonpain-related distress such as the child being hungry, thirsty, frightened, too hot, too cold, tired, or sleepy; requiring a nappy change; wanting comfort; or requiring burping (passing of wind). This functionality comes up as an alert before proceeding to facial assessment. Previous research has found good correlation of scores between these tools (r=0.88, 95% CI 0.85-0.90; P<.001) [8]. However, the focus of this study was on evaluating the use of these tools by parents at home. Furthermore, high accuracy of PainChek Infant, with areas under the curve of 0.964 (standard mode) and 0.966 (adaptive mode), was shown [22]. PainChek Infant was also previously shown to perform well across various feasibility components [22].

ObsVAS Tool

ObsVAS is a tool that is commonly used to measure and quantify pain and distress [8,23]. The scale consists of a 100-mm line. In this line, 0 mm represents no pain or distress and 100 mm represents the worst possible pain or distress. It has been reported that VAS has good to excellent intrarater reliability and strong criterion validity [23]. Additionally, like PainChek Infant, ObsVAS was also previously shown to have good responsiveness in relation to the change of pain scores following a painful procedure [8].

Parent Education and Pain Assessment Diary

All parents who were using an iOS mobile device were approached to use the PainChek Infant app and were also trained on its use before their child was discharged from the hospital. Other parents who did not use iOS devices were approached to use the ObsVAS instrument. All parents participating in this study and consenting to use one of the pain assessment tools at home to assess and monitor their child's pain were educated by their doctor on pain management and use of the pain assessment tool provided. As part of the training process, the correct use of both tools was demonstrated by a research assistant, who was a medical doctor by training and was specifically trained and competent in the use of both tools as well as the protocol of the study. When completing pain assessments at home, parents were also asked to record results in a diary. This was also covered in the training process. In relation to ObsVAS, parents were instructed to mark on the 100-mm line the score that corresponded to their perceived assessment of their child's pain. Considering that PainChek Infant is a digital assessment tool, its results were also recorded automatically and synchronized via a cloud transmission system. For both tools, parents were instructed to perform a pain assessment when they suspected their child was in pain. When conducting a pain assessment, parents were instructed to record the results following a pain assessment in the diary in the morning (between 8:00 AM and 12:00 PM), afternoon (between 12:01 PM and 6:00 PM), or evening (after 6:00 PM), or when required if the assessment was outside of those timeframes. If an intervention was administered (pharmacological or nonpharmacological), parents were asked to record the intervention and then also perform further assessments 30 minutes and 60 minutes after the intervention. Parents were educated by the surgeons on pain intervention and management and were instructed to follow their doctors' recommendations. Additionally, parents were informed that the results from the pain assessment instrument should not be used solely to decide whether to use analgesic therapy or to determine the required analgesic dosing and that this should be based on their doctors' instructions. Moreover, they were told to consult with the doctor if they were not sure. Decisions undertaken by parents to manage postsurgical pain included medication administration (paracetamol or ibuprofen), feeding (breastfeeding, formula, or food), consoling (nursing or toys), and no action. These broad actions were also reclassified as no intervention, medicinal intervention, or nonmedicinal intervention.

Data Analysis

Analysis was conducted using IBM SPSS (version 29) unless otherwise stated. Parents' education levels were described using frequency (n) and percentage (%). Infant age was recorded as the age at admission for the circumcision procedure and was recorded as weeks or months. For 10 infants, the age recorded in weeks was converted to months by multiplying weeks by 0.23. Infant age was described using mean, SD, median, and 25th to 75th IQR. Normality was assessed using the Shapiro-Wilk test with age found not to be normally distributed, and appropriate nonparametric tests were applied. The Mann-Whitney *U* test examined age between pain assessment tool groups (ObsVAS versus PainChek Infant), with the standardized test statistic reported.

The chi-square analysis (or Fisher-Freeman-Halton exact chi-square test where cell counts <5 with exact 2-sided *P* values are reported) was undertaken to compare differences between the intervention used (none, medicinal, or nonmedicinal) and pain presence (absent or present). The test was conducted for the full sample and separately for PainChek Infant and ObsVAS. Binary logistic generalized estimating equations (GEEs) were used to examine if pain was present and assess the likelihood of an intervention occurring (Wald χ^2 and *P* value reported), with parameter-estimated odds ratios (ORs; Exp(β)), 95% Wald CIs for Exp(β), and *P* values reported for medicinal or nonmedicinal intervention compared to no intervention. The model accounted for individuals with repeated measurements and the within-subject variable of time. The confounding effects for age, instrument, and parent education were each examined separately in the basic model, with Quasi-likelihood under the Independence Model Criterion (QIC) goodness of fit indices used to compare models, and a lower number was associated with a better model fit [25]. The GEE method enables regression estimates when analyzing repeated measures with no assumption of the distribution of the response outcome [26,27].

Construct validity was assessed in several ways. First, GEE with standardized pain score as the outcome was evaluated with instrument, intervention, and age as fixed effects, accounting for individuals with repeated measurements and the within-subject variable of time. Model residuals (Q-Q plots) were visually assessed and assumptions were met. Estimated marginal means (EMMs) with 95% CIs were calculated, with Wald χ^2 and *P*-value model effects reported and Bonferroni-corrected pairwise comparisons for instrument and intervention undertaken. Separate models were also analyzed for each instrument on their original measurement scale. Second, we evaluated if pain scores improved after intervention (medicinal, nonmedicinal, or no intervention), with improvement categorized in 2 ways for analysis: pain relief and general pain reduction. For pain relief, a binary (Y/N) response to "did the pain score reduce to no pain" (PainChek Infant <2, ObsVAS=0) was used. For pain reduction, three groups were calculated: (1) no change or worse standardized pain score; (2) small standardized pain score improvement (≤33%); and (3) clinically important pain score improvement (>33%), standardized pain score returned to no pain (PainChek Infant ≤33%, ObsVAS=0%), or pain resolved (no further assessment undertaken at the final recorded timepoint, either 30 or 60 minutes). Receiver operating characteristic (ROC) analysis with sensitivity (true positive rate) and 100-specificity (false positive rate) was conducted using NCSS software (v21.0.14 2021) to assess whether there was a specific pain score where an intervention (generally) or medical intervention (specifically) was undertaken. Youden Index was used to determine the diagnostic accuracy across potential cutoff points (sensitivity + specificity – 1). The summary of area under the curve (AUC) scores overall and for each instrument has been reported. Each time period was a separate data entry for individuals.

Sensitivity analysis was conducted on baseline characteristics (age and education level) between parents who collected pain data versus those who did not. A Kruskal-Wallis test examined between-group differences for age (test statistic reported), while a Pearson chi-square (χ^2) (Fisher-Freeman-Halton exact [cell counts <5]) test examined differences for education level. Two-sided *P* values have been reported throughout.

Ethical Considerations

This study was approved by the research ethics committee of the Faculty of Medicine, University of Prishtina (approval number: 4860/22).

Results

Participant Characteristics

Parents of 109 infant boys undergoing circumcision were recruited in the study before the circumcision procedure and completed baseline measures (infant age and parent education). After surgery, 40 (36.7%) participants did not take any further part in the study (5 assigned to the ObsVAS group and 35 assigned to the PainChek Infant group). Sensitivity analysis did not detect any differences in age across participants who participated in postsurgery activities versus those who did not. A significant difference was detected in parent education, with those who did not return pain diaries coming from among university-educated parents (χ^2_3=12.0; *P*=.005). Of the remaining, 69 participants completed postsurgery pain assessments and returned their pain diaries. Of these, 24 (35%) were allocated to the ObsVAS group and 45 (65%) were allocated to the PainChek Infant group. Infants had a mean age of 5.1 months (SD 3.2 months; median 5.0 months, IQR 2.5-7.0 months). No significant difference in age was detected between the ObsVAS (mean 5.0, SD 3.6 months; median 4.0, IQR 2.0-7.5 months) and PainChek Infant (mean 5.1, SD 3.1 months; median 5.0, IQR 3.0-7.0 months) groups (*U*=–0.4; *P*=.68). Parents were predominantly university educated (50/69, 73%), with the remaining being high school educated or lower (19/69, 28%). There was no significant difference between the ObsVAS (high school: 7/24, 29%; university: 17/24, 71%) and PainChek Infant (high school: 12/45, 27%; university: 33/45, 73%) groups (χ^2_1=0.05; *P*>.99).

Postsurgery Pain Presence and Pain Intervention Results

A summary of pain interventions administered after surgery over 3 days is provided in Table 1, with feeding alone and feeding with medication being the most common interventions reported by parents, followed by the use of medication alone. Parents also chose not to intervene. Among the medications administered, paracetamol was the most commonly reported, with ibuprofen used only in 3 instances.

Pain interventions were further described as no intervention, medicinal intervention, or nonmedicinal intervention (Tables 2-4). At baseline for each timepoint, a comparison was performed between pain present and absent and the pain intervention undertaken. Significant differences were only detected for day 2 afternoon and evening, and day 3 evening. For each, the absence of pain had a higher percentage of no intervention compared to the presence of pain, which had the lowest percentage of no intervention. Similar trends were seen when PainChek Infant and ObsVAS were examined separately. Further details are provided in Tables 2-4.

Pain presence and absence for the total sample and for the PainChek Infant and ObsVAS subsamples are reported in Table 5. From baseline assessments to 30-minute assessments and then 60-minute repeat assessments, there was a general reduction in the proportion of pain assessments, indicating the presence of pain, and there was a concomitant increase in those indicating no pain. A similar trend of decreasing pain presence versus pain absence was seen in assessments performed from day 1 to day 3. Some differences between PainChek Infant and ObsVAS were found across the time points, with PainChek Infant typically reporting a higher percentage of no pain and ObsVAS tending to report a higher percentage of pain present.

[a] PainChek Infant: ≤1=no pain, >1=pain; ObsVAS: 0=no pain, >0=pain.

[b] Morning: 8:00 AM to 12:00 AM.

[c] Afternoon: 12:01 PM to 6:00 PM.

[d] Evening: after 6:00 PM.

[e] PRN: required basis outside of those timeframes.

[f] Statistically significant difference between PainChek Infant and ObsVAS for the absence and presence of pain at baseline (chi-square Fisher exact test 2-sided *P* value).

[g] Statistically significant difference between PainChek Infant and ObsVAS for the absence and presence of pain at 30 minutes (chi-square Fisher exact test 2-sided *P* value).

[h] Statistically significant difference between PainChek Infant and ObsVAS for the absence and presence of pain at 60 minutes (chi-square Fisher exact test 2-sided *P* value).

[i] ObsVAS: Observer-Administered Visual Analog Scale.

Regarding the association between pain and intervention, the basic GEE model found that when pain was present, an intervention was likely (χ^2_2=21.4; *P*<.001; QIC=550.5). Specifically, medicinal intervention had the highest odds (OR) of 12.6 (95% CI 4.3-37.0; *P*<.001), followed by nonmedicinal intervention with an OR of 5.2 (95% CI 1.8-14.6; *P*=.002) compared to no intervention when pain was present. The inclusion of a pain instrument in the basic model improved model fit (QIC=513.5), with both intervention (χ^2_2=27.5; *P*<.001) and instrument (χ^2_1=13.10; *P*<.001) being significantly associated with a pain outcome. Higher odds were reported for medicinal intervention (OR 17.5, 95% CI 5.9-51.8; *P*<.001) and nonmedicinal intervention (OR 7.3, 95% CI 2.4-22.1; *P*<.001) compared to no intervention when pain was present. ObsVAS had a higher odds of pain present (OR 4.4, 95% CI 2.0-9.9) compared to PainChek Infant. A model with an interaction term between intervention and instrument did not improve model fit (QIC=517.3), and the interaction term was not statistically significant (χ^2_2=2.1; *P*=.36).

The addition of age to the model improved model fit (QIC=510.9); however, age was not a significant effect (χ^2_1=2.7; *P*=.10), with both intervention (χ^2_2=30.3; *P*<.001) and instrument (χ^2_1=12.1; *P*<.001) being significantly associated with a pain outcome. Slightly higher odds were reported for medicinal intervention (OR 19.2, 95% CI 6.6-56.1; *P*<.001), and nonmedicinal intervention was more likely to occur (OR 6.9, 95% CI 2.3-20.6; *P*<.001) than no intervention. ObsVAS had higher odds of pain present (OR 4.3, 95% CI 1.9-9.9) compared to PainChek Infant. The addition of parent education to the model did not improve model fit (QIC=517.5), with it not having a significant effect (χ^2_1=0.1 *P*=.75).

ROC analysis results are summarized in Table 6, and ROC curves are depicted in Figure 1. Youden Index determined cutoff values for the PainChek Infant and ObsVAS instruments and reported respective cutoff points for intervening values of ≥2 and ≥20 for intervention (medicinal and nonmedicinal) versus no intervention and similarly for medicinal intervention versus no intervention or nonmedicinal intervention. The combination of pain instruments using the standardized pain score Youden Index determined cutoff values of ≥10 for intervention (medicinal and nonmedicinal) versus no intervention; however, it reported values of ≥20 for medicinal intervention versus no intervention or other intervention, indicating a higher pain threshold for medicinal intervention to occur.

Evidence for construct validity assessed via GEE for standardized pain score reported a significant effect for instrument (χ^2_1=7.2; *P*=.007) and intervention (χ^2_2=43.4; *P*<.001) but not age (χ^2_1=1.9; *P*=.17). Pain scores were higher for PainChek Infant (EMM 27.5, 95% CI 22.6-32.3) compared to ObsVAS (EMM 18.5, 95% CI 14.2-22.9). Pain scores were the highest when a medicinal intervention was undertaken (EMM 34.2), followed by a nonmedicinal intervention (EMM 23.5), and were the lowest for no intervention (EMM 11.25). All Bonferroni-corrected intervention pairwise comparisons were significant (Table 7). Similar trends were seen for individual instrument models of PainChek Infant and ObsVAS, with EMM summarized by intervention presented in Table 7. It was noted that Bonferroni-corrected comparisons did not reach significance between medicinal and nonmedicinal interventions (*P*=.20) for the PainChek Infant instrument, and between no intervention and nonmedicinal intervention (*P*=.17) for the ObsVAS instrument.

For a subset of assessments indicative of pain (n=237), we assessed if the pain was relieved (ie, scores reduced to “no pain” levels). Of these, 178 (75.1%) infants recorded a change from pain to no pain. In this group recording an improvement to no pain, 37.6% (n=67) received medicinal intervention, 50.6% (n=90) received nonmedicinal intervention, and 8.9% (n=21) received no intervention. The instruments were also considered separately. For PainChek Infant (subset n=114) regarding improvement to no pain, 42.4% (n=42) received a medicinal intervention, 48.5% (n=48) received a nonmedicinal intervention, and 9.1% (n=9) received no intervention. For ObsVAS (subset n=123) regarding improvement to no pain, 31.6% (n=25) received a medicinal intervention, 53.2% (n=42) received a nonmedicinal intervention, and 15.2% (n=12) received no intervention. GEE reported a significant effect for instrument (χ^2_1=6.32; *P*=.01) and intervention (χ^2_2=7.3; *P*=.03). The PainChek Infant instrument was more likely to report a change from pain to no pain (OR 4.1, 95% CI 1.4-12.3) compared to the ObsVAS instrument.

Further descriptive analysis was used for this subset of assessments where pain was detected (n=237) to assess general pain reduction. Of these initial assessments of pain, 224 (94.5%) were followed by a reduction in pain at 30 minutes or 60 minutes after intervention, with 13 (5.5%) resulting in no change or worse pain. These were observed equally between medicinal intervention (n=100, 44.7%) and nonmedicinal intervention (n=102, 45.5%), with 9.8% (n=22) improving with no intervention. Observationally, similar trends were seen for PainChek Infant and ObsVAS. For PainChek Infant (n=114), when an intervention was undertaken, 110 (96.5%) assessments reported improvement in pain, with 4 (3.5%) reporting no change or worse pain. These were observed equally between medicinal intervention (n=49, 44.5%) and nonmedicinal intervention (n=51, 46.4%), with 9.1% (n=10) indicating improvement with no intervention. For ObsVAS (n=123), when an intervention was undertaken, 114 (92.7%) assessments reported improvement in pain, with 9 (7.3%) reporting no change or worse pain. These were observed equally between medicinal intervention (n=51, 44.7%) and nonmedicinal intervention (n=51, 44.7%), with 10.5% (n=12) indicating improvement with no intervention.

Discussion

Principal Findings

In this study, we reported parental assessment and management of pain at home following same-day circumcision surgery after hospital discharge for up to 3 days. Our findings showed that parents usually decided to undertake an intervention when their child was in pain. In this regard, they most commonly opted to choose either feeding alone or using medication together with feeding. Paracetamol was mostly used by parents (as opposed to only 3 cases of ibuprofen use). These results are in line with what was recommended and prescribed by the operating surgeons and what is consistent with recommendations from drug monographs of these medications [28,29]. It was interesting to note that in a number of cases, parents chose not to intervene even when pain was identified. There may be a number of reasons for this, but it is worth noting that fear of using analgesics as well as misconceptions regarding analgesic use by parents have been previously reported in the literature [14,17,18,30]. Nonetheless, our findings confirm that there was a relationship between the presence and absence of pain when an intervention was undertaken by parents (ie, pain assessments with pain as a result, for both PainChek Infant and ObsVAS, had the lowest proportion of no intervention). While similar trends were observed in this regard for both tools throughout various pain assessment timeframes, some differences were identified for day 2 afternoon and evening.

Our findings suggest that both tools were able to demonstrate the effectiveness of the intervention used by parents considering that the number of assessments indicating no pain generally increased over time following the intervention (both the 30- and 60-minute time points) and throughout days 1 to 3. While, as expected, pain presence reduced over this timeframe, our findings are consistent with the results by Freeman et al [12], which suggested that pain is persistent for a few days following circumcision. In cases where there were significant differences between tools, our findings indicated that ObsVAS was associated with reporting a higher proportion of the presence of pain in comparison with PainChek Infant. When it comes to these instrument-specific differences, it should be noted that assessments with different instruments were not conducted on the same subjects. Additionally, PainChek Infant has a clear cutoff (≥2 out of 6) for pain as opposed to ObsVAS, which considers any score above 0 to indicate pain, and a low score in ObsVAS is not necessarily a clinically important score indicative of pain. While it was noted that the aggregated proportion of ObsVAS assessments indicative of pain was higher compared to PainChek Infant, it is important to note that when exploring threshold pain scores in relation to intervention, these were similar (ie, ≥20 out of 100 [20%] for ObsVAS and ≥2 out of 6 [33%] for PainChek Infant). Nonetheless, the determination of the cutoff score for PainChek Infant confirms previous results reported by Hughes et al [22], providing additional evidence on its pain score threshold and clinical utility. Previous validation of the tool was conducted using prerecorded videos of children undergoing immunization, and assessments were undertaken by trained assessors on those video recordings, as opposed to parents conducting assessments in a "real-life" environment at home [8,22]. Another key point of the difference between the instruments used is that PainChek Infant is AI-enabled and fully automated, while ObsVAS relies on the ability of parents to observe and then rate their child's pain. In this regard, variability in parents' judgment related to pain assessment and subjectivity when using observational scales have been reported previously [19,31,32]. Therefore, this should be taken into consideration when interpreting the results obtained when parents use ObsVAS.

Our findings, based on the GEE model, confirm the likelihood of parents undertaking an intervention when pain is identified with either PainChek Infant or ObsVAS. A medicinal intervention, which included pharmacological treatment (mainly paracetamol), was more likely during pain presence as opposed to a nonmedicinal intervention such as breastfeeding or comforting. Additionally, when pain was present, parents were more likely to select a nonmedicinal intervention as opposed to no intervention at all. Furthermore, for both instruments used, there was a clear relationship between higher pain scores and the choice of intervention, with the highest pain scores being more closely associated with medicinal intervention, followed by nonmedicinal intervention. No intervention category was associated with the lowest pain scores. These findings confirm the ability of parents to respond to the presence of pain in their child and to choose a treatment option to manage the pain. This was observed independent of parents' education levels. Our findings confirm the effectiveness of the interventions undertaken by parents considering that the presence of pain, which was indicated by most assessments, improved to no pain. While this trend was observed for both instruments, the use of the PainChek Infant instrument was associated with a higher likelihood of change from pain to no pain compared to ObsVAS. Nonetheless, our results suggest that both instruments assisted parents in identifying pain and making decisions on pain management and helped in rechecking that the pain experienced by their child had diminished.

One of the key strengths of this study is that it provides insights into parents' use of standardized pain assessment tools to identify and make decisions on the management of their child's pain at home. There is scarce literature in this area. However, there are a number of limitations that should be considered overall and that should be taken into account when interpreting our findings. First, the study was conducted with a small number of parents at 1 hospital center only. The issues of small sample size and single-center design limit the generalizability of our findings to a broader audience of parents, and this should be considered when interpreting our findings. Furthermore, other hospitals may have different protocols for managing infant pain following minor surgical procedures, which may affect how parents behave during pain management at home. Second, while ObsVAS was only offered to parents who were using an Android device, it is difficult to judge how this group of parents would have behaved if they were iOS users. Previous studies have already reported on behavioral differences between Android and iOS users [33,34]. At the time when the study was conducted, PainChek Infant was only available on iOS. Moreover, it remains unclear why a higher proportion of those parents using an iPhone device (approached to use PainChek Infant) failed to complete the study despite follow-up attempts. Additionally, it should be noted that the majority of parents who participated in this study were female. The differences may have been driven by greater recruitment of parents using iOS devices, and female individuals have been reported to be more inclined to use iOS devices as opposed to Android devices [34]. Considering this, the recruitment of Android users may have resulted in a higher percentage of male participants conducting pain assessments, which may have impacted the study findings regarding intervention choices. This limitation suggests that there is a need for more research comparing differences between iOS and Android users, especially in the area of postsurgical infant care and specifically pain management. This was not a focus of our study. Another consideration regarding the interpretation of our study findings is parents' education levels, with the majority of parents administering PainChek Infant and ObsVAS having completed tertiary-level education. Nonetheless, our results appear to not have been affected by this particular factor considering that our findings suggest that the ability of parents to respond to the presence of pain in their child was independent of their education. The potential overlap of pain- and nonpain-related distress among parents during the assessment of pain should also be considered. This is a potential limitation that has been acknowledged by a number of other studies reporting on the use of other pain assessment tools [8,35,36]. However, given that in both groups of parents (ie, PainChek Infant and ObsVAS users) the source of pain was known (ie, circumcision procedure), the possibility for this overlap was reduced. To further mitigate this issue, parents using PainChek Infant had the ability to rule out other common causes of nonpain-related distress, such as the child being hungry or tired, as this functionality is built into the PainChek Infant app itself. This could also explain some differences identified between the 2 instruments and may have affected parents' decisions regarding the choice of intervention after ruling out nonpain-related distress. Further studies are needed to explore this issue. The study could have also benefited from the exploration of other available pain assessment tools used in infants, such as the Neonatal Facial Coding System. However, this decision was balanced against potential implications related to recruitment and the need for further training of parents. Further research in this area is recommended.

Although this study had the abovementioned limitations, it provided valuable insights into parents' use of standardized pain assessment tools at home, the selection of interventions when pain is detected in their infants, and the effectiveness of these interventions. Additionally, the study provided further evidence regarding the construct validity and clinical utility of both PainChek Infant and ObsVAS, which were used by parents to assess pain at home for over 3 days after surgery. Both tools were able to inform clinical decision-making and were instrumental in determining the effectiveness of interventions chosen by parents.

Conclusions

Our findings provide insights into parental assessment and management of pain in their infants at home following hospital discharge from same-day surgery (ie, circumcision). Feeding alone and a combination of feeding with medication use were the key pain intervention strategies used by parents after identifying pain using standardized pain assessment tools. We further demonstrated the construct validity and showed that PainChek Infant and ObsVAS have similar clinical utility in assisting parents regarding the selection of pain interventions and the determination of their effectiveness, thus supporting their clinical decision-making.

Acknowledgments

We thank all parents who participated in the study and all administrative and technical staff at the hospital who assisted with the recruitment and study procedures. This study was supported by PainChek Ltd.

Authors' Contributions

KH, FS, and JH conceived the idea and designed the study. PC conducted the statistical analyses, and PC, KH, FS, and JH reviewed the outputs. KH drafted the initial manuscript, which was reviewed by all authors. SC engaged in participant follow-up. FS, SS, KU, and SC provided clinical oversight of the study. All authors critically reviewed the manuscript and approved its final version.

Conflicts of Interest

KH and JH are shareholders in PainChek Ltd (formerly known as EPAT Technologies Ltd), which is commercializing PainChek Infant. They are also named as coinventors with Mustafa Atee on the patent entitled “A pain assessment method and system,” which has been granted in the United States, China, Europe, and Japan. KH is employed as a consultant by PainChek Ltd and also serves as a Professor at the University of Prishtina. JH is employed as the Chief Scientific Officer of PainChek Ltd and holds an Emeritus Professor appointment at the Curtin Medical School, Curtin University. PC was engaged through DATaR Consulting and was paid as an independent private consultant to undertake the biostatistical analysis for the project by PainChek Ltd. PC also serves as Manager Research Support and Development, Child and Adolescent Health Service and holds an adjunct appointment at the School of Medical and Health Sciences, Edith Cowan University. FS serves as a Professor at the University of Prishtina and is employed at Kavaja Hospital. SC, SS, and KU are also employed by Kavaja Hospital.

Abstract

Background: COVID-19 mitigation measures enhanced increases in children’s weight and BMI due to decreased physical activity and increased energy intake. Overweight and obesity were major worldwide problems before the pandemic, and COVID-19 increased their severity even more. High BMI directly correlates with health disadvantages including cardiovascular diseases, musculoskeletal disorders, and mental health diseases. Therefore, it is vitally important to develop counteracting interventions to maintain children’s health during exceptional situations like pandemics. However, worldwide data from such interventions are limited, and to our knowledge, no suitable study has been carried out during the pandemic in Austria.

Objective: This study was conducted to examine a 15-week web-based intervention with email support, the EDDY (Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children’s Lifestyle) program and the effect of nutritional education and physical activity on children’s BMI z-score during the COVID-19 pandemic in Vienna, Austria.

Methods: The intervention consisted of 3 weekly videos—2 physical activity and 1 nutritional education video, respectively—and a biweekly email newsletter for the parents. This study was conducted in a Viennese primary school from February to June 2021 by a team of physicians, nutritionists, and sports scientists, including both professionals and students. The study population included an intervention group (who received web-based nutritional and physical activity training) and a control group (who received no intervention), comprising in total 125 children aged 8 to 11 years. Due to COVID-19 mitigation measures, the control group was a comparative group observed during the prior school year (2019-2020). Anthropometric measurements were obtained before and after the intervention in both groups.

Results: Due to a high dropout rate (n=57, 45.6%) because of the mitigation measures, there were 41 children in the intervention group and 27 in the control group. At baseline, the BMI z-score was 1.0 (SD 1.1) in the intervention group and 0.6 (SD 1.2) in the control group (P=.17). After the study period, the BMI z-score decreased by 0.06 (SD 0.21) in the intervention group, whereas it increased by 0.17 (SD 0.34) in the control group (P<.001). Comparing the change in BMI z-scores within BMI categories in the intervention group and control group revealed a statistically significant difference in the normal-weight children (P=.006). Further results showed that the decrease in BMI z-score was significant in the intervention group among both boys (P=.004) and girls (P=.01).

Conclusions: A web-based intervention with combined nutritional education and physical activity training might be an adequate tool to lessen the enhanced increase in body weight during a pandemic. Therefore, additional studies with greater sample sizes and different locations are needed. As the implementation of such intervention programs is essential, further studies need to be established rapidly.

Introduction

Since the implementation of COVID-19 restriction measures to reduce the transmission of the disease, the daily routines of adults and children have changed dramatically. As a consequence, an increase in energy intake and a decrease in physical activity (PA) has been reported in schoolchildren [1-3], affecting their BMI and increasing the severity of overweight and obesity [1,2]. In Austria, studies have also reported an increase in body weight and BMI during lockdowns [4-6], affecting boys especially. The restriction of daily activities, the stay-at-home orders, and the closure of playgrounds and sports facilities led to decreased levels of PA in children. Moreover, school PA education classes were interrupted, which may have influenced the observed decrease in cardiorespiratory fitness measurements reported previously [4]. A decline in PA was also described worldwide [3,7], being greater among boys and those who lived in apartments or houses with limited space. Being physically active has proven beneficial in improving physical fitness, BMI [8], and markers of cardiovascular health, as well as bone and mental health [9].

In contrast, obesity is known to have many health disadvantages. There is a direct correlation between elevated BMI and elevated risk for cardiovascular diseases, diabetes, musculoskeletal disorders, cancer, and mental disorders [10,11]. Therefore, implementing programs to prevent and tackle childhood obesity is one of the main research aims of the World Health Organization [12] to maintain children's health.

Further studies suggest that school-based interventions play an essential role in the prevention of childhood obesity [13-16]. The combination of PA and nutritional education is most effective [17]. Additionally, parental involvement in nutrition and PA [3] interventions is crucial to promote healthier lifestyle behavior. Since parenting practices and parent-child interactions are formative in children's health-related behaviors, studies suggest that interventions with parental involvement are more effective [18]. Moreover, parents and children ask for realistic approaches, such as ideas for active games and activities or healthful meals and snacks that families can enjoy [19].

Furthermore, study authors have recommend the opportunity to use web-based interventions to promote healthy behaviors [14]. Online training programs have been suggested to support healthy eating and active movement [5,20-22]. A parent-focused online intervention in Australia led to improvement in dietary-related practices and self-efficacy [23]. Also, evidence indicates that implementing web-based programs at schools could be beneficial, as a high number of people can be reached and they are easy to conduct [24]. Results from web-based studies with other outcome variables, such as alcohol drinking prevention, tobacco knowledge, and eating disorder prevention in children and adolescents, also indicate the usefulness of web-based interventions in children and adolescents [24-26]. Communication tools provide useful means to develop digital health content that can be accessed easily through social media platforms such as YouTube. However, to be effective, this content should be age tailored, involve limited equipment [20], and be able to motivate children [27]. Compared to face-to-face programs, online intervention programs offer advantages such as convenience and self-engagement with PA. On the other hand, family income could be a limitation regarding internet access, mobile device availability, proper space [28], or adequate equipment [29] to perform PA.

Recent studies have called for further investigations focusing on a combination of settings [15,17] and on parents' involvement [30]. As the COVID-19 pandemic and its effects on children increased the severity of childhood overweight and obesity [1,2], it is of major importance to find a way to execute a web-based preventative intervention in this specific setting in order to gather more knowledge, as there is expected to be an increased risk of other infectious disease outbreaks with climate change [31].

Therefore, we aimed to examine the effects of a 15-week web-based nutritional and PA intervention with email support and parental involvement on BMI z-score among children aged 8 to 11 years during a school year that took place in the context of the COVID-19 pandemic in Vienna.

Methods

Study Design

This intervention study was designed to involve children and parents as part of the EDDY (Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children's Lifestyle) program. The EDDY program focuses on nutrition and PA training to prevent childhood obesity and takes place in primary schools in Vienna, Austria. It was founded by the Austrian Academic Institute for Nutrition in Vienna in cooperation with the Institute for Sport Science of the University of Vienna by a professional team consisting of physicians, nutritionists, and sports scientists, as well as students studying for these professions. The EDDY program was implemented in 2012 in the primary school VS (Volksschule; German for "primary school") Haebergasse 1120, Vienna, and is part of the school's fourth-grade curriculum [32]. Thus, all fourth-grade students are candidates to participate in the study with previous consent from their parents or legal guardians. The planned intervention and all anthropometric measurements were performed in the school setting.

In the 2019-2020 school year, a 6-month school-based nutritional and PA intervention was planned. Due to the outbreak of the COVID-19 pandemic, the school-based intervention had to be stopped after 3 weeks in March 2020, but baseline and end measurements could still be obtained. During the 2020-2021 school year, an on-site intervention was difficult to schedule due to the sustained restriction measures. Therefore, a 15-week web-based nutritional and PA intervention program was developed covering areas of knowledge and practices related to healthy meals, snacks, and drinks, as well as PA. Moreover, parents received an informative email newsletter.

Due to the COVID-19 pandemic, the web-based intervention could only be carried out at one school due to mitigation restrictions and the Austrian government being stringent with school studies during that time. To simplify the intervention's feasibility, the intervention sample comprised all 3 of the school's fourth-grade classes.

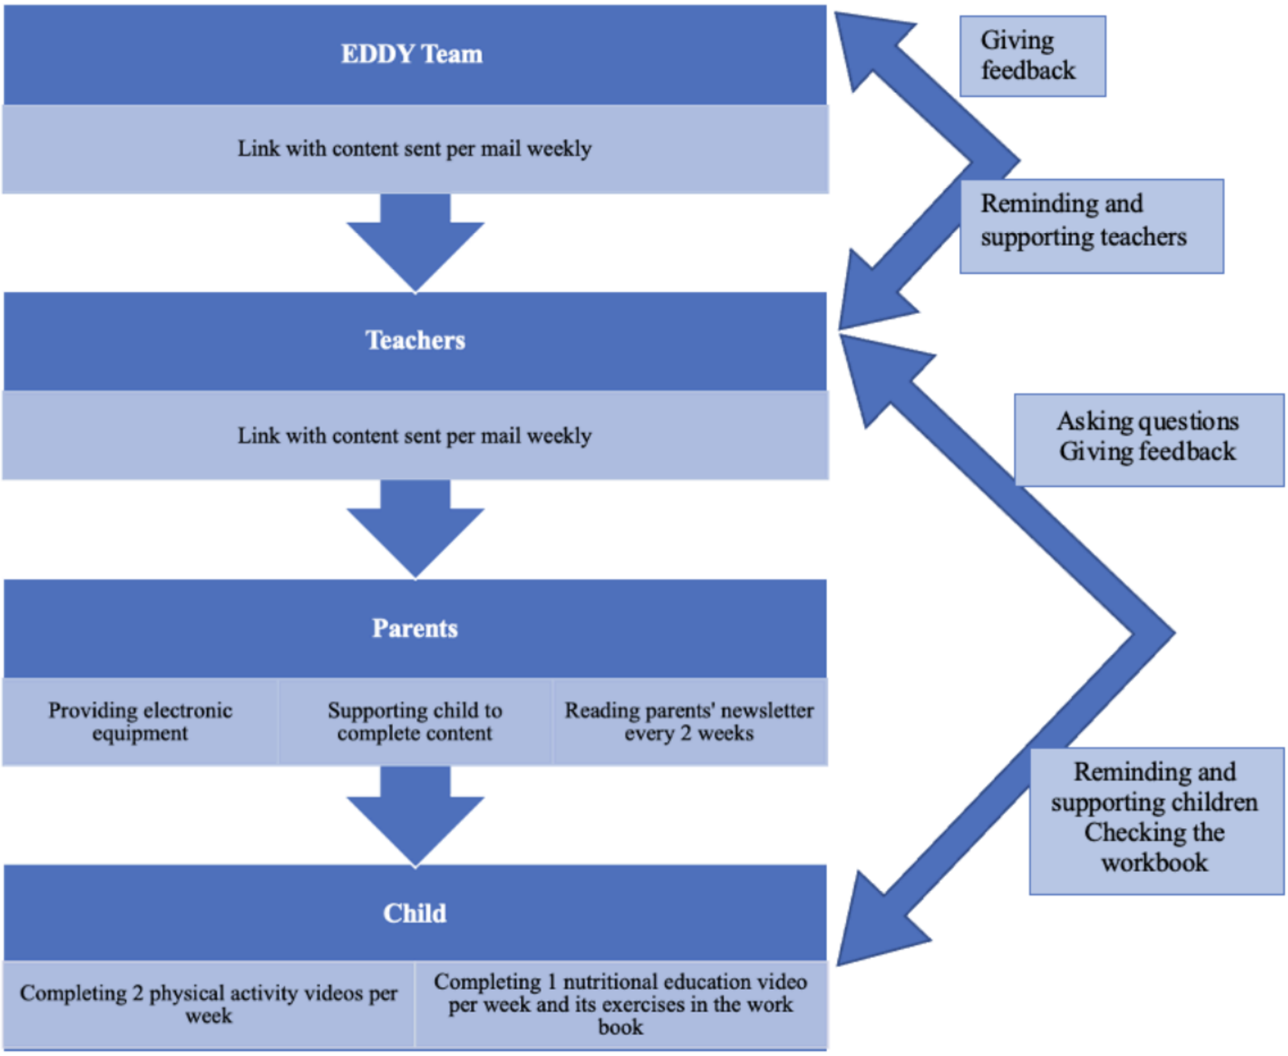
Ethical Considerations

The study was approved by the research ethics committee at Sigmund Freud University in Vienna, Austria (PAFGRW9O@EFQV885378). Legal guardians of all children enrolled in the study provided written informed consent for participating in the study after receiving an informative letter about the procedure of the intervention. The children themselves gave their own consent. The ability to opt out was provided at any point. All gathered data in this study were anonymized. As the EDDY program is part of the school curriculum, compensation was not provided to study participants.

Description of the Intervention

The web-based intervention implemented in this study consisted of 2 main components: (1) nutritional education and (2) stimulating a PA routine during a 15-week period from February to June 2021 with 3 videos per week. Educational and movement content was provided as videos via YouTube. As the videos were not publicly available, the parents received a weekly email with a link to access the content. Therefore, parents needed to instruct their children to watch the videos and support them with electronic equipment. Figure 1 shows a description of the intervention and each participant's role.

Figure 1. Description of the intervention and each participant's role. EDDY: Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children's Lifestyle.



Nutrition

Previous nutritional lessons from the EDDY program have been adapted for web-based training [32]. The educational content was recorded by nutritional scientists and medical school students. It includes both theoretical and practical age-targeted content focusing on food with high nutrient content (vegetables, fruits, and legumes), relevance of timing in eating, and skills to prepare and select healthier food choices, such as recipes for easy, healthy snacks and identification of suitable portion sizes. The content is based on food groups and the healthy plate [33]. Videos were delivered once a week with a duration ranging from 10 to 20 minutes.

Additionally, a workbook with worksheets was provided, including questions about the content of the videos, quizzes, and practical tasks. Progress was monitored for feedback and positive reinforcement.

PA Training

The PA training was designed and conducted by a team of sports scientists, physicians, and students. Since we provided web-based videos and did not have face-to-face contact with the children, the workouts were designed to not require any equipment and use only the participants' own body weight.

Each week, the children received two 25-minute videos via YouTube; one focused on strength training and the other on endurance training. The strength training started with a warm-up phase (coordination exercises and warm-up games) that focused on the correct execution of the subsequent strength exercises. The intensity of the exercises was slow to moderate. The warm-up phase was followed by 10 to 15 minutes of strength training that incorporated 4 to 6 exercises (eg, squats, stretch jumps, push-ups or plank exercises, spider walking, duck walking, sit-ups, and wall sitting) for the entire body. Two series with a repetition count of 15 to 20 repetitions were targeted per exercise. The strength training was taught in a playful way that included the use of children's stories.

The endurance training was structured as follows: The primary focus was to keep children moving continuously over a 25-minute period. The intervention included standing endurance runs, knee runs, heel runs, jumping jacks, frog jumps, boxing exercises, and gymnastic exercises with moderate to high intensity. In addition, dances were choreographed to child-friendly pop music to increase the entertainment factor. All videos ended with a short relaxation and cool-down session. Here, yoga and stretching movements were incorporated and relaxation stories involving fantasy journeys were told in order to achieve better body awareness and to recover from the PA.

The videos were repeated 2 times during the 15-week intervention period to create confidence and enthusiasm for improving physical fitness through the repetition effect.

Intervention for Parents

A major part of the intervention was the inclusion of parents or legal guardians. During the intervention period, the parents received an email newsletter every 2 weeks with healthy lifestyle recommendations, nutrition facts, recipes, and tips on how to increase the amount of time spent physically active. Information on how to increase PA during the period of social distancing and restriction measures (eg, self-use of outdoor gyms and playgrounds and indoor family workouts) was a particular focus. Also, parents received all the intervention videos for the children from their teachers (in the teachers' experience, parents are always more conscientious when being texted by school staff). Therefore, they were in charge of providing electronic equipment and supporting their child in completing the weekly videos.

Involvement of Teachers

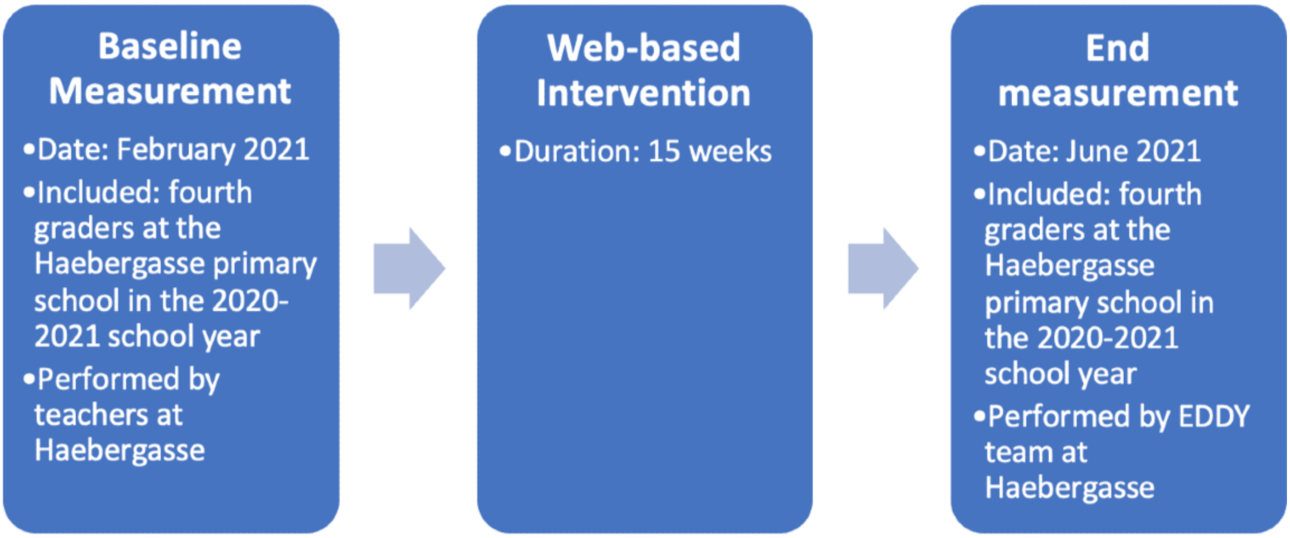
The teachers acted as a link between the children and their legal guardians. At baseline, they received workbooks and distributed them to the children. All videos, newsletters, and information during the 15 weeks of the intervention were sent to the teachers and forwarded to the study participants via email. Teachers interacted closely with the study team, reminded the children to complete the videos, and checked on their workbooks approximately every 2 weeks. Every few weeks, the teachers gave feedback on how the children responded to the content of the intervention.

Participants

Intervention Group

Primary school children from the fourth grade at VS Haebergasse 1120 in the 2020-2021 school year were included and received 15 weeks of web-based nutritional and PA intervention. Anthropometric measurements were performed in February 2021 (before the intervention) and June 2021 (after the intervention) at the school facility. The children were not randomly allocated to the intervention group; instead, all fourth graders in the 2020-2021 school year were eligible for the study to make it more feasible for teachers to organize. As the EDDY program is part of the school's fourth grade curriculum, only children opting out did not receive the weekly videos (Figure 2).

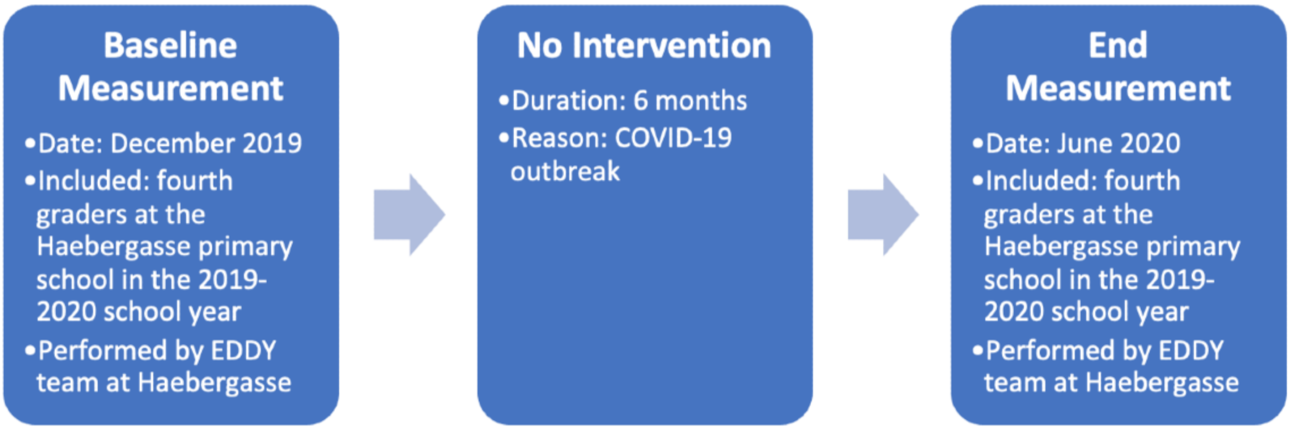
Figure 2. Description of the intervention group's timeline. EDDY: Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children's Lifestyle.



Control Group

For this analysis, primary school children from the fourth grade at VS Haebergasse 1120 in the 2019-2020 school year comprised the control group. During this study year, no repetitions were recorded. Therefore, no children were part of both the control and intervention groups. Anthropometric measurements were performed in December 2019 (before the planned intervention) and June 2020 (after the planned intervention) at the school facility. The planned 6-month intervention could not be carried out due to the outbreak of COVID-19 and state-imposed school closures. The children were not randomly allocated to the control group; instead, all fourth graders in the 2019-2020 school year were eligible for the study to make it more feasible for teachers to organize. Therefore, only children opting out were not included in the measurements (Figure 3).

Figure 3. Description of the control group timeline. EDDY: Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children's Lifestyle.



Inclusion Criteria

To be eligible for this analysis, the participants needed to fulfill the following eligibility criteria: be aged 8 to 11 years, be a student in the fourth grade at the specific primary school where the intervention took place, complete all measurements, and provide written informed consent (both legal guardians and children).

Exclusion Criteria

The exclusion criteria were as follows: be aged <8 or >11 years, not be a student in the fourth grade at the specific primary school where the intervention took place, miss at least one measurement, change class or school during the intervention, and not provide written informed consent (both legal guardians and children).

Outcome Measures

Body weight was measured to the nearest 0.1 kg with a bioelectrical impedance analysis scale (Tanita MC-780MA) without shoes or excessive clothing. Body height was evaluated to the nearest 0.1 cm with a portable stadiometer (Seca) with the participant standing and maintaining their head in the Frankfort horizontal plane position without shoes.

BMI was calculated as weight (kg) divided by square of height (m^2) and classified according to age and sex. BMI z-scores were used for further analysis [34]. SDs for the BMI z-scores were calculated and BMI categories were classified in reference to Kromeyer-Hauschild et al [35]. The obesity category was considered as the sum of obesity and extreme obesity.

Measurements were performed at 2 time points for both groups at the primary school. Due to COVID-19–related school closures in December 2020 and January 2021, baseline measurements of the intervention group were postponed to February 2021. Due to ongoing COVID-19 restrictions and social limitations, the EDDY team could not perform baseline measurements of the intervention group themselves; therefore, they were performed by the teachers at school with the school doctor's equipment. To obtain accurate measures, the EDDY team standardized the measurement procedures among the teachers by giving instructions via video. End measurements of the intervention group were performed by the EDDY team. The control group was measured by the EDDY team at both measurement time points.

Statistical Analysis

For statistical analysis, all data were analyzed with SPSS (version 27; IBM Corp). Continuous variables were expressed as means (range) and categorial variables were expressed as absolute numbers or proportions. Age and sex differences between excluded and included students were determined with the χ^2 test and Mann-Whitney *U* test. Age differences between the study groups were determined using the Mann-Whitney *U* test. Shapiro-Wilk tests were performed to determine standard distribution for BMI, age, weight, height, and BMI z-score at baseline and for BMI z-score differences over the study period. BMI z-score differences in groups and between sex over the study period were assessed using Mann-Whitney *U* tests. For all the above tests, statistical significance was considered as $P<.05$. BMI z-score differences between study groups within the BMI categories were tested with the Mann-Whitney *U* test. Therefore, the Bonferroni test was used as a post hoc analysis, for which statistical significance was considered as $P<.017$.

Results

Study Population at Baseline

At baseline, 125 children (age range 9.25 to 11.75 years) were eligible to participate in the study (n=68 boys and n=57 girls);

there were 56 children in the intervention group and 69 students in the control group. Eventually, 57 children (45.6%) could not be included due to quarantines or absence from school and missing measurements; 15 children in the intervention group and 42 in the control group. The total number of excluded students included 22 girls and 35 boys. The mean age in the dropout group was 10.34 (SD 0.57; range 9.25 ‐ 11.75) years. The excluded and included students did not differ by sex (*P*=.15) but did differ by age (*P*=.02).

Finally, there were 41 children in the intervention group and 27 in the control group. Anthropometric data for the study participants are shown in Table 1.

The mean age in the intervention group was 10.2 (SD 0.5; range 9.41 ‐ 11.17) years and 10.0 (SD 0.5; range 9.33 ‐ 11.08) years in the control group. There was no significant difference in age between the intervention and control groups (*P*=.09).

At baseline, n=8 (20%) children in the intervention group and n=4 (15%) children in the control group were classified as obese, with excessive BMI (≥90th percentile) for their age and sex. In the intervention group, 2 (1 female, 1 male) of 8 children with obesity were classified as extremely obese (≥99.5th percentile). Additionally, in the control group, 1 (female) of 16 children with normal weight was classified as low weight but was represented as normal weight in the figures and tables due to the small number. BMI classification at baseline testing and end testing in each study group is shown in Table 2.

Table . Age and anthropometric data of study participants at baseline.

	Intervention group, mean (SD)			Control group, mean (SD)			*P* value
	Total (n=41)	Female (n=23)	Male (n=18)	Total (n=27)	Female (n=12)	Male (n=15)	
Age (years)	10.2 (0.5)	10.0 (0.4)	10.4 (0.6)	10.0 (0.5)	9.9 (0.4)	10.1 (0.6)	.09[a]
Weight (kg)	43.0 (10.8)	40.4 (8.6)	46.3 (12.6)	39.5 (9.6)	39.3 (11.1)	39.7 (8.6)	.24[a]
Height (m)	142.8 (6.4)	142.3 (6.4)	143.5 (6.5)	142.1 (7.3)	142.0 (7.9)	142.2 (7.1)	.69[b]
BMI (kg/m^2)	21.0 (4.5)	19.8 (3.6)	22.4 (5.2)	19.4 (3.8)	19.3 (4.4)	19.5 (3.4)	.16[a]
BMI z-score	1.0 (1.1)	0.8 (0.9)	1.2 (1.3)	0.6 (1.2)	0.5 (1.4)	0.7 (1.1)	.17[b]

[a] Mann-Whitney *U* test.

[b] Student *t* test.

Table . BMI classification in the study group at baseline testing and end testing.

		Control group participants (n=27), n (%)	Intervention group participants (n=41), n (%)
Baseline testing			
	Normal weight	16 (59)	24 (59)
	Overweight	7 (26)	9 (22)
	Obese	4 (15)	8 (20)
End testing			
	Normal weight	17 (63)	25 (61)
	Overweight	4 (15)	7 (17)
	Obese	6 (22)	9 (22)

Change in BMI z-Score After Intervention

After the implementation of the web-based study, the average BMI z-score decreased by −0.06 (SD 0.21) in the intervention group and increased by +0.17 (SD 0.34) in the control group; this was statistically significant (*P*<.001) (Figure 4).

Within the normal-weight BMI category at baseline, there was a statistically significant difference (*P*=.006) between the control group and intervention group for change in BMI z-score. Within the overweight (*P*=.039) and obese (*P*=.062) BMI categories at baseline, there was no statistically significant difference between the control group and intervention group for change in BMI z-score. In the intervention group, the percentage of participants in the overweight BMI category decreased from 22% (n=9) to 17.1% (n=7), representing a change of −4.95%, and the percentage in the obese BMI category increased from 19.5% (n=8) to 22%(n=9; +2.5%). In the control group, the percentage in the overweight BMI category decreased from 25.9%(n=7) to 14.8% (n=4; −11.8%), and the percentage in the obese BMI category increased from 14.8% (n=4) to 22.2% (n=6; +7.4%).

Figure 5 shows the exact change for BMI z-score within the BMI classification at baseline.

Figure 4. Change in BMI z-score during study period. *Mann–Whitney *U* test: *P*<.001.

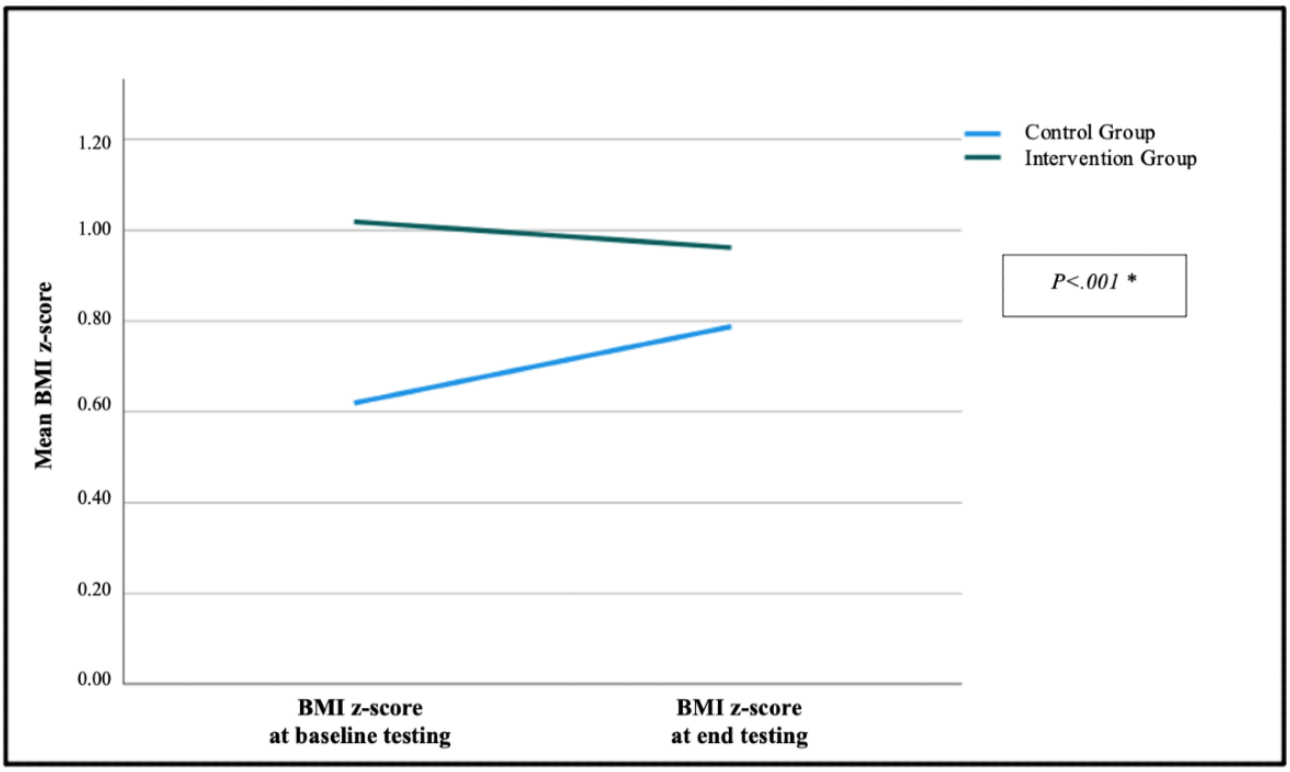


Figure 5. Change in BMI z-score after 15 weeks within the BMI classifications. *Mann–Whitney *U* test for each category: normal weight: *P*=.006; overweight: *P*=.039; obese: *P*=.062. Statistical significance was set after Bonferroni correction at *P*=.017.

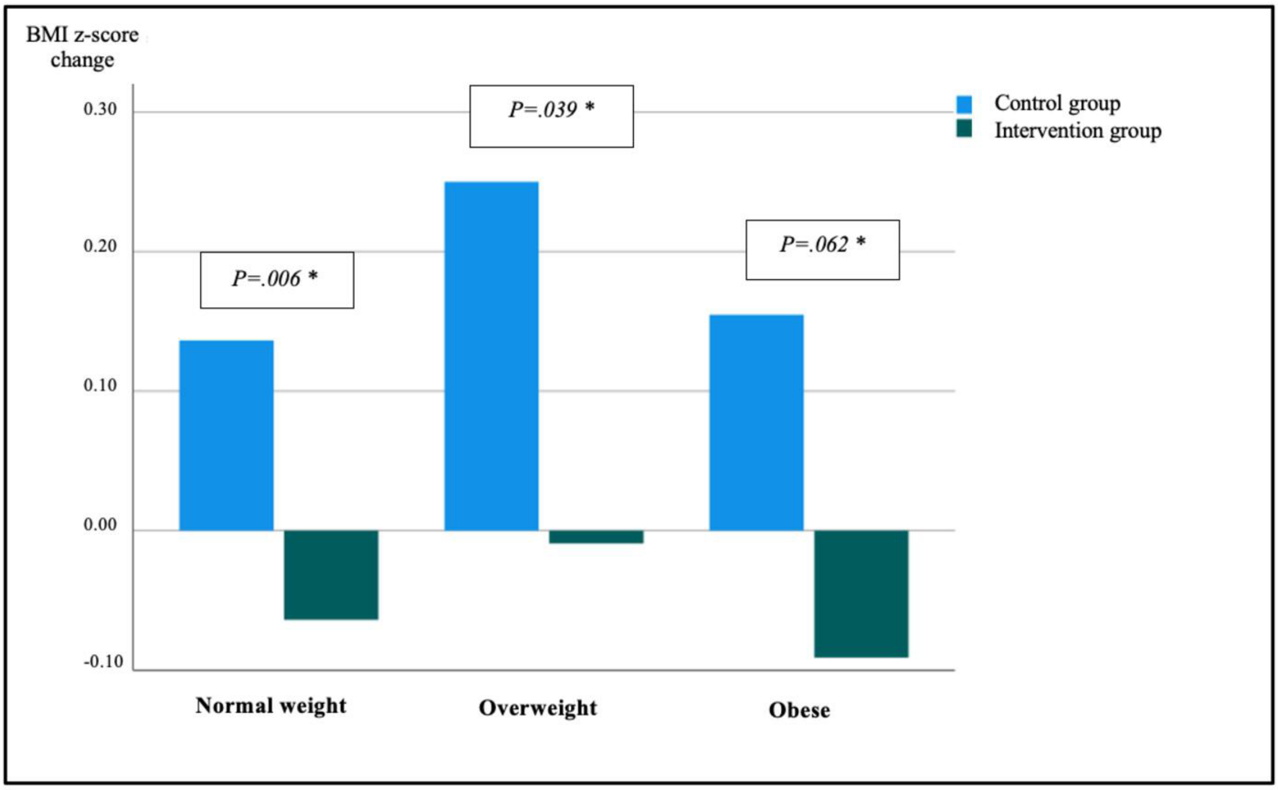

Change in BMI z-Score After Intervention According to Sex

Over the study period, the average BMI z-score for girls in the intervention group decreased by −0.04 (SD 0.23) and increased by +0.14 (SD 0.43) in the control group (*P*=.01). Among the boys, BMI z-score decreased by −0.08 (SD 0.19) in the intervention group and increased by +0.19 (SD 0.27) in the control group (*P*=.004). Figures 6 and 7 show the change for BMI z-score over the study period by sex and study group at baseline.

Figure 6. Changes in BMI z-score after 15 weeks in boys according to study group. *Mann–Whitney *U* test: *P*=.004.

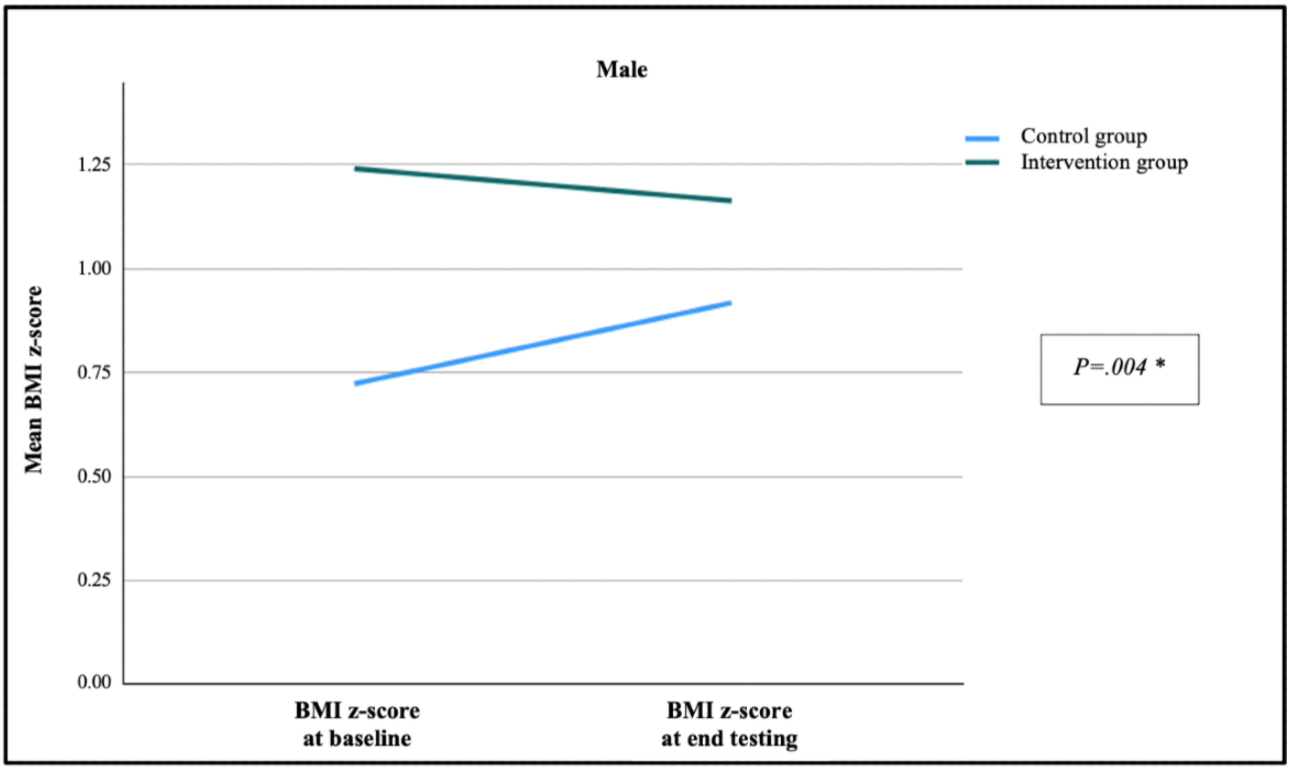

Figure 7. Changes in BMI z-score after 15 weeks in girls according to study group. *Mann–Whitney *U* test: *P*=.01.

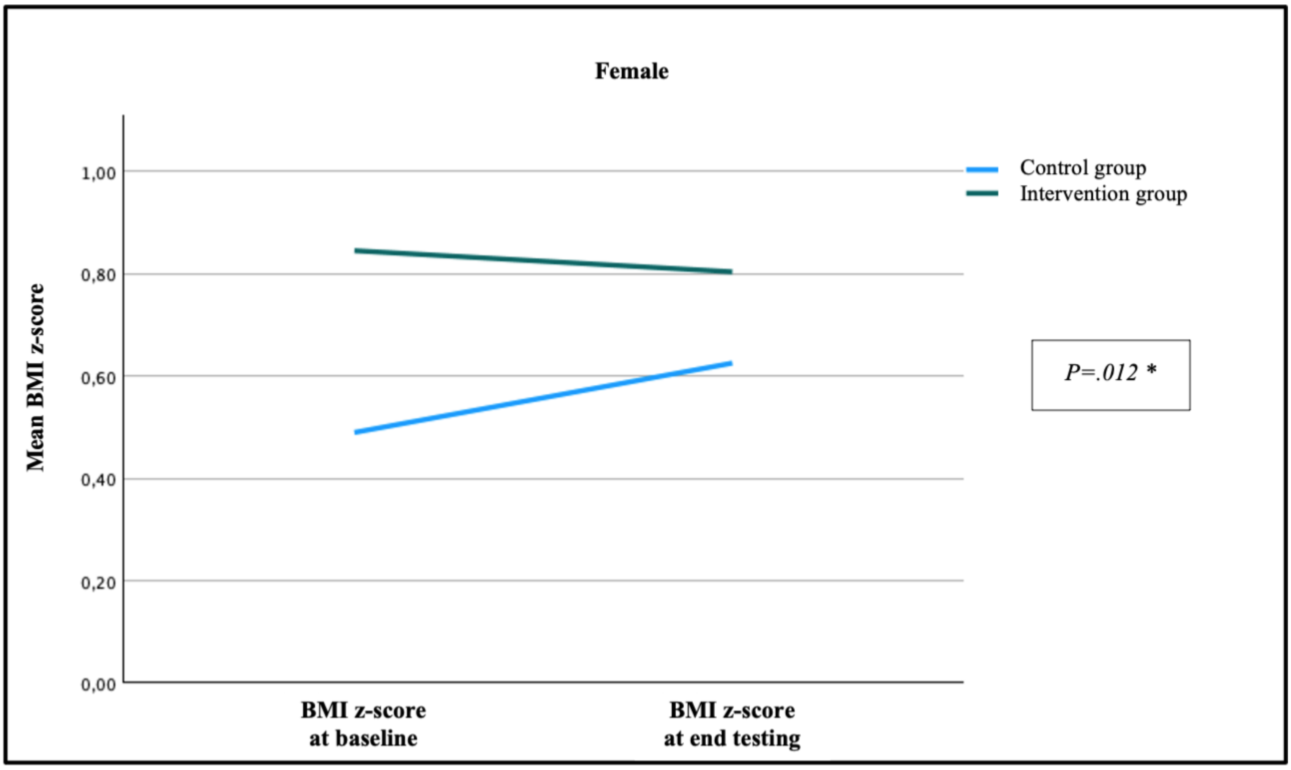

Discussion

In Austria, EDDY is one of the few science-based projects for the prevention of childhood overweight and obesity and its secondary causes. When creating the EDDY online program, we aimed to demonstrate the effect of a web-based nutritional education and PA training course with email support on BMI z-score in primary school children during the COVID-19 pandemic. A 15-week nutritional education and PA intervention was performed, and a control group of the same age and at the school, but from the prior school year, was used for analysis. The mean BMI z-score in the intervention group decreased significantly, by 0.06, over the study period. Here, it should be noted that the control group was measured during the first period of the pandemic, which might have affected the results due to different life circumstances. Recent studies from Austria show that the first period of the pandemic had the biggest impact on children's BMI [6,36]. However, Brown et al [37] recently also showed a mean decrease of 0.05 in the BMI z-scores of children aged 6 to 12 years in a systematic review of 20 RCTs, which supports the results of this analysis. However, all studies included took place outside of the context of a pandemic. To our knowledge, there is no other comparable online nutritional and PA program that was carried out during the COVID-19 pandemic. Even outside the pandemic context, online interventions as a method of overweight and obesity prevention have not been widely used. Data from international web-based studies are limited. A positive effect on the eating habits of children and adolescents is often reported [38]. The implementation of an online intervention study, such as the EDDY online program, has numerous advantages. A web-based model, which was used for this intervention, can be used with minimal staffing costs [39]. The COVID-19 pandemic led to difficulties in performing ordinary on-site intervention studies, but led to new ways of teaching, such as distance learning. Thus, the study participants in the EDDY online program were able to take part in the intervention despite school closures and social distancing, which could be beneficial in other exceptional situations, like other pandemics. Moreover, by delivering the intervention content through videos, children with language difficulties had the opportunity to repeat the videos as many times as required and choose their own pace. These could be advantages of an online setting, but further studies are required. As reported by the headmaster, the percentage of children in this primary school with a migratory background and a non-German first language was very high. Studies from Austria indicate that children with non-German first languages have a higher prevalence of obesity [40]. This could be supported by the higher mean BMI (intervention group: 21.0 kg/m^2; control group: 19.4 kg/m^2) in this study group. The latest Childhood Obesity Surveillance Initiative data indicate a mean BMI of 17.2 kg/m^2 in urban children aged 7 to 11 years [41]. This could have led to selection bias; therefore, studies need to be carried out at different schools in different regions with a higher number of study participants.

Moreover, using BMI alone to assess children's body fat has several limitations [42,43]. BMI cannot determine body fat, which is essential to assess cardiovascular and metabolic risk [44]. Adding waist circumference would be a valid way to assess visceral fat [43]. However, recent studies have shown that assessing body composition is the most precise way to determine children's body fat [42,45] and therefore their obesity-related health level. Due to the COVID-19 pandemic and its mitigation measures in Austria, the determination of body composition was not possible in this study, but further studies should use body composition to evaluate childhood interventions.

Furthermore, studies show that the BMI of children has a high correlation with the BMI of their mothers and fathers [46]. Therefore, the inclusion of parents is essential [47,48]. During the EDDY online program, parents were included in 2 main ways: indirectly, by having the chance to join their children's intervention (eg, engaging in PA training together), and directly, by receiving newsletters (eg, healthy meal ideas and outdoor PA ideas). Studies show that parents are interested in online interventions, especially if they have high flexibility [49] and if they use a realistic approach [19]. This study provided flexibility for parents and children, as there was no time limit on accessing the newsletters and children could make their own time schedule within a school week. Some studies have also assessed improved effects when children and parents receive separate interventions [50]. Hence, developing a more enhanced and more extensive intervention (eg, with informative videos and online workshops) solely for parents could have potential.

Additionally, web-based studies make it difficult to analyze participation rates and the duration of attendance [21,51]. As the EDDY team used YouTube as a sharing platform due to easy accessibility [21], it was possible to track the views on videos. As it was also possible to watch videos more than once, to engage with the video together with classmates, or to watch the video but not engage in PA, it was not possible to analyze the exact participation rate or duration of attendance. Also, assessing if and how long parents read the newsletters was not possible. Nonetheless, the teachers reported a high participation rate in the beginning, which slightly decreased over the 15-week intervention. Further studies need to develop tools for children and parents to better analyze the duration of attendance and participation rate per study participant. Furthermore, the content delivered in this web-based intervention for children needs to be evaluated through further studies. Borra et al [19] showed that children request "cool" music. Hence, the EDDY team used popular music (eg, Disney music) for PA content. Children also liked the idea of a website solely for them with chatrooms to communicate with other participants or counsellors [19]. In Austria, schools often use online platforms to communicate with children and parents, check attendance rates, and upload school documents. Using a preexisting school platform and creating an exclusive section for children where intervention content can be delivered could, therefore, have potential. This could lead to easier access and handling. Delivering content via online games could also be beneficial [19,52]. Mack et al [53] concluded that video games as an additional tool could help increase the compliance of study participants. Protecting children is very important for parents [19]; data security needs to be considered carefully when using other technologies.

This study has some limitations that need to be addressed and could have influenced the results. First, the number of participating children was small; therefore, our findings may not generalize to Austria's child population. Our analyses of sex and BMI category should be interpreted with caution due to the even smaller sample sizes. Second, participating children were from a single school that was already familiar with the EDDY program, which could have led to higher feasibility and a better response from the participants and teachers. Third, the number of participants in the intervention and control groups differed, which may have led to limited comparability. Due to the pandemic, many children were missing one measurement point in the control group because of quarantine, sickness, or deregistration from school. Consequently, the results need to be interpreted carefully because of possible selection bias, though the age difference between the 2 study groups was tested statistically prior to the intervention. Fourth, due to mitigation restrictions, the baseline measurements of the intervention group could not be obtained by the EDDY team and were instead obtained by the teachers under close guidance using the school doctor's equipment, which may have led to minor differences in measuring. Fifth, the observation period differed by 10 weeks between the control and intervention groups, and measurements in the control and intervention groups were also obtained in 2 different years. This might also have impacted the results due to possible differences in lifestyle, environment, or mitigation measures. However, a different approach was not feasible in this study.

Due to the COVID-19 pandemic and restricted physical presence at school, health-prevention interventions were not realizable on site, but technology-based interventions could be used to promote age-appropriate health education. The EDDY online nutritional and PA intervention study with email support aligns with the goal of using a multicomponent approach to tackling childhood obesity and preventing excessive weight gain during periods of social distancing. The study demonstrated a significant decrease in the BMI z-scores of a sample of Viennese primary school children, both in the group overall and when they were divided by sex, after an intervention duration of 15 weeks. Furthermore, the study showed a statistically significant change in the children with normal weight at baseline in the intervention group. However, as this study has several limitations, the results need to be interpreted cautiously. Further studies with fewer limitations are needed to determine whether the results generalize to the entire child population.

This study indicates that this could be a new method to improve children's health during a pandemic. In the future, assessing body composition, enhancing interventions for parents, evaluating the intervention content, and, in particular, creating methods for the analysis of participation rate and duration of attendance are highly recommended.

Acknowledgments

We thank all EDDY (Effect of Sports and Diet Trainings to Prevent Obesity and Secondary Diseases and to Influence Young Children's Lifestyle) members that helped create and perform in the video content and who provided technical support for the web-based intervention. We also thank the headmaster and teachers of the primary school Volkschule Haebergasse 1a, 1120, Vienna, for their collaboration and great interest in the prevention of obesity and its secondary diseases.

Data Availability

The data sets generated during and/or analyzed during this study are not publicly available due to no proper open database having been developed in Austria, but they are available from the corresponding author on reasonable request.

Abstract

Background: Entertainment media content is often mentioned as one of the roots of children’s unhealthy food consumption. This might be due to the high quantity of unhealthy foods presented in children’s media environments. However, less is known about the role of the centrality of food placement, that is, whether foods are interacted with, consumed, verbally mentioned, or appear unobtrusively. We also lack longitudinal research measuring both children’s unhealthy and healthy food consumption behaviors as outcomes.

Objective: The aim is to connect content analytical data based on children’s actual media diet with panel data in order to explain children’s food preferences. Moreover, this study not only focuses on the amount of healthy and unhealthy foods children are exposed to, but also on how these foods are presented (ie, centrally or not). Furthermore, we looked at the question of how parental coviewing can diminish (or enhance) the effects of unhealthy (or healthy) food depictions, and we measured healthy and unhealthy consumption as dependent variables.

Methods: We conducted a 2-wave panel study with children and one of their parents (of 2250 parents contacted, 829 responded, for a response rate of 36.84%; 648 valid cases, ie, parent-child pairs, were used for analysis), with 6 months between the 2 panel waves. We linked the 2-wave panel data for the children and their parents to content analytical data for movies (n=113) and TV series (n=134; 3 randomly chosen episodes per TV series were used) that children were exposed to over the course of 6 months.

Results: There was no significant relationship between exposure to unhealthy food presentation and unhealthy (b=0.008; *P*=.07) or healthy (b=−0.003; *P*=.57) food consumption over time. Also, healthy food presentation was unrelated to unhealthy (b=0.009; *P*=.18) or healthy (b=0.000; *P*=.99) food consumption over time. However, there was a significant, positive interaction between unhealthy food presentation and presentation centrality on unhealthy food consumption (b=0.000; *P*=.03), suggesting that the effects of unhealthy food presentation rise with increasing levels of centrality. There was no interaction between unhealthy food presentation and presentation centrality on the consumption of healthy foods (b=0.000; *P*=.10). Also, exposure to healthy food presentation interacted with centrality (b=−0.001; *P*=.003). That is, when a healthy product was presented at maximum centrality, it led to less unhealthy food consumption in children. Coviewing did not interact with exposure to unhealthy foods when explaining unhealthy (b=0.003; *P*=.08) or healthy (b=−0.001; *P*=.70) food consumption.

Conclusions: We conclude that simply presenting more healthy foods is not sufficient to combat children’s unhealthy food preferences. Further regulations may be necessary with respect to representations of unhealthy foods in children’s media.

Introduction

Background

There is a great debate among parents, teachers, politicians, and marketers as to how the media contributes to the development of childhood obesity [1]. Recently, meta-analytic data [2-4] and literature reviews [1,5] summarizing a large corpus of empirical studies have suggested that children's confrontation with media content, particularly persuasive content—such as traditional TV commercials [6,7], product placements in movies [8], brand presentations in YouTube videos [9], or online advertisements [10,11]—impacts their food preferences and eating behaviors, particularly regarding the consumption of foods high in fat, salt, or sugar.

Media content creates a very narrow food environment for children. Most of the content children are exposed to presents foods high in fat, salt, or sugar [12-17]. This kind of content is not only shown most often, the characters in children's movies also consume these items most frequently and evaluate them predominantly very positively [15]. The consumption of highly processed products that are high in fat, salt, or sugar but low in nutritional value (ie, minerals or vitamins) is contributing to the development of overweight and obesity and therefore can be categorized as unhealthy. The overrepresentation of these foods in audiovisual media content is indeed worrying [18].

Drawing on the notion of cue reactivity, this paper describes a nonexperimental study linking content analytical data with panel survey data on the food preferences of children. We first review the literature on media effects on children's food preferences and then explain the goals, methods, and findings of the study.

Prior Work

Regarding children's media environment, it has been argued that products integrated within editorial content, interrupting the content, can be more influential on product choices than classical advertisements [19]. This is especially true for children because they are still developing their cognitive abilities and might therefore not be aware of attempts to persuade them that are integrated with the entertainment content [20]. A study on the Reactivity of Embedded Food Cues in Advertising Model (REFCAM) [21] found that when such presentations were integrated within the editorial content, it first led to a kind of cue reactivity. This cue reactivity revealed itself with an increased heart rate [22] or a higher likelihood of thinking about the presented product [23]. In the next step, this cue reactivity influenced children's eating habits [21]. The authors described this pathway as being influenced by individual susceptibility factors, such as children's BMI or age, and also by "the level of integration" of a product [21]. Thus, how a product is presented might influence children's reactions.

Although scholars have theorized that the "food-related media diet" is also represented in children's actual diet, this assumption has never been formally tested to date. The available evidence comes from experimental and survey research focusing on unhealthy [24-28] and healthy foods [28-30]. Whether healthy food presentations have the power to influence healthy food choices is not entirely clear from current empirical evidence [19,31].

It might not be sufficient to only consider what food is presented in media content targeted at children; it will also be necessary to consider how the presented food is shown [32]. Since drawing attention to the food is crucial for arousing appetite, reinforcing appreciation for that food and thus triggering eating behaviors [21,33] is more likely when the depicted food plays a central role in the media content. Therefore, presentation centrality, which is commonly connected to interaction with a product (ie, whether one of the characters on screen handles a product, consumes it, or verbally mentions it) [34], is an important factor that needs to be considered. A study by Charry [30] showed that audiovisual presentations of fruit led to higher intentions of choosing fruit compared to a presentation that was only visual. Similarly, findings by Naderer and colleagues [35] suggest that a character handling or consuming the food elicits higher food consumption for the presented snack compared to the food being only visually presented.

Furthermore, social factors can play a crucial role in influencing obesity in children [36]. Parents heavily shape their children's food environment and thus play a significant role in both establishing children's food preferences and gatekeeping the media food environment of their children [37]. The theory of parental mediation states that parents' behaviors can influence how children access, receive, process, and react to media content and to what extent children adopt behaviors presented in media [38]. Parental mediation encompasses a variety of distinct social behaviors [39] that can be important in the prevention of negative media effects in children [40]. One behavior is called social coviewing, which is the joint viewing of media content by parents and children without necessarily talking about the content [39,41].

Experimental data measuring food choices and eating behaviors shortly after exposure to persuasive content suggest that media depictions do significantly shape unhealthy eating behaviors among children [3,4]. However, as valuable as experimental studies are, they do not allow conclusions about long-term effects, and they typically test specific food depictions, not the food-related media diet as a whole. Cross-sectional data examining the correlation of media consumption and children's BMI indicate that children with factors such as extensive TV viewing also are more prone to be overweight or obese [42]. Some first longitudinal examinations also speak to this relationship [43,44]. However, these studies do not take into account the actual content that children are exposed to.

Goal of This Study

With an extensive and externally valid design, this study aimed to link content analytical data on children's actual audiovisual media content—that is, food depictions in movies and TV series they were exposed to—with their food preferences, measured with survey data. This study used panel data from children and their parents over 6 months. The content analytical data represent the appearance and centrality of unhealthy foods, but also—as another urgent area for research—those of healthy foods. The survey data included parental coviewing measures that may diminish (or enhance) the effects of unhealthy (or healthy) food depictions. As dependent variables, unhealthy, but also healthy, food consumption of children was integrated within the model.

Methods

Ethical Considerations

The study was approved by the ethics committee of the University of Vienna (00343) and the principals of the respective schools. Prior to each wave, the children were asked to take home an information sheet, a consent form, and a survey for their parents. All children who returned a consent form that was signed by one of their parents at the first measurement point (T1) were then asked for their oral consent; if they agreed, we interviewed them individually and measured their weight and their height. Data were anonymized.

Procedure

Overview

This longitudinal linkage study combined survey data from parents and children with content analytical data. A 2-wave panel study was conducted with children and 1 of their parents (n=648) with 6 months in between the 2 panel waves. The study combined this approach with a content analysis of movies (n=113) and TV series (n=134; 3 randomly chosen episodes per TV series) that the children or their parents indicated they had been watching during the last 6 months at the second measurement point (T2).

Panel Survey

The data for this study originated from a larger project for which a 2-wave panel survey was conducted among a convenience sample of children and parents who were recruited via primary schools in Austria.

Parents were told that the purpose of the study was academic and that participation was voluntary. We ensured that both the children and their parents were aware that they could withdraw their consent or choose not to answer at any point in time. All parent surveys that were returned were then matched with the data provided by the children. This procedure was followed for both waves. The data for the first wave were collected from March to May 2019; data for the second wave were collected 6 months later.

Initially, the required documents were handed out to approximately 2250 children in 12 primary schools (n=6, 50% of the schools were in urban areas and n=6, 50% in rural areas). Overall, the response rate was 36.84%; thus, initially, 829 children returned the signed informed consent form. Due to some cases of illness and other issues, 795 children were interviewed at T1; 734 of the children at T1 participated again at T2. Comparing the children who remained with those who dropped out revealed no significant difference with respect to gender (*P*=.96), age (*P*=.66), or BMI (*P*=.29)

Moreover, 778 of the children's parents again returned a questionnaire at T2. For the analysis, our primary interest was the data from the children who participated in both waves (n=734). However, the parents' answers were also important to obtain a good picture of what audiovisual content children watched during the 6 months between the 2 measurement points. Overall, 559 parents at T2 filled out the questions concerning their children's consumption of audiovisual content. To construct a meaningful linkage, only cases with at least 3 named movies or TV series over the past 6 months according to the data provided by children or by their parents were included. Following this procedure, the final analyses were based on the data of 648 children aged between 5 and 11 years (T1: mean age 7.78, SD 0.50 years [n=15 missing]; n=313, 48.3% female [n=17 missing]; T2: mean age 8.26, SD 1.24 years; n=313, 48.4% female).

Content Analysis

To determine the sample for the content analysis, the movies and TV series that were named by children and parents in the open-ended questions about past media consumption and the parents' selections from a list in the parental survey at T2 were combined. All movies and TV series that were watched by at least 5 children were considered. Furthermore, audiovisual content named by a child or a parent was only coded if the child had watched at least 3 different movies or TV series. However, to avoid excessive dropout, movies and TV series were included if they were mentioned by fewer than 5 children if at least 1 of them had not mentioned at least 3 other movies or TV series.

The following criteria were applied to determine whether the movies and TV series were relevant for this study: First, all movies and TV series were excluded that were inappropriate for children according to their age rating (we included age ratings up to 12 years). Second, all media content was excluded that did not have a clear storyline; hence, game shows, educational TV series, and cooking shows were removed. Third, all media content was excluded that was not available in German. Finally, movies and TV series were excluded that were not available on streaming platforms or on DVD/BluRay. If multiple movies from the same movie series had been named, a randomizer selected one, again taking into account their availability on streaming platforms or via the Vienna Public Libraries; also, a randomizer selected 3 episodes from each TV series following the same procedure. The final sample consisted of 113 movies and 3 episodes each from 134 named TV series.

Measures

Exposure to Unhealthy and Healthy Products

To determine the independent variable, that is, the children's audiovisual content exposure (ie, movies or TV series) within the 6 months between the 2 waves, the children and their parents were asked which movies and TV series they had seen during this period. In addition to this open-ended question, the parental survey also contained a list of (at the time) popular audiovisual media content for children, as well as content specifically directed at children that was currently available on Netflix (Netflix, Inc) or Amazon Prime Video (Amazon.com, Inc, from which parents were able to choose.

Then, all food and beverage placements within each scene of the 113 movies and 3 episodes from each of 134 TV series were coded; scenes were defined as 5-minute segments. Five coders were extensively trained and, after completing a total of 2 rounds of reliability testing involving a total of 450 scenes, were deemed reliable (healthfulness of the product: Krippendorff α=0.79; food presentation centrality: Krippendorff α=0.85).

Each food placement (n=12,358) was either deemed healthy, unhealthy, or mixed. This differentiation was based on the recommendations of the World Health Organization [45] and former studies as follows: (1) unprocessed products with a high nutritional value were categorized as healthy, including water, unsweetened tea and juice, and fruit and vegetables (n=2953, 23.9% placements); (2) highly processed products high in fat, salt, and sugar were categorized as unhealthy, including sweets, french fries, and soft drinks (n=4926, 39.7%); and (3) products that included healthy as well as unhealthy ingredients were categorized as mixed products, including combined meals (n=4479, 36.2%). However, this study focused on the exposure effects of healthy or unhealthy products.

The total number of healthy and unhealthy placements within each watched movie or TV series (in the latter case, we added up the data from the 3 episodes we coded) per child was calculated; each child saw a mean 20.87 (SD 9.36) unhealthy products and a mean 11.23 (SD 4.43) healthy products.

Additionally, food placement centrality, that is, whether the placement was a focal point (if one of the characters on screen interacted with the product, consumed it, or verbally mentioned it, it was scored a 1; if it was not a focal point, it was scored a 0) was coded. Overall, 7738 (62.4%) product references appeared as focal points. The total number of focal-point placements within each watched movie and TV series per child was calculated (mean 36.99, SD 13.25 placements).

Coviewing

Based on on the work of Valkenburg and colleagues [41], parental coviewing was measured with 4 items on a 7-point Likert scale at T1 (1=never to 7=very often [in response to the question "How often do you watch a movie/TV series together with your child because you both like it?"]; at T1: Cronbach α=0.82; mean score 4.51, SD 1.47) in the parental survey.

Food Preferences

The dependent variables were measured in the panel survey of the children. We assessed how often the children consumed unhealthy food with 4 items ("How often do you eat [drink] sweets/salty snacks/soft drinks?"; 1=never to 4=very often; at T1: Cronbach α=0.65; mean score 2.20, SD 0.60; at T2: Cronbach α=0.68; mean score 2.19, SD 0.57). Furthermore, the children's healthy food consumption was assessed with 3 items ("How often do you eat [drink] fruit/vegetables/water?"; 1=never to 4=very often; at T1: Cronbach α=0.54; mean score 3.36, SD 0.56; at T2: Cronbach α=0.61; mean score 3.41, SD 0.55). In an additional analysis, water was excluded from the index, which did not affect the findings reported in the Results section.

Control Variables

The children's BMI at T1 was included as a control variable. Therefore, the children's weight and height were measured. For the analyses, their zBMI (SD score of BMI [46]) was calculated to adjust their BMI to their age and their gender (T1: n=628; zBMI: mean 0.09, SD 1.12; n=90, 14.3% overweight; n=33, 5.6% obese; n=20 missing). Furthermore, the children's overall audiovisual media exposure was included as a control variable. Children's media consumption was assessed at T2 using 2 items that respectively focused on movies ("How many movies are you allowed to watch on TV or on the internet at home in one week?"; 1=none, 2=one during the weekend, 3=one per day, 4=as many as I want) and TV series ("How many series are you allowed to watch on TV or on the internet at home in one week?"; 1=none, 2=one episode; 3=several episodes; 4=as many as I want). The items formed a reliable index (Cronbach α=0.63; mean 2.58, SD 0.65). Furthermore, we controlled for the children's age (mean age 7.78, SD 0.50 years; n=15 missing) and gender (n=313, 48.3% female; n=17 missing).

Table 1 provides an overview of variables used in the models.

Table . Description of measured variables.

Variables	Values, mean (SD)
Unhealthy food consumption (score; wave 1)	2.20 (0.60)
Unhealthy food consumption (score; wave 2)	2.19 (0.57)
Healthy food consumption (score; wave 1)	3.36 (0.56)
Healthy food consumption (score; wave 2)	3.41 (0.55)
Age (years; wave 1)	7.78 (0.50)
BMI (score; wave 1)	0.09 (1.12)
Media consumption (score; wave 2)	2.58 (0.65)
Unhealthy food presentations (n; wave 2)	20.87 (9.36)
Healthy food presentations (n; wave 2)	11.23 (4.43)
Focal-point placements (n; wave 2)	36.99 (13.25)
Coviewing (score; wave 1)	4.51 (1.47)

Statistical Analysis

A moderated regression analysis was performed controlling for healthy or unhealthy food consumption as autoregressive paths. All predictors were entered simultaneously and terms were mean-centered prior to computing interaction terms.

Results

The expectations were that exposure to unhealthy food products would be (1) positively related with unhealthy food consumption and (2) negatively related with healthy food consumption. Neither of these expectations found support. There was no significant relationship between exposure to unhealthy food presentations and unhealthy (b=0.008; *P*=.07) or healthy (b=−0.003; *P*=.57) food consumption over time. Moreover, this study examined how healthy food presentations in children’s media would relate to unhealthy and healthy food consumption over time. As indicated in Table 2, there were no significant relationships (unhealthy food consumption: b=0.009; *P*=.18; healthy food consumption: b=0.000; *P*=.99).

We found that exposure to unhealthy food presentations and presentation centrality had a significant positive interaction effect with unhealthy food consumption (b=0.000; *P*=.03). The positive sign of the interaction suggests that the effects of unhealthy food presentation rose with increasing levels of centrality. The probing of the interaction [47] is shown in Figure 1: starting from a level of presentation centrality of 1.65, the relationship is significantly positive (b=0.088; *P*=.05) and rises to an effect of b=.034 (*P*=.03). However, unhealthy food presentation and presentation centrality had no interaction with the consumption of healthy foods (b=0.000; *P*=.10).

When it comes to healthy food presentations, there was also a significant interaction with centrality (b=−0.001; *P*=.003). As can be seen in Figure 2, only for low food presentation centrality, there was an effect of exposure to healthy foods on unhealthy food consumption. Probing of this interaction revealed that for a mean-centered centrality lower than −5.196, the effect of healthy food presentations was significantly positive (*P*<.05) and was largest for the lowest centrality (b=0.40; *P*=.003). For values of centrality higher than 31.434, the effect turned significantly negative (*P*<.05) and was largest for the highest centrality (b=−0.07; *P*=.009). This means that when a healthy product was presented at maximum centrality, it led to less unhealthy food consumption in children. In contrast to expectations, healthy food presentation and presentation centrality had no interaction with healthy food consumption (b=−0.000; *P*=.22). Presentation centrality had no significant relationship with unhealthy food consumption (b=−0.005; *P*=.21) or healthy food consumption (b=0.001; *P*=.71).

Table . Unstandardized coefficients for predicting unhealthy food consumption (n=591; R^2=0.299).

Predictors	Unhealthy food consumption (wave 2)	
	b (SE)	*P* value[a]
Constant	1.608 (0.175)	<.001
Unhealthy food consumption (wave 1; autoregressive)	0.384 (0.037)	*<.001*
Gender	0.087 (0.041)	*.03*
Age (wave 1)	−0.050 (0.017)	*.004*
BMI (wave 1)	−0.014 (0.018)	.43
Media consumption (wave 2)	0.111 (0.034)	*.001*
Unhealthy food presentation (wave 2)	0.008 (0.005)	.07
Healthy food presentations (wave 2)	0.009 (0.007)	.18
Presentation centrality (wave 2)	−0.005 (0.004)	.21
Coviewing (wave 1)	0.044 (0.013)	*.001*
Unhealthy food presentations × presentation centrality	0.000 (0.000)	*.03*
Unhealthy food presentations × coviewing	0.003 (0.002)	.08
Healthy food presentations × presentation centrality	−0.001 (0.000)	*.003*
Healthy food presentations × coviewing	−0.002 (0.003)	.60

[a] Significant *P* values are italicized.

Figure 1. Effects of unhealthy food presentations on unhealthy food consumption by presentation centrality.

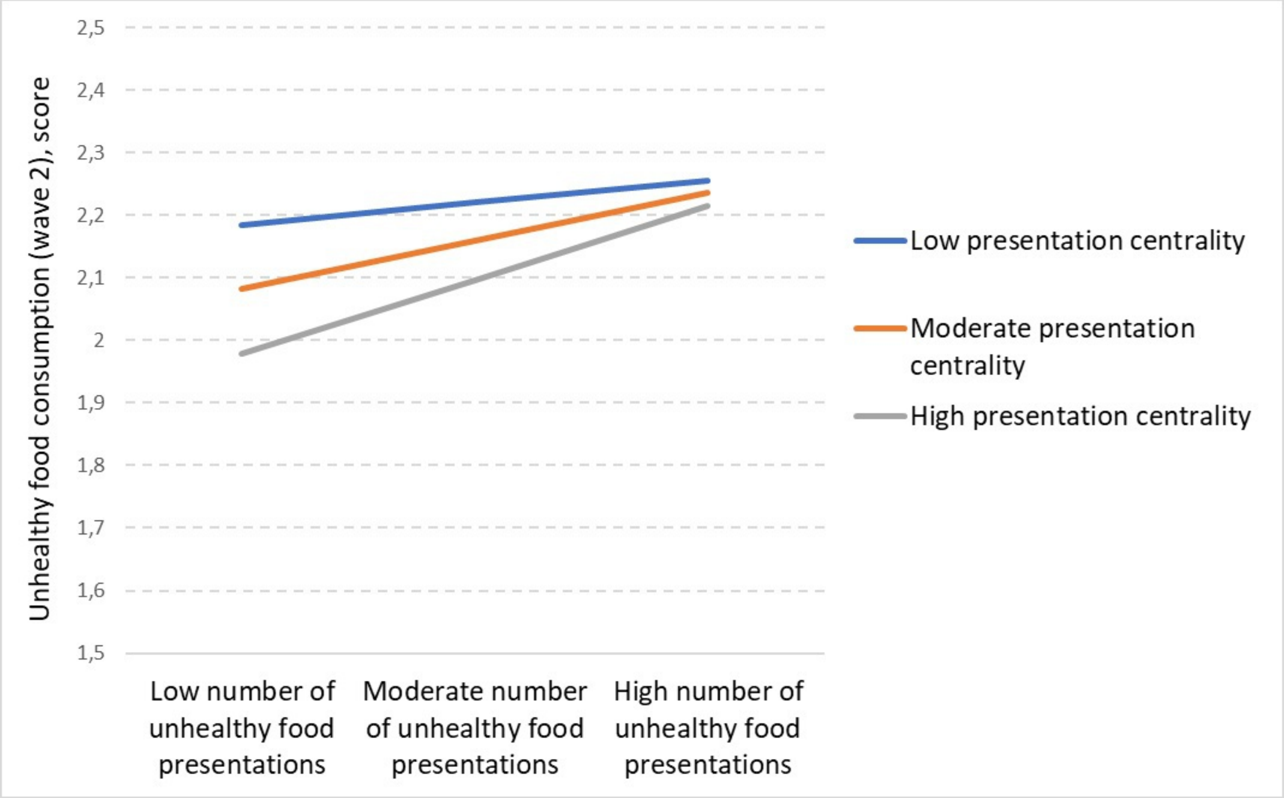

Figure 2. Effects of healthy food presentations on unhealthy food consumption by presentation centrality.

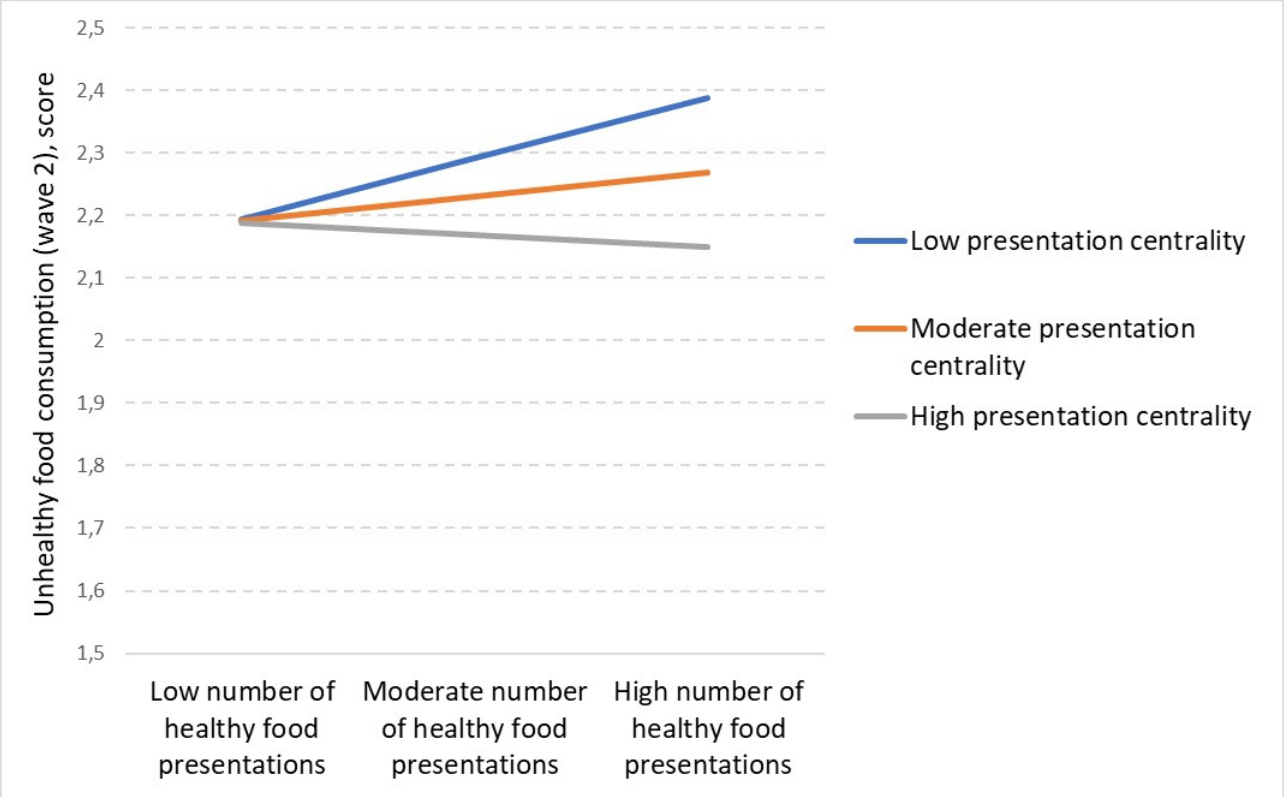

Coviewing did not interact with exposure to unhealthy products in audiovisual media when explaining unhealthy (b=0.003; *P*=.08) or healthy (b=−0.001; *P*=.70) food consumption behavior of children over time. It also did not interact with the presentation of healthy products with regard to unhealthy (b=−0.002; *P*=.60) or healthy (b=0.001; *P*=.74) food consumption. Surprisingly, coviewing was associated with higher unhealthy food consumption over time (b=0.044; *P*=.001), but it was unrelated to healthy food consumption (b=0.005; *P*=.69).

As for the controls, boys were more likely than girls to consume unhealthy foods, and age was positively correlated with unhealthy food consumption. Both gender and age were unrelated to healthy food consumption. Overall media consumption was positively related to the consumption of unhealthy foods and unrelated to healthy food consumption. Children's zBMI had no relationship with either type of food consumption. Tables 2 and 3 show detailed findings from the controls.

Table . Unstandardized coefficients for predicting healthy food consumption (n=591; R^2=.322).

Predictors	Healthy food consumption (wave 2)	
	b (SE)	*P* value[a]
Constant	1.431 (0.175)	<.001
Healthy food consumption (wave 1; autoregressive)	0.537 (0.035)	*<.001*
Gender	0.010 (0.040)	.80
Age (wave 1)	0.021 (0.017)	.21
BMI (wave 1)	−0.015 (0.017)	.40
Media consumption (wave 2)	−0.020 (0.032)	.53
Unhealthy food presentations (wave 2)	−0.003 (0.004)	.57

Discussion

Principal Results and Comparison With Prior Work

Evidence is abundant for the effects of unhealthy food presentation in children's media on children's consumption behaviors [4,19,48]. The aim of this study was to revisit this evidence, not only with respect to the presentation of unhealthy foods, but also healthy ones. For the first time in the existing research, content analytical data from movies and TV series that children were exposed to over a time span of 6 months were combined with panel data from children and their parents. With this data linkage design, this study could test how effects evolved over time.

As the findings reveal, even though unhealthy food exposure was much higher overall, exposure to unhealthy and healthy foods alone was not related to children's healthy and unhealthy consumption behaviors. The results show that the centrality with which the products were presented greatly mattered for the relationships. When foods were presented centrally, that is, when they were zoomed in on or when the characters interacted with them, consumed them, or verbally mentioned them, exposure to unhealthy food presentation was positively related to unhealthy food consumption. This effect can be explained by the fact that centrality eases the perception of unhealthy foods, thus increasing cue reactivity, leading to a "wanting" of that product [33]. That is, centrality plays a role in reminding children about their food preferences.

Interestingly, this relationship was different for the presentation of healthy foods. For healthy foods, centrally placed healthy food products were negatively related to unhealthy food consumption. One could argue that children are made aware of the importance of healthy foods for their diet and thus their preference for unhealthy foods decreases. Yet to create such an awareness, a central placement of the food is necessary. Of course, more empirical evidence is needed to corroborate that claim.

However, when healthy foods were placed noncentrally, they were positively related to children's consumption of unhealthy food over time. This finding is in line with a prior study [19] suggesting that healthy food placement can promote unhealthy eating behaviors. Subtle presentation of healthy foods can activate children's inherent preference for unhealthy foods, for instance, by serving as a cue for appetite [32]. When appetite is cued, then children automatically prefer unhealthy over healthy options. However, when the centrality of healthy foods rises, this automatic process may be impeded; children may be reminded about the importance and necessity of healthy food and consume less unhealthy food over time. Again, the precise underlying mechanisms remain to be studied. Overall, even though unhealthy foods were presented more often, the amount of food exposure was not a key element influencing unhealthy food consumption. However, persuasive strategies (ie, centrality) in connection with unhealthy as well as healthy food presentation are more important in that regard.

Against expectations, foods presented in the media that children were exposed to did not show any relationship to healthy food consumption. Healthy food consumption could hardly be explained empirically. One explanation could be that children have an inherent preference for unhealthy foods [49,50]. As a consequence, unhealthy food consumption may be triggered more easily as compared to healthy food consumption. This is also in line with former research testing the effects of different persuasive strategies concerning healthy food consumption [23,51,52]. It seems that more than just a central placement is needed to positively impact children's healthy eating habits [32].

Finally, coviewing by parents did not moderate the effects on healthy and unhealthy food consumption; however, it was positively related to unhealthy food consumption overall. This finding is arguably hard to explain, as theory would suggest the opposite. Perhaps coviewing exerts an indirect effect: when coviewing, parents, too, are exposed to unhealthy food presentations (which are clearly dominant in children's media) [15], and they may also be affected by them. These effects on parents may then, in a second step, facilitate the unhealthy eating habits of their children. In such a scenario, potential effects on children could run via 2 paths: unhealthy food presentation could shape children's eating behaviors directly (ie, by affecting them), and indirectly (ie, by affecting their parents, who then affect their children). This indirect mechanism is certainly speculative and cannot be properly tested in a panel survey; it would thus necessitate strict experimental designs.

Limitations and Future Research

This study relied on self-reported data when assessing the specific movies and TV series that children were exposed to. As always, such self-reported data are prone to perceptual biases, as specific movies and TV series may be more likely to be mentioned for reasons that cannot be measured. However, considering that in this study both children and parents were asked about movies and TV series, and content viewed over 6 months would generally be possible to remember, we are confident that we obtained an account of the content the children were exposed to. Also, when it comes to the dependent variables, self-reported consumption behaviors, which are not the same as actual food choices, were assessed [53]. Related to that, this study can only make correlative conclusions regarding the relationship between mediated exposure to foods and children's consumption behaviors.

The sample relied on the most frequently was movies and TV series. However, this study was unable to include smartphone content or determine the type of screen on which the content was consumed. For the age group of this study (between 5 and 11 years) and their typical content preferences, this seemed reasonable. In addition, the models controlled for overall media consumption to rule out effects of the frequency of exposure to other content not assessed in this study, but future research should take a 360 degree account of children's media diet. This may be challenging for practical reasons, but integrating several types of content in one study is important. Relatedly, we did not predict reciprocal relations (ie, food presentation by consumption), because food presentation refers not only to exposure, but also to content, and the content of the movies cannot be predicted by consumption. However, future research should follow up on this.

This study focused on the centrality of presentation. As important as centrality is [33], it is only one presentation factor that may shape food preferences [32]. Also, this study did not explicitly distinguish between several types of centrality, such as interacting with a product, consuming it, or mentioning it. When it comes to coviewing, several dimensions should also be distinguished in future research, such as intentional versus passive coviewing. Moreover, the age range used in this study deserves further scrutiny. Children younger than 5 years are frequently exposed to media content containing food. These children are, arguably, particularly susceptible to the presentation of unhealthy and healthy food and thus deserve more attention. Finally, no data on the specific schools the children were attending were collected since these would not have been in line with the ethical standards regarding anonymization. Therefore, this study was not able to control for schools in the models.

Conclusions

When discussing the roots of children's unhealthy food consumption and childhood obesity, educators, journalists, and policy makers have been very quick to point their fingers at the media, particularly media that targets a young audience. At first sight, the evidence for the media's role in obesity and unhealthy consumption is overwhelming. Not only are unhealthy foods presented more frequently, more prominently, and more positively as compared to healthy foods [15,54], experimental [19,24,28,48] and survey research [43,44] also suggests that the presentation of unhealthy foods can significantly shape unhealthy consumption habits among children.

This study demonstrates 3 things. First, the findings of this study suggest a more nuanced picture. Linking panel survey data to content analytical data on the content that children were exposed to showed that unhealthy or healthy presentation alone were not related to healthy or unhealthy consumption behaviors. Such relationships may be observable in forced-exposure experimental studies with strong stimuli and measures briefly after stimulus exposure, but not in a longitudinal study sampling actual content [55].

Second, and related to that, this study shows that the way in which foods are presented matters. Centrally placed unhealthy foods do in fact show a positive relationship to unhealthy eating behaviors; centrally placed healthy foods, however, appear to have the opposite effect. Also, healthy foods placed noncentrally seem to prime unhealthy eating habits, not healthy ones.

Third, by and large, children's movies and TV series seem to be more likely to be positively related to unhealthy than healthy eating behaviors. Healthy consumption behaviors were completely unrelated to exposure to media content. Also, when centrality was low, even healthy foods in the media seemed to foster unhealthy consumption.

Overall, these findings inform and qualify the debate about the media's impact on healthy and unhealthy consumption behaviors among children. Most importantly, the call to simply place more healthy foods in children's media may, according to our findings, not be sufficient to combat unhealthy eating and childhood obesity.

Acknowledgments

JM, AB, and BN conceptualized the study, drafted the initial manuscript, and reviewed and revised the manuscript. JM conducted the statistical analysis. MF, IS, HK, and MS administered the study and reviewed and revised the manuscript. All authors approved the final manuscript as submitted and agreed to be accountable for all aspects of the work. The research was partly supported by a grant from the Central Bank of the Republic of Austria (grant 17715).

Abstract

Background: Fathers play a pivotal role in parenting and child feeding, but they remain underrepresented in intervention studies, especially those focused on disadvantaged populations. A better understanding of fathers' experiences and needs regarding support access and child nutrition information in the context of disadvantage can inform future interventions engaging fathers.

Objective: This study aims to explore fathers' experiences; perceived enablers; and barriers to accessing support and information related to parenting, child feeding, and nutrition and to co-design principles for tailoring child nutrition interventions to engage fathers.

Methods: Australian fathers of children aged 6 months to 5 years with lived experience of disadvantage participated in semistructured interviews and co-design workshops, primarily conducted via videoconference. Creative analogies were used to guide the ideation process in the workshops.

Results: A total of 25 interviews and 3 workshops (n=10 participants) were conducted, with data analyzed using reflexive thematic analysis and the Capability, Opportunity, and Motivation–Behavior model. The interview data illuminated factors influencing fathers' initiation in seeking support for parenting, child feeding, and nutrition, including their experiences. It highlighted fathers' diverse information needs and the importance of an inclusive environment and encouragement. Enablers and barriers in accessing support related to parenting and child nutrition were identified at the individual (eg, personal goals and resource constraints), interpersonal (family support and false beliefs about men's caregiving role), organizational (inadequate fathering support), and systemic levels (father-inclusive practice and policy). Digital data collection methods enabled Australia-wide participation, overcoming work and capacity barriers. Videoconferencing technology was effectively used to engage fathers creatively. Key principles for engaging fathers were co-designed from the workshop data. Interventions and resources need to be father specific, child centered, and culturally appropriate; promote empowerment and collaboration; and provide actionable and accessible strategies on the *what* and *how* of child feeding. Fathers preferred multiformat implementation, which harnesses technology-based design (eg, websites and mobile apps) and gamification. It should be tailored to the child's age and targeted at fathers using comprehensive promotion strategies.

Conclusions: Fathers faced barriers to accessing support and information related to parenting and feeding that may not adequately address their needs. Future interventions could integrate the co-designed principles to engage fathers effectively. These findings have implications for health service delivery and policy development, promoting father-inclusive practice.

Introduction

Background

Nurturing care is a central tenet for fostering optimal growth and development in children. This supports children in attaining good health through adequate nutrition, feeling safe and secure, and receiving responsive caregiving and learning opportunities [1]. Child feeding that focuses on the reciprocal positive relationship between the caregiver and the child is an opportunity that integrates all components of nurturing care. Efforts to promote early childhood development recommend incorporating responsive caregiving as part of interventions aimed at optimizing the nutrition of young children [2].

Fathers play a pivotal role in nurturing care, including feeding, and influencing children's eating [1,3]. Although mothers often take on the primary responsibility for feeding children, fathers increasingly participate in various aspects of child feeding, from selecting and preparing foods to sharing family meals [4-6]. Despite an emerging trend of involving fathers in parenting and child health research, there is limited evidence documenting fathers' experiences and needs regarding nutrition and feeding, and they remain underrepresented in intervention studies [7,8]. In a 2017 systematic review of randomized controlled trials (RCTs) targeting child obesity prevention and treatment (n=213), only 10% of participants were fathers, and just 2 studies reported targeted attempts to recruit fathers [9].

A barrier to the inclusion of fathers is their reported reluctance to participate in research even when invited, as they may doubt they have contributions to make to studies on children's eating [10]. On the basis of their own research experience, Moura and Philippe [10] found that fathers with a lower socioeconomic background expressed discomfort with being involved in research, perceiving researchers as *too knowledgeable* to provide additional insight into their work. In another survey study (n=303), >80% of fathers perceived their underrepresentation in child health research as stemming from not being invited to participate in these studies [11]. Fathers living with disadvantage can be considered as *hard to reach* because of structural barriers, including work commitments, limited financial resources, low literacy, or reduced capacity to travel [12]. Consequently, researchers have tended to focus on populations that are easier to reach, typically more advantaged mothers. Targeted strategies are necessary to make participation more accessible and engaging for fathers, particularly those facing disadvantage. Remote and digital data collection methods emerge as promising tools to engage with disadvantaged populations, breaking structural barriers to inclusive participation [13]. The nature of remote technologies, in which participants operate within their settings and control their devices and degree of involvement, also creates a safe environment and balances power dynamics between researchers and participants.

Understanding how to tailor research and service design, including intervention objectives and content, delivery mode, and location, is crucial for the effective engagement of fathers. Moura and Philippe [10] identified practical facilitators to enhance the inclusion of fathers in child nutrition research, including explicitly recruiting *fathers* rather than *parents*, offering web-based participation options, and using interactive methods. However, these suggestions have emerged from reflection and review rather than directly drawing on the lived experiences of fatherhood. To develop tailored interventions that will optimize child nutrition and maximize success in reaching fathers from diverse backgrounds, participatory research, in which fathers are considered experts in their lived experience, may produce more concrete and realistic solutions.

Objectives

Understanding fathers' experiences and needs regarding child nutrition interventions in the context of disadvantage can inform future intervention development. This research aimed to understand the following: (1) fathers' experiences; perceived enablers and barriers in accessing support and information related to parenting, child feeding, and nutrition and (2) how child feeding and nutrition interventions can be effectively tailored to engage fathers through co-design.

Methods

Ethical Considerations

Both studies were approved by the Queensland University of Technology (QUT) Human Research Ethics Committee (2022-5253-7746 and 2023-6687-16117).

Context

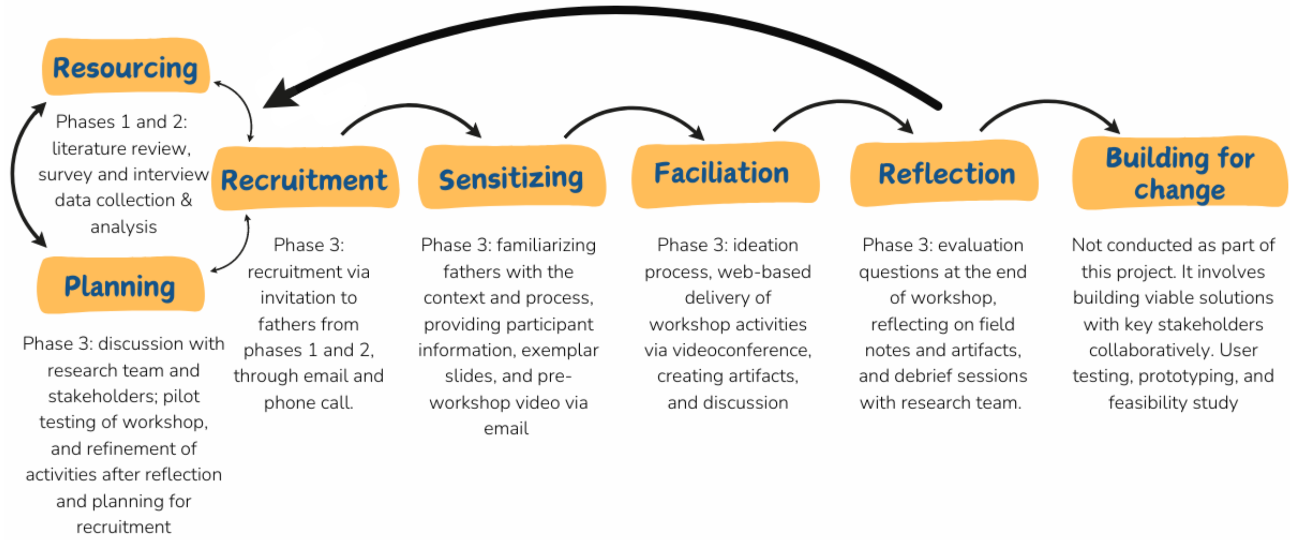
The data presented in this paper come from the research project Dads at Mealtimes (DAM), which consisted of 3 phases: a web-based survey (phase 1), interviews (phase 2), and co-design workshops (phase 3). The overarching research explored the feeding roles and practices of Australian fathers in the context of disadvantage. The survey and interviews were conducted in 2022, informing the subsequent co-design workshops in 2023. All studies primarily used digital tools because of the COVID-19 pandemic, during which digital data collection became more common. This paper focuses on findings from the interview and workshop phases.

The interviews aimed to explore three aspects: (1) paternal roles and contributions in child feeding, (2) enablers and barriers to responsive feeding practices, and (3) experiences and perceived enablers and barriers in accessing support and information related to parenting, child feeding, and nutrition. Objectives 1 and 2 have been reported elsewhere [14]. This paper focuses on data from the interviews, which contribute to objective 3.

The co-design workshops aimed to gain insight into how child feeding and nutrition interventions can be effectively tailored to engage fathers. The workshop uses co-design as a participatory approach, methodology, and method that includes end users in the intervention's conception, development, or evaluation [15]. Underpinned by the principles of equity and partnerships [16], co-design seeks to build capacity, harness creativity, and deepen collaboration between professionals and people experiencing or impacted by the issues [17-19]. Thus, co-design has the potential to create socially and contextually appropriate solutions aligned with the circumstances and contexts of end users [20]. The DAM project aligns with the Kennedy et al [21], extended model of the co-design framework originally developed by Trischler et al [22]. The framework is inherently iterative, with an evolving and flexible design process of resourcing, planning, and recruitment, which is reflective of different study phases and multiple workshops. An overview of the 7 steps and their alignment with the DAM study phases is depicted in Figure 1 [21,22].

Phases 1 and 2 of the DAM study served as the first step (resourcing) in Figure 1 to gain an understanding of the issue. Of the 264 fathers who completed the survey, two-thirds reported having prepared meals (67%) and assisting their child with eating (69%) at least once a day. More than three-quarters (77%) of participants were food insecure, and 55% reported having unmanaged stress [23]. From the interviews (objectives 1 and 2), personal, interpersonal, and systemic enablers (eg, food skills, adequate resources, and support) and barriers (eg, low self-efficacy in feeding, financial and mental strain, food insecurity, and gendered stereotypes) were identified as influencing paternal feeding experiences [14]. The insights from phases 1 and 2 informed the workshop's scope, aim, and activities for engaging fathers in child nutrition interventions. These findings underscored the need for intervention design that harnessed fathers' lived experiences to provide tailored strategies.

Figure 1. Overview of the co-design framework and mapping to the study phases and activities of the Dads at Mealtimes project.



Theoretical Framework

The conceptual framework for the broader study incorporates the Capability, Opportunity, and Motivation–Behavior (COM-B) model of behavior change [24]. This model conceptualizes *capability*, *opportunity*, and *motivation* as the main components for facilitating behavior change. Adopting this behavior change perspective provides a basis for highlighting key attributes in engaging fathers in child nutrition. Consequently, it integrates findings from phases 2 and 3 to inform intervention design.

Positionality

The researchers' positionality is of pivotal importance as coconstructors of meaning in both studies. The first author (JTHS), a male PhD student, conducted recruitment and performed data collection and analyses for both the interview and workshop studies. Not a father himself but involved in caring for young children within an extended family household, he has a background in nutrition and dietetics and completed training in qualitative research. The coauthors (KAB, SN, RB, and DG) are academic dietitian-nutritionists specializing in child nutrition and have experience in qualitative research and co-design. They are mothers of children spanning a broad age range. None of the authors had any prior relationship with the participants.

Interviews

Recruitment

Recruitment procedures for participating in DAM have been detailed previously [14]. Briefly, participants self-identified as fathers or male caregivers with a child aged 6 months to 5 years living with disadvantage. The following question served as an indicator of socioeconomic disadvantage: do you sometimes struggle to pay the bills? The screening question was informed through consultation with parents with the aim of using language that sensitively recruited individuals who were struggling financially and, therefore, at risk of food insecurity [25]. Interview participants were predominantly recruited from a pool of participants who completed the survey (phase 1) and expressed interest in future research. In addition, participants were recruited via promotional flyers distributed to stakeholders, such as family and child services. Consent and demographic information were obtained through a brief web-based questionnaire. All web-based data collection tools were developed using REDCap (Research Electronic Data Capture; Vanderbilt University) [26,27], which was hosted by QUT.

Data Collection

A semistructured interview guide was informed by a literature review and the COM-B model. Pilot testing of the interview questions was completed with 3 fathers to check for comprehension and flow. These questions explored paternal perceptions of their roles and feeding practices, experiences of food insecurity, and accessing support and child nutrition information [14]. Indicative questions relevant to this paper's findings were as follows: (1) Can you tell me any advice you received from anyone or anywhere about child feeding and nutrition? (2) Do you think you received enough support and information about child nutrition? The decision on the sample size is guided by the concept of *information power*, which posits that the greater the relevant information the sample provides, the fewer participants are required [28]. Participants were compensated with an Aus $25 (US $16.6) e-gift card. All interviews were recorded and transcribed verbatim using an automated transcription service, Otter.ai [29]. Participants were invited to review the transcripts. Those who opted to receive the transcripts proposed no alterations. Debriefing sessions were conducted with the research team during data collection and analysis to foster theoretical and reflective thoughts.

Analysis

A detailed description of the data analysis is reported elsewhere [14]. The analysis used the 6-phase process of reflexive thematic analysis [30]. The first author conducted manual coding using inductive and deductive approaches underpinned by a symbolic interactionism lens [31]. Coauthors independently coded a subset of transcripts (n=3) and engaged in discussions to sense check ideas and refine themes. The codes and themes derived from the interview data allowed the researchers to identify enablers and barriers to support access among fathers across individual, interpersonal, and systematic levels. This analysis process was guided by the COM-B model, which was integrated with the workshop findings.

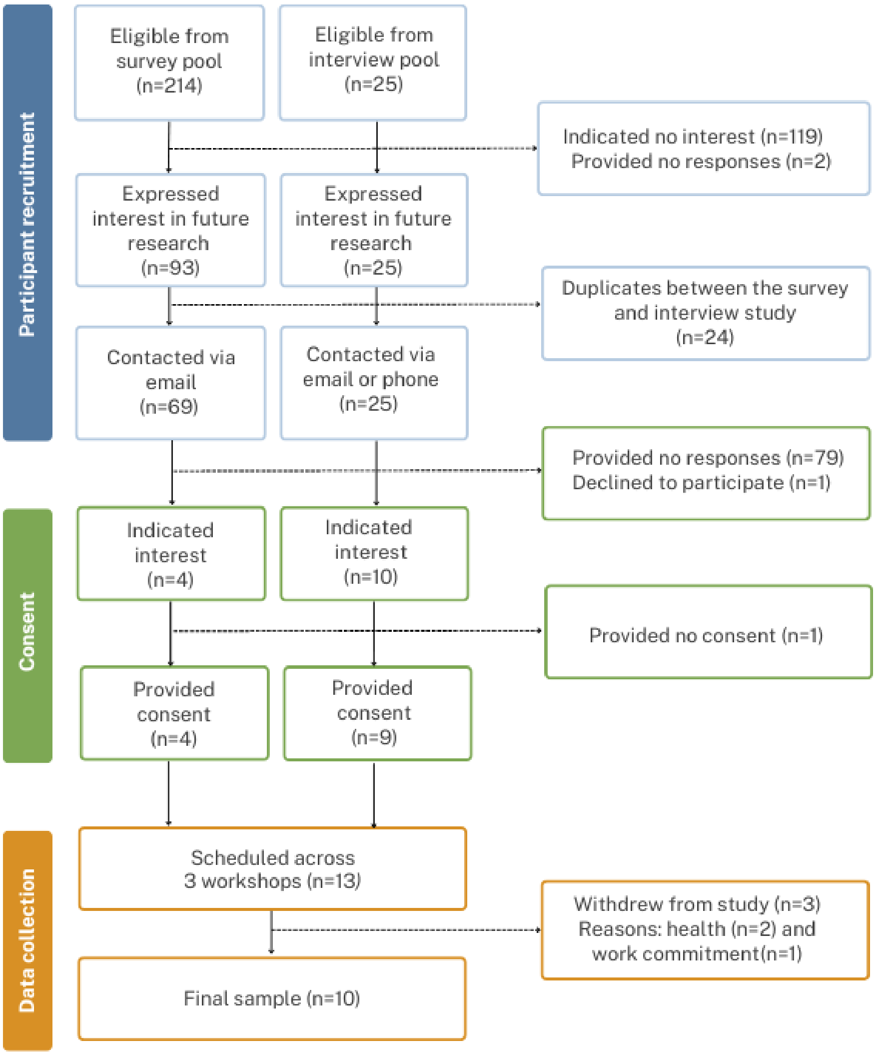
Co-Design Workshops

This section of the paper outlines the recruiting, planning, sensitizing, facilitation, and reflecting steps for the co-design workshops. As part of sensitizing, participants who completed the interview (phase 2) received a summary of findings before phase 3 data collection.

Recruitment

Workshop participants were recruited from a pool of fathers who completed either phase 1, phase 2, or both and expressed interest in further research. Purposeful sampling was adopted to optimize participation from those who completed both phases. Given the sequential design, rescreening for eligibility was not completed. Fathers were invited to participate via email or telephone and were informed that workshops involved several creative web-based activities to design solutions to engage fathers in child feeding and nutrition. Consent and participants' availability were collected via a web-based questionnaire using REDCap [26,27], which was hosted by QUT. The participant flow diagram is presented in Figure 2.

Figure 2. Workshop participant flow diagram, including reasons for exclusion.



Data Collection

The first step in developing the workshop guide was a literature review on fathers' participation in parenting and child nutrition research [10,11,32] and co-design methodologies [19,33]. Discussions were then held among research team members with expertise in child nutrition, socioeconomic disadvantage, and co-design. This was followed by a consultation with a design practitioner-academic with expertise in co-design. After these discussions, a decision was made to conduct workshops of shorter duration and with more streamlined ideation activities focusing on paternal engagement. Drawing on the first author's experience with other co-design studies and sense checking the ideas with other fathers (not part of the final sample), creative analogies that resonate with men were deemed appropriate. The workshop using *superhero* analogies was pilot-tested with 3 fathers (not included in the final sample). These fathers considered the activities and analogies acceptable and enjoyable in eliciting creative ideas. They provided feedback on simplifying the language in the materials (eg, workshop guide, visual slides, and videos) and suggested probes and examples to enhance the concepts and understandability. The workshop overview is provided in Textbox 1.

The preliminary sample size for the workshops was 8 to 10, guided by *information power* [28]. The plan included conducting 2 to 3 workshops, each lasting 70 minutes, with 3 to 4 fathers in each session to facilitate small group discussions. To enable participation across Australia and provide flexibility, workshops were conducted via videoconference using the Zoom platform (Zoom Video Communications) [34]. This reduced barriers to participation and met fathers' preference for web-based activities [10,35]. Features of the platform that were used included screen share, audiovisual recording, and live chat, and it was compatible with mobile or computer use. The *superhero*-themed workshop was complemented by a short preworkshop animated video sent to participants 3 days before the workshop. This video aimed to familiarize fathers with the context, objective, activities, and exemplar personas. These personas were presented as comic characters, incorporating key attributes and findings from phases 1 and 2 (refer to Multimedia Appendix 1 for exemplar personas and related presentation slides).

Each workshop was facilitated by the first author (JTHS), who was one of the coauthors acting as a scribe (DG, KAB, and SN). A presentation slide guided the ideation activities throughout the workshop. Activity 1 involved creating their persons guided by exemplar personas (refer to image C in Multimedia Appendix

1 for 1 father's drawing of their persona). Fathers were asked to ideate their vision and key features of designed solutions in activity 2. Figures 3A and 3B demonstrate the exemplar slides used in this activity. The screen-sharing feature allowed facilitators to share the slides to guide the ideation process and enter responses (provided verbally or via chat) onto these slides in real time for participants to view, validate, and elaborate (refer to Figures 3C and 3D for generated presentation slides). Participants were encouraged to use the live chat function to contribute to the activities or ask questions. At the end of each workshop, the cofacilitator gave a summary of the discussion, providing an opportunity for participants to validate and add further comments. Evaluation questions were posed (ie, What do you like most and least? What would you change?), serving as a short reflection to conclude the workshop. This allowed researchers to refine procedures between the workshops. After the first workshop, this process resulted in a modification to send participants sample slides and questions ahead of time. Participants received an Aus $30 (US $19.9) e-gift card for their involvement.

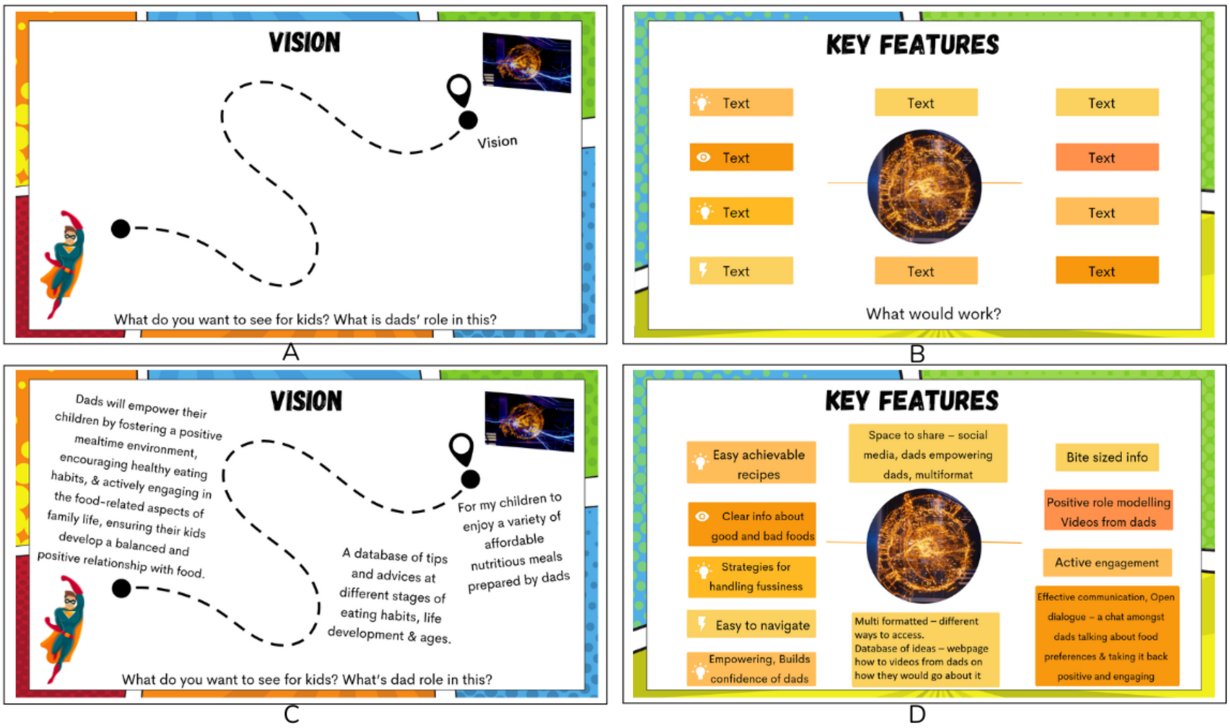
All workshops were video-recorded and transcribed verbatim using Otter.ai [29]. The first author (JS) also completed field notes on each workshop. Artifacts, including drawings, transcripts of chat conversations, and presentation slides (ie, visions and key features created on the slide with fathers), were collated. The research team held debriefing sessions throughout the data collection and analytic process.

Textbox 1. Workshop overview and activities.

Overview

- Study objective: to co-design tailored child nutrition intervention design principles for engaging fathers
- Approach: creative analogies using the *superhero* theme
- Workshop name: Superdads: The New Age of Nourishing Kids
- Workshop activities and indicative questions
  - Activity 1: making superheroes (15 minutes)
    - Description: fathers created their personas, guided by exemplars.
    - Tools: screen sharing of visual slides, drawing, and group sharing.
    - Indicative question: Tell us about yourself (family role, education, cultural background, and life experience), alias (superhero name), your kids, a tip of advice (superpower), challenges (evil nemesis), and information sources.
  - Activity 2: feeding into (fictional artificial intelligence name in the comic) (45 minutes)
    - Description: Participants ideated their vision and brainstormed the key features of the designed solutions; ideas were refined with probes (considerations and challenges informed by phases 1 and 2).
    - Tools: live chat function, group discussion, and presentation slide with real-time responses (ie, facilitator entering words on slides).
- Indicative questions
  - What do you want to achieve for dads and kids regarding child nutrition and eating? (collective vision).
  - What are your ideas for possible solutions for dads, what would work? What are your top 3 design features if we create something for dads about child nutrition? Why are they important?
  - What format could these solutions take on the basis of these features?
- Probes
  - Consider space—where is the best place to reach dads?
  - Consider time—when is the best time to target dads?
  - Consider what empowers dads, their strengths, and challenges. Think about the personas we created.
  - Consider the target group (father only, family focused, and children). Who do you trust to give credible information (male, peer, partner, general practitioner, and health professionals)?

Figure 3. Exemplar slides: (A) template slide for identifying the vision, (B) template slide for identifying key features, (C) completed slide of participants' vision (workshop 1), and (D) completed slide of identified key features (workshop 1).



VISION

Vision

What do you want to see for kids? What is dads' role in this?

KEY FEATURES

Text

Text
Text
Text
Text
Text
Text
Text
Text
Text
Text

What would work?

VISION

Dads will empower their children by fostering a positive mealtime environment, encouraging healthy eating habits, & actively engaging in the food-related aspects of family life, ensuring their kids develop a balanced and positive relationship with food.

A database of tips and advices at different stages of eating habits, life development & ages.

For my children to enjoy a variety of affordable nutritious meals prepared by dads

What do you want to see for kids? What's dad role in this?

KEY FEATURES

Easy achievable recipes

Clear info about good and bad foods

Strategies for handling fussiness

Easy to navigate

Empowering, Builds confidence of dads

Space to share – social media, dads empowering dads, multiformat

Multi formatted – different ways to access.
Database of ideas – webpage how to videos from dads on how they would go about it

Bite sized info

Positive role modelling Videos from dads

Active engagement

Effective communication, Open dialogue – a chat amongst dads talking about food preferences & taking it back positive and engaging

Analysis

Underpinned by the constructivist paradigm that views reality as socially constructed, workshop data (video and chat transcripts, presentation slides, field notes, and artifacts) were analyzed using the same approach as the interviews with inductive coding. Specifically, the enablers and barriers constructed from the interview findings (objective 3) were interpreted together with the workshop data using the COM-B model. In this interpretive process, coauthors were involved in sense checking ideas, generating, naming, and defining the key themes (design principles).

Results

Demographics

A total of 25 fathers participated in semistructured interviews conducted from April to September 2022 (n=24, 96% completed the interviews digitally). Three co-design workshops were held with a sample of 10 fathers (3 or 4 fathers in each workshop) between October and November 2023. The demographics of participants are presented in Table 1. In total, 60% (6/10) of workshop participants completed both phases 1 and 2, and 40% (4/10) completed the survey (phase 1) only.

Table 1. Characteristics of the fathers participating in the interview and workshop studies.

Characteristics	Interviews (n=25)	Workshops (n=10)
Father’s age (years), mean (SD)	35 (6)	35 (4)
Biological father to the index child, n (%)	25 (100)	10 (100)
Days living with the child per fortnight, n (%)		
Full time (14 days)	19 (76)	8 (80)
Part time (7 days)	3 (12)	1 (10)
Less than part time (2-4 days)	3 (12)	1 (10)
Marital status, n (%)		
Married or in a de facto relationship	18 (72)	9 (90)
Separated or divorced	6 (24)	1 (10)
Widowed	1 (4)	0 (0)
Cultural and ethnic group, n (%)		
Australian	18 (72)	8 (80)
New Zealander	1 (4)	1 (10)
Aboriginal or Torres Strait Islander	1 (4)	0 (0)
Other[a]	5 (20)	1 (10)
Education level, n (%)		
University	14 (56)	6 (60)
Certificate or diploma	5 (20)	3 (30)
Year 12	5 (20)	1 (10)

1	13 (52)	7 (70)
2	10 (40)	2 (20)
3-4	2 (8)	0 (0)
Number of children (aged 6-17 years)[c], n (%)		
0	18 (72)	6 (60)
1	3 (12)	1 (10)
2	1 (4)	1 (10)

Characteristics	Interviews (n=25)	Workshops (n=10)
3-6	3 (12)	2 (20)

[a] Cambodian, Chilean, Congolese, Indian, and Indonesian for the interview sample; Cambodian for the workshop sample.

[b] For interviews, of the 25 participants, 14 (56%) were full-time, 1 (4%) was part-time, and 5 (20%) were casual employment. For workshops, employment type was not collected.

[c] The household size is reported for the father's household.

Interviews

Overview

The interview data illuminated fathers' experiences in accessing support and information related to parenting, child feeding, and nutrition. These experiences are reflected by the following themes: (1) factors influencing the initiation of support related to parenting and child feeding, (2) experiences when seeking support, (3) diverse information needs, and (4) inclusive environment and encouragement. ID numbers are assigned to participants' quotes to preserve anonymity.

Factors Influencing the Initiation of Support Related to Parenting and Child Feeding

Fathers reported multifaceted factors that influenced their likelihood to seek and access support *in relation to parenting and child feeding*. These included resource constraints, such as time, location, high mental load, and traditional masculine values, when seeking help might be regarded as a weakness. When asked about their experiences obtaining support around feeding children, 1 father stated the following:

> *As a dad, you don't want to ask for help, it's not a manly thing to do.* [ID64]

How fathers perceived their fatherhood roles and responsibilities regarding caregiving or feeding guided whether and how they sought information. Some fathers believed caregiving to be instinctual (a *gut instinct*) and perceived nutrition as *common sense*. Thus, they are driven by responding to the emotions and behaviors of their child rather than seeking external advice. Others only sought information when they were looking for specific nutrition knowledge. For example, a father indicated the following:

> *When we face questions we didn't know...we tried to solve it early, went to GP, went to nutritionist at the time.* [ID122]

Awareness of available support and gendered expectations, in which fathers perceive and abdicate the responsibility of seeking health and nutrition information to mothers, also influenced whether they sought external support:

> *My wife does like all the research...she drives what we're doing—Okay, we're going to move on to more solid foods or feed her this...she's part of a lot of mother's groups as well, it's a lot of information from there and I just don't have the time so there's no point in doubling up.* [ID61]

Experiences When Seeking Support

When fathers sought child health information and feeding support, experiences were mixed. Although some fathers reported good support from health care workers, others recounted negative experiences in which they received minimal help. One father shared his experience after the birth of his baby:

> *No help for dads...I said—Could you show me how to wash her and all that, my wife couldn't at the time and [the medical staff] said you have to wait until your wife is ready...she got a lot of help but nothing to teach the men how to feed a kid or change a nappy… at the moment I need the help, so teach me.* [ID8]

The stigma of fathers being perceived as uninvolved or unimportant was also raised:

> *There's stigma about dads not being involved as much as they should be. But when you go into an appointment with the mum...you don't exist. It's like mum made the baby and you're just brushed to the side.* [ID118]

In some instances, fathers reported feeling treated as auxiliary parents, in which child health information and systems are geared toward mothers who are designated as primary caregivers:

> *There's information that when you go through the system, the support and consultations. [But] the system is obviously more focused on the mother, so if the mother is not in a state to absorb that information, there's not as much information provided to the father.* [ID74]

Other fathers shared concerns about being judged and harbored distrust toward health professionals when seeking child health information. Information was regarded as *generic* or *overwhelming*. In 1 father's words, he felt coerced and judged by health institutions:

> *You feel a lot of pressure from government agencies that if [the child is] not eating this, you're not doing the right thing.* [ID95]

Highlighting the insufficient father-specific support in caregiving, feeding, and mental health, fathers expressed the importance of services to be sensitive to diverse family structures and care arrangements. One father indicated the following:

> *[I wish I have] more information about feeding, like how often do they feed, because my partner got that information, I got information of looking after [my] partner.* [ID213]

Such experiences could hinder fathers' self-esteem, creating barriers to seeking further support and developing their capabilities in child feeding:

> *No mental health side for the dads. When things got tough, I had to take all the responsibilities on...There's no one to talk to for my side of things.* [ID8]

Diverse Information Needs

Most fathers sought information on child nutrition and feeding from a range of sources, including family, health care providers, mass media (internet, television, and web-based videos) and social media, printed materials (leaflets and books), and community groups. The topics covered a broad spectrum, encompassing breastfeeding and bottle feeding, complimentary food, recipes, child appetite cues and eating behaviors, food safety, and allergies. Fathers often trusted their partners, deeming them as more organized and well informed. Family members, including grandparents and peers, acted as *sounding boards*, providing validation for ideas. Fathers also took measures to assess the reputability of the sources, such as using government websites. In addition, fathers value the expertise of health care workers who have a shared understanding of being a dad:

> *There was a doctor that was a dad, he gave us the rundown...you know, don't worry, it's just a dad thing. It was nice talking to a dad who is also a doctor.* [ID 8]

Inclusive Environment and Encouragement

To address fathers' unique needs and promote paternal involvement in child health, an inclusive environment where fathers feel welcomed is crucial. One father stated the following:

> *A workshop with the kid [would] be beneficial as long as you don't feel judged, [because] you are already feeling really vulnerable.* [ID64]

This vulnerability arises from experiencing financial and food insecurity while navigating fatherhood despite perceived gender stereotypes regarding parenting roles. Although some fathers discussed the need for self-determination in caregiving and feeding, others believed that child health initiatives and professionals should play a role in actively advocating for fathers' involvement, building relationships, and dismantling traditional gender stereotypes:

> *Having an ad campaign [and] for the midwife or paediatrician or obstetrician [to] brought up at the start of the pregnancy that it is going to be helpful if dad comes. When they get letters to attend appointments, have it addressed to the mum and the dad or says dad is encouraged to attend.* [ID118]

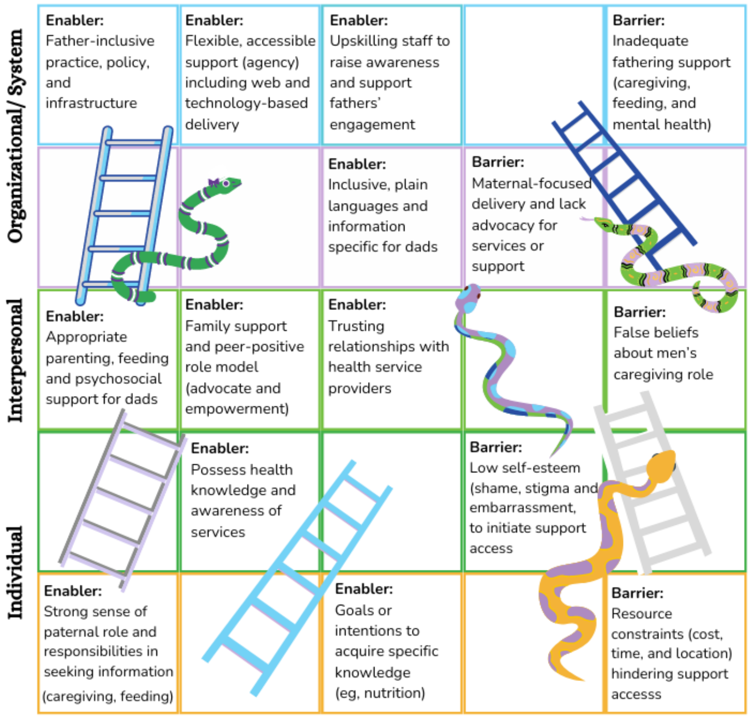
There was also a call for mothers to encourage fathers to fulfill the caregiver role and participate in feeding. For example, a father said the following:

> *If you're a mum, it's okay to tell your partner, that dads are allowed to do things.* [ID3]

Enablers and Barriers to Support Access

Figure 4 presents the interrelated enablers and barriers influencing fathers' access to support across individual, interpersonal, organizational, and system levels. The interviews first provided insights into fathers' enablers and barriers. The workshops allowed for more in-depth exploration, focusing on how to overcome barriers and leverage enablers through co-designed solutions. These factors were embedded into the workshop videos and activities, including the exemplar personas and presentation slides, to facilitate the ideation process.

Figure 4. Enablers and barriers for accessing support: presented as snakes and ladders.

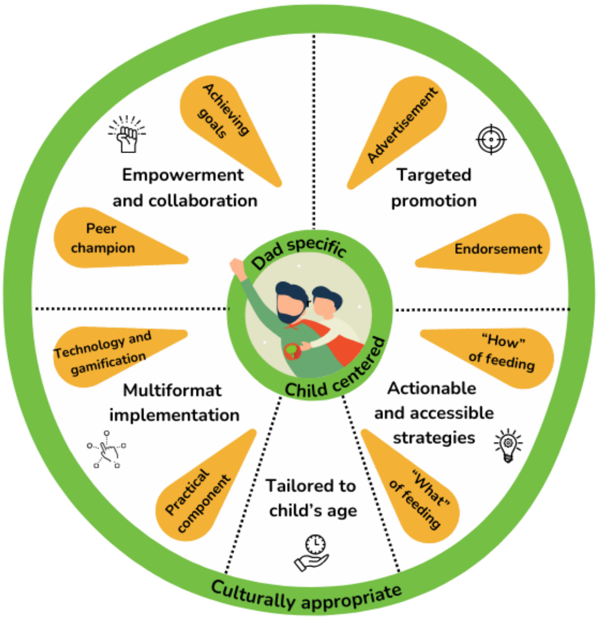


Co-Design Workshops

Overview

From the workshop data, 7 principles for engaging fathers in child nutrition interventions and resources were identified. These include (1) father specific and child centered, (2) empowerment and collaboration, (3) actionable and accessible strategies, (4) multiformat implementation, (5) culturally appropriate, (6) tailored to the child's age, and (7) targeted promotion. Illustrative quotes of each principle, along with the superhero name (if provided) or pseudonym and workshop number, are presented in Multimedia Appendix 2. These design principles encompass various aspects of interventions, from recruitment to content development, and are visually presented in Figure 5.

Figure 5. Design principles for engaging fathers in child nutrition interventions.



Father-Specific and Child-Centered

Fathers identified the need for child-centered interventions specifically designed for fathers themselves, given that most current food and nutrition content predominantly target mothers. Proposed *hooks* for actively engaging fathers in nutrition interventions included strengthening family connections through food, promoting personal growth, and enhancing father-child relationships. This involves supporting fathers to create affordable and nutritious meals, model healthy eating habits, and foster children's positive relationship with food. In 1 father's words, it is important that "dads lead by example [for their child], showing enthusiasm for healthy eating and trying new foods" (W1, Captain Aus). Interventions should involve the child in providing bonding opportunities, such as through "engaging recipes [so] the child can partake in cooking" (W2, Dr Strange). Personalization can support active engagement, which includes providing personalized meal plans and recipes and feedback on performance through using technologies such as mobile apps. Others described web-based tailored support with a moderator who would be able to drive conversations and respond to inquiries within father group chats:

> *Whoever monitors the dad groups—got to keep it positive to try and engage everyone. A lot of people join up to them, but no one comments [or] wants to go first, so if you're there positively backing up comment...The more people comment, you can get an active involved community...* [W1, Hulk]

Empowerment and Collaboration

Interventions should harness peer empowerment and collaboration to facilitate fathers' engagement. Fathers discussed the collective goals of addressing "the stigma that dads are not as good as mums" and being "proud to be a good dad and doing the best for our kids" (W3, Captain Wellness). Creating an interactive fathers' community to exchange ideas about child eating and demonstrate role modeling was thought to be a powerful avenue to build trust and confidence. Seeing other father ambassadors who "do not know how to cook" and realizing "their struggles are the same" was considered valuable:

> *It does [motivate you and empower fathers' identity] if we can create something...I have a family, I'm a father, but I'm independently able to do it...I cook an amazing meal and everyone eats it, it's like "damn right, I did that." It's good for the soul...* [W1, Superdad]

Fathers identified the opportunity for empowerment through self-monitoring and incentivizing behaviors, such as tracking progress and earning badges when mastering a food ingredient and technique or budgeting skills. The ability to act as a peer champion, coaching novice fathers or competing with others, was considered effective in fostering collaboration:

> *I'm always driven to be better than I was yesterday...I see cooking as my own development...In a digital environment, I would look for ways that show progress...like last 12 months, I've made x amount of meals, and gone from beginner to more advanced or*

> *experience more recipes or more ingredients in a way that I can sort of compete with myself and my peers.* [W2, Dr Strange]

Actionable and Accessible Strategies

Fathers described the necessity for bite-sized and actionable strategies regarding the *how* and *what* of child feeding and eating. This includes guidance on teaching nutrition-related information to their child, improving basic food skills (eg, gardening and cooking), and addressing common concerns around infant feeding (eg, allergies and food safety) and fussy eating behaviors:

> *Showing dads how different foods can improve your kids in different ways, like your kids need to have this because it can help with bones or be more active like this. If they don't have it, it may affect them like that.* [W2, Panther]

Fathers highlighted the importance of variety and simple recipes for an enjoyable meal preparation experience for the whole family. They discussed providing clear instructions and using language that resonates with fathers (eg, *recipes presented as a tech manual* and *building a meal*). Accessibility is crucial, considering factors such as time, location, cost, and literacy. Interventions that use technology and build fathers' capacity might overcome these challenges:

> *With time poor, budget constraints and income pressures, [the app, website, or workshop] sort of met the ideas of gaining control...and your competence in making [the meal]. So you sort of alleviate those stresses...* [W2, Flash]

Multiformat Implementation

Fathers sought to move beyond traditional handouts to use technology-based delivery for more personalization. Suggestions included popular social media platforms to host group discussions and websites and mobile apps to provide child nutrition information. These elements should be complemented with behavioral prompts that provide simple educational messages or reminders to prompt action (eg, fridge magnets in prominent places or email reminders). In addition to information provision, practical components, such as video or in-person cooking workshops involving children, remain critical. Gamification could be integrated to enhance engagement, adding an interactive and playful dimension:

> *It would have to be multiformat. One format may not work. The more engagement you can get whether it is one central platform, then you run workshops off the side to get engagement. That's [what] I would enjoy more.* [W1, Superdad]
>
> *I see an app supported by a website, [which] give the same info, but the app would gamify it...This makes it fun, something my son and I can work towards together. He understands games and that keeps him engaged...[like] list of foods to try, get rewards when we try them.* [W3, Thor]

Culturally Appropriate

Food embodies connections, experiences, and culture. Interventions should consider cultural diversity, family dynamics and values, the cost of food, and the skills of those doing the preparation, recognizing that the significance of food extends beyond nourishment to encompass cultural identity and shared experiences. For example, 1 father discussed the need for intervention design to be sensitive to cultural identity:

> *Different cultures, food and family dynamics...It's how you brought up [and] your key beliefs. My wife eats certain foods that I don't eat because of our backgrounds, so my children get to choose what they eat. So saying this is what we're going to eat and this is the recipe, cook on this day wouldn't work for everyone. I'd have to consider different backgrounds and cultures.* [W3, Captain Wellness]

Tailored to Child's Age

Fathers discussed the provision of timely materials tailored to the development stages of children, considering the introduction of complementary foods and eating milestones (eg, supporting breastfeeding, age-appropriate recipes, transitioning food texture, and key nutrients). Some fathers suggested that it would be beneficial to provide resources on food allergies and food safety (eg, choking risks) as well as children's capabilities to engage in different food tasks (eg, holding a knife) at different ages:

> *I guess my vision is a database...of tips, hints, and advice of different stages of eating and what to do or try. Obviously different stages of age and life development they go through different eating habits...* [W1, Superdad]

Targeted Promotion

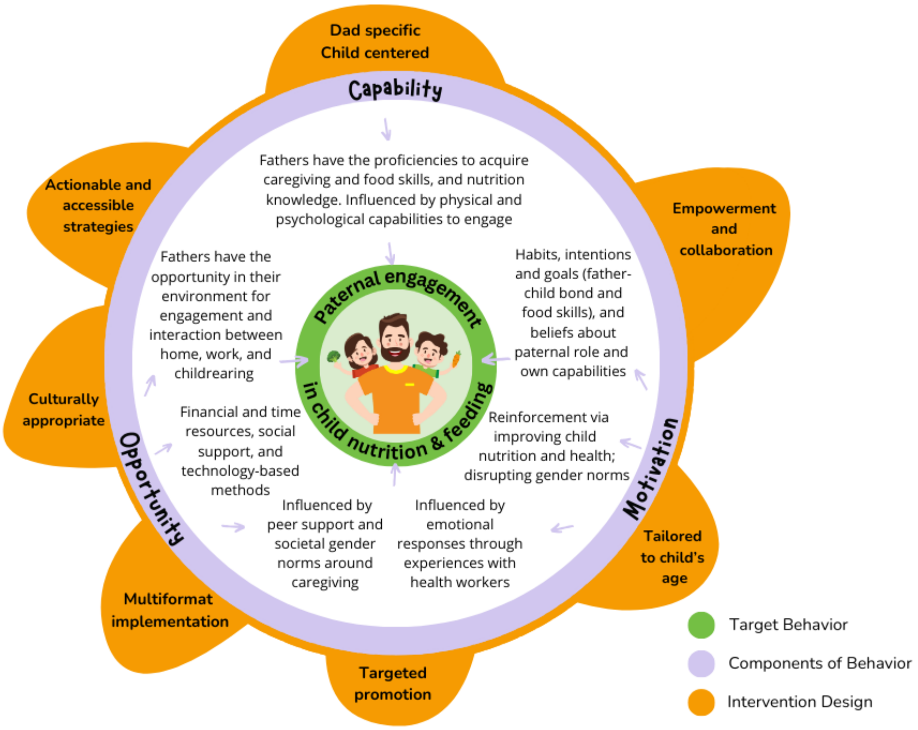
Fathers described a comprehensive, father-targeted promotion strategy using various channels. Marketing was recommended in places traditionally directed at men (eg, hardware and sports venues), web-based platforms (eg, YouTube and Facebook) and community spaces (eg, childcare centers, sports venues, and grocery shops). They acknowledged the influential role of mothers in effectively reaching fathers. Framing of the intervention was key to appealing to fathers, specifically using the word *dads* and father images for promotion purposes. Fathers emphasized the value of endorsement from peers (*someone like me*) and experts (eg, celebrity chefs, health professionals, and academics), who are also fathers, to enhance relatability and trust:

> *I guess like [facilitator's name], PhD, told me something, it's good. I'd go along with it because you got the credential...I'm happy to follow the authorities and the research, peer reviewed studies...well, okay I will do that.* [W1, Hulk]

Integration With the COM-B Model

The COM-B model provided a theoretical lens to integrate findings to inform intervention design that facilitates fathers' engagement in child nutrition. Figure 6 visually illustrates the underlying components of behavior change, encompassing capability (eg, physical and psychological capabilities to acquire food skills and nutrition knowledge), opportunity (eg, material and time resources and social support), and motivation (eg, intentions, goals, and reinforcement). The intertwined design principles can be leveraged to address each component: capacity (eg, through actionable and accessible strategies), opportunity (eg, via multiformat implementation and targeted promotion), and motivation (eg, by being father specific and fostering empowerment and collaboration).

Figure 6. Intervention design: integrating findings with the Capability, Opportunity, and Motivation–Behavior model.



Discussion

Principal Findings

This research offers valuable insight into fathers' experiences when accessing support related to parenting and child feeding and nutrition information, recognizing the enablers and barriers at individual, interpersonal, organizational, and systemic levels. Fathers' intrinsic motivation concerning fatherhood, trusting relationships, social support, and perceived usefulness of information are crucial for active paternal engagement in accessing support related to parenting and child feeding. Conversely, support access is hindered by adverse experiences with health services, fear of judgment, resource constraints (ie, time and location for face-to-face delivery), and gender expectations.

Key principles for child nutrition interventions were identified through co-design. The results indicated that interventions and resources need to be (1) father specific and child centered; (2) leverage empowerment and collaboration; (3) provide actionable and accessible strategies on the *what* and *how* of child feeding; (4) implemented in multiple formats, including technologies; (5) culturally appropriate for diverse practices and values; (6) tailored to child's age and developmental needs; and (7) promoted directly to fathers to engage them effectively.

Drawing from the COM-B model, it is crucial to identify and address barriers when designing interventions to optimize parental feeding and nutrition in children. One significant barrier to fathers' inclusion in public health nutrition initiatives is rooted in gender ideology. Traditional masculinities (reflecting *motivation* of behavior change), characterized by risk taking, invulnerability, plenitude, and autonomous decision-making [10,36], can impede fathers from seeking support in regard to child health and nutrition. These gendered traits may manifest in child feeding, in which the nurturing role or responsibility for child health is typically associated with maternal identity. In this study, some fathers considered healthy eating as *common sense*. Thus, these role expectations and perceptions may deter fathers from seeking information on their children's nutrition.

Qualitative studies with fathers have shed light on the barriers to paternal involvement in child health and nutrition initiatives, such as the Special Supplemental Nutrition Program for Women, Infants, and Children in the United States [37]. The key challenges reported in this study include pride in masculinity, coercion, unacknowledged roles, and feelings of exclusion [37]. Although aiming to improve the health and nutrition of low-income women and children aged <5 years, only a few local offices strive to invite men to participate [38]. The Special Supplemental Nutrition Program for Women, Infants, and Children's name, program structures, and staff-client interactions have been criticized for being unwelcoming and unresponsive to family dynamics and paternal roles [37]. Similarly, fathers in this study stressed the importance of encouragement, inclusiveness, and a father-specific environment (linking both *opportunity* and *motivation* of COM-B) as they navigate their fatherhood role. Thus, intervention designs should engage fathers as a distinct target demographic, using platforms and resources that resonate with men (eg, father imagery and wordings in the promotion and educational materials, technology-based activities, and suitable time outside of regular work hours when providing support).

Many fathers in this study actively sought information on child nutrition from various channels, including health care workers, family, peers, and the internet. Future interventions need to account for the diverse sources fathers seek information from by leveraging these platforms to reach fathers effectively. For instance, health care workers can raise awareness of intervention studies through their services, or mothers can act as agents to promote study information to fathers (*opportunity*). Accessing information through other fathers suggests the potential benefits of mobilizing peer empowerment as a resource to facilitate paternal engagement in child nutrition interventions (*motivation*). Participants in the workshops further expressed an interest in learning about nutrition (*capability*), particularly if their children are the focus. This child-centric approach is consistent with previous research [35,39]. For example, fathers preferred engaging in nutrition intervention with their children and the whole family rather than being targeted themselves [35]. Communicating a clear goal and benefits of fostering father-child bonding has been suggested to be valuable for parenting interventions targeting fathers [40]. This bonding opportunity can be applied to the feeding context, in which emphasizing positive father-child feeding interactions may enhance future intervention uptake.

This study highlights the underlying motivators for paternal engagement in child nutrition, including supporting fathers as role models for their children's eating behaviors and building positive relationships with food (*capability*). Fathers clearly indicated a preference for participating in interventions *with* their children rather than *for* them, whether through in-person programs or technology-based platforms. The success of the *Health Dads, Healthy Kids* (HDHK) and *Healthy Youngsters, Healthy Dads* (HYHD) community-based RCTs in Australia serves as a renowned example internationally [41,42]. Both programs effectively engage fathers and children (aged 5-12 years in HDHK and aged 3-5 years in HYHD) in learning about healthy eating and physical activity [41,42]. Notably, these interventions yielded favorable effects on various outcomes, including improved fathers' and children's weight outcomes, physical activity levels, and dietary intakes [41,43-45]. A core feature of HDHK and HYHD is its family-based approach, which aims to improve men's and children's well-being simultaneously, focusing on fathers as positive role models and implementing effective parenting strategies. Incorporating practical and theoretical components, the programs offered activities and resources for fathers (eg, manual for dads) and children (eg, activity handbook) individually, as well as opportunities for joint participation (eg, rough and tumble play) [41,42]. HDHK and HYHD have been tailored to men using humor, language, and content that cater to their needs. In addition, they used behavior change techniques, such as monitoring, goal setting, and social support. However, these programs have been implemented with older children. Nutrition interventions involving young children may necessitate adaptations to match their developmental stages and warrant further investigation with fathers and other stakeholders.

In-person delivery, such as that offered by the HDHK or HYHD programs, could pose barriers for certain families, such as those with time and geographic constraints and work commitments. Indeed, fathers in this study emphasized there is no one-size-fits-all approach, advocating for multiformat implementation (*opportunity*). Interventions using technology, such as websites, web-based chat groups, social media, and mobile apps, were recognized as providing more pragmatic options while maintaining interactive elements. This is comparable to a survey study examining Australian fathers' preferences for child nutrition interventions, in which web-based programs were deemed the most popular delivery mode, followed by written materials [35]. Similarly, the *Fathers Infant Feeding Initiative* reported paternal preferences for the internet, email, and video as the basis for delivering perinatal programs supporting breastfeeding [46]. Digital delivery offers a cost-effective and scalable format to provide family-based health programs while overcoming accessibility issues [47]. *Milk Man* is a father-focused app that exemplifies using mobile technology to provide social support and information about breastfeeding [48]. In their process evaluation involving 586 fathers, push SMS text messaging notifications and web-based conversation forums were found to be integral to the app's success, prompting fathers to post comments and access articles and external links. One-third of users also indicated gamification as a key motivator for app use [49]. A previous review of RCTs using gamification found promising results in enhancing nutritional knowledge and dietary behaviors among children and adolescents [50]. Fathers in this workshop study similarly favored interactive games and visual content. Therefore, technology-based intervention designs can be expanded to target other areas of child nutrition. Additional research is crucial to examine the acceptability and feasibility of game-based interventions for fathers with young children.

In a systematic review of interventions designed to shift men's attitudes and behaviors in relation to gendered stereotypes, interactive learning, co-design, and peer leadership emerged as cornerstones for maximizing impact [51]. In a recent practice article, Moura and Philippe [10] proposed recommendations for recruitment, focus, and methods to facilitate fathers' engagement in child-feeding research. They advocated for culturally appropriate, child-focused interventions with a clear framing of the *father* and a focus on lived experiences, using participatory web-based activities and tailored and flexible materials. Several studies also recommended peer-based recruitment and messages (*someone like me*) based on fathers' interests and characteristics (ie, small-time commitment and incentives) [10,11,40,52]. The co-designed principles derived from the workshops corroborate with these recommendations, incorporating insights from fathers experiencing disadvantage. An earlier study involving fathers with low-income status emphasized that nutrition education should focus on food as opposed to complex nutritional knowledge, as well as framing basic nutrition information positively [39]. Simple, actionable strategies that translate knowledge into practice were paramount for fathers in this study. Equally important is the provision of evidence-based information, demonstrated by their efforts to seek credible sources and experts' advice. Collaborative input from fathers on content and messages, combined with professional expertise, can create solutions that prioritize relationships and maximize intervention impact.

These findings present new perspectives that diverge from existing research. For instance, Jansen et al [35] reported that fathers preferred a whole-of-family focus over a fathers-only program. This contrasted with this study, in which participants emphasized the need for a father-only community for sharing and peer encouragement. This was rationalized by their shared experience pertaining to fatherhood and their collective goal of addressing gender stereotypes. Although some fathers discussed sharing information with other family members (apps and websites), certain elements of the intervention (eg, chat groups) that remain father exclusive may be beneficial.

An SMS text message–based intervention has been shown to be acceptable in providing men breastfeeding support in Ethiopia [53] and in Australia, where programs such as *SMS4dads* offered perinatal support related to mental health and parenting [54]; this intervention mode was not raised by fathers in this study. However, digital modes of intervention emerged as a common thread in the discussions. Although SMS text messaging may not offer sufficient practicability for certain nutrition topics, such as food skills and recipes, communication through emails, text messages for promotion, and linked information is considered feasible. Intervention design would benefit from building on this co-design study to determine how individual components and formats can complement each other to elicit positive outcomes. This is of great importance for scaling up programs to be embedded into services and informing policies.

Limitations

The interview and workshop studies have limitations that should be considered in interpreting the results. Fathers who took part in this research were less representative of the Australian male population in terms of education levels. National data indicate that approximately 38% of men aged 25 to 44 years held a university degree [55], a proportion lower than the 57% observed in this sample. Most participants were in relationships, resided with their child full time, and identified as Australian. The self-selection nature of the studies may inadvertently exclude fathers who are less involved, less interested in child nutrition, or more susceptible to entrenched disadvantage, such as single fathers, those with lower literacy, individuals who are unemployed and socially isolated, Indigenous Australians, or culturally and linguistically diverse communities. Future studies could use a more comprehensive sampling strategy to ensure diversity, including fathers with varying education levels, ethnicities, relationship statuses, family sizes, and relationships with the child (ie, biological vs social).

Furthermore, the workshop findings should be considered in light of the group setting and technology used. Individuals less inclined toward group discussion or lacking English language proficiency may not have participated. The study design may favor those who are familiar with using videoconference software. Consequently, these factors pose a potential limitation to the generalizability of the findings, particularly concerning preferences for technology-based and interactive interventions. Future research should strive to identify and recruit a more diverse range of male caregivers. Child nutrition interventions would gain from fathers' perspectives from various family dynamics, such as same-sex fathers and nonbiological fathers and diverse cultural backgrounds, to co-design culturally appropriate engagement strategies.

Implications for Research, Practice, and Policy

This research holds implications for practice, research, and policy. Amplifying fathers' voices in child health research recognizes the developmental benefits of paternal involvement in nurturing care and optimal nutrition. Co-design, which harnesses the lived experience expertise of fathers facing disadvantage, strengthens their capacity to contribute to public health initiatives. Future interventions seeking to effectively engage fathers could incorporate the co-designed principles into their planning and delivery.

Although the primary aim of this research was to inform intervention design, the findings have the potential to be extrapolated for health service delivery and policy development. Existing evidence suggests that fathers encounter accessibility barriers when engaging with services. For example, a study on Australian fathers' participation in antenatal care highlighted a gendered approach in providing parenting support, lack of knowledge and decision-making involvement, and paternal anxiety as notable barriers [56]. In addition, paternal depression symptoms were found to be linked to fathers' perceived lack of support and poor father-child and coparent relationships [57]. The design principles identified in our workshops align well with best practice and father-inclusive guidelines, which advocate for a revaluation of how services are planned and delivered to be responsive to fathers' needs and recognize their strengths [58,59]. The enablers and barriers identified provide valuable direction for parenting and child health services, policies, and infrastructure, especially in tailoring child nutrition information for fathers. These findings underscore the importance of a systemic approach to dismantle gender stereotypes, provide feeding and psychosocial support, and strengthen father-child relationships to achieve positive outcomes for children.

Conclusions

Fathers encounter substantial barriers when accessing support and information related to parenting and child feeding, and existing resources are inadequate for their needs. To harness the lived experience of fathers, future interventions could incorporate the co-designed principles developed in this study to effectively engage fathers. These findings hold implications for health service delivery and policy development, advocating for practices that foster fathers' engagement.

Acknowledgments

JTHS received a PhD scholarship from Queensland University of Technology and a top-up from the Queensland Children's Hospital Foundation (QCHF). KAB and DG are supported by a philanthropic grant from QCHF via Woolworths. Neither Woolworths nor QCHF were involved in the research design and data collection, the evaluation of the scientific quality of the research, or the establishment of the center governance. They have no access to the raw data from the research and no control over the dissemination of findings. RB is supported by an Australian Research Council Discovery Early Career Research Award (DE230101053). The authors had no financial relationships or activities that could appear to have influenced this work. The authors sincerely thank the participants for their generosity and time participating in the interview and workshop study. The authors would also like to acknowledge the family and child service providers, organizations, and individuals who assisted with recruitment for the interviews. The authors appreciate the contributions of Dr Jeremy Kerr in terms of his expertise and feedback on the workshop design. Finally, the authors thank the fathers who participated in the pilot workshop.

Authors' Contributions

This study was conceptualized by all authors. JTHS collected and analyzed the interview and workshop data and drafted the manuscript. KAB, SN, and DG assisted during the co-design workshops. All authors contributed to the interpretation of results, writing of the paper, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Rising childhood obesity rates in Asia are adding risk for the future adult burden of obesity and noncommunicable diseases. Weak policies across most Asian countries enable unrestricted marketing of obesogenic foods and beverages to children. Television is the common medium for food marketing to reach this audience.

Objective: This study aimed to assess the extent and nature of television food and nonalcoholic beverage marketing in 9 Asian countries (Bangladesh, China, India, Malaysia, Mongolia, Nepal, the Philippines, Sri Lanka, and Vietnam) with capacity building support from the International Network for Food and Obesity/Non-Communicable Disease Research, Monitoring and Action Support, who enabled harmonization of data collection method and content analyses.

Methods: Advertised foods were categorized as permitted or not permitted based on the nutrient profile models established by the World Health Organization regional offices for South-East Asia (SEARO) and the World Health Organization regional offices for Western Pacific (WPRO). Overall rates of food advertisements (advertisements per hour per channel) and persuasive strategy use were analyzed along with comparisons between children's peak viewing time (PVT) and non-PVT.

Results: Cross-country comparisons, irrespective of country income level, indicated that not permitted food advertising dominated children's popular television channels, especially during PVT with rates as per WPRO or SEARO criteria ranging from 2.40/2.29 (Malaysia) to 9.70/9.41 advertisements per hour per channel (the Philippines). Persuasive strategy rates were also comparatively higher during PVT. Sugar-sweetened beverages, sugar-containing solid foods, and high salt- and fat-containing snacks and fast foods were frequently advertised. Evaluation of the application of WPRO and SEARO nutrient profile models identified inconsistencies due to regional taste and cuisine variations across Asia.

Conclusions: This study clearly showed that unhealthy food marketing through popular children's television channels is widely occurring in Asia and is a clear breach of child rights. Evidence outcomes will benefit advocacy toward stronger policy regulations to control unhealthy food marketing and strengthen strategies to promote a healthier food environment for Asia's children.

Introduction

Rising childhood obesity rates are a global health issue, with Asia not immune to this trend. Almost half of the world's children younger than 5 years of age who are overweight or obese are living in Asia [1], a region that is also rapidly facing an upsurge in the prevalence of noncommunicable diseases (NCDs) such as diabetes, cardiovascular disease, and hypertension [2]. Even low- and middle-income countries (LMICs) in Asia, dealing with undernutrition as the traditional public health challenge, are not exempt from childhood overweight and obesity, particularly in urban settings [1]. Childhood obesity predicts NCD development in adulthood [3,4].

A systematic review of evidence examining interventions to prevent childhood obesity in the Asian region revealed that interventions tended to focus on children's school settings and targeted behavioral modification through nutrition or health education and physical activity sessions [5]. Focusing on such nutrition and physical activity promotion programs fails to account for the effects of the wider food environment, where unhealthy foods and beverages high in saturated and trans fats, added sugars and sodium (termed as high in fat, sugar, and salt [HFSS]), and usually highly processed [6] are highly available, accessible, and heavily promoted [7,8]. This food environment is consistent with growing transnational and regional food business across Asia [9].

Television advertising of unhealthy foods is a big driver of children's exposure to unhealthy food marketing [10-12]. Without question, children who are highly exposed to powerful marketing of HFSS foods are vulnerable to negative food behaviors that are conducive to overweight and obesity development [13-15]. Increased exposure of children to the marketing of unhealthy foods increases purchase requests [13,14] and develops tastes, preferences, and habits [16-19] for these foods. The habituation of unhealthy foods and beverages in children through advertising exposure is suggested by the World Health Organization (WHO) to be linked to childhood obesity [20].

Expenditure on television advertising rose from the year 2000 in the Asia-Pacific to reach US $55,692 million in 2024 [21]. Free-to-air, cable, or satellite television is a major media source in Asia [22] and comparatively more accessible for low-income households than digital media [23]. Therefore, the dominant influence of food marketing is through children's popular television channels, as observed in Malaysia [24], Thailand [25], and India [26]. Children's exposure to food advertising on television across Asia is largely unchecked because of weak or nonexistent regulations [27]. Slow policy progress is perpetuated by the lack of local research to document the extent of the issue and to hold industries accountable for protecting children from exploitation [8]. Further, current evidence on television food advertising is largely limited to high-income countries, and efforts are needed to support monitoring the nature of this advertising in low-resource settings [28]. Although some data are available for selected countries in Asia, including Malaysia [24,29] and Korea [30], only data from Korea have been able to inform favorable policy design. A major limitation of these Asian studies was the lack of uniform methodology, with researchers adopting varying approaches to categorize nutritional profiles of advertised foods. An Asia-Pacific comparison [31] involving China, Korea, Indonesia, and Malaysia benefited from the use of one standard methodology for data sourcing, recording, and coding but benchmarked nutritional comparisons to core and noncore food criteria rather than a standardized WHO nutrient profile model (NPM).

Acknowledging these gaps, a situational analysis was warranted to explore the extent and nature of unhealthy food and nonalcoholic beverage marketing through television across Asia. Further, the protection of children from exploitation as defined in the Conventions on the Rights of the Child [32] and specifically from unhealthy food marketing [33] constitutes child rights, which emphasizes the need to conduct this research in Asia. Keeping this in mind, we report on the outcomes of a collaboration between 9 Asian countries comprising 7 LMICs (Bangladesh, India, Mongolia, Nepal, the Philippines, Sri Lanka, and Vietnam) and 2 upper- and middle-income countries (China and Malaysia) [34]. This collaboration adopted the International Network for Food and Obesity/Non-Communicable Disease Research, Monitoring and Action Support (INFORMAS) food promotion module's television protocol [35], which harmonized data collection procedures to enable country comparisons on key variables measuring children's exposure to unhealthy food marketing in television. INFORMAS is a global network of public-interest organizations and researchers aiming to monitor, benchmark, and support public and private sectors to foster healthy food environments and combat obesity, NCDs, and their associated inequalities [36]. INFORMAS also served as a research stakeholder by supporting intensive capacity building in implementing a methodology for achieving the project's milestones.

Methods

Study Design

The 9 Asian countries in this collaborative study agreed to adopt the INFORMAS protocol for food promotion [35]. Briefly, this protocol requires country-specific contextual information to be collected through the recording of children's popular television channel broadcasting in order to identify food advertisements embedded between and during programs. This approach did not include other types of marketing such as product placement in shows and sponsorship of television shows. Food advertisements covered both solid foods and nonalcoholic beverages.

The INFORMAS methodology was adapted to enable a standard recording format to fit across the diverse food cultures, seasonal events, and children's schooling and holiday periods of each country. Further, the advent of COVID-19 introduced a disruption to obtaining country clearance, funding disbursements, and data recording schedules. This meant that data recording could not be conducted simultaneously for all countries.

Ethical Considerations

Depending on individual country regulations, some countries were exempted from obtaining ethics approval (India, Malaysia, Nepal, and the Philippines). Ethical clearance was not required for these countries for studies not involving human or animal subjects. Ethics approval was required for Bangladesh (IPH/AW/IRB/2020-21/03, institutional review board of the Institute of Public Health, Dhaka), China (202023, institutional review board of the Chinese Centers for Disease Control and Prevention), Mongolia (253, Ethics Committee under the Ministry of Health), Sri Lanka (EC-20-047, Ethics Review Committee, Faculty of Medicine, University of Colombo), and Vietnam (IRB-VN01057/IORG0008555, institutional review board of the National Institute of Hygiene and Epidemiology).

Sample Selection

Defining Children's Age Limit

Information on audience viewing patterns is usually sourced from media monitoring services and typically reported for children's age limit set <12 years [37,38]. However, for this study's purpose, age was defined according to country-specific regulations and considering the definition of the United Nations's Conventions on the Rights of the Child [6,32]. Most country teams set children's age as up to 18 years, except for India (up to 14 years), Sri Lanka (up to 15 years), the Philippines (up to 17 years), and Malaysia (up to 19 years).

Defining Popular Television Channels

The top 3 children's popular television channels for each country were selected based on children's viewership data [35]. These data were available from commercial media monitoring companies in China (Kuyun), India (Broadcast Audience Research Council), Malaysia (Nielsen), Mongolia (Maxima Consulting), the Philippines (Nielsen), Sri Lanka (Kantar), and Vietnam (Nielsen). Whereas in Bangladesh, popular channels were determined based on expert opinions (n=22), comprising television channel experts, advertising experts, food marketing officials, and caregivers. While in Nepal, expert opinions (n=6) were representative of the Ministry of Information Technology and Communication, national television children's program specialist, cable television service provider, the National Codex committee, and caregiver. Additionally, cross-sectional surveys on television viewing habits were conducted with children and caregivers in Bangladesh and Nepal (n=400 and 51, respectively). In China, findings from a digital survey on parents (n=193) of children and adolescents, aged 3-18 years, were used to validate the commercial data.

Defining Culinary Ingredients

Groceries such as rice, cooking oil, and seasonings were also being advertised in some countries during the sampled day's program broadcasting. These items were targeted to homemakers, as they were also television viewers during children's programs in Asia. Collaborating teams agreed to exclude these items from recorded data, as the intention was to count only packaged food and beverage products cognizant of children's exposure, direct purchasing request, and consumption. A list of these ingredients is provided in Table S1 in Multimedia Appendix 1, and the rates for these ingredients are compared in Table S2 in Multimedia Appendix 1.

Defining Peak Viewing Time

Television viewership data were also used to define peak viewing time (PVT) in each country. PVT represented the top five 1-hour time slots across the broadcast day, separated between weekdays and weekend days [39].

Training

Group training was conducted via videoconferencing by the project management team (PMT) formed by TK, GRO, and SSN with INFORMAS faculty support from SM and BK, to harmonize methodology across countries, prior to data collection.

Recording Protocol

An adapted recording protocol was adopted by all countries, whereby (1) the recording period was within a 3-month period, (2) convenience sampling was used to record for 4 weekdays and 4 weekend days, (3) the 8 recording days were within normal schooling weeks and excluding any public or school holidays and special events (eg, elections), and (4) concurrent recording was performed for 3 selected top channels with a recording duration up to 18 hours per day (6 to 12 AM).

Verification of Recording Procedures

Recording procedures were verified individually by the PMT for each country in one-to-one videoconferencing sessions, with support by faculty to troubleshoot issues. All country teams met the minimum data collection requirement. Some teams completed recording in 2020 (China, Malaysia, and Vietnam). Four teams rerecorded in 2021 (Bangladesh, Mongolia, the Philippines, and Nepal) due to limited viewership data access, school reopening after the COVID-19 lockdown, and data corruption issues. India and Sri Lanka teams completed recording after mid-2022 due to delays in obtaining their country clearance. The recording was performed by most countries using their own research teams, with the exception of outsourcing to providers by China (Kuyun) and Mongolia (Maxima Consulting) teams.

Coding for Healthy Versus Unhealthy Foods

Overview

Each country team assigned at least 2 researchers (student, research assistant, or coinvestigator) to perform the coding of recorded food advertisements. Ongoing support was provided by the PMT and INFORMAS faculty. The primary coding steps involved (1) coding variables for broadcast television channel, date, day, program name or category, and time slot. The time slot variable was classified into PVT or non-PVT. (2) Categorizing all advertisements in the recorded data into food and nonfood items. Advertised food products required brand information (name, description, and parent company). (3) Coding recorded data of advertised foods and beverages according to the NPMs proposed by the World Health Organization regional offices for Western Pacific (WPRO) [40] and World Health Organization regional offices for South-East Asia (SEARO) [41]. The NPMs allow for the classification of foods that should be "permitted" and "not permitted" to be marketed to children based on nutrient thresholds [40,41]. Both models were used, as the participating countries spanned both regions. Additionally, the INFORMAS food classification system was adopted for food products not included in the NPM classifications, such as infant formula, alcohol, and dietary supplements [35]. (4) Coding up to the 3 most prominent food products, as defined by INFORMAS protocol [35], where multiple food products were being promoted in an advertisement. In cases where coders were unable to determine the level of prominence, coding priority was based on the first products shown or coding from the top-left quadrant of the food advertisements for the purpose of sequencing [35]. (5) Conducting market surveys, preferably in physical stores or through digital resources in each country, to retrieve an advertised product's nutrient values to facilitate nutrient profiling. Products without nutrition information were labeled as "insufficient nutrition information panel." Products that were not covered by the WHO NPMs (eg, 1- to 3-year follow-up milk formulae) were identified as "not applicable." (6) Excluding data for banner advertisements and product placements during programs.

Reliability Testing

Intercoder reliability (IRR) testing within each country was performed by researchers who were responsible for the dataset coding. This required a randomly selected hour of television recording for testing reliability between coders according to the formula [35]:

$$\text{Agreement}/(\text{agreement}+\text{disagreement})\times 100$$

The minimum required IRR score was 90% agreement between researchers. If this was not achieved, then additional training was provided to the coder before retesting coding reliability with another television recording sample. Once the minimum IRR was achieved within a country, then IRR testing was conducted between countries. This required each country to submit coded data to the PMT for a random hour of recording. The PMT's coding for this dataset served as a comparator. The minimum required score was 80% agreement, and if this was not achieved, then a second or even a third IRR testing trial was conducted for a different hour of recording, following further training provided to the concerned country's primary coder.

Coding for Persuasive Power Strategies

Additional coding was performed for persuasive power strategies of marketing, comprising the use of power strategies and premium offers [35]. Up to 3 strategies per food advertisement were recorded.

Data Processing

Cleaning

Upon completion of data entry, cleaned Microsoft Excel datasets were provided to the PMT for cross-checking. Country teams corrected datasets based on feedback. Differences were resolved through discussion with the PMT and INFORMAS faculty.

Aggregation

Data were weighted based on weekdays and weekend days. Advertisements were aggregated into hourly time slot intervals. Factors explored for advertisement rate analysis were (1) children's viewing time (PVT vs non-PVT), (2) marketing permissibility (permitted vs not permitted), and (3) the use of persuasive power strategies.

Statistical Analysis

Statistical analysis was performed using SPSS (version 26.0; IBM Corp). A data analysis training workshop (KC, SM, and BK) was conducted for country teams. The PMT checked and consolidated all countries' datasets, before performing the final country comparator analyses.

Outputs for descriptive analysis to understand the extent of television food marketing were reported as mean (SD) for rate parameters (advertisements per hour per channel) applicable to all food advertisements, permitted food advertisements and not permitted food advertisements, and their ratios (permitted:not permitted) derived according to both WPRO and SEARO NPMs. Wilcoxon signed rank tests assessed comparisons between permitted versus not permitted food advertisements. Additionally, the Mann-Whitney *U* test assessed rate comparisons between PVT and non-PVT for not permitted food advertisements. Persuasive marketing strategies engaged for not permitted food advertisements, and interpreted as power strategies and premium offers, were also similarly assessed. Frequency analysis was then performed to understand the popularity of categories of not permitted food advertisements promoted on television according to WPRO and SEARO NPMs. This required coded items to be further consolidated to rank the top 5 most frequently advertised not permitted food categories (%). The significance threshold for all analyses was set at $P<.05$.

Results

Country Comparisons of Food Advertisement Rates for Permitted and Not Permitted Foods

For all 9 Asian countries investigated, food advertisement rates for not permitted foods were significantly higher (all $P<.05$) compared to permitted foods (Table 1). This trend was consistent, whether applying the criteria of the WPRO or SEARO NPMs. Advertisement rates for not permitted foods as per WPRO criteria were highest for the Philippines followed by Sri Lanka>Mongolia>India>Bangladesh>China>Nepal>Vietnam>Malaysia. This trend was also repeated when applying the SEARO criteria, except for not permitted food advertisement rates for China being greater than Bangladesh. However, comparisons between countries regarding the concentration of not permitted food advertisement rates, interpreted as ratio of permitted:not permitted advertisements, indicated that they were lowest for Sri Lanka and China, whereas the ratio of permitted:not permitted food advertisements was highest for Malaysia and Vietnam due to fewer permitted foods being promoted. Of interest, ratios for India and Bangladesh were higher with WPRO criteria than with SEARO criteria.

Table 1. Food advertisement rates for Asian countries as per World Health Organization regional offices for Western Pacific (WPRO) and World Health Organization regional offices for South-East Asia (SEARO) criteria.

Country	All food advertisements[a]	Food advertisement rates (advertisements per hour per channel)							
		WPRO				SEARO			
		Permitted, mean (SD)	Not permitted, mean (SD)	*P* value	Permitted:not permitted	Permitted, mean (SD)	Not permitted, mean (SD)	*P* value	Permitted:not permitted
Bangladesh	8.17 (8.32)	0.43 (1.21)	6.23 (6.67)	<.001	1:14.5	0.72 (1.29)	4.25 (6.00)	<.001	1:5.9
China	11.53 (10.07)	2.13 (2.84)	5.03 (8.57)	<.001	1:2.4	1.57 (2.07)	5.49 (9.60)	<.001	1:3.5

[a] All food advertisements include solid foods and beverages advertised. Includes advertisements for culinary ingredients, nutritional supplements, baby food, and follow-up formula. Additionally, the term also covers advertisements for food companies, retailers, and outlets that do not promote specific food products.

[b] For Vietnam, permitted:not permitted could not be determined with SEARO criteria.

Extent of Food Advertisements During PVT and Non-PVT

We further measured the appearance of not permitted food advertisements during PVT and non-PVT for all 9 countries (Table 2). For most countries, not permitted food advertisement rates occurring during PVT were significantly higher compared to rates during non-PVT regardless of both NPMs. For India and Nepal, there was no difference in the rates of not permitted food advertisements between PVT and non-PVT irrespective of both NPM criteria. For China, the rates of not permitted food advertisements when classified using the SEARO model were significantly higher during non-PVT. The difference observed for China as per WPRO (1.45 advertisements per hour per channel) and SEARO (1.29 advertisements per hour per channel) remained comparable but not significant.

Table 2. Appearance of not permitted food advertising during peak and nonpeak viewing times on television.

[a] Not permitted food advertisements include solid foods and beverages. It excludes advertisements for culinary ingredients, nutritional supplements, baby food, and follow-up formula.

[b] WPRO: World Health Organization regional offices for Western Pacific.

[c] SEARO: World Health Organization regional offices for South-East Asia.

[d] PVT: peak viewing time.

With both NPM criteria, not permitted food advertisement rates during PVT compared to non-PVT were nearly 1.7 times higher for Mongolia (WPRO: mean 11.19, SD 8.60 vs mean 6.62, SD 6.81 advertisements per hour per channel and SEARO: mean 10.99, SD 8.33 vs mean 6.62, 6.66 advertisements per hour per channel), nearly 2 times higher for Malaysia (WPRO: mean 3.58, SD 4.76 vs mean 1.95, SD 3.37 advertisements per hour per channel and SEARO: mean 3.45, SD 4.72 vs mean 1.85, SD 3.14 advertisements per hour per channel) and Bangladesh (WPRO: mean 9.31, SD 8.00 vs mean 5.04, SD 5.65 advertisements per hour per channel and SEARO: mean 6.73, SD 7.11 vs mean 3.30, SD 5.22 advertisements per hour per channel), and nearly 3 times higher for Vietnam (WPRO: mean 5.66, SD 7.18 vs mean 1.54, SD 4.65 advertisements per hour per channel and SEARO: mean 5.62, SD 7.32 vs mean 1.63, SD 4.81 advertisements per hour per channel).

Defining Engagement of Persuasive Strategies in Not Permitted Food Advertisements

We conducted content analyses to probe the nature of engagement used by persuasive strategies for not permitted food advertisements targeting children in the context of power strategies and premium offers, with comparisons during PVT and non-PVT (Table 3).

Rates for power strategies, irrespective of both NPMs, were significantly higher (*P*<.05) for most countries during PVT than non-PVT, with the highest rate observed for the Philippines (WPRO: 8.91 advertisements per hour per channel and SEARO: 8.82 advertisements per hour per channel) and the lowest for Malaysia (WPRO: 1.88 advertisements per hour per channel and SEARO: 1.84 advertisements per hour per channel). In contrast, rates of power strategies for not permitted foods in China and Nepal were significantly higher during non-PVT compared to PVT when classified using WPRO criteria, whereas power strategy rates in India remained similar during PVT and non-PVT irrespective of both NPMs.

When probing premium offers given for not permitted food advertisements, rates were significantly higher (*P*<.05) during PVT compared to non-PVT for most countries by either WPRO or SEARO criteria. Rates were the highest for Bangladesh (WPRO: 1.59 advertisements per hour per channel and SEARO: 1.59 advertisements per hour per channel) and lowest for China (WPRO: 0.06 advertisements per hour per channel and SEARO: 0.05 advertisements per hour per channel) irrespective of both NPMs. No premium offers were broadcast during PVT and non-PVT on Nepal television.

[a] Not permitted food advertisements include solid foods and beverages. It excludes advertisements for culinary ingredients, nutritional supplements, baby food, and follow-up formula.

[b] WPRO: World Health Organization regional offices for Western Pacific.

[c] SEARO: World Health Organization regional offices for South-East Asia.

[d] PVT: peak viewing time.

[e] Not available.

Nature of Most Frequently (%) Advertised Not Permitted Food Categories

We observed that the highest frequency (%) of advertisements for not permitted food categories, irrespective of both NPMs, was driven by HFSS foods and beverages (Figure 1), which varied between countries and likely reflected local popular tastes. When categorized by WPRO criteria, the highest advertisement frequency related to “other beverages” for Nepal, Bangladesh, and Mongolia; “savoury snacks” for China; “chocolate and sugar confectionery, energy bars, and sweet toppings and desserts” for India and Sri Lanka; “ready-made, convenience foods and composite dishes” for Malaysia; and “milk drinks” for Vietnam and the Philippines. When categorized by SEARO criteria, advertisement frequencies were still reflecting local taste preferences for HFSS products as per “water-based flavored drinks” for Bangladesh and Nepal, “milk and dairy based drinks” for Vietnam, the Philippines, and Mongolia; “confectionery” for India and Sri Lanka; “composite foods (prepared foods)” for Malaysia; and “cheese and analogues” for China.

We further appraised the combined share of the sugar and nonsugar sweetener–based beverage products for each country (Figure 2), which were prominent among the top 5 frequently advertised not permitted foods. As per WPRO criteria, this totaled 72.2% (n=2207) for Bangladesh, 67.4% (n=1583) for Vietnam, 66.6% (n=1607) for Nepal, 51.1% (n=3115) for the Philippines, 36.7% (n=1004) for China, 33.8% (n=2237) for Mongolia, 32.8% (n=1403) for India, 29.7% (n=1543) for Sri Lanka, and 24.2% (n=437) for Malaysia. Of note, the WPRO category for “energy drinks, tea and coffee” included beverages marketed without sweetening agents such as teas and coffees, which likely targeted adult consumers. With SEARO criteria, these data changed: 68.3% (n=1527) for Nepal>55.5% (n=1180) for Bangladesh>54.3% (n=1320) for Vietnam>52.9% (n=3506) for Mongolia>43.3% (n=2573) for the Philippines>22.7% (n=1185) for Sri Lanka>19.9% (n=348) for Malaysia>14.2% (n=540) for China>8.4% (n=277) for India.

High sugar-containing foods were also frequently advertised (Figure 3), with the combined share as per WPRO criteria being the highest for Sri Lanka (n=2103, 40.7%)>India (n=1384, 32.3%)>Malaysia (n=1384, 28.1%)>Nepal (n=550, 22.8%)>China (n=472, 17.3%)>Mongolia (n=1105, 16.7%)>Bangladesh (n=474, 15.5%)>the Philippines (n=621, 10.2%)>Vietnam (n=144, 6.1%). With SEARO criteria, some differences were indicated with India (n=1466, 44.6%)>Sri Lanka (n=2093, 40.1%)>Malaysia (n=507, 29%)>Bangladesh (n=474, 22.3%)>Nepal (n=454, 20.3%)>Mongolia (n=1105, 16.7%)>the Philippines (n=869, 14.7%)>China (n=254, 6.7%)>Vietnam (n=141, 5.8%).

Not permitted food advertisements characterized by high-sodium and high-fat content as per both NPM thresholds were among the top 5 frequently advertised foods in China. These were identified as "savoury snacks" (n=931, 34%) under WPRO, whereas "cheese and analogues" (n=1323, 34.8%) and "ready-to-eat savouries (savoury snack foods): potato, cereal or starch-based (from roots, tuber, or legumes) and animal based (from skin)" (n=911, 24%) were products categorized under SEARO (Figure 4). Similarly for Malaysia, Mongolia, and the Philippines, high advertising frequency trends were observed under WPRO criteria relating to "ready-made and convenience foods and composite dishes" and under SEARO criteria relating to "composite foods (prepared foods)."

Figure 1. Top 5 (%) most frequently advertised not permitted foods by WPRO and SEARO criteria. LMIC: low- and middle-income countries; SEARO: World Health Organization regional offices for South-East Asia; UMIC: upper- and middle-income countries; WPRO: World Health Organization regional offices for Western Pacific. *Example of other beverages includes chocolate malt beverages, juice drinks, mineral water, and carbonated soft drinks.

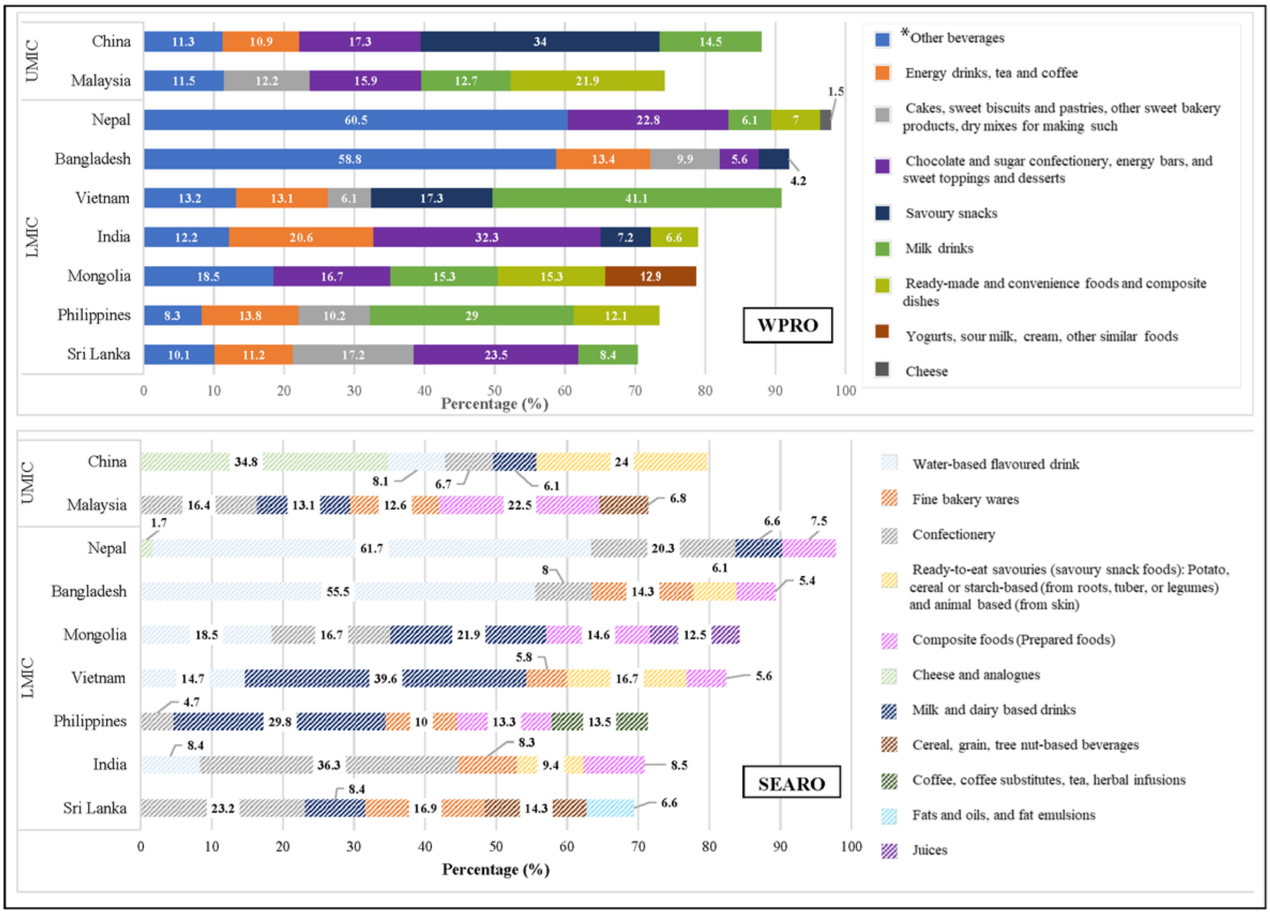

Figure 2. Top 5 (%) most frequently advertised not permitted products by WPRO and SEARO criteria as per combined estimates for sugar and nonsugar sweetener–based beverage products. LMIC: low- and middle-income countries; SEARO: World Health Organization regional offices for South-East Asia; UMIC: upper- and middle-income countries; WPRO: World Health Organization regional offices for Western Pacific.

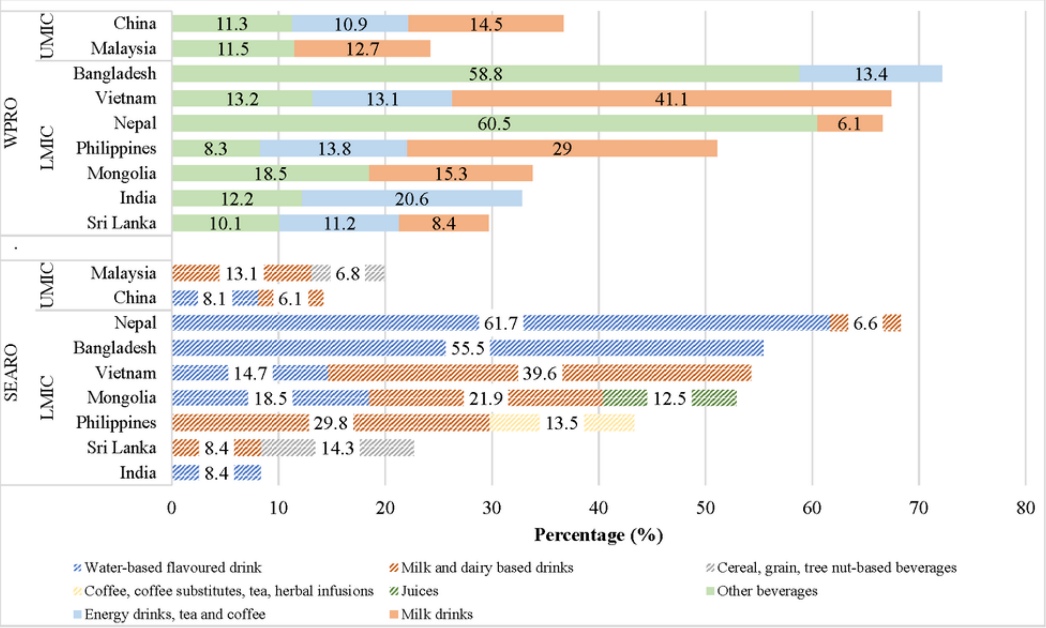

Figure 3. Top 5 (%) most frequently advertised not permitted products by WPRO and SEARO criteria as per combined estimates for sugar-concentrated solid food products. LMIC: low- and middle-income countries; SEARO: World Health Organization regional offices for South-East Asia; UMIC: upper- and middle-income countries; WPRO: World Health Organization regional offices for Western Pacific.

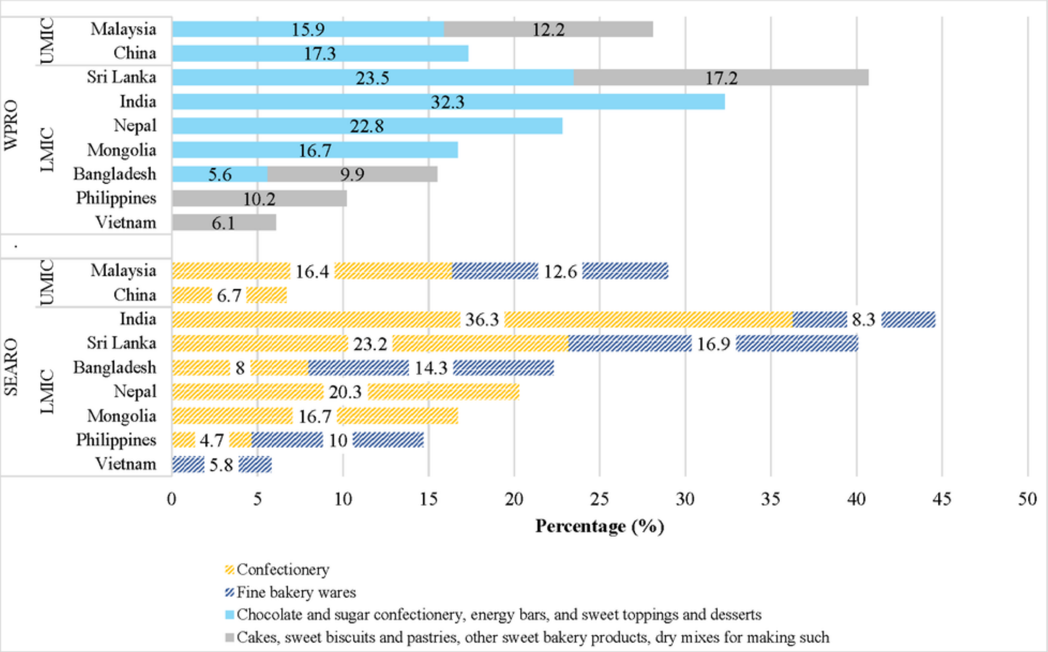

Figure 4. Top 5 (%) most frequently advertised not permitted products by WPRO and SEARO criteria as per combined estimates for high sodium- and fat-containing food products. LMIC: low- and middle-income countries; SEARO: World Health Organization regional offices for South-East Asia; UMIC: upper- and middle-income countries; WPRO: World Health Organization regional offices for Western Pacific. *Relevant products were not recorded.

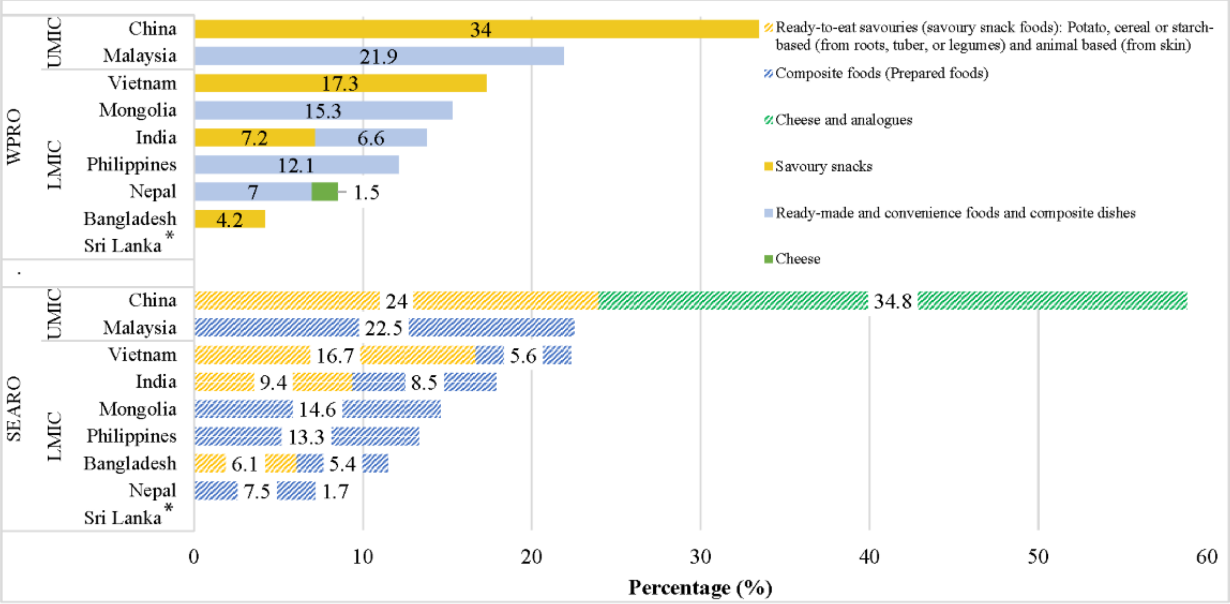

Discussion

Principal Findings

Rapid economic growth occurring in Asia over the last decades, accompanied by nutrition transition, has unfortunately seeded childhood obesity in many countries. This phenomenon of obesity is driven through the globalization of trade and the growth of transnational and regional food businesses, which nurtured increased access to unhealthy foods and beverages [9,42-44]. Much of the food manufactured for the Asian market promotes HFSS foods and beverages, and the extent of their marketing channeled through children's settings such as popular television was little understood in Asia [11,24,25,29,31,45]. This research provides the first baseline evidence on the extent and nature of unhealthy television food marketing to children and adolescents across 9 Asian countries (Bangladesh, China, India, Malaysia, Mongolia, Nepal, the Philippines, Sri Lanka, and Vietnam) using the uniform approach of INFORMAS [35]. Participating countries representing LMICs at various stages of epidemiological, demographic, and nutrition transitions presented an opportunity to compare and contrast the extent and type of marketing. Policy commitments to regulate unhealthy food marketing on television and other media are not mandatory in most Asian countries [27], and industry commitments to self-regulate appear to be the norm for some of the countries participating in this study.

Using INFORMAS methodology to harmonize measurement approaches, we showed that unhealthy foods, defined as "not permitted" by WHO criteria for the NPMs established for the WPRO and SEARO regions in Asia [40,41], overwhelmingly dominated food advertising through children's popular television channels in the 9 Asian countries studied. The advertisement rate was highly varied between countries, ranging from almost 10 "not permitted" food advertisements per hour in the Philippines and Sri Lanka to 2 per hour in Malaysia. The rates observed in this study were lower than an earlier cross-country study in the Asia-Pacific region in 2014, which used a different food classification system to rate "noncore" (unhealthy) food advertising, reported rates ranging from 2.3 advertisements per hour per channel for South Korea to 16.7 advertisements per hour per channel for Indonesia [31]. This finding aligns with studies from Slovenia, Chile, and Thailand, which, in benchmarking food advertisements to standards of perceived thresholds for the "danger" HFSS nutrients, detected a high concentration of unhealthy food advertisements on children's popular television channels [46-48].

With the exception of India, China, and Nepal, most countries observed higher rates of not permitted food advertisements during the broadcast periods most popular with children compared to non-PVTs. This aligns with earlier studies [31,39,49], which also found higher rates of unhealthy food advertising during children's PVTs. Uniquely, China had significantly lower rates of not permitted food advertisements during children's PVTs compared to non-PVTs based on the SEARO classification. This may be attributed to local advertising regulations in China, which require several advertising slots to be reserved for public service advertisements (including healthy food such as fresh fruit) during these broadcast periods [50].

The use of persuasive marketing techniques embedded in not permitted food advertisements was also significantly higher during children's PVTs in most of the participating countries, which also concurs with previous multicountry studies [31,39] showing higher rates of promotional characters and premium offers during children's PVTs compared to non-PVTs. Taken together, the higher rate of unhealthy food marketing during popular broadcast times for children and the higher use of persuasive marketing techniques that appeal to children during these broadcast times clearly suggest advertisers are targeting children with unhealthy food advertising.

As this study used both the WPRO and SEARO NPM to classify advertised foods, it became possible to explore differences in the performance of these systems in categorizing food marketing across Asian countries. SEARO is the NPM applicable to India, Nepal, Sri Lanka, and Bangladesh, whereas WPRO is applicable to China, Malaysia, Mongolia, the Philippines, and Vietnam. Prior to this study, most studies investigating content analyses [12,39,51] related to the WHO model of the Europe Regional Office [52]. Applicable to the Asian scenario, this study therefore is the first to relate content analyses of food advertising to WPRO [40] and SEARO NPMs [41].

Application of the SEARO model compared to the WPRO model led to a lower ratio of "permitted" to "not permitted" advertised foods for most countries, except China and Sri Lanka, where ratios were comparable between the 2 NPMs. Differences occurred when healthy food and beverage items such as plain mineral water were included under WPRO but not included in the SEARO model. Another reason for higher ratios associated with WPRO was the exclusion of culinary ingredients, which otherwise would be identified as permitted food advertisements.

Upon further comparing WPRO and SEARO criteria, the fewer beverage categories available under WPRO lead to more products to be accommodated within a category. For example, both carbonated and chocolate malt drinks are grouped under "other beverages." Whereas under SEARO, these beverages are grouped separately as carbonated drinks under "water-based flavoured drinks" and chocolate malt beverage products under "cereal, grain, tree nut-based beverages." In scrutinizing the combined share of beverages among the top 5 frequently advertised not permitted foods, we noted higher frequencies for India and China using WPRO criteria for 2 categories, namely "energy drinks, tea and coffee" and "other beverages." However, the single beverage category of the SEARO criteria, vis à vis "water-based flavoured drink," generated lower frequencies when combining the top 5 beverages. Food advertisements categorized under "energy drinks, tea and coffee" as per WPRO criteria would be considered as not permitted with or without sugar content [40]. Whereas a total sugar threshold of up to 2 g would be permitted for categories such as "coffee, coffee substitutes, tea, herbal infusions" and "water-based flavoured drink" (which included energy drinks) or up to 6 g for "cereal, grain, tree nut-based beverages" under the SEARO criteria [41].

Even when considering sugar-concentrated solid food products, differences between NPMs could be explained by categories such as "chocolate and sugar confectionery, energy bars, and sweet toppings and desserts" as well as "cakes, sweet biscuits and pastries, other sweet bakery products, dry mixes for making such" were not allowed to be marketed under WPRO regardless of sugar level [40]. Whereas SEARO allowed a total sugar threshold of up to 6 g [41]. Contrarily, the "cheese" category under SEARO, despite identifying foods with high-sodium and high-fat thresholds as not permitted, includes an additional criterion of "zero" tolerance for added sugar [40,41].

Advertising of fast foods is a concern for Malaysia, Mongolia, and the Philippines with high advertising frequency trends for "ready-made and convenience foods and composite dishes" under WPRO and composite foods (prepared foods) under SEARO criteria. The implication for Malaysia, in particular, is a failure of a self-regulatory policy known as the *Guideline on the Advertising and Nutrition Information Labelling of Fast Foods* [53,54]. This guideline was introduced in 2008 to restrict advertising of fast food during children's programs if ≥4% of children aged 4-9 years comprise the television viewing audience. However, the guideline is not legislated, and government-led monitoring for the guideline is lacking [54].

A trait of television advertising in Asia is featuring culinary ingredients even during PVTs [24,26,45]. It is noted that PVT equates to prime time for Asian families, running between 6 and 11 PM, which also attracts the viewership of the whole family. It is not surprising that this period also carries advertisements for culinary ingredients targeting women, as women traditionally purchase foods for their household, cook foods, and decide what the family consumes [55]. Additionally, labels of culinary items featured in advertisements will not provide serving size, as they are ingredients combined with other ingredients in cooking meals. Unique culinary practices in the Asian region follow recipes prepared in the home requiring many staples (eg, uncooked rice, cooking oil, spices, seasoning powder, uncooked meat, chicken or vegetable stock, recipe premix, plain sugar, stevia, plain flour, breading mix, lentils, and coconut milk). For Malaysia and Vietnam, items such as uncooked rice and soybean cooking oil would otherwise be identified as permitted foods as per WPRO criteria (Table S2 in Multimedia Appendix 1). We, therefore, excluded culinary ingredients from our analyses.

Strength and Limitations

A major strength of this study was the harmonized measurement approaches adopted by all 9 Asian countries, enabled comparisons between countries using 2 WHO NPMs for determining the extent, intensity, and nature of unhealthy food marketing on television. The comparative assessment of WPRO and SEARO NPMs across the 9 Asian countries facilitated the identification of inconsistencies in their application to categorize food advertisements due to regional and cuisine differences, thereby indicating the need for improvement across these 2 models. Overall, the findings from this study contribute evidence of the need to strengthen local regulatory frameworks in each country to stimulate advocacy to stakeholders. Of priority, there is an urgent call for mandatory policy action in Asian countries to restrict children's exposure to unhealthy food marketing on television to protect them from the harmful impact of food marketing [6]. Ultimately, a comprehensive regulatory framework with consistent monitoring over time should enable the reduction of exposure and power of unhealthy food marketing directed to children. A further benefit in conducting this study was that the collaboration achieved between country teams and INFORMAS experts enabled the exchange of technical knowledge and building the capacity of researchers across the 9 Asian countries.

This study's protocol required recording advertisements shown on the top 3 children's popular television channels for each country rather than measuring actual children's media exposure. The latter approach to measure actual targeted media exposure of children to television is experimental, with behavioral research methodology being varied and challenging to execute in multicountry scenarios where a harmonized protocol in low-resource settings is critically required [56]. Second, as this study was initiated during the COVID-19 lockdown occurring in all countries, we adopted convenience sampling to accommodate permitted travel days to the recording site. However, COVID-19 may have changed the nature of advertising, as this period may not have reflected the usual advertising pattern. Coding challenges for food products were encountered where countries lacked mandatory labeling regulation, such as Vietnam. In such cases, researchers would refer to their country's or the neighboring country's food composition database.

Future Directions

Future research on television food marketing in individual countries should consider recording more television channels, such as in India and China. Ideally, randomized sampling for recording days should be adopted, but randomization should be appropriate to the cultural diversity and practices in Asia. Given this successful collaboration between the Asian countries on television food marketing, there is now a need for explorative research on the digital food marketing landscape in Asia, as the food industry has expanded its marketing strategy to digital media platforms.

Conclusions

This project's collaboration and use of harmonized methodology generated country-level evidence for 9 Asian countries on the exposure and power of unhealthy food marketing on television to children. Cross-country comparisons, irrespective of country income level, indicated that unhealthy food advertising dominated children's popular television channels with frequent advertising of sugar-sweetened beverages, sugar-containing solid food and snacks, and fast foods high in salt and fat, especially during PVTs. Clearly, unhealthy food marketing through popular children's television channels is occurring widely in Asia and is a clear breach of child rights. Evidence outcomes could be used to advocate for stronger policy regulations and implementation to control unhealthy food marketing, which will strengthen strategies promoting a healthier food environment for Asia's children.

Acknowledgments

The authors appreciate receiving extensive ground-level support from many research workers to execute research activities for this project, and the following persons are acknowledged as per country: Bangladesh: The authors acknowledge Sk Mizanur Rahman, Dr Atias Parvin, Dr Aysha Akter, and Dr Md Mofijul Islam Bulbul for data collection and coding. The authors also appreciate Prof Dr Shahnila Ferdousi for facilitating institutional support for this project. China: The authors acknowledge Kuyun Eye Grow for providing the data. The authors specifically thank Lei Nan, Xiang Lin, Cui Jia, Ye Lihong, and Liang Kaipeng for coding and conducting the market survey. India: Ms Nidhi Yadav and Ms Ankita Walia are appreciated for assistance with data collection and coding. The authors also appreciate Dr Vijay Pal Singh for technical support. Malaysia: Dr Ng See Hoe, a postdoctoral fellow, is acknowledged for initiating the groundwork for this project. Ms Cordelia Lim Kheng May is appreciated for managing all "news" communications with country teams until study completion. The authors acknowledge and appreciate Nielsen Malaysia for providing viewership data. Mongolia: The authors acknowledge the Nutrition Research officers from the Ministry of Health, Mongolia, for supporting the data collection and coding activities required for this project. Nepal: Dr Bhim Acharya (Mr; SAIFRN-Nepal chairperson) and Ms Shweta Rawal (research officer, SAIFRN-Nepal) are acknowledged for carrying out all research activities for this study until its completion. Philippines: Ms Michelle dL delos Santos and Ms Rica Magracia are acknowledged for data cleaning. Sri Lanka: Ms SMDR Samarakoon led data collection and data coding. Additional data coding was provided by Ms ANY Senevirathne, Ms H Abeysinghe, Ms BGWWP Piyasena, and Ms PP Weerasinghe. Prof Carukshi Arambepola guided data analysis, and Prof Piyanjali de Zoysa guided the market survey. Vietnam: The authors would like to thank staff from the Department of Non-Communicable Disease Control and Prevention and the National Institute of Hygiene and Epidemiology, Hanoi, Vietnam, who collected and coded the data. This study was fully supported by the International Development Research Centre, Canada (grant 109170-001).

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

TK, BS, SMMR, JZ, NK, BJ, RKP, EQB, TT, and NTTT conceptualized the project and contributed to the study design. TK, GRO, and SSN served as the project management team in providing training and data management for all participating countries. SM and BK provided a capacity building in the adoption of the International Network for Food and Obesity/Non-Communicable Disease Research, Monitoring and Action Support protocol. They together with KC also provided faculty support in the training involved for data analyses. Data collection and coding were mainly managed by individual countries' principal investigator and coprincipal investigator (TK, MJS, GRO, SMMR, MAU, YT, JZ, NK, NKS, BJ, ED, RKP, RP, EQB, ACR, TT, VPW, NTTT,

and PTH). The project management team consolidated the data from all participating country and conducted the statistical analysis. KC reviewed each country's results. TK, GRO, and SSN developed the first draft of the manuscript. All authors reviewed, revised, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The European Foundation for the Care of Newborn Infants (EFCNI) has promoted the importance of parental involvement in the care of children.

Objective: The study aimed to examine how the time required by parents to achieve autonomy in the care of their very low–birth weight newborn infants was modified during the implementation of a training program.

Methods: This was an observational prospective study in the context of a quality improvement initiative. The Cuídame (meaning "Take Care of Me" in English) program was aimed at achieving parental autonomy. It was implemented over 2 periods: period 1, from September 1, 2020, to June 15, 2021; and period 2, from July 15, 2021, to May 31, 2022. The days required by parents to achieve autonomy in several areas of care were collected from the electronic health system.

Results: A total of 54 and 43 families with newborn infants were recruited in periods 1 and 2, respectively. Less time was required to acheive autonomy in period 2 for participation in clinical rounds (median 10.5, IQR 5 - 20 vs 7, IQR 4 - 10.5 d; *P*<.001), feeding (median 53.5, IQR 34 - 68 vs 44.5, IQR 37 - 62 d; *P*=.049), and observation of neurobehavior (median 18, IQR 9 - 33 vs 11, IQR 7 - 16 d; *P*=.049). More time was required to achieve autonomy for kangaroo mother care (median 14, IQR 7 - 23 vs 21, IQR 10 - 31 d; *P*=.02), diaper change (median 9.5, IQR 4 - 20 vs 14.5, IQR 9 - 32 d; *P*=.04), and infection prevention (median 1, IQR 1 - 2 vs 6, IQR 3 - 12; *P*<.001).

Conclusions: Parents required less time to achieve autonomy for participation in clinical rounds, feeding, and observation of neurobehavior during the implementation of the training program. Nevertheless, they required more time to achieve autonomy for kangaroo mother care, diaper change, and infection prevention.

Introduction

The European Foundation for the Care of Newborn Infants (EFCNI) has promoted the importance of parental involvement in the care of children [1]. It has been expected that parental autonomy will result in additional benefits. Some programs have been created [2-4] to achieve such training. However, the time required by parents to become autonomous is unknown, particularly in the case of premature children.

The main objective of this study is to compare the number of days required by parents of very low–birth weight (VLBW) newborn infants to be autonomous in different areas of care during the 2 periods of implementation of a parental training program.

Methods

Overview

This observational prospective study was associated with a quality improvement initiative, aimed at increasing parental autonomy in the care of VLBW newborn infants during the implementation of the Cuídame (meaning "Take Care of Me" in English) program in a IIIC-level Spanish neonatal unit.

Prior to the implementation of this program, in 2020, materials were prepared, and meetings with the most sensitive health care providers to neurodevelopmental-centered care issues were conducted. The program was implemented over 2 periods (Table 1). Period 1 was from September 1, 2020, to June 15, 2021, representing the start of the implementation of the Cuídame program. Period 2 was from July 15, 2021, to May 31, 2022, representing complete implementation along with greater experience of the neonatal team.

Table . Actions carried out in the neonatal unit aimed at the implementation of the Cuídame program over time, as well as the events that could act as barriers to the implementation.

Periods	Actions	Barriers
Prior to the implementation	• The use of family rooms had already begun • Design of the Cuídame program • Approval by the Ethics Committee • Selection of professionals responsible for monitoring the program • Presentation of the program to the professionals	• Family members are restricted due to the COVID-19 epidemic
Period 1: from September 1, 2020, to June 15, 2021	• Start of the implementation of the Cuídame program	• Family members are restricted due to the COVID-19 epidemic
Period 2: from July 15, 2021, to May 31, 2022	• Complete implementation of the Cuídame program	• Family members are restricted due to the COVID-19 epidemic • Summer vacation • Incorporation of new professionals

This program included several areas of care and a paper called a road map, where the parents were encouraged to write down the dates they achieved autonomy under the supervision of the neonatal nursing staff [5]. Health professionals provided information about the Cuídame program at a time close to the admission. There was no standardized day to initiate the information provision. The team adapted to the individual situation of each child and family. A responsible professional was assigned to each family to monitor the autonomy of the parents in caring for their babies. In addition, professionals received file books with the criteria and indicators that parents had to meet to advance in every step.

The families who recorded the dates of autonomy in all areas of care on their road maps were included. Autonomy scores were not based on whether the primary caregiver was the mother or the father. In the context of clinical management, the families of newborns infants with a severe disease focused on caring for children at the end of their life, families with newborn infants who died during the first month of life, or those with important language barriers were excluded.

The autonomy of parents in caring for their VLBW newborn infants during their admission to the neonatal unit and the dependent variables related to the morbidity of VLBW newborn infants were defined based on scientific literature [5]. Autonomy in kangaroo mother care was achieved when parents transferred newborn infants from the incubator to their chest, placed their children properly in the kangaroo position, and then transferred the children back to the incubator. With respect to feeding, autonomy was achieved when parents were able to recognize the signs that their infants were hungry and feed them orally. Autonomy in the observation of neurobehavior was achieved when parents identified their infants' daily achievements and helped them reach the next neurobehavioral step. The parents were considered autonomous in handling, posture, and contact when they created the cradle nest, chose the bedding, placed the infants properly, and executed postural changes in the incubator. Autonomy in diaper change occurred when the infants' diaper were changed by the parents themselves. When parents detected their infants' pain or stress signs and applied nonpharmacological analgesic measures, they were considered autonomous in stress and pain prevention. Autonomy in the prevention of sensory deprivation was achieved when the parents talked to their infants, chose stories to tell them, and conveyed the importance of this initiative to other parents. Autonomy in patient safety involved ensuring that the parents dealt with their babies, were familiar with the monitoring system, and alerted the team about any detected incident. It also involved knowing the medication and the type of milk that the infants were receiving. Parents who cleaned their infants properly according to their corrected age were considered autonomous in cleanliness. Autonomy in the prevention of health care–associated infections involved the removal of bracelets or watches before contact with the infants, the use of hand sanitizer before touching them, and reminding professionals to use hand sanitizer as well. Finally, autonomy in participation in clinical rounds was achieved when the parents provided suggestions to the team during clinical rounds.

Comparisons between the 2 time periods were performed using the nonparametric Mann-Whitney *U* test and the chi-square test or Fisher exact test. Comparative analyses were adjusted for gestational age and birth weight.

Ethical Considerations

The Ethics Committee of the Biomedical Research Institute of the 12 de Octubre University Hospital approved the project (21/123). All participants were sent an information document. No compensation was given to families; they voluntarily participated in the care of their children.

Results

During the study period, a total of 159 VLBW newborn infants were admitted to the neonatal unit. The parents of 107 VLBW newborn infants recorded the dates of complete autonomy in the areas of care at discharge on their road maps. Four families were excluded because of a significant language barrier, and 6 families were excluded because of the death of the newborn in the first month of life. Overall, 54 (72%) out of 75 families were recruited during period 1, and 43 (51%) out of 84 families were recruited during period 2. No statistical differences were found between the infants in periods 1 and 2 (*P*>.50).

The median gestational age and birth weight were 28.7 (IQR 26.8 - 31) weeks and 1080 (IQR 850 - 1270) g in period 1, respectively. In period 2, they were 27.8 (IQR 26.7 - 30.4) weeks and 1000 (800 - 1200) g, respectively. The number of days required by the parents of VLBW newborn infants to be autonomous in the 11 care areas included in this study is described and compared in Table 2. It should be noted that the prevention of health care–associated infection was an area of care where health care providers and parents required fewer days to be autonomous (median 6, IQR 3 - 12 d), and feeding required more days (median 44.5, IQR 37 - 62 d). Additionally, different behaviors can be highlighted when the numbers of days needed to be autonomous were compared between periods 1 and 2. Thus, the number of days required to be autonomous in period 2 decreased for participation in clinical rounds (median 10.5, IQR 5 - 20 vs 7, IQR 4 - 10.5 d; *P*<.001). In contrast, the time required in period 2 was significantly increased in 3 areas of care: kangaroo mother care (*P*=.02), diaper change (*P*=.04), and prevention of health care–associated infections (*P*<.001).

Table . The time required by parents of very low–birth weight newborn infants to acquire the highest degree of autonomy in the 11 care areas of the Cuídame program during the implementation.

Area of care	Days, median (IQR)		*P* value	*P* value adjusted for birth weight and gestational age
	Period 1: from September 1, 2020, to July 15, 2021 (n=54)	Period 2: from July 15, 2021, to May 31, 2022 (n=43)		
Kangaroo mother care	14 (7 - 23)	21 (10 - 31)	*.04*	*.02*
Feeding	53.5 (34-68)	44.5 (37-62)	.39	*.049*
Observation of neurobehavior	18 (9 - 33)	11 (7 - 16)	*.04*	*.049*
Handling, posture, and contact	16.5 (7-36)	22.5 (11-37)	.24	.17
Diaper change	9.5 (4-20)	14.5 (9-32)	*.01*	*.04*
Stress and pain prevention	13 (6 - 26)	12 (7 - 26)	*<.001*	.61
Prevention of sensory deprivation	6.5 (2.5-16)	7 (4.5-9)	.35	.82
Patient safety	9 (4-17)	9 (5-19)	.90	.90
Cleanliness	15.5 (7.5-39)	23.5 (13-37)	.25	.07
Prevention of health care–associated infections	1 (1-2)	6 (3-12)	*<.001*	*<.001*
Participation in clinical rounds	10.5 (5-20)	7 (4-10.5)	*.049*	*<.001*

Discussion

Our study revealed that the implementation of the Cuídame program changed the culture of care in our neonatal unit, resulting in the autonomy of most families in caring for their newborn infants under the supervision of a health care professional during their admission. The prevention of health care–associated infections was the first area where parents achieved the autonomy, and feeding was the last one.

The implementation of a program aimed at achieving parental autonomy in the care of newborn infants does not affect every area of care in the same way. In our case, the time required by parents of VLBW newborn infants to be autonomous in kangaroo mother care, prevention of health care–associated infections, and diaper change increased in the second period. One possible reason for this difference is that health care providers became more demanding during the implementation of the program.

Some limitations should be considered, such as how the COVID-19 epidemic could have acted as a barrier to the implementation of the Cuídame program.

Based on our results, it can be concluded that some areas of care could have different behaviors during the implementation of a training program aimed at achieving parental autonomy. The number of days required by parents to achieve autonomy in kangaroo mother care, diaper change, and the prevention of health care–associated infections increased in our case, even though the team was more experienced. This leads us to believe that achieving parental autonomy is a complex process that depends on several factors in the implementation of a training program.

Abstract

Background: Globally, high rates of maternal and infant mortality call for interventions during the perinatal period to engage pregnant people as well as their loved ones in care. Mobile health technologies have become ubiquitous in our lives and in health care settings. However, there is a need to further explore their safety and effectiveness to support and improve health outcomes locally and globally.

Objective: The aim of this study was to review and synthesize published literature that described the development process or effectiveness evaluations of maternal and infant apps.

Methods: We applied a methodological framework for scoping reviews as well as the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines; in addition, the systematic review platform Covidence (Veritas Health Innovation Ltd) was used to facilitate the review of included studies. Search terms were developed collaboratively, and health sciences–associated databases were searched for studies conducted between January 1, 2000, and February 4, 2022. We excluded studies about apps that only gathered or tracked data or targeted care providers.

Results: A total of 1027 articles were included for title and abstract screening, of which 87 (8.47%) were chosen for full-text screening. Of these 87 articles, 74 (85%) were excluded with reasons, and 19 (22%) were included. Four articles were added at data extraction from hand searching and 2 others were excluded. Thus, we reviewed and synthesized data from 11 unique studies reported in 21 articles published between 2017 and 2021. The included studies represented 8 different countries. Most of the apps (8/11, 73%) were in English, although apps were also developed in Arabic, Bahasa Indonesia, and Nepali. The articles reviewed revealed the early stage of development of the field of maternal and infant health apps, with modest evidence of app use and achievement of study outcomes. Only 1 (9%) of the 11 apps was endorsed by an independent health care provider society. App development and evaluation processes emerged, and specific app features were identified as vital for well-functioning apps. End-user engagement occurred in some, but not all, parts of app research and development.

Conclusions: Apps to improve maternal and infant health are being developed and launched in enormous numbers, with many of them not developed with mothers' needs in mind. There are concerns about privacy, safety, and the standardization of current apps as well as a need for professional or institution-specific guidelines or best practices. Despite challenges inherent in currently available apps and their design processes, maternal and infant app technology holds promise for achieving health equity goals and improving maternal and child health outcomes. Finally, we propose recommendations for advancing the knowledge base for maternal and infant apps.

Introduction

Overview

Achieving the global health goal of health for all requires engaging and empowering individuals, families, and communities for increased social participation and enhanced self-care and self-reliance in health, in addition to universal health coverage (UHC) and primary health care (PHC) [1-4]. Globally, high rates of maternal and infant mortality call for interventions during the perinatal period to engage pregnant people as well as their loved ones to ensure that they remain in care during pregnancy and the postpartum period [5-10]. As mobile health (mHealth) technologies such as smartphone apps emerge and become ubiquitous in our lives and in health care settings, there is a need to further explore their potential to support and improve health outcomes locally and globally. The COVID-19 pandemic demonstrated the capacity for widespread uptake of mHealth technologies in every aspect of life [11,12]. Before the COVID-19 pandemic, there were numerous smartphone apps being developed to support many diverse health goals [7-9,12-14]. However, many maternal and infant health apps are short lived or constrained to specific health care systems or networks, and few of them are evaluated for effectiveness in improving health outcomes for the mother, their children, and families or endorsed or reviewed by health professionals or organizations independent of app development teams [14-19]. Despite the existence of a plethora of apps to support parents, especially during the perinatal and postpartum periods, documented scientific data remain meager. The limited peer-reviewed published evidence about the development process and effectiveness of apps in supporting mothers or parents with the challenges they face during the perinatal or postpartum period makes the content of the available apps questionable, which may influence their efficacy.

Background and Significance

Apps to Prevent Maternal and Infant Morbidity and Mortality

Numerous apps have been developed to support and improve maternal and infant health, including during pregnancy and the postpartum period. These apps can be an efficient means of providing information for parents, and the number of apps is rapidly increasing [20,21]. However, most apps lack the information needed and searched for by mothers with low income and non–English-speaking mothers with low income belonging to minority groups. It is well documented that people with low income, those with low income belonging to minority groups, and non–English-speaking people have a lower rate of pregnancy app use [22,23]. Most maternal and infant apps are not designed for women with low income and culturally diverse non–English-speaking women [24-26]. In the United States, it is estimated that most women (92%-95%) aged between 18 and 34 years own a smartphone [27]. This large proportion of smartphone users may have easy access to apps during pregnancy and the postpartum period when they could benefit from app-based maternal and infant health information. Evidence is emerging that maternal and infant apps have been developed and tested in resource-constrained settings and for use in humanitarian crises [7-9,14,28]. However, most existing pregnancy apps lack commercial regulation and standardization, making their content questionable [29]. Potential harm from several pregnancy mHealth intervention apps have been identified by health professionals [30]. Many apps have not been evaluated for content accuracy, making it difficult for users to assess the reliability of the information presented in them [31,32]. Many apps currently lack information that would be most helpful for women during pregnancy [33,34]. Neither medical nor health care societies have issued guidelines for mHealth apps [18,19,29,35,36]. Few studies exist that report on the outcomes from the use of such apps [29].

Regulatory agencies are constrained under current regulatory frameworks to provide effective and efficient regulation of apps that can be classified as software as medical device (SaMD) [17-19,35]. The US Food and Drug Administration (FDA) takes the position that the regulation of apps needs to be tailored to the risk and benefit profiles of the apps but has *no* standards for apps [35]. The FDA "oversees apps intended to treat, diagnose, cure, mitigate, or prevent diseases or other conditions as medical devices under federal statute" [35]. The FDA seeks to empower patients and clinicians through innovation, including the creation of regulatory frameworks that instills confidence in the performance and reliability of apps [35]. The International Organization for Standardization (ISO) has articulated assessment processes and quality requirements for health apps [17]. There are international standards for product safety and lifecycle processes that are applicable to health apps. However, because of the time investment involved, most health-related apps are not evaluated [17]. This lack of effective regulatory oversight has led to calls for user-centered reforms to improve the accuracy, usability, accessibility, and privacy protection features of apps, especially health apps [18,19].

The current research and regulatory landscape offers little data or regulatory guidance to inform people about the effectiveness of available apps that aim to improve health outcomes among mothers, especially mothers with low income, mothers with low income belonging to minority groups, and non–English-speaking mothers. The lack of regulatory frameworks and guidelines for the development of safe and effective maternal and infant apps limits the confidence of patients and clinicians and may lead to harms derived from the use of currently available apps [18,19,35,36]. Increasing knowledge in this area is important because the population of people with low income and those with low income belonging to non–English-speaking minority groups continues to grow, and these groups tend to have poorer maternal and infant health outcomes. In addition, there is an increased need for maternal and infant apps in languages other than English.

App Searches

Mobile apps are downloaded by end users on their smartphone. However, there are little data on why people search for apps, although major life events seem to be drivers for mobile app installations [37]. People experiencing major life events—change in marital status, moving, job change, pregnancy, or the birth of a child—install 2.5 times more apps than those without any significant life changes. There are studies reporting how end users find apps [37]. More than half of app users (55%) found apps based on recommendations from friends, family members, and colleagues [37]. In addition, 1 in 3 consumers found apps through app store recommendations; searching in an app store; and advertisements on the web, social media, and television. Most consumers (74%) downloaded apps after viewing mobile advertisements for them [38]. There are little data documenting that consumers' app searches and downloads are based on scientific recommendations [38,39].

Brief Overview of Currently Available Parent and Infant Health Apps

An extensive review of currently available maternal and infant apps is beyond the scope of this review. In 2018, a total of 5276 Android maternal and child health (MCH) apps and 877 iOS MCH apps were identified [40,41]. There are estimated to be >350,000 health apps available worldwide, and it is estimated that 250 new health apps are released every daily [42].

Positionality Statement

Our scoping review team includes professionals and researchers with a variety of perspectives that inform our evaluation of the literature reviewed. We represent multiple cultural backgrounds, migrant statuses, sexes, and genders. In addition, our multiple academic disciplines include computer technology and IT, communications, human rights law, informatics, speech-language pathology, medicine, and maternal and child nursing. We have team members from multiple contexts globally. Our varied lived experiences and knowledge support analysis of the literature reviewed from a wider perspective of world views to inform future development of computer-mediated technologies, such as smartphone apps, to improve the health of mothers, their infants, families, and communities.

Objectives

The purpose of this scoping review study was to review and synthesize published literature that described the development process or effectiveness evaluations of maternal and infant health apps, with a specific emphasis on determining the use of the apps by the target population; provided evidence of outcomes with mothers, fathers, infants, or children; and explained whether the apps have been reviewed or endorsed by a health care provider. The research question guiding this scoping review study was as follows: what evidence exists that describes the development and effectiveness evaluation of maternal and infant health apps?

Methods

Scoping Review Approach

Because of the scarce evidence of apps being systematically evaluated for effectiveness, we used a scoping study methodology to review and synthesize the existing literature. The scoping review approach was originally described by Arksey and O'Malley [43] and has since been adapted by Islam et al [44], Levac et al [45], and Westphaln et al [46]. The original scoping review method included 5 steps: identifying the research question (step 1); search strategy (step 2); study selection (step 3); charting the data (step 4); and collating, summarizing, and reporting the results (step 5). Two additional steps were added subsequently: consultation (step 6) [45,46] and quality assessment (step 7) [44]. We used the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines to enhance transparency in our approach to our scoping study [47]. The PRISMA-ScR guidelines checklist is available in Multimedia Appendix 1.

Steps Taken

The identification of the research question (step 1) and the development of our search strategy (step 2) were developed collaboratively during team meetings. The research question addressed by the scoping study was as follows: what evidence exists that describes the development and assessment of the development and effectiveness of parent and infant health apps? Specifically, we sought to identify extant studies that described the use of the apps by the target population; provided evidence of outcomes with mothers, infants, or children; and explained whether the apps have been reviewed or endorsed by a health care provider or health care provider society (eg, American Academy of Pediatrics). Our search strategy included literature published between January 1, 2000, and February 4, 2022. The search terms included "((mother* OR mom* OR matern* OR pregna* OR parent* OR postpart*) AND (infan* OR newborn OR neonat* OR prenat* OR perinat* OR postnat* OR bab*) AND (app OR mobile app OR apps OR mobile device applications OR mobile apps OR smartphone) AND (health*))." The search resulted in 1895 citations being identified. The search process commenced on January 27, 2022, with a preliminary search of Academic Search Complete (EBSCO), Bibliography of Indigenous Peoples in North America (EBSCO), CINAHL, Communication Source (EBSCO), Education Source (EBSCO), and Global Health (EBSCO). The citations identified from this search (163/1895, 8.6%) were imported into the systematic review platform Covidence (Veritas Health Innovation Ltd) [48]. MEDLINE (Ovid) was also searched on January 27, 2022, and the citations identified (398/1895, 21%) were imported into Covidence [48]. Citations from Scopus (64/1895, 3.38%), PubMed (656/1895, 34.62%), and Web of Science (614/1895, 32.4%) were identified in an additional search on February 4, 2022, and added to Covidence [48]. Of the 1895 citations, after screening, 892 (47.07%) duplicates were removed.

Study selection (step 3); charting the data (step 4); and collating, summarizing, and reporting the results (step 5) were facilitated using Covidence [48]. Study selection occurred in 2 stages: title and abstract screening and full-text screening. All articles at each stage were reviewed by at least 2 team members. Any conflicts were resolved during team meetings for title and abstract screening. During full-text screening, any conflicts were resolved by team members who had differing opinions about inclusion discussing their differences and coming to an agreement about whether to include a citation for data extraction. Inclusion and exclusion criteria (Textbox 1) were specified during team meetings and adapted as needed through team consensus. All team members had the opportunity to participate in title and abstract screening, which aligns with our approach to consultation (step 6) that was inclusive of the multiple perspectives of our team members.

Textbox 1. Literature review inclusion and exclusion criteria.

Inclusion criteria

- Published primary research article (eg, completed studies)
- Review article (eg, systematic review or scoping review)
- Apps for pregnant people (people), parents (include fathers if they are part of the app's target audience), postpartum people (people), infants and children, and mothers and infants
- Language: app in any language; articles limited to publications in English
- Any country
- Article describes app development process or how effectiveness was determined (eg, randomized controlled trial or evaluation)

Exclusion criteria

- Study or app focused on pathology or psychopathology (eg, gestational diabetes mellitus, preterm or premature birth, anxiety, and depression)
- Study protocols
- Thesis or dissertation
- Commentaries, editorials, and letters to the editor
- Apps for health care or community services workers only
- Apps for data gathering or tracking
- Computer-mediated platforms: websites, communication platforms (eg, WhatsApp, Facebook Messenger, and FaceTime), and social media or social networking platforms (eg, Twitter, Facebook, and Reddit)

Our team developed a data extraction tool for charting the data (step 4). This instrument was then entered into Covidence to facilitate data extraction. Three authors (JCP, JH, and SZ) completed data extraction. All other team members had access to the data extraction outputs in Covidence [48]. The final outputs of the data extraction process—the charted data—were shared with all team members for review and discussion at a team meeting. Collating, summarizing, and reporting the results (step 5) were completed using the PRISMA-ScR process [47]. To ensure rigor in reporting our findings, we used a 3-stage process [45]. First, we provide numerical summaries of key aspects from the reviewed studies (eg, country where app was designed to be used, app language, and study population). Second, narrative summaries, tables, and figures are used to present our findings and facilitate comparisons between, and contrasts across, the reviewed studies. Finally, in the *Discussion* section, we elaborate on the implications of our findings for the future research and development of maternal and infant apps. We also propose recommendations for improving the development, usability, end-user uptake, evaluation, quality assessment, as well as policies for funders and regulators in the field.

Consultation (step 6) was incorporated into this scoping review by including the multiple personal and professional perspectives of the members of our diverse and inclusive team, which is briefly described in the *Positionality Statement* subsection. We did not consult outside our research team for conducting this scoping review study. Our future research endeavors will include wider community consultations to include the experiences and perspectives of the people who use maternal and infant apps.

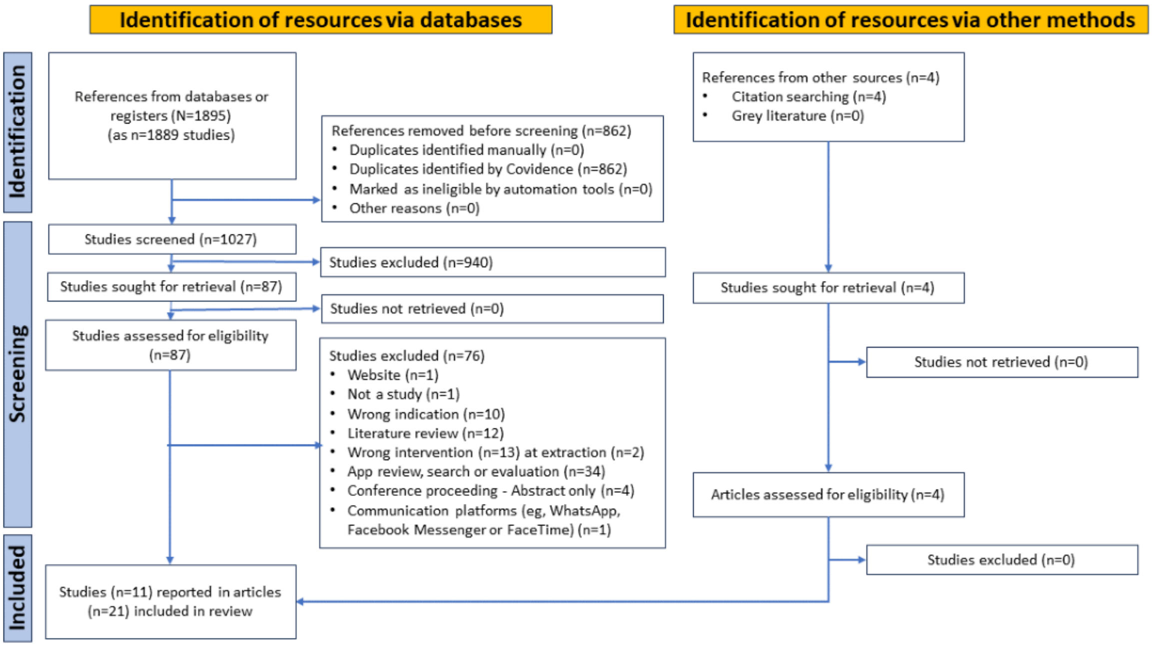
Quality assessment (step 7) is a potentially fraught process for scoping review studies, but efforts are underway to develop an appraisal tool for them [49]. Some researchers have included this step to enhance scoping review quality [44]. For the purposes of our review and given the early developmental stages of the science regarding the development and effectiveness evaluations of smartphone apps, quality assessment was not part of the inclusion criteria for this study. The assessment of the selected studies will be made in a separate study after recommendations for the critical appraisal of scoping reviews have been more formalized [49].

Results

Overview

Of the 1889 studies identified, after removing 862 (45.63%) duplicates, 1027 (54.37%) articles remained. Of these 1027 articles, 940 (91.53%) were excluded during the title and abstract screening. Of the remaining 87 articles that were assessed for eligibility during full-text screening, 74 (85%) were excluded for reasons stated in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram (Figure 1 [50]), resulting in 19 (22%) articles reporting on 13 distinct studies that were included for data extraction. At data extraction, 4 articles [51-54] describing aspects of 1 (8%) of these 13 studies were added from a hand search of the literature, yielding a total of 23 articles for data extraction. Of the total 23 articles, 2 (9%) were excluded at data extraction; 1 (4%) was excluded because the app is limited to podcasts, which may not offer a range of engagement opportunities and communication modalities for app users and has less potential for use with multiple languages [55]; and 1 (5%) was excluded because the study tested a model of care that included an encrypted digital app that facilitated text-based communication between patients and their care team, not an app with multiple functionalities [56]. Each of these excluded articles reported on a study, which yielded the final total of 11 studies reported in 21 articles included. Of these 11 studies, 2 (18%) were reported in multiple articles, 1 (9%) was reported in 3 (14%) of the 21 articles [7-9], and 2 (18%) studies were each reported in 5 (24%) of the 21 articles [51-54,57-62]. Ultimately, we reviewed and synthesized data from 11 unique studies reported in 21 articles, published between 2017 and 2021.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Characteristics of Included Studies

Table 1 summarizes characteristics across the 11 included studies. The lead authors of the included studies represented 8 different countries, with Australia (3/11, 27% studies reported in 7/17, 41% of the articles) [57,59-64] and the United States (3/11, 27%) [16,65,66] having the greatest representation. The other represented countries included Indonesia (1/11, 9%) [28], Jordan (1/11, 9%) [14], Morocco (1/11, 9%) [67], Nepal (1/11, 9% study reported in 3/21, 14% of the articles) [7-9], and Singapore (1/11, 9% study reported in 5/21, 24% of the articles) [51-54,58]. The health discipline of the primary authors varied, with the most common being medicine (3/11, 27%) and nursing (3/11, 27%). The other disciplines included public health (2/11, 18%), followed by computer technology fields: computing and informatics (1/11, 9%), IT (1/11, 9%), and biomedical engineering (1/11, 9%). Most of the apps were in English (8/11, 73%); other app languages included Arabic (1/11, 9%) [14], Bahasa Indonesia (1/11, 9%) [28], and Nepali (1/11, 9% study reported in 3/21, 14% of the articles) [7-9]. English-language apps were developed for use in Australia (3/11, 27%), the United States (3/11, 27%), Morocco (1/11, 9%), and Singapore (1/11, 9%).

Table 1. Key characteristics of reviewed studies (n=11).

Country (language); authors and year	Studies (n=11), n (%)	Articles (n=21), n (%)	Disciplines	Endorsed by independent HCP[a]
Australia (English)	3 (27)	7 (33)		
Dalton et al [64]; 2018			Anthropology, media, communications, and health (health, arts, and design)	No
Meedya et al [63]; 2021			Medicine, nursing, social work, IT, computer science, and business	No
Scott et al [57]; 2021			Medicine, nursing, IT, dietetics, public health, and population health	No
White et al [59]; 2016			Medicine, nursing, IT, dietetics, public health, and population health	No
White et al [60]; 2018			Medicine, nursing, IT, dietetics, public health, and population health	No
White et al [61]; 2016			Medicine, nursing, IT, dietetics, public health, and population health	No
White and Scott [62]; 2019			Medicine, nursing, IT, dietetics, public health, and population health	No
United States (English)	3 (27)	3 (14)

Nepal (Nepali)	1 (9)	3 (14)		
Kayastha et al [7]; 2021			Social work, IT, and computer science (female community health volunteers were part of the sample studied)	No
Mueller et al [8]; 2020			Social work, IT, and computer science (female community health volunteers were part of the sample studied)	No
Mueller et al [9]; 2020			Social work, IT, and computer science (female community health volunteers were part of the sample studied)	No
Singapore (English)	1 (9)	5 (24)		
Shorey et al [58]; 2017			Nursing and psychiatry	No
Shorey and Ng [51]; 2019			Nursing and psychiatry	No
Shorey et al [52]; 2019			Nursing and psychiatry	No
Shorey et al [53]; 2021			Nursing and psychiatry	No
Shorey et al [54]; 2018			Nursing and psychiatry	No

[a] HCP: health care provider.

[b] UNRWA: United Nations Relief and Works Agency for Palestine Refugees in the Near East.

The studies included a variety of study designs, including randomized controlled trial (2/11, 18% studies reported in 3/21, 14% of the articles) [51,57,58], observational study (1/11, 9%) [66], multisite cross-sectional study (1/11, 9%) [14], diagnostic test accuracy study (1/11, 9%) [16], mixed methods study (1/11, 9%) [63], case study methodology report of a pilot study (1/11, 9%) [65], retrospective review (1/11, 9%) [64], app development reports (2/11, 18%) [28,67], and qualitative articles with participants from the main study (4/11, 36%) [51,53,54,60]. Of the 11 apps, 4 (36%) were designed for use in resource-constrained settings: Indonesia [28], Morocco [67], Nepal (reported in 3/21, 14% of the articles) [7-9], and Palestine refugee camps in Jordan [14].

All studies reviewed reported that they had funding to conduct the research for the study. Of the 11 studies, 7 (64%) were funded by a governmental agency, whereas 1 (9%) was funded by a state Medicaid office [65], 1 (9%) was funded by the United Nations Relief and Works Agency for Palestine Refugees in the Near East (UNRWA) [14]; 1 (9%), reported in 5 (24%) of the 21 articles, was funded by a university [51-54,58]; and 1 (9%) was funded by a health system [66]. Funding specific for app development was reported in 5 (46%) of the 11 studies reported in 7 (33%) of the 21 articles [7-9,28,65-67]. Funding to support app sustainability was not specifically reported in any of the studies but could be assumed in 3 (27%) of the 11 studies [14,16,65]. It was not clearly specified whether app development and sustainability funding were obtained for 2 (18%) of the 11 studies [14,16].

Evidence of Apps’ Use, Outcomes, or Endorsement

Characteristics of the study populations from the reviewed studies are summarized in Table 2, and evidence use of the apps by the target population is presented in Table 3. Sardi et al [67] described an app in development and proposed a study to evaluate the effectiveness of the app they developed in collaboration with postpartum people. Evidence of outcomes with mothers, fathers, infants, and children was limited and is summarized in Table 3. Evidence that apps have been reviewed or endorsed by a health care provider is presented in Table 1. Although all studies reviewed included health professionals or health care providers as members of their research and development teams, only 1 (9%) of the 11 apps was endorsed by an independent health care provider or health care provider society not involved in the app’s development or evaluation [67].

Table 2. Participant characteristics.

Authors	Population description	Recruitment method	Sample size, n	Sample characteristics
Sardi et al [67]	Physicians and nurses (app for puerperal women)	Hospital	NR[a]	NR
Wiweko et al [28]	Pregnant and nonpregnant people	Clinic patients	205	NR
Chaudhry et al [16]	Prenatal care coordination providers, social workers, and women	Clinic patients	9	• Age: 20-36 y • Ethnicity: African American (6/9, 67%); Hispanic (1/9, 11%); White (2/9, 22%) • Education: ≤high school (6/9, 67%); college (3/9, 33%) • Income: US $0-US $30,000/y
Meedya et al [63]	Pregnant people	News platform, paper flyers, and social media	7	• Age: 29-37 y • Race or ethnicity: Asian; European; Middle Eastern; White • Education: NR • Income: >US $6000/mo
Bush et al [65]	Pregnant people	Grass roots referrals	85	NR
Shorey et al [58]	Couples (mothers and fathers)	Clinic patients	250 (126/250, 50% [63 couples] received education support via app, whereas 124/250, 50% [62 couples] were in the control group)	• Age: 26-42 y • Ethnicity: Chinese; Malay; other • Education: NR • Income: >SG $6000 (US $4367)/mo
Shorey and Ng [51]	Couples (mothers and fathers)	Clinic patients	250 (126/250, 50% [63 couples] received education support via app, whereas 124/250, 50% [50] couples were in the control group)	• Age: 26-42 y • Ethnicity: Chinese; Malay; other • Education: NR • Income: >SG $6000 (US $4367)/mo
Shorey et al [52]	Couples (mothers and fathers)	Clinic patients	250 (126/250, 50% [63 couples] received education support via app, whereas 124/250, 50% [50] couples were in the control group)	• Age: 26-42 y • Ethnicity: Chinese; Malay; other • Education: NR • Income: >SG $6000 (US $4367)/mo
Shorey et al [53]	Couples (mothers and fathers)	Clinic patients	250 (126/250, 50% [63 couples] received education support via app, whereas 124/250, 50% [62 couples] were in the control group)	• Age: 26-42 y • Ethnicity: Chinese; Malay; other • Education: NR • Income: >SG $6000 (US $4367)/mo
Shorey et al [54]	Couples (mothers and fathers)	Clinic patients	250 (126/250, 50% [63 couples] received education support via app, whereas 124/250, 50% [62 couples] were in the control group)	• Age: 26-42 y • Ethnicity: Chinese; Malay; other • Education: NR • Income: >SG $6000 (US $4367)/mo
Nasir et al [14]	Parents (mothers and fathers)	Clinic patients	1042	• Age • Mothers: 23-33 y • Fathers: 29-39 y • Ethnicity: Palestinian (refugees) • Education: NR • Income: US $0
Cawley et al [66]	Postpartum mothers	Mail	567	• Age: 20-36 y • Race or ethnicity: Asian (74/567, 13%); Hispanic (46/567, 8%); White (360/567, 63%); other (87/567, 15%) • Education: ≤high school (82/567, 14%); college (482/567, 85%) • Income: US $0-US $70,000/y (276/567, 49%); >US $70,000-US $150,000/y (201/567, 35%)

Table 3. Target group involvement, app use, and outcomes.

Authors	Target group	Involvement	App use	Outcomes reported
Sardi et al [67]	Mothers and infants	App development	N/A[a] (app in development phase)	• Clinical staff examined app features and functionalities. • A future study with mothers is planned.
Wiweko et al [28]	Mothers	Implementation phase	Mothers	• App provides pregnant people directions to nearest health centers, access to medical staff, and saves patient's medical records to easily obtain professional help needed immediately.
Chaudhry et al [16]	Mothers and infants	App development	Pregnant people	• Low use by both providers and mothers.
Meedya et al [63]	Mothers	App development	Breastfeeding mothers	• App was piloted with, and revised based on, mothers' feedback.
Bush et al [65]	Pregnant people	NR[b]	Pregnant people	• There was a statistically significant increase in the completion of prenatal visits (*P*=.02). • There was an association between the use of the app and lowered incidence of low birth weight infants (*P*=.06).
Shorey et al [58]	Postnatal mothers and fathers	Research process	Postnatal mothers and fathers	• There was an increase in the parenting confidence of new parents, better perceived social support (parents were encouraged to proactively seek help), and greater parenting satisfaction.
Shorey and Ng [51]	Postnatal mothers and fathers	Research process	Postnatal mothers and fathers	• There was an increase in the parenting confidence of new parents, better perceived social support (parents were encouraged to proactively seek help), and greater parenting satisfaction.
Shorey et al [52]	Postnatal mothers and fathers	Research process	Postnatal mothers and fathers	• There was an increase in the parenting confidence of new parents, better perceived social support (parents were encouraged to proactively seek help), and greater parenting satisfaction.
Shorey et al [53]	Postnatal mothers and fathers	Research process	Postnatal mothers and fathers	• There was an increase in the parenting confidence of new parents, better perceived social support (parents were encouraged to proactively seek help), and greater parenting satisfaction.
Shorey et al [54]	Postnatal mothers and fathers	Research process	Postnatal mothers and fathers	• There was an increase in the parenting confidence of new parents, better perceived social support (parents were encouraged to proactively seek help), and greater parenting satisfaction.
Nasir et al [14]	Pregnant people and mothers	No community involvement	Pregnant people and mothers	• The number of participants who downloaded the app was reported. • Having other apps (OR[c] 6.17; *P*<.01), staff knowledge of the app (OR 11.82; *P*<.01), using the Internet as a source of medical information (OR 1.63; *P*=.01) and having internet access at home (OR 1.46; *P*=.05) were associated with app download.
Cawley et al [66]	Mothers and infants	Research process	Pregnant people	• The app provided access to personalized and evidence-based health information. • The app was associated with an increase in healthy behaviors and health knowledge.
Scott et al [57]	Mothers and fathers	Research process	Fathers	• The study did not demonstrate a measurable impact of father-focused support for breastfeeding.
White et al [59]	Mothers and fathers	Research process	Fathers	• The study did not demonstrate a measurable impact of father-focused support for breastfeeding.
White et al [60]	Mothers and fathers	Research process	Fathers	• The study did not demonstrate a measurable impact of father-focused support for breastfeeding.
White et al [61]	Mothers and fathers	Research process	Fathers	• The study did not demonstrate a measurable impact of father-focused support for breastfeeding.
White and Scott [62]	Mothers and fathers	Research process	Fathers	• The study did not demonstrate a measurable impact of father-focused support for breastfeeding.

Authors	Target group	Involvement	App use	Outcomes reported
Kayastha et al [7]	Pregnant people and mothers	App development	Pregnant people and mothers	• Participants gained more knowledge on maternal health than on neonatal health.
Mueller et al [8]	Pregnant people and mothers	App development	Pregnant people and mothers	• Participants gained more knowledge on maternal health than on neonatal health.
Mueller et al [9]	Pregnant people and mothers	App development	Pregnant people and mothers	• Participants gained more knowledge on maternal health than on neonatal health.
Dalton et al [64]	Mothers	App development	Pregnant people	• There was a high rate of noncompletion among study participants.

[a] N/A: not applicable.

[b] NR: not reported.

[c] OR: odds ratio.

App Development and Evaluation Processes

The studies reviewed revealed several approaches to app development. Some of the studies (4/11, 36%) used systematized app development strategies, including software requirements specification [67], rapid iterative testing and evaluation [16,57], and persuasive system design model and principles [63]. Most of the studies (9/11, 82%) included formalized evaluation processes. Standardized approaches to the evaluation of the apps included the Computer System Usability Scale [16], the Mobile Application Rating Scale [57,59,61], and investigator-developed evaluation instruments or processes [7-9,14,59].

App Features

Each app included features intended to improve the end users' experience. A full list of app features described in the studies is beyond the scope and purpose of this scoping review report. Textbox 2 summarizes the key features and functionality reported across the studies.

Textbox 2. Summary of the key app features and functionality reported across the reviewed studies.

Feature and functionality

- Health status tracking: mechanism to record various health indicators and observe changes over time
- Care support and access to information: provides information to guide care and increase knowledge
- Usability: enhances the app user's experience
- Health data protection and privacy: protects the end users' health data gathered by, or shared through, the app
- Data transfer: allows for the sharing of information between patients and providers
- Communication with health care providers: facilitates dialogue and communication between patients and providers
- Behavior change techniques: mechanisms to change health-promoting or risk behaviors

End-User Engagement

End-user engagement in app development was reported in 5 (45%) of the 11 studies, which were reported in 8 (38%) of the 21 articles [7-9,16,28,63,64,67]. Mothers were involved in app development in 7 (64%) of the 11 studies, which were reported in 4 (19%) of the 21 articles [16,28,63,67]. Fathers were involved in app development in 1 (9%) of the 11 studies, which was reported in 3 (14%) of the 21 articles [7-9]. End users were engaged in the research process in 3 (27%) of the 11 studies, which were reported in 11 (52%) of the 21 articles [51-54,57-62,66]. Of the 11 studies, 2 (18%) included mothers and fathers in the research process, as reported in 10 (48%) of the 21 articles [51-54,57-62]; and 1 (9%) included postpartum mothers in the research process [66]. Of the 11 studies, 1 (9%) included pregnant and nonpregnant people in the implementation phase of app development [28], whereas 2 (18%) did not report including end users in any aspect of the study [14,65].

Discussion

Principal Findings

Overview

Our scoping review is consistent with what has been previously reported in the literature. Apps have been developed for, and used in, a variety of settings globally. There are little data and regulatory guidance to inform people about the effectiveness of available apps that aim to improve health outcomes among mothers, especially mothers with low income, mothers with low income belonging to minority groups, and non–English-speaking mothers. This includes geographic locations with constrained resources and humanitarian crises (both human-made and natural disasters) [7-9,14,28]. The studies we reviewed reinforce the importance and usefulness of maternal and infant health apps to support global PHC objectives and confirm that they can be useful tools to facilitate the achievement of UHC [1-4]. However, our findings highlight several research gaps and challenges for the effective and sustainable development, implementation, and evaluation of maternal and infant health apps.

App Development Process

Currently, the development of maternal and infant health apps (including for use during pregnancy and the postpartum period) is on the rise; however, as documented in the literature and the results of this scoping review study, evaluation is lacking. Consistent with previous research, these apps are an efficient means of providing a wide range of health and safety information, and most women and parents, regardless of background or language, own a smartphone [7-9,14,20,21,28]. In fact, >85% of the world's population in advanced economies [68] and >67% of the global population own a smartphone, with >90% owning a mobile phone [69,70]. Smartphone ownership makes health information on pregnancy and perinatal periods easily accessible through maternal and infant health apps. However, as seen in our study, maternal and infant health apps lack commercial regulation and standardization, making their content questionable, which has been previously documented [29]. As there is a lack of regulation and standardization, potential harm has been identified by health professionals with several pregnancy mHealth intervention apps [18,19,30,35]. Our review as well as other studies have found that many apps have not been evaluated for content accuracy, making it difficult for end users to assess the reliability of the information presented in them [31,32]. Some apps also lack information that would be most helpful for women and their families during the perinatal period [33,34]. No medical society has issued guidelines for mHealth apps [29], although the ISO and FDA offer guidance to support further development of guidelines [17,35], and legal scholars have proposed a framework for user-centered approaches to improve the safety and security of all apps, including mHealth apps [18,19].

In this scoping review study, we found that the outcomes reported demonstrated slight increases in behavior and knowledge [9,52,58,63,65,66], whereas other studies reported low use [14,16,64] or were in the development stages with no outcomes reported [28,67]. This is similar to other studies reporting on outcomes regarding the reasons why most apps developed are targeted at English-speaking White women without regard for women of other cultures and non–English-speaking people [8,14,22,23,28,29]. This has been attributed to a lack of app development designed for culturally diverse non–English-speaking women [25,71]. Few studies with culturally diverse women with low income and their use of mHealth apps have been reported or have examined language and cultural issues as potential barriers to app use [8,14,72,73]. Our study indicated that most of the apps (8/11, 73%) were in English. However, our scoping review study documents emerging evidence to support the use of maternal and infant health apps in other languages and cultures [7-9,14,28,51-54,58,67]. Studies have reported high uptake and use of linguistically and culturally tailored apps [74,75].

The findings of our study help in assessing similar conclusions in other recent studies that women using maternal and infant health apps during pregnancy and the postpartum period prefer greater and immediate access to information that is relevant to their local health care context, which includes support offered by health care professionals [25,76].

App Features

A summary of key features to include in future apps are described in Textbox 2. Key features for inclusion in apps include health status tracking, care support and access to information, usability, health data and privacy protection, data transfer, communication with health care providers, and behavior change techniques. Health status tracking facilitates recording various health indicators that can be monitored over time. Care support and access to information build knowledge to improve health outcomes. Usability enhances the end users' experience when using an app. Health data and privacy protection protects the end users' health data gathered by, or shared through, the app. Data transfer allows for sharing information between patients and health care or social services providers. Communication with health care providers facilitates dialogue and communication between patients and health care or social services providers. Behavior change techniques can be embedded in apps to support the achievement of health-promoting or risk behavior reduction goals. Additional information regarding app features is provided in a literature review conducted by Sardi et al [77].

In resource-constrained settings, such as Nepal [7-9], the app served multiple purposes to achieve public health and safety objectives, including maternal health and disaster preparedness. In addition, in refugee settings, an app based on the *Maternal and Child Health Handbook* contains basic MCH information and promotes care-seeking behaviors, improves the continuum of care, and increases users' health-related behaviors [14]. This is evidence that apps can serve multiple health-related objectives, which has been documented in other settings during the COVID-19 pandemic [11,12]. In the context of health and humanitarian crises, the adoption of mHealth apps may be a wise use of scarce resources to address multiple public health–related and safety objectives simultaneously.

Potential risks related to mHealth and privacy exist and have been documented in the literature; for example, apps with the capacity to gather and store health data from end users need to have policies and protocols in place to ensure that the privacy of these data is maintained. These policies and protocols need to be transparent so that end users can be aware of who has access to their health data and for what purposes. In addition, algorithms, artificial intelligence, and machine learning can be used with the data gathered from apps. People who use these apps need to be aware of how these technologies are used with the data they share in apps [36]. Finally, risks can occur related to end users' capability and capacity to read and understand content embedded in apps, even if the app is developed in the end users' native language.

End-User Engagement

A fundamental feature of PHC that effective maternal and infant mHealth apps can offer is engaging people in their health care through empowerment and opportunities for enhanced self-care and self-reliance [1-4]. End-user engagement ought to be an essential part of the development of all maternal and infant health apps as well as other mHealth apps. Including end users in all stages of app development, implementation, scale-up, evaluation, and research across all stages is critical to the sustainability of apps and may enhance app longevity. Strategies for how to engage end users of apps in research have been described previously [78]. None of the studies included in this scoping review included participants in all aspects of app research and development. Most of the studies (9/11, 82%) included end users in part of the app research and development process, including app development, reported in 7 (33%) of the 21 articles [7-9,16,63,64,67]; the implementation of the app [28]; and the research process, reported in 11 (52%) of the 21 articles [51-54,57-62,66].

Quality Appraisal and Risk of Bias

The current state of the science for app development and evaluation limits the ability to evaluate the published studies for risk of bias [49]. Furthermore, there is debate about whether and how to review study quality and risk of bias in scoping reviews [49,79]. As our scoping review included a variety of different research approaches or app development reports, it was difficult to conduct a thorough quality appraisal of the potential for risk of bias, especially because we did not exclude any study based on quality appraisal or risk of bias. Our finding that the current literature may not meet criteria specified in many quality appraisal and risk-of-bias tools aligns with the challenges in the field of mHealth app development and evaluation with which regulatory and standards agencies are currently grappling [18,19,35].

Strengths and Limitations of the Review

This scoping study used a methodological approach that has demonstrated success in other settings. In addition, we used the PRISMA-ScR guidelines to guide our study, which increases the transparency of the processes used to conduct the study. The limitations of this review include the fact that we may have missed some studies by only searching English-language literature. As we excluded studies with a primary focus on mental health outcomes, we may have missed some studies that reported on apps that have demonstrated efficacy and have begun to surmount the concerns with regard to quality and reliability as well as the accuracy, usability, accessibility, and privacy protection features of apps [18,19,35].

Conclusions

In conclusion, this is one of the few studies reviewing the research regarding apps for maternal and infant health. These apps are increasingly being developed and launched in the marketplace in enormous numbers with little to no evaluation criteria in place. Many of the current maternal and infant health apps being launched are not developed with the pregnant person or mother's needs in mind. Although the use of maternal and infant apps in health research is a relatively new area, there are concerns about the safety of these apps for end users. Future initiatives are needed to support health researchers to navigate the landscape of maternal and infant health apps and evaluate the impact of their efforts to develop effective and sustainable apps. Given the concerns related to safety and standardization, future research needs to focus on providing additional direction to health researchers on how to set policies in place. This could include the development of professional or institution-specific guidelines or the development of best practices. Furthermore, there is a need for research to determine the influence and implications of the integration of apps within health care information systems. The integration of apps into health care information systems architecture and environments may pose unique challenges that directly influence the acceptability and usability of these apps for end users and may limit an app's utility, uptake, and sustainability. Despite challenges inherent in currently available apps and their design processes, maternal and infant health app technology holds promise for achieving health equity goals and improving MCH outcomes.

Recommendations

Funders should consider strategies to support the sustainability of effective apps that achieve their stated purpose and are accessible, acceptable, safe, and secure for their end users. This will facilitate the sustainability of apps that have demonstrated effectiveness among pregnant people, parents, and their families. This implies that a quality appraisal or effectiveness evaluation of apps would need to be built into the app development, implementation, and scale-up processes.

We advocate for regulation to ensure that maternal and infant apps support the needs of mothers, fathers, and others who use them to improve health outcomes for mothers, infants, and their families. The regulatory framework proposed by Knox and Tenenbaum [18,19] would be useful to inform and guide regulatory advances in the field, as would the inclusion of strategies to protect the private information of people who use apps [18,19,36]. One aspect of this recommendation is for funders and policy makers to consider requiring end-user engagement in all aspects of app development and research that is consistent with the principles of PHC and UHC [1-4].

Researchers, policy makers, and patient advocates should advocate for the safe and wise use of new technology advances such as the artificial intelligence chatbots ChatGPT and Bard. These technologies may further advance opportunities for computer-mediated approaches that support improvements in MCH. These technologies hold tremendous potential to revolutionize health care but must be used to support goals for improved health outcomes, not for nefarious purposes.

Acknowledgments

The authors are grateful to the participants and researchers whose lives and work formed the basis for this scoping review study.

Data Availability

All data analyzed in this study are cited in this paper and available in the public domain. Data extraction tables are available from the corresponding author.

Conflicts of Interest

None declared.

Abstract

Background: While the benefits of fathers' engagement in pregnancy are well researched, little is known about first-time expectant fathers' information-seeking practices in Southeast Asia regarding pregnancy. In addition, there is a notable gap in understanding their information-sharing behaviors during the pregnancy journey. This information is important, as cultural norms are prevalent in Southeast Asia, and this might influence their information-sharing behavior, particularly about pregnancy.

Objective: This study aims to explore and analyze the pregnancy-related information-sharing behavior of first-time expectant fathers in Southeast Asia. This study specifically aims to investigate whether first-time fathers share pregnancy information, with whom they share it, through what means, and the reasons behind the decisions to share the information or not.

Methods: We conducted semistructured interviews with first-time Southeast Asian fathers in Indonesia, a sample country in the Southeast Asian region. We analyzed the data using quantitative descriptive analysis and qualitative content theme analysis. A total of 40 first-time expectant fathers were interviewed.

Results: The results revealed that 90% (36/40) of the participants shared pregnancy-related information with others. However, within this group, more than half (22/40, 55%) of the participants shared the information exclusively with their partners. Only a small proportion, 10% (4/40), did not share any information at all. Among those who did share, the most popular approach was face-to-face communication (36/40, 90%), followed by online messaging apps (26/40, 65%). The most popular reason for sharing was to validate information (14/40, 35%), while the most frequent reason for not sharing with anyone beyond their partner was because of the preference for asking for information rather than sharing (12/40, 30%).

Conclusions: This study provides valuable insights into the pregnancy-related information-sharing behaviors of first-time fathers in Southeast Asia. It enhances our understanding of how first-time fathers share pregnancy-related information and how local cultural norms and traditions influence these practices. In contrast to first-time fathers in high-income countries, the information-sharing behavior of first-time Southeast Asian fathers is defined by cultural nuances. Culture plays a crucial role in their daily decision-making processes. Therefore, this emphasizes the importance of cultural considerations in future discussions and the development of intervention programs related to pregnancy for first-time Southeast Asian fathers. In addition, this study sheds light on the interaction processes that first-time fathers engage in with others, highlighting areas where intervention programs may be necessary to improve their involvement during pregnancy. For example, first-time fathers actively exchange new information found with their partners; therefore, creating features or platforms that facilitate this process could improve their overall experience. Furthermore, health practitioners should take a more proactive approach in engaging with first-time fathers, as currently there is a communication gap between them.

KEYWORDS

pregnancy; first-time fathers; information sharing; Southeast Asia; information-seeking behavior; cultural factors

Introduction

Background

In the realm of pregnancy, the traditional focus has predominantly centered on mothers as the primary seekers and bearers of knowledge [1]. However, contemporary perspectives increasingly emphasize the integral role of fathers in the journey to parenthood [2]. Fathers' participation in maternal-fetal health care offers profound benefits; for example, it is associated with a reduction in birth-related risks [3] and improved cognitive outcomes in infants [4]. Consequently, the Cairo Initiative [5] and recommendations from the World Health Organization [6] advocate for the promotion of a father's engagement during pregnancy. The Cairo Initiative emphasized the importance of reproductive health and the shared responsibilities of men and women in family planning and health-related decisions while promoting men's involvement in pregnancy to support maternal health and ensure better pregnancy outcomes.

Fathers have emerged as active participants in the pursuit of pregnancy-related information [7,8]. This is one of the many ways fathers become involved in the pregnancy journey, which involves obtaining information about pregnancy to improve their knowledge [2]. Fathers navigate the vast landscape of the internet and engage with specialized app, websites, blogs, and online support groups [9-12]. This digital terrain resonates particularly with millennial fathers, who readily turn to internet-based resources for guidance and support [13]. While fathers' information-seeking practices have garnered significant attention, it is crucial to acknowledge that the dynamics of this journey transcend mere information acquisition and extend to the pivotal aspect of information sharing. This is because fathers also actively engage with others to exchange information, experiences, insights, and support throughout the pregnancy journey [14].

Information sharing is a multifaceted aspect of human communication, driven by various motivations and yielding both advantages and disadvantages. People engage in sharing to disseminate knowledge, experiences, and insights, fostering collaborative and interactive communication [15,16]. The process is influenced by key variables, such as trust, risk assessment, perceived rewards, and the dynamics of relationships [17,18]. A rapid review study by Naeem et al [18] also emphasizes privacy concerns and the sensitivity of information as the multifactorial nature of an individual's willingness to share health information. Trust plays a pivotal role, as individuals are more inclined to share sensitive information when there is trust in the audience [18]. Assessing the risk associated with sharing and anticipating potential rewards, such as support or advice, further motivates information-sharing behaviors [15,17]. The advantages of sharing include the creation of a supportive community, the exchange of diverse perspectives, and the building of relationships [19]. Sharing can enhance one's understanding, contribute to a collective pool of knowledge, and provide emotional and practical support [10,19]. However, sharing also comes with disadvantages. Individuals may face the risk of judgment or misunderstanding [20] and the potential harm of information misuse or misinterpretation [21]. Striking a balance between the benefits and drawbacks of sharing is a nuanced consideration in various contexts, influencing individuals' decisions to engage in information-sharing behaviors.

In the domain of pregnancy information sharing, results of a research study demonstrate that fathers exhibit a willingness to share information acquired about pregnancy and fatherhood [11]. Fathers actively engage in both online and offline practices [22]. In the context of online information sharing, fathers contribute to discussions and seek advice within their digital communities [11]. They share relevant articles or seek guidance on parenting forums [10]. Some fathers disseminate their knowledge through online forums, while others opt to articulate their experiences via blogs [10]. Within these online forums, fathers recount their journey and provide mutual support [23]. In addition, fathers frequently indicate their participation in online support groups tailored to discussing various aspects of the pregnancy and fatherhood experience [24]. Furthermore, fathers have embraced social media apps as platforms for expressing their emotions and recounting their pregnancy journeys [9]. In these internet-based spaces, fathers actively share pregnancy-related information, fostering their involvement, bolstering their confidence, and encouraging their peers [25,26]. Conversely, offline information sharing predominantly takes place through face-to-face conversations. This emphasizes the significance of interpersonal relationships in the dissemination of information [27]. Fathers engage in discussions about pregnancy-related experiences during casual hangouts or directly seek advice from family members and friends [28]. This practice is driven by the desire to connect, collaborate, and contribute to collective knowledge [19].

While certain fathers actively share information about pregnancy with others [9,11,23], results of other studies suggest that some fathers may refrain from sharing pregnancy-related information [20,29]. First-time fathers, in particular, may seldom share personal experiences about the pregnancy journey, often due to feelings of unfamiliarity with the topic [29]. In addition, they may choose to keep pregnancy matters confidential, adhering to local cultural norms that discourage fathers from discussing such matters with others [29]. As seen in a previous study by Esmaeilzadeh [30], privacy concerns often influence the extent to which individuals are willing to share sensitive information, particularly in online environments like social media. A study by Nash [20] also reveals that, even though fathers share health information about pregnancy, they may withhold their feelings related to pregnancy or fatherhood due to concerns about judgment from other men, indicating a thoughtful risk assessment before sharing the information. These findings illuminate various reasons why fathers may opt not to share information, thereby limiting their potential benefits from engaging in this practice [31].

Studies on fathers' information-sharing behavior in the context of pregnancy information in high-income countries are well-researched [11,23,26]. However, there is a noticeable gap in research studies addressing pregnancy-related information-sharing practices in low- and middle-income countries, particularly in the Southeast Asian context. Southeast Asia is characterized by its diverse cultural norms, traditions, and varying degrees of digital literacy [32-34], providing a unique backdrop for examining how fathers participate in the sharing of pregnancy-related information. In the Southeast Asian context, cultural norms of privacy and reserved communications may impact fathers' information-sharing behaviors [30], influencing whether sharing is performed, what information fathers share, and with whom they share pregnancy-related information [35]. The cultural emphasis on societal expectations within Southeast Asian cultures further directs fathers toward traditional channels, such as consulting with extended family members or seeking advice from older people [36,37].

Adding to this landscape, Southeast Asia exhibits varying levels of digital proficiency, impacting how fathers share information and engage in online information sharing [38]. Specifically, this study was conducted in Indonesia, the most populous nation in Southeast Asia. Indonesia, being part of Southeast Asia, embodies a rich tapestry of diverse cultural norms, traditions, and varying levels of health and digital literacy [38-40]. The country's internal diversity provides a nuanced backdrop for exploring how first-time expectant fathers engage in sharing pregnancy-related information. Indonesia's cultural, linguistic, and contextual elements mirror the broader diversity within Southeast Asia [34,41,42]. The shared cultural threads and regional commonalities offer insights that may extend to other Southeast Asian countries [39,43].

Southeast Asia is a region with various ethnicities, religions, and languages [34]. These differences may impact the information-sharing behaviors of first-time expectant fathers. For example, fathers from Malay, Chinese, or Indigenous communities may have distinct traditions and customs related to pregnancy [36]. These differences may influence their communication patterns and the type of information they prioritize to search and share (or not to share). In addition, religious practices related to Islam, Christianity, Buddhism, and Hinduism may guide the behavior and decision-making process of fathers during pregnancy [44,45]. Finally, linguistic diversity may shape how fathers search for and share pregnancy-related information using their preferred language. Results of a research exploring cross-language information-seeking behavior showed participants implement different strategies and tactics when completing the search process depending on the language they used [44]. Therefore, fathers might have different strategies and approaches when searching and sharing, depending on the language used during the process.

This Study

An exploration of information-sharing practices in these contexts contributes valuable insights to our understanding of how these nuances shape fathers' behavior in the pregnancy journey, as it is likely to be different from the results of research studies conducted in high-income countries. Therefore, this study embarks on an exploration of information-sharing practices of pregnancy information among first-time fathers in Indonesia, a Southeast Asian low- and middle-income country, where cultural traditions and social networks intersect and may shape fathers' behaviors [45]. Our research question and follow-up questions are outlined as follows: Do first-time expectant fathers engage in information sharing about pregnancy? The follow up questions were as follows: (1) If information is shared, with whom is it shared? (2) Through what means the information is shared? (3) Why is the information shared? and (4) If not shared, what are the underlying reasons? This exploration is particularly salient within the temporal confines of the antenatal phase, a pivotal juncture in the transition to fatherhood [46]. Here, we draw a clear distinction between first-time fathers and those with prior parenting experience. The rationale is that first-time fathers bring a unique perspective as they prepare for fatherhood [29]. Furthermore, first-time fathers display heightened sensitivity to their new situation, leading to more pronounced information needs and interaction compared to fathers with prior experience [47]. The results of this study aim to enhance domain knowledge by providing answers to the research questions stipulated earlier.

Methods

Overview

In this study, a grounded theory approach [48] was used to investigate the information-sharing practices of first-time expectant fathers concerning pregnancy-related information. Grounded theory enables the development of theories derived directly from empirical data and provides a neutral perspective on human actions within a social context [49]. The grounded theory approach was used for this study due to the limited knowledge regarding the information-sharing practices of first-time fathers in the context of pregnancy-related information in Southeast Asia. This methodology facilitates the discovery of patterns, capturing lived experiences, exploring the themes, and systematically developing theories grounded in the data itself [50]. This methodological choice is particularly valuable in the context of this study as it allows for the in-depth exploration of the nuanced and context-specific behaviors of first-time fathers beyond surface-level observations. To enhance interpretive validity and intercoder reliability, personal reflexivity practices were implemented [51].

Recruitment

Recruitment notices were placed in health care facilities in Indonesia, community centers, and online social media portals. Participants were required to meet specific inclusion or exclusion criteria. Participants must be aged ≥21 years, first-time fathers, and have sought pregnancy-related information in the past 9 months. Importantly, participants must not be working in or have a formal qualification or be in the process of achieving an academic qualification in the health care or allied health care sectors to eliminate the possibility of health expertise and literacy influencing results.

Data Collection

Data collection involved the use of questionnaires and semistructured interviews. The questionnaire serves to capture information on sociodemographic, digital and health literacy levels, family situations, and pregnancy-related details. This is to provide an overview of the participants of this study and will not be used for analysis. The sociodemographic section encompasses details about participants' social and demographic characteristics. Digital literacy levels are self-assessed to gauge participants' proficiency and comfort with digital technologies. Similarly, health literacy levels are self-assessed to understand participants' capacity to comprehend health-related information effectively. These self-assessments provide insights into fathers' perceived literacy levels related to health and digital matters. Family situations are explored to uncover contextual factors that may influence information-sharing behaviors, considering the role of familial connections in the pregnancy journey. Finally, pregnancy-related details are gathered to gain insights into specific aspects of participants' experiences.

Semistructured interviews were used to collect data, enabling in-depth exploration of participants' thoughts and experiences [52]. The interviews were designed to be open-ended and revolved around the research questions outlined in this study. Participants were queried about their engagement in the sharing or nonsharing of pregnancy-related information. Participants who shared information were asked follow-up questions: (1) with whom the information is shared, (2) through what means the information is shared, and (3) why the information is shared. Participants who did not share pregnancy-related information were asked to elaborate on the reasons for this decision. Participants were allowed to choose whether the interview will be conducted in Bahasa Indonesia or English. An option was provided, as using the mother tongue in interviews can lead to more reliable and valid data [53]. The researcher is Indonesian, so the interview and translation were conducted by the researcher if the participants chose the interview to be conducted in Bahasa Indonesia. If the interview was conducted in Bahasa Indonesia, transcribing was done in Bahasa Indonesia to prevent the loss of meaning of the answers and collect as much culturally localized information as possible [54]. Thereafter, the interviews were translated into the English language [53]. All interviews were recorded and transcribed verbatim, ensuring a robust connection between the data and the researcher [55].

Data Analysis

Open coding technique was used with the grounded theory approach [56]. This method was used to examine participants' responses regarding their information-sharing practices [57]. Initially, a master list of codes was generated through inductive reasoning, with ongoing revisions after every third interview [58]. Subsequently, these codes were condensed into overarching themes using the constant comparative method, which entailed a systematic review of each response to identify prominent patterns and key themes [58,59]. Data analysis commenced immediately following each interview and continued until the study's completion [50]. This method of content analysis provided a comprehensive understanding of fathers' information-sharing practices about pregnancy and the underlying reasons for their behavior [50]. To ensure interpretive validity and intercoder reliability, personal reflexivity practice was undertaken [51].

Ethical Considerations

Before recruitment, ethics approval was obtained from the University of Canterbury, New Zealand (HREC 2022/66). Informed consent was obtained from all participants before their involvement in the study. Participants were provided with a detailed information sheet consisting of the study's objectives, procedures, potential risks, and benefits. They were also informed of their right to withdraw from the study at any time without any penalty. Their consent was recorded electronically. All identifiable information was anonymized, and unique codes were assigned to each participant. Participants were informed about how their data would be stored and used, which is based on the university's regulations. Data were stored securely on password-protected devices to prevent unauthorized access. There was no compensation for participants.

Results

Overview

In this section, we begin with a brief overview of the sociodemographic details of the participants. Following this, we delve into participants' information-sharing behaviors, categorized into those who shared information and those who did not. Information-sharing activities among first-time fathers who shared information are further explored, considering the audience, communication channels used for sharing information, and underlying reasons for sharing. In addition, further examination of first-time fathers who chose not to share information will be provided, revealing their underlying reasons behind this decision.

Sociodemographic Details of Participants

There were 40 participants in this study. Data saturation [60] for this study was achieved with 75% (30/40) participants. The data saturation point is generally reached in 15 interviews, with one-third of the number of interviews being added [61]. Similarly, a study showed that thematic saturation from the conducted interviews will be achieved by completing 30 interviews [62]. Furthermore, other studies exploring information-seeking behavior recruited 40 participants for the interviews to reach data saturation [63,64]. Therefore, in this study, after data saturation was achieved with 30 participants, the researcher added another one-third of the number of interviews, bringing the total to 40 participants.

Most participants fell within the age group of 26 to 30 years, constituting 68% (27/40) of the sample. Urban residency was predominant, with the majority residing in cities (21/40, 52%), while others living in suburbs (10/40, 25%) and rural areas (9/40, 22%). Educational backgrounds were diverse, with 65% (26/40) holding bachelor's degrees, followed by master's degrees (7/40, 18%), and high school qualifications (7/40, 18%). Language preferences for online searches indicated that most used the national language (Bahasa Indonesia; 25/40, 62%), rather than the local languages or dialects (ie, Javanese, Sundanese, Balinese, and Betawi). A national language is a language that is officially recognized and used formally at the country level. By contrast, local languages or dialects are specific to certain communities or regions with specific cultural markers. Most (24/40, 60%) participants worked in the private sector, followed by entrepreneurs (8/40, 20%). Monthly household income varied, with 45% (18/40) falling within the IDR 2-4.99 million (US $120-300) range, followed by the IDR 5-9.99 million (US $325-650) range (14/40, 35%).

In terms of social and familial aspects, 88% (35/40) identified with the Islamic faith. Furthermore, 62% (25/40) of participants perceived their family social systems as equal, including roles and responsibilities between husband and wife. Most (36/40, 90%) participants lived together with their partners. Most participants' partners were in the third trimester (20/40, 50%), followed by the first and second trimesters equally (10/40, 25%). Health and digital literacy levels varied, with 60% (24/40) of participants having moderate health literacy and 28% (11/40) having high health literacy. In terms of digital literacy, 50% (20/40) demonstrated high digital literacy, while 40% (16/40) exhibited moderate digital literacy.

Shared or Did Not Share

Results indicated that 90% (36/40) of the participants shared information, while 10% (4/40) of the participants did not share information with anyone. Within the 36 participants, 55% (22/40) participants only shared information with their partners. Furthermore, 20% (8/40) of the participants shared information solely with their partners, extended family, and the physicians. Results indicated that most (36/40, 90%) first-time fathers were "sharers" of pregnancy information.

Information-Sharing Activities of First-Time Fathers

The Audiences: Who Is Information Shared With?

Table 1 details participants' information-sharing patterns regarding pregnancy. Most (22/40, 55%) participants exclusively shared information with their partners. The second prevalent pattern involved a combination of sharing with partners, physicians, and extended family members (eg, mothers, siblings with pregnancy experience, or siblings with medical qualifications), amounting to 20% (8/40) of the participants. Furthermore, 10% (4/10) of the participants opted to share information with physicians, friends, colleagues, and their partners. Only a small proportion, 5% (2/40), extended their sharing to a social media audience, encompassing participants' social media connections or followers, in addition to partners, physicians, and friends. The findings indicated that fathers primarily share information with their partners only.

Table 1. Information sharing behavior of fathers (N=40).

Activity and audience	Participants, n (%)
Did not share information	4 (10)
Shared information	36 (90)
Shared information with	
Partner only	22 (55)
Partner, physicians, and extended family	8 (20)
Partner, physicians, friends, and colleagues	4 (10)
Partner, physicians, friends, and social media audiences	2 (5)

The Channels: How Is Information Shared?

Participants shared information using offline and online communication channels. Face-to-face communication was the favorite offline method used, as 90% (36/40) opted to share information with this method. As for online communication channels, 65% (26/40) of the first-time fathers used online messaging apps such as WhatsApp (Meta Platforms, Inc) or iMessage (Apple Inc) to share information. With this method, first-time fathers not only shared information using the text format but also sent links and screen captures. Aside from online private messaging platforms, 35% (14/40) of the first-time fathers shared information found on online posts or videos using social media features available on Instagram (Meta Platforms, Inc) and Facebook (Meta Platforms, Inc), such as "direct sharing." However, the "tagging" feature in social media platforms is not a favored method of sharing information, chosen by only 10% (4/40) of the fathers. In addition, only 5% (2/40) leveraged social media "post" features and "comment sections" to disseminate pregnancy information.

The results from Table 2 illustrate the diverse combination strategies used by first-time fathers in sharing pregnancy-related information. The participants in this study used various communication channels to share pregnancy information with their audiences. Face-to-face interactions emerged as the predominant offline method, with 90% (36/40) of the participants engaging with partners, 35% (14/40) with friends, 10% (4/40) with colleagues, and 10% (4/40) with extended family. Phone calls were used by 5% (2/40) of the participants when communicating with extended family. In the online realm, 65% (26/40) of the participants opted for online messaging apps with partners, 18% (7/40) with friends, 10% (4/40) with colleagues, 10% (4/40) with extended family, and 2% (1/40) with physicians or midwives. Online messaging app was used by 10% (4/40) of the participants with their friends and 20% (8/40) of the participants with their extended families. Notably, of the participants, the direct share feature on social media platforms was used by 35% (14/40) with partners, 5% (2/40) with friends, and 5% (2/40) with colleagues. The tag feature on social media was chosen by 10% (4/40) of the participants with partners and 5% (2/40) of the participants with friends. For broader dissemination, 5% (2/40) of the participants utilized the post feature, and 5% (2/40) of the participants engaged in the comment feature on social media platforms when targeting social media audiences.

Table 2. Information sharing strategies (N=40).

Communication channels and audience	Participants, n (%)
Offline	
Face-to-face	
Partner	36 (90)
Friends	14 (35)
Colleagues	4 (10)
Extended family	4 (10)
Physicians or midwives	14 (35)
Phone calls	
Extended family	2 (5)
Online	
Online messaging	
Partner	26 (65)
Friends	7 (18)
Colleagues	4 (10)
Extended family	4 (10)
Physicians or midwives	1 (2)
Online group messaging	
Friends	4 (10)
Extended family	8 (20)
Direct share feature on social media	
Partner	14 (35)
Friends	2 (5)
Colleagues	2 (5)
Tag feature on social media	
Partner	4 (10)
Friends	2 (5)
Post feature on social media	
Social media audiences	2 (5)
Comment feature on social media	
Social media audiences	2 (5)

The Reasons: Why Is Information Shared?

Table 3 presents 3 themes categorizing first-time fathers' reasons for sharing information. These themes are reciprocity and validation of information, compassion and sympathy, and information enhancement. Participants' reasons for sharing information mostly fit in the reciprocity and validation of information theme (14/40, 35%), followed by the compassion and sympathy theme (13/30, 32%). The least number of reasons fit under the information enhancement theme (9/40, 22%).

Table 3. Themes of reasons for sharing information about pregnancy (N=40).

Theme	Participants, n (%)	Quotes
Reciprocity and validation of information	14 (35)	• "I share pregnancy information to initiate a discussion. I also hope to get advice from others based on the discussion results." • "One way to validate the information that I have is by sharing it with others and letting them give feedback on the information given. I can get another perspective by sharing the information obtained." • "During the casual hangout, I share information about pregnancy with my other friends. So in that way, I can compare the information that I have and make it more comprehensive."
Compassion and sympathy	13 (32)	• "I know how confused I was when I dealt with something related to pregnancy problems. So, if my friends facing difficulties or asking for advice, and I have the information, then I will share it with them." • "When I have good or interesting information and I consider it as valid information, I will share it with my partners and my friends so they can also benefit from it." • "Sometimes I share experiences of what I have done based on information obtained from the Internet to others who have similar problems. Or at least, they can take preventive actions based on my experiences."
Information enhancement	9 (22)	• "Sometimes I share information that I obtained with my partners or my families, so they can add or complete the information that I missed." • "What I have in mind when I share the information I obtained from the Internet with my partner is that she can give me a response whether she experiences or feels the same thing or maybe if she hasn't and we need to figure it out further."

In the reciprocity and validation of information theme, participants expressed their motivation to share pregnancy information as a means to initiate discussions and seek advice. Sharing information served as a method for validating the information they possess, obtaining feedback, and gaining additional perspectives. During face-to-face conversations, participants engaged in mutual sharing, fostering a collaborative environment where they compare and enhance their collective understanding of pregnancy-related information.

In the compassion and sympathy theme, participants highlighted their tendency to share information not only to support their partner but also when their friends face difficulties or seek advice related to pregnancy problems. The desire to assist others in navigating the challenges of pregnancy was evident, with participants sharing information with friends. In addition, participants found value in sharing personal experiences based on information obtained from the internet, aiming to provide insights and preventive actions for those facing similar issues.

In the information enhancement, participants mentioned sharing information either with their partners or others to complement or complete information they may have missed. Participants sought to enrich their understanding by incorporating the perspectives and insights of others.

The Reasons: Why Is Information Shared With Their Partner Only?

The exploration into why most first-time fathers share pregnancy information with their partners only resulted in thematic clusters, as outlined in Table 4. These findings encompass 5 key themes: asking over sharing (12/40, 30%), no relevant audience (5/40, 12%), self-situation awareness (5/40, 12%), privacy and intimacy (3/40, 8%), and physician-specific constraints (11/40, 28%).

Table 4. Reasons for sharing information about pregnancy only with their partner.

Theme	Participants, n (%)	Quotes
Asking over sharing	12 (30)	• “Mostly, I prefer to ask others and the doctors rather than share first (even though it continues with asking or validating). By asking, after I get the answers, then I can just privately compare them with my information.” • “During casual hangouts with friends, when we discuss pregnancy, I’d rather ask questions rather than share information. That is my preference, even though sometimes I already possess some of the information. I am afraid if I share incorrect information, they will judge me as an irresponsible expectant father.”
No relevant audience	5 (12)	• “I used to share everything with my close friends. But now, they live far away, so it is difficult to share pregnancy information with them. We are not comfortable sharing this kind of information with colleagues or neighbours. Therefore, I only share information about pregnancy with my partner.” • “We are the youngest couple in our circle both in friendship, in a work environment, and families. They already have children. No other couples with a similar situation. It’s unlikely for us to share pregnancy information.” • “I don’t know where and to whom I share the information. As far as I know, there is no online forum for me (and other fathers) to share information about pregnancy. Maybe, I can comment on social media posts. But the other commenters are mothers, so I am not very comfortable with it (joining the conversation).”
Self-situation awareness	5 (12)	• “I think I do not have relevant information to share. I feel that the others have more information than me. Thus, I don’t share any information with others.” • “I feel like I am not an expert in this field. I only have a little knowledge about pregnancy. So, I am afraid that I might give false information to others that might harm them.” • “This is the first time I have searched and obtained information about pregnancy. I am a first-time father. I don’t have any experience with this before. I need to have more experience before I can confidently share information with others.”
Privacy and intimacy	3 (8)	• “I think information related to pregnancy, particularly if it is related to our partner’s condition, I consider it as private and intimate information. Thus, I don’t share it with others, other than my partner.” • “Because we are not announcing pregnancy, I don’t share any pregnancy information with others. In my culture, it’s prohibited to announce pregnancy as it can heavily impact the family (particularly the mother) if there is something wrong with the baby. We will announce the baby’s birth, but not the pregnancy.”
Physician-specific constraints	11 (28)	• “The doctor is very busy. He has so many patients. Our antenatal care meeting is very short and concise. It’s already filled with procedures for health checking. So, there is no time to have a longer conversation.” • “My doctor is very famous but he is also a very strict guy. He doesn’t like to answer questions other than what is in the meeting session scope. We just do the antenatal care procedures and nothing else.” • “I feel that we go to the doctors to get examined by the experts. They have been studying pregnancy for years. So, I trust them to give the valid information. I just silently compared to information obtained by myself. Furthermore, they have a high social status in society. I won’t bother them with questions from a person with a lack of literacy in pregnancy matters (me).” • “The ob-gyn doctor already explains everything in detail (I think). Therefore, I rarely have further questions or need to validate any information obtained online.”

The first theme, “asking over sharing,” manifests as first-time fathers expressing a preference for asking others rather than actively sharing information. This behavior extends not only to interactions with physicians but also with friends or colleagues who have experienced pregnancy. First-time fathers articulated a preference for asking questions rather than potentially facing judgment by sharing information they obtained. In addition, first-time fathers stated that the feeling of being judged does not appear when sharing information with their partners.

The second theme, “no relevant audience,” emerges from first-time fathers living far away from the intended audience, particularly family and close friends, or perceiving their situation as unique. First-time fathers prefer face-to-face conversations for sharing information, and distance creates barriers in this regard. Some first-time fathers noted a lack of friends in similar pregnancy-related situations. This limits their willingness to share information with others.

The third theme, “self-situation awareness,” encapsulates first-time expectant fathers’ acknowledgment of their novice status in the field and lack of experience. This self-awareness influences their decision not to share information, reflecting thoughtful consideration of their knowledge and expertise. They recognize their status as beginners, feeling the need to gain more information, validate it, and accumulate personal experience before sharing. However, with their partners, first-time fathers are aware that their partners are also newcomers in this matter. Therefore, they can collaborate to improve their knowledge about pregnancy.

The fourth theme, "privacy and intimacy," underscores first-time fathers' perception of certain information as private. This emphasizes a desire to maintain confidentiality surrounding specific aspects of pregnancy. Furthermore, some cultural matters prevent them from announcing a pregnancy before certain weeks of pregnancy. This limits their opportunity to share pregnancy-related information with others. Therefore, first-time fathers keep the boundary by only sharing pregnancy-related information with their partners, especially related to their partner's health situation.

Finally, "physician-specific constraints" form a distinctive theme encompassing various constraints related to physician-patient communications that are different from their communication constraints with others (ie, friends, colleagues, and extended family members). Factors such as limited meeting time, feeling unwelcome or encountering unresponsiveness, respecting physicians' roles, and perceiving a communication gap influence fathers' decisions not to share information in the medical context. These constraints create situations where fathers find themselves unable to share their findings on pregnancy information, leading to a passive role in discussions with health care experts. However, while addressing communication situations with their partners, first-time fathers did not encounter any of these limitations.

Non–Information-Sharing Activities of First-Time Fathers

A small number of participants, specifically 10% (4/40) of the participants, did not share pregnancy-related information with anyone (Table 5). In total, 2 themes emerged; these themes were partners' health qualifications (2/40, 5%) and work environment (2/40, 5%). Under the partner health qualification theme, the reason for not sharing information was because of the partner's professional qualifications in the health care field (eg, physician or midwife). This led first-time fathers to perceive their partners as possessing superior knowledge about pregnancy. Consequently, they deemed it unnecessary to gain information about pregnancy intensively, including sharing any pregnancy-related information. Another factor influencing nonsharing was the demanding work environment of the respondent, such as military service, which was perceived as a hindrance to engaging in discussions about pregnancy. Furthermore, they lived apart from their partners daily, so they were not involved in their partners' pregnancies. Despite not sharing information, these fathers still searched for pregnancy-related information, mainly driven by personal curiosity and preparation for the baby's delivery.

Table 5. Reasons for not sharing information with anyone.

Theme	Participants, n (%)	Quotes
Partners' health qualification	2 (5)	"My partner holds a degree in health/medicine. Therefore, I think I don't need to find information intensively or share pregnancy-related information obtained as she knows better. I sometimes still search for information about pregnancy just in case, and also to prepare for the baby's delivery and becoming a new parent."
Work environment	2 (5)	"I work in the army and live afar with my pregnant partner and family. Both in my work and casual conversation environment, we rarely talk about our personal matters. Even though we talk about our personal topics, pregnancy is not included. However, in some break time, I occasionally search for information about pregnancy and parenting."

Discussion

Summary of Key Findings

This study reveals that most (36/40, 90%) first-time Southeast Asian fathers share information with others. Most (22/40, 55%) first-time fathers share information only with their partners, while the remaining (14/40, 35%) extend this to a small circle, including physicians, extended family, and friends. The most popular communication method for sharing information is face-to-face (36/40, 90%), followed by online messaging apps (26/40, 65%). Social media sharing is less common, with 35% (14/40) of the participants engaging in private sharing and only 5% (2/40) sharing information publicly. First-time fathers' motivations for sharing information include validating information (14/40, 35%) and compassion for others (13/40, 32%), with a smaller group aiming to enhance their understanding by adding others' perspectives (9/40, 22%).

Among those who did not share information beyond their partners, the reasons included a preference for asking questions rather than sharing information (12/40, 30%), self-situation awareness (5/40, 12%), lack of relevant audiences (5/40, 12%), concerns about privacy (3/40, 8%), and physician-specific constraints (11/40, 28%). A small group of first-time fathers (4/40, 10%) did not share information with anyone, mostly due to their partner's professional health qualification (2/40, 5%) or demanding work environments (2/40, 5%). However, these first-time fathers remained engaged in information seeking, driven by personal curiosity and preparation for the baby's arrival.

Sharing Approaches Depending on Audience

Overview

First-time fathers demonstrate various approaches to sharing information depending on the audience. This is influenced by the relational dynamic of the relationship with their audience [17,65]. In contrast to high-income countries where first-time fathers actively share pregnancy-related information on the internet publicly [11,23,26], in the Indonesian context, only a small number (2/40, 5%) of fathers post information about pregnancy on the internet publicly. This behavior stems from first-time fathers' inclination to share pregnancy-related information predominantly with people they have formed close relationships with, such as their partners, close friends, or immediate family members [27].

Several factors may contribute to this observed difference in information-sharing behavior among first-time Southeast Asian fathers, particularly related to sharing information about pregnancy publicly. Cultural nuances, societal norms, and privacy concerns could be influential in shaping the information-sharing landscape in Indonesia [45]. The cultural context in Southeast Asia often places a high value on privacy, especially regarding personal matters, such as pregnancy [66]. This cultural emphasis on privacy may lead fathers to be more cautious about sharing such intimate details publicly, in contrast to the more open sharing practices observed in high-income countries. Moreover, the level of digital literacy and familiarity with online platforms may play a role. While there are many online sharing platforms in Southeast Asia, 10% (4/40) participants highlighted the lack of appropriate forums on social media for posting and engaging with other fathers to discuss pregnancy-related matters, leading to limited activity in social media environments concerning pregnancy. The findings also suggest a preference for face-to-face communication. Fathers in Indonesia may place a higher value on personal interactions and traditional modes of communication [41]. The findings suggest that first-time fathers feel more comfortable sharing information about pregnancy in more intimate and private situations and featuring 2-way communication. It reflects the importance of personal connections and the cultural context, where sharing sensitive information is often reserved for close-knit relationships in Southeast Asian societies [16].

Within this close-knit relationship, results of this study show that first-time fathers prioritize their partners as the primary audience for information sharing, with a substantial 90% (36/40) choosing to share pregnancy-related details. The strong inclination to share information with their partners reflects a foundational trust that underpins their communication, as first-time fathers feel secure when sharing sensitive information with their partners [17,18]. In addition, in this context, perceived rewards, such as increased emotional connection, mutual understanding, and the opportunity for shared decision-making, also encourage first-time fathers to share information [17]. This inclination also emphasizes the central role of the partner in the first-time expectant father's information-sharing network [67]. The partner is considered a crucial and central figure in the information-sharing process. The partner's role as the one carrying the child makes her a primary stakeholder in the pregnancy journey. First-time fathers might recognize that the well-being of the child and the success of the pregnancy are directly linked to the mother's experiences and knowledge [65]. Sharing information with the partner may also contribute to her knowledge discovery. This information enhancement collaboration could help parents make better-informed decisions that might positively impact both the mother's well-being and the neonatal development of the child [3]. The collaborative effort in seeking and sharing information may enhance the overall experience of pregnancy for both partners.

First-time fathers use various communication channels to share information about pregnancy with their partners. The importance of the information, types of information, and source of information may influence the choice of communication channel used [68]. Certain details or important information may be deemed more urgent or critical. Therefore, fathers might choose to use faster channels, such as online messaging. In addition, the nature of the information itself could dictate the preferred method of sharing. For instance, if there is a need to convey information with informative images, online methods might be favored. However, if first-time fathers need to share sensitive information, they may opt for face-to-face communication. In addition, first-time fathers may share information directly using social media features, as most of the information about pregnancy is found on social media. Thus, it might be more convenient for first-time fathers. However, in this reciprocity and validation of information, it remains unclear whether partners feel overwhelmed or have preferences regarding specific channels. Further investigation into partner preferences and perceptions of information-sharing methods would be valuable in understanding the dynamics of this communication process. This includes the frequency of receiving new information about pregnancy and the types of information.

While communicating with friends, fathers still assess the dynamics of the situation and the level of closeness with friends before sharing the information [20]. This assessment considers not only the potential benefits and risks for the first-time fathers but also the well-being and comfort of the friends as recipients of the information. Consequently, some first-time fathers express a preference for sharing sensitive pregnancy-related details in face-to-face interactions rather than through group communication channels. This inclination highlights the significance of trust in the sharing process, indicating that fathers feel the need to establish a level of trust with their friends before sharing or exchanging intimate information about the pregnancy [17,18]. This suggests that the nature of the information and the level of personal relationships play crucial roles in shaping first-time fathers' choices of communication channels when sharing with friends.

With colleagues, most first-time fathers rarely share pregnancy-related information with them. This could be due to the desire to maintain a professional connection at work. However, first-time fathers express an intention to share information with their close colleagues, driven by a need for feedback from experienced fathers regarding pregnancy information they have acquired. Therefore, fathers emphasize that they are inclined to share pregnancy-related information primarily through face-to-face interactions, mostly during their lunch breaks. This practice may be influenced by the limited communication time fathers have with colleagues from the workplace. Moreover, first-time fathers choose to share information about pregnancy privately, specifically with their closest colleagues or those who are experiencing similar situations [17]. This result is consistent with the findings of the study by Widén and Hansen [27], emphasizing the importance of the interpersonal relationship with the audience, which often occurs through private conversations in sharing certain types of information.

Extended family also plays a role in the information-sharing network, with some participants relying on familial connections for sharing information about pregnancy. Most of these interactions occur in online group chat, and some of them use phone calls as they live separately with the other extended family members. Notably, first-time fathers express a willingness to share pregnancy-related information within the family, driven by the perceived expertise, experience, and credibility of certain members [17]. This willingness is particularly evident when family members possess relevant experiences in pregnancy or backgrounds in health sciences. First-time fathers aim to obtain responses and feedback when sharing pregnancy information to enhance the information they possess. Moreover, this tendency to share information to seek advice from older people resonates with findings in cultural studies conducted in Southeast Asia, as highlighted by Ford and Lyons [41]. This cultural aspect highlights the value placed on seeking guidance from more experienced individuals in the community. In addition, extended family members may recommend traditional methods or practices related to pregnancy that align with cultural and social norms in Southeast Asia [69]. Sharing pregnancy information with extended family in Southeast Asia goes beyond seeking advice; it is rooted in cultural and social norms that emphasize communal bonds and the importance of intergenerational wisdom [70].

Health care professionals, particularly physicians or midwives, were identified as pivotal figures in the information-sharing process, with 35% (14/40) of the participants expressing a preference for consulting medical experts. This choice could be motivated by the specialized knowledge and expertise that health care professionals bring to discussions [71]. Notably, it also reflects a cultural norm within Southeast Asian societies, where a high value is placed on the authority of medical professionals in matters related to health and childbirth [71]. The nature of information sharing with physicians or midwives occurred in the formal setting of one-on-one antenatal care meetings. In these limited-time interactions, first-time fathers engaged in sharing information with the implicit intention of initiating first-time further discussion or seeking validation of the information they have gathered [17]. However, the cultural context might play a pivotal role here, as the hierarchical structure in Southeast Asian societies underscores respectful communication with authority figures, particularly health care professionals. This could restrict physician-father communication, which aligns with the findings of the study by Claramita et al [72], suggesting that these interactions are confined within the formal boundaries of antenatal care settings. This nuanced approach reflects the broader cultural context in Southeast Asia, where respect for authority figures, particularly in the medical field, is ingrained in societal norms. This hierarchical gap might influence first-time fathers' decisions to not share pregnancy-related information obtained with the physicians outside the antenatal care settings [72]. The study by Claramita et al [72] illuminates how patients face limitations in discussing or sharing any health information with their physicians due to various reasons, such as limited time, differences in social status, and communication gaps. Similar situations arise during antenatal care, providing fathers with a restricted opportunity to share the information obtained with health care professionals. When first-time fathers have an opportunity to interact with physicians, they tend to prefer asking questions rather than actively sharing information, a behavior often accompanied by seeking validation or clarification. This emphasizes the challenges and constraints within the health care setting that influence first-time fathers' information-sharing practices.

On the basis of the various approaches discussed, technology, particularly online text messaging and social media platforms, plays an important role in shaping the information-sharing behaviors of first-time expectant fathers in Southeast Asia. These platforms offer accessible and convenient avenues for fathers to easily share the information found online [10]. First-time fathers use online messaging apps, such as WhatsApp, to share information obtained from website search results. In this case, the messaging platforms allow for direct, quick, and personal communication with their immediate circle. In addition to messaging platforms, first-time fathers optimize the use of social media's sharing features when sharing information obtained with others. This feature allows first-time fathers to share posts, videos, and expert advice more efficiently [9]. However, when using this feature, most first-time fathers in Southeast Asia tend to opt for private sharing with others over public sharing on social media [30]. This may also explain why first-time fathers prefer Instagram and Facebook over Twitter (subsequently rebranded X), as Twitter is primarily used for public sharing rather than private sharing, which raises concerns about privacy [30]. This suggests that first-time fathers are leveraging these features for their convenience and efficiency rather than the capabilities to amplify and disseminate information to wider audiences. Consequently, first-time fathers might limit the opportunities to receive feedback, advice, or validation from others, potentially hindering their ability to enrich their information-seeking and sharing experience in an online environment [67].

Reasons Behind Information-Sharing Decisions

First-time fathers who actively share pregnancy-related information emphasize the reasons they share pregnancy information are to validate the information, be compassionate to others, and enhance the overall quality and completeness of pregnancy-related information. By participating in information-sharing activities, first-time fathers aim to initiate discussions, seek advice, exchange information for validation, and compare notes to enhance the comprehensiveness of the information they acquire. This finding aligns with the findings of studies by Savolainen [15] and Tangaraja et al [16], which underscores that individuals share information as a way to gather information through collaborative engagement. This reciprocity and validation of information among first-time fathers as new parents highlight the social nature of their information-sharing practices during the journey [73]. In addition, by sharing valuable and valid information and offering personal experiences for guidance, these fathers aim to contribute to the improvement of their relationship with other fathers [17]. The observed practices resonate with the broader social and cultural norms that emphasize the value of communal support and shared experiences in navigating significant life events [74]. This collaborative aspect of information sharing might have broader implications for paternal involvement in the pregnancy journey, as it fosters a sense of community and mutual support among fathers. Moreover, information enhancement motives highlight fathers’ active efforts to ensure the quality and completeness of shared knowledge. This underscores the importance of validation and cross-checking information before making decisions, which resonates with the results of a study by Fletcher and StGeorge [26], demonstrating that first-time fathers share information with the aim of bolstering their confidence. This study suggests that by receiving feedback and comments on shared information, first-time fathers might aim to enhance their understanding of pregnancy. Thus, it is expected to boost their confidence during the pregnancy journey. These findings suggest that the information-sharing practices of first-time fathers play a crucial role in fostering a supportive community and enhancing paternal involvement during the pregnancy journey.

Conversely, instances, where first-time fathers did not share information beyond their partners, reveal nuanced themes, including a preference for “asking” over “sharing,” a lack of intended audiences, self-situation awareness, privacy and intimacy, and physician-specific constraints. Most of the reasons for not sharing pregnancy information, as uncovered in this study, mirror the findings of a study by Onyeze-Joe and Godin [29], which was conducted in low- and middle-income countries. For instance, participants in both studies expressed reluctance to share pregnancy information due to their perceived self-awareness of unfamiliarity with the topics and a lack of experience. The cultural context emphasizing the privacy and intimacy of pregnancy information that leads first-time fathers to rarely share such experiences is also evident in the results of both studies. In addition, both studies highlight the impact of local cultural norms dictating that fathers keep pregnancy matters a secret and refrain from discussing them with others. Another concurrence is that first-time fathers do not share pregnancy matters due to concerns about being judged by other men [20]. Both studies revealed that first-time fathers, in light of potential judgment, prefer to ask questions rather than share information with others, particularly regarding new knowledge or experience. This suggests a shared cultural inclination influencing fathers’ information-sharing behaviors across multiple studies in low- and middle-income countries. These studies suggest that first-time fathers are reluctant to share pregnancy-related information beyond their partner due to cultural influence, situational constraints, and low capabilities.

These findings also indicate that support networks play an essential role in promoting information sharing and exchange during pregnancy [75,76]. Results of this study highlight that the primary themes behind the decision to share information—whether with others or with their partners only—heavily depend on the audiences who often act as support networks. For example, first-time fathers cite reasons for sharing information with others, such as reciprocity and validation of information, which underscores the importance of feedback from others as they seek affirmation to enhance their understanding. Furthermore, the most common reason for sharing with their partner only is “asking over sharing.” This means that first-time fathers need direct support from their partners in terms of obtaining pregnancy-related information. By enhancing support networks for first-time fathers, they can increase their confidence and improve their knowledge, which can lead to more involvement during pregnancy [75,76]. Furthermore, by creating intervention programs that encourage open discussions not only with partners but also within broader circles, including health care professionals and experienced extended family members, first-time fathers’ involvement in the pregnancy journey can be improved.

Limitations and Future Directions

Several limitations should be acknowledged while interpreting the findings of this study. First, the study primarily relies on self-reported data from an interview, which introduces the possibility of social desirability bias and recall inaccuracies. In addition, the nature of the research design restricts the ability to capture the dynamic nature of information-sharing behaviors over time. Furthermore, the study’s focus on Southeast Asian cultural contexts may limit the applicability of the findings to other cultural settings.

Despite efforts to ensure diversity, the study’s geographical concentration in Indonesia might not fully capture the regional variations within the country. Finally, the rapidly evolving digital landscape introduces a temporal dimension to the study, and the information-sharing behaviors observed may evolve with technological advancements. These limitations should be considered when interpreting the findings, and they underscore the need for future research to address these constraints and further refine our understanding of first-time expectant fathers’ information-sharing practices.

A potential avenue for further exploration related to this topic is delving into the impact of cultural variations within low- and middle-income countries on fathers’ information-sharing behaviors during pregnancy. This could involve comparative studies across different regions or cultural subgroups within Southeast Asian countries, offering nuanced insights into how cultural diversity influences communication patterns. In addition, future research could investigate the role of digital literacy and access in shaping information-sharing practices among expectant fathers. Understanding how varying levels of digital literacy impact the use of online platforms for sharing pregnancy-related information could provide valuable insights for designing targeted interventions or support systems. Furthermore, longitudinal studies tracking fathers’ information-sharing behaviors throughout different phases of pregnancy and early parenthood could uncover how these practices evolve over time. Exploring how fathers’ roles and information-sharing dynamics shift from pregnancy to post partum could also contribute to a more comprehensive understanding of their evolving roles within the extended family unit. Finally, as demographic factors were not included in the analysis for this research study, exploring the relationship between sociodemographic aspects and information-sharing behavior could provide deeper insights into the dynamics of paternal involvement during pregnancy.

Conclusions

In conclusion, the results of this study provide an understanding of the intricate interplay of factors that influence information-sharing practices among first-time expectant fathers in low- and middle-income countries. The existing gap in research on this subject prompted this study’s exploration, recognizing the unique cultural, digital, and contextual nuances within Indonesia. The country’s diversity in cultural norms and varying degrees of digital literacy serve as a rich backdrop for comprehending how fathers engage in the sharing of pregnancy-related information. By focusing specifically on Indonesia, with its diverse cultural landscape and regional commonalities, this study contributes essential insights that might be extrapolated to other Southeast Asian countries. In doing so, it addresses the existing research gap and enriches the global understanding of fathers’ roles in the intricate journey of pregnancy. This not only increases our knowledge of paternal engagement but also emphasizes the importance of nuanced approaches that take cultural variation into account in future theoretical discussions.

On a practical level, this study offers valuable insights with implications for policy makers, health care providers, and support organizations. On the basis of this study’s findings, physicians and midwives in Indonesia might need to allocate additional time and diversify communication channels during antenatal care to enhance paternal involvement. Developers can leverage these insights to create dedicated online forums tailored for fathers. For governmental intervention programs, the study suggests initiating awareness campaigns, workshops, and support groups to encourage fathers’ active participation in pregnancy discussions. In the workplace, employers can foster an inclusive environment through programs addressing the unique needs of expectant fathers, creating designated spaces for open discussions, and implementing awareness campaigns to destigmatize pregnancy conversations. These contributions aim to promote paternal involvement, enhance support networks, and foster a collaborative sharing environment. The extrapolation of findings to other Southeast Asian countries provides actionable knowledge for those working in the region that guides the development of culturally tailored strategies to promote paternal involvement during pregnancy. Overall, the study bridges the gap between theoretical advancements and practical applications in the context of paternal involvement in low- and middle-income countries.

Abstract

Background: Successful national safer sleep campaigns in the United Kingdom have lowered the death rates from sudden unexpected death in infancy (SUDI) over the past 3 decades, but deaths persist in socioeconomically deprived families. The circumstances of current deaths suggest that improvements in support for some families to follow safer sleep advice more consistently could save lives.

Objective: This study aimed to develop and evaluate a risk assessment and planning tool designed to improve the uptake of safer sleep advice in families with infants at increased risk of SUDI.

Methods: A co-design approach was used to develop the prototype interface of a web-based tool with 2 parts: an individual SUDI risk assessment at birth and a downloadable plan for safety during times of disruption. The advice contained within the tool is concordant with national guidance from the Lullaby Trust, the United Nations International Children's Emergency Fund (UNICEF), and the National Institute for Health and Care Excellence. User testing of the prototype tool was conducted by inviting health visitors, midwives, and family nurses to use it with families eligible for additional support. Qualitative interviews with health professionals and families allowed for iterative changes to the tool and for insights into its function and influence on parental behavior.

Results: A total of 22 health professionals were enrolled in the study, of whom 20 (91%) were interviewed. They reported appreciating the functionality of the tool, which allowed them to identify at-risk families for further support. They felt that the tool improved how they communicated about risks with families. They suggested expanding its use to include relevance in the antenatal period and having versions available in languages other than English. They reported using the tool with 58 families; 20 parents gave consent to be interviewed by the research team about their experiences with the tool. Families were positive about the tool, appreciated the trustworthy information, and felt that it was useful and appropriate and that the plans for specific infant sleeps would be of benefit to them and other family members.

Conclusions: Our tool combines risk assessment and safety planning, both of which have the potential to improve the uptake of lifesaving advice. Refinements to the tool based on these findings have ensured that the tool is ready for further evaluation in a larger study before being rolled out to families with infants at increased risk.

Introduction

Background

Recent data from the National Child Mortality Database show a strong link between known risks in the sleep environment (eg, infant prone sleeping and hazardous cosleeping) and sudden unexpected death in infancy (SUDI) in 2020, with at least 1 known factor present in 75% of the deaths [1]. These data also show the scale of inequalities, with a significantly larger proportion of unexplained deaths of infants living in the most deprived neighborhoods (42%) than of those in the least deprived neighborhoods (8%), a 5-fold increase. In 2017, a consensus process (based on the James Lind Alliance Priority Setting model) in identifying research priorities to reduce SUDI rated “developing and evaluating new ways to make safe sleep interventions more effective” as the top priority in the United Kingdom [2]. More recently, the Child Safeguarding Practice Review Panel has called for further efforts to increase the uptake of safer sleep advice in families in which the risks of SUDI are much higher than in the general population [3]. The Baby Sleep Planner was designed in response to recommendations to target support and resources to those families with infants most at risk, provide tailored and personalized risk information, and facilitate planning for infant safety during times when the normal routine is disrupted [3]. Risk assessment calculators for SUDI at the time of birth have not been widely used before in the United Kingdom, but the shift to increased prevalence among families living in the most deprived neighborhoods makes this more viable. The tool comprises 2 parts: a risk assessment at birth showing infant risk based on background and neonatal characteristics and a sleep environment planning section that provides an individualized plan for safety that can be downloaded as an image and shared with family and friends. Currently, most safer sleep advice and guidance in the United Kingdom is given by midwives, health visitors, and specialist nurses. Message delivery is often compounded by limited time and conflicting advice from multiple sources [4]. Health professional resources aim to increase parental knowledge of SUDI risks, and recent qualitative interviews with them suggest that they would welcome a targeted approach for families with infants at the greatest risk using parental input to come up with realistic strategies during disrupted routines [3,5]. A recent review of interventions to increase the uptake of safer sleep advice in families of infants at increased risk concluded that approaches moving away from “information giving” toward “information exchange” may be more effective for this group [6]. Using the detailed evidence we collected in Bristol and working closely with families whose infants are at higher risk to understand parental decision-making, we had a unique opportunity to derive a targeted intervention [4,7].

Objectives

This paper describes the development and evaluation of a web-based tool that aimed to improve the uptake of safer sleep advice in families with infants at increased risk of SUDI. The Baby Sleep Planner was designed together with health professionals, families, other academics, and a team of software developers. The objectives of this study were as follows:

1. To use a co-design approach to develop a prototype web-based interface that the target group can use
2. To conduct user testing of the tool, including training and data capture of tool answers
3. To conduct qualitative interviews with health professionals and family members who have used the tool to understand how the tool works in real-world conditions and refine it for testing in a future study

Theory-Based Approach

The Medical Research Council’s guidance on the development and evaluation of complex interventions puts developing and testing theory as a core concept [8]. By using previous research on the influences on behavior of our priority group, we hope to provide a transparent theoretical underpinning that can be tested in a future study.

The risk assessment and planning tool is based on a Capability, Opportunity, and Motivation–Behavior (COM-B; behavior change) model that considers the sources of behavior along with the behavior change techniques likely to work on the target behaviors [9]. The COM-B model proposes that capability, opportunity, and motivation interact to predict behavior and that intervention designers should consider how to influence these constructs. Our previous studies have provided the basis for identifying the behavioral targets for intervention and their corresponding behavior change techniques [4,5,10,11]. The goal of our intervention is to enable parents with infants at most risk of SUDI to consistently provide a safe sleep environment for their infants, especially during disrupted routines. We chose techniques that focus on increasing *capability* by providing information about their baby’s risk; *opportunity* by using their environmental context and resources to develop realistic strategies for providing a safe sleeping environment; and *motivation* through planning, goal setting, and increasing confidence (Table 1).

Table 1. Model of the intervention showing the Capability, Opportunity, and Motivation–Behavior (COM-B) model using Theoretical Domains Framework (TDF) domains and corresponding behavior change techniques.

COM-B construct and subconstruct	TDF domain	Finding or problem	Corresponding behavior change technique	Proposed mechanism of action of the Baby Sleep Planner
Capability				
Physical capability	• Physical skills	• Advice interpreted differently or misunderstood	• Instruction on how to perform the behavior	• Increased confidence to provide a safer sleep environment
Psychological capability	• Knowledge • Cognitive and interpersonal skills; memory, attention, and decision processes • Behavioral regulation	• Safer sleep advice too generic and not individualized • Disruption to the routine can create unplanned risky situations	• Information about health consequences • Behavior substitution	• Increased understanding of their own infant's risk status • Prioritizes safety over convenience
Opportunity				
Physical opportunity	• Environmental context and resources	• Poor-quality accommodation makes following advice harder	• Restructure the physical environment • Reduce exposure to cues for the behavior	• Increased confidence to maintain safety in nonstandard situations
Social opportunity	• Social influences	• Burden of following advice loaded on primary carer or mother	• Social support	• Sharing the plans with wider family and friends reduces burden and increases safety when the infant is cared for by others
Motivation				
Reflective motivation	• Social or professional role and identity • Beliefs about capabilities; optimism • Beliefs about consequences; intentions • Goals	• Trusted sources provide impactful information • "Just this once" mentality puts infants at increased risk during times of disruption	• Credible source • Goal setting • Behavioral contract	• Health professionals become trusted, and advice increases in credibility • Increased confidence to follow a personalized plan for safety
Automatic motivation	• Reinforcement • Emotion	• Fear of SUDI[a] can be stressful and overwhelming	• Reduce negative emotions	• Increased confidence that the plan is achievable and realistic

[a] SUDI: sudden unexpected death in infancy.

Methods

Ethical Considerations

The full study protocol was reviewed and given a favorable ethical opinion by the London – Chelsea Research Ethics Committee and granted Health Research Authority approval on June 21, 2022 (reference 22/PR/0445). Interview participants were compensated for their time with shopping vouchers.

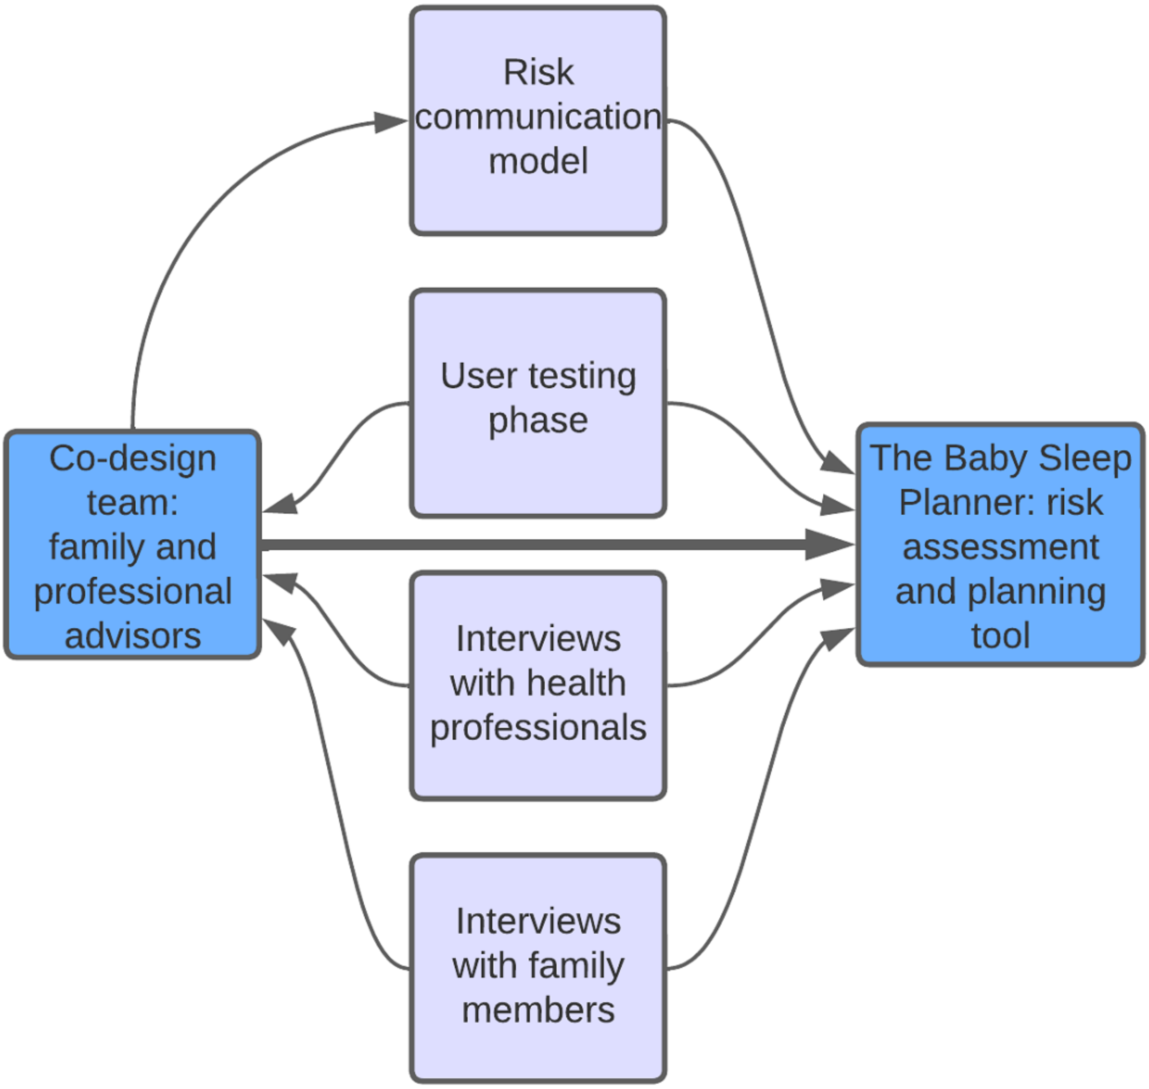
Professional Advisory Group

A group of experts was consulted to make sure that the content and advice within the tool supported the national advice for safer sleep. These experts comprised a professor of neonatology; a professor of midwifery and nursing; a professor of anthropology; a chief executive of a national SUDI charity; and a specialist health visitor for Gypsy, Roma, and Traveler families. Their input was sought during the development of the tool in conjunction with our co-design meetings.

Co-Design Meetings

Before developing the tool, we engaged a family advisory group made up of 15 families with infants at risk of SUDI or who were affected by SUDI. The group met regularly both before and during the evaluation phase to influence the concept and design of the tool. Members of this group were invited to join via local health visitors, family nurses, and our study website and social media accounts as well as through Little Lullaby, a branch of the Lullaby Trust specifically for young parents. Figure 1 shows the overall process of tool design, including the influence of the co-design team and evaluation activities.

Figure 1. Co-design process showing data sources used to design the risk assessment and planning tool.



Health Professional Recruitment

A total of 3 health professional roles were included in our process evaluation of the tool: midwives, health visitors, and Family Nurse Partnership (FNP) nurses. The midwives were all from a single community-based team for vulnerable and high-risk families. FNP nurses work solely with mothers aged ≤19 years, and 1 team from Bristol was invited to take part. Health visitors working with vulnerable families in 3 local areas (Bristol, North Somerset, and South Gloucestershire) were asked to volunteer to take part in the study by their managers. Study information sheets detailed all aspects of the research and included information on data security. Written consent to use the tool and take part in an interview was collected before participating in the study. All data collection for the evaluation followed the UK policy framework for health and social care research [12], including adhering to strict data protection guidance. Data were stored on secure university servers only accessible to members of the study team.

Health Professional Training

A training package comprising a handbook, video presentation, Microsoft PowerPoint (Microsoft Corp) slide show, and 30-minute session with a member of the study team was provided to each health professional. The handbook included information on the background of the tool, the evidence base, how it was developed, the structure of the tool, and details about how to use it with families. The video presentation covered both the structure and use of the tool and was presented at a 30-minute training session attended by every health professional. Completion of the training was a prerequisite for being sent the link to the tool. Health professionals were supported throughout the study with dedicated email and phone contact.

Health Professional Interviews

Semistructured interviews with health professionals provided insights at each stage into the conditions of delivery, including *adoption* of the tool (how it was used, which resources were used, how families were chosen, and which family members engaged), *appropriateness and acceptability* (response from professionals and ease of use), and *fidelity* (the details of implementation into practice vs what we envisaged). Health professionals were also asked about scope for widening the tool beyond safer sleep, for their suggestions for how to do this, and which other infant health or well-being topics would be relevant to their work with families experiencing poverty. The interview topic guide was developed with input from our professional advisors, and iterations were made as the interviews progressed.

Family Interview Recruitment

Consent to be shown the tool was given verbally to the health professionals during initial conversations on safe sleep. Separate consent was also embedded into the tool to allow researchers to view the responses. Thus, it was possible to consent to be shown the tool without collecting any data or participating in an interview. Consent to be contacted regarding a possible interview about their experience using the tool was passed on to the research team via the health professional for follow-up. A member of the research team contacted each family member with a study information sheet and consent form. Recruitment took place via telephone, email, or SMS text message depending on participant preference.

User Testing (Health Professionals Using the Tool With Families)

The link to the Baby Sleep Planner was provided for a period of 12 weeks to allow enough time for each health professional to use the tool with 5 to 6 families. Once health professionals had recruited enough families, they took part in a qualitative interview. At the end of the user testing phase, the data were downloaded. Where consent was given, the tool collected data on each answer to the risk assessment and planning sections and which plan options were chosen. All questions were multiple choice, no personal details could be entered into the tool, and no responses were stored locally on any device to prevent accidental data breaches or identification of any participants.

Family Interviews

Qualitative telephone interviews used a topic guide with families focused on *acceptability* (engagement with the tool and ease of use), *appropriateness* (language and literacy access and perceived targeting by professionals), and evidence of *influence on behavior* (experiences with using the plan and spreading awareness to other parents or carers). The interview topic guide was developed with input from our family advisory group, with iterations as the interviews progressed. Individuals aged <16 years, anyone who lacked the cognitive capacity to consent, and anyone unable to complete an interview in English were not eligible to take part in the study.

Interview Analysis

The interviews took place via telephone or face-to-face. The audio recordings were transcribed, anonymized, coded, and investigated using a framework analysis allowing for a systematic approach to generating themes [13]. An initial analytical framework of codes was developed inductively using the first 5 transcripts, agreed upon by 3 team members, and then applied consistently (deductively) across the remaining transcripts. Separate frameworks were developed for family and health professional interviews. Team members coded transcripts using double coding across 50%, and discrepancies were resolved through team discussion.

Results

Objective 1: Co-Design of the Tool Interface

Overview

Our family advisory group, together with the research team, developed a model for delivering risk information (Figure 2) to caregivers of infants involving five stages: (1) being honest about the risks, (2) giving reasons for the risks and feedback on reducing them, (3) showing options for reducing the risks (using other families' real experiences), (4) asking what would work and support planning, and (5) making it shareable for other caregivers. Using this input, we worked together with the software development team and a graphic designer to make the tool meet each of those 5 stages. We adapted the planning option wording and images based on the recommendations of the family advisory group and included advice specific to a wider range of families thanks to their focus on the realities of infant care, such as nonstandard housing and looking after more than 1 baby at a time.

Following the co-design meetings, we produced a flowchart of tool functions showing the questions and functions for each stage. This flowchart was refined through further family advisory group meetings and with feedback from our professional advisory group members. Decisions were made based on the complexity of the tool, the costs of the design, and how well it enabled each of the behavior change techniques.

During this process, we kept the risk assessment and sleep environment planning sections separate, with an option to complete them together if suitable. Feedback from professionals in our advisory group suggested that the separate risk assessment could be a useful stand-alone tool for professionals working with families to know who to target with additional support for safer sleep and to complete before using the tool with a family. The risk assessment is based on nonmodifiable family background and birth characteristics, whereas the sleep environment section is based on modifiable behavior.

An initial prototype of the tool interface was available for feedback from our professional advisors, after which any final refinements were made. Table 2 shows example changes made throughout the co-design process. The family and professional advisory groups also reviewed the training materials.

Figure 2. Risk communication model designed by the co-design team.

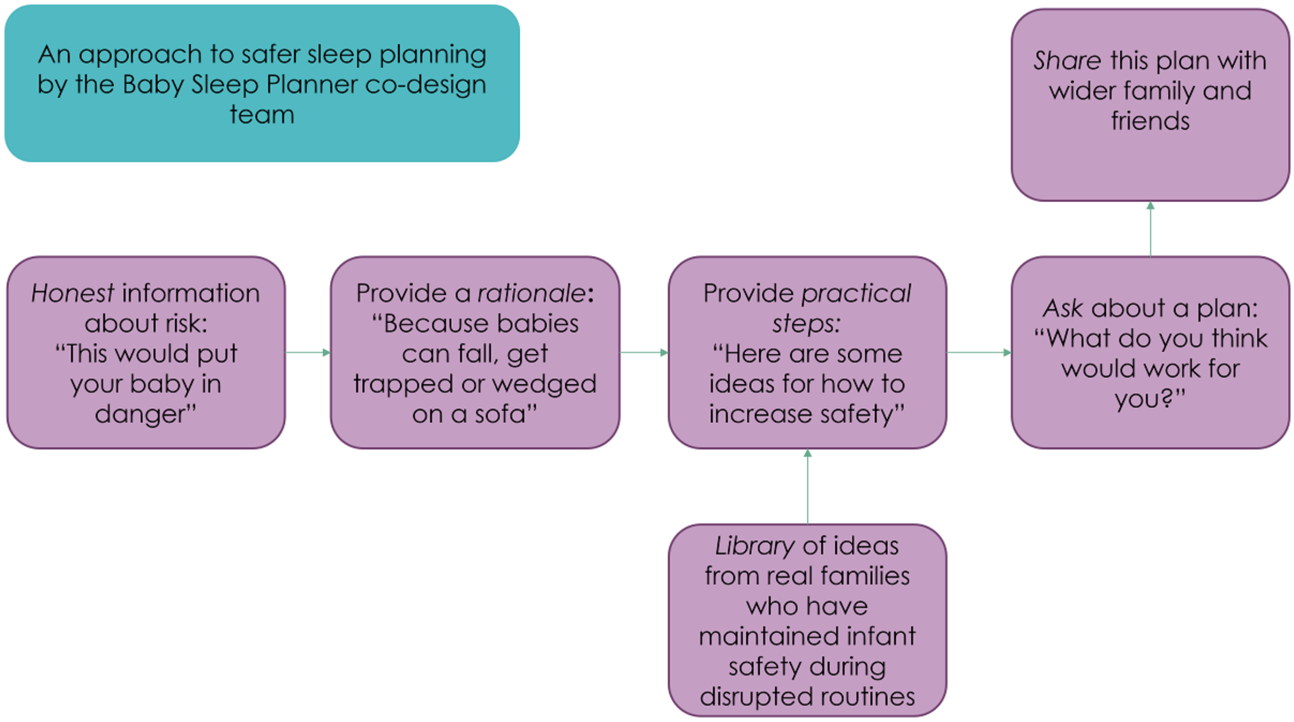


Table 2. Example changes from the co-design process and professional advisory groups.

Feedback, question, or wording in tool	Change	Reason and example
"Which one best describes your relationship to the baby?"	Add in an answer option for "both parents or caregivers"	Feedback from health professional advisor—if they are talking to both parents at the same time (eg, in midwifery clinic)
"Babies in larger families, especially if the mother is young, are nearly three times more at risk of SIDS."	Change to the following: "Babies in families with 2 or more children, especially if the mother is young, are nearly three times more at risk of SIDS."	Feedback from professionals and family advisors that 2 children is not really a "large" family
Feedback that the nonmodifiable nature of the risks feels unfair	Add in the following: "Your baby's background risk is fixed and often not something you can control. You can have control over your baby's sleep environment and reduce their risk greatly by following the advice."	Feedback from family members; this change may help give families a feeling of acknowledgment that their baby's risk status is not within their control and empower them to reduce risks by following safer sleep advice
Things to think about if answered "sheets or blankets": "Make sure sheets and blankets can't cover the baby's face. Putting the baby at the bottom of the space can stop them wriggling under blankets."	Change to the following: "Make sure sheets and blankets can't cover the baby's face. If baby is in a cot, putting their feet at the bottom of the cot can stop them wriggling under blankets."	Feedback from family advisors so that people do not interpret "bottom of the space" as the bottom of an adult bed
Question: what will be covering the baby?	Add in options for "nothing." If "nothing" is selected, add the following text: "If it is very hot in the room where the baby will sleep, it may be best not to use any bedding. You can also try to cool the room, please visit this site for more advice: [link to relevant Lullaby Trust web page]"	Feedback from health professionals and families during a heat wave to accommodate hot weather scenarios
Add in more detail when "blankets" is chosen: "Make sure sheets and blankets can't cover the baby's face. If baby is in a cot, putting their feet at the bottom of the cot can stop them wriggling under blankets."	Change to the following: "Make sure sheets and blankets can't cover the baby's face. If baby is in a cot, putting their feet at the bottom of the cot can stop them wriggling under blankets. Make sure sheets and blankets don't make the baby too hot—for advice about temperature please visit: [link to relevant Lullaby Trust web page]"	Feedback from health professional advisors to add information about thermal regulation and room temperature
Details about the risks of smoking	Added in a link to relevant Lullaby Trust web page.	Requested by professionals to support conversations about smoking cessation

The Baby Sleep Planner Intervention

The Baby Sleep Planner (Figure 3) is a web-based risk assessment and planning tool with 2 sections that can be completed together or separately. The risk assessment tool includes 8 questions about the background characteristics of the infant, usually delivered shortly after birth, and assigns a score based on an algorithm [14]. These questions include maternal age, number of children, smoking during pregnancy, partner support, partner smoking, infant sex, birth weight, and neonatal unit admission. A total of 7 other nonmandatory questions are asked to inform the research, including infant age, gestation, multiple births, ethnicity, relationship to the baby, whether this is the first time using the tool, and whether there is a health professional present. Each question is categorical, with 3 levels of risk assigned: lower, slightly higher, and higher risk. The information in the results is tailored to the risks present in each infant. The results are presented with information about research evidence and a key message that risks can be substantially lowered by following safer sleep advice.

Figure 3. Final design of the Baby Sleep Planner.

The planning tool includes 6 questions about the infant's sleep environment, including room sharing, sleep location (eg, cot or adult bed), sleeping position, items in the sleep space, coverings (eg, blankets or sleeping bag), and feeding method. The results of these questions comprise 3 categories: things going well, things to think about, and things to change. Feedback includes links to further information from a national advice charity, the Lullaby Trust. Users are then given 14 "plan options" comprising images with safety messages and asked to pick between 2 and 4 to create their own baby's plan. The plan can be downloaded to a device (eg, mobile phone) as an image that can be shared with wider family and friends.

The intervention includes training for health professionals, a 30-minute web-based session with a member of the research team to explain the background, theory, and use. For this evaluation, the tool was only available for use as part of a conversation with a health professional, and the link to the website was not shared directly with families. Although the tool is under development, we wanted to make sure that the content and interpretations were as intended.

Objective 2: User Testing, Including Tool Use Database Development

The tool and associated training were completed by 22 health professionals: 9 (41%) midwives, 8 (36%) health visitors, and 5 (23%) family nurses. In total, health professionals reported using the tool with 58 families, and the tool database recorded 55 uses of the tool. Of these responses, 48 (87%) were for the combined risk assessment and planning tool, 5% (3/55) were for the risk assessment tool only, and 7% (4/55) were for the sleep planner only. It was not possible to match tool use to a particular user because of data security, so we do not know whether the database responses are from real conversations with families or health professionals trying out the tool. We also do not know whether the tool was completed more than once per participant, although the reports from the health professionals suggest that it was not completed more than once. Health professionals reported that all the families they spoke to consented to seeing the tool, and the majority also consented to the research team seeing their answers. However, as we were unable to match the database responses, we could not quantify how many refused to provide information to the researchers, although it is thought to be a small number.

Objective 3: Qualitative Interviews

Health Professional Interviews

A total of 22 health professionals volunteered to take part in the process evaluation (Table 3), were recruited for the study, and attended either over the web or face-to-face training. In total, 9% (2/22) of the health professionals subsequently withdrew, both going on long-term sick leave. In total, 20 health professionals, comprising 9 midwives, 8 health visitors, and 3 family nurses, were interviewed.

Table 3. Description of health professionals recruited for the process evaluation.

ID	Role (n=22)	Training in person or over the web (n=11 in person and n=11 over the web)	Families shown the tool (n=58), n (%)	Took part in an interview? (n=20)
MW1	Midwife	In person	2 (3)	Yes
MW2	Midwife	In person	5 (9)	Yes
HV1	Health visitor	Over the web	4 (7)	Yes
HV2	Health visitor	Over the web	3 (5)	Yes
HV3	Health visitor	Over the web	1 (2)	Yes
HV4	Health visitor	Over the web	4 (7)	Yes
HV5	Health visitor	Over the web	5 (9)	Yes
FNP1	Family nurse	In person	1 (2)	Yes
FNP2	Family nurse	In person	0 (0)	No—off sick
FNP3	Family nurse	In person	0 (0)	No—off sick
FNP4	Family nurse	In person	2 (3)	Yes
MW3	Midwife	In person	0 (0)	Yes
MW4	Midwife	In person	5 (9)	Yes
HV6	Health visitor	Over the web	5 (9)	Yes
HV7	Health visitor	Over the web	5 (9)	Yes
HV8	Health visitor	Over the web	6 (10)	Yes
MW5	Midwife	In person	1 (2)	Yes
MW6	Midwife	In person	4 (7)	Yes
MW7	Midwife	Over the web	1 (2)	Yes
MW8	Midwife	In person	0 (0)	Yes
MW9	Midwife	Over the web	3 (5)	Yes
FNP5	Family nurse	Over the web	1 (2)	Yes

Practical Use and Engagement

Health professionals found the tool easy to use and appreciated its ability to engage parents in conversations regarding the risk of SUDI. They commented on its simplicity, plain language, and visual design. Some commented that it took a little bit of time to get used to using it, and some had difficulties accessing the internet while with the families:

> *...it was really good, and parents really engaged with it, because it was very much tailored to them, and so compared to other sleep conversations they were much more engaged and interested in it.* [HV7]
>
> *With anything it takes a little bit of getting used to, but it was easy enough once you have done it once with a family. You were both learning at the same time really with the first family I did it with.* [HV1]

Communicating About Risk

Health professionals appreciated the balance between being honest and up-front with families while being careful to avoid making parents feel anxious or judged. They described using the tool to support conversations that empower parents with knowledge about their individual infants, which then supports the need for the safer sleep messages:

> *What I liked about the tool is that directness about it...it gave me support, because often I feel like as a practitioner I was saying this stuff and can come across a little bit naggy...Whereas this was a really helpful tool to back up what we're asking of families.* [FNP5]
>
> *...you need to understand a certain level of risk, but it wasn't making people feel worse going through the questions, and going through the outcomes, it didn't*

> *make parents feel more anxious about the situation.* [HV6]

Beyond the Messages

Advice given to families is often didactic, and health professionals commented that the tool allowed them to go further than just giving out the safer sleep messages. They liked that it supported a conversation rather than just telling families what to do. They described being able to get more information across, feeling that parents were more involved in the conversation, and being able to delve into specific messages that parents wanted to discuss:

> *...she has some learning difficulties as well, so I was quite surprised she could focus throughout the whole thing really. It felt like that they were being involved, rather than just being told, and also I think what it did was it meant we talked about it for longer.* [FNP1]

> *...she could then ask questions just about little other areas, just talking about when can they have a pillow, what age? And it facilitated a little bit more of a wider discussion around safe sleep really.* [FNP5]

> *So engaging with people, listening to what they have to say, and then maybe just bringing it up more in conversation than this is what I'm telling you to do.* [MW9]

Wider Family Support

Advice about safer sleep is often given solely to the primary carer of the infant, and some health professionals described how they used the tool to encourage mothers to share their plans with their wider friends and family. Some found it difficult to send the image to the mother's device and would have preferred a printed option; however, there was a consensus that supporting how mothers communicate about safer sleep with their families is important:

> *We used it to help her communicate what was important to her with the paternal family, so that she could ensure her baby was safe, and those steps that she was taking at home could be continued in a different environment.* [FNP5]

> *We find this with a lot of our clients' parents in that they're giving a lot of advice themselves, so it's important that they are given the up to date advice so they can support the mum in making decisions.* [FNP1]

Barriers to Use and Changes Suggested

Health professionals cited time as a limiting factor in tool use as well as internet access problems and battery issues with work laptops. The timing of use was also raised, with some seeing value in repeating the process and starting sleep planning conversations during the antenatal period. They described seeing the value of the tool for all parents, not just those with infants at increased risk. Some suggested a variety of options for sharing the sleep plan image with the family, including printing it off for those without mobile devices. Changes suggested included versions in languages other than English, more information on the risks associated with smoking, rethinking our description of larger families, information on ideal room temperature, and more details on blanket use:

> *For some people having a visual maybe on the fridge printed off, that's what I intended to do but it got lost in the ether when I downloaded it on my phone and I couldn't find where it had downloaded to. For others, their phones break every week, and getting new numbers, something printed like that would be ideal.* [MW1]

> *More about smoking around the baby or smoking in the same room as baby?* [HV2]

> *Would you need a different tool for antenatals to look at the risk factors, and you could discuss those risk factors then with them?* [HV4]

> *The girl had only had two children, but it came up with a message at that point from babies from larger families are more at risk, and I wouldn't class two children as a larger family.* [MW3]

Scope for Future Work

Health professionals were asked about other topics they thought would be of benefit to the families they worked with, and they raised a variety of issues. The limited capacity for home visits and relationship building owing to heavy workloads was a constant problem. Some had ideas for widening the scope of the Baby Sleep Planner to be able to use it during pregnancy and with non-English speakers, and 1 health visitor suggested adding reminders that could be sent via email to parents to support the changing needs of infants over the first year, for example, at 6 months, when babies can potentially be moved into a room of their own. Several suggested including more detail in the existing tool focusing on use of substances, both prescribed and illicit, to increase awareness of the risks associated with cosleeping when parental responses may be impaired. Another health professional suggested incorporating a planning aspect into stressful parenting situations, for example, planning activities to reduce stress and potential injury to the infant, similar to ICON (a program to reduce abusive head trauma in infants). Finally, 1 family nurse suggested an intervention focused on domestic abuse, in particular on the effects of coercive control on parenting capacity:

> *Something about domestic abuse? Domestic abuse like to care and control, and neglect, of them not being able to focus and care for their babies, because of stuff going on in their relationship.* [FNP1]

> *More information about smoking or strong painkilling medication that might make someone sleepy.* [MW3]

> *In the future would it send parents reminders and things at all if they signed up for this planner and things? I think that would be good. As health professionals we don't see them as often as we can do, but just if they signed up they could get a text or whatever about sleeping, or if it was an app you would get a notification wouldn't you about remember these things, it's really important, your baby is 6 months, they can move into their own room, but they*

> *still can't have a pillow or duvet, that kind of thing.* [HV1]

Family Member Interviews

Health professionals sent contact details for 32 family members who had agreed to be contacted about a research interview. All were invited to take part in an interview except for 1, whose contact details were sent to the research team after data collection had been completed and recruitment was closed. A total of 20 families gave consent to be interviewed and completed a telephone interview (Table 4). In total, 4 interviews included both the mother and the mother's partner. Joint interviews were analyzed together, and 1 mother was still pregnant at the time of the interview. Risk scores (using the algorithm for interview participants' infants) ranged from 0 to 153 (mean 58.7, SD 49.5). A total of 3 of the infants had risk scores of >115, indicating increased risk of sudden infant death syndrome using our recently developed algorithm.

Table 4. Families interviewed, with corresponding infant risk status.

ID	Relationship to baby	Maternal age (y)	Infant sex	Birth weight (g)	NICU[a] admission	Parity	Smoking during pregnancy	Partner support	Partner smoking	Infant risk assessment score
01	Mother	<21	Male	≥2500	No	1	No	Yes	No	79
02	Mother	21-24	Female	≥2500	No	1	No	Yes	Yes	65
03	Mother	≥25	Male	≥2500	No	1	No	Yes	No	15
04	Mother	≥25	Female	≥2500	No	1	No	No	N/A[b]	18
05	Mother and partner	21-24	Male	≥2500	No	1	No	Yes	No	46
06	Mother	≥25	Male	≥2500	No	1	No	Yes	No	15
07	Mother	<21	Female	≥2500	No	1	Yes	Yes	Yes	146
08	Mother and partner	≥25	Male	≥2500	No	1	No	Yes	No	15
09	Mother and partner	≥25	Male	≥2500	No	1	No	Yes	No	15
10	Mother	<21	Male	≥2500	No	2	No	Yes	No	111
11	Mother and partner	≥25	Male	Pregnant	Pregnant	1	No	Yes	No	15
12	Mother	≥25	Male	≥2500	No	1	No	No	N/A	33
13	Mother	<21	Male	≥2500	No	1	No	Yes	No	79
14	Mother	≥25	Male	≥2500	No	1	No	Yes	No	15
15	Mother	≥25	Female	≥2500	Yes	2	Yes	No	N/A	114
16	Mother	≥25	Female	≥2500	No	1	No	Yes	No	0
17	Mother	≥25	Female	≥2500	No	2	No	Yes	No	32
18	Mother	<21	Female	1749-2499	No	1	Yes	Yes	Yes	153
19	Mother	<21	Male	≥2500	No	1	No	Yes	No	79
20	Mother	21-24	Female	≥2500	No	2	Yes	No	N/A	129

[b] N/A: not applicable.

Tool as a Trusted Source

Parents commented on how they felt that they could trust the information they received from the tool and that this was supported by its delivery from a health professional and alignment with national advice. They appreciated the wording as "factual" and not judgmental. Some liked that it was interactive and tailored to their baby, whereas others felt that they knew the information already and this was just a useful reminder:

> *I thought it was presented very simply, but not in a patronising way. It just the imagery and the just having a few words around it just made sense, and made it a bit more engaging.* [ID04]

> *...it's not judgemental but straight down the middle factual, but not trying to ward people off. I think the wording was fine for me.* [ID03]

> *...as a first time mum it was very useful, because I wouldn't have...people tell me stuff, but to hear it from somebody professional who actually knows was a lot more helpful.* [ID02]

> *The hospital went over it when I was discharged, and my community midwife, but that was about it...They*

> *were the same but they weren't in as much detail as your survey.* [ID07]

> *I think it's good when they come across the whole planner about it, because I think a lot of people would like to go through it just so that they've got all the information they need as well.* [ID20]

Risk Assessment Process

Lower-risk parents reported feeling reassured by the results of the risk assessment, whereas higher-risk parents described it as unsurprising and supportive in that it encouraged them to follow the advice. Some described difficult feelings regarding the algorithm risks being unchangeable or related to things that they did not have any control over:

> *So yeah it was reassuring to know that as far as anyone can predict we are at lower risk. So that I found quite helpful.* [ID04]

> *I believe it came out that I was high risk, that it was high risk, but with doing everything that I'm doing she said it was okay, do you know what I mean?* [ID15]

> *The difficult one about with the single parent is unsupported partner. That's the one thing that was difficult for me was you're three times higher risk with SIDS, what can I really do about that? That was difficult. Tilted cot, fine I can change that, but I can't change a supportive partner thing.* [ID12]

> *Yeah, and I think at the end when you get your risk as well and it's like you're at this much of a higher risk, it opens your eyes and you're like wow and you're like okay, do you know like...yeah.* [ID20]

Sleep Planning Process

Parents had mostly positive things to say about the sleep planning process, commenting that it included all the information they would need and appreciating that it explained the reasons for the advice without just telling them what to do. Most of the parents had answered the sleep environment questions remembering a real sleep that had taken place recently or with what they normally did. Changes to this part of the tool may be required to encourage parents and caregivers to use the sleep planning process to imagine what might happen in times when the normal routine is disrupted, for example, when staying away from home overnight. Several of the parents commented that they did not receive their plan image from their health professional:

> *Because as well the idea is that it doesn't just tell you what to do or what you should do, it tries to explain why.* [ID15]

> *I think we've been quite realistic with our plan, so I think we could stick to it most nights, depending on how things go with the baby, things could change in terms of feeding patterns and that kind of thing. But I generally it would be quite straightforward to stick to.* [ID03]

One mother shared how she had used the sleep planning tool and downloaded the plan as a picture to share with her family members who were responsible for her baby's overnight care once a week:

> *This is what we done, we took a picture so then we could send it to them, because I thought it would be more helpful to them, whereas if they don't have him as much, so they're not...they don't know him as well in his sleep than what I would do. So I thought it would help them a lot more.* [ID01]

Changes Since Using the Tool: Potential Impact

Several parents described things that had changed as a result of using the tool with their health professionals. These changes included, taking items out of the Moses basket, tucking blankets in, using age-appropriate sleeping bags, and keeping unsupervised pets away from sleeping babies. Others felt that they were doing everything they could but still appreciated the reassurance that this gave them:

> *...it was nice that there was something on there that I hadn't considered. I felt a little bit nervous about the fact that he's been sleeping with a slant, but it was only for seven to ten days, and I've rectified that now.* [ID12]

> *I didn't know that you didn't have to...you weren't allowed anything in the Moses basket.* [ID07]

> *...a lot of things we were doing already, and it was good to get the advice about tucking the blanket under the mattress, because that bit we had been like oh how do we keep it secure so it doesn't go over his face? So yeah, no it was useful.* [ID09]

Barriers to Use and Changes Suggested

Some of the barriers included not being able to access the plan images and preferring to go through the tool on their own without their health professional present. Some suggested having more links to click through for more in-depth explanations of how the messages protect infants. Several parents felt that the way in which the risks were explained could be better, using pictures or comparators that were known to them. One parent commented that there could be more emphasis on the ways in which they can lower the risks and less on things that they cannot change:

> *...perhaps being able to click on something and go through to a bit more information. So as you were saying about the feet to foot of the bed, so if you want to know more about it you can click on the icon and go through and have a bit more information about why that's the recommended sleeping position and those sorts of things.* [ID04]

> *I suppose the only thing that would be easier to use would be something digitally, like an app, or something that could be sent through to you to do rather than being shown two you on another laptop.* [ID11]

> *...having this baby here that I need to look after on my own all night with no support from his dad, and then to look at that statistic it was like oh no, and what can I do about that apart from bring down all*

> *the other risks? That's the only feedback I would have in terms of there was no okay well what can I do to make sure that I'm lowering that risk in that way.* [ID12]

Discussion

Principal Findings

This study developed a risk assessment and planning tool that is pragmatic for use in a real-world setting. It has the potential to be used in clinical practice for the identification and support of high-risk infants and for families to use to reduce proven risk factors in the infant sleep environment. Interviews with users demonstrated how the tool could enable enhanced support to reach those most at risk while also reducing the burden of work for health professionals. Health professionals reported that they found the tool more conversational and less didactic, and families reported that they appreciated this approach.

Comparisons With Existing Literature

Our findings align with those of other research into behavior change for this group, including a recent COM-B analysis of interventions to improve the uptake of safer sleep that found that, although increasing capability by passing on information about risks was common, more effective interventions incorporated motivational factors such as goal setting and making plans [11]. The risk assessment and planning tool incorporates motivational factors within the planning part of the tool, asking about where and how the baby will sleep, providing feedback on a variety of answers, and inviting users to prioritize their goals for safety in an individualized safety plan. In our study, families appreciated the approach to bed sharing taken in the tool, aligning with recently updated advice from the National Health Service in England to acknowledge that bed sharing occurs in planned and unplanned ways and offering advice to reduce the risks in bed-sharing situations [15]. In a 2016 review of behavioral interventions, Moon et al [16] suggested that interventions should be multilevel, incorporating contextual factors into the design, as we have attempted to do in this study. They also recommended formal process evaluations and future studies that can measure effectiveness as needed to support wider implementation [16]. Other reviews have found similar issues with measuring effectiveness and concluded that creative methods may be needed, as well as interventions that include the wider family and peers [17].

Strengths and Limitations

The inclusion of a theory-based approach incorporating co-design elements, along with the evidence for behavioral influences that work for this group, gives this intervention a solid basis for effectiveness. Findings from the interviews support the theory that sharing individual risk status information (ie, "information about health consequences") may increase parental understanding of their own infant's safety needs. Sharing achievable and realistic plans may increase social support for following safer sleep advice, and having personalized conversations about safer sleep with health professionals as credible and trusted sources may enhance parental confidence and decision-making, especially during times of disruption to the normal routine. Integrating feedback from both health professionals and family members into the design and function of the tool meant that we were able to align the needs of both groups by ensuring that the tool provides evidence-based information in a way that supports the individual needs of each family. Testing the prototype intervention under real-world conditions provided insights into implementation and highlighted necessary changes. Issues with accessing the downloaded plan image meant that some families were not able to use this aspect of the tool, and this needs further consideration, with options for printing where possible. There were promising signals from the evaluation that understanding the risks to their baby and planning for safety during times of disruption may influence decision-making regarding the sleep environment, prioritizing safety at all times. The finding that some families found the unchangeable risks difficult to hear prompted further work to investigate how the risk assessment results can be presented as honest but not hopeless, providing more emphasis on how safer sleep planning can reduce the risks as much as possible even for an already higher-risk infant. It may be that the decision to describe infants as "higher risk" is unhelpful, and this should be explored in future work. This wording is currently used based on advice from our family advisors that being honest about the risk status of infants is important, as shown in the model in Figure 2. Most of the suggestions for changes to the tool were mainly minor, and we were able to incorporate them fairly quickly (see Table 2 for examples). Other changes, such as non–English language versions, will take longer. This was a small evaluation study using a prototype intervention. Our original aim included the development of a stand-alone tool that families could use independently, but studies that can collect more data on the safety and appropriateness of the tool to be used in this way will be required first. The risk status of the infants referred to the research team was also lower than we had expected; only 15% (3/20) of the families had infants at increased risk of SUDI, although every family except 1 had at least 1 risk factor present. We were also only able to include English-speaking families in this study, and future work to translate the tool for use in other languages should be included as part of future evaluations. Challenges with health professional recruitment because of current National Health Service pressures led to delays in data collection, resulting in health professionals using the tool with any families they thought suitable rather than those with higher-risk infants only. We were also unable to analyze the background tool data in this study as we were not able to discern "real" conversations with families from health professionals practicing with the tool. Improvements to tool background data collection have been made to make it possible to use these data to understand the characteristics of the families using the tool in future studies. We have also changed the wording of our "data usage" question to prevent this problem in future studies. To test the tool in "real-world" conditions, we did not restrict health professionals in terms of who they used the tool with, and some of them reported that they appreciated being trusted to use the tool with whom they thought best, including anxious parents with low-risk infants who would be reassured by the results. The implications of tool use for this population should be included in future evaluations without undermining the focus on families with infants at increased risk.

Conclusions

The Baby Sleep Planner was designed with involvement from families and key stakeholders and shows promise as a useful tool for health professionals having conversations about safer sleep with caregivers of infants. The web-based tool was acceptable to family members, midwives, health visitors, and FNP nurses. Further work should investigate whether the uptake of this intervention will significantly reduce known risk factors in the infant sleeping environment associated with sudden infant deaths and whether this algorithm can identify families with infants at risk of other causes of death.

Acknowledgments

The authors are grateful to the health professionals and families who took part in this study; for the support from the Bristol, North Somerset, and South Gloucestershire Integrated Care Board; to the midwives at the Royal United Hospitals Bath; and to Sirona Care and Health. Abstract

Background: Parent training interventions support and strengthen parenting practices and parent-child relationships and improve child behavior. Between March 2018 and February 2020, a community-based parenting program conducted 38 in-person Chicago Parent Program (CPP) groups. In response to the COVID-19 pandemic, we modified the delivery of the in-person CPP to hybrid delivery using the self-administered, web-based version of the CPP (*ez*Parent) paired with web-based, videoconferenced group sessions.

Objective: This study aims to describe the delivery transition and implementation outcomes of the hybrid delivery of the CPP (ezParent+group) during community-based dissemination.

Methods: This single-group, mixed methods retrospective evaluation examined the implementation outcomes using the RE-AIM (Reach, Efficacy, Adoption, Implementation, and Maintenance) framework. We report on data from hybrid *ez*Parent delivery between September 2020 and August 2022. Parents completed pre- and postprogram surveys that included motivation to participate and perceived changes in parent-child behavior. Digital analytics captured *ez*Parent completion. Facilitators completed fidelity assessments and participated in postintervention interviews.

Results: In total, 24 hybrid *ez*Parent groups (n=240 parents) were delivered by 13 CPP-trained facilitators. Parents reported high levels of satisfaction with the program and improvements in their feelings of parenting self-efficacy and their child’s behavior following their participation in hybrid *ez*Parent. On average, parents completed 4.58 (SD 2.43) 6 *ez*Parent modules. The average group attendance across the 4 sessions was 71.2%. Facilitators found the hybrid delivery easy to implement and reported high parent engagement and understanding of CPP strategies.

Conclusions: Using the hybrid *ez*Parent intervention is a feasible and effective way to engage parents. Lessons learned included the importance of academic and community-based organization partnerships for delivering and evaluating robust programs. Implementation facilitators and barriers and future research recommendations are discussed.

Introduction

Background

Behavior parent training (PT) is considered the gold standard for supporting and strengthening parenting practices and parent-child relationships and for the prevention and treatment of child behavior problems [1,2]. Positive parenting practices are a protective factor in buffering the negative effects of childhood trauma or early adverse experiences [3,4]. Parenting practices are often informed by family of origin, community, and social connections, and parents often look to their community for parenting support and guidance and many community-based agencies offer evidence-based PT [3].

Unfortunately, community organizations delivering PT experienced major disruptions in the provision of services with an abrupt ending of all in-person services due to the onset of the COVID-19 pandemic and shelter-in-place orders. These disruptions exacerbated an existing access gap for many communities, particularly those who were providing in-person individual or group-based PT. In addition, while parents lost access to parenting supports and child activities (eg, group activities, child care, school, and playgrounds), they experienced a substantial burden of shelter-in-place requiring a balance of work and parenting responsibilities [5,6]. Partially due to social isolation, balancing of responsibilities, and limited access to information and resources, data suggest a surge in negative mental, emotional, and physical health outcomes for parents and children [5,7,8]. Therefore, resources and support to mitigate the effects of the pandemic were crucial during this time.

Many community organizations shifted delivery of in-person PT and other parent supportive services using technology (eg, using videoconferencing for groups and web-based programming) [9-12]. The purpose of this paper is to describe the transition of a group-based PT program (ie, the Chicago Parent Program [CPP]) to a hybrid delivery model using the web-based PT of the CPP (*ez*Parent) paired with videoconferenced group sessions and implementation in a community-based parent support program. This study is the result of a community-academic partnership in which representatives from each coled the design, implementation, and interpretation of the data.

The Chicago Parent Program

The CPP is for parents of children aged 2 to 8 years and designed as a strength-based approach to promote positive parenting skills (ie, warmth, positive engagement, and support), support optimal child social and emotional development, and enhance parent-child interactions [13-16]. The CPP is a 12-session, group-based program that was developed with input from an advisory board of Black and Hispanic parents in low-income neighborhoods and aims to be contextually and culturally relevant for families from diverse racial, ethnic, and income backgrounds. Currently, the third edition of the CPP is broadly used in community agencies, pediatric primary care, early childhood care and education centers, and schools [17].

*ez*Parent is the web-based version of the CPP and was designed to deliver the core parenting skills and strategies in the CPP via 6 self-directed modules. Similar to the group-based delivery, *ez*Parent content and delivery was informed by an advisory group of Black and Hispanic parents and designed to help parents develop positive and effective parenting skills and decrease physical punishment through the use of behavioral strategies (eg, routines and labeled praise), brief videos of parents using the strategies, activities, quizzes, and practice assignments [18]. The web-based delivery of the CPP was developed to increase access by addressing challenges for parents and providers related to in-person delivery, including logistic barriers (eg, work demands, scheduling, childcare, and transportation), access to in-person groups, and potential for stigma [18,19].

Rochester Area Parenting Program

The Rochester Area Parenting Program (RAPP), a program initiative at the Children's Institute Inc in Rochester, New York, began implementing the group-based CPP in 2018. From March 2018 through March 2020, RAPP supported 35 CPP groups in collaboration with 6 partnering community programs across 14 sites (eg, churches, Head Start, childcare centers, and a large urban school district). During this time, 396 parents participated in CPP groups led by 23 CPP-trained group leaders. A key community engagement parent empowerment and leadership initiative of RAPP is to identify parents who completed CPP groups and subsequently support these parents in completing CPP training to become group leaders; thus, 25% of CPP-trained group leaders were parent graduates of CPP groups. At the onset of the COVID-19 pandemic shelter-in-place orders (ie, March 2020), RAPP suspended 3 in-person CPP groups and canceled 2 groups that were scheduled to start and began exploring options for alternative delivery methods of CPP to assure continued service provision and support for the families they serve. The RAPP coordinators engaged the CPP developers to determine options for delivery. During this time, many in-person CPP groups nationally moved to web-based delivery using videoconferencing platforms and adapted aspects of group delivery (eg, role-play, group activities, and discussion format). This option was presented to the RAPP leadership team, a group that provides strategic leadership and input on RAPP programming. The RAPP leadership team is a community collaboration with RAPP administrators and agency directors, staff, parent graduates of RAPP programming, trained facilitators, and faculty experts from partnering community agencies, schools, and universities. The RAPP leadership team reached consensus that 2-hour videoconferenced groups over 12 weeks would be challenging for the parents they serve due to logistics and competing demands on parents' time. In addition, the RAPP leadership team considered parent feedback from the group-based CPP indicating that parents highly valued peer and facilitator interaction and support. Therefore, RAPP worked closely with the CPP developers to develop a hybrid model of delivery where parents would complete *ez*Parent modules independently and participate in four 1-hour videoconferenced group sessions led by 1 CPP-trained facilitator.

The purpose of this paper is to describe the implementation outcomes of the hybrid delivery model of self-administered, web-based PT (ie, ezParent) and group sessions during community-based dissemination. Specifically, we seek to evaluate the implementation outcomes, using the RE-AIM (Reach, Efficacy, Adoption, Implementation, and Maintenance) model, of delivering the *ez*Parent program, and identify facilitators and barriers to implementation delivery to support the sustainability of program implementation.

RE-AIM Framework

The RE-AIM framework was designed to provide a model to enhance the quality, speed, and public health impact of efforts to translate research into practice using 5 dimensions: *reach* the intended target population; *efficacy* of the intervention and implementation strategies; *adoption* by trained facilitators and settings (agencies); *implementation*, including fidelity and consistency of delivery; and *maintenance* of intervention effects in individuals and implementation in settings over time [20,21]. In this evaluation, we will report on the reach, efficacy, adoption, and implementation components and present maintenance as part of the discussion.

Methods

Study Design

This single-group, mixed methods evaluation examined the implementation outcomes using RE-AIM of 24 hybrid *ez*Parent groups (n=240 parents) delivered by 13 CPP-trained facilitators in the northeastern United States. We report on survey and interview data from hybrid *ez*Parent delivery between September 1, 2020, and August 1, 2022.

Ethical Considerations

Exempt approval for this project was granted by the Ohio State University Institutional Review Board (number 2022E0128).

ezParent Hybrid Delivery

Although the change in delivery was reactive to the COVID-19 pandemic shutdown, the delivery modification was a thoughtful and engaged process occurring between April and August 2020. Modifications occurred as part of a collaborative effort between CPP and *ez*Parent developers, RAPP coordinators, and the RAPP leadership team to assure congruence with underlying CPP theory and content and RAPP family needs with the goal of maximizing intervention fit and implementation success. Refer to Textbox 1 for a description of key team members involved in the implementation of hybrid *ez*Parent. We describe the adaptation process in Table 1 using the last 4 of 8 categories of the Framework for Reporting Adaptations and Modifications–Expanded (FRAME) outline [22]. The FRAME provides a structure for reporting the delivery adaptation. The FRAME categories include what is changed or modified, at what level of delivery the modification is made, type or nature of context or content-level modifications, extent to which the modification is fidelity consistent, and the reasons for the modification (ie, the intent or goal of the change and contextual factors that influenced the decision). What did not change as part of the adaptation was the *ez*Parent program and core CPP skills and strategies, participation incentives provided for parents from RAPP, and groups facilitated by trained CPP group leaders.

The hybrid *ez*Parent program began with an introductory videoconferenced group session with the facilitator and parents. The purpose of this session was to introduce parents to the purpose of the *ez*Parent program and the groups sessions (eg, to review content parents were learning, review key strategies, and discuss parents’ successes and challenges in using the strategies) and to prepare them for the next session. The purpose of subsequent group sessions was to clarify the content, promote social connection and engagement, and help keep parents engaged in using *ez*Parent. At the introductory session, parents were instructed to complete module 1 and 2 over the next 2 weeks before the next group session. This schedule is repeated for modules 3 to 4 and 5 to 6, each followed by a group session (Figure 1).

Textbox 1. Key team members implementing hybrid ezParent.

Title and role in hybrid *ez*Parent implementation

- **Chicago Parent Program (CPP) and *ez*Parent developers**: authors of CPP and ezParent
- **Facilitators**: CPP-trained *ez*Parent group facilitators
- **Parents**: hybrid *ez*Parent participants
- **Rochester Area Parenting Program (RAPP) coordinators**: administrative support and coordination of Hybrid *ez*Parent
- **RAPP evaluator**: RAPP data manager and evaluator
- **RAPP leadership team**: community collaborative board providing leadership and input to RAPP programming
- **RAPP site**: community partner or organization providing *ez*Parent to families

Table 1. Description of parent program adaptations using FRAME[a].

Modification	Goal of modification	Who was involved in the decision and modification?	Level of delivery[b]	Nature and goal of modification
Contextual format (delivery modifications [eg, format, setting, personnel, and population])				
Videoconferenced group sessions	Intervention engagement and social connection	CPP[c] or *ez*Parent, developers, RAPP[d] coordinators, RAPP leadership, and team	Parent participants and facilitators	Parents complete the *ez*Parent independently and participate in 4 videoconferenced group sessions to promote *ez*Parent program completion and review of parenting strategies
Groups facilitated by 1 CPP-trained group leader	Feasibility and cost	RAPP coordinators, RAPP leadership, and team	Facilitators	Smaller groups and less administrative burden for the group leader than in-person groups
In-between group texts	Intervention engagement and social connection	CPP or *ez*Parent, developers, RAPP coordinators, and facilitators	Parent, participants, and facilitators	Text groups managed by the facilitators for weekly encouragement for program completion
Provided tablets and hotspots to parents	Reach, engagement, and equitable access to all program components	RAPP coordinators, RAPP leadership, and team	Parent and participants	Parents receive tablets and short-term internet access to access *ez*Parent and participate in videoconferenced groups
Training and evaluation (how staff are trained and how the intervention is evaluated)				
Facilitator training	Assure competency in *ez*Parent delivery and review virtual facilitator guide	CPP or *ez*Parent, developers, and RAPP coordinators	Facilitators	2-hour training to review *ez*Parent and the virtual session facilitator guide
Fidelity assessment	Evaluate facilitator adherence to group session protocol and parent engagement	CPP or *ez*Parent, developers, and RAPP coordinators	CPP or *ez*Parent developers, RAPP coordinators, and facilitators	Developed a facilitator self-report fidelity assessment tool (adaptation of CPP fidelity checklist [23] to evaluate adherence to the session components)
Implementation and scale up activities (strategies used to implement or spread the intervention)				
Administrative dashboard	Track *ez*Parent completion for stipend remittance to parents.	RAPP coordinators and CPP or *ez*Parent developers	RAPP coordinators, facilitators, CPP or *ez*Parent, and developers	A web-based administrative dashboard was created for RAPP coordinators and facilitators to track parent completion of ezParent modules
Tech support	Support program delivery	RAPP coordinators, CPP or *ez*Parent, and developers	RAPP coordinators, CPP or *ez*Parent, and developers	Tech support link provided to parents for support with *ez*Parent program

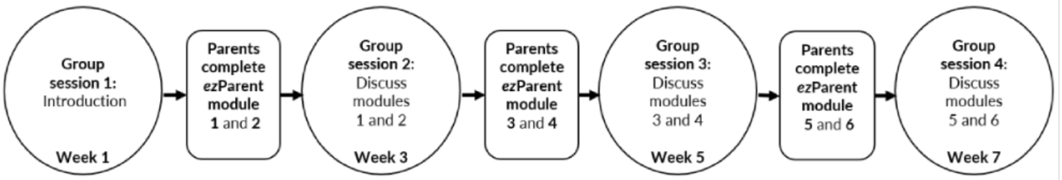
[a] FRAME: Framework for Reporting Adaptations and Modifications–Expanded.

[b] Level of delivery=for whom or what is the modification made.

[c] CPP: Chicago Parent Program.

[d] RAPP: Rochester Area Parenting Program.

Figure 1. Hybrid *ez*Parent schedule of delivery.



Setting and Sample

The RAPP partnered with 6 community organizations (hereafter referred to as RAPP sites). These sites included a large Head Start and Early Head Start program serving over 1000 families; a child care center serving families of children aged 0 to 5 years; a community organization providing childcare, free education and comprehensive services to support Latino/a families; a community organization with the goal of optimizing an nurturing and supportive environment to empower women; a child care network providing early care and education services, including universal PreK; and the Rochester City School District Early Childhood Education Department, serving over 2800 children (aged 3-4 years) and their families.

Parent Recruitment and Enrollment

The RAPP site managed parent recruitment to participate in the hybrid *ez*Parent and used successful recruitment techniques used for other programming for the parents they serve. Promotional flyers were provided by RAPP coordinators and emails were sent to parents to provide information about the *ez*Parent, provision of an android tablet, monetary incentives, and details on how to sign up. If there was in-person contact at the agency or school (eg, child drop-off or pickup), parents were provided with information regarding the program. All sites had a capacity of 10 parents per group. If more than 10 parents expressed interest, the sites kept a waiting list. In subsequent groups at the RAPP site, parents on the waitlist were invited first to participate.

Once the parents enrolled, they were invited to complete presurveys (refer to the Measures section) and received an android tablet computer that had been preloaded with the *ez*Parent program, zoom access, and internet access for the duration of program participation. Parents kept their android tablet at the end of the program for their personal use. Parents were instructed that all surveys throughout the course of the intervention were voluntary. A waiver of consent was obtained for these data as the parent data were anonymous and aggregated. In addition, parents were given instructions related to their first videoconferenced introductory group and paper copies of the curriculum handouts. Parents received US $20 for each group session and US $20 for completion of each module of *ez*Parent (ie, total possible US $200). These conditional cash incentives were provided using a debit card registered in the parents’ name. Conditional cash incentives have been shown to be an effective method for supporting engagement in programming [24,25]. The debit card was either sent to their address or hand delivered. Of note, using debit cards was selected by parents and the RAPP leadership team as the best and most effective way to compensate parents.

Measures

RE-AIM Components

Table 2 provides a description of the RE-AIM components and corresponding variable and measure and data source for the implementation evaluation [21]. Study results will be presented by RE-AIM component and include facilitators and barriers to implementation.

Table 2. Variables and measures aligned with the RE-AIM[a] component.

RE-AIM component and variable	Measure or data source
Reach	
Number of groups that could be supported by agencies and parent participation	Administrative data[b]
Reasons why parents choose to participate in the program	Presurvey
Characteristics of the parent	Presurvey
Parent program completion	*ez*Parent digital analytics and group attendance logs
Efficacy	
Change in parent behavior	End-of-program survey
Change in child behavior	End-of-program survey
Parents’ satisfaction with the program	End-of-program survey
Adoption	
Proportion of trained CPP[c] group leaders adopting *ez*Parent hybrid	Administrative data
Facilitators’ characteristics	CPP pretraining survey
Implementation	
Facilitators’ adherence to group session protocol	*ez*Parent fidelity checklists

Implementation technical issues	Administrative data

[a] RE-AIM: Reach, Efficacy, Adoption, Implementation, and Maintenance.

[b] Administrative data are information collected by RAPP coordinators as part of ongoing management of program implementation.

[c] CPP: Chicago Parent Program.

Presurvey

Parents completed the presurvey before the first group session. The presurvey includes general parent demographics (ie, race and ethnicity, parent education level, and relationship with child) and an 11-item list of reasons for participating in the parenting program [26]. Parents selected all that applied to the list of reasons for participating with *no, yes,* and *most important*. Sample items include “I would like the chance to talk with other parents with young children,” “I would like help disciplining my child,” “I’m always looking for ways to be a better parent,” “I would like extra money for participating in the program,” and “I am required/have been asked to take a parenting class.”

Parent Program Completion

Digital tracking of use of the *ez*Parent program provides a measure of module completion. At the end of each *ez*Parent module, parents are awarded a module completion badge. Module completion is determined by parent receipt of the module completion badge. Facilitators and RAPP coordinators can view module completion in the administrative dashboard (Table 1) in real time. Group attendance logs are completed by the facilitators and submitted to RAPP coordinators for attendance tracking.

End-of-Program Survey

Parents were invited to complete an end-of-program survey after the last group session (approximately 7 weeks after baseline). This survey is an adaptation of the CPP and *ez*Parent end-of-program surveys [23,27]. The survey included items related to parent perception of the usefulness of the program in managing child’s behavior (2 items), perceived program impact on participant as a parent (2 items), overall program satisfaction (2 items), and acceptability of intervention delivery format procedures (3 items). In addition, parents responded to 3 open-ended prompts: What would you tell other parents who are interested in joining *ez*Parent? What did you find the most helpful or useful about the *ez*Parent Program for changing child behavior? What did you find the least helpful or useful in the *ez*Parent Program for changing child behavior?

Characteristics of Facilitators

Facilitators participated in a 2-day CPP group leader training between 2018 and 2021. At the time of training, trainees completed a demographic survey that included their report of race, ethnicity, education, employment status, current position, and experience working with families of young children and leading groups with families. Either facilitators were paid a stipend or they facilitated the *ez*Parent groups as part of their work responsibilities.

Hybrid ezParent Fidelity Checklists

After each videoconferenced group session, facilitators were invited to assess their adherence to the session protocol using a 7-item (session dependent) measure adapted from the CPP fidelity checklist [28]. Facilitators were not required to complete fidelity forms as the RAPP leadership team were concerned about burden on facilitators. Facilitators indicated *yes* or *no,* depending on whether they performed the expected action during the group session. Examples of adherence items include review of group ground rules, review of module summary of important points, and discussion of the *ez*Parent module practice assignment. In addition, facilitators self-reported the length of time of the group (in minutes), rated parents level of engagement (eg, the overall groups interest and active involvement in the discussion) during the group session on a 3-point scale (ie, *high*, *mixed*, *and low*), and assessed the extent parents seemed to understand the program strategies (ie, *high*, *moderate*, *and low*). Finally, facilitators could provide additional comments or feedback as an open-ended response.

Administrative Data

As part of program implementation, the RAPP coordinators monitored the number of groups that could be supported by RAPP sites and parent participation. This was driven by funding constraints, and coordinators balanced program costs to increase the number of groups available to reach the maximum number of parents. Parents using the *ez*Parent program could report technical issues related to *ez*Parent through a link in the program or contact coordinators for other technical support needs. Data logs of technical issues were maintained by the coordinators. Finally, coordinators met with the facilitators on an as needed basis to meet specific training and implementation needs. Coordinators kept a log of any implementation adaptations reported during these meetings.

RAPP Facilitator Interviews

In spring 2022, 8 facilitators who were currently involved with RAPP and hybrid *ez*Parent delivery at the time of the evaluation were invited to participate in a brief (<30 minutes) postprogram interview. The goal of the interview was to assess facilitators opinions regarding the hybrid delivery methods (ie, implementation in RE-AIM framework), use of the discussion guide to support the conduct of the group session, and evaluate the strengths and weaknesses of the implementation model. An interview guide was developed (Multimedia Appendix 1) and interviews were conducted by 2 of the authors (RP and SMB) who were independent of the RAPP. Interviews were not recorded; detailed notes were taken during the interview. In total, 6 participants (response rate: 6/8, 75%) completed the informed consent process and the phone interview. Participants received a US $25 gift card as a thank you for their time and input.

Data Analysis

All statistical analyses were conducted using SPSS (version 29; IBM Corp) [29]. Descriptive statistics were used to describe the sample and the reach, adoption, and implementation components of the RE-AIM model.

A thematic analysis focused on identifying implementation outcomes aligned with the implementation component of the RE-AIM model. Specific implementation categories were identified a priori (ie, facilitator adherence to group session protocol, length of group sessions, and facilitator perception of group delivery and parent engagement). Two authors (RP and SMB) reviewed the data independently, then met to review quotes for consensus and alignment with the implementation variables. Data from the interviews were used in a convergent design [30] to corroborate and provide examples of the quantitative data.

Results

Reach

Number of Groups and Parent Motivation for Participation

From September 1, 2020, to August 1, 2022, a total of 24 hybrid *ez*Parent groups were conducted by 13 facilitators. The goal for each group was 10 parents per group and the average group size was 10 (SD 0.42). All enrolled parents (n=240) were invited but not required to complete the pre- and postsurveys. In total, 77.9% (187/240) of eligible parents responded to the presurvey and 61.3% (147/240) of the eligible parents responded to the postsurvey. Of the 187 parents responding to the presurvey, 180 (96.3%) endorsed at least 1 motivation for participating in the program. Parents could endorse multiple motivations as *most important*. As shown in Table 3, the top-rated items endorsed as a motivator by over 94% of the respondents included “I would like to learn better ways to communicate with my child,” “I’m always looking for ways to be a better parent,” and “I would like to learn better ways of managing my child’s behavior.” The top items not endorsed as *most important* included “I am required/have been asked to take a parenting class” and “Another parent recommended I take this program.”

Table 3. Reasons parents (n=180) endorsed motivating their participation in the program[a].

Motivation	Most important, n (%)	Yes, n (%)	No, n (%)
I’m always looking for ways to be a better parent[b].	101 (56.4)	73 (40.8)	5 (2.8)
I would like to learn better ways to communicate with my child.	91 (50.6)	85 (47.2)	4 (2.2)
I would like to learn better ways of managing my child’s behavior.	82 (45.6)	88 (48.9)	10 (5.6)
I would like the chance to talk with other parents with young children.	33 (18.3)	128 (71.1)	19 (10.6)
I would like help disciplining my child[b].	30 (16.8)	84 (46.9)	65 (36.3)
I was motivated by the recruiter to take this program[b].	18 (10.1)	88 (49.2)	73 (40.8)
I would like the extra money for using the new parenting skills with my child.	15 (8.3)	104 (57.8)	61 (33.9)
I would like the extra money for attending the parent group.	8 (4.4)	109 (60.6)	63 (35)
I am required/have been asked to take a parenting class.	6 (3.3)	12 (6.7)	162 (90)
My child’s teacher recommended that I participate in this program.	3 (1.7)	55 (30.6)	122 (67.8)
Another parent recommended I take this program[b].	3 (1.7)	43 (24.0)	133 (74.3)

[a] Parents could select multiple items as most important.

[b] One respondent picked multiple conflicting responses (eg, “no” and “most important”); therefore, these were not included in the summary.

Parent Characteristics

Of the 187 parents responding to the presurvey, 112 (59.9%) identified as Black or African American, 46 (24.6%) as White, and 42 (22.5%) identified as Hispanic. Of the 103 parents who reported their relationship with their child, 90 (87.4%) were mothers, 8 (7.8%) were fathers or stepfathers, and 5 (4.9%) were foster parents or grandmothers. Finally, parents (n=180) reported their highest level of education being less than high school (n=16, 8.9%), high school (n=59, 32.8%), some college (no degree; n=46, 25.6%), associate degree (n=29, 16.1%), bachelor’s degree (n=15, 8.3%), and graduate degree (n=15, 8.3%).

Parent Program Completion

On average, parents (n=240) completed 4.58 (SD 2.43) of the 6 *ez*Parent modules and 72.1% (173/240) of the parents completed all 6 modules. A total of 47 (19.6%) parents did not complete a single module. Average group attendance across all participants (N=240) was 71.2% across the 4 sessions. Of those who attended at least 1 group session (219/240, 91.3%), average attendance was 77.7% across the 4 sessions.

Parent Satisfaction and Parent and Child Behavior

Parents reported high levels of satisfaction with the program and improvements in their feelings of self-efficacy and their child’s behavior following their participation in *ez*Parent hybrid. Specifically, 81.5% (110/135) reported that the concerns they had about their child’s behavior were *better* or *much better* and 82.6% (109/132) felt their child’s behavior was *better* or *much better* following their participation in hybrid *ez*Parent. Before participating in hybrid *ez*Parent, 42.5% (57/134) of the parents indicated that they were *not at all* (n=13) or *a little* (n=44) confident about managing their child’s behavior and 57.5% (77/134) reported feeling *confident* (n=45) or *very confident* (n=32) managing their child’s behavior. After participating in hybrid *ez*Parent, 92% (126/137) of these same parents reported they were *confident* (51/137, 37.2%) or *very confident* (75/137, 54.7%) about managing their child’s behavior, while 8% (11/137) remained *not at all* or *a little* confident about managing their child’s behavior.

Parent Satisfaction

Parents (n=137) responded to a program satisfaction question and 89% reported they were very satisfied (n=90, 65.7%) or satisfied (n=32, 23.4%) and 10.9% (n=15) of parents reported they were either dissatisfied (n=10, 7%) or very dissatisfied (n=6, 4%) with the program. When asked if they would recommend hybrid *ez*Parent to another parent, responding parents (n=117) reported they would highly recommend (n=94, 80.3%) or recommend (n=21, 17.9%) the program.

Most parents (104/117, 88.9%) said it was not at all hard to use the *ez*Parent program and 83.7% (98/117) felt the time spent using the program was "just right." Similarly, 88% (103/117) of the parents found the *ez*Parent program very helpful and 91.2% (107/117) found completing the module practice assignments was "not at all hard." Although these group sessions were conducted remotely, 71.8% (84/117) of the parents indicated their intention to remain in contact with other members of their group.

Adoption

Of the 23 facilitators who conducted in-person CPP groups sessions, 11 (48%) facilitated *ez*Parent group sessions. Two additional trained facilitators ran *ez*Parent sessions who had not previously conducted in-person groups. Overall, this was a diverse group of facilitators with 69% (9/13) identifying as Black, 17% (2/12) identifying as White, and 17% (2/12) identifying as American Indian (individuals could select all that apply). In addition, 17% (2/12) of the facilitators identified as Hispanic ethnicity. Of the 13 *ez*Parent facilitators, 2 (15%) reported having a high school degree, 5 (39%) having an associate degree or some college, with the remaining of the sample having a bachelor's degree (n=2, 15%) or a graduate degree (n=4, 31%). Facilitator (N=13) experience at the time of training varied with greater experience working with individual families (*a lot*: n=6, 46%; *quite a bit/some*: n=7, 54%) and less experience leading groups of families *a lot*; n=2, 15%; *quite a bit/some*; n=10, 77%; *a little*; n=1, 8%).

Implementation

In total, 38% (n=5) of the 13 facilitators completed end of session adherence self-reports, representing 31 of the 96 group sessions (32.3%). In addition, 6 of the 8 current facilitators participated in the facilitator interviews. Refer to Table 4 for facilitator quantitative and qualitative themes for implementation from adherence self-reports and facilitator interviews. Overall, facilitators found the hybrid delivery easy to implement and reported high parent engagement and understanding of CPP strategies. Implementation technical issues were infrequent and related to issues with the parent tablet which were administratively resolved. Only 1 technical issue was reported for the *ez*Parent program and was related to logging in. RAPP coordinators experienced technical issues related to the *ez*Parent administrative dashboard that was developed for this project. Because of these technical issues, *ez*Parent prepared monthly parent use reports for the RAPP coordinators to assure accurate use data for parent incentives.

Times of the group meetings were determined based on parent polls, most groups occurred on weekday evenings (ie, Monday through Thursday) between 5 PM and 7 PM, 1 group was held at lunch time (ie, noon to 1 PM) and 1 group was held on a Friday evening from 6 PM to 7 PM. No parents indicated wanting a weekend meeting time. Facilitators reported several adaptations to address challenges to hybrid delivery.

Three main challenges were identified by facilitators, including completing a group session in 1 hour, fostering parent engagement in the program, and building connection in the virtual environment. As 1 facilitator noted, "for in-person groups we had more bonding time, it was hard to build relationships virtually." To address these challenges, several facilitators would stay on the videoconference an extra 30 minutes to provide time for the parents to continue sharing. A facilitator reported, "I would say I'm here to stay on and many would stay on to discuss, talk it out, vent, I let them. They need that. In person they would have the time they needed." In addition, facilitators created text groups and provided text reminders for group sessions and to engage parents in completing the practice assignment with their children. As 1 facilitator noted "one thing I liked was the text messaging—once I started doing that—parents would thank me for reminding them—they liked that."

Although the facilitators felt positive about the group session delivery, they reported needing to tailor facilitation methods for videoconferenced groups. This included creating strategies to keep parents' attention and promoting group sharing, as one facilitator noted, "I had to get creative to keep everyone's attention." Strategies included, asking parents to keep videos on, calling parents by name, and responding to nonverbal behaviors. One facilitator reported "For the last session I did a round robin and asked each parent what their take was away from completing the modules. I also asked if they were practicing. Each parent shared what really stood out for them and what helped them the most."

Despite the challenges, facilitators found the hybrid delivery convenient for them and for parents. Facilitators reported that the hybrid delivery was logistically easier for them compared with in-person groups. In addition, although many reported that there was some loss in group connection compared with in-person groups, facilitators agreed that the convenience and ability for parents to participate in the "comfort of their own homes" might outweigh the challenges. Additional benefits of delivering the hybrid program included managing childcare (for both parents and facilitators), not having to spend time in gathering food and beverages for in-person group meetings, and not needing to spend time driving to and from the group. In addition, facilitators reported that parents were highly engaged and would readily report what they were learning from the program and changing in their own lives and the group session helped parents learn from each other's experiences.

Table 4. Implementation outcomes.

Implementation variable	Quantitative (RAPP[a] facilitator self-report; n=31 group sessions)	Qualitative (RAPP facilitator interviews; n=6)[b]

Facilitator adherence to group sessions	• 92% facilitator adherence to the group protocols[b]
	• 57% (17/30) *agree*[c] *or strongly agree* that the guide was helpful in running group sessions
		• Facilitators reported high consistency in delivery and the group session guide was helpful.
		  • "Every time I start a new class—go back to the group book—and I get how to facilitate the session"
		  • "Followed the facilitator guide closely; it was really helpful"
		  • "Used the script as a guide—but not so stringent. Always feel like room for flexibility..."

Length of groups	• Mean 60.5 (SD 14.7; range 34-90) minute
	• 73% (22/30) reported *about the right amount of time* and 27% (8/30) reported *not enough time for group discussion*.
		• Facilitators reported parents wanted to talk more and sessions often would run over time.
		  • "...a little more time is always needed. One hour is not enough time to cover and allow everyone to be able to express what they are feeling, experiencing and get the feedback needed to help motivate and encourage."
		  • "I felt like I am rushing the parents through the conversations"
		  • "One and half hour would be ideal. There were plenty of times that conversation could continue"
		  • "I think if we stay virtual, not a bad thing—need to add more time or do weekly"

Facilitator perception of group delivery and parent engagement	• Parent engagement was *high* (23/31, 74%) and *mixed* (8/31, 26%).
	• Parent understanding of program strategies was *high* (18/22, 82%) and *moderate* (4/22, 18%).
	• Affective tone of the group was *positive* (30/31, 97%) and *neutral* (1/31, 3%).
		• Parents came to the groups consistently and web-based delivery was convenient for them.
		  • "Felt like got better attendance in virtual than in person"
		  • "I think it is a very safe method—families feel comfortable"
		  • "Parents in the group reviewed everything so they would know what was coming"
		• Parents were overall engaged but often multitasked during the sessions.
		  • "I could tell they were engaged because of the conversation—it would be consistent"
		  • "Would often see parents nodding, paying attention, a matter of everyone joining in and they would share"
		  • "See them cooking dinner, feeding children"
		  • "They have the kids in and out—trying to do the session and getting interrupted"
		• The group discussions reflected grasp of material learned from the ezParent module and parents discussed putting the parent strategies learned in the modules into practice in their household.
		  • "Several parents would say we tried this, most of them had an example of what worked"
		  • "One father even shared that he now dances with his son—something that he never did before."
		  • "There was one parent who said that all of them helped her because she is learning how to take care of herself so that she can take better care of her children."
		  • "One parent told the group that the child now has a schedule that she even follows on the weekend."
		  • "I was skeptical, but the program does work."

[a] RAPP: Rochester Area Parenting Program.

[b] Adherence frequency is based on a sum the adherence items (session-dependent) across the 31 fidelity reports received from the group leaders.

[c] Italicized words represent survey response choices.

Discussion

Principal Findings

The purpose of this paper was to describe the implementation outcomes of the hybrid delivery model of *ez*Parent during community-based dissemination in response to the COVID-19 pandemic lockdown causing in-person intervention to be unavailable. Using the RE-AIM framework, we found that the *ez*Parent program was successful in reaching a diverse sample from the city of Rochester, New York, resulting in high levels of parent satisfaction and improvements in confidence in managing their child's behaviors. Our findings for parent satisfaction are consistent with prior research investigating general parent satisfaction with *ez*Parent [31]. The improvements in parental confidence in managing their child's behaviors within hybrid *ez*Parent is consistent with prior research conducted with CPP [13].

Overall, the trained facilitators easily adopted the new delivery format and implemented the sessions with minimal difficulties. As the aim of launching hybrid *ez*Parent was not to conduct research but support the community during the COVID-19 pandemic, we were unable to determine potential sustainability (ie, *M*aintenance) as proposed by the RE-AIM framework. While we were able to demonstrate success within the implementation of *ez*Parent, it is imperative to identify facilitators and barriers to implementation delivery to support the sustainability of the implementation of the program using the hybrid delivery model.

Facilitators and Barriers to Implementation

Factors that eased *ez*Parent implementation included the support and strength of the RAPP leadership team relating to decisive actions in implementing the new modality, the use of community-based facilitators who were familiar with the community which was represented in the group and in CPP delivery, flexibility of timing of the group sessions including the length of the meeting (60-90 minutes), parental preference in day and time of meetings, and ability to participate from anywhere. Group day and times were parent driven, not chosen by the facilitator or the community partner. One facilitator polled parents for the best time to meet and was overwhelmed and challenged by the variety of responses. We recommend community organizations provide parents with a few meeting times to lessen variability while providing an opportunity for parents to choose. Most groups were held between 5 PM and 7 PM on weekday evenings as parents identified this as the best timeframe. However, there were competing priorities during synchronous group sessions, including childcare or preparing dinner that may affect parent engagement. However, many parents were able to creatively address these competing priorities. For example, some parents arranged their meal break at work for the group session. We believe this flexibility contributed to the proportion of parents who attended at least one session (91.3%) and of those who engaged in all 4 group sessions (77.7%). Attendance in this sample was slightly below parent attendance rates recently reported for videoconferenced delivery of 12-session CPP (82.3% of the enrolled parents attended at least 1 group session) [32]. We calculated our engagement metrics (ezParent use and group attendance) for all parents who enrolled in the program regardless of attending group to assess program adoption.

In addition to providing access and flexibility for parent engagement, the RAPP facilitators enjoyed the flexibility in the internet-based groups and conserving efforts and resources to manage in-person meetings. However, increased flexibility seemed to come with a loss of the reported social connection that came with in-person groups. Therefore, facilitators used other tools, such as group text messaging to stay in contact with parents between group sessions and to help build and maintain a sense of community. Social connection and building community are vital components to successful group interventions and the pandemic gave rise to challenges in maintaining social connectedness. The facilitators' use of digital tools to create, maintain, and enhance a sense of community within their groups were found to be useful ways to engage parents and create community. These results are consistent with Plesko et al [32], highlighting the challenges with moving from in-person CPP to web-based group meetings.

We recommend using a variety of communication means to engage parents in-between sessions to support completion of the *ez*Parent module, support parent enactment and practice of parenting skills, and to remind parents of the next scheduled group sessions. Although not included in our hybrid delivery model, we suggest including a booster session 6 to 8 weeks after the last live session to determine if parents have any questions or barriers to practicing and implementing new behaviors to support their children. This will also aid in obtaining data for the Maintenance component of the RE-AIM framework.

Limitations and Strengths of the Project

Evaluation Metrics

When developing the hybrid delivery model, priorities were focused on the community needs during the height of a global pandemic and not on the project's evaluation. Upon analysis of the outcomes, we determined that our measures were not set up in a way that supported investigating parent changes over time or evaluating baseline data relationship with program engagement. For example, using unique identifiers for the baseline and follow-up questionnaires is planned for RAPP delivery of hybrid *ez*Parent starting August 2024. In our evaluation, the lack of paired surveys allowed only for independent and unrelated group analyses; however, in conducting the evaluation, we were able to identify this need highlighting the importance of academic and community-based organization relationships. The strengths that each partner brings to hybrid *ez*Parent will allow for continued support in reaching the most underserved populations in the Rochester area and an opportunity for more formal and robust outcome evaluations in the future. An additional strength includes the inclusion of facilitator interviews to examine perceptions of implementation outcomes. This provides a first-hand account of the benefits and drawbacks of the videoconferenced group sessions and examples of problem-solving that facilitators implemented to best support parents' needs.

Parental Motivation in Participating

Parent motivation is an important factor in PT delivery; thus, a question was asked about the parent's motivation in participating in hybrid *ez*Parent. However, respondents could select all that apply for motivational reasoning, and we could not determine each parent's primary motivation to participate. Given the nature of the responses, it was difficult to determine the most salient reason for participating; however, our results showing parents endorsing, "I'm always looking for ways to be a better parent" as a motivator is consistent with prior research [25]. In addition, most selected items for motivation related to strengthening parenting skills and supporting their child. For evaluation purposes, we recommend implementing a primary motivation question and then a way to assess other motivations to see if results differ by motivation factor.

Although approximately 8% (15/180) of the parents identified the financial incentive as a *most important* motivator for participating, 57.8% (104/180) to 60.6% (109/180) endorsed incentives as *a* motivator to attend sessions and complete practice. This finding is consistent with previous work related to incentive-based attendance as motivators for behavioral change interventions [24,25]. In a previous study of CPP and financial incentives, 71% of parents identified receiving extra money as a motivator and this was a predictor of program attendance [25]. In this study, the *ez*Parent dissemination was part of a community-led initiative through RAPP and funded through these programs, representing a sustainable method for maintaining implementation and supporting program engagement. Although providing financial incentives and a tablet for program access increases the overall cost of program delivery, these barrier reduction strategies may be important to support program access and parent engagement.

Lessons Learned

While reflecting on the implementation and evaluation of hybrid *ez*Parent, there are several lessons learned for future community-based dissemination. During year 1 of implementation, parents were sent a web-based link for the presurvey and anecdotal comments, which indicated that this was seen as impersonal and not particularly relevant for parents to complete. In year 2, we changed this to a paper survey being administered at the time of disbursement of the tablet. This change resulted in a more robust completion of the presurvey by parents. In addition, parents were not incentivized to complete the presurvey and postsurvey; therefore, we suggest that parent participants receive an incentive to complete surveys. This may improve response rates and allow for more rigorous evaluation of the program outcomes.

An *ez*Parent administrative dashboard was developed for this project; however, RAPP coordinators reported multiple technical issues. On the basis of these concerns, revisions have been made to the dashboard and we anticipate more autonomy for RAPP coordinators to process desired reports accurately and efficiently. In addition, further refinements of the *ez*Parent dashboard have been implemented based on these findings and others [33] to assure relevance to community organizations implementing *ez*Parent. For example, the ezParent dashboard now allows lists of users to be created based on cohort as well as the main page having a summary of users. If the user needs more detailed information on a participant, they can easily access the information from the main page.

Our results indicate that using the hybrid *ez*Parent is a feasible and effective way to engage parents. We also found that facilitators and parents enjoyed the flexibility that a web-based group session provides. Future research should comprise of more rigorous evaluation processes so that changes in the outcomes of hybrid *ez*Parent participants can be explored more precisely. In addition, more research needs to be conducted on the processes surrounding implementation of the *ez*Parent program and its dissemination.

Acknowledgments

The successful completion of this paper and program dissemination has been made possible through the dedication and support of numerous individuals and organizations. First, the authors would like to express their deep appreciation to the phenomenal facilitators and parents whose tireless commitment to children in the community is the bedrock of this project. The authors also extend their sincere thanks to Kathy Embt and Craig Maurer at the Children’s Institute. Their relentless efforts behind the scenes, from coordinating logistics to providing essential resources, were indispensable in making this project come to fruition.

The authors would like to acknowledge the following funders who have supported the Rochester Area Parenting Project: Action for a Better Community Inc, Greater Rochester Health Foundation, Rochester Area Community Foundation, ESL Charitable Foundation, New York State, Max and Marian Farash Charitable Foundation, Substance Abuse and Mental Health Services, United Healthcare, and United Way of Greater Rochester and Finger Lakes.

Conflicts of Interest

Under an agreement between Rush University and author DG, author DG is entitled to remuneration from sales of the Chicago Parent Program, which was described in the study discussed in this publication. This arrangement has been reviewed and approved by the Johns Hopkins University in accordance with its conflict-of-interest policies. All other authors declare no other conflicts of interest.

Abstract

Background: Parenting support programs enhance parents’ health and their child’s development. The COVID-19 pandemic necessitated the delivery of these programs over the internet. After the pandemic, internet-based programs are still preferred by some.

Objective: We aimed to understand Indigenous parents’ experiences engaging in internet-based parenting support programs; thus, an interpretive description study was conducted.

Methods: A total of 20 Indigenous (female, male, and Two-Spirit) parents of children aged <5 years participated in semistructured interviews; data underwent collaborative thematic analysis with Indigenous community partners informed by the Two-Eyed Seeing framework and ethical space.

Results: Parents’ experiences were classified into five themes: (1) Purpose: Program Delivery and Content, (2) Belonging: Building Relationships and Connections, (3) Hope: Cultural Connection, (4) Meaning: New or Improved Parenting Skills and Mental Wellness, and (5) Recommendations for Organizations.

Conclusions: The study findings can inform internet-based parenting program delivery to enhance engagement for Indigenous families.

child; parenting; qualitative; Indigenous health; support programs

Introduction

Background

Parenting programs provide critical support to individuals parenting a child. Research indicates that these programs have numerous positive outcomes for parent and child health and wellness, such as improved parent mental health and positive child development outcomes [1,2]. Parenting programs are especially important for parents of young children (aged <5 years) as this stage in life is a critical time for learning and child development [3]. Early childhood experiences impact brain development, and healthy relationships with adults are pivotal to that development [3]. Problems or delays not addressed in early childhood could potentially have long-term implications for health and wellness [4].

Parenting programs typically target specific populations, such as parents of children aged <5 years, parents of children with unique needs (eg, autism spectrum disorder), or parents belonging to groups or communities who are marginalized by mainstream society. Indigenous-specific parenting programs incorporate cultural teachings and traditions, including the presence of elders, ceremonies, and crafts [5]. These programs are congruent with Indigenous parenting approaches that draw from traditional roles and a community-oriented approach with family kinship models and nonnuclear families and are distinct from Western parenting approaches [6].

Parenting programs in Ontario, Canada, include the generic and Indigenous-specific Healthy Babies Healthy Children, Head Start, and EarlyON programs, which offer education and activities by licensed early childhood educators to promote healthy parenting and early childhood development [7-10]. Aboriginal Health Centres and Indigenous-led community centers such as the Indigenous Friendship Centres in Ontario also offer a wide array of programs and services, including parenting programs with a culturally grounded approach [11,12]. Indigenous parents can choose to access any of these programs according to their needs and availability.

Parenting programs can be offered in various formats: in person; internet based (self-guided); or facilitated and supported by a service provider over the internet, which may include early childhood educators or those otherwise trained to provide parent and child programs. During the peak of the COVID-19 pandemic, many parenting programs were exclusively offered over the internet and have continued with that mode of delivery. The efficacy of internet-based parenting programs on child and parent health has been previously well documented in the literature [1,2,13]. A meta-analysis of the effectiveness of internet-based parenting programs, for example, found that the programs increase positive parenting, parent confidence, parent satisfaction, and positive child behaviors and were effective in reducing negative parent-child interactions, parent stress, child behavior problems, and child anxiety [1].

Despite the benefits of parenting programs, parent attendance and engagement are not consistent across all parenting programs. The opportunity to meet other parents and exchange ideas, the ability to learn new skills, and trust in the person delivering the program [14] facilitate engagement in parenting programs. However, barriers such as limited resources; feeling judged or discriminated against; inadequate program funding; programs that are not culturally relevant; and program-specific factors such as delivery, content, and support impact attendance and participation in these programs for some families [15,16]. Typically, attendance and engagement by parents who need the services the most is low [15].

In view of the positive impacts of parenting programs on the parent and child, parental attendance and engagement in programs is important. With an increase in internet-based parenting programs since the COVID-19 pandemic, an understanding of how to effectively engage parents in parenting programs over the internet is needed. This need was also identified by the Hamilton Regional Indian Centre (HRIC), a nonprofit organization sitting on the traditional territories of the Haudenosaunee and Mississauga Nations that provides culturally relevant Indigenous programs and services, including programs aimed at supporting urban-residing Indigenous parents of young children and their families. These programs address topics such as prenatal guidance, parent-infant bonding, building communication skills, emotional regulation, and nutritional education, to name a few. Service providers follow a curriculum provided by the HRIC and adjust content to meet their clients' needs, including integrating teachings that align with the specific cultures of the program's attendees. During the COVID-19 pandemic, parenting programs at the HRIC switched from in-person to internet-based delivery, facilitated and supported by service providers in real time with varying success. Service providers at the HRIC have shared their challenges with internet-based program delivery, including initiating and maintaining parental engagement.

Given the importance of Indigenous parents receiving culturally relevant parenting support, especially for parents of young children, it is important to members of leadership and staff at the HRIC to understand the experiences of Indigenous parents who attend internet-based parenting programs—what is helpful for their engagement and what poses challenges. However, no studies were located that explored the experiences of Indigenous parents engaging in parenting programs over the internet. Thus, examining the perspectives of parents who have attended internet-based programs in a study will help identify the barriers to and facilitators of engagement in internet-based parenting programs, contribute to the existing gap in the literature concerning the experiences of Indigenous parents, and provide the HRIC with information to optimize delivery and improve parental engagement in their internet-based parenting programs.

The Indigenous Wellness Framework as an Organizing Structure

Fostering the wellness of parents is a key objective of Indigenous parenting support programs; thus, the Indigenous Wellness Framework [17] was selected for structuring this study and organizing the study findings described in this paper as it reflects the HRIC's holistic understanding of health and wellness. The Indigenous Wellness Framework was developed through a partnership between the Assembly of First Nations and the First Nations and Inuit Health Branch of Health Canada, along with Indigenous mental health leaders, as a shared vision for mental wellness and services for First Nations [17]. The framework was designed to strengthen mental wellness programs and support but has also been used to provide guidance for communities who wish to adapt or optimize their mental wellness programs and services to address their own priorities. At the core of the Indigenous Wellness Framework are 4 *directions* or main wellness outcomes: *purpose*, *belonging*, *hope*, and *meaning*. Within the framework, *purpose* is described as the sense of purpose that people gain through their education, employment, caregiving activities, or cultural ways of being and doing. *Belonging* is the sense of connectedness with their families, community, and culture. *Hope* is described as hope for the future and that of their families, grounded in a "sense of identity, unique values and a belief in spirit" [17]. Finally, *meaning* is an understanding of how their lives and that of their families is part of Creation and a rich history.

Study Purpose and Research Questions

The purpose of this study was to understand Indigenous parents' experiences engaging in internet-based parenting support programs. Specifically, the research questions were as follows: (1) What do parents identify as factors that facilitate or impede engagement in internet-based parenting support programs? and (2) What strategies do parents recommend for enhancing the experience of engaging in internet-based parenting programs?

For this study, internet-based parenting support programs were defined as programs that provide parents with information or support for their role as parents. These internet-based programs had to be offered via a platform whereby content was delivered and supported by an individual from an organization in real time. As the HRIC provides programs and services to clients representing many First Nations, Inuit, and Métis communities and cultures, the term *Indigenous* in this paper is used to refer to parents or parenting programs that reflect more than one cultural group.

Methods

Steering Committee and Positionality of the Researchers

A steering committee was established to oversee the development of the research plan and conduct of the research in collaboration with the HRIC. The steering committee comprised authors VM, BJ, MLB, and ALW; members VM and BJ from the HRIC led the committee. All steering committee members had previously collaborated on research, most notably members VM, BJ, and ALW, who have a long-standing relationship of >10 years working collaboratively on research projects aimed at understanding the needs of Indigenous parents to better service the community though programs. In addition to the steering committee oversight, research and administrative support for the study was provided by authors YJW and EMF.

When conducting research with Indigenous Peoples, a relational and community-led approach to research is ethically imperative and morally necessary [18,19]. As such, it is important that we situate ourselves by providing the positionality of the research team. First, the first author, MLB, is a non-Indigenous nurse researcher with clinical expertise in neonatal nursing and healthy parenting and a parent of 2 children. She has worked alongside the HRIC on projects for 4 years. YJW is a Mi'kmaw and settler woman from the Acadia First Nation, Squlj Clan, living and working in the S pekne'katik district within the traditional territory of Mi'kma'ki of what is now known as Nova Scotia, Canada. She has an academic background in public health and strives to uplift the voices of Indigenous Peoples in her work. VM and BJ are First Nations from Six Nations of the Grand River in Ontario, Canada. VM is of the Cayuga Nation, Turtle Clan, and BJ is from the Mohawk Nation, Bear Clan, and a Knowledge Holder. Both act as managers at the HRIC overseeing portfolios consisting of cultural safety training for local non-Indigenous organizations, programming and staffing at the HRIC, and child protection advocacy. They are both mothers and have close relationships with clients at the HRIC. EMF is a non-Indigenous nurse and mother of 3. Finally, ALW is a non-Indigenous nurse researcher and clinician with European settler ancestry and lives with her husband and children in the traditional territories of the Haudenosaunee and Mississauga First Nations in Southern Ontario, Canada. She strives to use her unearned privilege as a White scholar and academic to support the research needs of the Indigenous communities and organizations with whom she collaborates in a community-led approach to research. Together, the team worked collaboratively, deferring to those with Indigenous lived experience and integrating the perspectives of other staff members and parents at the HRIC throughout the project.

Guiding Principles for the Research

The Two-Eyed Seeing framework [20] and the principles of the ethical space of engagement [21] guided the research. First, the Two-Eyed Seeing framework guided the steering committee in valuing seeing the world with one eye grounded in an Indigenous worldview and the other eye with a Western worldview [20]. In particular, the Two-Eyed Seeing framework guided our collaborative approach to the study. The focus of this research was identified through cooperative dialogue with service providers from the HRIC and Indigenous parents in Hamilton, Ontario, to discuss community strengths and challenges related to the availability and delivery of parenting programs. This study, including the development of the research questions and data collection procedures, was designed in collaboration with First Nations staff from the HRIC to ensure that they were culturally appropriate and safe. The steering committee oversaw the project, including assisting with recruitment, data analysis, and conceptualization of modalities of knowledge dissemination outputs that best suit the needs of the community.

Second, the principles of the ethical space offered guidance on cooperative dialogue and engagement between 2 diverse groups with differing worldviews—First Nations community members, including a Knowledge Holder (BJ), and non-Indigenous researchers originating from and trained within a Westernized worldview [21]. The ethical space was a safe space for engagement for both groups, with a valuing of the concept of equality and a recognition and respect for the diversity created by philosophical and cultural differences [21]. Throughout this collaboration, the research team deferred to First Nations partners and their understandings of the local context, cultures, traditions, and protocols. Their understanding was especially important during analysis as this informed the findings.

Research Design

Interpretive description methodology was selected to address the study aims to understand what facilitated and impeded parents' ability to engage in parenting programs that were offered in an internet-based format and what strategies parents identified to improve parental engagement in internet-based parenting programs [22]. Interpretive description is a qualitative research approach that transcends the description of a phenomenon [22]. The approach not only allows for an understanding of the characteristics, themes, and patterns within subjective perceptions of a phenomenon but provides an interpretive account that can guide and inform practice [22]. Interpretive description emphasizes the integration of expert knowledge, including the perspectives of those participants who have lived experience of the phenomenon. As such, our use of this methodology facilitated the cocreation of knowledge with HRIC service providers, who have a deep understanding of the contextual forces impacting parents' experiences of internet-based programs. Along with parents' experiences, this collective understanding can inform change at the program delivery level, promoting more effective and engaging internet-based program delivery for Indigenous parents and young children.

Setting and Sample

A purposive sample of 20 parents who had used an internet-based parenting support program was recruited. Parents met the following inclusion criteria: (1) self-identification as Indigenous or being members of a family who self-identified as Indigenous, (2) engagement in an internet-based offering of a program related to parenting in southern Ontario, and (3) having been expecting or parenting a child aged <5 years when they participated in the parenting program. Parents who had only engaged with in-person parenting programs were excluded.

Purposeful, maximum variation sampling allowed for the selection of a diverse group of parents [23] who had used internet-based parenting programs. Specifically, we sought parents of varying ages, support (partner involved or not), socioeconomic statuses, previous parenting experiences, previous use (or not) of in-person, non–internet-based parenting programs, and experiences of parenting a child with or without health or developmental challenges. To complement the purposive sampling, snowball sampling was also used to increase the sample size and offer access to potential participants that otherwise may not have been reached. A sample size of 15 to 20 was considered a reasonable target to capture the diversity of parents who attended the programs. The sample size was ultimately determined when information power and conceptual redundancy were achieved [24].

Recruitment

Parents were recruited using two primary methods: (1) via parenting program staff at the HRIC and (2) through social media. A research flyer identifying the study purpose, eligibility criteria, and contact information for the research coordinator was distributed by HRIC staff via email to their program attendees, or printed copies were physically shared with parents attending parenting programs, as well as posting it on the information board at the center. The flyer was also made available on social media platforms, including one research team member's professional Twitter (subsequently rebranded X) account and on HRIC social media platforms. Participants were encouraged to share the flyer with other parents they knew had experience participating in internet-based parenting programs.

Data Collection

Parents providing informed consent participated in individual, in-depth, one-on-one semistructured interviews via Zoom (Zoom Video Communications) or telephone at a mutually agreeable time. Author YJW, a research team member with experience in qualitative study interviewing, conducted the interviews. Before commencement of the interview, YJW first prioritized establishing rapport with the participant, taking a relational approach to research and as a way to facilitate reciprocity through promoting a positive experience for the participant [18,19]. YJW then reviewed the consent form and reminded the study participant that they may choose not to answer some or all the questions. A semistructured interview guide was used to elicit parents' perspectives on their engagement in internet-based parenting programs. The interview guide was developed based on the study purpose and literature on internet-based parenting support. The interview guide was pilot-tested with 2 First Nations community members and modified accordingly to make certain that the questions adequately explored the topic of focus and were clear and culturally appropriate. The interviewer also verbally administered a short demographic questionnaire at the beginning of the interview. The demographic questionnaire included questions such as the age of the parent, self-identified gender, educational level completed, number of children they were parenting at home, relationship with a partner, number of people living in the home, and cultural background. Each interview was 30 to 80 minutes in length depending on how expressive the participant was and was video or audio recorded.

Data Management

All digital recordings of the participant interviews were transcribed using an automated transcription service. Transcripts were reviewed by a research assistant for accuracy, and identifying information such as names or places was removed. The NVivo software (version 12.0; QSR International) [25], a computer-assisted qualitative data management program, was used to organize, analyze, and store the data during analysis.

Data Analysis

In keeping with the interpretive description research design, data collection and analysis occurred concurrently in an iterative process [26]. Data collection continued until conceptual redundancy and information power occurred [24]. Inductive thematic data analysis was used guided by the Two-Eyed Seeing framework [20]. Coding strategies as described by Saldana [27] were used to conduct several iterations of coding until final themes were identified. The themes were the patterns of meaning identified and derived from the data. Demographic data from the semi-structured interviews were entered into SPSS (version 26; IBM Corp) and summarized using descriptive statistics.

Using a Two-Eyed Seeing approach, data analysis was a collaborative process with all members of the steering committee, and authors VM and BJ guided the analysis to ensure that local Indigenous ways of knowing and service providers' expertise were incorporated and accounted for in the results. Non-Indigenous researchers deferred to Indigenous ways of knowing throughout the analysis.

Rigor

Strategies were used in the research to promote the rigor or trustworthiness of the study findings, including approaches to promote credibility, transferability, dependability, and confirmability [28]. Credibility or the truth value of the study findings was promoted through investigator triangulation, whereby more than one member of the research team conducted the data analysis and the findings were validated with the entire steering committee to confirm the interpretation of the findings. Transferability was promoted through documentation of a thick description of the research context and study participants. Strategies to enhance dependability included memos to describe the process of analyzing and interpreting the data as part of an audit trail. Reflexivity (journaling) of the team members helped enhance the confirmability of the data collection and interpretation of the study findings [28].

Ethical Considerations

Research ethics approval was obtained from the University of Toronto Research Ethics Board (#43372), and the study was reviewed by the Hamilton Integrated Research Ethics Board (#15047). Researchers adhered to the principles of the Tri-Council Policy Statement 2 [29] and the 4 Rs of research (respect, relevance, reciprocity, and responsibility) [18]. All eligible participants were informed of their right to end the interview at any time or refuse to answer any question they were uncomfortable answering. All participants gave written and oral consent to the research coordinator or interviewer before beginning the interview. Throughout the study, measures were instituted to maintain the confidentiality of the data and the privacy of the study participants. Participants were assigned a code number, and several privacy and safety features of Zoom were enabled during internet-based interviews. The First Nations principles of ownership, control, access, and possession (OCAP) [30] governed the ownership, protection, and storage of the research data, which will be held locally at the Six Nations Polytechnic knowledge institute for access and use by community members to meet community-identified needs at study completion. In addition, findings from the community gathering have been translated into graphic form and made available in paper and electronic formats, including on a public-facing website [31], for the HRIC to distribute to their clientele and use to further inform their programs and services. All study participants were provided with a CAD $50 (US $35.80) gift card as a thank you for their participation.

Results

Participants

A total of 20 parents participated in individual interviews; 19 (95%) were Indigenous (First Nations: 15/20, 75%; Métis: 4/20, 20%), and 1 (5%) was non-Indigenous but their household family members were Indigenous. Those who identified as First Nations represented the Cree, Ojibwe (including the Anishinaabe and Chippewa Peoples), Oji-cree, Mohawk, Oneida, Onondaga, Seneca, Algonquin, and Mississauga Nations. Most parents (16/20, 80%) identified as women, whereas the remainder identified as men (2/20, 10%) or Two-Spirit (2/10, 10%). Parents had a mean age of 34.7 (SD 10.33; range 20-67) years. More than half (11/20, 55%) of the participants had completed college, had some university education, or had completed a university undergraduate or graduate degree; approximately one-third (6/20, 30%) had some college education, whereas the highest level of education of a small portion of the parents (3/20, 15%) was the completion of high school. Participants were primarily residents of 1 of 2 large cities in southern Ontario, Canada—Hamilton (10/20, 50%) or Toronto (6/20, 30%)—with other parents residing in the surrounding Greater Toronto Area or Niagara region. None of the participants lived in on-reserve communities. The household size of participants ranged from 2 to 7 individuals. Approximately one-third (7/20, 35%) of the parent participants were caring for only 1 child, whereas the remainder had 2 (6/20, 30%), 3 (5/20, 25%), or 5 (2/20, 10%) children.

Participants shared experiences of using a range of internet-based programs, including Indigenous-specific programs and non-Indigenous programs. Indigenous-specific programs included government-run early childhood programs, known as EarlyON in Ontario, Canada, and programs run by Indigenous-led organizations, including Aboriginal Health Centres and Indigenous Friendship Centres. Non-Indigenous programs encompassed those run by the Boys and Girls Clubs of Canada, non-Indigenous EarlyON programs, prenatal programs, and a young parent–focused program. Most participants (13/20, 65%) drew on experiences from at least 2 parenting programs, whereas 35% (7/20) had used only 1 parenting program.

Thematic Summary

Overview

Study participants identified numerous factors that facilitated or impeded their engagement in internet-based parenting support programs. These factors encompassed many facets of the program and its delivery—from the point in time when parents learned that the program was being offered to the effect of program engagement on them as individuals and parents. Parents also provided many suggestions for organizations to enhance programs and encourage other parents to engage in the internet-based parenting support programs more actively.

The steering committee, as noted previously in this paper, selected core elements from the Indigenous Wellness Framework [17] as a structure for sharing the study findings. Specifically, the 4 main outcomes of the framework are the structure under which the themes are presented. Collectively, the findings of the analysis of the individual interviews are classified into four main themes and organized under the Indigenous Wellness Framework: (1) *Program Delivery and Content (Purpose)*, (2) *Building Relationships and Connections (Belonging)*, (3) *Cultural Connection (Hope)*, and (4) *New or Improved Parenting Skills and Mental Wellness (Meaning)*. A fifth and final theme, *Recommendations for Organizations*, was also identified in addition to those presented under the Indigenous Wellness Framework. Each theme and its respective subthemes are presented in the following sections, including exemplars from study participants.

Purpose: Program Delivery and Content

Effective parenting program delivery that purposefully met parents' informational needs through providing their desired program content was a major theme among study participants. Parents identified their need to be aware of programs being offered, the importance of accessible delivery, and the program content they valued.

Awareness of the Program

Before parenting program delivery, organizations advertised their program offering to parents. Parents in this study noted the importance of being aware of programs that would be of benefit to them. Most parents in the study did not voice concerns about *how* they became aware of available programs, but rather, a few parents found it difficult to learn about *what* programs were being offered. One parent, for example, noted the difficulty they had in finding a parenting program:

> *...you have to really do your researching and find them kind. It seems...they were all given through certain providers and stuff like that throughout the community. So unless it's like, how do you say, marketed type thing through them, it's very hard to find them.*

Many parents learned about the programs offered through social media. Despite the efficiency and reach of that medium, other parents felt that sharing through physical flyers would also have benefits, as noted by a participant:

> *...I dunno, maybe there's lots of people out there who it's just easier when you're walking, you see a flyer, it's like, oh, I didn't know. And then you just take it and go, or you see it and you take a photo and just, yeah.*

Accessible Delivery

Accessible program delivery was important for parents and facilitated their engagement in programs. Parents identified two areas that were needed to optimize the accessibility of the parenting program for them: (1) equipment plus internet connectivity and (2) skills and support to use technology.

Equipment Plus Internet Connectivity

Access to a laptop or other electronic device was essential for a parent to engage in internet-based programs. Participants emphasized the importance of having a device and that the lack thereof impeded engagement with the program. In addition, parents needed internet access to be able to participate in internet-based parenting programs, and access to this service was a potential barrier perceived by some parents. This participant compared her experience to that of her family member's, who did not have access to a laptop to participate in the internet-based program:

> *I guess if you don't have a laptop or a computer, that could be an issue. Cause I think I remember telling my cousin about it because she had kids young too. She has kids my younger son's age. And I was like, oh, why don't you do this? You could sign up...but she's like, oh, my laptop, the kid's actually broken her laptop. So she was like, I don't know. I'm like, oh. She said, can I go on my phone and do it? I'm like, maybe if your camera's working, I guess. But then I think she did. She complained about it saying like, oh, on the phone, it's so small, the screen. And was, that was an issue. So I think back to your question, I think it's definitely no issue signing up and accessing it if you have a laptop that's working, that's good connection. But if you don't, then yeah, there could be some barriers there because your phone wouldn't be the best and it wouldn't really keep the kids' attention cause it's so small, you can't really stationary it so that they can just sit down or something. They have to hold it and their kids are always moving around. So it's just kind of chaotic.*

Another parent noted the following:

> *It would be nice to ensure everybody has this kind of access. I don't know how feasible that is. I know there were parents struggling when school went online and scrambling to get their children tablets and not everybody has internet. And that was a big struggle...I don't think we're doing anybody any good by not having that accessibility.*

A lack of the appropriate equipment or electronic connectivity meant that some participants had to travel outside their home to obtain the needed equipment and resources to participate, as described by one parent:

> *And I know for a fact there are people that go to the library just to be able to have access to the basics that you and I probably take for granted. And maybe people are going to the library and engaging in programs that way, but it sucks that you have to, in the middle of minus 30-degree weather, have to trek down to your local library to be able to access that.*

Skills and Support to Use Technology

The ability to use technology to connect with the internet-based parenting program was a new skill for some participants and created an immense learning curve. One parent verbalized how this learning curve was a stressor:

> *The one thing that really got in the way of it being able to be really helpful is the virtualness, it's hard to deal with, it's just learning how to use the different programs and stuff online seeing if my phone can actually run certain programs. That was definitely something that came in the way of me being able to completely throw myself in.*

This limited experience or challenges with using technology was felt by some participants as a barrier to actively engaging with the program, as one parent noted:

> *It really all just had to do with the technology. I think it was just because with...in-person groups and everything, it's really different cause you, you're have something in your hand and you're focusing on something else and try to read this and trying to read that. You're really more focused when you're in person. But then online it was really just for lack of a better explanation, it was just all the technology and trying to get used to one program and then go to a different program to do something else. And then it was just very, very confusing.*

Despite the challenges experienced by parents due to limited skills in the use of technology, parents were pleased to obtain support from individuals conducting or supporting the delivery of the parenting program. The ability to connect with a program facilitator or staff member via telephone to troubleshoot problems was felt by parents to be important in facilitating their participation in programs.

Content Valued by Parents

Overview

The parenting support programs provided education for parents on caring for and parenting their children. Parents valued several specific content areas of the parenting support programs that prompted their engagement. These were (1) prenatal care and infant health and development and (2) parenting strategies.

Prenatal Care and Infant Health and Development

Parents felt that it was important to learn about what to expect during labor and understand how to prepare for this event. This information was valued not only by expectant mothers but also by their partners who would be providing support. Parents valued the opportunity to learn about infant health, including breastfeeding, nutrition, and infant safety related to sleep and water. Parents also felt it important to have a cardiopulmonary resuscitation (CPR) training and certification course. Parents valued the prenatal and infant education thoroughly and enjoyed learning this information as it helped prepare them for their new role as parents.

Another content area that parents valued was learning about infant and child development and developmental milestones. Parents appreciated knowing what to keep an eye out for as their children grew to ensure that they were healthy and on track for their age.

Parenting Strategies

Parents valued parenting support program content that provided various strategies related to parenting effectively. This included strategies to promote engagement with their child, how to address frustrations encountered during parenting, and coping mechanisms to use. For example, one parent described their learning related to strategies to promote engagement with their child:

> *I know this is about parent engagement, so just from a child and parenting standpoint...I've learned more about just how to better engage with your children and appreciate the time you have and to take time.*

Parents also expressed the positive impact of strategies learned through parenting:

> *They warned us about crying and how frustrating it can get and just that if they're okay and they just keep crying to take a minute to yourself, go take 30 seconds a minute, take a few breaths, come back. That has really helped me work on my patience with my daughter.*

Belonging: Building Relationships and Connections

The second major theme noted in the data was that the relationships developed with other parents and the parenting program facilitator aided participants' engagement in the programs. In general, it was important for parents to develop connections and build relationships, particularly during the pandemic as the social distancing measures dramatically changed how parents received services and connected with other parents or supports before, during, and after the birth of their child.

Other Parents

Parents wanted to develop relationships with other parents in the programs. New mothers or parents most notably felt that developing these relationships was extremely critical. These new parents were particularly postnatally isolated during the pandemic with limited opportunity to interact with other parents.

Although parents sought interpersonal relationships with other parents in the program, this might not be feasible with or desired by all parents attending a support program. However, it was still deemed important by parenting program participants to generally know the other parents in the program. Even if parents did not seek friendship with other parents, they felt that they had to get to know them as they were sharing personal information about themselves and their families during the program.

Program Facilitators

Parents sought and felt that it was important to have a relationship with parenting program facilitators and other workers supporting the parenting program. One parent described why they felt that this relationship was so important:

> *I think it was important to have that relationship because when you're talking about child development and parenting, that's a spectrum and there is so much unknown to that. It's good to have people in your corner that can support you and have that, that knowledge.*

The need for a good interpersonal relationship with program staff and facilitators was largely attributed to the desire to be close with those surrounding and supporting their families—those who knew personal, intimate information about them. Parents described that workers with whom they had a good relationship were almost like friends—people they could go to in a time of need and not feel fear or judgment, as one parent explained:

> *The relationship that I think we built was a solid one...So she was kind...all the way around. So it didn't just become a therapeutic relationship, it was also kind of a confidant...Somebody you could turn to if you needed help or advice.*

A Sense of Belonging and Shared Experience

Developing a sense of belonging to a community and having a sense of shared experiences was a subtheme that was repeatedly discussed by almost all parents who participated in the study. Parents valued the opportunity to have a sense of community during a time when in-person interactions and social connections were limited. They also appreciated the ability to share individual experiences with others, to know that they were not alone in some of the situations they encountered and the subsequent emotions that ensued during that time. One parent spoke about how participating in the parenting support programs made them feel:

> *I think it felt really good, especially with the pandemic of not having anyone and not just being secluded to your family. So I feel like it gave you a sense of community, a sense of belonging, just kind of like, okay, something to look forward to, something to pencil into your days.*

Another parent expressed how the ability to have a sense of community was especially important when others whom they typically relied on were not available due to the restrictions of the pandemic:

> *Also just still being able to connect with people in a time where we weren't able to, and especially with our families even...It was the same way with the Indigenous perspective and lines. Traditionally, you have your community there, you have your aunties, your uncles, your brothers and sisters, and we didn't have that in that time. So it was good to connect with people and still be able to talk and ask questions in a judgment free space, which is something that you would get from your family or could expect, hopefully expect from your family. I mean...mentally it made me feel better in ways too, just to be able to socialize and laugh and joke with people about things and to share feelings. And over time you built a relationship.*

This value of a sense of community and connectedness with other parents was also echoed by another parent:

> *So I think that that sense of community and not feeling alone is probably the most important thing. You can take all the parenting classes, they can give you all the advice that's important, but you need to give parents an opportunity to connect and talk just [to] them, whether that's a focus group where you get together and you talk about different topics every week, or a book club where you read different, it can be parenting books, it can be self-help books, it can be whatever. And then you get together and you talk about it. As much as those may not be formally parent related, I do believe that a happy parent is a good parent. And to have that, I feel like you do need to feel like you're not alone.*

This sense of belonging was extremely important as parents noted that they were more likely to share and participate more if they felt connected with other parents and workers.

Hope: Cultural Connection

Parents felt that participating in parenting programs provided them with an important opportunity to connect more deeply with their culture and traditions; having this cultural connection was the third major theme in the study data. Parents wanted cultural elements such as traditional teachings, crafts, or cooking included in the programs they accessed. They placed a higher value on programs that integrated cultural components than programs that did not:

> *I think this is fairly obvious is the cultural connections that you're able to attain through online. I'm a busy lady and I can't necessarily commit to evenings a week...to take language courses. So, I'd see another benefit is just being able to connect culturally on a different platform...It's another connection...I think especially with our agencies...that cultural component. And even in our food, the food that they try and bring that culturally relevancy to their programs, and I really appreciate that. So, I think there's a good balance of just fun and engaging and cultural. I think there's a big balance there.*

Parents felt that the parenting support programs offered information that served as a reminder of culture that they could share with their children:

> *There's things in my childhood that I'm grateful for culturally that I want my child to have that same, to be that fortunate, to have that privilege. And those are words that shouldn't really be used when you were talking about culture, but when we're talking specific to First Nations, to Indigenous people, it's scarce now. So that's something I want to have instilled in our child. And I just reflect back on different sessions and it's like I said, those reminders. So it, it's weird because I think there's not maybe a week that goes by that I don't think about these programs in some ways, something that they've offered.*

The cultural elements of the programs also helped address gaps that parents felt they had in their own knowledge that they could teach their children:

> *A lot of things I've learned that my mother couldn't teach me...I'm teaching my children that well; I'd like to say my partner is fully native and he doesn't know anything about his background really. So it has to be my job. So that's why I need [Program Name]. This is why I need [Parenting Program Name]. This is why I need the HRIC to show them because I don't know myself.*

The cultural elements desired among study participants varied. Participants wanted programs that included crafts and art, such as medicine bags, beading, ribbon skirts, moccasins, and dreamcatchers. Participants wanted to learn more about traditional foods and recipes, such as bannock and Three Sisters soup. Parents wanted programs to be land based if possible and have opportunities to learn their Indigenous languages. Parents desired opportunities to learn more about traditional teaching and ceremonies, such as the Seven Grandfather Teaching, moon ceremonies, powwows, and drumming. They also wanted to learn more about traditional medicines. Learning about how to raise children through a cultural lens was also deemed important.

Meaning: New or Improved Parenting Skills and Mental Wellness

Overview

Parenting support programs helped create meaning in parents' lives through the development of new parenting skills or enhancing their current repertoire of skills. The programs also helped create meaning through supporting parents' mental wellness. This was the fourth and final major theme in the study data.

New or Improved Parenting Skills

Nearly half of the parents interviewed reported that engaging in internet-based parenting programs improved their parenting skills and strategies. This included response strategies that were more appropriate than the ones they had either previously used or grown up with. Some parents also described how their newfound skills and abilities—such as cooking—inspired them to be more involved with their children and come from a place of love and patience rather than aggression:

> *The whole point of that was to learn different methods that my child's going through to learn different techniques, to not be the type of parent that my father was. So, I've definitely sat back and watched my son go out into the world and come back and check in and then go back out into the world and come back and check in. Just like we learned all about in* [Parenting Program Name]

These new skills being learned had a positive impact on individuals' ability to parent:

> *I feel that I'm a better parent now learning new things, how to not go at it aggressively, but to go at it at different approaches.*

Mental Wellness

During the pandemic, parents also reported that they enrolled and participated in internet-based programs when components of health and wellness were included or focused on self-growth. As mental health was a prominent issue during the pandemic, parents appreciated and valued programs that included components of self-care, mental wellness, and strategies for coping with stress. The positive impact of focusing on well-being in the programs was explained by one parent:

> *It was a really good space to just express...to talk about experiences in the past and really go into...there were some sessions there where we...focused on wellbeing and so we'd sort of look back and talk about things that happened in the past and why, how they maybe have been carried over the years and impact things that, how we think what we do, the way we do things in the present. So, it was really nice to have those opportunities for inner reflection and building that self-awareness and how that can impact your relationships with others, including your kids.*

Recommendations for Organizations

Overview

Throughout the study, parent participants discussed program elements that facilitated their engagement. Recommendations for organizations to help promote parental engagement in parenting support programs included improved accessibility, delivery that is interactive and engaging and has inclusive support, and incorporation of family-oriented activities. In addition, parents wanted to ensure that food and mental wellness were incorporated as components of the programs. Each of these recommended parenting program elements are discussed in more detail in the sections that follow.

Accessibility

Overview

Parenting programs had to be accessible for parents to engage with them and reap their benefits. Parents recommended more scheduling options for programs, alternate ways to access programs, and strategies to optimize accessibility of the programs. Sign-up for programs had to be straightforward, and the internet-based parenting program platform had to be uncomplicated and easy to navigate.

Scheduling

Challenges were experienced by parents in relation to the scheduling of programs, with few options available that fit parents' schedules. This challenge was also applicable to the times offered for parents to pick up or for the program team to deliver material or food kits to be used in the program. Thus, parents recommended that more program timeslots be available. However, parents recognized that funding and resources might limit the ability of staff to provide additional program offerings and, therefore, suggested archived recordings (where appropriate) as an alternate way for parents to access the program and relevant information; this would address scheduling challenges.

Parents provided other recommendations to facilitate program accessibility and scheduling. This included posting monthly calendars of all programs available rather than distributing individual flyers for each program to make it easier for parents to plan and choose the program that would work best for their needs, interests, and availability. Another suggestion by parents was for program managers and facilitators to administer a poll to all parents enrolled (or interested) in a program to determine their availability. A unique time that works (mostly) for everyone could then be offered rather than having a prescheduled offering of the program.

Sign-Up, Log-In, and Navigation

Parents were less likely to participate or continue in a parenting support program if the sign-up and log-in processes were difficult or overcomplicated. The sign-up for programs had to be straightforward to reduce the potential for parents to choose not to participate due to challenges experienced in enrolling in the program. For example, navigating websites to sign up for programs was sometimes difficult, and some parents preferred the option of calling in to register for programs. Parents recommended that the internet-based parenting program platform have an uncomplicated log-in process and that the program needed to be easy to navigate on the internet. Keeping track of log-in emails and passwords or using several websites, apps, or platforms during the program was difficult for parents. Several parents felt that they were not "tech savvy" and, therefore, a lot of the programs offered were particularly difficult to navigate. These factors should be considered by organizations when setting up future programs to make sign-up, log-in, and navigation as simple and streamlined as possible.

Delivery

Overview

Parents mostly preferred in-person over internet-based programs for a number of reasons, including improved supports, services, and activities; fostering deeper and more meaningful connections with other parents and workers; better instruction; and the ability for their children to play or interact with other children to develop their social skills. However, parents recognized the value of internet-based programs and thoroughly appreciated the accommodation provided during the pandemic. Parents provided recommendations for enhancing internet-based program delivery, including interactive and engaging programs, inclusive support, and activities.

Interactive and Engaging Programs

Parents repeatedly expressed the importance of having programs (and facilitators) that were interactive and engaging. This included not only programs specifically for parents or those who were expecting a child but also family-oriented programs that involved children. Activities that parents viewed as *interactive* or *engaging* included tactile activities, drumming and singing, arts and crafts (with children), cooking, and activities that incorporated opportunities to talk to other program attendees.

Inclusive Supports

Parents desired supports and services that were more inclusive. Some explained that they would like programs to be inclusive of a wider children’s age range (ie, beyond 12 months). Other parents wanted to see more Two-Spirit and lesbian, gay, bisexual, transgender, and queer support for children; specific activities for children with attention-deficit/hyperactivity disorder and autism spectrum disorder; and multigenerational programs that included elders and other family member roles rather than only the parent and child. Several parents identified the need to increase the number of current supports and programs available to teenage and young moms, as well as individuals who are expecting to be parents for the first time or are new mothers.

Activities

Parents sought programs that were activity based and family oriented so that they could spend quality time with their children. Programs that were hands-on and interactive, such as drumming and singing circles or cooking classes, were often chosen to maintain engagement and excitement and avoid feelings of boredom or repetition. Parents appreciated it when there was an educational component (ie, traditions, healthy recipes, and infant care) included in these activities.

Program Components

Parents wanted food to be a part of the program components and content included that addressed health and wellness.

Food

Parents described the value of having food incorporated into internet-based programs. Some programs included a weekly food delivery kit as a cooking class to provide recipes and offer a fun activity to do with children. Others taught how to make traditional teas and medicines, such as elderberry juice. Although some organizations offered food delivery services during the pandemic to support food security, the inclusion of food in the programs was viewed by parents as an important consideration for future internet-based programs.

Health and Wellness

Parents expressed the need to include more content on self-care (particularly after delivery and in the early stages of parenthood) and mental wellness tips in parenting support programs. Parents wanted to see the incorporation of emotional support and sharing groups into programs—as a means of support and social interaction. Parents also identified healthy eating and the importance of proper nutrition in supporting the body, mind, and spirit as an area for inclusion in parenting programs.

Discussion

Principal Findings

This study provides important insights into parents’ perspectives on what facilitates or impedes their participation in Indigenous parenting support programs that are delivered over the internet. While some of the findings of this study echo those in the literature on mainstream internet-based programs, many are novel as this is the first study to consider the unique perspectives of *Indigenous* parents using internet-based parenting programs. In particular, parents’ priorities to use internet-based programs to build relationships and a sense of community with other new parents; the importance of cultural connections to families; and specific ways in which programs can be more inclusive of families impacted by attention-deficit/hyperactivity disorder and autism spectrum disorder and those who are multigenerational, as well as Two-Spirit and lesbian, gay, bisexual, transgender, and queer parents, are important additions to the literature.

One of the major findings of this study was the importance of program delivery, which included accessibility to programs. The need to have the appropriate equipment and internet access was critical. This is not unlike the challenges that many, such as the educational sector, experienced when they had to pivot to internet-based delivery in the early weeks and months of the COVID-19 pandemic; many families did not have computers at home for their children’s schooling [32]. Organizations delivering programs need to consider the need for these technology resources when planning programs and have the resources necessary to provide to parents through a strategy, such as a loan program for devices with internet access. Given the limited resources that many service sector organizations have, working with public libraries to facilitate clients’ access to computers and the internet would be another potential strategy to facilitate internet access. However, this strategy may create another barrier if parents planning to participate are geographically not located close to a library or have limited resources available for transportation to a public library. For example, many Indigenous communities in Canada face high internet costs and slow, unreliable speeds or a lack of internet access entirely [33]. Parents may need to modify screen use to accommodate slow speeds and resort to less ideal formats, such as direct messaging rather than video calls [33]. Organizations need to consider their local context to design strategies to improve access to their programs.

Another component revealed in this study related to accessibility was parents' steep learning curve in setting up and using the technology or the platform for delivery of the program. Given that parents felt that support from staff via telephone helped them navigate these technological challenges, organizations should consider dedicating a staff person to online support when initially commencing an internet-based program. This will help facilitate program access for parents who have limited experience with technology.

Content that parents valued was another study finding that was identified by parents as facilitating engagement. Not surprisingly, expectant parents valued learning about prenatal care, whereas parents in general valued learning about infant health and child development, in particular elements such as child safety and sleep. These are important areas that are typically included in many programs to support expectant or new parents, such as a public health offering of *Healthy Babies Healthy Children* [7]. However, the difference in this study is that parents emphasized the importance of Indigenous culture and an Indigenous lens when presenting content. Thus, an Indigenous parenting support program would provide this valued lens when delivering content, which parents would not receive in other generic parenting programs.

Parents also valued learning about Indigenous culture and saw this knowledge as a facilitating factor to their program engagement. This is not surprising considering the devastating impacts that colonialism has had on Indigenous Peoples and the resulting loss of cultures, language, and identity [34]. Indigenous parents living in urban areas may not have as strong a connection with their culture as those living on a reserve and may be seeking to reconnect with and learn about their history, culture, and traditional ways [5,35-37]. A study exploring family engagement and well-being in the Aboriginal Head Start programs in British Columbia, Canada, suggests that engagement was most active when families established relationships with elders, facilitating the sharing of Indigenous ways of knowing [5]. This sharing of knowledge and teachings that celebrates culture created a sense of belonging for families and helped programs be culturally inclusive [5]. Access to culturally inclusive parenting programs can increase family wellness and provide support and healing from the harms of colonization [16]. These studies emphasize the need to continue offering programs that integrate culture throughout their educational content. In addition, incorporating activities that create the opportunity for parents to learn about or revisit cultural teachings is extremely important. However, to avoid a pan-Indigenous approach to programs that results in cultural erosion, service providers should reach out to elders or Knowledge Holders from their clients' home communities and Nations and incorporate information and activities that reflect their unique cultures into their programs.

Relationships with other parents and program facilitators were important to participant parents. Throughout the COVID-19 pandemic, interpersonal relationships were limited to household contacts and some internet-based connections with family and friends for those who had technology. This restriction on interpersonal interactions created a stressor for many individuals and the need for a connection with others. This connection is important, most notably in times when support is more likely to be needed, such as during the transition to parenthood or even when engaging in the day-to-day challenges that many individuals encounter as they parent their children [38]. Thus, the delivery of programs over the internet during the COVID-19 pandemic was very important. It provided individuals with an opportunity to build relationships that became key sources of support when encountering the challenges of parenting or enduring the isolation that the pandemic created. Given this, organizations should consider having opportunities within their programs for individuals to build relationships with other parents attending the program and with program facilitators and staff. Having contact information for the facilitator, if feasible, would also be helpful so that parents can have contact with an individual to support them or refer them to resources as needed.

The parenting support programs provided many benefits or positive outcomes for attendees. It is not surprising that the programs created a sense of belonging and improved mental wellness, especially due to the limited interpersonal interaction posed by the pandemic. Given that mental wellness is important and some parents—such as those in the early postpartum period—are at risk of depression [39], these programs provide a key source of support to help optimize positive mental health.

Despite the overall positive experience and beneficial outcomes that parents had from engaging in parenting support programs, parents did offer recommendations for enhancing programs. Parents verbalized that they wanted interactive, engaging programs that were family oriented. They felt that incorporating food into programs was important. In addition, health and wellness should be considered when developing future programs. These recommendations are important for organizations to consider as they engage in budgeting and planning for future program delivery. Eliciting the help of a few parents in an advisory capacity might be beneficial for exploring how to implement these recommendations cost-effectively and in a way that is responsive to parents' needs.

Strengths and Limitations

This interpretive description study incorporated rigorous design elements that contribute to the strength of the research and the credibility of the study findings. Our community-engaged approach ensured that the study met the needs of the local community, including helping improve programs at the HRIC, and that it was guided by leaders and parents at the HRIC. Our purposive sampling approach allowed us to understand the diverse experiences of Indigenous parents, although most participants identified as First Nations. Inuit and Métis parents' experiences were not adequately captured in this study, and therefore, their experiences with internet-based programs may differ from those in the findings presented here. In addition, we recognize the diversity of First Nations Peoples, and as such, the experiences of the parents in this study may not reflect those of other Nations and communities. Similarly, the experiences of men were not well represented, with only 10% (2/20) of the participants identifying as men. This represents a gap in understanding that should be further explored. Next, we were able to achieve information power and redundancy of concepts [24] and themes during our concurrent approach to data collection and analysis. We engaged in triangulation throughout our collaborative approach to data analysis, which included all members of the steering committee and other First Nations parents. Finally, parents provided their experiences of participating in several different programs that offer support to Indigenous parents, which was a study strength. However, how many programs parents participated in and their frequency of use was not consistently discussed with all participants and could have helped provide further insight into the context of parents' experiences with specific internet-based parenting support programs.

Conclusions

Collectively, parents engaging in internet-based, available, Indigenous parenting support programs had positive experiences. The programs facilitated parents' engagement, providing them with opportunities to develop new parenting skills, develop relationships with other parents and program staff, create a sense of belonging, and deepen their connection with their culture. Organizations offering internet-based Indigenous parenting support programs should consider integrating these recommendations into their programs to better engage parents and children in services.

Acknowledgments

This work was funded by the Canadian Institutes of Health Research (funding reference 171393). The authors would like to acknowledge the service providers and staff members at the Hamilton Regional Indian Center who provided feedback and guidance on the project. In addition, they are grateful for the Indigenous parents who graciously gave their time before this project and met with the steering committee to provide guidance as to how the Hamilton Regional Indian Center could better meet their parenting needs.

Abstract

Background: Sudden unexpected infant death (SUID) remains a leading cause of infant mortality; therefore, understanding parental practices of infant sleep at home is essential. Since social media analyses yield invaluable patient perspectives, understanding sleep practices in the context of safe sleep recommendations via a Facebook mothers' group is instrumental for policy makers, health care providers, and researchers.

Objective: This study aimed to identify photos shared by mothers discussing SUID and safe sleep online and assess their consistency with infant sleep guidelines per the American Academy of Pediatrics (AAP). We hypothesized the photos would not be consistent with guidelines based on prior research and increasing rates of accidental suffocation and strangulation in bed.

Methods: Data were extracted from a Facebook mothers' group in May 2019. After trialing various search terms, searching for the term "SIDS" on the selected Facebook group resulted in the most relevant discussions on SUID and safe sleep. The resulting data, including 20 posts and 912 comments among 512 mothers, were extracted and underwent qualitative descriptive content analysis. In completing the extraction and subsequent analysis, 24 shared personal photos were identified among the discussions. Of the photos, 14 pertained to the infant sleep environment. Photos of the infant sleep environment were then assessed for consistency with safe sleep guidelines per the AAP standards by 2 separate reviewers.

Results: Of the shared photos relating to the infant sleep environment, 86% (12/14) were not consistent with AAP safe sleep guidelines. Specific inconsistencies included prone sleeping, foreign objects in the sleeping environment, and use of infant sleeping devices. Use of infant monitoring devices was also identified.

Conclusions: This study is unique because the photos originated from the home setting, were in the context of SUID and safe sleep, and were obtained without researcher interference. Despite study limitations, the commonality of prone sleeping, foreign objects, and the use of both infant sleep and monitoring devices (ie, overall inconsistency regarding AAP safe sleep guidelines) sets the stage for future investigation regarding parental barriers to practicing safe infant sleep and has implications for policy makers, clinicians, and researchers.

Introduction

In the United States, approximately 3500 infant deaths are attributed to the category of sudden unexpected infant death (SUID) on a yearly basis [1]. SUID includes death due to sudden infant death syndrome (SIDS), accidental suffocation and strangulation in bed, and ill-defined deaths [1]. SUID is the leading cause of unintentional, injury-related infant death in the United States [2] and is often related to unsafe infant sleep environments, including, but not limited to, prone sleeping, bed sharing, use of soft bedding, or unsafe sleep surfaces [3,4]. Recent characteristics of identified SUID deaths included that almost 60% of infants were sharing a sleep surface when they died and at least 76% had multiple unsafe sleep factors present [5].

The medical community has faced challenges in terminology associated with SUID [6], and the US Centers for Disease Control and Prevention recently updated reporting forms [7] to code such deaths more accurately. Confusion regarding SUID terminology also exists among parental groups [8]; for instance, parents often use the term "SIDS" when discussing SUID-related deaths. Progress related to the prevention of SUID has stalled since the Back to Sleep campaign in the 1990s [6,9]; therefore, further investigation into barriers to parental practices of safe sleep is warranted.

Social media is widely used among parenting groups and for health communication [10-12]. Mothers especially seek community and informational support—often found in online environments [8,13]. Given the breadth of information shared on social media, analyzing data from this source can identify concerns and practices of specific populations. Due to the stagnation in the prevention of SUID [1,2], we believed it would be helpful to complete a qualitative content analysis on Facebook and assess how mothers discuss SUID and safe sleep. In completing this analysis, we noted shared photos posted throughout the forum. Assessing infant sleep environments in the home setting is challenging [14]; thus, analyzing photos shared in an online community in the context of SUID and safe sleep discussions can yield invaluable insight into the reality of infant sleep environments. Understanding actual infant sleep environments in the home setting can also help in the development of research and prevention efforts regarding SUID.

This study therefore aimed to analyze photos shared among mothers engaged in discussions about SUID and safe sleep on a Facebook mothers' group. Specifically, we were interested in the following question: If applicable, are the shared photos consistent with safe sleep guidelines as defined by the American Academy of Pediatrics (AAP) [1]?

Methods

Overview

Details regarding the extraction process and qualitative content analysis of the data have been published, and findings shared [8]; however, this will be briefly discussed here. Data were extracted from a Facebook mothers' group in May 2019. This specific Facebook group was for women only, based in the southern United States, and had approximately 17,500 members. After trialing various options, "SIDS" was selected as the most effective term resulting in the most relevant conversations surrounding SUID and safe sleep. Thus, "SIDS" was entered in the search toolbar without additional filters applied. This search resulted in 20 posts and 912 comments from 512 mothers, all relevant to the topic of SUID and safe sleep. Once the data were identified, the posts and related conversations were transferred to an extraction spreadsheet and later analyzed via qualitative descriptive content analysis, as described by Sandelowski [15]. The descriptive analysis process was completed as per Miles et al [16] via Atlas.TI (ATLAS.ti Scientific Software Development GmbH) and was guided by the socioecological model of human development [17] and the uses and gratifications approach [18]. Inductive coding was completed so that codes emerged progressively, and all data were analyzed by 2 reviewers to ensure trustworthy findings and increase reliability [16].

During data extraction, photos shared among mothers were noted on the extraction spreadsheet. Two reviewers analyzed the photos to identify those related to the infant sleep environment. The identified photos related to the infant sleep environment were then assessed for consistency with safe sleep guidelines. The photos were analyzed based on 5 criteria derived from the AAP safe sleep guidelines (including risk factors and protective factors) that were current at the time of the analysis. These included (1) a supine sleep position, (2) no bed sharing, (3) the absence of soft bedding (crib bumpers, positioners), (4) a safe sleep surface, and (5) pacifier use [3]. If there was a discrepancy in assessing the safety of the environment, this was discussed among the members until a consensus was reached.

Ethical Considerations

This study was submitted for review by the institutional review board (IRB) at the University of Texas at Austin and deemed exempt as the study did not meet the criteria for human subjects research. IRB review and oversight was not required because the activities involved obtaining information from publicly available data sets. Despite the exempt status, any personal or identifying information was removed from the data set to maintain confidentiality. Thus, privacy and confidentiality were maintained throughout the data collection and analysis process. Additionally, in discussing the findings, we have chosen to share minimal details regarding specific posts and will not share the actual photos included in this analysis.

Results

Sleep Environment Assessment

Among the data extracted from the Facebook group, 24 personal photos were identified. Of these photos, 14 were related to the infant sleep environment, 10 of which included sleeping infants. The remaining photos, which were not included, depicted infants and toddlers that were awake, personal photos of infant monitoring devices, and screenshots of personal monitoring device results via applications originating from monitoring devices.

After review, 8 of the 10 photos of infants sleeping were classified as being inconsistent with AAP safe sleep guidelines. Reasons for being deemed inconsistent included prone sleeping, the use of sleeping devices, and foreign objects in the sleeping environment (blankets, stuffed animals, crib bumpers). Four of the photos depicted infant sleeping environments but did not have the infant present. Despite the absence of the actual infant, the shared photos depicting sleeping environments were all classified as being inconsistent with AAP safe sleep guidelines after review. Examples of these environments included foreign objects in the sleeping environment (blankets, stuffed animals, diapers, wipes). In evaluating the photos shared among this specific Facebook group, it is important to consider the context in which the photos were initially shared.

Context of Shared Photos

To better understand the mothers' intentions in sharing photos, some of the scenarios will be discussed in more detail. However, it is worth noting that significant effort was made to maintain the anonymity of the Facebook members and actual photos are not available for viewing.

Most of the photos shared among members were "for attention" or to discuss infant sleeping habits rather than to clarify whether the sleeping environment was safe. For example, a mother was considering using crib bumpers and asked the group for advice since her infant slept with his head touching the side of the crib. In posting her question, she shared a photo of her infant in the crib, in which there were multiple foreign objects present and the infant was sleeping prone. This resulted in other shared photos among the mothers. For instance, a mother commented, "This is how my son sleeps! We have used crib bumpers with all 3 of my kids" and included a photo of her infant sleeping prone in the crib with crib bumpers present. She also added there were "cute" crib bumpers available via Amazon. A different mother stated, "I've used a bumper with every one of mine" and shared a photo of her infant, supine with a stuffed animal and crib bumpers present in the crib.

When another mother asked how many parents went against pediatrician recommendations for infants sleeping on their backs, she posted a photo of her infant sleeping prone on a blanket with the caption "Picture of my LO for attention!!" In response to this post, another mother shared a photo of her infant sleeping prone in their crib from that morning and commented "Do what works for you!" Within the same concept of prone sleeping, another post inquired about mothers who have infants that "tummy" sleep and shared a photo of her infant in her lap, "just because."

One mother asked the group for advice for "any product similar" to the Owlet baby monitor (Owlet Baby Care Inc), as she was looking for a solution to "always getting up to check that they're still breathing." In response to this question, a different mother commented, "DO IT!!" Along with this comment, this mother shared a photo of her infant, aged 4 months, sleeping in a Rock n Play (Fisher-Price Inc) with a neck bandana and an Owlet.

The selected Facebook group also discussed transitioning infants to different sleep settings, such as from a bassinet to a crib. This topic resulted in shared personal photos of various sleeping environments. For example, one mother demonstrated her transition to a crib via a pack and play pictured with netting cut out and multiple foreign objects present. Another shared photo depicted a bassinet in which the mother emphasized the importance of keeping her essentials, "diapers and stuff," in the bassinet in order to be successful with nighttime diaper changes.

It is worth noting that one of the personal photos of an infant sleeping (classified as being consistent with AAP safe sleep guidelines) was an infant lying on their back, with the glow of a baby monitoring device clearly visible through their onesie. Another photo of an infant that was awake (also classified as consistent with safe sleep guidelines based on the visualized sleep environment) included text referencing that the infant slept in a bassinet, "in the middle of our bed," thus implying an unsafe sleep environment in actuality.

Only one photo in this analysis was posted with the mother's intent to ensure a safe sleep environment. This mother sought confirmation that her infant was sleeping "appropriately" and shared a personal photo. This was one of the few environments consistent with safe sleep guidelines among the sample, as there were no foreign objects in the crib. In summary, among the main posts and associated comments, 14 personally shared photos were related to the infant sleep environment, and 86% (12/14) were inconsistent with AAP safe sleep guidelines.

Discussion

Unsafe Infant Sleep Practices

These specific data are unique in that the users openly shared their photos in a forum, a Facebook mothers' group, without researcher interference. The photos were also shared within the context of discussing SUID and safe sleep. It is therefore interesting that most of the shared photos demonstrated sleep environments inconsistent with AAP safe sleep guidelines.

Our findings are concordant with prior analyses of actual infant sleep practices [14], although our analysis involved photos and assessed the home setting rather than an artificial environment. Prior research on this topic has identified unsafe sleep environments depicted on Instagram [19], in stock photographs [20], in magazines [21], in crib marketing [22], and among websites resulting from a Google search [23].

At the time of the study, AAP guidelines were clear regarding use of a firm sleep surface and restriction of objects in the crib, yet guidelines were not clear regarding infant monitoring devices. Thus, repeating this study after device recalls [24-27] and subsequent federal regulations on the use of infant sleep devices [28] might be worthwhile.

Limitations

This study is not without limitations. The number of photos analyzed is small and does not necessarily represent the general population. Furthermore, the photos analyzed represent snapshots and may not fully capture typical sleeping conditions. Additionally, there is concern for potential bias in what photos were shared among the members and in what context. For example, a member may have shared a photo if they were unsure about the safety of the environment; therefore, this study might overestimate environments inconsistent with AAP safe sleep guidelines. However, when assessing the context of the shared photos, only one photo was shared with the mother's intention of inquiring about the safety of the sleep environment.

Results from this photo analysis do not necessarily represent all parents, especially those who do not use Facebook or engage in groups on Facebook. Demographic information regarding the mothers was also not obtained, further limiting generalizability of the findings and resulting in an inability to verify the accuracy of the information shared by mothers.

Despite such limitations, visualizing the actual sleep environment in a naturalistic setting provides helpful insight into true parental practices of infant sleep and has implications for future research and practice.

Conclusions

The commonality of sleep environments inconsistent with AAP safe sleep guidelines should be considered by policy makers, health care professionals, and researchers when aiming to prevent the occurrence of SUID. The practice of infant sleep is complex [8], and despite the known risks of bed-sharing, parents are often motivated to use infant sleep practices inconsistent with AAP guidelines [29]. Additionally, infant sleep is a controversial parenting topic, and while bed-sharing is discouraged in the United States, this practice is commonplace worldwide [30]. While much research focuses on knowledge-based interventions regarding infant sleep practices, we suggest a shift to focus on supporting parents so they can create a sleep environment consistent with AAP guidelines.

This shift involves broad policy changes, such as paid parental leave and financial assistance so families can afford to live in a home with a sufficient number of bedrooms or can purchase safe environments for their infant to sleep (eg, a pack and play or crib). Other suggested policy changes include extending health care coverage for the birthing person up to a year postpartum to ensure adequate care and social services for the mother-infant dyad. Additionally, continued federal regulations are needed to safeguard families. Research has identified widespread use [8] and popularity of infant sleep and monitoring devices among families [31]; however, despite deaths attributed to the use of these devices, their regulation [24-27] has lagged. For instance, the Safe Sleep for Babies Act of 2021 [28], which bans inclined sleepers and crib bumpers, only passed in 2022 despite documentation that such devices have contributed to infant deaths since the 1990s [32].

Health care organizations and personnel should aim to emulate a comfortable environment where parents can engage in open discussions about their infant sleeping practices. Parents seek support from social media [8,11] because it is often a place of acceptance; health care professionals should aspire to be another source of support while providing anticipatory guidance regarding infant sleep. Additionally, health care providers should approach this conversation with the intent to empower parents to create safe sleep environments while having honest conversations about barriers to these practices. Health care personnel should also aim to address infant sleep environments when counseling parents—beginning at pregnancy and throughout the infant's first year of life.

Lastly, since SUID remains the leading cause of unintentional, injury-related infant death in the United States [2], future research should prioritize investigating parental barriers to creating sleep environments consistent with AAP guidelines. Efforts should be made to find new ways to support parents, rather than focusing on knowledge-based interventions. In conclusion, this study highlights the critical need for policy makers, health care professionals, and researchers to engage in the prevention of deaths attributed to SUID by supporting families at the interpersonal, community, and system levels.

Acknowledgments

This research was supported by grant T32 NR018407 from the National Institute of Nursing Research, as well as financial support from the Robert Wood Johnson Foundation, Sigma Theta Tau, and the National Association of Pediatric Nurse Practitioners.

Authors' Contributions

KP conceived the idea and designed the study, extracted the data, raised funds, and wrote the manuscript. SK and EC assisted in data analysis and proofread the manuscript.

We acknowledge that not all birthing persons identify as women or mothers; however, our analysis included a group of individuals who self-identified as "mothers."

Conflicts of Interest

Abstract

Background: In the digital age, social networking sites (SNSs) have revolutionized the approach to parenting. These platforms, widely used to access parenting information and support, affect parents both positively and negatively, with negative effects potentially increasing for those experiencing loneliness or anxiety.

Objective: This study examined the relationship between SNS use and psychological distress among parents of young children, controlling for the moderating effects of loneliness and parenting anxiety. We hypothesized that higher SNS use correlates to greater psychological distress, particularly among parents with elevated levels of loneliness or parenting anxiety.

Methods: A cross-sectional survey design using a closed web-based questionnaire was employed. Participants included 429 parents (205 mothers and 224 fathers) of children aged 0 - 3 years recruited through a web-based survey company in Japan. The majority of the participants were couples, with some living with extended family members. The sample also encompassed individuals in cohabiting partnerships and single parents. The survey included measures of psychological distress, loneliness, parenting anxiety, frequency of SNS use for parenting, and covariates. Analytical models to explain psychological distress included interactions between loneliness or parenting anxiety and SNS use, individually for both fathers and mothers.

Results: For mothers, a significant interaction effect was determined only between parenting anxiety and SNS use (b=0.247, SE 0.091; P=.008). Meanwhile, for fathers, significant interaction effects were observed for both loneliness (b=0.324, SE 0.127; P=.012) and parenting anxiety (b=0.144, SE 0.069; P=.038) with SNS use. A simple slope analysis for mothers indicated that SNS use was related to psychological distress only at higher levels of parenting anxiety (b=0.304, SE 0.090, β=.317; P<.001). Among fathers, SNS use was associated with psychological distress at higher levels of either parenting anxiety (b=0.330, SE 0.069, β=.346; P<.001) or loneliness (b=0.390, SE 0.098, β=.409; P<.001).

Conclusions: The study concluded that the relationship between SNS use and psychological distress among parents of young children is moderated by loneliness and parenting anxiety. The findings highlight the need for tailored approaches to help parents manage SNS use, particularly focusing on those with higher levels of loneliness and parenting anxiety. It is imperative that health professionals provide nuanced guidance to parents on SNS use, considering individual psychological factors and potential gender differences in the impact of SNSs on mental well-being.

Introduction

In the wake of rapid digitalization, social networking sites (SNSs) such as Facebook, X (formerly Twitter), and Instagram have changed the landscape of parenting. Parenting-related SNS use is increasingly common, with parents employing these platforms to obtain parenting information and support [1,2]. This specific use of SNSs in parenting has both positive and negative implications. Parenting-related SNS use provides access to a wide range of information that may be unavailable offline [3,4] and offers solutions related to parenting, particularly by expanding maternal social networks [5,6]. However, parenting-related SNS use tends to disseminate idealized images of parenting, posing a risk of loss of confidence due to unrealistic expectations and pressures [7]. The idealized parenting images prevalent on SNSs may prompt parents to compare their parenting methods with others’, potentially triggering depressive symptoms and negative emotions [8,9]. Given the dual nature of parenting-related SNS use, it is critical to determine methods of use that minimize drawbacks while maximizing benefits.

Among the negative impacts of social media use is psychological distress, which is generally characterized by emotional experience marked by symptoms of depression and anxiety [10]. It has been theoretically demonstrated that psychological distress can impair parenting practices [11], and understanding its mechanisms is crucial for supporting effective parenting functions. The impact of social media use on mental health varies widely [12], highlighting the need to focus on the differences in effects based on users' backgrounds when exploring the relationship between psychological distress and social media.

Psychological distress associated with SNS use may be driven by the loneliness experienced by parents. Loneliness can be defined as a "negative psychological state in which there is a discrepancy between one's actual and desired social relationships" [13]. Parental loneliness raises the risk of child maltreatment and may be associated with potential maladjustment in children [14,15]. Lonely people tend to prefer social interactions on the web, reducing the time spent undertaking offline interactions [16]. Although they use social media to compensate for the lack of offline interpersonal relationships, they may not always realize satisfying web-based social relationships [17,18]. Consequently, parents with higher levels of loneliness may rely on limited social relationships through SNSs and experience greater psychological distress owing to unsatisfactory connections. Moreover, the correlation between mothers' high levels of loneliness and the negative emotions experienced through social comparisons on SNSs [19] suggests that the degree of loneliness may influence psychological distress on SNSs.

In addition to loneliness, parenting anxiety may influence parents' psychological distress driven by SNS use. Parenting anxiety, characterized by confusion and fear regarding a child's health, development, and parenting methods, could increase the risk of child maltreatment and child anxiety disorders [20,21]. Parents with high levels of parenting anxiety reportedly use social media more frequently and consider it useful in alleviating anxiety [22]. However, in general, people tend to share information focusing on the successful aspects of their lives on SNSs, facilitating upward comparisons with others who appear to have achieved their goals [23]. Numerous studies have reported that such upward comparisons on SNSs could have negative effects on mental health [24-26]. Given the prevalence of idealized images of parenting on SNSs [7], parents with high parenting anxiety may be increasingly vulnerable to psychological distress from upward comparisons. In addition, elevated parenting anxiety often correlates with lower parenting self-efficacy and self-esteem [27]. Lack of parenting self-efficacy may attenuate the comforting and anxiety-reducing effects of addressing concerns through smart devices [28].

Systematic reviews of the relationship between SNSs, loneliness, and social anxiety indicate that individuals who are lonely or experience social anxiety are more likely to engage in problematic social media use [29], suggesting that such individuals may be increasingly vulnerable to psychological distress from SNSs. Despite the accumulation of knowledge on the relationship between social media, SNSs, loneliness, anxiety, and depression, research in the context of parenting remains limited [30]. Knowledge regarding SNS use among parents of young children is particularly limited, and studies concerning social media use in parenting have predominantly focused on mothers. Exploring the relationship between SNS use and psychological distress in parenting, taking into account levels of loneliness and parenting anxiety for both fathers and mothers, may provide nuanced evidence for SNS use in parenting and professional support.

The usage of SNSs exhibits cultural differences [31], and Japan has its own unique cultural characteristics. In Japan, the widely known international platforms, such as X (formerly Twitter), Instagram, and Facebook, are used alongside LINE, which is popular in some parts of Asia [32]. Compared with other countries, Japanese users tend to employ SNSs more for browsing than for sharing information [33]. SNS use comprises 2 aspects: active and passive use [34], with a tendency for passive use to be more prevalent in Japan. Passive use of SNSs is often linked to negative impacts on mental health [35]. As Japanese users are predicted to be a group potentially at risk of psychological stress due to SNS use, it is significant to focus on this issue.

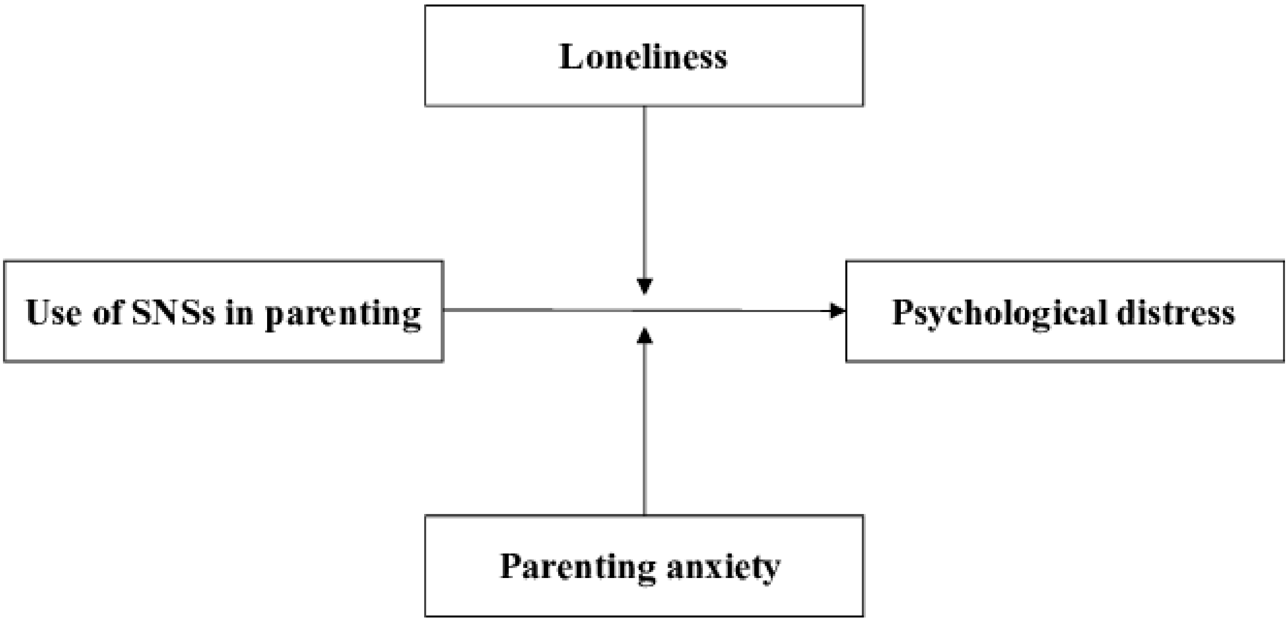
This study elucidates the moderating effects of loneliness and parenting anxiety on the relationship between SNS use and psychological distress among mothers and fathers of young children. This study focuses on the individual experiences of fathers and mothers, as it is predicted that their parenting roles differ qualitatively owing to sociocultural and biological factors, despite sharing commonalities as parents. In Japan, there is a strong gender role division where fathers are seen as responsible for work outside the home, while mothers are responsible for household chores and child-rearing duties [36]. As of 2021, surveys on parenting time in Japan reveal a significant disparity in the time spent on child rearing, with wives contributing substantially more time than husbands [37].

In addition, it is generally observed that women engage in the exchange of support on social media more frequently than men [38]. While it is widely recognized that mothers use social media to share information and support regarding child-rearing [5], social media platforms specifically targeting fathers are limited [39], indicating a gender disparity in web-based parenting resources. Therefore, it is crucial to conduct analyses that consider gender differences. Moreover, lonely individuals may lack a sense of fulfillment from social relationships on social media [17,18]. Upward comparisons, which are more likely to occur on these platforms, may particularly harm the mental health of individuals with parenting anxieties [24-26]. These risks can affect both fathers and mothers. Accordingly, we constructed a hypothetical conceptual model (Figure 1), and the following hypotheses were formulated:

- Hypothesis 1: Mothers use SNSs for parenting more frequently than fathers.
- Hypothesis 2: Only when mothers and fathers have high levels of parenting anxiety, frequent SNS use for parenting is associated with high psychological distress.

- Hypothesis 3: Only when mothers and fathers have high levels of loneliness, frequent SNS use for parenting is associated with high psychological distress.

Figure 1. Hypothetical conceptual model. SNS: social networking site.



Methods

Study Design

This study used a cross-sectional design with a closed web-based questionnaire. To ensure the quality and transparency of research, the work employed the Survey Reporting Checklist (CROSS) developed by Sharma et al [40] and the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) developed by Eysenbach [41]. This study reports a subset of data from the “Information Behavior on Social Networking Services Among Parents Raising Infants” survey.

Operational Definitions

In this study, SNSs were defined as communication platforms where participants can consume, produce, and interact with a stream of content generated by connections on the site [42]. Specific SNSs considered were X (formerly Twitter), Instagram, Facebook, and YouTube, taking into account the context of Japan. LINE, which is widely known in Japan, was excluded from this category owing to its limited use of the feed function characteristic of SNSs and its primary use as a tool for routine communication with acquaintances. The use of SNSs for parenting was operationally defined as usage to gather information related to parenting, monitoring other families, and building social relationships.

Participants

This study included 429 parents of 0- to 3-year-old children. The eligibility criteria required that the participants were actively parenting at least 1 child aged between 0 months and 3 years and 11 months at the time of the survey. There were no restrictions based on the health status of the parents or children or on family structure. The exclusion criterion was the absence of any experience using SNSs for parenting-related activities.

Sampling was conducted using convenience sampling from the national panel managed by Cross Marketing, Inc, a web-based survey company in Japan, which manages more than 5 million active web users and provides academic web-based survey services to a wide range of demographic groups. The company’s active panel comprises a wide variety of web users, creating a large-scale monitor that is not biased by influx from specific sites or advertisements. The recruitment process began with a one-time survey invitation sent by the survey company to a randomly selected group of approximately 2000 individuals deemed eligible for this study. Those who received the invitation first answered a question regarding their child’s age; inconsistent responses were excluded. Subsequently, individuals who agreed to participate in the study were directed to the web-based questionnaire link via a click of an “agree” button after reading the research request document prepared by the authors. The study aimed to include 200 fathers and 200 mothers, and distribution continued randomly until this goal was reached, at which point the survey distribution was halted.

Data Collection

Data were collected in August 2023 using a web-based survey. The questionnaire was developed and administered by the authors using the Qualtrics web-based survey system [43]. Qualtrics ensures data management through encryption, redundancy, continuous monitoring, and single sign-on, and is FedRAMP-authorized as well as ISO27001-certified. The questionnaire was designed by the authors to be user-friendly and was pretested to avoid design issues. Participants who completed the questionnaire received a web-based reward based on Cross Marketing, Inc standards.

Measures

The survey included sections on SNS use, SNS use for parenting, psychosocial characteristics, and basic demographics. The questionnaire was developed through the following process.

First, the content validity of the questionnaire was reviewed by a researcher (RO) with extensive experience in public health nursing practice and research, who also has experience in child-rearing support. Potential common errors in the questionnaire (eg, double-barreled questions, confusion, and leading questions) were checked by a representative from Cross Marketing Inc, who has extensive experience in designing web-based surveys, and appropriate revisions were made. In addition, face validity for all survey items was ensured through pretesting with 4 university students and 5 mothers with infants and older children. Owing to the limitations of the pretest sample size, the factor structure and internal consistency were confirmed in the main survey. Details of the survey items are shown in Multimedia Appendix 1.

SNS Use

Data were collected with regard to the possession of digital devices (smartphones, tablets), currently used SNSs (X, Instagram, Facebook, YouTube, LinkedIn, etc), and overall frequency of SNS usage by participants. The frequency of SNS usage, based on previous research [34], considered both active and passive usage aspects. Active usage was mainly related to information production (eg, posting updates on SNSs, sending private messages), while passive usage concerned information consumption (eg, scrolling through news feeds and viewing other users' profiles). The frequency of active and passive SNS usage over the past week was assessed, with response options ranging from 1 (not at all) to 8 (more than 10 times a day).

SNS Use for Parenting

Considering the lack of a specific scale to measure SNS use for parenting, original measurement items were created. Based on previous studies [44] and interview data from mothers in the parenting phase, 3 categories were formulated for SNS use in parenting: "information gathering," "monitoring," and "connecting." Each category consisted of 2 items, with "information gathering" including items related to gathering information on parenting and children. "Monitoring" included tracking other families' parenting and their children's conditions, while "connection" included making friends in parenting and communicating with peers in parenting. Items were measured on a 5-point scale (1=never use to 5=always use), with the mean value calculated within a range of 1‐5, and higher scores indicating greater subjective frequency of use.

An exploratory factor analysis using maximum likelihood promax rotation was conducted to determine the handling of the scale for SNS use in parenting. The applicability of factor analysis was confirmed by ensuring that the Kaiser-Meyer-Olkin measure was greater than 0.8, and Barlett's test of sphericity was significant. The number of factors was determined by examining the scree plot and using eigenvalues greater than 1. A factor loading of 4.0 or higher was employed as the criterion for item selection. Reliability was assessed by calculating Cronbach α.

Table 1 shows the results of the exploratory factor analysis. Bartlett's sphericity test for the 6 items measuring SNS use in parenting was significant (χ^2_{15}=2319.43; *P*<.001), and Kaiser-Meyer-Olkin values were above 0.8, confirming the suitability of the data for exploratory factor analysis. Exploratory factor analysis with maximum likelihood promax rotation revealed a 1-factor structure for the 6 items (Table 1). An attempt was made to confirm a 3-factor structure considering the 3 categories, but eigenvalues for the factors after the first were lower than 1, indicating that the model was not suitable. Therefore, the study measured SNS use for parenting by employing the total score of all items, with a Cronbach α value of 0.92.

Table . Exploratory factor analysis (N=429).

Statements	Factor loading	Communality
Parenting insights browsing	0.93	0.86
Observing childhood moments	0.91	0.82
Gathering parenting-related information	0.80	0.65
Gathering child-related information	0.78	0.61
Building a parenting community	0.72	0.52
Communication among parenting peers	0.72	0.52

Psychosocial Factor

Psychological Distress

The Japanese version of the K10 scale developed by Kessler et al [45,46], a globally recognized gold standard screening tool for mood and anxiety disorders in the general population, was used to measure the level of psychological distress but not in screening for mental disorders; therefore, no cutoff value was applied. Higher scores indicated greater levels of psychological distress. Sample items were rated on a 5-point Likert scale (1=not at all to 5=all the time), and the mean was calculated within a range of 1‐5. Cronbach α value for this study was 0.95.

Parenting Anxiety

A subscale of the Parenting Emotions Scale developed in Japan [47] was employed to measure parenting anxiety. The parenting anxiety subscale, one of the negative emotion subscales, includes aspects of anxiety about the child's development and parenting methods, with established reliability and validity [47]. For example, items such as "Feeling unsure about how to parent" were rated on a 4-point Likert scale (1=not at all to 4=often), with the mean value calculated within a range of 1‐4, and higher scores indicating greater parenting anxiety. Cronbach α value for this study was 0.86.

Loneliness

The Japanese version of the 10-item short form of the UCLA Loneliness Scale (Version 3) [48,49], validated among mothers of infants, was employed. Items were rated on a 4-point Likert scale (1=not at all to 4=always), with the mean value calculated within a range of 1 - 4, and higher scores indicating greater feelings of loneliness. Cronbach α value for this study was 0.79.

Social Support

A subscale related to support from significant others from the Japanese version of the Multidimensional Scale of Perceived Social Support [50-53] was also used. It includes 4 items rated on a 7-point Likert scale (1=very strongly disagree to 7=very strongly agree), with higher scores indicating higher perceived social support. Example items include “I have someone with whom I can share joys and sorrows.” The average score for each subscale was calculated on a scale of 1 - 7. The reliability and validity of this scale have been previously established [50]. Cronbach α value for this study was 0.91.

Participant Characteristics

Data were collected on participants’ age, number of children, age of youngest child, cohabiting family members, occupation, level of education, subjective economic status, and division of childcare and housework.

Statistics

Initially, descriptive statistics were first applied for all variables in the study, stratified by fathers and mothers. To identify differences between variables for fathers and mothers, *t* tests or chi-square tests were performed. Thereafter, separate multiple regression models were constructed for mothers and fathers, with psychological distress as the outcome variable and SNS use for parenting, parenting anxiety, and loneliness as predictor variables. Interaction terms between SNS use for parenting and parenting anxiety and loneliness were included in the model to examine their interactions. Covariates included parental age, which influences affinity for digital devices; number of children and age of youngest child, which influence childcare realities; subjective economic status, which was found to be related in univariate analyses; and active or passive use, reflecting the impact of SNS use in contexts other than parenting. Comprehensive checks were undertaken to ensure that the necessary assumptions for the use of multiple regression analysis were met. First, the skewness and kurtosis of the dependent variable were evaluated to ensure that the analysis was not affected by nonnormality. Second, the linear relationship between the dependent and independent variables was visually assessed using scatter plots. Third, the Durbin-Watson ratio was confirmed to be around 2 to ensure the independence of the observations. Fourth, normality and homoscedasticity of errors were visually assessed using normal Q-Q plots of residuals and studentized residuals. Fifth, multicollinearity was assessed by ensuring that the variance inflation factor for independent variables was lower than 10. Moreover, for significant interaction terms, a simple slope analysis [54] was conducted by plotting psychological distress scores at low (−1 SD) and high (+1 SD) levels of loneliness or parenting anxiety at low and high levels of SNS use for parenting.

Statistical analyses were performed using JMP Pro 16.0 (SAS Institute) with a significance level of 5%. Sample size was calculated using G-power, assuming an effect size (f_2) of 0.15 (medium), α error probability of .05, power of 0.8, and a number of predictors of 24, confirming that a sample size of 124 or more was required. In addition, in the analysis, when missing values for psychological distress, loneliness, parenting anxiety, and perceived social support were less than half of the items, missing values were imputed by predicting values based on the least squares method using the nonmissing parts of each scale. If more than half the items were missing, they were treated as missing data. Participants with missing values in nonpsychological scale items were also treated as having missing data. While participants with missing values were included in the analysis because of research ethics, they were excluded from the creation of multiple regression models. During this process, the usage of parenting-related SNSs and other psychological scale scores was compared between participants with missing data and those with no missing data, ensuring that there were no significant differences.

Ethical Considerations

Informed consent and opt-out procedures were implemented as follows. First, individuals referred by the web survey company were provided with written information detailing the study's purpose, the voluntary nature of participation, the absence of any penalties for nonparticipation, the right to refuse to answer, the maintenance of anonymity, the use of data solely for research purposes, and the strict management of personal information. Second, participants were given the choice to either agree or decline participation in the survey; only those who clicked the consent button were considered to have consented to participate, thereby ensuring the opportunity to opt out. In addition, all survey questions included an option to decline to answer. Respondents’ personal information was not disclosed to the researchers, and the data remained fully anonymized, ensuring that researchers had no means of identifying individuals. Participants received digital reward points as compensation for their effort in completing the survey, in accordance with the web survey company’s guidelines. This study was conducted with the approval of the ethics committee for research involving human subjects at Toyama Prefectural University (approval number: R5-16, dated August 10, 2023).

Results

Descriptive Statistics

Among those who returned the survey, responses from 429 individuals with experience using SNSs for parenting and no missing data on SNS use were analyzed. Table 2 illustrates the descriptive statistics and differences between mothers (205 individuals; 205/429, 47.8%) and fathers (224 individuals; 224/429, 52.2%). The differences were related to parental age, age of the youngest child, employment status, educational level, and division of childcare and housework. No differences in psychosocial factors were determined between fathers and mothers.

Gender Differences in SNS Use

Table 3 presents the descriptive statistics and differences in SNS use between fathers and mothers. As regards digital device ownership, a significantly greater proportion of fathers owned a computer than mothers ($\chi^2_1=25.12$; $P<.001$). In terms of SNS usage, a significantly higher percentage of mothers used Instagram than fathers ($\chi^2_1=41.87$; $P<.001$). The frequency of SNS use showed that mothers were significantly more passive than fathers ($t_{427}=-2.45$; $P=.006$).

[a] Multiple selection.

[b] Not applicable

[c] SNS: social networking site.

Regarding the frequency of SNS use for parenting, mothers were significantly more likely than fathers to gather parenting (t_{427}=−4.62; *P*<.001) and child-related information (t_{427}=−4.24; *P*<.001), browse parenting insights (t_{427}=−2.61; *P*=.01), and observe childhood moments (t_{427}=−3.33; *P*=.001). The mean scores for the frequency of SNS use for parenting, divided by the number of items, were 2.15 (SD 1.08) for fathers and 2.46 (SD 1.02) for mothers. An independent *t* test indicated that mothers had significantly higher scores than fathers (t_{427}=−3.04; *P*=.003).

The Effect of SNS Use for Parenting on Psychological Distress

Multiple regression models were created for both mothers and fathers to explain psychological distress with SNS use for parenting, loneliness, parenting anxiety, and covariates (Table 4). The model was constructed for mothers ($F_{12, 177}$=11.78; *P*<.001; R^2=0.44) and fathers ($F_{12, 189}$=15.43; *P*<.001; R^2=49.5). In the mothers model, a significant interaction effect was found only between parenting anxiety and SNS use for parenting (*b*=0.247, SE 0.091; *P*=.008). Meanwhile, in the fathers model, significant interaction effects were found between loneliness (*b*=0.324, SE 0.127; *P*=.01) and parenting anxiety (*b*=0.144, SE 0.069; *P*=.04) following SNS use for parenting.

Moderation Effects of Loneliness and Parenting Anxiety

The results of the simple slope analysis are illustrated in Figures 2 and 3. The mothers model showed that, at higher levels of parenting anxiety, SNS use for parenting was related to psychological distress (*b*=0.304, SE 0.090, β=.317; *P*<.001) but not at lower levels (*b*=−0.044, SE 0.090, β=−.046; *P*=.63). In the fathers model, SNS use for parenting was related to psychological distress at higher levels of parenting anxiety (*b*=0.330, SE 0.069, β=.346; *P*<.001) but not at lower levels (*b*=0.127, SE 0.097, β=.133; *P*=.19). In addition, SNS use for parenting was associated with psychological distress in fathers at higher levels of loneliness (*b*=0.390, SE 0.098, β=.409; *P*<.001) but not at lower levels (*b*=0.067, SE 0.089, β=.070; *P*=.45).

Discussion

Major Findings

This study examined the moderating influence of loneliness and parenting anxiety on the relationship between SNS use for parenting and psychological distress among mothers and fathers of young children. We observed that mothers used parenting-related SNSs more frequently than fathers, primarily for gathering parenting information and monitoring others' parenting activities. In addition, parenting anxiety moderated the relationship between SNS use for parenting and psychological distress in both genders, whereas the effect of loneliness was discernible only in fathers. Therefore, hypotheses 1 and 2 were fully supported and hypothesis 3 was partially supported. This novelty in our findings suggests the presence of both common and divergent elements in dynamics through which SNS use in parenting precipitates psychological distress in fathers and mothers. Previous research on SNS use and mental health has shown that the quality of interactions on SNSs (positive or negative) [55] and the attitude toward their use (passive or active) [56] can result in either positive or negative impacts on mental health. A systematic review of the relationship between SNS use, loneliness, and social anxiety [29] found that high levels of loneliness and social anxiety are correlated with problematic SNS use. However, it also highlighted the need for studies that simultaneously address these factors to explore their complex interrelationships. Most studies focusing on SNS use, loneliness, and anxiety have concentrated on adolescents, where SNS research is prevalent, leaving limited insights into both fathers and mothers in the context of early childhood parenting. This study extends previous findings by specifically examining SNS use in parenting and simultaneously addressing loneliness and anxiety to explore their moderating effects.

First, the moderating role of parenting anxiety was substantiated for both fathers and mothers regarding the association between SNS use in parenting and psychological distress. This suggests that parents struggling with heightened parenting anxiety may inadvertently exacerbate their psychological distress when using SNSs to cope with parenting challenges. An earlier study demonstrated that using information from smart devices to alleviate parenting concerns can paradoxically amplify anxiety when those concerns are severe [44]. Our findings align with previous research, hinting at the limited benefit for highly anxious parents in seeking comfort through SNSs. The background of psychological distress experienced by fathers and mothers with high parenting anxiety owing to SNS use may be related to low parenting self-efficacy and self-esteem, which are correlated with anxiety [27]. It is conceivable that parents burdened with acute parenting anxiety lack buffers such as self-efficacy and self-esteem against negative web-based influences, making them more vulnerable to psychological distress. In addition, parents prone to parenting anxiety inherently possess neurotic traits, which may foster upward social comparisons on SNSs and lead to increased psychological distress [57].

Second, the moderating effect of loneliness was observed solely among fathers, indicating that only those with significant levels of loneliness showed a strong correlation between intensive SNS use for parenting and high psychological distress. In general, higher levels of loneliness correlate with lower socioeconomic status [58]. In Japan, a persistent belief in gender roles assigns work responsibilities to men and domestic and child-rearing responsibilities to women [36]. Fathers of young children may identify strongly with the role of breadwinner and feel a deep sense of duty and pride. For fathers who feel isolated owing to socioeconomic constraints, SNS platforms that facilitate peer comparison [23] may exacerbate feelings of inadequacy regarding their family parenting practices, thus fostering psychological distress. Similarly, fathers who experience loneliness following strained partner relationships may face psychological distress from upward comparisons to seemingly idyllic families on SNSs. Furthermore, the lack of SNS platforms that naturally facilitate information sharing and camaraderie among fathers in the parenting domain may have also contributed to the distress experienced by lonely fathers. While social media and platforms for pregnant women and mothers are prevalent, there is a dearth of resources for fathers, including face-to-face peer support [39]. On more open platforms such as Instagram, X, and Facebook, fathers may find opportunities to connect with their peers, but in environments in Japan with strong gender-role divisions [36], they are likely to encounter more mother-centered information exchange. The use of SNSs in the context of fathers seeking connections and information sharing in parenting may have exacerbated psychological distress by creating a sense of alienation among them.

It is worth noting that no moderating effect of loneliness among mothers could be determined. This suggests that, regardless of loneliness, increasing SNS use for parenting among mothers is indicative of psychological distress. Previous studies have suggested that women experience significantly higher levels of depression owing to social comparisons on social media than men [59]. Mothers, as opposed to fathers, may be more susceptible to the mental health detriments of SNS use, regardless of whether or not they experience loneliness. In addition, the literature presents conflicting views on whether SNSs contribute positively by fostering desired social relationships [60,61] or negatively by forming unsatisfactory social connections for lonely individuals [18]. Previous research demonstrated that, for mothers in the parenting phase, the extent of their social networks on SNSs is inversely related to feelings of loneliness [62], suggesting that SNSs may not necessarily accentuate negative effects for lonely mothers.

Furthermore, given that this study is cross-sectional, there is the possibility of a reverse causal relationship, where parents with high levels of loneliness and parenting anxiety may engage more actively in SNS use for parenting because of their high psychological distress. Previous research reported that individuals with neurotic tendencies, which precede psychological distress, tend to use social media excessively or compulsively [63]. It is possible that parents experiencing high psychological distress, along with loneliness and parenting anxiety, may inherently possess neurotic tendencies and, consequently, may frequently use SNSs for parenting.

Implications

This study highlights the differences in the moderating effects of loneliness and parenting anxiety on the relationship between SNS use and psychological distress among parents. It was observed that both fathers and mothers experiencing heightened levels of loneliness or parenting anxiety reported that SNS use in parenting activities was associated with increased psychological distress. This observation suggests that SNS use may not always be beneficial for parents experiencing loneliness or parenting anxiety, and it might be useful for professionals to discuss the potential drawbacks of relying heavily on SNSs for parenting support. Conversely, it is also suggested that parents experiencing high psychological distress, along with loneliness and parenting anxiety, may use SNSs frequently for parenting. As SNSs might serve as necessary support for parents in distress, it is crucial for professionals to support its moderate use while considering the limitations of its benefits. Given that SNS use for parenting is more common among mothers, it is important for professionals to recognize mothers as a group potentially more susceptible to both the positive and negative impacts of SNS use. Finally, enhancing SNS platforms specifically for lonely fathers as a parenting resource may be beneficial.

Limitations

This study has several limitations. First, owing to its cross-sectional design, causality cannot be established. Second, the study relies on self-reported questionnaires, which does not eliminate the possibility of information bias. Third, the use of convenience sampling by a specific survey company in Japan may have introduced selection bias. Specifically, the sample may have been biased toward those with a high affinity for web-based information and high information literacy, thus limiting the generalizability of the results. Fourth, the study did not use a validated scale to measure SNS use for parenting, and although it considered real-life parenting situations through interview data, it lacks clear conceptualization and validation of construct validity, limiting the accuracy of the phenomenon measured. Fifth, the study did not consider the information literacy of the participants. Future research should use scales that more accurately measure the concept of SNS use in parenting. In addition, because a bidirectional causal relationship between SNS use and mental health is assumed, longitudinal studies that test for causality could provide higher-resolution insights into SNS use and parenting mental health.

Conclusions

This study examined the moderating effects of loneliness and parenting anxiety on the relationship between SNS use and psychological distress among parents of young children. The moderating effect of parenting anxiety on this relationship was confirmed for both fathers and mothers, but the moderating effect of loneliness was established only for fathers. Given that different mechanisms underlie the loneliness experienced by fathers and mothers, the impact of SNS use on mental health may differ. Health and medical professionals might well need to tailor guidelines for SNS use in parental support taking into account gender. For fathers, a cautious approach to SNS use when feeling lonely is recommended, while for mothers, guidance on how to effectively balance SNS use with other support resources based on the level of parenting concerns may be needed.

Abstract

Background: In recent years, women’s fertility desire has attracted increasing attention in China.

Objective: This study aims to detect attitudes toward giving birth among young female users on Douban, a very popular Chinese social media platform.

Methods: A total of 2634 valid posts from 2489 users discussing the topic “What does childbirth mean to a woman” on Douban were crawled and retained for analysis. We utilized content and thematic analysis methods to capture users’ concepts of childbirth.

Results: The findings reveal that a significant majority of users conveyed generally neutral (1060/2634, 40.24%) or negative (1051/2634, 39.90%) attitudes toward childbirth, while only about one-fifth of users expressed positive (523/2634, 19.86%) sentiments. Notably, posts with negative attitudes garnered more replies and likes, and the proportion of posts expressing negativity exhibited fluctuations over time. Health risk (339/2634, 12.87%) emerged as the most frequently cited aspect of childbirth cost, with subjective happiness and the fulfillment of mental needs identified as primary benefits. Surprisingly, only a minimal number of posts (10/2634, 0.38%) touched upon the traditional objective benefits of raising children for old-age care. Thematic analysis results suggest that discussions about fertility on social media platforms might contribute to an exaggerated perception of health risks among women. Additionally, a lack of knowledge about childbirth was observed, partially attributable to longstanding neglect and avoidance of communication on these matters, likely influenced by traditional cultural biases. Moreover, there is a prevailing assumption that women should naturally sacrifice themselves for childbirth and childcare, influenced by the idealization of the female figure. Consequently, women may harbor hesitations about having a baby, fearing the potential loss of their own identity in the process.

Conclusions: The results indicate a shift in the perception of childbirth among modern Chinese women over time, influenced by their increasing social status and the pursuit of self-realization. Implementing strategies such as public education on the health risks associated with pregnancy and delivery, safeguarding women’s rights, and creating a supportive environment for mothers may enhance women’s willingness to undergo childbirth.

KEYWORDS

childbirth willingness; social media; risk perception; childbirth cost; childbirth benefit

Introduction

The academic community in demographics has centered its attention on fertility issues, and China is currently grappling with a significant challenge in population development due to its low fertility rate. In August 2020, the National Health Commission of the People's Republic of China issued a document highlighting that the low fertility rate has emerged as a major risk impacting the balanced development of the country's population. To mitigate the consequences of population aging and the decline in demographic dividends resulting from the low fertility rate, China introduced the "Universal Two-Child Policy" in January 2016, followed by the "Three-Child Policy" in May 2021. The implementation of these policies has elevated individual childbirth willingness as a crucial factor influencing the childbirth rate [1]. The determinants of childbirth are multifaceted and intricate; past research indicates that cultural norms and values play a substantial role in shaping both the concept and behavior associated with childbirth [2,3]. Research on the willingness to have a second child among Chinese women has indicated that cultural concepts play a pivotal role in influencing the decision to pursue a second child [4]. In the context of a highly "mediatized" modern societal culture, where the media not only exerts influence but also, to some extent, shapes cultural attitudes [5], it appears that women's fertility desires are more significantly impacted by media exposure compared with men [6].

In contemporary society, the internet has emerged as one of the foremost cultural media. As of June 2022, the number of internet users in China had surpassed 1.051 billion, with an adoption rate of 74.4% [7]. Serving as a crucial platform for individuals to articulate their perspectives, the internet fosters cultural diversity and the expression of values. This, in turn, influences personal attitudes toward marriage, inspiring individuals to seek independence, personal happiness, and a heightened awareness of emotional connection and respect for individuality [8]. The evolution of the internet is concurrently driving a shift in the concept of gender roles among rural residents, transitioning from traditional to modern perspectives. This influence is evident in both men and women, with a notably more pronounced effect on women compared with men [9]. Social media, as a novel form of online communication, provides users with an extensive platform for active participation. It embodies features such as engagement, openness, real-time communication, community-building, and connectivity [10]. Social interaction serves as a crucial mechanism by which media can shape fertility behaviors and concepts [11]. Consequently, the utilization of social media can influence people's perceptions of fertility and their intentions regarding it. Examining discussions about fertility on social media becomes valuable in gaining insights into the collective understanding of fertility among the populace.

In recent years, a growing number of women have been actively sharing comments on childbirth-related topics, including discussions about the "2-child" and "3-child" policies, expressing their personal insights and thoughts on the matter. A notable distinction is that the majority of discussions on foreign social media platforms exhibit a predominantly positive attitude toward childbirth [12,13]. Nevertheless, the discourse on fertility in China's social media landscape is characterized by a prevalence of antifertility sentiments [14]. On the one hand, the textual information available on the internet partially mirrors the childbirth concepts held by contemporary women. On the other hand, public opinion expressed on social media platforms may exert an influence on women's perceptions of childbirth, potentially diminishing their willingness to pursue childbirth [15,16]. In this study, content analysis was used to delineate the predominant attitudes evident in posts within a social media topic focused on childbirth. Additionally, the analysis aimed to identify the costs and benefits associated with childbirth that garnered attention and concern among the participants. Furthermore, thematic analysis was utilized to reveal the underlying childbirth themes embedded in the posts under this particular topic.

Methods

Sample

Selection of Research Platform

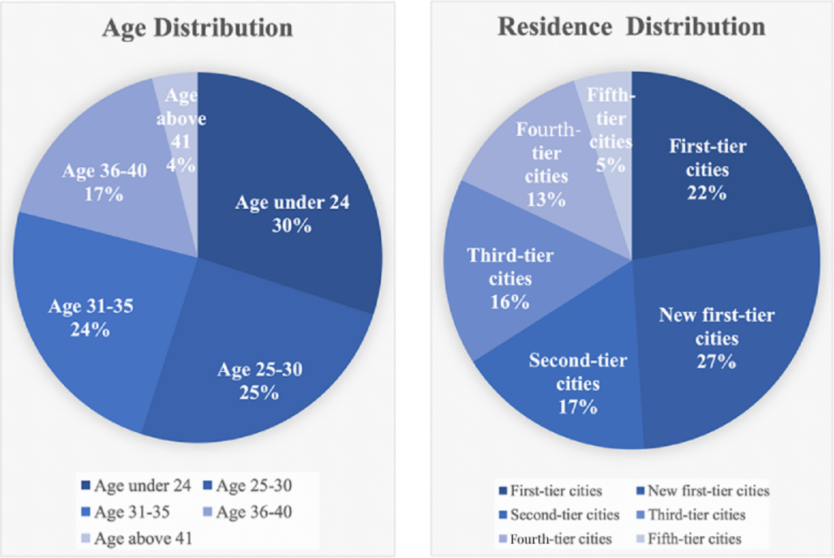
This paper selected Douban (Beijing Douwang Technology Co. Ltd.) as the source platform for data collection based on the considerations outlined in Textbox 1.

Textbox 1. Considerations for data collection.

1. To identify suitable social media data for the study, the research team conducted a screening of childbirth topics across various popular platforms in China, such as Weibo (Weibo Corporation), WeChat (Tencent Holdings Limited), TikTok (ByteDance), Bilibili (Bilibili Inc.), and Douban. It was observed that the feature settings of Douban and Weibo rendered them more conducive to text analysis. However, on Weibo, no topics closely aligned with our research objective were found, and the word count and content quality of Weibo posts were found to be inferior to those on Douban.

2. Douban stands out as a popular social media platform, particularly among young women of childbearing age. As per data from the "Qianfan" query platform, which serves as a digital economy market information and data terminal, Douban boasts a monthly active user base of 10.51 million. Notably, within this user demographic, women constitute a significant majority at 63.3%. In comparison to other social media platforms such as Weibo and WeChat, Douban exhibits a higher proportion of female users. The bulk of Douban's user demographic falls within the childbearing age range, with 30.07% aged under 24 years, 24.83% aged 24-30 years, and 24.25% aged 30-35 years. Additionally, 49.14% of users originate from first-tier or new first-tier cities. This demographic profile underscores that a significant proportion of Douban users are urban women of childbearing age. Consequently, their discussions on childbirth have the potential to reflect the attitudes and concerns toward childbirth among Chinese women to a considerable extent. It is noteworthy that many studies focusing on Chinese women have selected Douban as their research platform (Figure 1, [17-20]).

Figure 1. User groups in May 2022 according to the “Qianfan” query platform.



Selection of Research Topic

Among the numerous childbirth-related topics on Douban, this paper selected the one most pertinent to women’s concept of childbirth and with the highest number of posts. Specifically, the chosen topic is “What does childbirth mean to a woman.” Initiated in June 2020, this discussion has garnered significant engagement, accumulating 3655 posts as of August 5, 2022. Notably, the most popular post on this topic received 5596 likes. The substantial quantity and the evident quality of the posts led us to conclude that they met our inclusion standards.

Selection of Posts Under the Research Topic

This study focused on analyzing the discussions within the topic “What does childbirth mean to a woman,” and data were collected by crawling posts from June 10, 2020, to July 16, 2022. A total of 3403 raw posts from 2838 users were gathered, encompassing information such as post time, content, and likes. Additionally, permanent residence details were obtained for 2128 users. Recognizing the contextual nature of replies below the posts and the challenges associated with their identification and categorization, we opted to solely crawl the original posts. Replies beneath the posts were not included in the data collection process, acknowledging the potential complexity in comprehending their content without the necessary context from the original posts.

The crawled posts underwent a standardized screening and cleaning process, which unfolded in 2 steps. Initially, 2 categories of invalid data were systematically removed. The first category encompassed elements such as emojis, symbols, pictures, and blanks, which were deemed unsuitable for text analysis. The second category included irrelevant posts or those with an ambiguous attitude toward childbirth, such as advertisements, personal life records, ambiguous sentences, questions, and posts from men, among others. Following these criteria, a total of 460 posts were eliminated in the first step of the cleaning process. In the second step, for users who posted more than once, we analyzed their attitude toward childbirth. If all posts from the same user exhibited a consistent attitude, the post with the highest number of likes was retained. In cases where posts had the same number of likes, the one with the greater word count was preserved, and any remaining posts were eliminated. This approach aimed to distill the most representative content from users with multiple posts on the same topic. If a user’s attitude toward childbirth changed, the post with the highest number of likes under each different attitude was retained. For instance, if a user’s attitude shifted from positive to neutral and then to negative, 3 posts would be retained. Adhering to this criterion, a total of 309 posts were sequentially eliminated. Importantly, to maintain the focus on women’s concepts of childbirth, all posts where the posters identified as male were removed. While the data did not explicitly specify the gender of the posters, given the topic’s nature, the predominant female user base on Douban, and the thorough data cleaning process, it is argued that most of the retained posts after elimination originated from women. In the end, 2634 valid posts from 2489 users were retained for analysis.

Ethics Approval

To safeguard user privacy, this study used the practice of using the first letter of each word in the username to replace the full name. For English usernames, the first 3 letters were utilized. Additionally, the post time was appended after each post. The study adheres to ethics code H15009 and obtained approval from the Institutional Review Board at the Institute of Psychology at the Chinese Academy of Sciences.

Content Analysis Procedure

Content analysis aims to describe the prevailing attitudes of people toward childbirth and their concerns about the costs and benefits associated with childbirth. We referenced the methods from MacPherson et al [21] and Liu et al [22]. Two investigators (TY and YHW), with an in-depth understanding of Douban’s cultural environment, conducted the content analysis. Initially, the 2 researchers read 10% (340/3403) of the posts and then engaged in discussions to generate coding criteria for attitudes toward childbirth, the costs of childbirth, and the benefits of childbirth (Tables 1, 2 and 3). Subsequently, they randomly selected 50 posts to verify the saturation of the coding criteria.

Following that, both researchers independently coded all the data based on the coding criteria. During this process, they conducted regular cross-checks to ensure the consistency of their coding results, and any disagreements were adjudicated by the third researcher (NH). After that, quantitative descriptive results concerning childbirth attitudes, childbirth costs, and childbirth benefits were obtained.

Table 1. Coding criterion for attitudes toward childbirth.

Category and definition	Example
Negative	
• Willingness not to give birth or regret to give birth	• If I had known that childbirth would deprive the freedom to live an unconstraint life, to cook, to attend an exhibition, and to sleep late at weekends, to improve myself and play at night, I truly would not have a baby. [Poster and Time: CC, June 23, 2020, 16:21:08]
• Negative effects of childbirth	• It means my belly not going back to how it was before I was pregnant, anterior pelvic tilt, fat saddlebags, diastasis recti abdominis, sagging breasts and no freedom. [Poster and Time: LTGZ, October 12, 2020, 15:02:29]
• Sharing of personal experiences or stories that makes researchers feel subjective negative attitudes toward childbirth	• Today, a colleague returned to work after maternity leave. Her office cubicle was no longer available in the department. I asked if there was a need to register in new financial software for her, while the manager said he didn’t know. Then, the leader said to seal her employment separation certificate. What a sad story! [Poster and Time: PSH, April 27, 2021, 21:12:27]
Neutral	
• A view that agrees with both giving and not giving birth	• It means freedom and rights. As a woman, getting married or having children is only one of the choices. Whether to get married or not, whether to have children or not is our own choice. [Poster and Time: WZHYLDN, June 11, 2020, 15:07:05]
• Positive or negative effects of childbirth with no indication of personal willingness	• Having a baby means the loss of your own life. Isn’t taking care of children a part of your life? There is no accounting for tastes. Opportunities and costs are everywhere and need to be chosen. [Poster and Time: MISS, October 15, 2020, 08:43:17]
• Sharing of personal experiences or stories does not make researchers feel subjective attitudes toward childbirth	• I don’t have a child, but I have a friend who already has a baby. I see her state, there are gains and losses. What childbirth means to women may depend on their own state of mind/family attitudes. [Poster and Time: QHCD, November 28, 2020, 23:44:33]
Positive	
• Willingness to give birth	• Most likely, because my own family is incomplete, I personally want to get married and have children to start a new family. [Poster and Time: NKWKBKN, June 13, 2020, 04:31:45]
• Positive effects of childbirth	• For me, I am very happy, I have a sense of responsibility, one more person I care about, more maturity and stability. It is like a seed, growing with my care, and I have a sense of achievement and pride. [Poster and Time: XYCDXWB, June 11, 2020, 12:18:34]
• Sharing of personal experiences or stories makes researchers feel subjective positive attitudes toward childbirth	• I chatted with my friend last night, who was the same age as me. Her daughter is five years old, and I thought she would become complaining, grumpy and anxious like other mothers, but she doesn’t. She has a strong ability of introspection and awareness to change and adjust her state of mind. [Poster and Time: YYSH, June 17, 2020, 10:12:49]

Table 2. Coding criterion for the costs of childbirth.

Category	Posts (N=2634), n (%)	Definition	Example
Health risks	339 (12.87)	Severe reactions during pregnancy, physical pain of childbirth, sequelae of childbirth, and postpartum depression	*After giving birth, I still feel pains in some part of my body. The arms, knees and heels feel cold even in summer, so that I have to wear socks to sleep every day. As the mother of two daughters, I hope that they will choose not to marry and be infertile in the future.* [Poster and Time: QQWDBB, June 18, 2020, 10:14:30]
Constraint on freedom	232 (8.81)	Constraint on freedom and the lack of self-personality caused by childbirth	*It means losing freedom and self within an uncertain period.* [Poster and Time: LSSJL, July 17, 2020, 22:08:34]
Energy investment	162 (6.15)	Energy investment during pregnancy and parenting, such as the inability to sleep due to breastfeeding	*After being a mother, 24 hours a day is not enough. I don't want to sleep more, just want to fight for more time of my own.* [Poster and Time: CXMY, July 19, 2020, 08:50:38]
Influence on occupation	159 (6.04)	Workplace discrimination and the impact of childbirth on occupation	*Having a baby means your career will be forced to stagnate for 3 to 5 years. The tiredness and concern for children are really a major cost for women in the workforce.* [Poster and Time: BBQDJXK, April 18, 2021, 02:02:55]
Parenting responsibility	84 (3.19)	Responsibility for childbirth and education of children	*I don't know why. But when I see the topic, the first thought coming into my mind is responsibility, being responsible for myself and for my baby. If I can't do it well, I will not give birth. I don't yearn for giving birth. And I will not regret if I don't have any children.* [Poster and Time: CSG, June 11, 2020, 19:31:50]
Influence on appearance	84 (3.19)	Influence of appearance, figure, scar, etc	*After giving birth, it is easy to welcome the coming of a new baby but is difficult to face with the linea nigra, stretch marks on the thighs and flabby belly.* [Poster and Time: LKNT, May 1, 2021, 02:53:04]
Family relationship	69 (2.62)	Negative effects of family relationships caused by childbirth	*Many spouses will engage in emotional abuse. I have seen numerous examples around me, where after the wife gave birth, the husband became particularly distant and cold towards her.* [Poster and Time: DY, November 20, 2020, 01:38:22]
Financial investment	33 (1.25)	Financial investment due to childbirth	*My baby is 16 weeks old. I need to have the Down syndrome screening, Mediterranean anemia test, and an ultrasound. These tests will cost 953 yuan, which is really expensive......* [Poster and Time: PTR, December 30, 2021, 09:31:21]

Table 3. Coding criterion for the benefits of childbirth.

Category	Posts (N=2634), n (%)	Definition	Example
Parenting experience	196 (7.44)	Well-being, love, and happiness felt in the parenting process	*It is lucky for a woman to be able to deliver a baby, because only by giving birth can you know how happy it is to be a mother. A little baby who is as small as a meat ball can grow up after your care. And every progress he achieved will let you feel happy. I think companion is the best moment in the world.* [Poster and Time: HL, June 13, 2020, 17:37:32]
Self-growth	115 (4.37)	Growth of knowledge, the reconstruction of world outlook and values, and the maturity of self-character	*I think giving birth is an opportunity for a woman and a man to grow up. The deeper life goes, the greater the difference and the resistance to seeking common ground. Because of children, we have the desire to seek common ground, so the creativity to overcome resistance is stronger and the vitality is also stronger.* [Poster and Time: KGZDM, June 30, 2020, 17:09:09]
Continuation of life	38 (1.44)	The social value of propagation of the race and the significance of the personal continuation of life	*I chose to have children just because I think child is still a continuation of our blood in this world when my husband and I died, which can prove that we have been here. It is beautiful to think about it, isn't it?* [Poster and Time: NL, June 16, 2020, 08:14:36]
Children's company and psychological support	23 (0.87)	Children's daily company, psychological sustenance, etc	*Parents accompany you in the first half of your life, and children do the same in the second half of your life. People will feel reassured when there is always a person accompanying you in your life.* [Poster and Time: TK, June 23, 2020, 12:18:10]
Complete life	22 (0.84)	The integrity of personal values and life experiences	*I think childbirth has completed a transformation from being a woman to a mother for me. It lets me realize the greatness and selflessness of my mother. It also makes my life as a woman more complete.* [Poster and Time: HX, June 15, 2020, 21:01:44]

Thematic Analysis Procedure

Thematic analysis aims to explore more intricate childbirth concepts, providing an exploratory theoretical explanation for the results of content analysis. More specifically, the results of the thematic analysis can provide explanations and insights into why there is a widespread prevalence of negative childbirth attitudes, why some childbirth costs are of particular concern, and what kind of support individuals require from the government and society. While content analysis helps identify themes based on frequency, thematic analysis reveals potential themes within the data that can present a more nuanced perspective [23]. This study utilized the thematic analysis approach with the 5 phases outlined by Braun and Clarke [23]. In the first phase, the authors immersed themselves in the data through repeated readings and viewing, critically contemplating the meanings within the content of the posts. In the second phase, the research team identified initial codes. Moving into the third phase, the authors shifted from identifying codes to identifying themes, interconnecting the codes logically to form themes. The fourth phase involved reviewing each theme's relation to the data overall and to the other themes to determine the boundaries of each theme. In the fifth phase, the research team defined, named, and elaborated on each theme and extracted illustrative examples of the final themes [24].

Results

Content Analysis

Basic Attitude

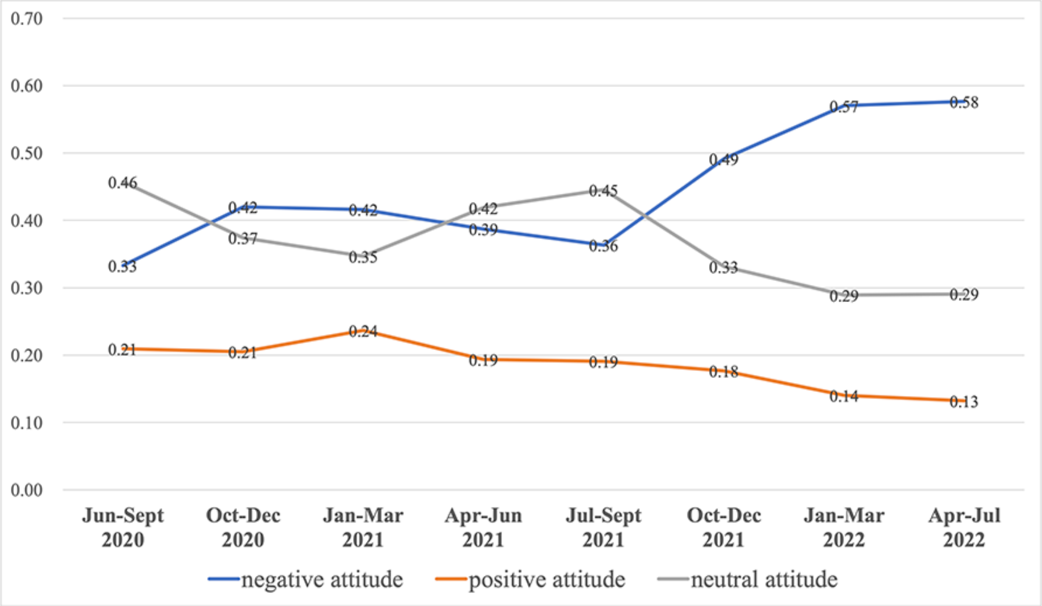
In the content analysis, we identified coding criteria related to attitudes toward childbirth, and Table 1 illustrates specific criteria and examples. The basic classification of the attitude toward childbirth showed that 1051/2634 (39.90%) posts had a negative attitude, 523/2634 (19.86%) posts had a positive attitude, and 1060/2634 (40.24%) posts had a neutral attitude. This indicates that the public attitude toward childbirth is generally neutral or negative, with fewer instances of a positive outlook. By extracting and classifying the top 10 most-liked posts, we found that there were 5 posts with a negative attitude (50%), 2 posts with a positive attitude (20%), and 3 posts with a neutral attitude (30%). The negative ratio was higher, but it was basically consistent with the whole distribution. From the word count, the posts with a positive attitude are the longest, but the number of likes is the lowest. By contrast, the posts with a negative attitude are the shortest, but the number of likes is the highest (Table 4).

If the factor of time is taken into account and the changes in the proportion of childbirth attitudes in different periods are analyzed, it can be found that the proportion of posts with a negative attitude fluctuates to rise, the proportion of posts with a neutral attitude fluctuates to decline, and the proportion of posts with a positive attitude has small fluctuations and shows a downward trend (Figure 2).

Table 4. Distribution of childbirth attitude of posts.

Category	Posts (N=2634), n (%)	Top 10 most-liked posts, n (%)	The average number of words in 1 post	The median number of words in 1 post	The average number of likes in 1 post	The median number of likes in 1 post
Negative	1051 (39.90)	5 (50)	277.64	103	41.27	4
Neutral	1060 (40.24)	3 (30)	352.87	101	28.48	3
Positive	523 (19.86)	2 (20)	415.86	158	26.26	3

Figure 2. Changes in the proportion of three childbirth attitudes with time.



Childbirth Costs and Childbirth Benefits

In the content analysis, we identified coding criteria for the costs and benefits of childbirth, and the proportions in Tables 2 and 3 refer to the proportion of posts mentioning this category in the total number of posts. It should be noted that the content of posts under research topics varies in length. Some posts involve multiple categories, while others only indicate attitudes without involving any categories. Therefore, the total proportion of categories related to childbirth benefits and costs does not equal 100%.

Among all the categories related to childbirth cost, health risk is the most common category, including severe reactions during pregnancy, physiological pain during childbirth, sequelae of childbirth, and postpartum depression. In addition, limited freedom, energy input, negative influence on the workplace, parenting responsibility, and appearance change are the childbirth costs that people are more concerned about.

Among all the posts, the parenting experience is generally recognized as the greatest childbirth benefit, which includes happiness and love felt in the process of parenting. Compared with childbirth costs, childbirth benefits are mostly subjective feelings and spiritual needs, such as parenting experience, the continuation of life, companionship of children, and the integrity of life. There were only 10/2634 posts (0.38%) that mentioned the objective benefits of bringing up children for the purpose of being looked after in old age.

Thematic Analysis

Overview

Results of thematic analysis generated 4 childbirth concepts from all posts: (1) amplified perception of childbirth risk; (2) hidden childbirth experience and childbirth knowledge spread through informal channels; (3) gender equality and childbirth trap; and (4) the deification of the mother figure. Each theme is presented with detailed descriptions and illustrative examples from the posts.

Amplified Perception of Childbirth Risk

In the discussion under the topic, the frequency of mentioning childbirth costs is much higher than that of childbirth benefits, and the explanation of the former makes it easier to attract the attention of the audience and get more likes. Taking the cost of health risks as an example, many users share their personal childbirth experiences, and the real delivery process highlights the physiological pain of childbirth.

> *I felt regular contractions at two o'clock in the morning when I gave birth to my daughter. When my cervix dilated to about 2cm, I was extremely painful. When it dilated to about 3cm, I couldn't bear it, so I asked for painless childbirth. After the injection of epidural, I felt tired and breathless without any*

> *energy. My head went blank and I couldn’t help to trembling. There was no way but call an anesthesiologist to stop the epidural. Then, I couldn’t feel anything but the pain of contractions. On the second day after I was discharged from the hospital, my lateral incision broke along the suture and became inflamed, so it had to be sutured twice. It was my second time in the delivery room. But this time, I had to have a suture without anesthetic. It was so painful that I even wanted to die and would never forget that feeling in my life.* [Poster and Time: XXXXAX, November 1, 2020, 13:42:03]

These negative posts may make many unmarried and childless women fear giving birth and then show resistance to childbirth. In addition to the pain and discomfort of pregnancy and childbirth, the complications of pregnancy strengthen the negative perceptions of netizens about childbirth.

> *Some worries include severe morning sickness during pregnancy, frequent urination at night, a sense of breathlessness as the stomach gets bigger, overwhelming back pain after sitting or standing for a long time in class, too much or too little fetal movement...* [Poster and Time: LLL, September 29, 2020, 20:09:01]

> *Pregnancy makes pelvic floor muscles loosen and natural labor will cause bladder prolapse, which takes a long time to heal.* [Poster and Time: QSXX, June 24, 2022, 14:02:12]

Pregnancy discomfort reactions and recovery processes after childbirth are common experiences for pregnant women, and these symptoms vary in different pregnancy periods and for different individuals. However, many posts emphasize that childbirth will inevitably bring significant health effects and attribute some individuals’ postpartum health changes to childbirth.

> *Childbirth is a gamble, and it is common to make you get out of shape and have urinary incontinence. Apart from that, you may suffer from some lifelong diseases such as diabetes and eclampsia. Two of my relatives and friends have systemic lupus erythematosus (SLE) after delivery.* [Poster and Time: MDAY, October 29, 2020, 00:46:09]

> *Childbirth is a gambling which risks a mother’s life to deliver a baby. Even if it is a successful delivery process, the harm to women is irreversible. My mother used to be a long-distance runner, who is even stronger and healthier than most men. But now this 50-year-old woman still feels cold in winter even when we use many ways to get her warm by opening air conditioner and underfloor heating.* [Poster and Time: PER, June 21, 2020, 09:46:47]

By browsing so many negative posts listed under this topic, viewers are inclined to think that “childbirth must be painful and will bring negative effects to the body.” In addition to physical health, limited freedom and influence on occupation are important childbirth risks. Without correct guidance, these posts will increase viewers’ perception of childbirth risk to a certain extent and then prevent their willingness from giving birth. Of all the posts, 34/2634 (1.29%) posts mentioned the negative impact of browsing this discussion.

> *I feel very scared when I view this topic by accident. It seems that I fear marriage and childbirth. I suddenly want to withdraw my couple seeking post. Well, it’s fine to just live alone.* [Poster and Time: JDXJ, February 7, 2021, 21:21:59]

> *Whenever I have doubts and shake my faith in marriage and childbirth, I will find this topic to see the advice of my predecessors, and I think I will be safe without marriage and childbirth.* [Poster and Time: WAQDZ, April 15, 2022, 18:38:57]

Hidden Childbirth Experience and Childbirth Knowledge Spread Through Informal Channels

On the one hand, the deviation in viewers’ perception of childbirth risks, especially health risks, comes from the influence of the spread of network information, and on the other hand, it is due to the lack of systematic, complete, and scientific childbirth knowledge. In the posts, many users expressed their lack of relevant knowledge, suggesting that the popularization of childbirth knowledge in schools and society, especially women’s childbirth health, is still insufficient.

> *There are countless books on the market that teach people how to have a healthy and intelligent child from conception, but few books tell people what damage childbirth will cause to women’s bodies and how to minimize this damage as much as possible. China’s policymakers attach great importance to prenatal and postnatal care. There are all-around and multilevel support means from card establishment during pregnancy, and prenatal care check-ups to breastfeeding and pediatric health care after delivery. But there is almost no means of support for the physical and mental health of mothers. I think this is a result caused by the whole society, paying too much attention to children and neglecting mothers.* [Poster and Time: OYSS, July 17, 2020, 11:43:46]

Childbirth is an important event that most women in China will experience, and its specific process and health risks rarely appeared in the public field in the past. From the perspective of older females in traditional society, they were ashamed to discuss the childbirth process and its sequelae. Moreover, because every woman in society has to experience this kind of pain, there is no need to emphasize it. Therefore, women are less likely to get relevant experience from relatives and older individuals.

> *Until the moment I give birth, I never know what it means to my body. Before this, no relatives and friends who become mothers around me have talked about this topic with me. I remembered that in college, I asked my cousin-in-law who gave birth to a child this question and she replied: I feel like I have grown up all of a sudden. When I was a graduate student, I asked my cousin, and she replied: You will know the answer when you deliver a baby—maybe she is shy*

> *or maybe she doesn't know where to start to answer my question.* [Poster and Time: PAS, December 5, 2020, 04:14:16]

There are various reasons why women lack knowledge about health risks during pregnancy and delivery. For a long time, the whole society has had an insufficient understanding of women's childbirth, as pointed out by some posts.

> *For a long time, we have not been allowed to talk about our bodies in public, and some details and experiences including the physiological period, pregnancy and childbirth, are regarded as taboo. But, if we don't talk about it, we can't communicate with each other, let alone attract a public concern in society. And if we don't pay attention to our own body and mind, no one will.* [Poster and Time: MMJJ, December 13, 2020, 17:16:08]

Gender Equality and Childbirth Trap

With the progress of modernization, a growing number of women have gained access to education, actively participated in employment, and started to seek fair labor remuneration and equalized social status. All these factors combined have led to the rise of feminism. Feminism strives to attain gender equality and promote equal rights, opportunities, social recognition, and space for development for all family members, irrespective of gender. The most significant biological difference between men and women lies in the distinct reproductive function of women. Women's reproductive behavior is a key factor contributing to inequality between men and women, manifesting in various aspects such as access to educational resources, career opportunities, and labor remuneration. Consequently, in the online public opinion environment, discussions related to feminism are often sparked by the topic of childbirth.

Under the research topic, 172/2634 (6.53%) posts mentioned content related to feminism, covering aspects such as unequal reproductive responsibilities between men and women, protection of women's rights, gender discrimination, abortion rights, and reproductive rights. Among these, 115 posts expressed a negative attitude toward reproduction. In these posts, the reproductive function was no longer perceived as a biological advantage or a gift to women but rather as a negative factor hindering women from pursuing personal development and achieving self-fulfillment. The reason is that the career development of many professional women often comes to a standstill during childbirth, especially during the postpartum period. After giving birth, their incomes suffer as well because a significant portion of their energy has to be invested in caregiving. This has a notable negative impact on those who seek freedom, equality, and socioeconomic status as modern, independent females.

> *Childbirth has made me a complete feminism and understand the plight of women who can only fight back by not having children. At least at this stage, feminism and childbirth are still at odds with each other. The enormous amount of energy and time required to bear and raise a child is an exponentially increasing workload that has been placed on women for a long time as a 'punishment for motherhood'. Women are tied to unrecognized labor, and their status is naturally inferior. In addition, there is no security. Now the only option for women to achieve equal economic status is not to have children, not to take on this unrecognized part of the work, but to fight for rightful social status.* [Poster and Time: TTZ, October 15, 2021, 17:53:04]

In addition to the reality of career stagnation and the unrecognized value of domestic work, the collected posts argued that childbirth can have other negative spiritual effects. These include the identity shift after reproduction, which can confuse women's self-perception and a lack of self-subjectivity. Moreover, in some cases, childbirth even becomes a tool for society to discipline women.

> *Marriage and childbirth mean disciplining and reshaping women. The gender concept tends to be traditional, and what once believed, insisted on, and pursued may be annihilated in the trivialities of life and other people's demands. I fear that kind of change is irresistible, and the fear of losing a part of myself makes me resistant to marriage and childbearing.* [Poster and Time: YSBG, July 13, 2020, 00:36:04]

Some posts even expressed the belief that childbirth has become a kind of original sin for women, and it does not bring any benefits to them.

> *Having children is a life choice. In a male-dominated society, childbearing is a disaster for women.* [Poster and Time: WT, October 7, 2020, 21:10:08]
>
> *A pair of bulging breasts and a uterus is the sole source of modern female woe, in a society marinated in misogynistic thinking.* [Poster and Time: PLPLB, June 27, 2022, 14:22:05]

Admittedly, many of the posts were, to some extent, radical. However, it is essential to consider that the subject of female fertility discourse has been historically obscured for so long that, once people gain the right to free speech, they may resort to language for a thorough emotional release. While women are expressing their repressed feelings, the court of public opinion can influence women who are not married or pregnant, leading to negative evaluations of marriage and fertility.

These feminism-related posts intensively conflict with traditional concepts. In agricultural societies, reproduction and fertility are among the most important values attributed to women in the family. Although modern women are gradually finding new sources of value from education, careers, and society, and to some extent, detaching their self-worth from reproduction, traditional cultural evaluations are slow to change. Many posts also indicated that fertility behavior is subject to social and family pressure.

> *For a woman who is about to enter her 30 s, the real feeling is that no one (especially the elders) cares about what you want to do in the future, whether you are happy with your life or what your career plan is, but only when you are going to prepare for pregnancy? When are you going to have a baby? It*

> *seems that only having a child is the most important thing in your life, and your life is not complete without it!* [Poster and Time: BLZ, December 31, 2021, 03:45:34]

> *My mother's classic quotes are 'A woman is not complete without a child; bearing no child is a waste of womb; at least have one child, otherwise there is no point in living; a woman will definitely be miserable if she does not have a child......' In the eyes of traditional women like my mother, the major prerequisite for a woman to have value is that she must have children, otherwise she will not be happy in any way.* [Poster and Time: SAN, October 4, 2020, 19:39:56]

The Deification of the Mother Figure

The image of motherhood is often perceived by society as great, loving, and sacrificial. Becoming a mother is also a process of self-growth for many women. Self-growth is one of the most frequently cited childbirth benefits under the topic, and it includes the maturation of character, usually embodied in the shift from self-centeredness to child-centeredness. However, this shift can sometimes be overdone and give rise to a lack of self.

> *Childbearing means that henceforth she will literally become a so-called attachment to the family in the eyes of the world; it means that henceforth she is better off realizing her value as a virtuous wife and mother than as an independent human being in the eyes of the world.* [Poster and Time: HEL, November 21, 2020, 23:23:08]

> *In a life of constant reinforcement, people take the phenomenon that a mother gives 100% of her love and care her children for granted. However, the truth is that the independence of the woman herself has been overlooked. Imagine you are going to visit a friend who recently gave birth to a baby, will you prepare a gift for the baby?* [Poster and Time: DHAXX, November 22, 2020, 10:39:39]

It is not difficult to see that this neglect of the mother's subjectivity is socially structured, with all the attention from the mother herself to family relatives and even society revolving around the child. The lack of maternal subjectivity is based on the cultural notion that it is obligatory and common for mothers to sacrifice for their children. When a family accommodates a child, the child becomes the most important being in the family. When a woman becomes a mother, society expects her to become a great mother. Being shackled by such an expectation, the woman's sacrifices become deserved and her feelings become secondary.

> *A woman who is married and has children is taken away from the immunity of making mistakes and is by default an indestructible file. She is supposed to understand everything and bear all the hardships. Those who have experienced it know that it is anguished, but she is not allowed to cry out in pain.* [Poster and Time: LHQ, February 21, 2021, 20:17:02]

The deification of the mother figure is also reflected in society's belief that women should do their best in all aspects of the childbirth process for the good of their children and that it is common to sacrifice a mother's time, energy, and even health to do so.

> *I think society has a very strong tendency towards perfectionism in the mother-infant relationship. Anytime you see contents like mom's hands make the best supplements (what about dad's or grandparents' hands?) Even if it's just bottle-feeding, it's believed that mom ought to do it herself (does it truly have that much of a negative impact if someone else does it?) As a woman, I think we need to realize that these requirements may not actually be very scientific. Most people grew up with a handful of 100 in examinations, so how is possible that when you get to raise a child you suddenly become perfect at everything?* [Poster and Time: AHJM, August 15, 2021, 19:32:23]

The high expectations of society for mothers may be internalized and transformed into high standards for themselves. Admittedly, it has a positive impact from this aspect, as mothers would actively seek to grow if they want to take better care of their children or use themselves as role models.

> *I myself do not truly like little kids, but after becoming a mother, I always want to set an example so that my baby feels that his mother is also an awesome person.* [Poster and Time: DAR, June 23, 2020, 22:17:02]

> *After you lost your temper and lashed out at your child, you are likely to think you are not a competent mom after calming down, and cringe at not being able to control yourself. Then, you will naturally want to be better in order to be a role model for your child. As a mother of a three-and-a-half-year-old kid, childbirth for me was something I needed to become stronger, better, and more mature.* [Poster and Time: Sayly, August 1, 2020, 14:17:49]

While such high standards can promote women's self-growth to some extent, these standards may bring about negative emotions, such as anxiety, if they are too high to meet. For example, some posters indicated that they would feel guilty for not loving their children enough or for not prioritizing them above all else.

> *I was recently reading The House on the Slope, and I clearly remembered that the main character, Risako, faced the challenge of not having enough breast milk after becoming a new mother. The idea of exclusive breastfeeding instilled in her by people around her made her feel less confident, doubt, and deny herself. There was even one time she became tired of parenting and only wanted to escape. Is it true that if you cannot breastfeed exclusively, you are not a good mother and therefore not worthy of being a human being?* [Poster and Time: XRK, September 29, 2021, 12:28:33]

> *I don't want to be a mother anymore. It's too hard. I always unintentionally hurt my child, such as underdressing her, overcovering her, holding her*

> *incorrectly, accidentally bumping her, and not being able to give her a comfortable living environment. She cries, and in many cases, I don't even know why.* [Poster and Time: TJDSXJ, December 8, 2020, 21:03:02]

The unreasonably high standards dissuade women who are not married or pregnant. Many of the users posting are not afraid of bearing children but are apprehensive about not being able to be a "perfect" mother and not being able to take responsibility for their children's upbringing and education.

> *I don't have confidence that I can provide a good enough life for him, that I have enough patience to educate him, and that I can give up something for him without regret.* [Poster and Time: YKDGJ, May 5, 2021, 23:56:59]

Discussion

Principal Findings

Based on the representative topic of childbirth, this study analyzed the ecology of online public opinion on childbirth using a mixed method of content and thematic analyses. It has been found that women's attitudes toward childbirth were generally neutral (1060/2634, 40.24%) or negative (1051/2634, 39.90%), with only a few showing a positive stance (523/2634, 19.86%). Messages with negative attitudes received more follows and likes. This finding is consistent with existing Chinese literature analyzing childbirth willingness from online texts [25,26]. Previous studies showed that there are often more negative posts on fertility-related topics on Weibo [14], TikTok [27], WeChat [28], and other social media platforms in China. By analyzing the trend of women's attitudes toward childbirth, we found that the proportion of posts expressing a negative attitude fluctuates and rises over time. According to previous reports [26,29,30] and the analysis of this study, we believe that both environmental factors and personal subjective factors interact to affect women's attitudes toward childbirth. On the one hand, environmental factors, including rising housing and living costs, intense competition in child education, and the job market, as well as increased work pressure, lead young people to choose to have fewer children. On the other hand, from the perspective of subjective factors, the need for self-realization has motivated women to pursue higher education and success in their careers, leading to a delay in the age of marriage and childbirth, and a choice to have fewer children [31].

Childbirth costs and benefits are common concerns for women. In this study, health risk, restricted freedom, and energy input were the most frequently mentioned aspects in the broad topic of childbirth costs. This finding differs from Gao [25], who used textual analysis on childbirth-related content crawled from other social media. In our study, health risks were discussed more frequently and received more attention, whereas Gao [25] found that economic impacts such as financial investment were more important. The difference may be attributed to the fact that different social media have different audiences and public opinion climates. Compared with other social media such as Weibo and WeChat, Douban's users have a higher proportion of female users. Currently, Chinese families generally have more financial responsibilities borne by men, while most of the users posting under the topic of childbirth are women. Therefore, the collected posts were mostly generated from women's perspectives, which naturally include health risks, restricted freedom, and energy input. Turning our attention to childbirth benefits, we found that posters focused on spiritual needs and subjective feelings, such as parenting experience, self-growth, and the continuation of life. However, only 10/2634 posts (0.38%) mentioned the objective benefits of bringing up children for the purpose of being looked after in old age. It shows that the childbirth concept of urban women has gradually changed from the traditional ones of "passing on the family line" and "bringing up children for the purpose of being looked after in old age" to the modern ones of "emotional experience," "spiritual needs," and "the pledge of love." This finding is consistent with the findings of previous studies investigating childbirth motivation and childbirth willingness [4].

Concept of Childbirth

Childbirth was described as a painful process in social media. Some women have pregnancy complications. Physical pain during childbirth is a major source of fertility fear for young women [32]. Some social media users vividly describe their childbirth experience in detail. It makes viewers feel like they went through the same situation personally. Negative events could be widely spread on the internet and attract public attention [33]. This negativity can affect social media users through emotional contagion [34]. In line with previous findings on the relationship between social media and risk perceptions [28], this paper concludes that social media indeed increase women's childbirth risk perceptions. Taking a step further, this paper also provides specific examples for the expansion of women's risk perception.

This study also finds that many women lack comprehensive and scientific knowledge about the health risks of pregnancy and delivery. Without systematic and scientific health knowledge, many women are not only unable to properly cope with potential health risks but also have a misleading perception or wrong expectations of childbirth risks, thereby increasing their anxiety about childbirth due to the information received through informal channels. At present, the internet has become an essential means for women to gather knowledge about childbirth health [35,36]. However, most of them did not discuss the information they retrieved from the internet with their health care professionals [37,38]. Social media such as Twitter, Reddit, and Facebook provide forums for private citizens to freely express their views, including those about medicine and health care. Yet, the content disseminated through websites and online communities is largely unregulated [39]. This situation highlights that the internet, as an informal communication channel, may unfavorably bias women's fertility perceptions. Currently, network information has become a crucial means for people to acquire knowledge about childbirth, with some blogs focused on the popularization of childbirth knowledge and sharing childbirth experiences gaining widespread attention on the internet. Under this topic, among the top 20 posts, 3 (15%) are about personal health changes and sharing information about breast milk. This reflects the prevalence of personal blogs discussing childbirth health knowledge and also underscores the demand for this type of information among the audience.

The discussions on the topic of childbirth illustrate that modern women are influenced by both traditional and modern fertility concepts. On the one hand, women seeking independence and equality are easily swayed by internet trends, believing that childbirth contributes to gender inequality and impedes personal self-fulfillment, leading to resistance to marriage and childbirth. On the other hand, they face significant pressure from traditional family values, as mentioned earlier. The collected posts reflect that the value of childbirth to women has become ambiguous and contradictory as the approaches to women's self-worth have broadened. Zhang et al [27] also pointed out the ambivalent mindset of the new generation of women regarding childbirth and self-evaluation. This shift in gender concepts often has a negative impact on fertility [40].

In addition, the shift in women's family identity brought about by childbirth leads many of them to feel a lack of subjectivity. The image of motherhood is often perceived by society as great, loving, and sacrificial. Most women believe that motherhood is a rite of passage for women, characterized by the transition from a selfish child to a selfless adult [41]. The maternal norms constructed by society embody characteristics of self-sacrifice. All mothers are expected to adhere to the moral standards of being a "good" mother. These norms make some mothers feel uncomfortable and distressed [42,43]. This kind of sacrifice has also faced criticism from some feminists because sacrifices made for children and partners might perpetuate oppressive gender norms, burdening women and further relinquishing their freedom [44,45].

This article reveals that the elevated social expectations imposed on mothers can be internalized, leading to the establishment of high standards for themselves. While this motivation drives them to pursue self-growth, it simultaneously triggers anxiety about parenting. These heightened social expectations have the potential to not only induce anxiety in mothers who have experienced childbirth but also instill fear among those who have not given birth.

Strengths and Limitations

To our knowledge, only a limited number of previous studies have explored the influence of social media on women's perceptions of childbirth. Among them, even fewer have delved into the analysis of user-generated text on social media platforms. Instead, some studies opted to assess the sentiments of their study participants through questionnaires and interviews. In this study, we conducted a thorough analysis of the posts and discussions shared by users on Douban, a social media platform known for attracting a large population of highly educated young individuals. This user base contributes to the clarity, completeness, and rationality of the points expressed in the discussions. The chosen research method enables us to gain new insights, particularly highlighting how the deification of the mother figure may result in elevated public expectations, pressuring women to sacrifice themselves to attain the ideal of a perfect mother. Women may be hesitant to become mothers as they fear losing their sense of self. Another noteworthy insight is that longstanding social and cultural biases in China may have hindered open discussions on the childbirth process and its health implications, consequently contributing to a lack of comprehensive childbirth knowledge among young women.

The findings of this study should be considered in light of certain limitations. The majority of Douban users reside in urban areas, limiting the generalizability of the results to rural women who may have different perspectives on childbirth. Future research on the attitudes and concepts of childbirth among rural women is warranted. However, previous studies have indicated that the internet's development also influences the gender role concepts of rural residents, transitioning from traditional to modern, with women being significantly more affected than men [9]. The suggestion is made that the influence of cultural concepts via the internet is present in both urban and rural areas, and analyzing urban women's concepts is valuable for understanding those of rural women. Additionally, the gender of all users in this study could not be determined. However, based on the content of the topic and the detailed study of part of the selected sample, it is considered that the majority of the sample consisted of females. While it cannot be ruled out that a few users might be male, it is considered that this would not significantly alter the analysis results and findings.

Conclusion and Suggestions

This study discovered that users generally held neutral or negative attitudes toward childbirth, with fewer expressing a positive stance. Additionally, posts with a negative attitude garnered more attention and likes. Moreover, there was an observed increase in posts with negative attitudes in recent years compared with earlier years. A significant number of young women lack comprehensive and scientific knowledge about the health risks associated with pregnancy and delivery. They tend to rely on the internet to gather relevant information. However, the internet, functioning as an informal communication channel, may inadvertently skew women's perceptions of fertility. As women's socioeconomic status has elevated, there is a redefinition of the value attached to childbirth. In Chinese society, women often encounter greater restrictions on their freedom and are required to invest more energy in childcare compared with men, leading them to hesitate or even resist childbirth [46,47]. Moreover, the structural neglect of mothers' needs and desires in Chinese society creates a perception among women that they might lose themselves due to childbirth and child-rearing, contributing to their hesitation or resistance to giving birth.

The study findings highlight the importance of monitoring public expressions on the internet, offering guidance to women seeking information on pregnancy and delivery, and assisting them in developing a scientific understanding of childbirth. Furthermore, enhancing the public childcare system, safeguarding women's rights, and creating a supportive societal environment for mothers could potentially contribute to an increase in women's fertility desires.

Abstract

Background: Social media has become extremely popular among parents to seek parenting information. Despite the increasing academic attention to the topic, studies are scattered across various disciplines. Therefore, this study broadens the scope of the existing reviews by transcending narrow academic subdomains and including all relevant research insights related to parents' information seeking on social media and its consequent effects.

Objective: The aims of this systematic literature review were to (1) identify influential journals and scholars in the field; (2) examine the thematic evolution of research on parenting and social media; and (3) pinpoint research gaps, providing recommendations for future exploration.

Methods: On the basis of a criteria for identifying scholarly publications, we selected 338 studies for this systematic literature review. We adopted a bibliometric analysis combined with a content thematic analysis to obtain data-driven insights with a profound understanding of the predominant themes in the realm of parenting and social media.

Results: The analysis revealed a significant increase in research on parenting and social media since 2015, especially in the medical domain. The studies in our review spanned 232 different research fields, and the most prolific journal was *JMIR Pediatrics and Parenting*. The thematic analysis identified 4 emerging research themes in the studies: parenting motivations to seek information, nature of parenting content on social media, impact of parenting content, and interventions for parents on social media.

Conclusions: This study provides critical insights into the current research landscape of parenting and social media. The identified themes, research gaps, and future research recommendations provide a foundation for future studies, guiding researchers toward valuable areas for exploration.

Introduction

Background

The experience of transitioning into parenthood often elicits a feeling of being overwhelmed [1], through which parents may encounter an intricate transformation of their identity [2]. Achieving a balance among their parental obligations, roles as partners, and individual identities presents a difficult challenge [3]. In addition, they are confronted with social pressures and societal norms surrounding parenthood [3]. In today's digital era, social media plays an important role in how parents manage everyday issues and decisions [4,5]. This comes as no surprise given the massive popularity of social media, with 4.89 billion users worldwide in 2023 [6]. The largest group of users is aged

25 to 34 years [7], which corresponds to the age group of many young parents [8]. Research has demonstrated that parents actively seek online social support and parenting information [5,9,10]. Previous generations have often relied on family and close friends for parenting information, whereas today's parents depend heavily on social media, where they share information and experiences with like-minded others [10]. Obtaining this informational and emotional support empowers parents to feel prepared and confident in their new roles, easing their transition into parenthood [11].

The impact of social media on parents has been studied across various fields, such as health sciences, communication, and pedagogic research [12,13]. For example, within the field of persuasive communication, *momfluencers* (a portmanteau of the words "mom" and "influencer") have been demonstrated to generate feelings of support and understanding among parents but can also cause stress, lower parental efficacy, and anxiety [8,14,15]. Within the health information domain, Chan and Chen [16] found that social media represents an effective source for improving maternal health, mental health, and pregnancy knowledge. Hence, various individual studies from different research domains have made significant contributions by examining parents' information seeking on social media and its consequent impact on their lives and decision-making [13,17,18].

While considerable research exists at the intersection of parenthood and social media, comprehensive review papers that summarize collective insights in this domain are extremely limited. Within the overall field, we identified 6 review papers that addressed subtopics related to that of this study. In total, 2 papers evaluated specific social media interventions for parents [16,19], 2 focused on health information for parents [10,20], and 2 addressed subdomains such as a target group (eg, military families [21]) or a specific variable (eg, family connectedness [22]). Moreover, it is crucial to highlight that a significant proportion of studies that have explored the impact of social media on contemporary parenting are predominantly situated within the realm of medical research [10,19]. However, despite the notable interest of media and communication scholars in this subject [15,22], their research remains fragmented. Consequently, a comprehensive systematic review of parenting information disseminated through social media from a media and communication perspective can significantly enhance our understanding of this field.

To address this gap, this study broadens the scope of existing reviews by transcending narrow academic subdomains and including all relevant research insights related to parents' information seeking on social media and its effects. Using both bibliometric and content thematic analyses, our approach combined objectivity and data-driven insights with an understanding of key themes in the realm of parenting and social media [23,24]. This allowed us to provide an overview of the research, detect patterns, delineate topics, and identify knowledge gaps [24]. The main objectives of this study were to (1) identify the journals and scholars who are actively involved in, contribute significantly to, and exert the most influence in the field; (2) examine the themes explored in existing research on parenting and social media and how they have evolved over time; and (3) highlight current research gaps and provide recommendations for further exploration in this domain.

Literature Review

Several review papers in the field of parental information seeking on social media are pertinent to our study. Among them, 6 were found to align with our focus on social media, whereas 1 fell outside due to its focus on the internet in general. Nevertheless, the findings of the aforementioned systematic literature review were deemed relevant and, therefore, are briefly discussed as follows. Plantin and Daneback [25] consolidated research on how parents use the internet to access child-, health-, and family-related support and information, as well as how professionals use it to offer support and information to parents. They concluded that parents' tendency to seek online information is explained by the desire to seek support and information. They argued that this is mostly driven by the anonymous nature of online information seeking and its round-the-clock accessibility. For professionals, key benefits include cost-efficiency and reaching a large audience. However, the study was published 14 years ago, and the studies in the authors' sample were mostly conducted during the Web 1.0 era, when the internet predominantly consisted of static, informational websites. Since then, parents' online experiences have significantly evolved with increased interactivity and the widespread use of social media. Therefore, we considered it important to reassess and synthesize the research on how parents engage with the wealth of real-time information on social media, which often includes personalized, user-generated advice, creating collaborative, global communities of parents.

The aforementioned 6 review studies that focused on social media had specific thematic focuses on interventions [19]; particular subdomains of parenting information, such as health information [10]; specific target groups, such as military families [21]; or demarcated variables, such as family connectedness [22]. The following paragraphs discuss these 6 reviews on social media and parenting.

Of the reviews, 2 evaluated the effectiveness of social media interventions for parents. First, Hamm et al [19] conducted a systematic review in 2014 analyzing 25 studies on the use and effectiveness of social media in child health interventions. Their review provided insights into how social media is used in interventions promoting child health, such as encouraging healthy eating and exercise among children and adolescents [19]. The authors highlighted that social media interventions that aim to improve children's health predominantly focus on adolescents rather than on children and parents [19]. In addition, they evaluated the effectiveness of these interventions and the factors driving their success [19]. Despite reported benefits from interventions using discussion forums, no studies using such forums achieved significant health outcomes [19]. Second, Chan and Chen [16] conducted a meta-analysis of 16 papers on the effectiveness of social media and mobile apps in pregnancy care. In contrast to the study by Hamm et al [19], their review found that interventions using mobile apps and social media in the context of pregnancy care were effective, with moderate to large effect sizes in maternal health, mental health, and pregnancy knowledge [16].

Furthermore, 2 studies focused on specific target groups or variables [21,22]. Wood et al [21] conducted a scoping review of social media and internet-based communication use by military families. Their research included 11 papers, identified the most popular social media platforms, and highlighted the challenges and advantages of social media use during military deployment [21]. In another systematic review, Tariq et al [22] examined 14 quantitative studies exploring the link between social media use and family connectedness. They discussed how families are connected through social media and its impact on parent-child relationships and broader family connectedness [22].

Finally, 2 review papers examined parents' use of social media for health information [10,20]. First, Pretorius et al [20] conducted an integrative review of 12 studies on parents' motivations and use of social media to obtain information about their children's health, with attention to race, ethnicity, and region. Second, Frey et al [10] conducted a similar scoping review (N=42) on parents' motivations, understanding, and evaluation of health information on social media and its consequent impact. Both studies found that parents obtained valuable online health information and received support from like-minded others [10,20]. An important difference is that Pretorius et al [20] focused on differences in motivations and platform preferences by race and region, whereas Frey et al [10] focused more on parents' perceptions and sentiments toward health information on social media.

This systematic review built on but diverged from the previous reviews by adopting a multidisciplinary perspective, integrating various dimensions, and providing a comprehensive and holistic understanding of insights on social media and parenting. It offers a comprehensive overview of parents' motivations to seek information and the parenting information available on social media and its impacts.

Methods

Literature Search and Selection

To collect relevant papers for this systematic literature review, we adhered to the criteria by Kraus et al [23] for identifying scholarly publications. First, we determined relevant keywords and the search formula. All words related to parenting, such as "parent," "mother," "father," "maternal," "mom," "dad," "paternal," "pregnancy," "conception," "postnatal," "prenatal," "family," "kid," and "child," were identified, as well as words related to social media, such as "social media," "influencer," "Instagram," "YouTube," "vlog," "Facebook," "Twitter," and "TikTok." We combined these terms using Boolean operators (eg, AND and OR) to form the final search formula: *TITLE, ABSTRACT, KEY ([Parent* OR mother* OR father* OR maternal OR m?m* OR dad* OR paternal OR pregnancy OR conception OR postnatal OR prenatal OR family OR kid* OR child*] AND [*fluencer* OR Instagram OR youtube OR? log* OR facebook OR "social media" OR twitter OR TikTok]).*

Second, a literature search was conducted using the search formula on the Scopus database. Scopus was chosen for 2 main reasons. First, Scopus is the largest multidisciplinary database for science, technology, medicine, social science, and arts and humanities, which is useful for mapping a smaller and more multidisciplinary research field, such as parenting and social media research [26,27]. Second, the Scopus database provides various document data formats, allowing bibliometric software to process them conveniently. All relevant studies published before June 2023 were identified, resulting in 2600 articles in the initial search. The results were saved in RIS format, and information such as title, abstract, authors, keywords, and references was exported. Moreover, we refined the selected articles. The articles collected in the initial search included various document types written in a variety of languages. To guarantee the quality of the papers included in the data analysis, we only focused on full-length and peer-reviewed articles; therefore, other document types, such as conference proceedings and books, were excluded [23]. Furthermore, considering that English is the most common language of research, we only included papers written in English [23]. After this screening, of the 2600 articles, a total of 1540 (59.23%) remained.

Subsequently, we carefully reviewed the remaining papers' titles, abstracts, and main texts based on the inclusion and exclusion criteria. The inclusion criterion was papers on how parents search for and consume parenting information on social media. All research methodologies, whether empirical studies or reviews, were considered eligible for inclusion in this comprehensive review. Conversely, papers discussing parental mediation and influencers' motivations to share parenting content were excluded as they fell outside the scope of this review. This procedure left us with a total sample of 338 articles. To guarantee completeness, a snowball literature search was conducted by reviewing the references in each included study, but no new relevant studies emerged.

Data Analysis

To map the development of parenting and social media research, we conducted a bibliometric and thematic content analysis.

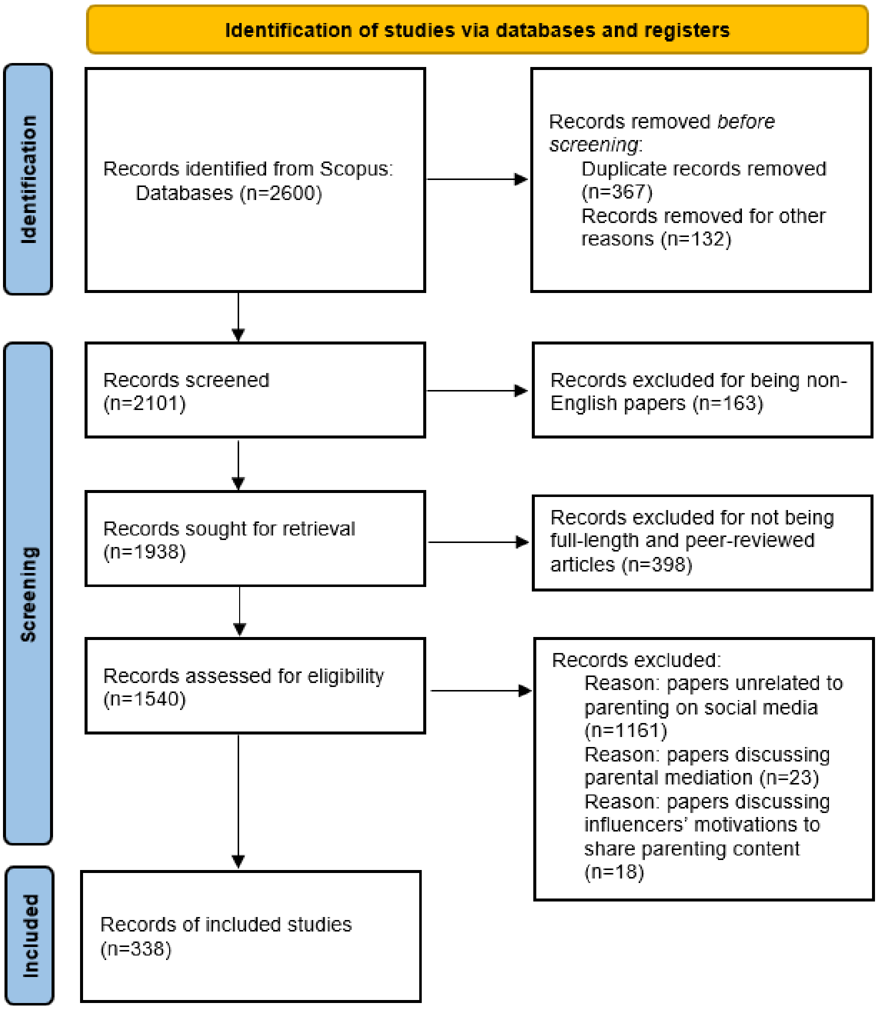
In the bibliometric analysis, we provided a descriptive overview of the research. On the basis of the authors, journal, reference, and publication time, we depicted the evolution of published studies throughout the years, identified the most prolific journals and authors, and detected the most influential articles and authors. BibExcel was used to extract relevant information and perform data analysis.

In the thematic content analysis, we further explored research developments and trends. A keyword analysis examined titles, keywords, and abstracts to identify frequently used words or phrases. A co-occurrence analysis using VOSviewer visually represented the relationships between keywords, creating a co-occurrence network. These analyses enabled us to pinpoint key research topics related to parenting and social media. On the basis of the identified research topics, we conducted a further in-depth investigation of the studies' contents to categorize them in relation to the research topics. Each study underwent a comprehensive qualitative analysis, which involved screening based on the scientific domain, primary focus, dependent and independent variables, methodology used, target audience, and social media platform used.

Results

Figure 1 presents a detailed overview of the literature search and refinement process.

Figure 1. Literature search and refinement criteria for the bibliometric analysis.



Bibliometric Analysis

Development of Parenting and Social Media Research

From the graph in Table 1, one can infer that parenting and social media is a relatively emerging research area. The first relevant study was published in 2009. From 2009 to 2014, only 4.4% (15/338) of the papers were published. Conversely, between 2015 and 2022, there was a remarkable surge in the number of publications on parenting and social media. This period encompasses 85.5% (289/338) of the papers analyzed in this study. Moreover, 10.1% (34/338) of the papers were published over the first 5 months of 2023, which indicates that the current general trend of parenting and social media research is rapid growth.

Table 1. Number of publications on parenting and social media over the years (n=338).

Year	Publications, n (%)
2009	1 (0.3)
2010	0 (0)
2011	3 (0.9)
2012	2 (0.6)
2013	3 (0.9)
2014	6 (1.8)
2015	10 (3)
2016	11 (3.2)
2017	19 (5.6)
2018	26 (7.7)
2019	33 (9.8)
2020	46 (13.6)
2021	68 (20.1)
2022	76 (22.4)
2023	34 (10.1)

Most Prolific Journals and Authors

The articles that we examined were published in 232 different journals, which underscores the broad scholarly attention to the topic of parenting and social media. Of the 232 journals, 13 (5.6%) contributed ≥4 articles, accounting for 20.7% (70/338) of all articles (Table 2). The journal with the most publications related to the topic of parenting and social media was *JMIR Pediatrics and Parenting*, which published 11 articles, followed by *the Journal of Medical Internet Research*, *New Media & Society*, *Feminist Media Studies*, *JMIR Research Protocols*, *Human Vaccines & Immunotherapeutics*, and the *International Journal of Environmental Research and Public Health*. Upon closer examination of the scholarly domains represented by the journals that have disseminated research on parenting and social media, it became apparent that they encompassed a wide spectrum of academic disciplines as classified by Scopus. These disciplines comprised communication, education, medicine, health science, social science, immunology, and allergy. This emphasized the multifaceted research interest in this subject matter.

Table 2. Journals that contributed ≥4 articles on parenting and social media research (N=70).

Journal name	Subject matter	Articles n (%)
JMIR Pediatrics and Parenting	Technologies, medical devices, apps, engineering, informatics applications for patient and parent education in pediatrics, training and counseling and behavioral interventions, and preventative interventions and clinical care for children and adolescent populations or child-parent dyads [28]	11 (16)
Journal of Medical Internet Research	Digital health, data science, health informatics and emerging technologies for health, medicine, and biomedical research [29]	9 (13)
New Media & Society	Communication; sociology and political science [30]	6 (9)
International Journal of Environmental Research and Public Health	Global health, health care sciences, behavioral and mental health, infectious diseases, chronic diseases and disease prevention, exercise and health-related quality of life, environmental health, and environmental sciences	5 (7)
Human Vaccines & Immunotherapeutics	Vaccinology and immunotherapy [31]	5 (7)
Feminist Media Studies	Feminist approaches to the field of media and communication studies, with attention to historical, philosophical, cultural, social, political, and economic dimensions and analysis [32]	5 (7)
JMIR Research Protocols	Medical and health-related research and technology innovations [33]	5 (7)
PLOS ONE	General biochemistry, genetics, and molecular biology [34]	4 (6)
BMC Public Health	Focus on the social determinants of health; the environmental, behavioral, and occupational correlates of health and disease; and the impact of health policies, practices, and interventions on the community [35]	4 (6)
BMC Pediatrics	Health care in neonates, children, and adolescents, as well as related molecular genetics, pathophysiology, and epidemiology [36]	4 (6)
Family Relations	Central focus on families within a wide range of topics of interest to both scholars and practitioners, such as child and parent relationships, cross-cultural and international issues that impact families, family health, family interventions, family life education, and much more [37]	4 (6)
Health Communication	Provider-patient (or family) interaction, health campaigns, health information, health promotion, interviewing, health public relations, and gerontological concerns [38]	4 (6)
Journal of Child and Family Studies	Behavioral health and well-being of children, adolescents, and their families [39]	4 (6)

Moreover, a total of 1447 different authors made contributions to the development of parenting and social media research. Of the 1447 authors, 1342 (92.74%) published only 1 study on parenting and social media, whereas the remaining 105 (7.26%) published at least 2 papers included in our sample. Scheibling (5 articles) published the most parenting and social media studies in the sample, followed by Cino, Moreno, and Evans, each with 4 publications (Table 3). All other authors in Table 3 published 3 of the studies each. These results indicate that there is no dominant author on the topic of parenting and social media. However, examining the academic collaborations among these authors revealed that many of them share strong academic relationships. For example, Klein and Gonzalez-Hernandez coauthored 4 studies. Buller, Walkosz, Berteletti, Pagoto, Bibeau, Baker, Hillhouse, and Henry worked together on all their published studies. Regarding authors' affiliations, we found that authors currently affiliated with the University of Toronto, Università Cattolica del Sacro Cuore, University of Wisconsin–Madison, University of Pennsylvania, and Cedars-Sinai Medical Center contributed the most to parenting and social media research.

Table 3. Authors who contributed ≥3 articles on parenting and social media research. This table only considers papers published before June 2023.

Author	Current affiliation	Publications, n (%)
C Scheibling	University of Toronto, Canada	5 (0.01)
D Cino	Università Cattolica del Sacro Cuore, Italy	4 (0.01)
MA Moreno[a]	University of Wisconsin–Madison, United States	4 (0.01)
YN Evans[a]	University of Washington, United States	4 (0.01)
MA Bryan[a]	University of Washington, United States	3 (0.01)
AZ Klein[b]	University of Pennsylvania, United States	3 (0.01)
G Gonzalez-Hernandez[b]	Cedars-Sinai Medical Center, United States	3 (0.01)
DB Buller[c]	Klein Buendel, United States	3 (0.01)
J Berteletti[c]	Klein Buendel, United States	3 (0.01)
BJ Walkosz[c]	Klein Buendel, United States	3 (0.01)
SL Pagoto[c]	University of Connecticut, United States	3 (0.01)
J Bibeau[c]	University of Connecticut, United States	3 (0.01)
K Baker[c]	East Tennessee State University, United States	3 (0.01)
J Hillhouse[c]	East Tennessee State University, United States	3 (0.01)

Most Influential Authors and Publications

Next, we conducted a local and global citation analysis to identify the most influential authors (Table 4) and publications (Table 5) in our sample. The local citation times refer to the number of citations within the sample, whereas the global citation times refer to the number of citations in the Scopus database. Hence, the discrepancy between the global and local citation index refers to the impact that a paper or author has in domains other than parenting and social media research. In addition, the authors' local *h*-index was explored, which refers to an author's number of parenting and social media papers (*h*) that have each been cited at least *h* times by other parenting and social media studies. This index provides an insight into both the quantity (in terms of the number of studies in the domain) and quality (in terms of the impact on other scholars) of an author's parenting and social media publications. To measure the impact (in terms of shares, discussions, and likes) of parenting and social media research concerning society, we used the Altmetrics score. This score provides an insight into the number of mentions in online media, such as Facebook, Mendeley, Twitter (subsequently rebranded X), and Wikipedia.

Table 4. The 20 most cited authors in the parenting and social media area. This table only considers papers published before June 2023.

Author	Local citation times, n	Global citation times, n	Local *h*-index	Altmetrics score
AG Fiks[a]	27	84	3	34
RS Gruver[a]	27	84	3	34
S Virudachalam[a]	27	84	3	34
M Gerdes[a]	23	74	2	18
GK Kalra[a]	23	74	2	18
A Lieberman[a]	23	74	2	18
RI Berkowitz[a]	23	74	2	18
TJ Power[a]	23	74	2	18
J Shults[a]	23	74	2	18
AW Suh[a]	23	74	2	18
CT Bishop-Gilyard[a]	23	74	2	18
LK Lopez	20	139	1	10
JM Sullivan[b]	19	155	1	403

[b] These authors have close academic cooperation.

[c] These authors have close academic cooperation.

Table 5. The 10 most cited papers regarding parenting and social media. This table only considers papers published before June 2023.

Publication	Local citation times, mean	Local citation times, n	Global citation times, n	Altmetrics score	Research topic
Jorge et al [40]	7	7	13	6	Examining the self-presentations of mummy and family influencers on social media
Moon et al [5]	3	12	47	34	Parental perceptions of the advantages and disadvantages of the internet and social media as sources of parenting and health information regarding their infant
Baker and Yang [41]	2.8	14	70	7	Investigating the critical role of social media in providing social support for mothers' lives
Archer and Kao [42]	2.4	12	33	9	Discussing both the negative and positive aspects of social media use for new mothers
Orton-Johnson [43]	2.17	13	48	16	Discussing both the liberating and constraining roles of motherhood in the digital terrain
Haslam et al [44]	2	12	48	74	The status of parents' use of social media and the potential factors that motivate its use for parenting support
Fiks et al [45]	2	12	36	9	The effectiveness of a Facebook peer-group intervention for low-income mothers to foster behaviors that promote healthy infant growth
Pretorius et al [20]	2	8	16	1	The impacts of social media use on parenting
Ouvrein [46]	2	2	11	31	The impact of exposure to mommy influencer content on parental self-efficacy
Bartholomew et al [47]	1.73	19	155	403	The relationship between new parents' Facebook use and parenting satisfaction, parenting self-efficacy, and parenting stress

Fiks, Gruver, and Virudachalam obtained the highest number of citations within our sample, indicating that they are the most influential scholars in the parenting and social media domain (Table 4). Among the prolific authors identified in Table 4, they also had the highest local *h*-index, which denotes their substantial body of high-caliber publications. Noteworthily, we found that most of the prolific authors (eg, Scheibling, Cino, Moreno, Klein, and Gonzalez-Hernandez) were not yet highly cited authors. A likely explanation for this finding is that they have only become devoted to this research topic in recent years, and thus, their publications have had less time to accumulate citations. For instance, Scheibling, the most prolific author among them, published all of his studies in the past 3 years. Furthermore, the high deviation between local and global citations of Sullivan, Bartholomew, Schoppe-Sullivan, Kamp Dush, and Glassman indicates that their publications have been frequently cited not only within the area of parenting and social media but also by papers in other disciplines. In addition, their work garnered a high Altmetrics score, which indicates that their publications are frequently discussed and shared on the web.

Given that the citation frequency is closely related to the study's publication time, we compiled a list of the 10 most cited studies based on their average local citation count (Table 5). Among them, the most influential publication in our sample was by Jorge et al [40]. Their work revealed how mummy influencers reconcile motherhood and their career by examining the ways in which they portray parenting and family, work-life balance, and the boundaries for privacy and intimacy. In addition, the studies by Moon et al [5], Baker and Yang [41], Archer and Kao [42], Orton-Johnson [43], Haslam et al [44], and Pretorius et al [20] are also recognized as highly influential papers due to their substantial number of local and global citations. These papers cover a wide spectrum of topics, ranging from the impact of social media use on parental expectations and attitudes [46], the motivations to seek out parenting information on social media [44], and the effectiveness of social media peer-group interventions for promoting healthy infant growth [45]. Noteworthily, the study by Bartholomew et al [47] had the highest Altmetrics score, which indicates that it has received great attention on the web.

Thematic Analysis

Overview

An analysis of the title, keywords, and abstract fields revealed a total of 1599 title words that occurred 3620 times, a total of

894 keywords that occurred 1610 times, and a total of 5442 abstract words that occurred 42,620 times in our sample. All title words, keywords, and abstract words were then manually screened to group words with similar or identical meanings (eg, “blog” and “blogs”). On the basis of the results of the word segmentation, a keyword analysis and co-word analysis were conducted to identify the most prominent research themes in the area of parenting and social media.

Keyword Analysis

The keyword analysis aimed to assess the frequency of the words and phrases used within the titles, keywords, and abstracts of the research papers. A consistent pattern emerged in the use of specific words (Table 6). In particular, the terms “social,” “media,” and “social media” were found to be the most frequently used words or phrases. This prevalence was primarily attributed to their status as primary search keywords in our study. Similarly, terms referring to social media such as Facebook, YouTube, blogs, Instagram, Twitter, and the internet were also found to appear frequently.

Table 6. The 20 most frequently used words in paper titles, keywords, and abstracts[a].

Words or phrases	Frequency, n
Paper titles	
“Social”	186
“Media”	157
“Children”	61
“Facebook”	52
“Mothers”	45
“Parents”	43
“Information”	32
“Blogs”	31
“Pregnancy”	29
“Health”	27
“Support”	25
“Parenting”	23
“YouTube”	22
“Content”	21
“Instagram”	19
“Group”	18
“Family”	18
“Group”	18
“Parental”	18
“Covid-19”	16
Keywords	
“Social media”	167
“Pregnancy”	31
“Facebook”	27
“Parenting”	22
“Parents”	21
“Covid-19”	20
“Motherhood”	20
“Instagram”	18
“Internet”	18
“YouTube”	17
“Mothers”	16
“Blogs”	15
“Social support”	14
“Sharenting”	10
“Pediatrics”	9
“Twitter”	8
“Health information”	8
“Communication”	8
“Breastfeeding”	7
“Technology”	7

Words or phrases	Frequency, n
Abstract	
“Social”	928
“Media”	629
“Information”	388
“Parents”	330
“Health”	311
“Mothers”	282
“Posts”	239
“Facebook”	218
“Support”	215
“Children”	188
“Content”	183
“Online”	182
“Videos”	176
“Women”	171
“Group”	164
“Parenting”	149
“Pregnancy”	145
“Intervention”	113
“Family”	112
“Vaccine”	108

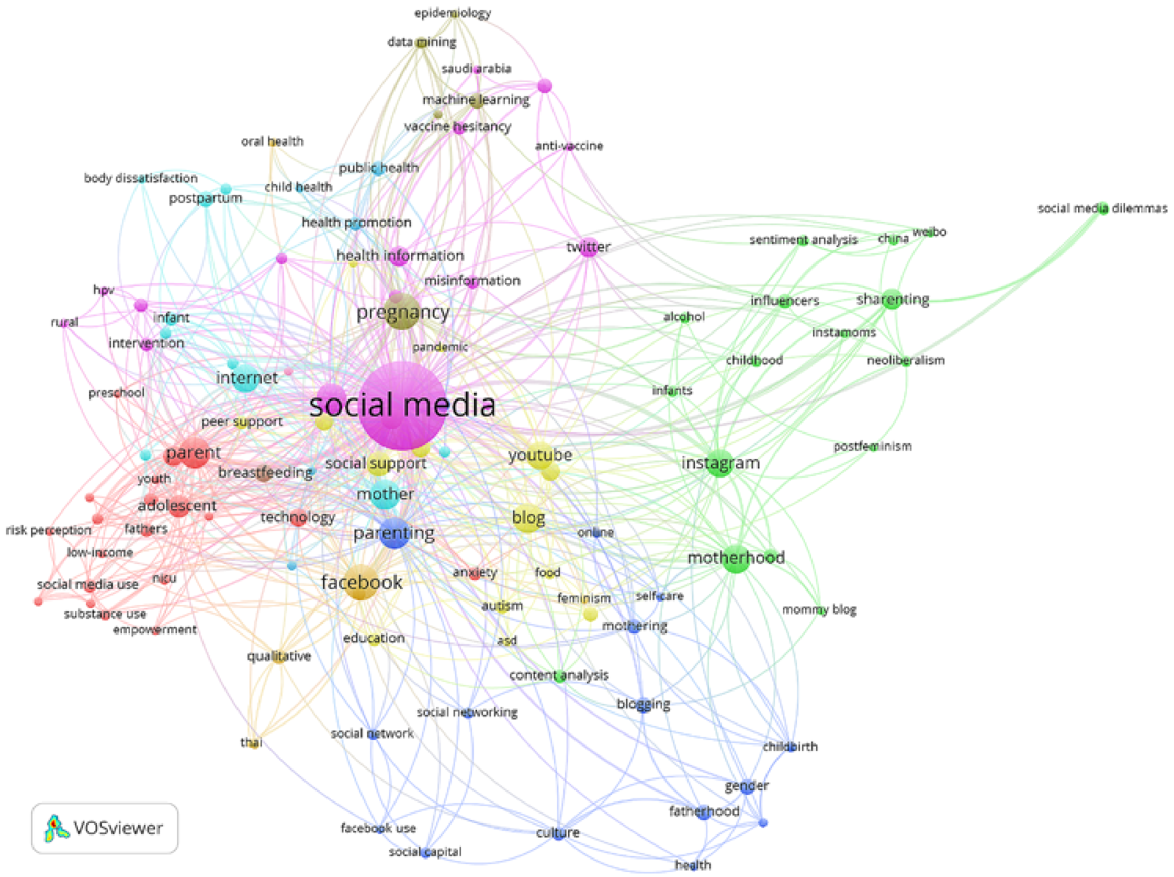
[a] Percentages corresponding to the frequencies of words in paper titles, keywords, and abstracts cannot be provided due to the unavailability of total word counts across the analyzed papers.

Furthermore, it was evident that words associated with familial relationships, including “mothers,” “parents,” “children,” “child,” and “family,” were frequently used, which aligns with their pivotal roles as stakeholders in the realm of parenting. In addition, terms such as “pregnancy,” “parenting,” “motherhood,” “pediatrics,” “Covid-19,” “vaccine,” and “breastfeeding” were found to appear frequently, which indicates that these topics are the core research concerns in the area of parenting and social media. Moreover, terms such as “support,” “health,” “information,” “health information,” and “social support” indicate the multifaceted purposes for which parents use social media. Finally, the prevalence of terms such as “group” and “intervention” within the abstracts highlights the substantial body of literature focused on interventions through social media.

The Co-Word Analysis

The co-word analysis aimed to map the co-occurrence of words that appear in different articles. A visualization of the keywords that often appear together was performed using VOSviewer, and it is depicted in Figure 2. Each node represents an independent keyword, and its size is proportional to the frequency with which the keyword appeared in the articles. The lines between the nodes indicate that the 2 connected keywords appear together in papers, and the thickness of the lines represents the frequency of their co-occurrence.

Figure 2. Visualization of the co-word analysis.



From Figure 2, one can infer that the nodes for “social media,” “Facebook,” “Instagram,” “YouTube,” “Internet,” “parent,” “parenting,” “mother,” “motherhood,” “pregnancy,” and “adolescent” are larger than those of other keywords, which indicates a strong focus on these topics. The analysis further revealed that all keywords could be grouped into 10 clusters (cf the 10 different node colors in Figure 2), which could be further grouped into 4 thematic research topics through a cluster labeling process.

The first research theme covered studies in clusters 3, 4, and 7. The keywords that reflect the theme were “health,” “health communication,” “health promotion,” “self-care,” “social support,” and “peer support.” Consequently, the first theme was inferred to involve research on parents’ motives to seek information on social media and the identification of variables that may predict the occurrence of this behavior. The second research theme covered studies in clusters 2, 8, 9, and 10, all of which were characterized by keywords closely tied to types of parent-related content on social media and text-mining methodologies—namely, “parenting forum,” “mommy blog,” “instamoms,” “feminism,” “neoliberalism,” “qualitative,” “data mining,” “machine learning,” “natural language processing,” and “sentiment analysis.” This research theme centered on the analysis of online parenting content, where the aim was to construct meaningful insights from such data. The third research theme covered studies in clusters 1 and 6, as indicated by keywords such as “mental health,” “postnatal depression,” “risk perception,” “depression,” “anxiety,” “body image,” and “body dissatisfaction.” These keywords suggest that researchers demonstrated interest in the impact of parenting information on social media. Finally, the fourth research theme covered studies in cluster 5, with keywords such as “intervention,” “obesity prevention,” “anti-vaccine,” “HPV,” and “vaccine hesitancy.” This research focused on parenting interventions with the use of social media.

Thematic Content Analysis

Overview

To obtain deeper insights into the research content of each of the 4 research themes identified through the co-occurrence analysis, we conducted a thematic content analysis. The first theme consolidated articles that pertained to the underlying motivations of parents to seek information on social media platforms, the second theme encompassed a significant number of articles that explored which parenting-related content can be found on social media, the third theme clustered all articles on the impact of parenting social media information on parents, and the fourth theme contained articles that evaluated interventions on social media. Given that some articles were related to topics across different research themes, we discuss those within the multiple clusters they belong. In the following subsections, we discuss the methodologies and specific social media platforms used in the selected studies. Subsequently, we provide more insights into the various research domains and emphasize the key findings within the extensively investigated research areas.

Theme 1: Parental Motivations to Seek Information on Social Media

A total of 14.8% (50/338) of the studies in our sample were found to examine parents' motivations to seek information on social media. While these studies used various methodologies, half (23/50, 46%) adopted a quantitative approach, primarily applying surveys to gather data. In contrast, the qualitative studies (22/50, 44%) mainly used focus groups, in-depth interviews, and qualitative content analyses to obtain insights into parents' motivations to use social media as platforms for seeking information. Only a small fraction of the studies (5/50, 10%) used mixed methods research approaches to explore the motivations of parents, mainly through combining surveys, content analysis, or interviews.

In terms of social media platforms, most of the studies within this scope (27/50, 54%) investigated parents' motivations for seeking information on social media in general rather than specifically focusing on 1 platform. These studies investigated the most popular social media platforms among parents and the motivations that drive them to seek information on social media [48]. Facebook emerged as the most popular platform for parents [48-50]. This is also in line with the keyword and co-occurrence analyses, where Facebook emerged as a big node. Unsurprisingly, studies that examined a specific platform primarily focused on Facebook (16/50, 32% [51,52]), whereas little attention was paid to exploring the motivations of parents on other social media platforms, such as blogs, Twitter, or forums (7/50, 14%).

Parents' motives to seek information on social media received the most attention in the domain of health information and medicine (34/50, 68%). These studies investigated parents' motivations for seeking information about general health issues (eg, physical activities), specific diseases (eg, cancer, cleft lip, and autism spectrum disorder), and health-related topics (eg, vaccinations). The 3 dominant motivations for parents to seek health information on social media were as follows: providing and obtaining support from peers, receiving advice and information about one's child's diagnosis to guide health decisions, and accessing a community with families who experience the same issues [5,10,50,52-56]. We observed a dominant focus on mothers in the other clusters, whereas the studies within cluster 1 predominantly focused on parents in general regardless of gender.

In addition, attention was paid to parents' information-seeking motivations within the domains of family science, pregnancy and childbirth, and child feeding (16/50, 32% [57-59]). Such studies did not solely focus on the broader category of parents as one homogeneous group (ie, encompassing both mothers and fathers) but also paid specific attention to mothers and pregnant women individually. Similarly, as in the health-related parenting studies, parents were found to seek informational and emotional support from peers and seek advice and information on various parenting topics, such as pregnancy, activities for their children, and motherhood [44,58,60-63]. However, community feeling was less prominently studied compared with studies in the health and medicine domain.

Across the multiple research subdomains, Moon et al [5] and Suminar et al [58] discovered that mothers attribute greater value to the information they obtain through social media compared with the information they acquire from their family and friends. One of the biggest advantages of social media compared with more traditional sources of parenting information is that information is always available and tailored to parents' interests and needs [5,20,63,64]. Consequently, young parents in particular exhibit a high level of trust in digital information and opinions provided by other parents on social media [5,44]. Given parents' great engagement with and active quest for parenting-related support and information on social media, it is evident that these platforms exert a profound impact on their lives and decision-making processes. These subjects are discussed in the following sections.

Theme 2: Type of Parenting-Related Content on Social Media

The studies in this cluster (174/338, 51.5%) focused on the types of parenting-related information available on social media. More than half (113/174, 64.9%) of the studies used a qualitative approach, primarily conducting qualitative content analyses to identify the various parent-related topics discussed on social media. Other qualitative methods, such as sentiment analysis, interviews, focus groups, and sociolinguistic analyses, were also applied but on a remarkably smaller scale. The quantitative studies within this cluster (49/174, 28.2%) mainly used quantitative content analysis, whereas a smaller number used surveys to obtain insights into the parenting information available on social media. Finally, some studies (10/174, 5.7%) used a mixed methods approach, mainly combining qualitative and quantitative content analyses to investigate the variety of parenting information. In total, 1.1% (2/174) of the studies were found to have not defined their methodology.

Moreover, to comprehensively analyze the diverse spectrum of parenting-related content on social media, researchers scraped data from various social media platforms. Most of the data in the studies within this cluster were gathered from blogs, YouTube, and Facebook (93/174, 53.4%). A smaller amount of studies (64/174, 36.8%) analyzed parenting content on Instagram or Twitter or examined content from multiple platforms. Other platforms, such as Weibo, online forums, Reddit, TikTok, and WhatsApp, were examined in a minority of studies (17/174, 9.8%). Noteworthily, some studies (11/174, 6.3%) did not explicitly mention or define the specific social media platform from which they gathered their data.

Furthermore, parenting information on social media was studied within a variety of research fields, including health information and medicine, pregnancy and childbirth, family science, nutrition, influencer marketing, and COVID-19. However, most research attention concerning parenting information on social media focused on the fields of health and medicine, followed by the fields of pregnancy and childbirth and family science. In the following paragraphs, we discuss these fields in detail.

First, in the domain of health information and medicine, 2 broad categories were identified—namely, parental health and child health. The studies that focused on parental health encompassed diverse topics, such as medication use, general health practices, alcohol consumption, and infertility [65-67]. The studies that focused on child health information for parents on social media covered a range of health-related topics, such as child vaccinations, autism, child diabetes, cancer, child obesity, sun protection for children, congenital anomalies, elbow fractures, rhizotomies, and mouth sores [68-73]. Across these 2 categories, some studies (14/174, 8%) also examined the quality of and level of trust that parents place in information obtained from social media platforms [72,74,75].

Second, considerable research was conducted in the domain of family science. Such studies primarily focused on the representation and narratives of motherhood and fatherhood on social media [76,77]. Various narratives surrounding the ideals of the "perfect mother" and the notion of a "bad mother" were identified. Other topics, such as the transition into fatherhood, genderfluid parenting, daily life of American families, and grief of parents were detected on social media.

Third, within the domain of pregnancy and childbirth, 3 prominent clusters of information were identified: childbirth (eg, birth stories, hypnobirthing videos, information about miscarriage, and maternal mortality), health and pregnancy (eg, vaccination, physical activities, alcohol, drugs, COVID-19, and anxiety), and representations of pregnancy on social media [78-80]. While research was also conducted in other research domains to map the information about parenting on social media (eg, influencer marketing and nutrition), the volume of such studies was relatively limited.

Theme 3: The Role of Parenting Information on Social Media in Parents' Lives

A total of 21.6% (73/338) of the studies were found to have investigated the relationship between parenting content on social media and parents' experiences. Most of these studies (41/73, 56%) adopted a quantitative approach, predominantly using surveys to explore the correlations between online parenting information and parents' daily experiences. Conversely, a smaller subset of studies (17/73, 23%) used qualitative methodologies to delve deeper into parents' experiences with parenting content on social media. The qualitative methodologies encompassed in-depth interviews, qualitative content analyses, and digital ethnographies. A total of 3% (2/73) of the studies conducted systematic reviews to consolidate existing findings. In addition, 14% (10/73) of the studies used mixed methods research combining various research approaches, such as ethnographies, interviews, focus groups, surveys, content analyses, discourse analyses, and social network analyses. A total of 4% (3/73) of the studies did not clearly specify their methodology.

Regarding the focus of the studies, a substantial portion (38/73, 52%) adopted a broader approach, concentrating on social media in general rather than choosing 1 specific platform. Most of these studies (24/38, 63%) conducted surveys to explore the correlations between parenting content on social media and various dependent variables. These variables include attitudes toward pregnancy and specific diseases, perceptions of social media information, parents' mental health, and child feeding practices [81]. Among the specific social media platforms, Facebook—particularly specific Facebook groups—was a popular platform to investigate (13/73, 18%). In addition, the studies examined other platforms, such as Instagram, Twitter, YouTube, blogs, or a combination of these (22/73, 30%).

The relationship between parenting content on social media and various variables (eg, parental self-efficacy) was studied within various research domains, such as family science, education, health information and medicine, nutrition, pregnancy and childbirth, advertising, and communication.

First, a notable portion (19/73, 26%) of the studies within this cluster were situated in the domain of family science. They explored a wide range of variables, such as well-being, anxiety, the role of humor in social media posts, the quality and credibility of information, family connectedness, perceived parental skills, and involuntary childlessness. Notably, a range of insights on different topics within the field of family science were identified. For instance, the experimental study by Germic et al [82] revealed that mothers who sought information from online sources had lower perceived self-efficacy than mothers who did not seek online information regardless of the content they were exposed to. Another qualitative study conducted a thematic content analysis and indicated that humor played an important and positive role in reducing parents' anxieties and distress during the pandemic [83].

Second, a smaller portion (12/73, 16%) of the studies on the role of parenting information in parents' everyday lives fell within the domain of communication. Most of these studies (9/12, 75%) were conducted in the field of influencer marketing, primarily focusing on "momfluencers." A momfluencer is a social media influencer (SMI) who has attracted a large number of followers on social media by actively sharing their everyday life of motherhood and who often participates in commercial collaborations [8,84]. More specifically, these studies revealed correlations between the idealized content of momfluencers on Instagram and lower well-being, more anxiety, and less parental self-efficacy among mothers [8,14,84,85]. However, Kirkpatrick and Lee [14] as well as Egmose et al [8] also suggested that momfluencers can have a positive influence by providing support and an online community. Moreover, Ouvrein [46] indicated that a positive relationship exists between regular exposure to momfluencer content and perceived parental self-efficacy for pregnant women. Other studies in the research area of influencer marketing focused more on the promotion of food products or the use and effects of disclosures and visual brand promotion [12,86]. Furthermore, a smaller subset of studies (3/12, 25%) delved into the role of social media in facilitating communication processes between families experiencing military separation or migration [21,87,88].

Finally, some studies (10/73, 14%) were conducted within the research area of pregnancy and childbirth. These examined the correlations between social media use and various aspects of pregnancy, including body satisfaction, childbirth, mental health, and eating disorders. Their findings suggest that social media content that addresses pregnancy-related subjects demonstrates associations with both positive and negative outcomes for pregnant women [89-91]. For instance, the experimental study by Tang et al [89] demonstrated that mothers exposed to body-focused social media posts exhibited higher levels of body dissatisfaction and poorer body image than mothers in the control group. Another study indicated that Facebook serves as a source of social support for new mothers, enabling them to interact with like-minded individuals and feel less isolated during maternity leave by staying in contact with their family and friends [42].

Theme 4: Professional Parenting Interventions on Social Media

Given that parents regularly consult social media platforms for parenting information [10], several studies developed professional interventions that targeted parents through various social media platforms. In particular, 12.1% (41/338) of the studies investigated various professional interventions on social media for parents and their children. These interventions were developed and implemented across multiple social media channels, and nearly half (20/41, 49%) were conducted within specific Facebook groups. In 20% (8/41) of the articles, the specific platform used for the intervention was not specified. Other platforms used for implementing the interventions included blogs (5/41, 12%), TikTok (1/41, 2%), WeChat (2/41, 5%), WhatsApp (1/41, 2%), or a combination of these (7/41, 17%).

The professional interventions can be categorized into 3 main research domains, namely, health (20/41, 49%), nutrition (11/41, 27%), and pregnancy (10/41, 24%). First, the interventions within the health domain focused on diverse health topics, such as vaccine concerns, parents of children with specific diseases, parents' mental health, breast cancer, and sleep in infants. A total of 10% (2/20) of the studies, which addressed parental vaccine concerns and hesitance, indicated that the interventions were effective in improving parents' attitudes toward vaccination [92,93]. In contrast, a human papillomavirus vaccine intervention by Chodick et al [93] was ineffective at improving the uptake of the vaccine among mothers' daughters. In addition, the interventions targeting children with specific diseases and their parents (5/20, 25%) were found effective [94]. The target audience of the health interventions varied, encompassing parents, caregivers, mothers, and children.

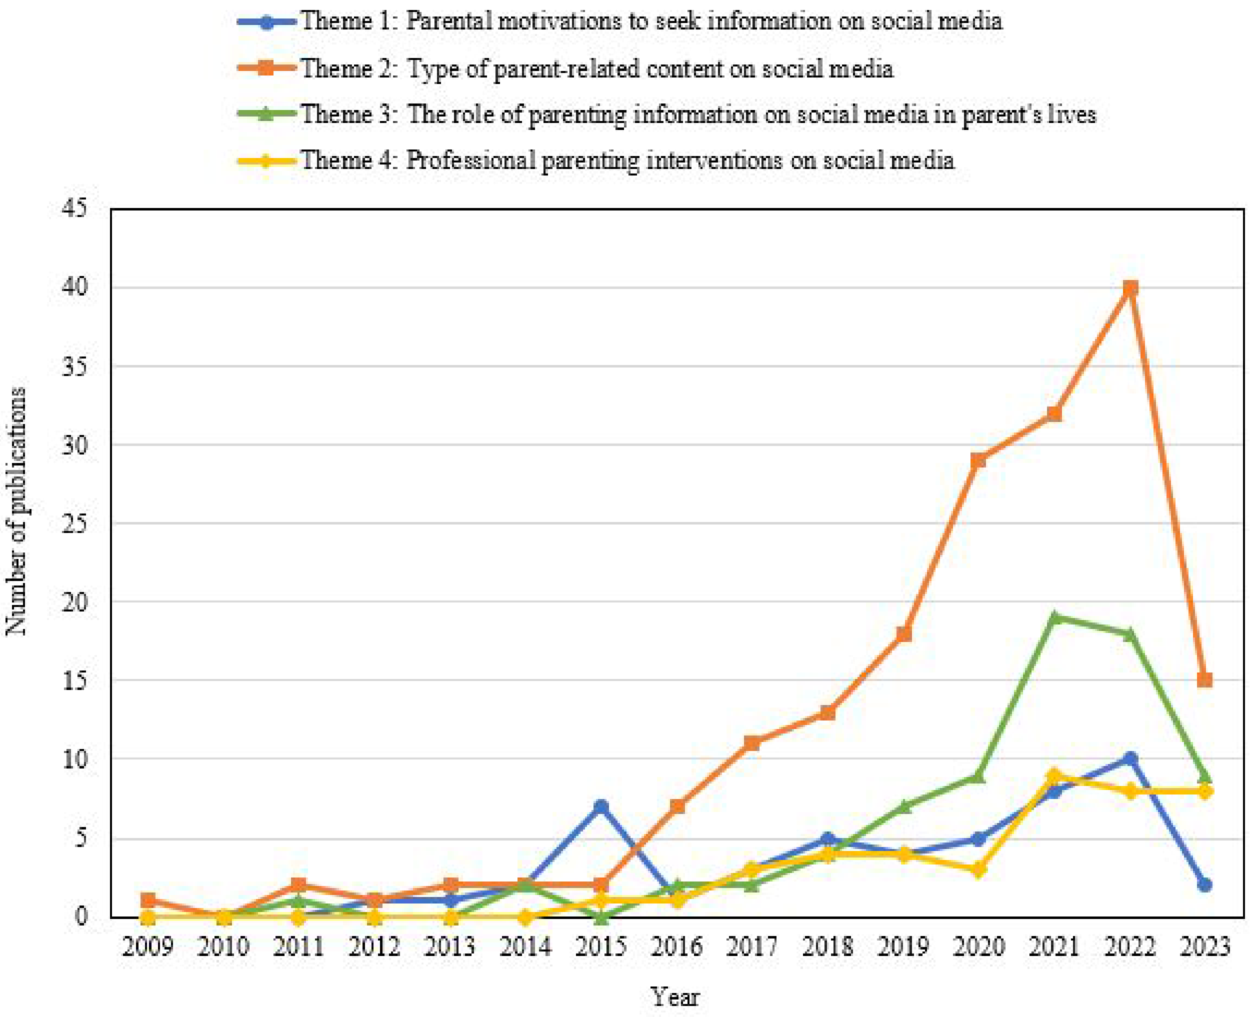
Second, the interventions in the nutrition domain aimed to enhance parents' food-related behaviors and decision-making processes. Noteworthily, all interventions that focused on nutrition were specifically tailored to parents, mothers, or caregivers, which is unsurprising given that parents—particularly mothers—are recognized as key influencers in shaping their children's eating habits [95]. Most of the interventions (30/41, 73%) were highly effective at improving the healthy food decisions that parents made for their children. For example, a peer-group intervention implemented through social media had a significant impact on specific feeding behaviors within families with infants at high risk of obesity [45].

Third, the interventions in the pregnancy domain were designed to improve various aspects, such as anxiety during pregnancy, knowledge about vaccines or pregnancy in general, prenatal stress, maternal mental health, and physical health. All interventions that pertained to pregnancy specifically targeted pregnant women and demonstrated positive outcomes. For instance, the self-help mindfulness intervention by Zhang et al [95] was effective at decreasing prenatal stress and negative affect as well as improving positive affect and mindfulness.

Thematic Evolution Analysis

Figure 3 illustrates the thematic evolution analysis that we conducted, offering insights into the progression of the identified themes over time in the realm of parenting and social media research. The analysis revealed notable trends in research focus across different periods. Theme 2, namely, the type of parent-related content on social media, emerged as the initial focal point in 2009 and consistently remained a central area of investigation with the exception of the year 2015. During this period, researchers redirected their attention to understanding the motivations that drive parents to seek information on social media platforms (theme 1). Subsequently, themes 3 and 4 gained prominence, with a growing emphasis on examining the effects of parenting information disseminated through social media channels and evaluating professional interventions.

Figure 3. Results of the thematic evolution analysis.



Discussion

Research Gaps and Future Research Recommendations

Overview

The area of parenting and social media has received growing academic attention since 2015, aligning with today's digital turn in information dissemination. In this section, we aim to provide a broader lens for understanding the overall domain of parenting information on social media. Therefore, we discuss the most crucial research gaps that we identified, followed by concrete recommendations for future research to help move our understanding forward of why and how parents consult and are influenced by social media. A summary of recommendations with research questions can be found in Multimedia Appendix 2. These research gaps and recommendations follow the structure of the communication model by Lasswell [96]—communicator, message, medium, audience, and effect—preceded by a brief discussion of the methodologies used in the included studies.

Methodologies

Few studies in our sample (28/338, 8.3%) adopted a mixed methods approach to conduct research on parenting information on social media. However, combining qualitative and quantitative research is highly valuable for addressing complex research problems in social sciences [97,98]. Quantitative data reveal the impact of parenting content, whereas qualitative data illuminate individual experiences. Mixed methods are increasingly used within various disciplines, including health sciences, nursing, sociology, psychology, and education [98]. Future research on parenting and social media should use more mixed methods to obtain a holistic understanding of parental interactions and behaviors on social media.

Communicator

Within the collected studies, we identified that little to no attention was paid to the sources of parenting content on social media. Crucial to note is that studies that examined the motivations of people to share information on social media were excluded from the sample as they did not align with our objectives. Nevertheless, little to no attention was devoted to answering the question of who is sharing parenting information (eg, everyday parents, medical experts, and parent influencers) on social media and which features characterize these individuals. Hence, numerous questions concerning the source characteristics of individuals sharing parenting information on social media remain unexplored and require further investigation.

Specifically, we noticed that only a fraction of the studies within our sample (13/338, 3.8%) focused on SMIs as sources of parenting information. However, scholars have consistently emphasized that the impact of SMIs on parents and society should not be underestimated [14,99,100]. Specifically, parent influencers provide support and establish a readily accessible and relatable community for parents who want to discuss various parenting topics [100]. Consequently, research has revealed that the content produced by parent influencers exerts a substantial influence on parents in various aspects, including the intention to initiate and sustain breastfeeding and the shaping of parenting ideologies [101-103]. In total, 2 types of momfluencers were distinguished: typical momfluencers who share their personal experiences and professional momfluencers who create content based on their education and professional background [8]. However, research on how parents judge and give meaning to the expertise of information sources on social media is lacking. In addition, while influencer marketing focuses on SMIs' commercial value, it lacks insights into their role in promoting prosocial behavior [104]. In the context of parent influencers, an important research gap exists in the lack of empirical insights on the effectivity of parent influencers as digital agents for promoting prosocial behavior [105].

Message

Studies related to the "message" construct by Lasswell [96] fell under theme 2 (ie, the "types of parenting-related content on social media"). These studies explored the nature of parenting content disseminated on social media, of which a substantial proportion was medical information. Notably, these studies primarily focused on the health information available on social media while often overlooking the assessment of its reliability. Scholars have raised concerns about disinformation on social media [106]. More specifically, one study has argued that there is an absence of gatekeepers for evaluating the information's veracity before its dissemination; moreover, peers share available information from both professionals and nonprofessionals at an unpredictable speed and pattern, making it difficult to distinguish reliable information [107]. Other research has similarly indicated that misinformation is frequently shared in parenting contexts [69].

When we examined the available parenting content more closely, we noticed that a variety of parenting topics were investigated, such as pregnancy, child vaccinations, nutrition, and specific diseases. This is also reflected in the fact that the studies examined within this scope were published in 232 journals. However, social media content related to parenting styles remained unexplored. Considering that mothers actively seek online parenting information [5,10], it is crucial to gain insights into the different parenting styles that are shared with peers on social media. Furthermore, little attention was paid to the commercial content targeting parents despite evidence showing their vulnerability in early parenthood [3] and the variety of sponsored content on the web [108]. Notably, and similar to the source cluster, little to no research exists on the type of parenting information shared by SMIs. However, momfluencers are extremely popular among pregnant women and first-time mothers, who regularly consult their profiles [8,14,84]. Given the influential voices of SMIs, it is crucial to study both influencer characteristics and the content they share with their large audiences.

Medium

This study identified some research gaps in the social media platforms studied. The co-word analysis highlighted "social media," "Facebook," and "YouTube" as prominent nodes, indicating a focus on Facebook groups and YouTube videos [109,110]. Instagram and TikTok are 2 increasingly important social media platforms that are currently overlooked. Instagram is highly popular among brand-new mothers, and the second largest group of Instagram users is aged 25 to 34 years [111]; thus, they represent the age demographic of a considerable number of young parents [8]. Similarly, TikTok's popularity extends beyond young demographics to encompass individuals aged 18 to 34 years, who account for 36% of the platform's users worldwide [112]. Given that parenting information on TikTok and Instagram remains largely uncharted in research, we recommend that future research endeavors encompass a diverse array of methodological approaches and cover all 4 thematic domains of this study (ie, motivations, content type, impact, and interventions). This multifaceted approach will enable a more comprehensive exploration of these social media platforms.

Audience

Most of the studies within this scope (326/338, 96.5%) focused on mothers or parents in general. Although mothers are identified as primary health information seekers and caregivers [113], it is crucial not to overlook the role of fathers. In the 21st century, there has been a discernible increase in fatherly involvement [114,115], as seen in the rise of dad bloggers [76,116]. Dad bloggers attempt to counterbalance the stereotypes and narratives of fatherhood that depict fathers as absent or incapable [116]. Given the scarcity of academic attention to dad bloggers, "dadfluencers," and fathers in general as a target audience, we recommend that future research explore modern family dynamics in an inclusive manner.

The results of our systematic literature review have already indicated that a substantial portion of research delved into parents' motivations to seek information on social media (cf cluster 1). Nevertheless, a notable research gap exists in the specific types of online information-seeking behaviors of parents. Furthermore, it would be interesting to investigate whether the types of information seeking are associated with parental consumer behavior as well as parents' decision-making processes. In addition, research could investigate whether certain types of information lead to more informed parenting decisions.

Effects

While there was a substantial number of studies on parenting content on social media (174/338, 51.5%), few examined its impact on parents' decision-making for their children. Thus, future research is necessary in several key areas. First, neoliberal parenting ideals, which emphasize the individual responsibility of parents and their focus on autonomy [117,118], are increasingly represented on social media [119], but their effects on parenting styles, decisions, norms, and practices remain understudied.

Second, parents devote a significant amount of time to social media seeking support and information [5,10] but face an overload of misinformation on the web [69]. Compounded by their non–"digital native" status, parents often grapple with limited digital knowledge, which necessitates further research on their media and advertising literacy [120]. While current studies predominantly focus on children and adolescents in this regard [121], obtaining insights into parents' media literacy is equally vital because they not only spend a lot of time on the web but also play a crucial role in their children's social media literacy [122]. In addition, the overload of health information available both on the web and offline was reported to overwhelm parents, leading to anxiety and confusion [123]. Future research should further investigate these negative effects of information overload on parents in the health domain as well as other domains, such as pregnancy and nutrition.

Third, a nuanced analysis of SMIs' influence is crucial. Current research mainly emphasizes the negative impact of momfluencers, particularly on mothers [85]. Nevertheless, studies have already indicated that SMIs could in general be interesting sources for promoting prosocial behavior [124,125]. Thus, leveraging momfluencers as allies to endorse prosocial behavior, such as advocating for healthy nutrition, is a highly interesting avenue for future research. However, it is imperative to exercise caution concerning the potential drawbacks associated with the commercial arrangements in which momfluencers engage. Richins and Chaplin [125] demonstrated that parents who seek to ensure their children's happiness through materialistic parenting inadvertently contribute to the development of materialistic adults in the future. Therefore, future research should scrutinize whether the commercial partnerships of momfluencers inadvertently promote materialistic parenting styles and propose strategies to mitigate such effects.

Conclusions

While parents easily find their way to social media for parenting information and questions, academic research in this area remains fragmented across diverse disciplines and is still in its infancy. This paper has presented the first study to use bibliometric and thematic content analyses to provide a systematic overview of parenting and social media research. This will enable researchers to have a general understanding of the current state of the art regarding research on parenting information on social media. Current research can be classified into the following 4 main categories: parents' motivations to seek parenting information, types of parenting-related content on social media, the role of parenting information on social media in parents' lives, and professional interventions for parents on social media. Insights from the thematic content analysis of these themes helped us identify research gaps and provide recommendations for future research.

However, this study has some limitations. One important limitation pertains to the keywords used to select relevant papers. While we included a comprehensive set of keywords related to parenting, such as "parent," "mother," "father," "maternal," "mom," "dad," "paternal," "pregnancy," "conception," "postnatal," "prenatal," "family," "kid," and "child," we did not initially include the terms "infant," "baby," or "foetus" in our search formula. Therefore, it is important to acknowledge that the absence of certain keywords in our search strategy may have impacted the inclusivity of our review. Another limitation pertains to the database's ability to scrape articles. In this study, we only searched for articles in 1 database, namely, Scopus. Even though it is the largest multidisciplinary database of science, technology, medicine, social science, and arts and humanities, we might have missed articles relevant to our topic.

Despite its limitations, this review has significant theoretical and practical implications. First, it highlights the broad interest among researchers from various disciplines, including vaccinations, dietary choices, and pregnancy, in understanding what information can be found for parents on social media and how it affects them. However, the dispersed nature of this research area poses a significant challenge, which could potentially lead researchers to overlook valuable insights from other domains. Therefore, this review serves as a clarion call for researchers to exert a concerted effort to synthesize knowledge across and within domains. Second, this review underscores the significant growth in research pertaining to parenting information disseminated through social media over the past 7 years. The rapid expansion in this field indicates its dynamic nature. As such, this review establishes a robust foundation on which researchers can build to further explore this emerging domain. In addition, we provided an extensive list of future research directions with concrete research questions. By providing this extensive list of research avenues, we aim to encourage future researchers to make substantial contributions and enrich the field's knowledge base. As for the practical implications, this review highlighted that there is an overload of information for parents on social media. The plethora of (often conflicting) information is often perceived as overwhelming for parents [126]. Therefore, it is crucial to equip parents with strategies for navigating the deluge of information effectively and empower them with the skills to discern and use information to their advantage.

Abstract

Background: In today's digital society, the acquisition of parenting information through online platforms such as social networking sites (SNSs) has become widespread. Amid the mix of online and offline information sources, there is a need to discover effective information-seeking methods for solving parenting problems.

Objective: This study aimed to identify patterns of information use among parents of young children in the digital age and elucidate the characteristics of these patterns through a comparative analysis of parental social support and self-efficacy.

Methods: An internet-based survey was administered to fathers and mothers of children aged 0-3 years. Convenience sampling, facilitated by an internet-based survey company, was adopted, and data from 227 fathers and 206 mothers were analyzed. The survey included questions on personal characteristics, frequency of use of different sources of parenting information (websites, SNSs, parenting apps, family, friends, and professionals), availability of parental social support, and parental self-efficacy. The Partitioning Around Medoids (PAM) clustering algorithm was used to identify patterns in parenting information use.

Results: A total of 4 clusters were identified: multisource gatherers (n=161), offline-centric gatherers (n=105), online-centric gatherers (n=86), and minimal information gatherers (n=68). The availability of parental social support was perceived to be relatively higher among multisource and offline-centric gatherers compared with online-centric and minimal information gatherers. Parental self-efficacy was highest among multisource gatherers, followed by offline-centric and online-centric gatherers, and lowest among minimal information gatherers.

Conclusions: This study contributes to the evidence that online information can effectively complement offline information in addressing parenting challenges, although its ability to fully replace offline sources remains limited. Parenting support professionals are encouraged to understand parents' current information use strategies and actively foster their social relationships, helping them to adopt more diverse and comprehensive approaches to information use.

Introduction

In the current digital age, the proliferation of applications designed to make pregnancy and parenting more convenient is changing the landscape of parenting [1,2]. The space for sharing parenting information and support has expanded from offline to online, becoming a normalized aspect of daily life [3]. The expansion of the online information space has provided many benefits for parents. Parents now have immediate access to a wide range of parenting information, including insights that are not available offline [4,5], and barriers to professional advice have reduced owing to parenting applications and online platforms [4]. Furthermore, online peer support has become increasingly active through platforms such as social networking sites (SNSs) [4], helping parents solve problems and learn about and establish parenting styles.

Since the outbreak of the COVID-19 pandemic, online family support services have rapidly expanded [6]. These services include professional family support through video conferencing tools [7] and online parenting programs [8]. The effectiveness of online parenting support programs has been shown to be comparable to that of in-person support programs [9], indicating that the digital society has brought about innovative advancements in the methodology of professional parenting support.

However, the online information space also presents certain challenges. Internet use that results in an information overload can overwhelm parents, complicate decision-making, and potentially lead to suboptimal actions due to misinformation, with the risk of triggering inappropriate parenting behaviors [5]. Furthermore, idealized images of parenting that proliferate on social media can create unrealistic expectations and pressures that undermine trust [10]. In addition, the “filter bubble” effect, where individuals are exposed only to information that aligns with their preferences and values, can promote biased parenting styles and isolate them from diverse viewpoints [11]. These challenges within the online information space pose the risk of complicating problem-solving processes in real-life parenting scenarios. Thus, online information related to parenting may have both positive and negative effects on problem-solving and the establishment of parenting styles. There is a need to accumulate knowledge that can help parents overcome the disadvantages of online information while maximizing its benefits in the context of parenting.

To examine the effective use of online information in parenting, it is critical to examine the interplay between online and face-to-face information. One explanatory model for the relationship between digital device use and human activity and well-being is the displacement-interference-complementarity (DIC) framework [12]. This framework offers a comprehensive understanding of the impact of digital devices on parenting by identifying 3 potential effects: displacement, interference, and complementarity. The displacement hypothesis suggests that digital devices may replace other activities, explaining that online social relationships serving as sources of parenting information may sometimes substitute for those in face-to-face settings. The interference hypothesis posits that digital devices may disrupt ongoing activities, indicating that parents’ use of online information could hinder face-to-face information gathering and support. Both hypotheses suggest that digital devices may limit face-to-face interactions in parenting, potentially negatively affecting positive parenting outcomes. In contrast, the complementarity hypothesis suggests that digital devices may provide access to information not available through face-to-face social relations, allowing parents to comprehensively use both online and offline sources of information to support their parenting efforts. By using the DIC framework, evidence can be provided to demonstrate the contexts in which online information benefits parents, contributing to a better understanding of how parenting support can be enhanced in the digital age.

Academic knowledge focused on technological advances is lagging [13], and research focusing on the interactivity between online and offline parenting information remains limited. For parents in the digital age, referring to or using online information has become commonplace. However, the affinity for digital technology varies among individuals, even within the so-called digital native generation, indicating diverse preferences [14]. In parenting, the level of online information use may vary based on factors such as the gender of the parent and the age of the child (in months) [15]. In the context of health information, information-seeking behaviors are significantly influenced by personal subjective norms [16]. This suggests that parents may exhibit a variety of patterns in their use of parenting information, ranging from those who integrate both online and offline sources to those who prefer online information or have traditional values and, therefore, use online resources sparingly. Exploring patterns of parenting information use, considering both online and offline sources, can provide nuanced evidence about the efficacy and challenges of digital information in parenting in light of the DIC framework.

To understand which component of the DIC framework online information falls under, it is important to consider parents’ social relationships as a potential influencing factor. Isolated individuals may use online communities, such as SNSs, to compensate for limited face-to-face interactions [17], suggesting that parents with limited social relationships might use online information as a substitute for face-to-face support. In addition, strong social support is correlated with higher health literacy [18], which in turn is associated with an increased rate of online health information searches [19]. This suggests that parents with extensive social networks are likely to be more adept at using both online and offline information, with online resources supplementing face-to-face interactions.

One outcome of effectively using parenting information to address parenting challenges is improved parenting self-efficacy, which is defined as parents’ beliefs about their ability to influence their children in ways that promote health and success [20]. High parenting self-efficacy is associated with positive outcomes in the parent-child relationship, child development, and parental mental health, underscoring its clinical importance [21]. Identifying the patterns of online or offline parenting information use associated with high parenting self-efficacy could provide insights into information use that enhances parenting performance.

Accordingly, this study aimed to explore the various patterns of combined online and offline parenting information use among parents in the digital age, categorize these patterns, and examine their characteristics by comparing the levels of parental social support and self-efficacy. This study seeks to answer 3 questions in particular:

1. What are the distinct patterns of the combined use of online and offline parenting information?

2. What are the demographic characteristics of the identified information usage patterns?
3. Which of these patterns of combined information use are associated with higher levels of parental social support and parenting self-efficacy?

Methods

Design

This study used a cross-sectional design, and a close-ended internet-based questionnaire survey was administered. To ensure the quality and transparency of the research, the Checklist for Reporting of Survey Studies (CROSS) developed by Sharma et al [22] and the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) developed by Eysenbach [23] were used. This paper reports a portion of the data from a survey titled "Information Behavior on Social Networking Services Among Parents of Infants and Toddlers."

Participants and Sampling

Convenience sampling was adopted for participant recruitment and was performed in collaboration with Cross Marketing Inc, an internet-based survey company that oversees nationwide sampling in Japan. With over 5 million active online users, Cross Marketing Inc provides academic survey services for diverse demographics. The panel managed by the company consists of a broad range of internet users, providing a large control group that is unbiased by specific sites or advertisements. In this study, 434 parents of children aged 0-3 years were recruited from the Cross Marketing Inc panel. As part of the recruitment process, a one-time survey invitation was sent by the research company to approximately 2000 randomly selected individuals deemed eligible for the study. Recipients who answered a preliminary question about their children's age that was inconsistent with the study criteria were excluded. Those who agreed to participate in the study clicked "agree" after reading the research request document, which directed them to the internet-based survey link. The target sample size was set at over 200 participants each for fathers and mothers. Recruitment concluded once this target was reached. However, some individuals submitted late responses after recruitment ended, resulting in a final number of respondents that exceeded the target.

Data Collection

In August 2023, data were collected through an internet-based survey involving those directed through the aforementioned process. The survey was created and administered by the authors using the Qualtrics online survey system, which ensures data security through mechanisms such as encryption, redundancy, continuous monitoring, and single sign-on, and is FedRAMP certified and ISO27001 accredited. The survey was user-friendly, designed by the authors, and pretested to avoid design problems. Participants who completed the survey received reward points or other rewards according to the protocols of Cross Marketing Inc.

Measures

The survey items used in the internet-based survey are presented in Multimedia Appendix 1.

Frequency of Use of Parenting Information Resources

In this study, the selection of parenting information resources used by parents in today's digital society was based on the concept of the information space surrounding parents of young children by Xie et al [3]. Parents' information space consists of offline and online communities defined by proximity and the broader public sphere—the lifeworld. Online communities include everyday online spaces such as web search platforms, SNSs, and online parenting communities. Offline communities represent more immediate everyday spaces that include family members, friends, and parenting peers. The lifeworld includes broader public institutions and services, both online and offline, including medical institutions and their websites. Accordingly, in this study, the categorization followed was "online resources" from online communities and lifeworlds and "offline resources" from offline equivalents. Online sources of parenting information were divided into websites, SNSs, and parenting-related applications. Websites included child- and parent-related websites, blogs, and hospital homepages. Given the Japanese context, SNSs included platforms such as X (formerly known as Twitter), Instagram, Facebook (Meta Platforms), and YouTube (Google), excluding LINE (LY Corporation) because of its primary use for personal communication and limited feed functionality. Parenting apps included those useful for pregnancy tracking, baby development updates, and immunization schedules. Offline resources were identified as family, friends, parenting peers, and professionals (including health and education professionals), who provided information from offline communities and lifeworlds. Participants rated their subjective frequency of use of 6 information sources on a 6-point scale from "1: Never use" to "6: Always use."

Parenting Self-Efficacy

The Parenting Self-efficacy Scale [24], which was developed and validated in the Japanese context, was used. It consists of 13 items rated on a 5-point Likert scale, with higher scores indicating greater parenting self-efficacy. The Cronbach alpha for this study was 0.85.

Parental Social Support

Drawing on the classification of social support proposed by previous research [25], I developed items based on another previous study in the context of parenting [26], focusing on informational and emotional support. It is assumed that the availability of support varies depending on the source; therefore, I established 4 categories of respondents: spouses (including partners), other family members, friends and parenting peers, and professionals. A total of 8 items were created to reflect both types of support. Respondents evaluated these items using a 4-point scale ranging from "1: Strongly disagree" to "4: Strongly agree." In cases where the designated respondent category did not apply (eg, if the participant was a single parent), respondents were instructed to select "0: Not applicable."

Participant Demographics

Data were collected on participants' age, number of children, age of the youngest child, occupational status, educational level, and subjective economic status.

Statistical Analysis

First, descriptive statistics for both fathers and mothers were conducted to examine differences in the frequency of information source usage and social support related to parenting. Next, the partitioning around medoids (PAM), a nonhierarchical clustering method applicable to ordinal scales, was used to identify patterns in gathering parental information. This approach addresses traditional challenges of hierarchical clustering, which may hinder finding optimal solutions because participants remain in specific clusters throughout all analysis steps. Unlike the k-means method, which relies on means, PAM uses actual data points (medoids) as cluster centers, maintaining rank information and providing robust clustering results in the presence of outliers or noise. Initial medoids are determined using a Greedy algorithm, which sequentially selects locally optimal solutions to minimize the total cost (the sum of distances from each data point to the nearest medoid), effectively reflecting the data's structure. The Manhattan distance was adopted as the distance metric, which, unlike Euclidean distance, represents movement along each dimension rather than straight-line distance, offering robustness against outliers and noise.

The number of clusters was determined based on theoretical and practical interpretability, along with results from the elbow method and gap statistic, both indicators of clustering appropriateness. The elbow method visualizes how the sum of squared errors (SSE) within clusters decreases as the number of clusters (k) increases, with the "elbow" point indicating the optimal number of clusters. In this study, SSE was plotted for values of k from 1 to 20 to locate the elbow. The gap statistic method compares the clustering results of observed data with those of randomly generated data to determine the optimal number of clusters, identifying the maximum gap statistic as optimal and indicating how much better the clustering results are compared with random data. A maximum of 500 bootstrap iterations was conducted for the observed data set from 1 to 20 clusters.

Initially, we conducted separate analyses for the father and mother, confirming similarities in their clustering. Given the observed similarities between both parents, the measures taken to reduce the sample size for each cluster, and the importance of integrating the clusters, we decided to consolidate all samples for cluster analysis. The Kruskal-Wallis test and the Steel-Dwass test were used for multiple comparisons to identify clusters based on the reference variables.

To investigate the association between the extracted clusters and demographic characteristics, as well as the availability of parental social support, we conducted the analysis using the Kruskal-Wallis test, Steel-Dwass test, or chi-square test. In addition, to compare parenting self-efficacy across clusters, 1-way ANOVA and Tukey honest significant difference (HSD) tests were performed for multiple comparisons. Statistical analyses were conducted using JMP Pro (version 17.0; SAS Institute) and R language (R Foundation for Statistical Computing), with a significance level set at 5%.

The required sample size for 1-way ANOVA was calculated using G-power, considering an effect size (f) of 0.25 (medium), α error probability of 0.05, power of 0.8, and 20 groups, resulting in a minimum required sample size of 360. The number of groups was based on the maximum expected in PAM for this study. Missing values in parenting self-efficacy were imputed using least squares prediction based on nonmissing values for each scale when less than half of the data were missing.

Ethical Considerations

Participants were provided written information about the following aspects related to the study and their participation: an overview of the study, voluntary participation, no penalty for nonparticipation, their right to refuse to answer, maintenance of anonymity, use of data only for research purposes, and strict management of personal information. Consent to participate was obtained when participants selected the consent button in the internet-based survey. All questions included the option for participants to refuse to answer if they preferred. This study was conducted following approval received from the Institutional Ethics Committee, the ethics committee for research involving human participants at Toyama Prefectural University (August 10, 2023, approval number: R5-16).

Results

Descriptive Statistics

Of the respondents who returned the questionnaire, data from 420 individuals—those without missing data on items related to the use of information sources in parenting—were included in the analysis. The basic demographic characteristics of the participants are presented in Table 1. The sample consisted of 201/420 mothers (47.9%) and 219/420 fathers (52.1%). The distribution of the Parenting Self-Efficacy Scale exhibited a skewness of –0.35 and a kurtosis of 0.14. None of the scales violated the thresholds (skewness: absolute value >2; kurtosis: absolute value >7) [27], which could potentially cause bias in parametric analyses.

Table 1. Demographics.

	Mothers (N=201)		Fathers (N=219)

[a] Not applicable.

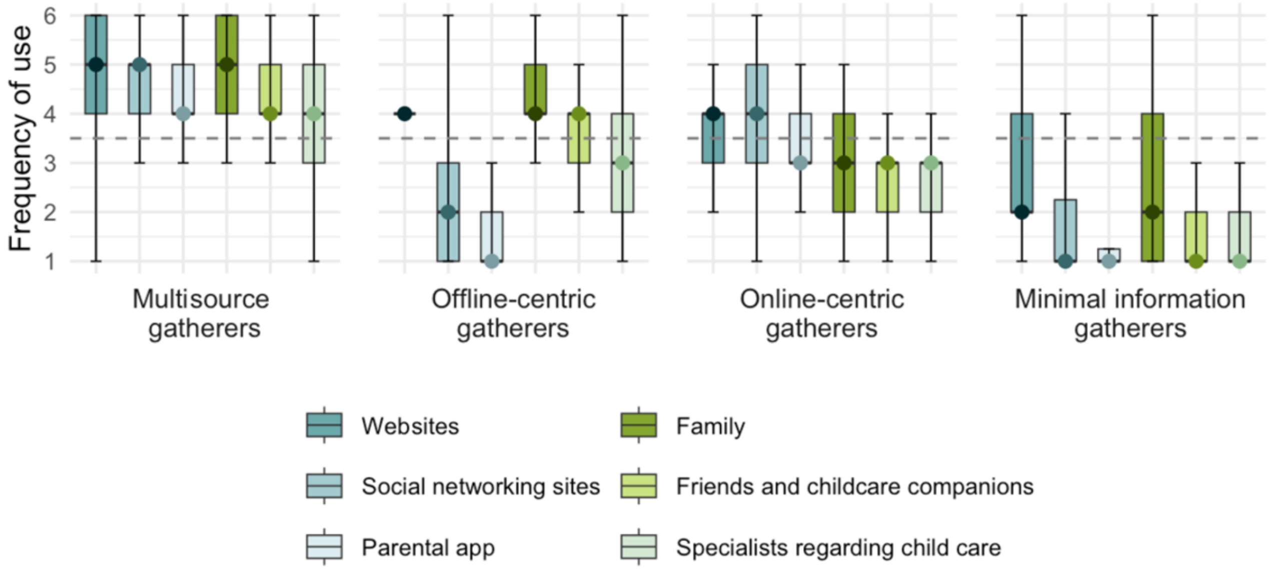
Gender Differences in Parental Information Use and Availability of Support

The frequency of using information sources in parenting and descriptive statistics for parental social support are presented in Multimedia Appendix 2. Among the parenting-related information sources, mothers more frequently used websites (*P*=.003), SNSs (*P*<.001), parenting apps (*P*<.001), and friends or parenting peers (*P*<.001) compared with fathers. Regarding parental social support, fathers perceived greater availability of informational support (*P*<.001) and emotional support (*P*=.02) from their partners compared with mothers. Conversely, mothers perceived greater availability of emotional support from friends than fathers (*P*=.01).

Cluster Analysis

Based on the clusters extracted by PAM, the elbow method was applied. Although a clear elbow point could not be definitively established, the reduction in the total within-cluster sum of squares became more gradual at k=4 (Multimedia Appendix 3). The gap statistic plot indicated that k=4 yielded the maximum value, followed by a slight decrease (Multimedia Appendix 4). Consequently, we decided to proceed with a cluster count of 4 (Figure 1 and Multimedia Appendix 5). The clusters were named based on the Kruskal-Wallis test and the Steel-Dwass test, as follows: Cluster 1, with a high frequency of use of all information sources, was named “Multisource gatherers (n=161).” Cluster 2, with a relatively higher frequency of use of offline sources compared with online sources, was named “Offline-centric gatherers (n=105).” Cluster 3, with a relatively higher frequency of use of online sources compared with offline sources, was named “Online-centric gatherers (n=86).” Cluster 4, with an extremely low frequency of use of all information sources, was named the “Minimal information gatherers (n=68).”

Figure 1. Clusters of use patterns of parenting information resources.



Differences of Demographics by Parent Information Use Patterns

The comparison results of the demographics of the 4 clusters are presented in Table 2. “Multisource gatherers” are relatively younger, have more mothers, fewer children aged 2, more often cohabitate with spouses, exhibit a higher prevalence of maternity and parental leave, and enjoy a better living situation. “Offline-centric gatherers” are relatively older, have more fathers, tend to have more families with two children rather than one, and predominantly work full-time with less maternity and parental leave; they also have a higher rate of university graduates. “Online-centric gatherers” tend to have more infants as their youngest children and fewer 3-year-olds, work more part-time, and have a higher proportion of junior college or vocational graduates, with fewer holding university degrees. “Minimal information gatherers” are relatively characterized by more fathers, a higher number of 2-year-olds, and a predominance of full-time employment.

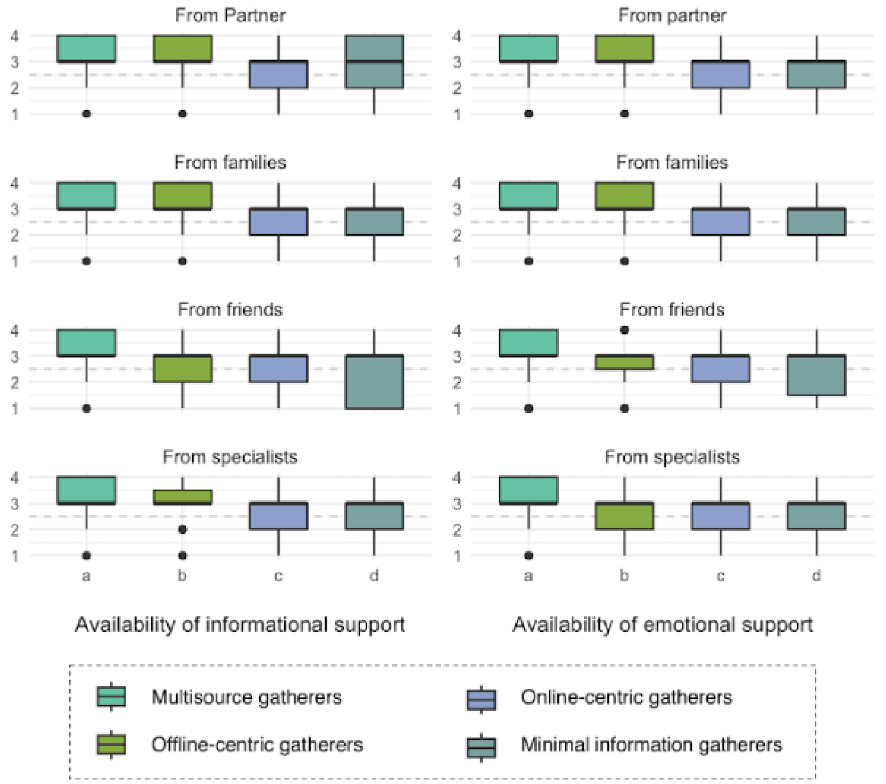
Comparison of Parental Social Support Based on Parenting Information Use Patterns

The comparative results of the availability of social support in childcare across the 4 clusters are presented in Figure 2 and Multimedia Appendices 6 and 7. A significant relationship was confirmed between all types of available support and clusters. Regarding spousal support, both informational and emotional aspects were more available to “Multisource gatherers” compared with “Online-centric gatherers.” For family support, both informational and emotional aspects were more available to “Multisource gatherers” and “Offline-centric gatherers” compared with “Online-centric gatherers” and “Minimal information gatherers.” In terms of support from friends and parenting peers, both informational and emotional aspects were higher for “Multisource gatherers” compared with “Online-centric gatherers” and “Minimal information gatherers,” while “Offline-centric gatherers” also had more availability than “Minimal information gatherers.” Finally, support from professionals showed greater availability in both informational and emotional aspects for “Multisource gatherers” compared with “Online-centric gatherers” and “Minimal information gatherers.”

Figure 2. Comparison of parental social support based on parenting information use patterns.

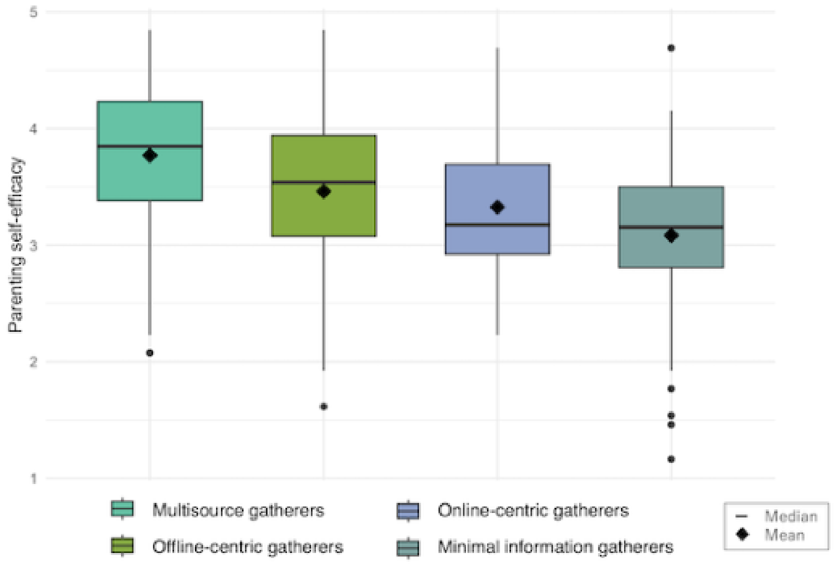


Note. The results of the Kruskal-Wallis test. The figure presents a box plot with median indicated by a bold line.

Comparison of Parenting Self-Efficacy Based on Parenting Information Use Patterns

The results comparing parenting self-efficacy based on parenting information usage patterns are presented in Figure 3 and Multimedia Appendix 8. The 1-way ANOVA revealed a significant relationship between parenting information usage patterns and parenting self-efficacy ($F_{3,414}$=22.86, P<.001). According to the Tukey HSD test, “Multisource gatherers” demonstrated significantly higher parenting self-efficacy compared with “Offline-centric gatherers,” “Online-centric gatherers,” and “Minimal information gatherers” (P<.001 for each). In addition, “Offline-centric gatherers” exhibited significantly higher self-efficacy than “Minimal information gatherers” (P<.001).

Figure 3. Comparison of parenting self-efficacy based on parenting information use patterns.



Note. The results of the one-way ANOVA. The figure presents a box plot with median indicated by a bold line and the mean represented by a diamond.

Discussion

Principal Findings

This study identified 4 types of parenting information use patterns among parents of infants and toddlers and elucidated their characteristics through comparisons of parental social support and parenting self-efficacy. The main findings of the study are discussed below.

Multisource Type

First, the “Multisource gatherers” tended to use both online and face-to-face information sources frequently. This suggests that online information resources may function as a complement for these groups, according to the DIC framework [12]. Parents of this type had higher levels of support from family, friends, and specialists related to parenting than did “Online-centric gatherers” and “Minimal information gatherers.” This suggests that they may have extensive social networks that allow them to access a wide range of information sources for parenting. In addition, individuals in this type had higher levels of parenting self-efficacy than those in the other types. Access to diverse information can contribute to problem-solving when information utilization skills are high; otherwise, it can lead to confusion owing to information overload [4]. These parents may effectively use diverse information from both offline and online sources to solve parenting challenges because of their information use and social relationship-building skills, which may contribute to higher parenting self-efficacy. However, given the cross-sectional design of this study, reverse causality is also possible. Parents with high parenting self-efficacy may experience a greater sense of reassurance when using smart devices to alleviate parenting anxiety, leading to reduced anxiety [28]. High parenting self-efficacy, which is associated with reduced psychological distress in parenting [29], may mitigate the negative aspects of online information, such as psychological distress from social comparisons on SNSs [30], enabling parents to use multichannel information effectively.

This type has a relatively high proportion of mothers and individuals on maternity or parental leave and a low proportion of full-time workers. In addition, this type, along with “Online-centric gatherers,” exhibits a high frequency of online information usage, which aligns with previous research indicating that women engage more frequently in internet use and the exchange of social support through SNSs [31,32]. Furthermore, working mothers are expected to have a broader social network due to their workplace connections compared with stay-at-home mothers. Mothers on maternity or parental leave are more likely to have more time to use their parenting networks than those currently used. As a result, it can be inferred that mothers on maternity or parental leave were leveraging both online and offline information to address parenting challenges.

Online Type

“Online-centric gatherers,” who exhibit a relatively higher frequency of use of online information sources centered around SNSs compared with offline sources, tend to show lower availability of informational and emotional social support in parenting compared to “Multisource gatherers” and “Offline-centric gatherers.” This type may be using online information to replace limited face-to-face social relationships, suggesting that online information acts as a substitute, according to the DIC framework [12]. The lower parenting self-efficacy observed in this type, compared to “Multisource gatherers,” suggests that substituting face-to-face information with online information may be limited to offer positive outcomes in parenting. Previous research has suggested that using digital resources as a substitute for family support in solving parenting challenges may lead to low parental role achievement [26]. The results of this study are consistent with previous research and strengthen the evidence regarding the effectiveness of online information as a complement to and its limitations as a substitute for offline information in resolving parenting challenges. Individuals struggling with social isolation or loneliness may have a high affinity for online information from SNSs [17], suggesting that parents of this type may have limited face-to-face social relations and may intentionally or unintentionally rely on online information to cope with these issues.

This type is characterized by a relatively high proportion of mothers with infants, part-time workers, and individuals with associate degrees. During the infant stage, the emphasis on caregiving is greater compared with the toddler stage, resulting in more restrictions in daily parenting life. This may have led to the use of online parenting networks, which are more easily accessible than in-person support. In addition, previous research [28] indicates that highly educated mothers tend to experience anxiety related to problem-solving in parenting when using smart devices. Parents of this type, owing to their higher educational status, may recognize concerns regarding online information, making them less likely to adopt an information use style that is heavily biased toward online sources.

Offline Type

“Offline-centric gatherers” preferred face-to-face to online sources of information. This type, likely a conventional type from the pre-SNS era, appeared to prioritize information obtained through face-to-face interactions for parenting. Despite the proliferation of digital technology and the tech-savvy population, there is a certain proportion of nonadopters who either intentionally or unintentionally choose not to use technology [33,34]. As such, those in the offline group may be similar to nonadopters of digital technology. Compared with the “Online-centric gatherers” and “Minimal information gatherers,” this type perceived greater availability of support from family and friends and appeared to rely on ample face-to-face resources for parenting without the need for online information. However, this type exhibited lower parenting self-efficacy compared with “Multisource gatherers.” This suggests that online information, as a complementary hypothesis, may contribute to higher levels of parenting self-efficacy. Using online information in this context may help further enhance the parenting self-efficacy of these parents.

This type is characterized by a relatively high proportion of fathers, parents with only one child, full-time workers, and individuals with university or graduate degrees. Compared with pregnant women and mothers, there are limited SNSs and peer support opportunities for fathers related to parenting [35], which may restrict their ability to expand online parenting networks and effectively use online information. In addition, the prevalence of highly educated individuals in this type is consistent with the aforementioned tendency for online use in problem-solving to evoke negative emotions [28].

Minimal Information Gatherers

“Minimal information gatherers” exhibited a generally low frequency of information use. This type recognized the availability of support from family, friends, and professionals to a lesser extent, and their self-efficacy in parenting was lower than that of all other types. This type may have limited access to all parenting information resources and an extremely narrow social network, both within and outside the family, indicating potential problems in social relations. Social isolation is a significant factor in worsening parental mental health [36] and a risk factor for maltreatment [37]. This type may represent a high-risk case that requires assistance from experts.

In this group, there was a high proportion of fathers and full-time workers among the samples. In Japanese society, owing to the influence of gender role division, mothers often take on the central role in child-rearing, while fathers’ involvement may be limited in some households [38]. Busy fathers, who may have less active involvement, might lack sufficient parenting experience, which could lead to lower self-efficacy in child-rearing. In addition, this group uniquely recognized the availability of informational support from partners as comparable with “Multisource gatherers” and “Offline-centric gatherers” while acknowledging the lower availability of emotional support from partners compared with the other two types. This implies that, despite problems in the emotional relationship between couples, the limited social networks they possess confine their sources of parenting information to their partners. Fathers may struggle more than mothers to distinguish negative emotions stemming from marital discord from those associated with parenting, which supports the “Fathering Vulnerability Hypothesis [39].” Considering this hypothesis, fathers in this category might experience complex negative emotions due to their reliance on partners for parenting information despite having emotional challenges in their relationships, thereby reinforcing negative experiences in parenting and leading to a decline in self-efficacy.

Implications

The results confirm that the DIC framework is generally applicable in the context of parenting information use. As those with the highest levels of parenting self-efficacy are “multisource gatherers,” it is recommended that parents use online information as a complement to face-to-face advice when seeking parenting information. On the other hand, it should not be used as a substitute for face-to-face information provision, as it is less likely to lead to favorable outcomes. However, parents who rely on online information may face potential issues, such as limited social networks. Therefore, simply reducing the use of online information does not guarantee an improvement in parenting outcomes.

Parenting support professionals are required to provide customized assistance based on the types of parenting information use identified in this study. “Multisource gatherers” are encouraged to enhance their ability to use diverse information sources, both online and offline. For “Online-centric gatherers,” there is a need to strengthen information literacy to assess the reliability and quality of online information, particularly given the variability in these factors in the short term. For example, reports indicate that interactive websites, parent-created sites, and sites originating from South America have significant room for improvement in ethical and content aspects [40]; therefore, parents should be cautious when using them. In the medium to long term, promoting enriched social relationships in parenting to facilitate a transition to “Multisource gatherers” would be effective. For “Offline-centric gatherers,” having robust offline social networks is crucial, and supporting the strengthening of these networks to obtain valuable informational support from family and community is beneficial. For “Minimal information gatherers,” identifying underlying issues, such as family discord or social isolation, and providing tailored professional support is effective. By addressing these underlying issues and enhancing social relationships in parenting may broaden information use patterns in parenting, leading to a transition to other categories.

Limitations

A few limitations of this study must be noted. First, causal inferences could not be made, given its cross-sectional design. Second, owing to the self-report questionnaire format, the possibility of information bias cannot be dismissed. Third, the convenience sampling approach adopted, collaborating with a specific survey company in Japan, does not eliminate the possibility of selection bias. In particular, online survey respondents may be biased toward higher online affinity and information literacy, thus limiting the generalizability of the results. Fourth, it is difficult to completely rule out the possibility of different clusters emerging from this study. It is crucial to confirm the reproducibility of the clusters identified in this study through cluster analysis using a larger, randomly sampled data set with more rigorous procedures. Fifth, this study did not consider information literacy when capturing the characteristics of the types of parenting information use patterns. Finally, the measure examining the availability of parenting support to investigate the characteristics of the clusters is a single-item scale, and its reliability and validity are not sufficiently guaranteed. It is also important to note the existence of parenting support networks, such as workplace colleagues, which could not be measured in this study.

Future research involving larger international samples and different methodologies not influenced by online affinity may increase the robustness of this study’s findings. In addition, it is expected that patterns of information use may change under the influence of various factors such as parents’ educational experiences and children’s age. Identifying the process of change and the factors involved could contribute to a more nuanced understanding of the characteristics of parenting information used in today’s digital society.

Conclusion

This study identified types of parenting information-seeking patterns among parents in today's digital society and explored their characteristics through comparisons of parental social support and parenting self-efficacy. The results indicated the following information-seeking patterns among parents: those who use both online and face-to-face information sources in a multichannel, hybrid manner; those with a bias toward either online or face-to-face information; and those with a generally low frequency of parenting information use. The type that used both online and offline resources exhibited the highest levels of parenting self-efficacy. The results of this study support the DIC framework and strengthen the evidence for the effectiveness of online information as a complement to and its limitations as a substitute for offline information in resolving parenting challenges. Parenting support professionals are encouraged to understand parents' current information use strategies and actively foster their social relationships, helping them to adopt more diverse and comprehensive approaches to information use.

Acknowledgments

I would like to express my sincere gratitude to 4 undergraduate students for their substantial assistance in the development of supplementary research questions. Their invaluable contributions significantly enhanced the depth and rigor of this study. This work was supported by the Japan Society for the Promotion of Science KAKENHI (grant 19K19728, Grant-in-Aid for Young Scientists) and Toyama Prefectural University Faculty of Nursing Discretionary Expenses for the Fiscal Year 2023.

Abstract

Background: In the United States, patients with monochorionic diamniotic twins who undergo in utero fetoscopic laser photocoagulation (FLP) for twin-twin transfusion syndrome (TTTS) may travel great distances for care. After delivery, many parents cannot return to study sites for formal pediatric evaluation due to geographic location and cost.

Objective: The aim of this study was to collect long-term pediatric outcomes in patients who underwent FLP for TTTS.

Methods: We assessed the feasibility of using a web-based survey designed in REDCap (Research Electronic Data Capture; Vanderbilt University) to collect parent-reported outcomes in children treated for TTTS at a single center during 2011 - 2019. Patients with ≥1 neonatal survivor were invited via email to complete 5 possible questionnaires: the child status questionnaire (CSQ); fetal center questionnaire (FCQ); Ages & Stages Questionnaires, Third Edition (ASQ-3); Modified Checklist for Autism in Toddlers, Revised With Follow-Up (M-CHAT-R/F); and thank you questionnaire (TYQ). The R programming language (R Foundation for Statistical Computing) was used to automate survey distribution, scoring, and creation of customized reports. The survey was performed in 2019 and repeated after 12 months in the same study population in 2020.

Results: A total of 389 patients in 26 different states and 2 international locations had an email address on file and received an invitation in 2019 to complete the survey (median pediatric age 48.9, IQR 1.0 - 93.6 months). Among surveyed mothers in 2019, the overall response rate was 37.3% (145/389), and the questionnaire completion rate was 98% (145/148), 87.8% (130/148), 71.1% (81/100), 86.4% (19/22), and 74.3% (110/148) for the CSQ, FCQ, ASQ-3, M-CHAT-R/F, and TYQ, respectively. In 2020, the overall response rate was 57.8% (56/97), and the questionnaire completion rate was 96.4% (54/56), 91.1% (51/56), 86.1% (31/36), 91.7% (11/12), and 80.4% (45/56) for the CSQ, FCQ, ASQ-3, M-CHAT-R/F, and TYQ, respectively.

Conclusions: This is the first study to use both REDCap and computer automation to aid in the dissemination, collection, and reporting of surveys to collect long-term pediatric outcomes in the field of fetal medicine.

Introduction

Background

Twin-twin transfusion syndrome (TTTS) results from unbalanced vascular communications in a shared placenta between monochorionic diamniotic (MCDA) twins. Bidirectional vascular communications are present in up to 95% of MCDA twins and allow for a single, shared circulatory system [1]. However, in 9% - 15% of MCDA twins, unbalanced vascular communications produce a pathological state in which one fetus (the donor twin) overtransfuses the cotwin (the recipient) [2,3]. Compensatory mechanisms result in progressive recipient polyhydramnios (excess amniotic fluid) and donor oligohydramnios (low amniotic fluid). Expectant management of this condition results in a mortality rate greater than 70%, typically due to sequelae from circulatory overload, compensatory hormonal dysfunction, and preterm delivery due to worsening polyhydramnios [4]. The gold-standard treatment for TTTS is intrauterine fetoscopic laser photocoagulation (FLP) of placental vascular anastomoses, which halts the abnormal blood exchange and yields better outcomes [5]. Despite this therapy, twins who survive TTTS may experience major disability at birth likely secondary to hemodynamic changes that occur in utero or sequelae of prematurity, as the average gestational age at delivery is approximately 32 weeks [6]. However, long-term outcomes for these surviving twins in the United States remain understudied, largely because of the logistical challenges of following patients who traveled far from home for treatment.

Prior Work

The data on long-term pediatric outcomes in patients who undergo FLP for TTTS come almost entirely from centers outside the United States. Centers with a local and homogeneous referral base are more likely to report in-person pediatric evaluations [7-10], although telephone and mail-in surveys have also been reported [9,11,12]. To date, there have been few attempts to collect long-term pediatric outcomes using web-based methods in the field of fetal surgery [13].

In the United States, patients referred for treatment of TTTS may travel upward of 2000 miles to receive care at a tertiary center of excellence [14]. The majority of these patients will travel home postprocedure and deliver at remote sites, which makes tracking neonatal and long-term outcomes challenging. At our center, thanks to considerable efforts from full-time research staff to collect maternal delivery and neonatal discharge records from patients' delivering hospitals, we have reported on the immediate and short-term neonatal complications (from time of delivery until hospital discharge) in patients who undergo FLP for TTTS [15]. However, prospectively collected in-person long-term follow-up of twins born after FLP in the United States would be exceedingly challenging and resource-intensive. Therefore, web-based collection methods may provide a viable approach.

Goal of This Study

The primary outcome of this study was to assess the feasibility of using computer automation to obtain, to the fullest extent, long-term pediatric outcomes from patients who underwent FLP for TTTS at a fetal center (FC) over a 2-year period.

Methods

Ethical Considerations

Approval was obtained from the Institutional Human Research Ethics Committee (IRB) (HSC-MS-19‐0363), and the study was conducted between June 1, 2019, and September 30, 2020. The IRB determined that our study did not need ethical approval.

Study Design

This was a cohort study of patients who were referred to the UTHealth Houston Fetal Center in Houston, Texas, and who underwent FLP for TTTS between 2011 and 2019. Eligible patients were identified retrospectively from a registry of patients treated at our center who had previously consented to prospective follow-up of short-term maternal and neonatal outcomes (HSC-MS-10‐0059).

Patients with TTTS who underwent FLP at our center during the study period and had both an email address on file and at least 1 surviving child from a monochorionic pair at the time of neonatal hospital discharge were eligible for participation in this study. Exclusion criteria included patients without a registered email or cases of dual fetal or neonatal demise.

Patient Recruitment and Consent

Patients who received the survey via email were instructed to follow a hyperlink to a web-based REDCap (Research Electronic Data Capture; Vanderbilt University) consent form, where details regarding study participation and confidentiality were provided. After giving e-consent, patients were emailed copies of the study protocol and directed to a subsequent child status questionnaire (CSQ). After indicating the survival status of both the ex-donor and the ex-recipient twins, the user was directed to a queue of web-based questionnaires, specific to the number of surviving children and their age.

Questionnaires

We designed research surveys in REDCap, an HIPAA (Health Insurance Portability and Accountability Act)–compliant, secure research data collection tool, which can be used to distribute web-based, mobile-friendly surveys. Surveys consisted of several pediatric age–specific questionnaires distributed via email to consenting parents. Details regarding the purpose, age applicability, and atypical screening threshold are present in Table 1.

Table . Summary of questionnaires in surveys distributed to participants.[a]

Questionnaire	Purpose	Applicability	Atypical screening threshold
CSQ[b,c]	• Confirm child survival status • Confirm if the child was the ex-recipient or ex-donor twin	Single questionnaire delivered to all consenting patients	N/A[d]
FCQ[e]	• 20 questions with “yes/no” responses related to general health and the use of special services	Parent-reported questionnaire for each child regardless of current pediatric age	N/A
ASQ-3[f]	• 40 questions with “yes/no” or “yes/sometimes/not yet” responses completed by parents designed to detect developmental delays in 5 domains: communication, gross-motor, fine-motor, problem-solving, and personal-social	Parent-reported questionnaire for each child between the ages of 1 and 60 months	Score of greater than or equal to 2 SD below the mean on any of the 5 domains assessed
M-CHAT-R/F[g]	• 20 questions with “yes/no” responses completed by parents to screen for autism spectrum disorder	Parent-reported questionnaire for each child between the ages of 16 and 30 months	Atypical response in 3 or more questions
TYQ[h]	• Obtain permission to distribute repeat survey in 12 months • Obtain appropriate contact information	Single questionnaire delivered to all consenting participants	N/A

[a] All questionnaires delivered via email through REDCap (Research Electronic Data Capture). Does not include the consent questionnaire, which was distributed to all eligible patients via email through REDCap and used the REDCap e-consent framework.

[b] CSQ: child status questionnaire.

[c] Age corrected for prematurity until 24 months of age.

[d] N/A: not applicable.

[e] FCQ: fetal center questionnaire.

[f] ASQ-3: Ages & Stages Questionnaires, Third Edition

[g] M-CHAT-R/F: Modified Checklist for Autism in Toddlers, Revised With Follow-Up.

[h] TYQ: Thank You Questionnaire.

First, all participating patients were sent the CSQ, a series of 2 ‐ 4 questions for each child, which provided confirmation of the child status as alive, demised in utero (fetal demise), or demised after birth (neonatal demise). The parent also reported the recipient or donor status for each child so that prenatal parameters could be accurately correlated with the correct twin. Based on user input indicating both the number of surviving children and pediatric age, specifically designed computer algorithms automatically tailored the number and type of survey questionnaires. Participating parents were sent any questionnaires applicable to their child’s pediatric age.

The fetal center questionnaire (FCQ) was adapted from a prior publication of long-term outcomes in twin gestations and was applicable to every surviving child [16]. The questionnaire consisted of 20 questions, the majority with “yes/no” responses, related to general health and the use of specialized services related to movement, speech, hearing, behavior, and education. The complete questionnaire is included in Multimedia Appendix 1.

The Ages & Stages Questionnaires, Third Edition (ASQ-3), a validated developmental screening tool with approximately 40 “yes/no” or “yes/sometimes/not yet” questions designed to be completed by parents, was applicable to every child between the ages of 1 and 60 months. This evaluation tool has high sensitivity and specificity to detect developmental delays in 5 domains: communication, gross-motor, fine-motor, problem-solving, and personal-social [17-21]. After obtaining permission from the publishers, we integrated all 21 age-specific versions of the ASQ-3 into REDCap as separate questionnaires.

The Modified Checklist for Autism in Toddlers, Revised With Follow-Up (M-CHAT-R/F), a validated autism screening tool with 20 “yes/no” questions designed to be completed by parents, was applicable to children between the ages of 16 and 30 months [22,23]. With permission from the publishers, the M-CHAT-R/F was distributed as a REDCap questionnaire. Participants whose children had a positive M-CHAT-R/F screen received a phone call and completed a series of follow-up questions per screening protocol.

The ASQ-3 and M-CHAT-R/F have been tested and validated in populations of children who are at risk for prematurity, autism, and abnormal neurodevelopmental outcomes [17-23]. They were selected for this survey due to ease of completion and ease of distribution as REDCap questionnaires.

Finally, all surveys were finished with a brief thank you questionnaire (TYQ). The TYQ consisted of 5 free text and “yes/no”-style questions requesting the following: permission to send a repeat survey 1 year later, the patient’s preferred method of contact for future studies, and permission to contact the patient to validate any results or obtain prior results from their child’s pediatrician’s office.

Distribution

The current age of all children surveyed was calculated, adjusting for prematurity until 24 months. For children who were older than 60 months, the CSQ, FCQ, and TYQ were distributed at a single timepoint. For children who were eligible for the ASQ-3, the survey was automatically distributed on a rolling basis approximately 3 weeks prior to the date at which a child’s age-specific ASQ-3 would no longer be applicable. Depending upon the child’s age and the number of surviving children (determined via the CSQ), parents’ survey queue (not including the single CSQ and TYQ) could contain as few as 1 FCQ questionnaire (eg, 1 surviving child at 6 years of age) and as many as 6 questionnaires (eg, 2 living children at 24 months of age). Patients who did not respond to the initial survey invitation within 1 week received 2 additional weekly reminders via email, followed by a phone call.

Scoring and Questionnaire Reporting

Scripts in the R programming language (R Foundation for Statistical Computing) were used to automatically score completed ASQ-3, accounting for an age-specific scoring rubric and adjustment for any skipped questions, and the M-CHAT-R/F. The ASQ-3 was considered high risk if any of the 5 domains assessed scored greater than or equal to 2 SDs below the mean. The M-CHAT-R/F examination was considered high risk if 3 or more questions had an atypical response. R language scripting was also used to both identify any child who had a high-risk ASQ-3 or M-CHAT-R/F screen and to automate the creation of custom reports in Microsoft Word (Microsoft Corp) using the *WordR* [24] and *officer* [25] packages. These reports were distributed to parents via HIPAA secure email within 2 weeks of survey completion.

Repeat Surveys

Patients who indicated they were amenable to a repeat survey received a second survey invitation in 2020 approximately 12 - 13 months after their 2019 response. All applicable age-specific questionnaires were repeated as part of a prospective analysis of pediatric developmental outcomes in this population. As part of the repeat 2020 survey, patients received a single email reminder but did not receive phone calls due to a lack of available research staffing. Questionnaires and follow-up reports were generated and distributed automatically within 2 weeks of survey completion.

Statistical Analysis: Power

As a purely observational study, no official power analysis was performed, as the primary objective was to collect, to the fullest extent, parent-reported long-term outcomes in this population over a 2-year period.

Results

Figure 1 is a flow diagram of patient recruitment and responses. In total, 475 patients underwent FLP for TTTS at our center between September 23, 2011, and February 13, 2019. Among them, 86 patients were excluded from the study: 52 had no neonatal survivors, 32 did not have an email on file at the time of the initial survey, and 2 did not consent to be contacted for future studies. A total of 389 mothers met the inclusion criteria and received an invitation via email to participate in the 2019 survey. Of these, 148 (38%) patients signed consent, and 145 patients completed or partially completed the full survey (CSQ, FCQ, ASQ-3, M-CHAT-R/F, or TYQ; 37.3% response rate). A total of 108 patients who responded in 2019 agreed to a repeat survey in 2020, of which 11 participants did not receive a repeat survey due to a technical error. In 2020, 97 patients from the 2019 cohort received a repeat survey, of whom 56 patients signed consent (57.8%) and 54 patients completed or partially completed the full set of questionnaires (55.7% response rate).

The majority of patients surveyed in 2019 and 2020 were from the southern United States (2019: 336/389, 86.8% and 2020: 80/97, 82.5%), had 2 neonatal survivors (2019: 325/389, 83.5% and 2020: 82/97, 84.5%), and underwent FLP for stage III TTTS (2019: 205/389, 52.4% and 2020: 52/97, 52.6%; Table 2). Slightly more than half of patients each year were from Texas (2019: 215/389, 55.3% and 2020: 51/97, 52.6%), and relatively few delivered within the same hospital system as the FC (2019: 41/389, 10.5% and 2020: 8/97, 8.2%). Compared with nonresponders, patients who consented to participate in the 2019 survey were older (30.0 vs 28.0 years; *P*<.001) and had younger children at the time of the survey (42.0 vs 52.0 months of age; *P*=.005), were less likely to have male children (68/145, 46.9% vs 143/244, 58.6%; *P*=.02), had a higher incidence of coexisting twin-anemia polycythemia sequence (10/141, 7.1% vs 5/239, 2.1%; *P*=.02), and had lower rates of coexisting selective fetal growth restriction (51/144, 35.2% vs 114/244, 46.7%; *P*=.03) and donor twins weighed more at delivery (1360 g vs 1570 g; *P*=.03). In both 2019 and 2020, there were no differences between responders and nonresponders with respect to race, number of surveys to complete, incidence of triplet pregnancies, TTTS Quintero stage, cervical length, gestational age at FLP, gestational age at delivery, child survival status, region of origin, distance from the FC, or incidence of delivery within the FC hospital system.

The completion rates and time to completion based on recorded survey timestamps in REDCap for each questionnaire are listed in Table 3. Reported completion times are limited to less than 60 minutes to exclude outliers who opened the questionnaire and completed it later. In 2019, 38% of eligible patients signed consent. In total, 98% (145/148) of consenting and eligible participants completed the CSQ, 87.8% (130/148) completed the FCQ in a median (IQR) of 3 (2-5) minutes, 71.1% (81/100) completed the ASQ-3 in 4 (3-8) minutes, and 86.4% (19/22) completed the M-CHAT-R/F in 2 (1-3) minutes. Of the patients who signed consent, 74.3% (110/148) completed the entire survey. Among patients who received a repeat survey in 2020, 57.8% (56/97) of patients signed consent. In total, 96.4% (54/56) of consenting and eligible participants completed the CSQ, 91.1% (51/56) completed the FCQ in a median (IQR) of 3 (2-5) minutes, 86.1% (31/36) completed the ASQ-3 in 6 (4 - 8.5) minutes, and 91.7% (11/12) completed the M-CHAT-R/F in 2 (1-3) minutes. Of the patients who signed consent, 80.4% (45/56) completed the entire survey.

The rates of atypical developmental screens are listed in Table 4. When analysis of the ASQ-3 was limited to the oldest assessment performed at ≥24 months of age for each child obtained in either 2019 or 2020, the overall rate of atypical ASQ-3 was 18.9% (18/95; recipient twin: 9/46, 19.6% and donor twin: 9/49, 18.4%). In 2019 and 2020, the rate of atypical M-CHAT-R/F screens was 11.1% (2/18) and 18.2% (2/11), respectively, for ex-recipient twins and 6.67% (1/15) and 9.1% (1/11), respectively, for ex-donor twins. In 2019 and 2020, the follow-up M-CHAT-R/F telephone confirmation was not performed for 3 children (total 2 recipient and 1 donor) due to the inability to reach the patient.

Patient willingness to undergo repeat survey and their preferred method of communication are listed in Table 5. Nearly 100% of patients in both years were amenable to a repeat survey in the following year. Respectively, most patients in 2019 and 2020 indicated a preference for email communication (99/110, 90% vs 43/45, 95.6%), followed by telephone calls (44/110, 40% vs 17/45, 37.8%), and finally mail-in post (24/110, 21.8% vs 11/45, 24.4%). In 2019 and 2020, 92.7% (102/110) and 95.6% (43/45) of responders were amenable to a follow-up call to sign a release of information waivers to request medical records from their child's pediatrician's office.

Figure 1. Patient recruitment and responses. ASQ-3: Ages & Stages Questionnaires, Third Edition; CSQ: child status questionnaire; FCQ: fetal center questionnaire; FLP: fetoscopic laser photocoagulation; M-CHAT-R/F: Modified Checklist for Autism in Toddlers, Revised With Follow-Up; TTTS: twin-twin transfusion syndrome; TYQ: thank you questionnaire. *Some response to any of CSQ, FCQ, ASQ-3, or M-CHAT-R/F. **Completed all age-appropriate questionnaires (Qs).

[a] Represents a subgroup of patients initially surveyed in 2019 who indicated they were amenable to repeat survey in 2020.

[b] Wilcoxon rank sum test, Fisher exact test, and Pearson chi-square test.

[c] Values in italics format indicate *P*<.05.

[d] Pediatric age corrected for prematurity until 24 months of age.

[e] Number of questionnaires to be performed based on child's age at the time of survey. Does not include child status questionnaire and thank you questionnaire.

[f] MCDA: monochorionic diamniotic.

[g] MCMA: monochorionic monoamniotic.

[h] All triplet gestations with the exception of a single quadruplet (dichorionic quadramniotic, nonrespondent).

[i] DCTA: dichorionic triamniotic.

[j] MCTA: monochorionic triamniotic.

[k] TTTS: twin-twin transfusion syndrome.

[l] TAPS: twin anemia polycythemia sequence.

[m] Defined as delta middle cerebral artery peak systolic value (MCA-PSV) ≥1. Excludes cases of isolated TAPS.

[n] sFGR: selective fetal growth restriction.

[o] Defined as ≥25% intertwin estimated weigh discordance and either donor or recipient twin estimated fetal weight <10 percentile at FI.

[p] FI: fetal intervention.

[q] FLP: fetoscopic laser photocoagulation.

[r] MCDA pregnancy in which cords too close for FLP, bipolar cord coagulation performed.

[s] Monochorionic monoamniotic with TTTS converted to bipolar after FLP (n=1); TTTS with sFGR, primary radiofrequency ablation of donor twin (n=1).

[t] Quintero stage II with poor visualization on diagnostic fetoscopy secondary to prior bleed, amnioreduction only performed (n=1).

[u] Quintero stage II FLP at 18 wk and 0 d, followed by recurrent TTTS or TAPS and ventriculomegaly in donor at 19 wk and 6 d and underwent radiofrequency ablation (n=1); Quintero stage II FLP for DCTA triplet gestation at 18 wk and 3 d with radiofrequency ablation of donor due to recurrent TTTS or TAPS at 20 wk and 1 d (n=1).

[v] Quintero stage III TTTS FLP at 21 wk and 2 d with recurrent TTTS at 24 wk and 5 d and underwent repeat FLP (n=1); Quintero stage IV at 16 wk and 3 d with recurrent TTTS at 24 wk and 0 d underwent repeat FLP (n=1); Quintero stage II TTTS FLP at 18 wk and 2 d with recurrent TAPS and amniotic band at 20 wk and 0 d had repeat FLP and amniotic band lysis from neck of plethoric fetus (n=1).

[w] Quintero stage III TTTS at 21 wk and 2 d with recurrent stage III TTTS underwent repeat FLP at 24 wk and 5 d (n=1); Quintero stage II TTTS FLP at 18 wk and 2 d with recurrent TAPS and amniotic band at 20 wk and 0 d had repeat FLP and amniotic band lysis from neck of plethoric fetus (n=1).

[x] Quintero stage IV FLP at 16 wk and 3 d with recurrent TTTS and repeat FLP at 24 wk and 0 d.

[y] Defined as intertwin estimated fetal weight discordance of ≥25% and either the donor or recipient estimated fetal weight <10%$^{(Hadlock)}$.

[z] GA: gestational age.

[aa] FC: fetal center.

Table . Survey response rate[a] among patients who had fetoscopic laser photocoagulation between September 23, 2011, and February 13, 2019.

	Eligible	Completed (% response rate)	Completion time (minutes)[b], median (IQR)

Typical	9 (81.8)	10 (90.9)	19 (86.4)
Atypical[f]	2 (18.2)[f]	1 (9.1)[g]	3 (13.6)

[a] ASQ-3: Ages & Stages Questionnaires, Third Edition.

[b] Represents the oldest ASQ-3 assessment performed at ≥24 months of age for each child obtained in either 2019 or 2020.

[c] Indicates at least 1 domain on the ASQ-3 for which the score was ≥2 SD below the mean.

[d] M-CHAT-R/F: Modified Checklist for Autism in Toddlers, Revised With Follow-Up.

[e] Indicates 3 or more atypical responses.

[f] Unable to contact a single patient to confirm atypical response.

[g] Unable to contact a single patient (flagged recipient and donor) to confirm atypical response.

Table . Results of thank you questionnaire.

Survey year	Ok to contact for repeat survey?, n (%)	Preferred method of future contact			Ok to inquire about pediatrician records?, n (%)
		Telephone, n (%)	Email, n (%)	Post[a], n (%)	
2019	109 (99.1)	44 (40.4)	99 (90.8)	24 (21.8)	102 (92.7)
2020[b]	45 (100)	17 (37.8)	43 (95.6)	11 (24.4)	43 (95.6)

[a] Two patients who requested communication via post and provided their current home address had moved 115 and 1577 miles since the time of initial evaluation for FLP.

[b] Represents a subgroup of patients initially surveyed in 2019 who indicated they were amenable to repeat survey in 2020.

Discussion

Principal Findings

In this survey study, we effectively gathered long-term pediatric parent-reported outcomes in patients treated with FLP for TTTS via email and electronic questionnaires. The overall response rates to our survey were 37.3% (145/389) in 2019 and 55.7% (56/97) in 2020. Notably, slightly less than half of the patients who responded were from outside of Texas (in 2019: 64/145, 44.1% and in 2020: 27/54, 50%), and the majority (in 2019: 128/145, 88.3% and in 2020: 51/54, 94.4%) delivered outside the FC hospital system. Of the patients who consented to our survey, the overall completion rate was 74.3% (110/148) in 2019 and 80.4% (45/56) in 2020.

Comparison With Prior Work

Compared with patients in Europe, the long-term pediatric outcomes in patients who travel for the treatment of TTTS in the United States have been poorly studied. Several Western European centers in which centralized health care systems exist have reported on the in-person evaluation of large cohorts of pediatric survivors of TTTS with nearly 100% follow-up rates [8,26,27]. Conversely, there is but a single report of long-term cognitive outcomes in children treated for TTTS and assessed solely in the United States [7]. In that study, only 13% of patients from outside the study center state were available for in-person assessment. This lack of data on long-term outcomes represents a critically missing component with which to counsel patients who are evaluated and treated for TTTS in the United States.

There are several challenges that contribute to the difficulty in assessing long-term pediatric outcomes in patients treated for TTTS in the United States. First, the geographic distance patients travel for specialized fetal intervention care is a physical barrier to in-person follow-up [14]. As a niche specialty, few high-volume academic centers account for the majority of FLP procedures performed annually [28]. Consequently, patients who reside outside these locations will travel great distances to receive care during their pregnancy, only to return home for follow-up care. This is evidenced by the geographic distance from our center in the population of patients surveyed and the high proportion of patients who delivered outside the FC hospital system.

Second, compared with other high-income countries, the United States ranks last regarding measures of health care affordability and access to care [29]. As of 2023, approximately 25.3 million people were uninsured in the United States [30]. Furthermore, as of 2016, there were 626 individual health systems identified across the United States [31]. Both the lack of access to care and the complex system of health care networks may contribute to the challenges in the longitudinal assessment of pediatric patients.

Finally, in most health systems in the United States, a fetus is not assigned a medical record number despite being exposed to disease, medications, and even fetal surgical interventions prior to birth. Both technical and legal challenges have likely contributed to the barriers surrounding the creation of a fetal electronic health record. Historically, fetal data are linked to pediatric outcomes via the maternal chart, so any attempt to fully describe an individual's medical history, from the time of conception to pediatric and adult life, requires the additional step of linking these 2 individuals. Despite some recent strategies to create nested or embedded fetal records within a maternal record [32], this has not been universally adopted in the field of obstetrics and fetal surgery.

Considering the challenges in obtaining long-term pediatric outcomes in patients treated for TTTS, validated parent-reported screening questionnaires delivered via electronic media are a potential starting point toward addressing this problem. We acknowledge that the gold standard for pediatric neurodevelopmental evaluation is in-person assessment. However, in the context of a population of individuals spread across a large geographic area and among various health care networks with diverse levels of access to care, remote screening provides a unique opportunity to assess outcomes in this population.

The use of electronic patient-reported outcome tools has increased with the growth of electronic health technologies. Significant advantages of this strategy include the ability to obtain information remotely over great distances and doing so at relatively low cost with the help of computer programming and automation. Furthermore, the real-time analysis of patient-reported data allows for early detection of positive screens and improvements in patient-clinician communication [33]. In our study, we developed scripts to automatically generate both accurate and personalized reports for children who had positive screens, which were subsequently returned to participants to share with their primary physician, thereby illustrating the potential clinical utility of this tool.

Strengths and Limitations

To our knowledge, this is the first report in fetal medicine of the ASQ-3 and M-CHAT-R/F being delivered to study participants via the REDCap questionnaire. Previous studies of survivors of TTTS describe the distribution of the ASQ-3 to patients via post [34-37], email attachment [34], or telephone interview [34], but incorporating these surveys into a digital format for research in fetal medicine has not been previously reported. This novel approach allowed for the application of computer-based algorithms to schedule the timely distribution of surveys, automate questionnaire scoring, and generate individualized reports for atypical screening responses. Furthermore, the costs to implement this system within an academic university hospital system where REDCap is an established research tool were minimal and involved licensing of the ASQ-3 for distribution as a research questionnaire. Unlike in-person assessments, which require significant human capital, the entire project was developed and executed by a few individuals with a background in both medicine and computer programming. Using this system, we received a partial or full response from patients in 20 different states at an average of 355 (SD 335; range 5.61-1629) miles from our center. Furthermore, among patients who consented to the study, the questionnaire completion rate was very high, suggesting that collection of long-term parent-reported outcomes via electronic format is technically feasible and that the questionnaires chosen for the study were not overly burdensome to complete. Finally, among participants who completed the study, there was a strong willingness to repeat a future assessment and a high rate of participation in the second year.

Regarding limitations, it is important to remember that the results from this study represent screening examinations and cannot necessarily be used to diagnose atypical pediatric development. As the data are parent-reported, there is a possible bias toward either underreporting or overestimating a child's capabilities [24]. Furthermore, when compared to nonresponders, the intertwin fetal growth discordance, a marker of placental insufficiency, and a risk factor for increased neonatal morbidity or mortality were lower in the patients who responded to the survey, which may bias the results toward a healthier population of individuals. Although most patients indicated they would consider providing pediatric records for evaluation, the study resources did not let us validate the questionnaires. It is, however, reassuring that the rates of atypical ASQ-3 screens in our cohort are comparable with rates of neurodevelopmental impairment, as assessed via Bayley Scales of Infant Development, which is administered in person, in several large European cohorts of patients treated for TTTS [8,26,27].

Patients in this study were identified retrospectively and were approached via email. It is possible that over time, patients' contact information and email addresses changed, which may explain why nonresponders tended to have older children. A future study in which patients are enrolled prospectively and receive an in-person explanation of the study procedures and study purpose may lead to improved initial response rates.

Unfortunately, 32 patients were not eligible for the study due to not having an email on file. These patients, in addition to the nonresponders, may be less technically savvy and could represent a digital divide bias that favors participants who are more computer-literate or can afford a computer. For this study, we chose to use email as the method of survey distribution due to ease of use within REDCap. Potentially offering the survey via telephone, via post, or via alternative electronic media such as SMS text messaging may have improved response rates. In addition, the response rate may have been improved if participation had been incentivized, as participation was entirely voluntary.

The project was also only available in English. It is possible some patients for whom English was not their primary language received the study, although it is unlikely that they would have completed the questionnaires. Additional limitations include a lack of information regarding patient insurance status, which may be an important contributor to neurodevelopmental outcomes, and the absence of a control group for comparison. Finally, 11 patients who agreed to repeat the survey did not receive a repeat survey invitation in 2020 due to a technical coding error, which was not identified until after study completion. Furthermore, we were unable to reach several patients to confirm the results of atypical M-CHAT-R/F screens.

Conclusions

This study represents the largest cohort of long-term outcomes reported in a population of patients treated with fetoscopic laser photocoagulation for TTTS in the United States. The novel use of computer programming and REDCap allowed us to automate the distribution, scoring, and generation of custom reports with ease and at relatively low cost. Future longitudinal studies in this population may benefit from prospective enrollment, incentivized participation, and survey distribution via alternative electronic methods such as SMS text messaging.

Acknowledgments

The authors would like to thank Dr Nathan Fox for contributing an initial version of the fetal center questionnaire, which was later modified for the study population.

Abstract

Background: The increasing need for child care is placing a burden on parents, including those with children with autism.

Objective: The aim of this study was to examine the employment status of Chinese mothers and fathers with children with autism spectrum disorder (ASD), as well as to investigate the factors that affected their employment decisions.

Methods: An online national survey was completed by the parents of 5018 children and adolescents with ASD aged 2-17 years (4837 couples, 181 single mothers, and 148 single fathers). The dependent variable was employment status—whether they kept working or quit to take care of their child. The independent variables were those characterizing the needs of the child and the sociodemographic characteristics of the family.

Results: The employment rate of mothers with children and adolescents with ASD was 37.3% (1874/5018), while 96.7% (4823/4988) of fathers were employed. In addition, 54.3% (2723/5018) of mothers resigned from employment outside the home to care for their children, while only 2.8% (139/4988) of fathers resigned due to caring obligations. Mothers' employment was positively associated with their single marital status, lower educational level, and having assistance from grandparents. Having the grandparents' assistance was positively associated with fathers' employment.

Conclusions: Gender inequalities in employment exist in China. Mothers caring for children with ASD had lower workforce participation than fathers. More female-friendly policies and a stronger gender equality ideology would be of benefit to Chinese society.

Introduction

Autism spectrum disorder (ASD) encompasses a range of neurodevelopmental disorders that are characterized by the following core deficits: (1) impairments in social interaction and communication, and (2) restricted, repetitive behaviors [1]. Due to the child's significant needs, daycare availability may be limited, leading to a parent needing to stay at home [2]. Comparative research suggests that parents of children with ASD spend more time providing care for their children at home than those of children without special health care needs [3]. There is strong evidence suggesting that having a child with ASD in the household adversely affects the employment status of the parents [4,5]. In the United States, approximately 30%-50% of caregivers of children with ASD have completely ceased working [6]. Studies have shown that the employment of parents of children with ASD is disproportionately affected when compared to families with children who have other disabilities [7,8]. In 2-parent households, the employment of mothers is disproportionately affected [9,10]. In Europe and the

United States, mothers, compared to their partners, are more likely to hold part-time, lower-status positions that do not offer commensurate compensation corresponding to their educational qualifications [11-13]. A systematic review and a case-control study in Israel showed that working mothers of children with ASD were at increased risk of not maintaining their working status over the 5 years following their child's birth [14,15]. It reported that US mothers of children with ASD were less likely to be employed and earned 56% less than mothers of children without ASD; simultaneously, there was no significant impact on the fathers' labor market participation [4].

Globally, women's labor participation and outcomes still fall behind those of men, primarily due to persistent gender inequality resulting from the impact of childbirth [16], which can be seen as a "motherhood penalty" [17]. It can doubly penalize mothers of children with ASD, as they face challenges related to both gender and their child's condition. Variations in family policies and societal gender norms across countries contribute to diverse circumstances for mothers. Scandinavian countries such as Denmark and Sweden demonstrate the lowest levels of the "motherhood penalty," while the United Kingdom and the United States fall in the middle, and Germany and Australia have the highest penalties [18].

Cultural factors, such as the traditional concept of "men outside and women inside" commonly found in East Asian cultures [19,20], as well as the evolving social norms influenced by market economics that emphasize the contributions of both women and men in Chinese society [21], may contribute to variations in the Chinese context. From a societal standpoint, higher rates of female labor force participation within extended families were observable in China [22,23], which was less prevalent in Europe and the Americas [24]. In China, there are no guaranteed free services; the significant economic burden this represents may drive women to seek employment. However, inadequate educational and childcare resources, along with inflexible employment arrangements, may compel women to leave the workforce after having a child with ASD. Unfortunately, the limited available evidence from China prevents a thorough examination of this topic. The employment situation for families with children with ASD remains uncertain, particularly in terms of gender dynamics, and the underlying mechanisms are not fully understood. Gender disparities in employment can be elucidated through 2 theories. First, the specialization theory suggests that the division of paid and unpaid work is a rational contract between partners driven by utility maximization [25]. The partner with the lower salary is expected to do more housework. Second, the gender role perspective posits that the ability to balance work and parenthood is influenced by individuals' identities as moral beings within their culture [26]. Different cultures may vary in their approach to these issues. Gaining a better understanding of the situation in China is crucial, not only for informing policymaking within the country, but also for providing valuable insights into the cultural ramifications. There are many factors that affect whether caregivers work or not. Previous research has found that caregivers' labor force participation is influenced by both individual factors (eg, child age, caregivers' age, educational level, marital status, the severity of ASD symptoms, or caregivers' medical conditions) and the availability of childcare resources or perceived social support [4,27-29]. Compared to mothers of children without exceptional health care needs, US mothers of children with mild ASD and moderate/severe ASD had a 12% and 25% lower probability of being employed, respectively [30]. Although literature from other countries has provided valuable insights, current research in this area still has limitations. First, there is a lack of in-depth discussion on gender differences in employment. Many studies focus on the impact of caregiving from a female perspective, ignoring gender inequalities within families. As most of the caregivers in these studies were mothers of children with ASD, the results may not be generalizable to fathers [31]. Second, there is a need for a better understanding of the factors associated with the employment of both mothers and fathers. By examining the factors that influence employment, policymakers can better target interventions toward the most vulnerable populations. Third, most studies have had small sample sizes and have predominantly focused on very young children. A broader age span sample can help capture the situation of families at different stages.

Parental employment in families with children with ASD is an area of particular significance. The employment status of parents in these families plays a vital role in reducing family stress, accessing essential resources, and promoting the well-being of both parents and children [32-34]. In this study, the primary goal was to uncover the employment status of parents in families with children and adolescents with ASD. The second goal was to investigate the factors associated with employment of mothers and fathers caring for children with ASD in China. The following assumptions were made: (1) parents' employment decisions can be influenced by both parental and child traits, and (2) there are differences between the factors influencing fathers' and mothers' employment decisions. A comprehensive understanding of how these factors influence parental employment could inform the development of effective policies to support these families.

Methods

Participants

This study used secondary data from the Survey on Family Circumstances and Demand for Support and Resources among Autistic Children in China in 2020. It was a survey that was distributed to members of an online parent community of children with ASD or other developmental disorders in China. The questionnaire was designed to collect information on various aspects of the families. Parents were asked to provide information about their employment status, including current work status, work history, and any work adjustments made due to their child's needs. Additionally, parents reported on their child's diagnosis. The other details of the survey have been described elsewhere [5]. A pilot field study (N=20) was conducted to refine the instrument and data collection procedures, and the results indicated that respondents generally understood the questionnaire, so only minor wording changes were made.

Data Collection

Families with children diagnosed with ASD were recruited if they met the following criteria: (1) they were between the ages of 2 and 17 years and were diagnosed with or suspected (children under 3 years old cannot be officially diagnosed) of having ASD at a hospital, and (2) the hospital had diagnostic qualifications and followed a Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition standard, not only through scale measurement but also via diagnosis by a medical professional. Exclusion criteria were individuals with ASD with severe comorbidities such as physical disability and cerebral palsy. The samples with obvious errors or omissions were also excluded in this study. Regarding omissions, we used the following strategies: (1) we needed complete data for the major variables that were essential to our primary analysis, and (2) we permitted some missing data for secondary variables and used multiple imputation to account for these omissions. Any questionnaire with a missing data rate exceeding 33% was excluded from the analysis. For questionnaires with a lower missing data rate, we used multiple imputation to handle missing values in noncore variables, maximizing the retention of data information. There were 8014 households investigated, with 5018 (62.62%) households included. This survey's gender ratio and family location distribution were consistent with China's overall population distribution. In total, 31 Chinese provinces and 380 cities or districts were included (see Table S1 and Table S2 in the Multimedia Appendix 1 for details).

Measures: Assessments of Employment Status

When assessing workforce participation, we used the primary categories of "work" and "nonwork" (as a stay-at-home parent). We used the term "nonwork" in this study to refer to parents who were either unemployed or out of the labor force. In order to further distinguish the effects of different employment types, this study constructed 4 employment status variables, namely "full-time," "flexible," "overtime," and "a long leave of absence." Full-time work generally refers to a person being formally employed, working a minimum of 40 hours per week, and enjoying corresponding wages, social insurance, and welfare benefits (as described in the Labor Law of the People's Republic of China). Flexible work refers to employment for which working hours (usually less than 30 hours per week) or working places are not fixed. Overtime work refers to working more than 40 hours per week. We created 2 variables for full-time parents so as to understand the reason for nonwork: "caregiving resignation" and "other." Caregiving resignation meant that the parent resigned after their child was diagnosed with ASD and that they were taking care of the child. Resigning due to caregiving responsibilities, which is considered an "involuntary resignation" or "involuntary unemployment," was considered as being beyond one's control. "Other" refers to those who resigned before their child's diagnosis of ASD or those who remained unemployed for other reasons after the child's birth (see Table S3 in the Multimedia Appendix 1 for definitions). In other words, "not working" referred to the current employment status, including those who resigned due to childcare needs and those who were not working for other reasons (including those who never worked). "Resigning" specifically referred to leaving a job due to childcare needs for their child with ASD.

Socioeconomic and Demographic Variables

The age of the children was their age at the survey point. The age of the children was divided into four age groups: 2 - 5 years, 6 - 9 years, 10 - 13 years, and 14 - 17 years. The severity of ASD was judged according to professional evaluation or the parents' subjective judgment. There were four categories: low-functioning autism (LFA), middle-functioning autism, high-functioning autism (HFA), and undetermined. The regional variables were "eastern," "central," and "western." The provinces in the eastern region were among the first to implement the coastal opening-up policy and have a high level of economic development. The provinces of the central region are economically underdeveloped, while those of the western region are even less so. We classified family income into 3 categories. According to the data distribution, the below-average group had an annual income of less than US $12,327 (80,000 yuan), the around-average group had an annual income of between US $12,327 (80,001 yuan) and US $23,112 (150,000 yuan), and the above-average group had an annual income of more than US $23,112 (150,000 yuan). Whether the children's grandparents were able to provide assistance was one way to measure informal social supports, so "grandparents' assistance" was included. The term "physical health status" was used to describe negative physical health status. We asked respondents about their subjective physical status using a 5-point Likert scale with 1="Extremely poor," 2="Poor," 3="Average," 4="Good," and 5="Very good" in response to the following question: "How do you evaluate your physical health generally?" The question referred to the 4 weeks preceding the survey. The answers to the items were divided, with 2 being the cutoff score for poor physical health status. A single-item question was used in previous research [35]; this single item has been reported to be reliable. Other background information was collected on children's gender, whether they have comorbidities or not, and parents' education and marital status.

Statistical Analysis

The mean (SD) of normally distributed data was used. The comparisons of characteristics (categorical) were analyzed using χ^2 tests and the comparisons of characteristics (continuous) were analyzed using F tests. Logistic regression models were used to identify the factors influencing employment status. Associations between predictors and independent variables were reported using odds ratios (ORs) and their 95% CIs. Group comparisons were made between mothers and fathers. All the estimated costs were converted to US dollar (US $) values in January 2021, when US $1 was equivalent to about 6.49 Chinese yuan. All statistical analyses were conducted using SPSS for Windows (version 22.0; IBM Corp).

Ethical Considerations

All families provided electronic informed consent before enrollment. All procedures involving human subjects/patients were approved by the ethics committee of the Peking University Institutional Review Board (approval number IRB00001052-20016). The informed consent process clearly outlined the study's purpose, procedures, and potential risks, with participants retaining the right to opt out at any time. Participant data were anonymized using unique identifiers to protect individual privacy. No direct financial compensation was provided, and no identifiable features of research participants were included in any research materials.

Results

Sample Descriptive Statistics

In total, 5018 households were included in this survey (Figure 1). Most of the children (4227/5018, 84.2%) were boys, and the mean age was 5.3 (SD 2.6) years old, with the leading ASD severity being middle function (2030/5018, 40.5%). In addition, 18.2% (913/5018) of the children had comorbidities such as attention-deficit/hyperactivity disorder and epilepsy. Most of the parents had a college degree (3430/5018, 68.4%) and 31.1% (1563/5018) of the parents received assistance from the children's grandparents. Mothers had a lower rate of employment than fathers. This survey revealed disparities regarding whether parents were employed, classified by the severity of ASD, parents' education level, whether parents were single, whether grandparents could give assistance, family income, and other factors. The results of the group comparisons can be seen in Table 1. There were statistically significant differences between the working and nonworking groups for parents (*P*<.05). From the perspective of whether children had comorbidities, there was no statistically significant difference between the parent working and nonworking groups (*P*<.05). The study population is further described in Table 1.

Predictors of Employment for Fathers and Mothers

Mothers with children with HFA were more likely to be employed than mothers who had children with LFA (OR 1.94, 95% CI 1.46 - 2.56; Table 2). Mothers who had a high school education or less were 3.64 times more likely to be employed than mothers who had a college degree or above (OR 3.64, 95% CI 2.89 - 4.57). Single mothers had higher odds of having a job (OR 2.03, 95% CI 1.26 - 3.08). Having assistance from children’s grandparents’ meant that both mothers and fathers were more likely to be employed (mothers: OR 5.57, 95% CI 4.67 - 6.64; fathers: OR 2.31, 95% CI 1.39 - 2.84). Children’s gender and age were not significantly associated with mothers’ and fathers’ employment status.

[a] OR: odds ratio.

[b] LFA: low-functioning autism.

[c] MFA: middle-functioning autism.

[d] HFA: high-functioning autism.

Resignations

We found that 37.3% (1874/5018) of children's mothers were employed; of these, 12.4% (622/5018) had a flexible job, 4.6% (232/5018) took an extended leave, and 1% (49/5018) chose to increase working hours. However, the proportion of fathers working full-time was much higher (3537/4988, 70.9%), while 7.5% (372/4988) of fathers worked flexible hours and 14.9% (743/4988) of fathers worked overtime (Table 3). In addition, 3.4% (171/4988) of fathers took a long leave of absence. Only 3.3% (165/4988) of fathers were unemployed, with the majority citing child care as the main reason. We found that 2.8% (138/4988) of fathers and 54.3% (2723/5018) of mothers resigned because they needed to care for their child with ASD.

Mothers with children with HFA were less likely to resign to take care of their children than the mothers with children with LFA (OR 0.66, 95% CI 0.51 - 0.86). Mothers who had no college degree were less likely to resign to take care of their children (OR 0.58, 95% CI 0.49 - 0.69). Single mothers had lower odds of resigning to take care of their children (OR 0.50, 95% CI 0.32 - 0.80). Mothers with poor physical health were more likely to resign to take care of their children (OR 1.35, 95% CI 1.09 - 1.68). Having assistance from the children's grandparents meant that both mothers and fathers were less likely to resign (mothers: OR 0.26, 95% CI 0.21 - 0.30; fathers: OR 0.30, 95% CI 0.16 - 0.56). Assistance from grandparents was the only factor influencing the fathers' decision to resign in this model.

Taking "salary of the last job before resignation was higher than the average" and "previous income's proportion of the total household income was higher than average" as independent variables, the logistic regression for involuntary resignation showed that even when mothers had a higher annual income from their previous employment or previously earned a higher proportion of the total household income, they were more likely to involuntarily resign. However, there was no such trend for fathers (Table 4). When we compared salaries between spouses, we found that 45.3% (63/139) of fathers who resigned to care for their children earned more than their spouses before resigning. On the other hand, only 13.7% (373/2723) of mothers who resigned to care for their children earned more than their spouses before resigning.

Table . Characteristics of employment status and reasons for not being employed by gender.

Characteristics	Father (n=5018), n (%)	Mother (n=5077), n (%)
Work		
Full-time	3537 (70.9)	971 (19.4)
Flexible	372 (7.5)	622 (12.4)
Overtime	743 (14.9)	49 (1)
Long leave	171 (3.4)	232 (4.6)
Nonwork		
Caregiving resignation	139 (2.8)	2723 (54.3)
Other	26 (0.5)	421 (8.4)

Table . The logistic regression for the higher income and proportion of household income for involuntarily unemployed parents.

[d] Models 1-4 controlled the age of the children, autism spectrum disorder severity, children having comorbidities or not, parents having college degree or not, parents' marital status, and the family's residence region and annual income. Independent variables were the salary of the last job before resignation being higher than the average (1=yes, 0=no) and its proportion being higher than the average (1=yes, 0=no).

Discussion

Principal Findings

This study provided a comprehensive analysis of the employment status and factors influencing employment among mothers and fathers who cared for children with ASD in China. It is the first study to investigate the gender differences in influencing factors among Chinese parents. The results of the study highlight a notable disparity, indicating that females in China are more likely to be unemployed and more likely to resign from their jobs due to child care responsibilities compared to males. This trend persists even as the children grow older and reach school age.

This research has shed light on the existence of gender inequalities in employment within the context of caring for children with ASD. That having a child has an impact on the mother's job and career is not unusual, as evidenced by previous research [11,27,36-38]. Previous studies have reported that the employment rate for mothers of children with ASD was 67%, while for fathers, it was higher (92%) [14]. Additionally, it was found that 79% of fathers and 44% of mothers with children with ASD were engaged in full-time employment [39]. It is noteworthy that in China, the issue of gender inequality in employment may be particularly pronounced. In this study, it was found that only 37.3% of mothers of children with ASD were employed, while the employment rate for fathers was higher (96.7%). This finding was consistent with the trends found in previous studies [14,39], but the gender difference in employment rates was more pronounced. The employment rate for mothers in this study was even lower compared to previous findings from other countries for parents of children with developmental disabilities; for instance, the employment rates were reported as 49% in Japan [40]. The reasons could be summarized as a difference in cultures, diagnoses, and research designs. It should be noted that this study was conducted during the COVID-19 pandemic, a context that might have influenced our findings. The pandemic had a dual impact on employment opportunities for parents of children with ASD. First, the overall economic downturn might have reduced job prospects, particularly for those living in informal settlements who rely on informal, precarious employment with irregular income [41]. Second, increased caregiving demands, such as those resulting from school closures, might have further constrained these parents' employment options [42].

Utilizing data from the China Family Panel Study spanning the years 2010 to 2018, research found that the employment rate for women was 68.5%, whereas for men, it was 93.3% [43]. Similarly, based on national survey data, the employment rate for Chinese women was 66.7%, with a lower rate of 51.4% observed for women with children aged 0 - 3 years [44]. These findings highlight the disparities in employment rates between genders in China. The employment rate of women in our sample was lower than the average employment rate of women in China. Across nearly all age groups of children with ASD, the employment rate for mothers was below 40% in this study. The employment rate for fathers did not differ, suggesting that mothers were more likely to assume the primary caregiver role. These findings aligned with previous research that indicated that mothers were often the ones who exited the workforce when caring for a child with a disability [45,46].

For those mothers who were employed, they were less likely to work full-time or for longer working hours. Only 4.6% of mothers in this study took a long leave. In addition, while 15% of fathers reported working overtime, only 1% of mothers did. These findings highlighted the disparity in working hours and overtime between mothers and fathers. Fathers were still the primary breadwinners in their families. When a child has a disability, families must frequently make the difficult decision to have one parent leave their job to become the primary caretaker while the other parent continues to work. This decision is tough and challenging [47]. Two theories, namely the specialization theory proposed by Becker [25] and the gender role theory introduced by Finch [26], can help explain the gender inequalities observed in employment. Although our findings suggest that mothers' lower relative salary compared to their spouses may play a role in their decision to take on primary caregiving responsibilities, it is likely that a combination of factors—including cultural norms, personal preferences, and family circumstances—also influence these decisions. There is evidence supporting both theories. How individuals balance work and parenthood is also influenced by individuals' identities as moral beings within their specific culture. However, it is important to note that the applicability of this theory may vary across countries.

Some factors, including culture, household income, and women's role identity, can influence women's labor participation and types of participation, though the results are generally inconclusive [27]. In this study, we found that the severity of the ASD symptoms increased mothers' caregiving needs and thus decreased employment, which was consistent with previous findings that the more severe the child's condition, the more challenging it was for the parents to work [48,49]. For fathers, having children with more severe disabilities had little effect on their labor market participation, which was consistent with a previous finding [13]. There were similar findings in other studies [38,50]. The effect seems to be stronger among more educated mothers, signaling the existence of education inequalities in mothers, but not in fathers. Our study revealed that highly educated mothers were more prone to resign to care for their children. This was likely due to higher spousal incomes rather than a lack of social supports. In fact, these educated mothers were more likely to receive childcare assistance from the children's grandparents. Our findings indicated that mothers with higher previous incomes were more likely to resign involuntarily, while those with lower incomes tended to continue working. This trend raises concerns for families with children with ASD, particularly regarding reduced access to intensive early interventions and the potential negative impact of work-related stress on parent-child interactions in dual-income households.

Social supports were an important influencing factor for employment for parents. The assistance provided by grandparents had a significant impact on the decision to work, especially for mothers. In traditional Chinese culture, parents of children with ASD may tend to seek help from their family rather than from other sources [19,51], but this does support mothers' employment. In this study, we found that single mothers were more likely to work, supporting the previous finding that single mothers worked more out of economic necessity [52]. Single fathers, on the other hand, did not have this tendency to work more. One of the explanations for this was that fathers may face discrimination due to their single-parent status [53]. Another possible cause was Confucianism, which holds that men are superior to women. Fathers were more inclined to rely on their parents' resources, which alleviated financial concerns [54]. Although we did not explicitly measure discrimination and parental resources in our study, it was plausible that this phenomenon existed among our participants. Additional research is necessary to substantiate these claims.

Previous research found that mothers who experience involuntary unemployment tended to have a lower quality of life [48]. It emphasized the critical role of mothers in caregiving as well as the potential negative impact of additional caregiving responsibilities. In the short term, to care for their children, women may have to interrupt or leave their careers, which can hinder their professional development. In the long term, women may experience a decline in their social status and decision-making power within the family. More research is still needed to verify this hypothesis in the future.

When it comes to addressing gender inequalities, there are valuable practices that can serve as examples. One such instance can be observed in Australia, where the motherhood penalty had been severe. However, the government implemented a range of proactive family policies to address this issue. There was a notable policy focus on supporting parents in their return to the workforce as soon as they were able. This was achieved through various measures, including investments in the improvement of childcare systems and the provision of increased subsidies for working parents [28]. Family policies that promote a dual earner-dual carer model have played a pivotal role in raising female employment rates and reducing gender disparities in employment [55]. These policies have proven to be particularly beneficial for women with lower and moderate levels of educational qualifications.

Limitations

This study had a number of limitations. First, the sampling method was nonprobabilistic, relying on voluntary participation rather than random selection, which did not allow for control stratification in sampling. To improve future studies, we could use more robust sampling survey methodologies. Second, the design of the study prevents the establishment of causal relationships. We can only test correlations between influencing factors and parental employment. This research would benefit from more sophisticated modeling techniques to investigate the ways in which the variables interact. Third, the data regarding the severity of the ASD symptoms was not professionally approved using the validated scales but rather was based on parental reports. Improved symptom classification will facilitate the creation of more appropriate aids. Fourth, although parents of children with ASD share some commonalities with parents of children with other disabilities, it is not clear whether the current findings are applicable outside of this particular case. Further research is needed to understand the extent to which these differences are related to the structure and arrangement of services. Fifth, the data collection for this study was completed during the COVID-19 pandemic, which may have affected the generalizability of our findings. Although the results provide insights into the situation during this period, they may not fully represent the typical employment experiences of these parents under normal circumstances. Future research comparing prepandemic, mid-pandemic, and postpandemic data would be beneficial to differentiate between the pandemic's specific effects and the longer-term employment trends for this population.

Conclusions and Implications

This research examines employment and factors that affected fathers' and mothers' employment decisions. Our data show that a considerable proportion of mothers choose not to work, suggesting that women bear the majority of caring obligations. Gender inequality in employment exists in China and it is more pronounced than that in Western countries. The shortcomings of public assistance, the rigidity of the paid workforce regarding family medical leave, and the absence of compensation for informal care work make it challenging for women, particularly low socioeconomic status women, to find jobs. Policymakers should provide the necessary welfare supports, particularly for mothers caring for children with severe disabilities, allowing them to work fewer hours and offering a more flexible schedule or leave policy. Coordinating care for the entire family may result in improved health and economical outcomes. More maternal health care and social supports are required to increase the workforce involvement and well-being of these mothers. Furthermore, more research is needed to investigate the roles of fathers. A stronger gender equality ideology and more women-friendly policies are needed not only in China but around the world.

Abstract

Background: Childhood mental health issues concern a large amount of children worldwide and represent a major public health challenge. The lack of knowledge among parents and caregivers in this area hinders effective management. Empowering families enhances their ability to address their children’s difficulties, boosts health literacy, and promotes positive changes. However, seeking reliable mental health information remains challenging due to fear, stigma, and mistrust of the sources of information.

Objective: This study evaluates the acceptance of a website, CléPsy, designed to provide reliable information and practical tools for families concerned about child mental health and parenting.

Methods: This study examines user characteristics and assesses ease of use, usefulness, trustworthiness, and attitude toward using the website. Platform users were given access to a self-administered questionnaire by means of mailing lists, social networks, and posters between May and July 2022.

Results: Findings indicate that the wide majority of the 317 responders agreed or somewhat agreed that the website made discussions about mental health easier with professionals (n=264, 83.3%) or with their relatives (n=260, 82.1%). According to the ANOVA, there was a significant effect between educational level and perceived trust (F_6=3.03; P=.007) and between frequency of use and perceived usefulness (F_2=4.85; P=.008).

Conclusions: The study underlines the importance of user experience and design in web-based health information dissemination and emphasizes the need for accessible and evidence-based information. Although the study has limitations, it provides preliminary support for the acceptability and usefulness of the website. Future efforts should focus on inclusive co-construction with users and addressing the information needs of families from diverse cultural and educational backgrounds.

Introduction

Childhood mental health (MH) issues concern up to 13.4% of children worldwide [1] and represent a major public health challenge [2]. However, parents’ and caregivers’ lack of knowledge in this area constitutes a major obstacle to their management of these issues [3]. Child and adolescent MH has substantially worsened in recent years, especially during the COVID-19 pandemic, notably in girls and vulnerable populations such as families with low income or children and adolescents with pre-existing MH difficulties [4].

The World Health Organization has promoted a shift from patient-centered health to family empowerment as a catalyst for health development especially in chronic diseases. This switch involved providing families with tools to understand their rights regarding health care and how to access health services [5]. For example, patient empowerment is known to enhance health literacy in people with diabetes through increasing expression, self-judgment, and critical thinking, especially communicative health literacy and critical health literacy that relies on interaction and communication skills [6]. Parent health literacy was also considered an essential element in minimizing childhood obesity in a meta-analysis [7]. In the specific case of MH, family empowerment is a mediator for positive changes by enabling better management of children's difficulties and providing a greater sense of confidence in parental problem-solving abilities, facilitating the resolution of future MH challenges [8].

Health literacy encompasses knowledge that helps individuals achieve and maintain good health, including the identification of symptoms and the ability to understand and evaluate health-related information effectively. More specifically, MH literacy has been defined as "understanding how to obtain and maintain positive MH; understanding mental disorders and their treatments; decreasing stigma related to mental disorders; and enhancing help-seeking efficacy" [9]. Parents and caregivers are in demand of MH knowledge—especially those concerned by previous experiences with MH. However seeking help and information might be limited by fear, stigma, and mistrust of the sources of information [10]. Indeed, the lack of MH knowledge and the stigma attached to mental impairments constitute major obstacles to health care access [11]. When faced with psychiatric difficulties in their children, many parents express a lack of knowledge and the necessary skills to address these issues effectively [12]. Consequently, almost all parents (96%) turn to online sources to find answers to health-related questions in general, with MH and parenting being the most frequently searched topics [13]. However, a study examining French-speaking MH websites conducted by Buteau-Poulin et al [14] revealed that only 43% of dedicated websites provided scientifically reliable content. Among these websites, only 42% addressed autism, 45% addressed learning disorders, and merely 10% covered language disorders and behavioral problems. Furthermore, MH information websites often employ language that exceeds the average parent's comprehension level [15].

Better functional and communicative health literacy was associated with reduced stigma and reluctance to seek MH support among adults [16]. Digital health interventions in particular have the potential to be an effective—and cost-efficient—method for increasing parental knowledge regarding MH difficulties in their children and adolescents. These interventions can assist parents in assessing valid information and understanding the organization of psychiatric services [17]. In line with this goal of supporting children and their families, we launched a website in March 2020, intended for families of children with MH disorders in the context of the first French lockdown during the COVID-19 pandemic. This website provides evidence-based knowledge on MH topics, practical tool kits, and know-how to deal with children's everyday difficulties. CléPsy is divided into categories (general information, anxiety and affective disorders, attention-deficit/hyperactivity disorder [ADHD], intellectual development disorder, addictology, autism spectrum disorders, language/learning disorders, and eating disorders). Examples of pages include information about augmentative and adaptive communication for children with autism spectrum disorders and how to use it, what early signs of ADHD should parents be aware of, or the mechanisms and risk factors of eating disorders. Authors are identified on each page and sources are mentioned when needed.

The main purpose of this study was to evaluate users' general acceptance of the design and the content of CléPsy, a website dedicated to helping families concerned with child MH through information and practical tools. A secondary objective was to evaluate the effect of users' characteristics on general acceptance.

Methods

Creation of the Online Platform

The first version of the website [18] was created and released in March 2020 by the authors of this paper as a rapid response to the MH concerns raised by families in the context of the COVID-19 crisis. A later version (rebranded as CléPsy [19]) was designed by a team of professional web developers and made available as of January 2021. The developer team sought general feedback from families and other website users to guide their strategy but did not implement specific focus groups. Since then, the platform has offered varied content covering a large array of MH topics in French. The content of the website was produced by the multidisciplinary staff of the Center of Excellence for Neurodevelopmental Disorders (Robert Debré Hospital, Paris), submitted to a proofreading committee, and had to follow specific editorial standards based on the eEurope 2002 Quality Criteria for Health Related Websites [20].

Questionnaires and Study Participants

A self-directed survey was made available through various methods between May and July 2022. First, the survey was directly sent to the CléPsy mailing list newsletter subscribers, which is usually used to give information about new content. Second, the survey was shared on social networks (Facebook, Twitter, and LinkedIn). Finally, posters with a QR code leading to the survey were displayed in Robert Debré Hospital. This web-based survey verified the recommendations of CHERRIES (Checklist for Reporting Results of Internet E-Surveys) for web survey quality [21] and was adapted from the questionnaire developed by Tlach et al [22] for the German e-portal Psychenet [23] and translated to French. The open survey was displayed on Lime Survey, and information about the aim and length of the survey was given before participants were asked if they consented to answer. No incentive was used to promote answering, and IP addresses were used to avoid multiple responses by the same visitor. The questionnaire first explores the baseline characteristics of respondents: age, gender, location, and educational level, as well as respondents' experience with MH. In a second acceptance/usability–related section, we used a 4-point Likert scale (1=disagree, 2=somewhat disagree, 3=somewhat agree, 4=agree) to explore four dimensions: "Perceived ease of use," which refers to the readability, design, and accessibility of the website; "Perceived usefulness," which refers more specifically to the content and how it helped participants; "Perceived trustworthiness," which is about how much the information on the website seems trustworthy and up to date; and finally, "general attitude toward the website" had questions about the tendency to recommend the website to others or to revisit it.

Web Analytics

Google Analytics was used to determine the number of connection sessions since the launch of the website as well as demographic information about the visitors, including the countries and cities associated with the users, the frequency and recency of the sessions, and the top site contents viewed. Google Analytics is a widely used web analytics service offered by Google that tracks and reports website traffic.

Data Analysis

The collected data on user characteristics and acceptance were analyzed on JMP statistical software (V17.0; JMP Statistical Discovery LLC). Our analysis was based on a similar work conducted by Tlach et al [22]. Only complete answers were analyzed. Means, SDs, and frequency distributions were calculated for each item to quantify the response. A total score for each of the four dimensions was calculated by summing the Likert score of all items in this dimension. One-way ANOVAs were conducted for interval-scaled variables (total scores of the four dimensions of acceptance and usability) to explore the effects of distinct participant characteristics (gender, age, educational level, experience with mental disorders, frequency of use) on the acceptance and usability of the website. A *P* value <.05 was considered to be significant for all analyses. The significance level was not adjusted as the tests served to generate hypotheses.

Ethical Considerations

This study was submitted to and approved by the local Assistance Publique - Hopitaux de Paris ethics board (2021 - 588).

Results

Overview

From May to July 2022, 53,911 pages were visited on CléPsy by 20,513 independent visitors. Among them, 693 (3.4%) accessed the web-based questionnaire and 614 (3%) consented to participate. Among these 614 respondents, half responded completely (n=317, 51.6%), of which almost all were female (n=297, 94%) with an average age of 46.2 (SD 10.1) years. We observed that 63.1% (n=200) of the complete respondents were MH professionals and 65.6% (n=208) were highly educated (master’s degree or a doctorate). Almost all respondents used the internet daily (n=298, 94%), and 49.2% (n=156) learned about CléPsy through social networks. Finally, 60.6% (n=192) of respondents visited CléPsy >5 times (Table 1).

Participants’ responses to the four dimensions are summarized in Table 2.

Table . Descriptive characteristics of access paths and website use (n=317).

Variable		Participants
Gender (female), n (%)		297 (94.0)
Age		
	Participants, n (%)	297 (94.0)
	Years, mean (SD)	46.2 (10.1)

Table . User rating on perceived ease of use, perceived usefulness, attitude toward using the portal, and perceived trust (n=317).

Variables		Agree, n (%)	Somewhat agree, n (%)	Somewhat disagree, n (%)	Disagree, n (%)
Perceived ease of use					
	The font of the website is easy to read	176 (55.5)	129 (40.7)	8 (2.5)	4 (1.3)
	The website is easy to use	152 (48.0)	152 (48.0)	8 (2.5)	5 (1.5)
	The presentation of the information is clearly arranged	141 (44.5)	151 (47.6)	19 (6.0)	6 (1.9)
	The information is easy to understand	184 (58.0)	121 (38.2)	8 (2.5)	4 (1.3)
	The design of the website is appealing	146 (46.1)	158 (49.8)	10 (3.2)	3 (0.9)
	The colors of the website are pleasant	168 (53.0)	132 (41.7)	15 (4.7)	2 (0.6)
	The pictures on the website are appropriate	143 (45.1)	159 (50.2)	13 (4.1)	2 (0.6)
	I can quickly find the information that is important to me	124 (39.1)	162 (51.1)	28 (8.9)	3 (0.9)
Perceived usefulness					
	The content of the website is interesting	224 (70.7)	87 (27.4)	2 (0.6)	4 (1.3)
	All in all, the website is useful for me	196 (61.8)	112 (35.3)	5 (1.6)	4 (1.3)
	The amount of information presented on the website is appropriate	158 (49.8)	138 (43.5)	17 (5.4)	4 (1.3)
	The website contains information that I need	157 (49.5)	141 (44.5)	17 (5.4)	2 (0.6)
	The information on the website has helped me with my concerns	152 (48.0)	148 (46.7)	14 (4.4)	3 (0.9)
	Through the website, I received references to other sources	114 (36.0)	160 (50.5)	41 (13.0)	2 (0.6)
	Through the website, I learned something new	145 (45.7)	145 (45.7)	23 (7.3)	4 (1.3)
	Now I’m able to talk better about mental disorders with my health professional	105 (33.1)	159 (50.2)	51 (16.1)	2 (0.6)
	Now I’m able to talk better about mental disorders with my relatives	101 (31.9)	159 (50.2)	54 (17.0)	3 (0.9)
Attitude toward using					
	I would recommend the website to others	232 (73.2)	76 (24.0)	5 (1.6)	4 (1.2)
	I will revisit the website if needed	249 (78.5)	62 (19.6)	2 (0.6)	4 (1.3)
Perceived trust					

Variables		Agree, n (%)	Somewhat agree, n (%)	Somewhat disagree, n (%)	Disagree, n (%)
	The information on the website is trustworthy	231 (72.9)	77 (24.3)	6 (1.9)	3 (0.9)
	The information on the website is up to date	184 (58.0)	120 (37.9)	10 (3.2)	3 (0.9)

Perceived Ease of Use

Almost all participants (n=304, 96%) stated that the website was easy to use, with 90.2% (n=305) indicating that they could easily find the information important to them. Additionally, 96% (n=304) found the design appealing. None of the main participants' characteristics had a specific effect on the perceived ease of use (Table 3).

Table . Effects of participants' characteristics on the perceived ease of use (n=317).

Perceived Usefulness

The majority of respondents agreed or somewhat agreed with the statement "All in all, the website is useful for me" (n=308, 97.1%). A significant percentage agreed or somewhat agreed that the website facilitated discussions about MH with professionals (n=264, 83.3%) or with their relatives (n=260, 82.1%). According to the ANOVA, there was a significant effect between frequency of use and perceived usefulness (F_2=4.85; *P*=.008; Table 4).

Table . Effects of participants' characteristics on the perceived usefulness (n=317).

Perceived Trust and General Attitude Towards Using CléPsy

The vast majority of respondents described the website as trustworthy (n=308, 97.3%) and up to date (n=304, 95.9%), and would recommend it to other people (n=308, 97.2%). None of the main participants' characteristics had a specific effect on their attitude toward using CléPsy (Table 5). According to the ANOVA, there was a significant effect relating perceived trust with the educational level (F_6=3.03; P=.007) and the frequency of use (F_2=5.30; P=.006; Table 6).

Table . Effects of participants' characteristics on attitudes toward the website (n=317).

Discussion

Principal Findings

In this web-based study, we investigated the acceptance of the design and content of a new website dedicated to children's MH information with the aim of gaining a better understanding of active users and areas for improvement to reach target users more effectively.

Among complete responders (n=317), almost all agreed (n=152, 47.9%) or somewhat agreed (n=152, 47.9%) with the affirmation that the website was easy to use. Those results were in line with previous studies exploring the ergonomics of online MH information. When evaluating the Psychenet website, Tlach et al [22] found equivalent rates of perceived ease of use. Engagement and perceived ease of use were equivalent regarding the Together for Wellness website, developed during the COVID-19 pandemic [24]. A preference for English and higher behavioral changes during the pandemic were predictors for higher comfort in using the Together for Wellness website. Concerning the design of the CléPsy website, most participants evaluated the font, the colors, the presentation of information, the illustrations, and the accessibility of information positively. User experience (UX) is an important feature of online MH information, and it can be a major barrier for end users [25]. In our study, perceived ease of use did not differ with participants' characteristics. This underlines the importance of working with UX and design professionals to create state-of-the-art internet navigation interfaces that are easy to use. This is especially true when implementing online health information.

The usefulness of the CléPsy website was largely appreciated by the respondents. This could be in line with an almost complete lack of accessible digital information about child and adolescent MH written in French. Furthermore, two-thirds of French people believe that digital tools can help them better understand health care strategies [26]. This is especially the case for MH information, which is one of the main topics researched by parents online when they are looking for pediatric health information [13]. Parents could also be more aware of their children's difficulties with the increasing awareness of MH issues in children and adolescents, especially since the COVID-19 pandemic [27]. For example, the online search for ADHD information has been increasing for several years, which could partially be explained by destigmatization induced by media coverage [28]. The perceived usefulness had a positive influence on the user's ability to discuss MH with health professionals (including their general practitioners) or family members. Indeed, as reported in a systematic review by Kubb and Foran [29], most parents expressed difficulties in talking to their physicians about health information found online. The main reasons expressed by parents for not talking to the physicians were a lack of time, a fear of disapproval, or difficulties in understanding technical medical terminology. Interestingly, physicians express reservations on the subject. In a qualitative study, Karatas et al [30] explored the main attitude of pediatricians confronted with eHealth-based questions. Most of them expressed concerns about inaccurate health information that could lead to detrimental decisions by families. They highlighted an increased length of consultations to answer the questions but acknowledged that it helped build a more collaborative relationship with parents. In our study, most respondents were MH professionals. This could reflect a need for regular updates on practices, especially regarding evidence-based interventions, even if the therapist's behavior seems to change not only with information but also with specific training [31]. A quantitative study confirmed the positive and bidirectional influence of the perceived usefulness of eHealth information on patient-physician interaction and trust [32]. From the patient's perspective, it enriches participation and cooperation through enhanced resource integration, and from the physician's perspective, it can improve the patient's understanding and the relationship.

The CléPsy website was considered trustworthy by 97.2% (n=308) of respondents, but ANOVAs found an effect of educational level on the perceived trust, contrary to the evaluation of Psychenet by Tlach et al [22]. Parents generally have difficulties evaluating the trustworthiness of their source of information when searching for child health information [33], but most of them would like health care professionals to help them identify reliable sources [34]. When parents from Switzerland were asked about their relationship to online health information seeking, most of them were skeptical about the correctness of the information, but one-third of them did not, or rarely, check the reliability of the website [35]. Interestingly, first-time parents and parents with high levels of education made higher use of web pages targeted at parents. Trust in online health information is predicted by sociodemographic factors such as higher income and educational level [36], but online information remained the least trusted source, behind media sources and interpersonal information.

Limitations

This study must be considered with regard to several limitations. First, contrary to our expectations regarding the main audience, the majority of respondents were MH professionals, whereas the website was created to address inquiries from families. Furthermore, a significant proportion of respondents had a high level of education (master's or doctorate). This may be attributed to the distribution method of the questionnaire, in particular via professional social networks, and to the institutional credibility of the Center of Excellence for Neurodevelopmental Disorders in France. In our analysis, the characteristics of the respondents did not have any effect on their answers. Considering the accessibility and usability of health websites, the literature shows that primary users and MH professionals tend to have the same opinion [37]. MH professionals could also be interested in our website due to the necessity to get valid information about the state-of-the-art practice in MH. Indeed, an important part of the French psychology curriculum is dedicated to psychoanalysis. Future studies would need to consider the differences between these audiences. Moreover, the representativeness of the respondent must be interpreted with caution as the response rate was very low compared to the total number of users during the same period. Second, the CléPsy website was created initially to address families' questions about their children's MH at the onset of the COVID-19 pandemic and facilitate the transmission of relevant content. However, due to this unique timeline, the current version of the website insufficiently meets the standard framework that recommends the co-construction of health information websites together with families and other users [38]. Focus groups with families have since been held by our team along with the UX professionals, resulting in a qualitative evaluation of parents' needs. Third, as expressed by Tlach et al [22], there is a lack of standardized instruments to evaluate the acceptability and usefulness of digital content, which limits comparison. However, the questionnaire was designed based on recent recommendations such as the CHERRIES checklist. Finally, adverse effects of online health information seeking such as cyberchondria were not evaluated and should be taken into account in further research [39].

Conclusion

Our study provides preliminary support for the acceptability and usefulness of a French MH information website dedicated to children and adolescents. Results show that users are in demand of trustworthy information on this matter. In the future, special attention should be given to the co-construction of such websites with concerned users to improve the pertinence, inclusiveness, and accessibility of the contents to a wide and varied public. Moreover, parental role and child diagnosis should be identified in future research.

Abstract

Background: Web-based self-help (WASH) has been found to be effective in the treatment of child externalizing behavior disorders. However, research on the associations of caregivers' use of WASH and symptom changes of child externalizing behaviors is lacking.

Objective: This study examined the longitudinal and reciprocal associations between the use of WASH by caregivers of children with externalizing behavior disorders and their children's externalizing behavior symptoms.

Methods: Longitudinal data of 276 families from 2 intervention conditions of a randomized controlled trial (either unguided or supported by a therapist over the phone) were analyzed. Caregiver- and clinician-rated child externalizing behavior symptoms were assessed before (T1), in the middle (T2), and after the 6-month WASH intervention (T3). Additionally, 2 indicators of the caregivers' use of the WASH intervention were considered: number of log-ins (frequency) and the percentage of completed material (intensity). Associations of caregivers' use during early (T1-T2) and late (T2-T3) treatment with child externalizing behavior symptoms were analyzed using path analyses (structural equation modeling).

Results: Frequency and intensity of use were higher during the first 3 months than during the next 3 months of the intervention period. The number of log-ins at early treatment was significantly but weakly associated with caregiver-reported child externalizing behavior symptoms in the long term (T3). Moreover, caregiver-reported child externalizing severity at T2 predicted the number of log-ins in the late treatment. The results were not replicated when considering the percentage of completed material as a measure of use or when considering clinician ratings of child externalizing behavior symptoms.

Conclusions: The findings provide the first, albeit weak, evidence for longitudinal associations between caregivers' use of WASH and improvements in caregiver-rated child externalizing behavior symptoms. However, as the associations were rather weak and could not be replicated across different rater perspectives and operationalizations of use, further research is needed to better understand these relations and their interplay with other putative influence factors (eg, quality of the implementation of the interventions, changes in parenting behaviors).

Introduction

Parenting interventions have been shown to reduce oppositional defiant behavior problems in children [1,2]. Behavioral parent management training (PMT) has led to a reduced number of problematic situations of caregiver-child interactions reported by caregivers of children with attention-deficit hyperactivity disorder (ADHD) [3]. Although previous research has demonstrated both self-directed and face-to-face PMT to be effective in reducing child externalizing behavior disorders, outcome ratings of PMT vary across different assessors (eg, parents, clinicians, objective observations), with stronger evidence for PMT in caregiver reports [4,5]. Improvements have been reported by caregivers (completers) for conduct problems (P=.001) and hyperactivity symptoms (P<.001) [6]. Moreover, it remains unclear what drives symptom-related improvements: Although some studies indicate that parental attendance and engagement in face-to-face PMT are associated with greater symptom reduction for disruptive behavior, ADHD, and oppositional defiant disorder (ODD) symptoms [7], others indicate no differences in child behavior outcomes between mothers who complete versus mothers who drop out of PMT [6]. In a systematic review of preventive child mental health programs, higher levels of caregiver participation engagement (CPE) were associated with greater improvements in child internalizing and externalizing behavior symptoms [8]. Additionally, parental outcomes (eg, warm interactions, reduced physical punishment) seem to be associated with the quality of participation (rated by a therapist, eg, completion of between-session homework or the amount of participation in the group) rather than with mere attendance in PMT for conduct problems [9].

Web-based PMT is an easily accessible treatment alternative to face-to-face PMT, with proven effectiveness in the treatment of, for example, externalizing behavior disorders [10,11] and anxiety disorders [12]. There is evidence for the efficacy of web-based PMT regarding the reduction in conduct disorder and ADHD symptoms, with mostly small-to-moderate effect sizes [13-18]. However, self-help interventions often fail to keep caregivers engaged, rendering them difficult to complete [19,20]. In a 3-arm randomized controlled trial (RCT), we demonstrated that web-assisted self-help (WASH) combined with therapist telephone support (Döpfner et al, unpublished data, August 2024) is superior to routine clinical care, as well as WASH alone, in reducing clinician-rated child externalizing behavior symptoms [21]. Compared to face-to-face therapy and in line with other research on online interventions, our study revealed a relatively low intensity of use (average 35%), although the majority of participants (89.4%) logged in to the intervention at least once [22].

Considering self-directed interventions based on booklets for caregivers of children with externalizing behaviors (eg, booklets), parental adherence is associated with improved child externalizing behaviors [23]. Research on attrition and usage provides indications that more frequent users of eHealth report a decline in their perceived burden compared with an increased perceived burden reported by nonusers [24]. Regarding web-based PMT for caregivers of children with anxiety and depressive symptoms, parental engagement (defined as stronger orientation toward recommended use, ie, task completion) predicted (caregiver-rated) preventive parenting and lower impairment in the child's quality of life [25]. However, parental engagement did not predict changes in (caregiver- and child-reported) internalizing symptoms. By contrast, the self-reported frequency of practicing skills (during the "Cool Little Kids" online program) was associated with a greater decrease in child anxiety symptoms [12].

Conversely, children's severity of externalizing behaviors at baseline for the intervention on which this research is based has previously been found to be 1 of the predictors for the use of WASH [22]. There is evidence that parental perception of the severity of a child's symptoms is predictive of their help-seeking behaviors [26]. However, factors that are associated with parental engagement in children's mental health treatment have yielded divergent results, with some research indicating, for example, child mental health symptoms as a predictor for parental engagement and others not [8,27].

Clearly, the actual use of web-based interventions is a prerequisite for their efficacy. To date, there is no common sense of how the use of web-based interventions is conceptualized and operationalized, with measures ranging from direct measures (ie, self-report) to objective measures (ie, automatic data tracking of, eg, the number of log-ins) [28]. In the context of face-to-face treatment, the terms "engagement," "participation," and "adherence" are often used interchangeably; however, they include different therapy-related behaviors, from active participation during a session to practice implementation between sessions (eg, practically adapting parenting behaviors) [27]. In a systematic review, the most commonly reported measure for adherence is the number of log-ins to e-therapies [29]. However, a unidimensional operationalizing of the term's use has been criticized by researchers [30,31]; for example, one can often log in to the intervention (frequency), while making little progress (intensity) in the intervention. These parameters, though, seem to be associated with one another [22,27].

To the best of our knowledge, no study on web-based PMT for child externalizing behaviors has analyzed the relationships between parental use and changes in child externalizing behavior symptoms. Moreover, associations between the use of online interventions and symptom changes have rarely been examined in other child mental health conditions. The few available studies differ regarding the type of intervention (eg, preventive program, booklet self-help, face-to-face group PMT), the target group (affected individuals, mostly adults, vs parents), operationalization of treatment use, outcome measures, and how outcome measures are assessed. In behavioral face-to-face PMT, research on the association between attendance and child externalizing symptom severity has yielded divergent results [8,27].

This study took an exploratory approach to examine the longitudinal and reciprocal associations between the use of WASH and child externalizing symptom severity using 3 subsequent assessment points of child externalizing behavior symptoms and in-between assessments of WASH uses. Although it might seem self-evident that the actual use of an intervention is a prerequisite for it to affect child externalizing behavior symptoms, previous research has yielded mixed findings in this regard [8,27]. Thus, we did not formulate specific a priori hypotheses for possible associations. Moreover, as a previous study using baseline data of the same data set as this study demonstrated the predictive value of baseline symptom severity for the subsequent use of WASH [22], we also exploratively examined longitudinal associations between previous symptom severity and subsequent use. As the agreement of different raters on child externalizing symptom severity is typically only low to moderate [4,5], we considered both caregiver and clinician ratings of child externalizing behavior symptoms to obtain a more comprehensive impression of their associations with use. Moreover, as previous research has often been criticized for considering only 1 possible measure of use, we considered both the number of log-ins (frequency of use) and the percentage of completed materials (intensity of use) to operationalize use. However, we chose to consider the number of log-ins for our primary analyses, as this is the measure most often used in previous research [29]. The study was based on the use of WASH PMT in terms of automatically tracked objective measures (number of log-ins, percentage of processed content) of using an online treatment, in which caregivers are free to take an interest-based approach in processing the training [22]. Findings for associations between the percentage of completed materials and child externalizing behavior symptoms are presented in a supplementary manner. The ultimate aim is to provide a basis for improving internet-delivered interventions, in turn contributing to the further development of an effective therapeutic supply for children with externalizing behavior disorders.

Methods

Study Design

Data for the analyses were collected as part of an effectiveness study on WASH [21]. The research compared 3 study conditions: (1) WASH alone, (2) WASH plus telephone-based support (WASH+SUPPORT), and (3) treatment as usual (TAU). The analyses included data from the first 2 conditions only. There were no restrictions regarding the use of further treatment options during study participation.

The RCT from which data for the analyses were gathered was registered at the German Clinical Trials Register (identifier: DRKS00013456; registered on January 3, 2018).

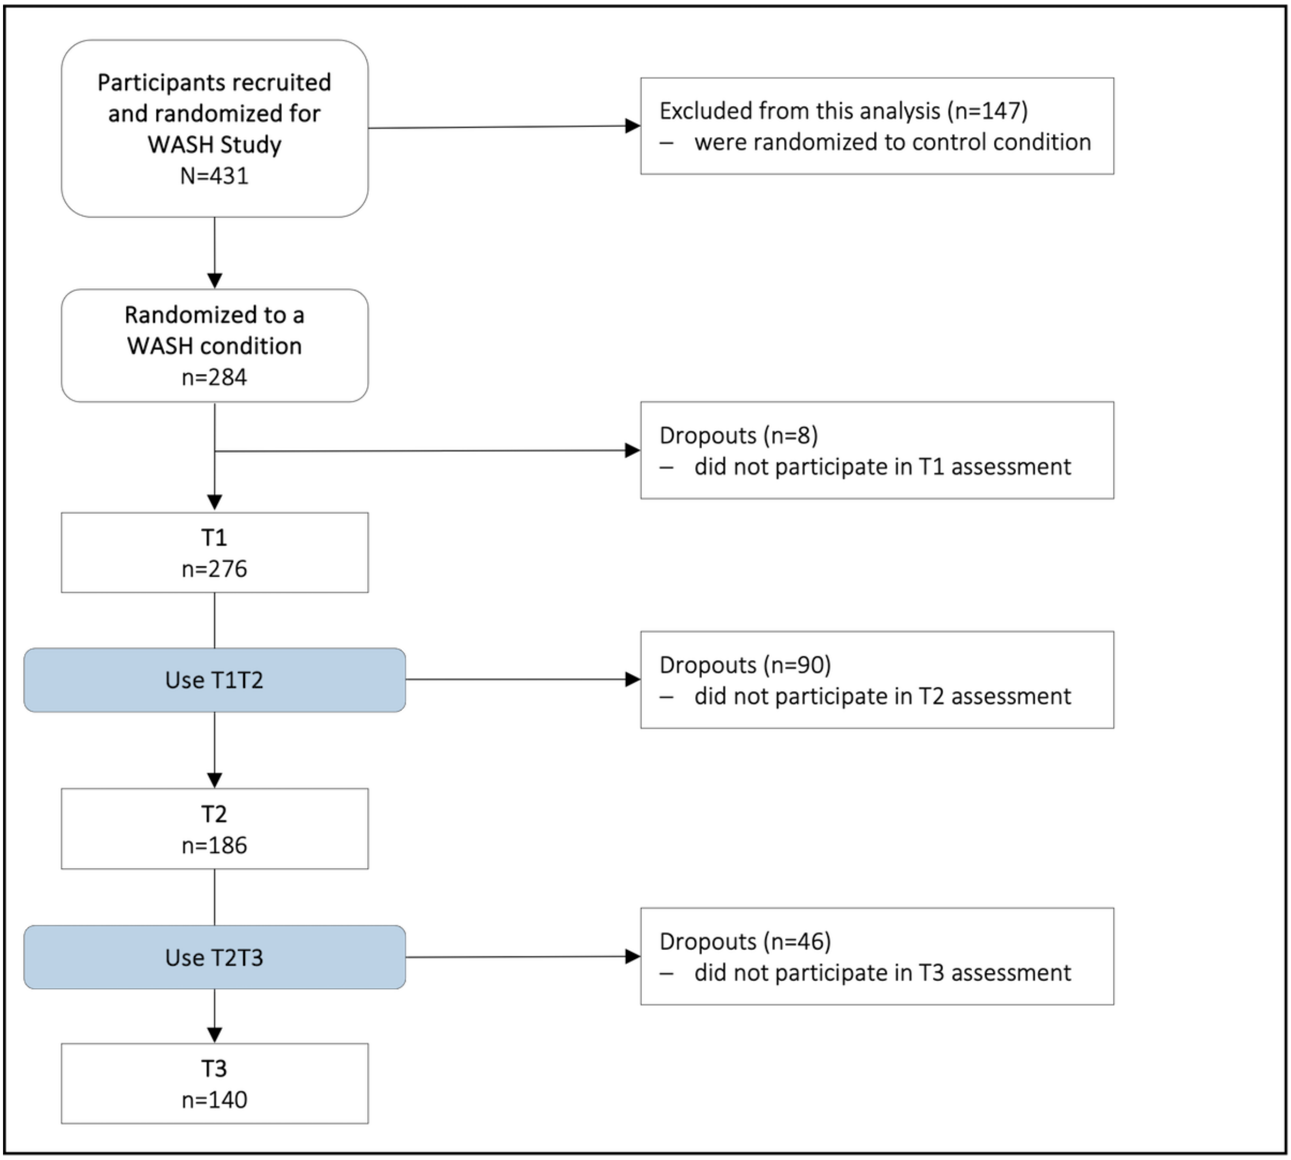
Ethical Considerations

This study was approved by the Ethics Committee of the Medical Faculty of the University Hospital Cologne (Germany; approval number: 17-273) and was performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki and its later amendments. All participating caregivers provided written informed consent before randomization.

Participants

Participants were caregivers of children with externalizing behavior symptoms. The inclusion criteria were child age between 6 and 12 years and elevated levels of ADHD or ODD symptoms at the first assessment point (clinician rated during the caregiver interview). A diagnosis of mental retardation or autism spectrum disorder or an indication for inpatient treatment led to exclusion from the study. For subsequent analyses, we used a subsample of 276 caregivers who were randomized to the 2 intervention conditions: WASH (n=135, 48.9%) and WASH+SUPPORT (n=141, 51.1%); see Figure 1. Participating caregivers (n=147) in the control condition (TAU) were excluded from the analyses as they did not use the intervention, and thus, we could not assess use in this group.

Figure 1. Participant flow. Note. T1: before the intervention; T2: in the middle of the intervention; T3: after the 6-month intervention; WASH: web-based self-help.



Intervention

The online intervention was based on previous manual-based self-help programs that have proven effective in reducing children's ADHD or ODD symptoms [32-34]. The WASH intervention comprises 4 modules: solving behavioral problems, positive relationship with your child, self-care, and psychoeducation. We provided recommendations regarding usage, but caregivers were generally free to navigate the program according to their interests. Participants in the WASH+SUPPORT group received up to 6 support calls from a trained and supervised professional. A detailed description is provided in the published study protocol [21]. Participants in both study conditions received reminders if they had not logged in within 5 days after randomization. Users in the WASH group were then free to use the program and were contacted for assessment (12 weeks, T2; 24 weeks, T3 after T1). Although there was a significant overall intervention effect on child externalizing behaviors, as rated by a blinded clinician (Döpfner et al, unpublished data, August 2024), the superiority of the WASH+SUPPORT condition over the WASH condition, revealed by subsequent pairwise comparisons, was compensated in this analysis by using the condition as a covariate.

Measures

Data were collected using a semistructured, telephone-based caregiver interview by a trained clinician and caregiver-rated online questionnaires before the intervention (T1), at a 3-month interim assessment point during the intervention (T2), and after the intervention (ie, at 6 months, T3).

Child Externalizing Behavior Symptoms

At each assessment point, a clinician rated the child's externalizing behavior symptoms based on a semistructured interview with the participating caregiver ("Diagnostic Checklist for Externalizing Behavior Disorders," DCL-EXT), conducted over the phone [35]. The interview covered ADHD symptoms (18 items) and ODD symptoms (8 items) according to the *International Classification of Diseases, 10th Revision* (*ICD-10*) and the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) and has been proven to be a high-quality diagnostic instrument for externalizing behavior disorders [36].

For our analyses, an overall externalizing symptom score was calculated by averaging all item scores. In the study sample, the internal consistency of this score was satisfactory (Cronbach α=.79).

Corresponding to the clinician ratings, at each assessment point, caregivers rated their children's externalizing behavior symptoms using 18 items of the German Symptom Checklist for ADHD and 8 items of the ODD subscale of the Symptom Checklist for Disruptive Behavior Disorders ("Symptom Checklist for Externalizing Behavior Disorders," SCL-EXT) [35]. The items were answered on a 4-point Likert scale (ranging from 0 for *not at all* to 3 for *very much/particularly severe*) [35]. Again, the total externalizing symptom score (SCL-EXT) was computed by averaging all item scores. The instruments have demonstrated factorial validity and satisfactory internal consistency [35,37,38]. The internal consistency in the study sample was satisfactory (Cronbach α=.90) for the combined total SCL- EXT score.

Intervention Use

For each caregiver, an automatically generated log file was extracted 3 months after baseline (at T2) and 6 months after baseline (at T3), including the number of log-ins (ie, frequency of use) in the first 3 months (T1-T2) and the next 3 months (T2-T3), respectively [39,40]. Beyond that, we calculated the percentage of completed tasks/videos (ie, intensity of use, %) between T1 and T2 or between T2 and T3 for each participant by dividing the number of finished tasks and videos in a module/for a specific situation by the maximum number of tasks and videos provided in that module [22]. Reliability analyses for this processing progress scale yielded an acceptable internal consistency (Cronbach α=.78).

Statistical Analysis

Analyses were conducted on the sample with complete questionnaires for at least T1. Before the main analyses, which included data from participants in both study conditions, independent samples *t* tests were performed to test for differences in child externalizing behavior symptoms between the study conditions at T1. To examine whether child externalizing behavior symptoms affect caregivers' use of the WASH intervention and vice versa, we performed path analyses. In these analyses, we considered associations between the severity of child externalizing behavior symptoms at T1 and the caregivers' use of the WASH intervention in the early intervention period (between T1 and T2), as well as associations between caregivers' use in the early intervention period and child externalizing symptom severity at T2. Accordingly, we regarded the associations between symptom severity at T2 and caregivers' use of the program during the late intervention period (between T2 and T3), as well as associations between this use in the late intervention period and symptom severity at T3. In addition to these paths, to account for temporal stability, we considered autoregressive correlations between child externalizing behavior symptoms measured at the different assessment points and between the use parameters assessed between the assessment points (see Figure 2).

The use of WASH took place between the measurements of children's externalizing behavior symptoms. For our main analyses, we examined 2 different models, with externalizing behavior symptoms rated by either clinicians (see Figure 2A) or caregivers (see Figure 2B) and with caregivers' frequency of use of WASH operationalized by the number of log-ins (log-ins in months 0-3 and log-ins in months 3-6). We chose this measure of use for our primary analyses as it has been reported in most of the previous research on use-symptom association and, thus, allows for comparability with previous findings. Moreover, due to automatic data tracking, this measure seems reliable. However, we additionally conducted analogous analyses on the question of whether the results can be replicated when using a different operationalization of use (ie, percentage of completed materials; intensity of use). The findings for these additional analyses are presented in the online supplement for this paper. In all analyses, we controlled for the effect of the study condition (WASH and WASH+SUPPORT) on the use parameters and on symptoms.

We reported standardized parameter estimates (ß). To evaluate the model fit, we considered the comparative fit index (CFI) and the standardized root mean square residual (SRMR), in addition to χ^2. In line with current recommendations, we considered CFI>0.90 and SRMR<0.08 as acceptable [22,41]. Despite its frequent use, we refrained from relying on the root mean square error of approximation (RMSEA), as this index is not suitable in the case of low degrees of freedom [42]. The analyses were conducted using the Statistical Package for the Social Sciences (SPSS) version 27 (IBM Corp) for descriptive statistics and *t* tests and Mplus version 7.4 (Muthén & Muthén) for path analyses.

Figure 2. Results of the path models examining the association between the caregiver's number of log-ins to the WASH intervention and clinician-rated (A) or caregiver-rated (B) child externalizing behavior symptoms. Results

Sample Description

Table 1 summarizes the demographic and clinical characteristics of the participating caregivers and their children. At T1, on average, clinicians indicated elevated levels of child externalizing behavior symptoms (DCL-EXT: mean 1.52, SD 0.36). Likewise, caregivers reported clinically relevant child externalizing behavior symptoms (SCL-EXT: mean 1.70, SD 0.46). The independent samples *t* tests revealed no significant differences between the 2 intervention conditions in caregiver-reported child externalizing behavior symptoms at baseline (t_{282}=1.32, *P*=.19). After 6 months (DCL-EXT T3: mean 1.08, SD 0.44; SCL-EXT T3: mean 1.36, SD 0.50), symptom levels were still considered as elevated, according to orienting evaluation without normative standards [35]. However, both clinician-rated (t_{193}=16.33, *P*<.001) and caregiver-rated (t_{158}=10.70, *P*<.001) child externalizing behavior symptoms declined significantly between T1 and T3.

On average, caregivers logged in to the WASH intervention 5 times (SD 4.38, range 0-18) during the early intervention period (months 0-3), with significantly fewer log-ins (mean 0.53, SD 1.20, range 0-9) during the late intervention period (months 3-6; t_{275}=17.40, *P*<.001). Additionally, the percentage of completed material was significantly higher in the first intervention period (mean 31.88, SD 26.08, range 0-96.70) than in the second intervention period (mean 1.93, SD 5.83, range 0-31.20; t_{275}=18.76, *P*<.001).

Associations of Caregivers’ Use With Symptoms of Children

Results of the path analyses on the associations between the number of log-ins and changes in child externalizing symptom severity are reported in Figure 2 and Table S1 in Multimedia Appendix 1. The model fit was acceptable for both models (associations between clinician-rated child externalizing behavior symptoms and the number of log-ins: CFI=0.97, SRMR=0.03; associations between caregiver-rated child externalizing behavior symptoms and the number of log-ins: CFI=0.92, SRMR=0.04). Although significant, the χ^2 value depends strongly on the degrees of freedom, which, at *df*=2, were considered acceptable (see Table S2 in Multimedia Appendix 1) [43,44]. The primary analyses yielded no significant associations between the number of log-ins and clinician-rated child externalizing behavior symptoms (see Figure 2 and Table S1 in Multimedia Appendix 1). A small significant negative association was found between the number of log-ins (months 0-3) and the caregiver-reported child externalizing behavior symptoms in the long term (T3; ß=–.13, *P*=.29). Moreover, the caregiver-reported severity of child externalizing behavior symptoms at T2 was significantly associated with a higher number of log-ins in the later phase (ß=.14, *P*=.29). The significant results must be classified as small effects based on the standardized ß coefficient [45]. To examine whether the findings for the use-symptom associations may be replicated when using a different operationalization of use, we conducted secondary analyses according to the main analyses but applied the percentage of completed materials as a measure of use (see Table S3 in Multimedia Appendix 1). The model fit and χ^2 for both secondary models were acceptable, too (see Table S2 in Multimedia Appendix 1). No significant associations were found, neither when considering clinician ratings nor when regarding caregiver ratings of child externalizing behavior symptoms.

Discussion

Principal Findings

To the best of our knowledge, this study is the first to systematically investigate the relationship between caregivers’ use of an online intervention and changes in their children’s externalizing behavior symptoms. Overall, use was low, especially during the second half of the intervention period. Our results hint at a bidirectional, albeit small, association between the caregiver’s frequency of use (ie, number of log-ins) and changes in caregiver-reported child externalizing behavior symptoms. That is, first, the more log-ins during the early phase, the less severe the externalizing behavior symptoms reported by caregivers in the longer term. Second, in contrast, the more severe the caregiver-rated externalizing behavior symptoms, the more frequent the log-ins to the intervention in the subsequent late intervention phase (months 3-6). However, none of the other use-symptom associations in this model were significant. Moreover, we were not able to replicate these findings when we considered clinician-rated rather than caregiver-rated externalizing behavior symptoms, nor when we operationalized caregivers’ use by the percentage of completed materials (intensity of use).

Consistent with research on the use of online treatment for depression, we found both more log-ins and higher task completion rates (frequency and intensity) in the first than in the second half of the intervention [46]. For the second intervention phase (months 3-6), the mean overall number of log-ins was low. Furthermore, the overall progress during the 6-month treatment was relatively low, with only about one-third of the program being processed, on average. In view of previous research, it is clear that low completion rates are a general problem of internet-delivered interventions [20,47]. In fact, participants did not receive clear guidelines regarding use but were allowed to work on the intervention and content according to their interests, and full program completion was neither recommended nor necessary, since the program offers a wide range of options for usage and parents are asked to choose the components that best suit their needs. As previous analyses of the data used in this study revealed that personal telephone contact is a main predictor of enhanced use [22], the lack of counseling support calls (during months 3-6) might explain the significantly lower use in this period. The lower use in this period, which was additionally associated with lower variance (see Table S4 in Multimedia Appendix 1), may contribute to the explanation of the small effect sizes and the nonsignificant associations in the models, including clinician-rated child externalizing behavior symptoms or the percentage of completed materials as a measure of use.

Considering the findings of at least some associations between caregivers' use of the intervention and child externalizing behavior symptoms, the low use underlines the need for measures to foster engagement in online PMT to improve intervention outcomes. Previous research has demonstrated that use can be enhanced by some kind of support (eg, personal contact over the phone or chat functions, reminders) [22,48]. Contrary to previous findings of no significant use-symptom associations for PMT in the field of child anxiety disorders [25], our results hint at some longitudinal associations between the number of log-ins to the WASH intervention and caregiver-reported child externalizing behavior symptoms.

Notably, we not only found that (1) single aspects (frequency) of parental use of WASH are associated with externalizing behavior symptoms in the longer term but also observed that (2) externalizing symptom severity during treatment predicts later frequency of use. Although the effects were rather weak, and findings varied for different (but correlated) operationalizations of use ($r=0.73$, $P\leq.001$) [22], we consider these results as providing initial exploratory evidence for use-symptom associations. The different results for frequency and intensity of use underline the need for a differentiated consideration of these 2 parameters [30], as they capture 2 different facets of use. Although the number of log-ins merely reflects participation in the program, the percentage of use provides an indication of the depth of processing of the program content. Based on the available information from the study, we cannot conclude why significant associations with symptoms were found for the number of log-ins and not for the percentage of use. Maybe the different findings might be explained by influences of child characteristics, disorder characteristics (eg, symptom severity), or caregiver characteristics (ie, own inattention problems), which might be related to either use behavior and child externalizing symptom severity or both. However, further research is needed first to determine whether the results of this study may be replicated and then to examine further reasons for the differing results for the number of log-ins and the percentage of use.

The negative association between frequency of use and subsequent symptom severity could not be replicated when regarding clinician-rated child externalizing behavior symptoms. Previous research on PMT aiming to compare/validate different outcome measures across different assessors (caregiver, teacher, clinician) has likewise found a lack of congruence across different raters [5]. The authors concluded that caregivers may overestimate the effects of PMT, potentially due to the resources they have invested in treatment use (effort justification). Moreover, changes in caregivers' perceptions of children's externalizing behavior symptoms lead to greater tolerance, leading them to rate behavioral problems as less severe [22]. Future research is needed to replicate our findings.

Overall, despite significant findings on some variables, the relationship between frequency of use and change in caregiver-rated child externalizing behavior symptoms is not strong. Thus, we may conclude that simply improving the use of the WASH program is insufficient to enhance treatment outcomes in clinical practice. Other factors that were not controlled for in these analyses may be more important for explaining the differences in outcomes and might be a more favorable starting point for improving interventions (eg, emotional and behavioral problems and competencies of the parents, quality of intervention implementation). For example, internet-delivered PMT—from a theoretical and practical perspective—seems to affect parenting skills or parental psychopathology [12,25], and previous research has demonstrated that the effects of PMT on child externalizing behavior symptoms are mediated by a change in (mainly negative) parenting behaviors [49]. A deeper examination of such additional factors and their interplay is necessary to obtain a more comprehensive impression of the processes leading to symptom changes and to draw conclusions on how to improve treatment outcomes in clinical practice. It is conceivable that the use of web-based PMT is a prerequisite for change in both child- and parent-related variables and that there is a complex interplay between these variables.

Future studies should examine more complex models, including additional moderators and mediators of the effects of web-based PMT on child externalizing behavior symptoms (eg, parental skills practice [12], parenting behaviors), and additionally focus on the use of individual techniques (eg, stimulus control, contingency management) to gain a deeper understanding of the relative contribution of treatment use and of the particular mechanisms that lead to symptom improvements. A combination of objective and subjective measures of the individual model components should be used to increase the validity of the findings. Moreover, measures to enhance treatment use (eg, additional support calls) and their relative importance for enhancing treatment outcomes should be examined in more detail. Recently, microtrials have examined the effectiveness of specific elements of face-to-face PMT (eg, stimulus control techniques vs contingency management) [50,51]. Transferring this approach to web-based PMT and linking it to the measures of treatment use may help further study and explain the associations between use parameters and symptom changes.

Strengths and Limitations

Although the study sample is larger than in many other studies, it is nevertheless small for this type of analysis, limiting the possibility of detecting significant associations [52]. Moreover, several analyses were performed, increasing the risk of detecting significant effects by chance. Unfortunately, no measures on the practice and implementation (homework practice) of, for example, problem-solving strategies and contingency management into daily life were conducted. Moreover, we cannot guarantee that users engaged with the content rather than merely absolving the intervention, as we did not conduct knowledge quizzes to prove the CPE. The use variables are objective measures extracted from the program but do not indicate whether a caregiver changed parenting behaviors following treatment. Future research should include these variables (CPE in sessions and between sessions and parenting behaviors) to examine their contribution to symptom changes connected with caregivers' use of WASH.

The strengths of the study are that we used 2 objective measures of use metrics (log data) and assessed child externalizing behavior symptoms from 2 different perspectives (ie, caregivers and clinicians).

Conclusion

The analyses in this study provide some, albeit limited, support for the directional, longitudinal associations of (1) the caregiver's early number of log-ins to WASH with child externalizing behavior symptoms in the longer term and (2) the severity of child externalizing behavior symptoms as an immediate predictor of following frequency of log-ins during the late intervention period. Although the results were inconsistent across different operationalizations of treatment use and raters (clinician vs caregiver) and although the effects were rather weak, these analyses provide the first evidence for use-symptom associations in web-based PMT for child externalizing behavior problems. Future research could try to replicate the results and consider complex models, including mediators and moderators of treatment outcomes (eg, parenting behaviors, parental psychopathology, sociodemographic variables, and effective elements). Ultimately, the respective results could be used to develop measures to improve the use of (web-based) PMT in clinical practice to enhance treatment outcomes.

The study was funded by the Council of the German Innovation Fund (ID: VF1_2016–058), located at the Federal Joint Committee (G-BA). The funding agency did not influence the study design, data collection, analysis, interpretation of the data, or the writing of this paper.

Data Availability

The data sets used and analyzed during the study are available from the corresponding author upon reasonable request.

Conflicts of Interest

CD receives royalties for self-help books for parents and teachers of children with attention-deficit hyperactivity disorder, published by Hogrefe. MD and JP receive royalties from publishing companies as authors of books and treatment manuals on parent management training and assessment manuals. None of the other authors of this study report any conflicts of interest.

Multimedia Appendix 1

Parameters for main analyses, model fit for all path models calculated on the association of use with the child's overall externalizing symptoms, parameters for secondary analyses, and description of usage parameters (early and late).

Abstract

Background: Despite the growing uptake of smart technologies in pediatric type 1 diabetes mellitus (T1DM) care, little is known about caregiving parents' skills to deal with electronic health information sources.

Objective: We aimed to assess the electronic health literacy of parents caring for children with T1DM and investigate its associations with disease management and children's outcomes.

Methods: A cross-sectional survey was performed involving 150 parent-child (8-14 years old with T1DM) dyads in a university pediatric diabetology center. Parents' electronic health literacy (eHealth Literacy Scale [eHEALS]), general health literacy (Chew questionnaire and Newest Vital Sign [NVS]), and attitudes toward T1DM care (Parental Self-Efficacy Scale for Diabetes Management [PSESDM] and Hypoglycemia Fear Survey [HFS]) were investigated. Children's treatment, HbA$_{1c}$ level, and quality of life (Pediatric Quality of Life Inventory Diabetes Module [PedsQL Diab] and EQ-5D-Y-3L) were assessed. Multiple linear regression analysis was performed to investigate the determining factors of 6-month average HbA$_{1c}$.

Results: Of the 150 children, 38 (25.3%) used a pen, 55 (36.7%) used a pen plus a sensor, 6 (4.0%) used an insulin pump, and 51 (34.0%) used an insulin pump plus a sensor. Parents' average eHEALS score (mean 31.2, SD 4.9) differed significantly by educational level (P=.04) and the children's treatment (P=.005), being the highest in the pump + sensor subgroup. The eHEALS score showed significant Pearson correlations with the Chew score (r=−0.45; P<.001), NVS score (r=0.25; P=.002), and PSESDM score (r=0.35; P<.001) but not with the children's HbA$_{1c}$ (r=−0.143; P=.08), PedsQL Diab (r=−0.0002; P>.99), and EQ-5D-Y-3L outcomes (r=−0.13; P=.12). Regression analysis revealed significant associations of the child's HbA$_{1c}$ level with sex (β=0.58; P=.008), treatment modality (pen + sensor: β=−0.66; P=.03; pump + sensor: β=−0.93; P=.007), and parents' self-efficacy (PSESDM; β=−0.08; P=.001).

Conclusions: Significantly higher parental electronic health literacy was found in T1DM children using a glucose sensor. The electronic health literacy level was associated with parents' diabetes management attitude but not with the child's glycemic control. Studies further investigating the role of parental electronic health literacy in T1DM children managed at different levels of care and the local context are encouraged.

electronic health literacy; parents; caregivers; diabetes mellitus; child

Introduction

Type 1 diabetes mellitus (T1DM) is one of the most common chronic diseases in children, with an increasing incidence and prevalence globally [1-3], which poses a significant social and economic burden on pediatric patients, their caregivers, and the society [4-11]. To reduce the effects of these consequences, efficient disease management and treatment strategies are needed.

Pediatric T1DM care has become increasingly technology-driven, with improved therapeutics, such as automated insulin delivery systems and continuous glucose monitoring sensors, being increasingly used in treatment [12-15]. These advanced technologies have a positive effect on disease outcomes as they can facilitate reaching glycemic targets and thus reducing diabetes-related complications [16]. Accordingly, international treatment guidelines recommend the use of the most advanced therapeutics that are readily available, affordable, and considered appropriate for pediatric patients with T1DM to maintain appropriate disease control and improve glycemic outcomes [17,18]. When introducing a new device into the treatment, patient and caregiver training is also recommended for proper device operation and use. Likewise, engagement in disease management and appropriate behavior are key factors to obtain the best results and achieve treatment goals. To meet these expectations, proper education of both patients and caregivers, considering their interest in and barriers to technology uptake, is of utmost importance, along with health literacy improvement, which was found to be associated with diabetes outcomes [18-24].

As a constantly evolving concept, there is a wide range of definitions for health literacy [25]. According to the most common and widely accepted interpretation, health literacy broadly refers to people’s ability to find, evaluate, understand, and use health-related information needed to make appropriate and informed health decisions [26]. As it follows from the definition, parents must have a certain level of health literacy to play an effective role in their child’s disease management and to be able to make informed and responsible health-related decisions [27]. However, as indicated by Sanders et al [28], parents often struggle with understanding their child’s health information owing to its increasing complexity, with approximately one-third of parents in the United States having insufficient health literacy. [29]. Furthermore, a low level of parental health literacy is associated with children’s poor health status [30] and may lead to poor disease outcomes such as insufficient glycemic control [31].

Owing to the recent significant growth in internet use, changing consumer habits, and widespread use of digital products, electronic information sources and even artificial intelligence–based technologies play an increasingly important role in the management of pediatric diabetes [32-35]. In a study by Macken et al [36], 43.5% of families of pediatric T1DM patients with internet access used the internet monthly or more often to find T1DM-related health information. At the same time, new sources pose challenges for parents, who need the appropriate abilities to deal with health information to manage their child’s disease properly [28,37]. In relation, the concept of electronic health literacy has been developed, which, building on general health literacy, can be defined as the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to address or solve a health problem [38].

Although the growing importance of health literacy has been accompanied by an increase in the number of tools used to measure it, diabetes-specific instruments are rarely available, which makes it difficult to assess parents’ diabetes-related health literacy in a pediatric setting. In a recent systematic review, out of 19 condition-specific instruments, 8 were diabetes-specific, but all were for use in the adult population, and none of them were designed specifically for T1DM [39]. The authors also identified 11 electronic health literacy measurement tools; however, none of them were diabetes-specific. Furthermore, only 3 instruments that assess parental health literacy were identified, but they were not related to pediatric diabetes. Consistently, in studies examining the association of caregiving parents’ general health literacy with their child’s diabetes outcomes and glucose control, parental health literacy was assessed with general tools such as the Short Test of Functional Health Literacy in Adults (S-TOFHLA) [31,40], Newest Vital Sign (NVS) [41,42], Parental Diabetes Numeracy Test (PDNT) [31], and National Adult Reading Test (NART) [43]. However, despite its increasing significance, the role of parental electronic health literacy in pediatric diabetes has not been investigated extensively, and its associations with the child’s disease characteristics and glycemic outcomes have remained unexplored.

The impact of the therapy on the course of the disease, complications, and overall life expectancy can be seen only over a long period, during which a large amount of data is accumulated. The therapeutic goal is to empower the parents and treat pediatric patients effectively at home rather than in the hospital, which is partly to reduce social costs. Hence, parents have become key players in the management of the disease, and it is therefore necessary to obtain an insight into their role in achieving the desired treatment outcome. Given the increasing use of digital technologies and the fact that many of today’s parents, mainly due to their age, have not received any or sufficient formal training at school on searching and using electronic information, their ability to navigate electronic health information requires particular attention.

In this study, we sought to fill the gap in the knowledge of this area. Our primary aim was to assess the electronic health literacy of the parents of children with T1DM, in light of their general health literacy. Moreover, we intend to investigate the associations of parents’ electronic health literacy with diabetes management (including treatment types, parental self-reported attitudes, and diabetologists' perceptions) and the child's disease outcomes (including medical and patient-reported outcomes).

Methods

Study Design and Participants

A cross-sectional, noninterventional, single-center survey study was performed in 2021-2022 at a university pediatric diabetology center in Hungary. Parents or caregivers and their children with T1DM attending routine diabetology care were invited to participate. Adult caregivers (≥18 years old) living part-time with the child and children (8-14 years old) diagnosed with T1DM for at least 3 months were included. Respondents were informed that participation was voluntary and that their data would remain anonymous and impersonal and would be used solely for scientific purposes. The survey consisted of 3 modules filled in by parents of the child with T1DM (Module 1), the child with T1DM (Module 2), and the child's treating diabetologist (Module 3). Module 1 was completed on the Qualtrics online survey platform. Modules 2 and 3 were administered on paper, and the responses were digitized and entered into the Qualtrics system. No personal data were recorded online.

Ethical Considerations

Written informed consent was obtained from all participants upon entry into the study. Ethical approval was obtained from the Hungarian Medical Research Council (IV/3848-1/2021/EKU; BMEÜ/1620-1/2022/EKU).

Parents' Survey (Module 1): Main Characteristics, Health Literacy, and Attitudes Toward the Child's T1DM

Basic demographic characteristics (sex, age, education, residence, marital status, and employment), household data (income and number of persons living in a household), and childcare circumstances were recorded. Parents' electronic and general health literacy and their attitudes toward the child's diabetes were assessed using standard measurement tools (eHealth Literacy Scale [eHEALS], Chew questionnaire, NVS questionnaire, Parental Self-Efficacy Scale for Diabetes Management [PSESDM], and Hypoglycemia Fear Survey [HFS]).

The eHEALS was developed to measure electronic health literacy, which refers to the respondent's self-assessed confidence; knowledge; and ability to find, understand, and use electronic health information [44]. The self-administered questionnaire contains 8 statements on respondents' awareness of health resources on the internet (items 1 and 2), internet searching skills (items 3 and 4), appraisal of health resources (items 6 and 7), and use of health information (items 5 and 8). Statements are rated on a 5-point Likert scale (possible answers: 1, strongly disagree; 2, disagree; 3, undecided; 4, agree; 5, strongly agree). Item scores are summed, resulting in a final score of 8-40, with a higher score indicating better eHealth literacy. In this study, the validated Hungarian version of the eHEALS questionnaire was used [45].

The Chew questionnaire is a prescreening tool to identify people with low health literacy. It comprises 3 questions concerning the frequency with which respondents feel confident to fill in forms independently, need help in interpretation, and have problems with understanding hospital documents [46,47]. Response options range from 0 (never) to 4 (always). To calculate the final score (range 0-12), the values of the answers are added together. Higher scores indicate lower health literacy [48].

The NVS questionnaire was developed to identify people with limited health literacy [49,50]. Respondents are presented with a nutrition chart and asked 6 questions. Basic reading comprehension skills and simple mathematical calculations are required to answer. The likelihood that a person has limited health literacy is determined by the number of correct answers as follows: 0-1 correct answers indicate a high likelihood of limited health literacy (50% or more); 2-3 correct answers indicate a possibility of limited health literacy; and 4-6 correct answers indicate adequate health literacy.

The PSESDM questionnaire was developed to assess parents' confidence in their ability to effectively manage their child's diabetes [51]. It consists of 8 statements with which the level of agreement can be indicated on a 5-point Likert scale (1 [strongly disagree] to 5 [strongly agree]). The final score is calculated by adding up the scores of responses, resulting in a total score of 8-40. A higher score indicates a parent's greater confidence in caring for their child's diabetes.

The HFS measures parents' fear of their children's hypoglycemic episodes [52]. The first part assesses the parent's actions to avoid hypoglycemia and related problems (10 statements), and the second part assesses the parent's concerns about their child's hypoglycemic episodes (15 statements). Parents are asked to indicate on a 5-level scale how true the statement is for them (response options: 0 [never] to 4 [almost always]). The final score (range: 0-100) is calculated by adding up the individual scores given for each item. Higher scores indicate a greater fear of hypoglycemia.

T1DM Children's Survey (Module 2): Health-Related Quality of Life

To assess health-related quality of life (HRQoL), participating children completed 2 validated measurement tools (Pediatric Quality of Life Inventory [PedsQL] and its Diabetes Module [PedsQL Diab] and EQ-5D-Y-3L) for evaluating their general and diabetes-specific quality of life.

The general module of the 23-item PedsQL assesses the following domains: physical functioning ("my health and activities" involving 8 questions), emotional functioning ("my feelings" involving 5 questions), social functioning ("my relationships with others" involving 5 questions), and school functioning ("school" involving 5 questions) [53,54]. Questions are asked for the past month, and responses are given on a 5-point Likert scale (possible answers: 0, never; 1, rarely; 2, sometimes; 3, often; 4, almost always). To calculate the final score, the answers to each question are transformed into a scale from 0 to 100 by inverse scoring (ie, the score for each answer is 0=100, 1=75, 2=50, 3=25, and 4=0), and then, the simple arithmetic average of the scores obtained for each answer is taken. A higher score indicates a better HRQoL.

Version 3.0 of the diabetes module of the PedsQL consists of 28 items and covers the following domains: symptoms of diabetes (“about my diabetes” involving 11 questions), difficulties with treatment (“treatment I” involving 4 questions), acceptance of treatment (“treatment II” involving 7 questions), worry about the disease (“concerns” involving 3 questions), and difficulties with communication (“communication” involving 3 questions) [55]. Response options and the evaluation of the questionnaire are the same as described for the general module. For both the general and diabetes modules, the validated Hungarian version of the questionnaire was used in this study [56,57].

EQ-5D-Y-3L is specifically designed to assess children’s and adolescents’ general HRQoL [58,59]. Its descriptive part contains 5 questions covering the following domains: mobility; taking care of myself; doing usual activities; feeling pain or discomfort; and feeling worried, sad, or unhappy. Each domain is rated on a 3-point Likert scale (1, no problems; 2, some problems; 3, a lot of problems). In this study, EQ-5D-Y-3L index values were calculated using the Hungarian value set [60]. EQ-5D-Y-3L includes a visual analog scale (EQ VAS) on which respondents can indicate their current health status on a vertical scale ranging from 0 (worst “health you can imagine”) to 100 (best “health you can imagine”).

Diabetologists’ Survey (Module 3): Children’s T1DM Disease Characteristics, Perceptions of Parents, and Disease Management

The following medical information was collected from treating diabetologists: child’s weight, height, duration of disease, duration of care at the center, route of insulin administration and blood glucose measurement (treatment modalities: pen without sensor, pen plus sensor, pump without sensor, and pump plus sensor), HbA_{1c} level, T1DM-related serious acute events (hypoglycemia, hyperglycemia, or other events requiring medical intervention or acute hospitalization) or device malfunction in the last 3 months, chronic complications, and comorbidities. Actual and 6-month average HbA_{1c} levels were recorded as percentage. Treating diabetologists were also asked about the management of T1DM (parents’ cooperation, diabetes knowledge, and knowledge of device use; T1DM being difficult to treat) with responses given on a visual analog scale (VAS), with 0 indicating the worst option and 10 indicating the best option.

Statistics

Variables were analyzed with descriptive statistical methods (mean, SD, minimum, maximum, and number of items). The average eHEALS score of the study sample was compared to the previously published Hungarian population norm with the Welch test. The effect size was measured with Cohen *d* (small effect=0.2; medium effect=0.5; large effect=0.8) [61]. Two-way ANOVA was carried out to test differences by sex, age, and education.

Subgroup comparisons by sociodemographics, treatment modalities, and T1DM complications were performed with the Welch and ANOVA tests.

Correlations between eHEALS and other measures were assessed by calculating the Pearson correlation coefficient (>0.5=strong; 0.5-0.3=moderate; <0.3=weak) [62].

Multiple linear regression analysis was performed to investigate the factors determining glucose control (6-month average HbA_{1c}). A total of 9 regression models were developed to examine the associations of variables and changes in model performance. The following explanatory variables were included: T1DM children’s characteristics (Model 1); parents’ demographic characteristics (Model 2); treatment modalities (Model 3); parental electronic and general health literacy (Model 4: eHEALS; Model 5: Chew; Model 6: NVS); and parents’ self-reported attitudes toward their child’s illness (Model 7: PSESDM; Model 8: HFS).

The model construction was systematic so that the variables included in Models 1 to 3 were included in all subsequent models, while for Models 4 to 8, the variables mentioned above were included one by one in a mutually exclusive manner. The final Model 9 included all variables together.

Statistical analysis was performed using Stata 17 software (StataCorp LCC).

Results

Parents’ Main Characteristics, Health Literacy, and Attitudes Toward Their Child’s T1DM

Altogether 150 parent-child dyads were involved in the study. Parents’ mean age was 42.5 (SD 5.8; range: 19-62) years, and 80.0% (120/150) were women. The sociodemographic characteristics are summarized in Table 1. Only 2 (1.3%) caregivers were not parents, and the majority (144/150, 96.0%) lived together with the child full-time in the same household. Moreover, 10 (6.7%) parents had diabetes mellitus themselves.

The distribution of responses by eHEALS items is presented in Figure 1 [44]. All 150 parents responded to all items. The proportion of “strongly agree” responses varied between 15.3% (23/150) and 26.0% (39/150) (mean 20.7%, SD 3.0%) across the 8 eHEALS items, indicating remarkable uncertainty of parents dealing with electronic health information resources, especially on having “the skills I need to evaluate the health resources I find on the internet” (item 6).

Table 1. Parents’ demographics, electronic and general health literacy, and attitudes as a caregiver for a child with type 1 diabetes mellitus.

[a] Percentages may not add up to 100% due to rounding.

[b] eHEALS: eHealth Literacy Scale.

[c] Higher scores indicate lower literacy levels.

[d] NVS: Newest Vital Sign.

[e] PSESDM: Parental Self-Efficacy Scale for Diabetes Management.

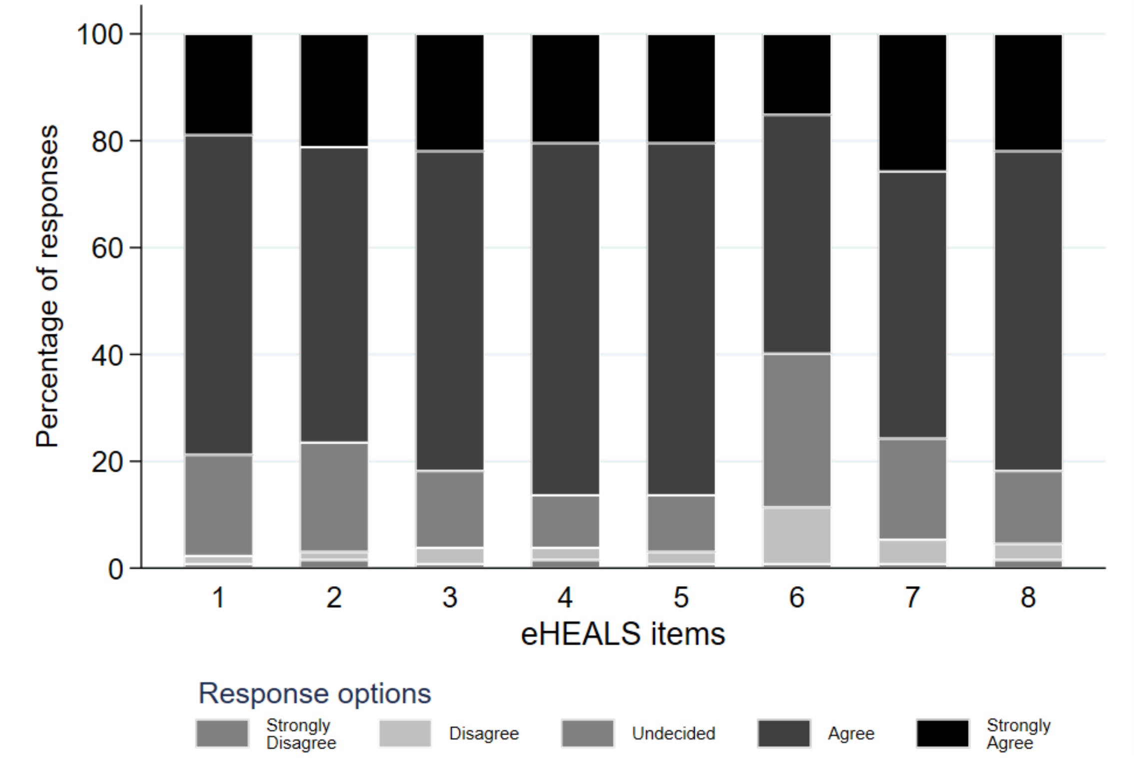
[f] HFS: Hypoglycemia Fear Survey.

[g] Higher scores indicate greater fear of hypoglycemia.

[h] Differences between groups were compared using Welch and ANOVA tests.

[i] T1DM: type 1 diabetes mellitus.

Figure 1. Distribution of responses by eHealth Literacy Scale (eHEALS) items. 1: "I know what health resources are available on the internet;" 2: "I know where to find helpful health resources on the internet;" 3: "I know how to find helpful health resources on the internet;" 4: "I know how to use the internet to answer my questions about health;" 5: "I know how to use the health information I find on the internet to help me;" 6: "I have the skills I need to evaluate the health resources I find on the internet;" 7: "I can tell high-quality health resources from low-quality health resources on the internet;" 8: "I feel confident in using information from the internet to make health decisions" [44].



In the total sample, the average parental eHEALS score was 31.2 (SD 4.9), which was significantly higher (P=.002) than that in the Hungarian general population [45]. The effect size was small, with a Cohen d of 0.41 (95% CI 0.16-0.67). Differences were observed between the study sample and the general population by sex, age group, and education, but the 2-way ANOVA revealed no significant associations (Multimedia Appendix 1) [45].

Parents' average Chew and NVS scores were 2.5 (SD 2.0) and 4.4 (SD 1.8), respectively, indicating adequate general health literacy in the total sample. Parental self-efficacy regarding diabetes management was generally high, with an average PSESDM score of 32.9 (SD 5.4). The average HFS score was 33.7 (SD 12.3).

Subgroup comparisons by sociodemographic characteristics revealed that parents' health literacy (eHEALS, Chew, and NVS) and self-efficacy (PSESDM) differed significantly by their educational level but not their fear of hypoglycemia (HFS) (Table 1).

Children's T1DM Disease Characteristics and HRQoL

In total, 150 children (girls: 69/150, 46.0%) were included, with a mean disease duration of 5.3 (SD 2.8) years. Their mean age, height, and weight were 11.7 (SD 1.9) years, 150.6 (SD 16.4) cm, and 45.9 (SD 16.3) kg, respectively. Altogether, 106 (70.7%) children used a glucose sensor. The most frequent insulin treatment modality was pen plus sensor, followed by pump plus sensor, pen, and pump (Table 2).

Table 2. Characteristics of children with type 1 diabetes mellitus and diabetologists' perceptions in the total sample and by treatment modality.

Variable	Total sample (N=150)	Pen (n=38)	Pen + sensor (n=55)	Pump (n=6)	Pump + sensor (n=51)	*P* value[a]
Age (years), mean (SD)	11.7 (1.9)	11.7 (2.0)	11.9 (1.9)	11.3 (1.6)	11.6 (1.8)	.84
Disease duration (years), mean (SD)	5.3 (2.8)	5.4 (3.1)	4.2 (2.3)	7.2 (2.8)	6.2 (2.8)	<.001
Duration of care at the center (years), mean (SD)	4.8 (2.6)	5.2 (2.7)	3.7 (2.3)	7.0 (2.7)	5.5 (2.3)	<.001
Current HbA_{1c} (%)[b], mean (SD)	7.6 (1.4)	8.6 (2.0)	7.4 (1.1)	7.2 (0.5)	7.2 (0.8)	<.001
6-month average HbA_{1c} (%)[b], mean (SD)	7.6 (1.3)	8.5 (1.9)	7.3 (1.0)	7.2 (0.5)	7.2 (0.7)	<.001
PedsQL[c] (range: 0-100), mean (SD)	81.4 (13.2)	78.3 (17.8)	81.5 (12.0)	86.4 (14.0)	82.9 (9.7)	.30
PedsQL physical subscore (range: 0-100), mean (SD)	85.7 (13.0)	82.9 (17.6)	87.0 (11.7)	86.5 (11.8)	86.3 (10.2)	.49
PedsQL psychosocial subscore (range: 0-100), mean (SD)	79.1 (14.7)	75.8 (19.6)	78.6 (13.6)	86.4 (16.1)	81.2 (10.8)	.22
PedsQL Diab[d] (range: 0-100), mean (SD)	74.4 (12.8)	72.0 (15.7)	73.8 (11.6)	84.4 (10.1)	75.7 (11.5)	.13
EQ-5D-Y-3L index (range: −0.485 to 1.000), mean (SD)	0.940 (0.097)	0.915 (0.119)	0.939 (0.097)	0.964 (0.058)	0.957 (0.077)	.21
Parents' cooperation (VAS[e,f]), mean (SD)	7.1 (2.4)	4.7 (2.0)	7.7 (2.1)	6.5 (1.6)	8.3 (1.7)	<.001
Parents' diabetes knowledge (VAS[f]), mean (SD)	6.9 (2.3)	4.6 (1.7)	7.5 (1.9)	5.7 (1.5)	8.1 (1.6)	<.001
Parents' device use knowledge (VAS[f]), mean (SD)	6.2 (2.7)	2.7 (1.6)	7.1 (1.9)	5.5 (1.0)	7.9 (1.7)	<.001
T1DM[g] being difficult to treat (VAS[f]), mean (SD)	6.6 (2.4)	4.3 (2.0)	7.2 (2.2)	5.8 (1.3)	7.7 (1.8)	<.001

[a] Differences between treatment modalities were compared with ANOVA.

[b] A higher HbA_{1c} level indicates worse glycemic control.

[c] PedsQL: Pediatric Quality of Life Inventory.

[d] PedsQL Diab: Pediatric Quality of Life Inventory Diabetes Module.

[e] VAS: visual analog scale.

[f] Based on diabetologists' assessments. Lower scores indicate worse cooperation and knowledge, and more difficulties in treatment.

[g] T1DM: type 1 diabetes mellitus.

The average EQ-5D-Y-3L index and PedsQL score in the sample were 0.940 (SD 0.097) and 81.4 (SD 13.2), respectively, indicating that the general HRQoL of children living with T1DM was high. The PedsQL Diab score was moderately low (mean 74.4, SD 12.8).

Any type of comorbidity was observed in 43 children (29 had T1DM-related thyroid disease; 12 had coeliac disease; and 1 each had growth hormone deficiency, juvenile idiopathic arthritis, congenital adrenal hyperplasia, and epilepsy). An acute event requiring a physician or a device malfunction in the past 3 months was reported in 4 children (3 had a severe hyperglycemic episode or ketoacidosis and 2 had device malfunction). T1DM-related chronic kidney complication was noted in 1 child.

Children's characteristics and differences by treatment modality are presented in Table 2. Both disease duration and time of care in the pediatric diabetology center were the longest among patients using an insulin pump (without sensor), while the highest average HbA_{1c} levels were observed in the subgroup using a pen (without sensor). HRQoL results (PedsQL, PedsQL Diab, and EQ-5D-Y-3L) did not differ significantly across treatment modality subgroups. No meaningful difference in the occurrence of comorbidities was found across treatment types.

Diabetologists' Perceptions of Parents and Disease Management

In the total sample, the average scores for parents' cooperation, diabetes knowledge, device use knowledge, and difficulty in managing the child's disease were 7.1 (SD 2.4), 6.9 (SD 2.3), 6.2 (SD 2.7), and 6.6 (SD 2.4), respectively. The relationship of these characteristics with parental age showed a nonsignificant concave pattern (Multimedia Appendix 2). Parents' cooperation with their child's diabetes management and disease-related knowledge (both of diabetes and device use) significantly differed by treatment modality (being the highest in the pump + sensor subgroup, followed by the pen + sensor subgroup). Treating the child's T1DM was found to be the least difficult in the pump + sensor subgroup and the most difficult in the pen (without a sensor) subgroup (Table 2).

Analysis by Treatment Modality and T1DM Complications

Parents' health literacy and attitudes toward their child's diabetes by major subgroups are presented in Table 3. The eHEALS score differed significantly by treatment modality, being the highest in the pump + sensor subgroup, followed by the pen + sensor, pen (without sensor), and pump (without sensor) subgroups. However, no differences were detected in terms of the occurrence of serious acute events, device malfunction, or prevalent comorbidities.

Table 3. Parents' health literacy and attitudes toward their child's diabetes by major subgroups.

Variable	Value (N=150), n	eHEALS[a]		Chew[b]		NVS[c]		PSESDM[d]		HFS[e,f]	
		Score, mean (SD)	*P* value[g]	Score, mean (SD)	*P* value[g]	Score, mean (SD)	*P* value[g]	Score, mean (SD)	*P* value[g]	Score, mean (SD)	*P* value[g]
Treatment modality			.005		.09		<.001		.002		.32

[a] eHEALS: eHealth Literacy Scale.

[b] Higher scores indicate lower literacy levels.

[c] NVS: Newest Vital Sign.

[d] PSESDM: Parental Self-Efficacy Scale for Diabetes Management.

[e] HFS: Hypoglycemia Fear Survey.

[f] Higher scores indicate greater fear of hypoglycemia.

[g] Differences between groups were compared using Welch and ANOVA tests.

[h] T1DM: type 1 diabetes mellitus.

[i] The events reported by the diabetologists were hyperglycemia or ketoacidosis requiring medical intervention and device malfunction.

Parents' NVS and PSESDM scores differed significantly by treatment modality, but there were no differences in the Chew and HFS scores. Parents whose children experienced any T1DM-related serious acute event or device malfunction in the last 3 months had lower general health literacy (NVS) and lower fear of hypoglycemia (HFS). The Chew score showed no significant difference by subgroups.

Correlations Between eHEALS and Other Measures

The correlation of the parental eHEALS score was moderate with the Chew score (r=−0.45; *P*<.001) and weak with the NVS score (r=0.25; *P*=.002). Moreover, a moderate positive correlation was seen with the PSESDM score (r=0.35; *P*<.001) but not with the HFS score (r=−0.03; *P*=.70). Regarding children's T1DM outcomes, the parental eHEALS score did not correlate significantly with children's 6-month HbA_{1c} level (r=−0.143; *P*=.08) and HRQoL outcomes (PedsQL Diab: r=−0.0002; *P*>.99; EQ-5D-Y-3L: r=−0.13; *P*=.12). Significant but low or moderate correlations were observed between the eHEALS score and how diabetologists perceived parents' cooperation (r=0.19; *P*=.02), diabetes knowledge (r=0.36; *P*<.001), device use knowledge (r=0.34; *P*<.001), and level of difficulty in managing the disease (r=0.22; *P*=.008). The results are shown in Figure 2.

Figure 2. Correlation of parents' electronic health literacy with child-related outcome measures and diabetologists' assessment scores (Pearson correlation). eHEALS: eHealth Literacy Scale; HFS: Hypoglycemia Fear Survey; NVS: Newest Vital Sign; PedsQL Diab: Pediatric Quality of Life Inventory Diabetes Module; PSESDM: Parental Self-Efficacy Scale for Diabetes Management; VAS: visual analog scale. *P<.05.

Regression Results

The determinants of glucose control in different regression models are presented in Table 4. Neither parental electronic and general health literacy (eHEALS, Chew, and NVS) nor fear of hypoglycemia (HFS) showed a significant association with the child's 6-month HbA_{1c} level. The final model (Model 9) that included all variables explained 47.0% of the total variance in HbA_{1c}, which was significantly associated with the child's sex (girls having a higher HbA_{1c} compared to boys), treatment modality (pen + sensor and pump + sensor users having a lower HbA_{1c} compared to pen users), and parental self-efficacy in managing their child's diabetes (PSESDM; a higher parental self-efficacy was associated with a lower child HbA_{1c} level).

Table 4. Determinants of glucose control (6-month average HbA_{1c}) in different regression models (N=150).

Discussion

In this cross-sectional clinical study, we investigated the electronic health literacy of parents caring for children with T1DM, using the eHEALS self-reported measurement tool, and results were analyzed alongside their general health literacy. Associations of eHEALS with disease management and disease outcomes were also investigated. On the eHEALS questionnaire, parents reported substantial problems with finding, understanding, and using electronic health information. Regarding disease management, eHEALS scores differed significantly according to the children’s treatment modality, being the highest in the pump + sensor subgroup, and there was a significant association of eHEALS scores with parents’ self-efficacy in managing diabetes (PSESDM) and the diabetologists’ perceptions of parents as T1DM caregivers. Regarding disease outcomes, we found no significant associations with parental eHEALS scores. Regression analysis revealed that the 6-month average HbA_{1c} level was associated with the child’s sex, treatment modality, and PSESDM score, but not with the electronic and general health literacy scores. To our knowledge, this is the first study to investigate parental electronic health literacy (eHEALS) in pediatric T1DM.

Comparisons with the international literature are hampered by the lack of electronic health literacy studies in this patient group and the variability of the general health literacy measurement tools used. In our study, more educated parents had significantly higher electronic (eHEALS) and general (Chew and NVS) health literacy, and these 2 differed significantly by income level as well. In contrast, previous studies involving young children [31] and adolescents [40] have reported no significant differences in parents’ general health literacy (assessed by the S-TOFHLA) by sociodemographic subgroups. Moreover, Al-Abdulrazzaq et al [41] found no association between parents’ NVS score and their educational level in a validation study of the Arabic version of the NVS. Parental self-efficacy in the child’s diabetes management (PSESDM) showed an increasing trend by educational level and income in our study, but parental fear of hypoglycemia (HFS) did not differ by sociodemographic subgroups. Marchante et al [51] reported that PSESDM was associated with the child’s sex. In the study by Amiri et al [63], neither parental self-efficacy (assessed by the Self-Efficacy for Diabetes Scale-Parent questionnaire) nor the HFS score differed significantly by demographic characteristics. These controversial results regarding the role of sociodemographics in parental health literacy and caregiver attitude need further investigation in large epidemiological studies. We consider it important to highlight the female dominance of parents (80%) in our sample. We acknowledge that we could have obtained different results in other care settings and that the child’s T1DM might affect the quality of life and employment perspectives of other family members. These points definitely deserve further exploration. Nevertheless, our results suggest that mothers play a key role in the T1DM care of their children. It is therefore worth paying particular attention to their electronic health literacy, capability, and willingness to operate modern devices, considering their preferences, and measuring how they can benefit from new digital technologies.

Our study revealed significantly higher parental electronic health literacy (eHEALS) in children using a digital sensor to measure their blood glucose level. The results suggest that parental electronic health literacy might affect the choice of insulin administration and glucose measurement mode. This choice may depend on various factors, including the judgement of the treating diabetologist, reimbursement rules, availability of devices, and access to devices, as well as on the acceptability of different treatment modalities (ie, parental consent and the child’s preferences). Further studies involving pediatric diabetes care providers from different levels and diverse patient groups are encouraged to explore in depth the decision-making process. Parents’ average NVS score also differed significantly by treatment groups, suggesting that general health literacy (focusing on skills for both words and numbers) might play a significant role in treatment decisions. This is in contrast with findings by Pulgaron et al [31], as parents’ reading and numeracy abilities were not associated with treatment modalities. However, it is important to note that much younger (aged 3-9 years; mean age 6.8 years) T1DM children were involved in their study.

HbA_{1c} is an important indicator of T1DM management. We found no significant correlation with parental eHEALS and Chew scores, but there were weak and moderate relationships with parental general health literacy (NVS) and self-efficacy (PSESDM), respectively. In the study by Pulgaron et al [31], parents’ numeracy skills were negatively correlated with the child’s HbA_{1c} level ($r=-0.52$), which strengthens our results with the NVS measure that also has a strong numerical focus. However, 2 other studies found no association between parental health literacy (S-TOFHLA and NVS) and the child’s HbA_{1c} level [40,41]. Ross et al [43] reported that glycemic disease control was worse for those children whose caregivers had lower literacy skills as measured by the National Adult Reading Test (NART).

An important observation of our study was that parental electronic and general health literacy scores and parental fear of hypoglycemia were not associated with the child’s HbA_{1c} level in the regression analyses, and contributed minimally to the total variance explained (R^2), indicating that these factors have a negligible effect on the child’s glucose control. We also found that apart from the child’s sex and parents’ PSESDM score, only pen + sensor and pump + sensor treatment modalities remained significantly associated with the HbA_{1c} level in the final regression model, when all relevant variables were added together. Thus, a digital glucose sensor can have a meaningful positive effect on the child’s glucose control. Our observations are consistent with previously published results. In most previous studies, higher HbA_{1c} levels were found among female young children than among male children both at diagnosis and during treatment [64]. Pulgaron et al [31] reported that parents’ numeracy skills could significantly predict HbA_{1c}, but the significance was lost when parents’ education was added as a covariate in the regression analysis. In their final model, only parental self-efficacy regarding diabetes management (Perceived Diabetes Self-Management Scale) remained a significant predictor of HbA_{1c}. Furthermore, Al-Abdulrazzaq et al [41] found that adequate health literacy was inversely associated with optimal HbA_{1c} levels, but adjusting for the treatment regimen cancelled its significant effect. We think, however, that the child's HbA_{1c} level is multifactorial, and not all relevant factors were taken into account in our research. For instance, at this university-based center, patients are closely monitored and have opportunities for consultation with highly qualified pediatric diabetologists and a multidisciplinary team. This tight control may partly balance the differences in parental disease management capabilities in terms of HbA_{1c} outcome. It is necessary to note that we ran the regression for HbA_{1c}, but it is not the only significant outcome of the disease. The benefits of new digital technologies, if used by properly trained users with great digital skills, can also be seen in areas not covered in our study. For instance, the possibility of remote control of the child's status might put the parents into a much better position in terms of feeling more safe and flexible in managing other family members and their own life. It would be worth also investigating how the electronic health literacy of main caregivers (mothers in our study) impacts long-term management decisions and disease outcomes in the patient's later adolescence and adulthood.

Some limitations of our study have to be mentioned. First, this was a single-center cross-sectional study in a university clinic, which limits the generalizability of our results. It would be interesting to investigate whether the role of eHEALS for HbA_{1c} levels is similarly negligible in jurisdictions where parents have less access to resources and high-quality, personalized, family-centered diabetology care [65], and are more reliant on information from the internet. It would be worthwhile to also assess in a follow-up study how parents' digital health literacy changes with digital device use and participation in diabetes care. Second, the tools used to measure parental health literacy were not specific to diabetes. Therefore, we may not have been able to capture all relevant aspects of parental knowledge. Third, only 4 children had serious acute events requiring medical intervention or device malfunction in the past 3 months. Hence, the importance of parental electronic health literacy in acute events needs further research. Fourth, only 6 children used an insulin pump without a sensor, which limits the generalizability of the results of this subgroup. Our study showed that disease duration and follow-up at this university-based clinic were the longest for this subgroup. Discussions with treating diabetologists confirmed that these patients have usually been using pump treatment for a long time and often struggle with switching from conventional blood glucose measurement to sensor measurement.

This first exploratory study provides insights into the electronic health literacy of parents caring for their child with T1DM. Parents' educational level was identified as an important sociodemographic factor affecting parental electronic health literacy and attitudes toward their child's diabetes. Meaningful differences in parental eHEALS and NVS scores were found by treatment modality, suggesting that parental electronic and general health literacy may be important factors in treatment decisions. In addition to being a male child, higher parental self-efficacy in diabetes management and sensor use were positively associated with better child glucose control. However, a lack of a direct association between this core outcome and parental electronic and general health literacy raises the issue of further influencing factors not considered in this study, as well as the need for diabetes-specific electronic health literacy measurement tools. Further prospective multicenter studies involving heterogeneous settings and care providers are recommended to strengthen and refine our observations.

Acknowledgments

The authors are grateful to the participants who took part in the study. The questionnaire survey was supported by the National Research, Development, and Innovation Fund of Hungary in the framework of the Thematic Excellence Program (TKP2020-NKA-02) at Corvinus University of Budapest. This study was supported by the National Research, Development, and Innovation Fund of Hungary in the framework of the "Development and evaluation of innovative and digital health technologies" ("Evaluation of digital medical devices: efficacy, safety, and social utility" subproject) research project (TKP2021-NKTA-36) at Óbuda University. In connection with writing this article, ÁH, ZZ, LG, LK, and MP received grant support from the same funding scheme (TKP2021-NKTA-36) and MP received grant support from the National Research, Development, and Innovation Fund of Hungary (grant number 2019-1.3.1-KK-2019-00007 under the 2019-1.3.1-KK funding scheme).

Abstract

Background: Behavioral health conditions among children have worsened over the past decade. Caregivers for children with behavioral health conditions are at risk for two types of caregiver strain: (1) an objective strain, that results directly from the child's condition and (2) subjective strain, that arises from the caregiver's feelings regarding these events.

Objective: This study aimed to evaluate the impact of a technology-enabled pediatric and family behavioral health service on caregivers' strain among a commercially insured population. We also explore the common symptom clusters of caregiver strain to better understand the caregiver presentation to inform future care planning.

Methods: We examined changes in caregiver strain using the Caregiver Strain Questionnaire-Short Form 7 over the course of their child's web-based behavioral health care between 2021 and 2023 using a pre-post study design. Common caregiver strain symptom clusters were identified using Ward hierarchical agglomerative clustering.

Results: The majority of children were White 60.8% (1002/1647), female 53.6% (882/1647), and aged between 5 and 9 years (33.7%, 555/1647). Families fall broadly into 4 groups based on what drives caregiver strain the most, namely those experiencing (1) disrupted family relationships and time interruption, (2) missed work, (3) worried about their child's future and feeling tired and sad, and (4) financial strain. Caregiver strain, which was associated with the child's disease severity (*P*<.001), decreased significantly in all therapeutic groups.

Conclusions: Web-based family-oriented behavioral health care can improve caregiver strain and reduce family and time disruptions, missed work, and financial strain. Sources of caregiver strain vary and may be overlooked when relying on the conventional scoring of the Caregiver Strain Questionnaire-Short Form 7.

Introduction

Over the past decade, the prevalence of behavioral health conditions among children has steadily worsened [1,2]. Currently, 17% of children aged 2 to 8 years are diagnosed with a mental health condition [3] and 37% of adolescents aged 12 to 17 years report persistent feelings of sadness or hopelessness [1,4]. The adults who care for these children are at risk for 2 types of caregiver strain, that are (1) an objective strain, that results directly from the child's condition (eg, disrupted family relationships, financial strain, and interruptions at work) and (2) subjective strain, that arises from the caregiver's feelings regarding these events (eg, guilt, anger, and sadness) [5]. Although the severity of the child's problems is often the best predictor of caregiver strain, poor access to convenient, affordable in-network providers is a common source of caregiver strain, even among commercially insured families [5]. Given evidence that reducing parental strain can improve the effectiveness of evidence-based treatments for children with mental illness [6,7], a robust understanding of the sources of caregiver strain may lead to more beneficial approaches for the whole family. While previous studies have evaluated caregiver strain in terms of internalizing and externalizing domains [8], specific sources of strain have not been documented.

The costs for outpatient behavioral care for commercially insured populations increased by 84% between 2018 and 2021 compared with an increase of 60% in overall behavioral health costs during that interval [9]. Self-insured employers pay a disproportionate share of these costs because they provide direct payment for mental health services, and bear indirect costs, such as reduced employee productive work time [10]. In response to the increased prevalence of mental health concerns and these escalating costs, approximately 80% of self-insured employers report implementing behavioral health benefits, including employee assistance programs and others that increase access to low-cost mental health services, including telemental health [9]. However, telehealth use among children and teenagers lags behind adults, despite recent telehealth expansions for behavioral health services [11].

In response to these trends, we implemented a comprehensive, technology-enabled pediatric and family behavioral health service for commercially insured populations. The intervention provides access to educational content, telebehavioral health coaching, and web-based psychotherapy and medication management. Children are triaged to either telebehavioral health coaching, telepsychotherapy, or telepsychiatry based on their clinical acuity.

In this study, we hypothesize that a telebehavioral health service is effective in reducing strain among parents caring for a child with a mental health condition. We also explore the common symptom clusters of caregiver strain to better understand the caregiver presentation to inform future care planning. In a secondary analysis, we evaluate the relationship between caregiver strain and child behavioral health severity, which were strongly correlated in a previous study [5]. We hope that this study will provide important observations around remediable symptoms and patterns of caregiver strain that will inform the development of telebehavioral health offerings for children and their families.

Methods

Overview

This study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline for cohort studies [12]. STROBE guidelines are used in observational studies to improve the quality, transparency, integrity, and reproducibility of scientific literature.

Intervention

Brightline is a technology-enabled behavioral health care platform for children (aged 18 months to 17 years) and their families [13,14]. Briefly, the web-based platform is provided to commercially insured populations in all 50 states through their employer-sponsored health benefits. Families have the option to receive care through a computer or smartphone. There are 4 main intervention offerings available, that are (1) psychoeducational content, (2) telebehavioral health coaching, (3) telepsychotherapy, and (4) telepsychiatry. A previous study from Brightline showed that 75% of children in coaching and 69% of children in telepsychotherapy and telepsychiatry demonstrated reliable improvement in their psychosocial functioning [14]. All families using the service have access to a rich library of scientifically informed educational content, including videos and exercises on a wide range of topics, including modules for children and their caregivers (eg, parent management training [PMT]). Families also have access to coaching support through chat.

Children and their caregivers, with preclinical or subclinical concerns, have access to a protocolized, evidence-informed 1:1 telecoaching program. Coaching programs typically last 4 to 6 sessions beginning with a structured assessment of the child's needs followed by either caregiver- or child-caregiver dyad–focused coaching. For example, caregiver skills training often includes understanding how to identify and focus on positive behaviors (as opposed to focusing on the child's negative behaviors), understanding and demonstrating effectiveness in using praise and other types of rewards to reinforce the child's positive behavior, and setting up behavioral plans and troubleshooting their implementation—modules developed based on best practices of PMT [15].

Families with children with higher acuity needs are referred to licensed therapists for evidence-based, family-centric telepsychotherapy. Interventions are derived from evidence-based approaches, including cognitive behavioral therapy, components of dialectical behavior therapy, and caregiver-mediated interventions (eg, PMT), rooted in trauma-informed and culturally responsive approaches to care. Standardized pathway-driven approaches, such as the Modular Approach to Therapy for Anxiety, Depression, Trauma, or Conduct Problems model (MATCH-ADTC), are used to support how care is implemented [16]. Children and teens who indicate plans to harm themselves or others have required admission to a psychiatric hospital or residential treatment facility within the previous 30 days, complicating substance use, or severely disordered eating are externally referred for immediate care and related care coordination.

In some instances, where the child can appropriately receive care from more than 1 type of program, families are able to enroll in a program of their preference.

Including a caregiver in care is standard. The focus of interventions differs based on age and presenting concerns, such that either a PMT (caregiver-only within sessions) or a dyadic care model (caregiver and child sessions; caregiver-only sessions are included) are used. In PMT, the child remains the focus, but the caregiver attends sessions alone, and the focus is on strategies to reduce negative behaviors in the home and improve positive connections between caregivers and their child. In dyadic care, the child and caregiver both participate in the course of care.

Participants

We included child-caregiver dyads who enrolled in the intervention between October 2021 and July 2023. Dyads must have completed at least 1 coaching, psychotherapy, or psychiatry session and completed a baseline and follow-up assessment. If participants' needs change as they progress through care and a different level of care is indicated, they may move to a different program. For this study, we exclude dyads that participated in more than 1 program.

Data Collected

Within each dyad, caregivers completed validated, self-reported assessments to evaluate the clinical effectiveness of receiving telebehavioral health coaching, telepsychotherapy, and telepsychiatry services. Baseline assessments were collected on the web before engagement with coaches and psychotherapists, and follow-up assessments were collected every 4 weeks during care [17].

Caregiver Strain

Caregivers completed the Caregiver Strain Questionnaire-Short Form 7 (CGSQ-SF7) [18], a caregiver-completed assessment of objective and subjective caregiver strain experienced over the past month. Potential causes of caregiver strain are rated on a scale from 1 (not at all) to 5 (very much). A total of 4 items assessing interruption of personal time, missing work, financial strain, and disruption of familial relationships due to the child's current challenges comprise the CGSQ-SF7 objective strain subscale, and 3 items assessing their own experience of sadness, worry, and fatigue or strain as a result of their child's challenges make up the CGSQ-SF7 subjective strain subscale. Subscale scores are calculated by taking the average of the item ratings. The CGSQ-SF7 total score is determined by adding the subscale scores together. The reliability and validity of the CGSQ-SF7 objective and subjective strain subscales are comparable to the full-length CGSQ [18].

Pediatric Symptoms

Caregivers completed the Pediatric Symptom Checklist-17 (PSC-17). The PSC-17 is a caregiver-completed survey that measures a child's total psychosocial functioning, with subscales that measure function in the areas of internalizing, attention, and externalizing concerns [19].

Analyses

For this retrospective cohort analysis, a pre-post study design was used based on CGSQ-SF7 assessments collected at baseline and discharge. If dyads were lost to follow-up, last-value-carried-forward imputation was implemented.

We separated the dyads into 2 groups, those with high caregiver strain and those with nonelevated caregiver strain. High strain was defined as having either a CGSQ-SF7 total score of 7.0 or more, objective score of 3.0 or more, or subjective score of 4.0 or more at baseline, and caregivers that did not meet any of these criteria were categorized as having nonelevated strain [20]. Counts of caregivers with reliable improvement were determined among dyads with high caregiver strain. Reliable improvement was defined as having a minimum detectable change of 1.13 or more on the total score, 0.66 or more for the objective score, or 0.76 or more for the subjective score [20]. Counts of caregivers that achieved maintenance were calculated for dyads with nonelevated strain at baseline. Maintenance was defined as having a minimum detectable change no less than –1.13 on the total score, –0.66 for the objective score, and –0.76 for the subjective score [20].

To evaluate patterns of symptom clustering among those with high caregiver strain at baseline, we used Ward hierarchical agglomerative clustering with Euclidean distances. Euclidean distance is the length between 2 points in a multidimensional space and is used to measure similarity among objects in cluster analyses [21]. Hierarchical agglomerative clustering is an unsupervised machine learning algorithm that progressively aggregates objects based on the distance metric and linkage criterion [22] and has been used for symptom clustering in previous studies [23]. Paired, 2-tailed *t* tests were used to evaluate changes in scores from baseline to follow-up across symptom clusters and CGSQ-SF7 subscales among caregivers with high strain at baseline. Cohen *d* was used to measure the effect size within each grouping.

To evaluate the relationship between caregiver strain and child behavioral health severity, we performed univariate linear regressions to test the association between CGSQ-SF7 and PSC-17 scores at baseline and the change in CGSQ-SF7 and PSC-17 scores from baseline to follow-up.

All statistical analyses were performed in R software (version 4.1.2; R Foundation for Statistical Computing).

Ethical Considerations

This study was classified as exempt from consent requirements under human subjects review by the Western Institutional Review Board (WIRB)-Copernicus Group Institutional Review Board, per Federal Regulations for the Protection of Human Research Subjects (45CFR 46.104(d)(4)) (protocol Brightline.004) [24].

Results

Participants

Demographics of the children are reported in Table 1. Of the 1647 children, 806 (48.9%) completed a course of care in coaching, 750 (45.5%) in psychotherapy, and 91 (5.5%) in psychiatry. Dyads, including teenagers (aged 13-17 years), made up the largest proportion of children in psychiatry and psychotherapy (56%, 51/91 and 39.1%, 293/750), compared with those who received coaching (23.1%, 186/806). The majority of children in the dyads were White (60.8%, 1002/1647); however, 12.8% (210/1647) reported identifying as multiracial. There were no differences in baseline CGSQ-SF7 scores by race of the child (Table 2). Overall, 882 (53.6%) of children in dyads were female. Notably, the proportion of females was larger than males in psychiatry and psychotherapy (63.7%, 58/91 and 57.1%, 428/749) compared with those who received coaching (49.1%, 396/806). On average, dyads completed 6.7 (SD 4.3) sessions in coaching, 10.6 (SD 6.8) sessions in psychotherapy, and 19.2 (SD 11.7) sessions in psychiatry.

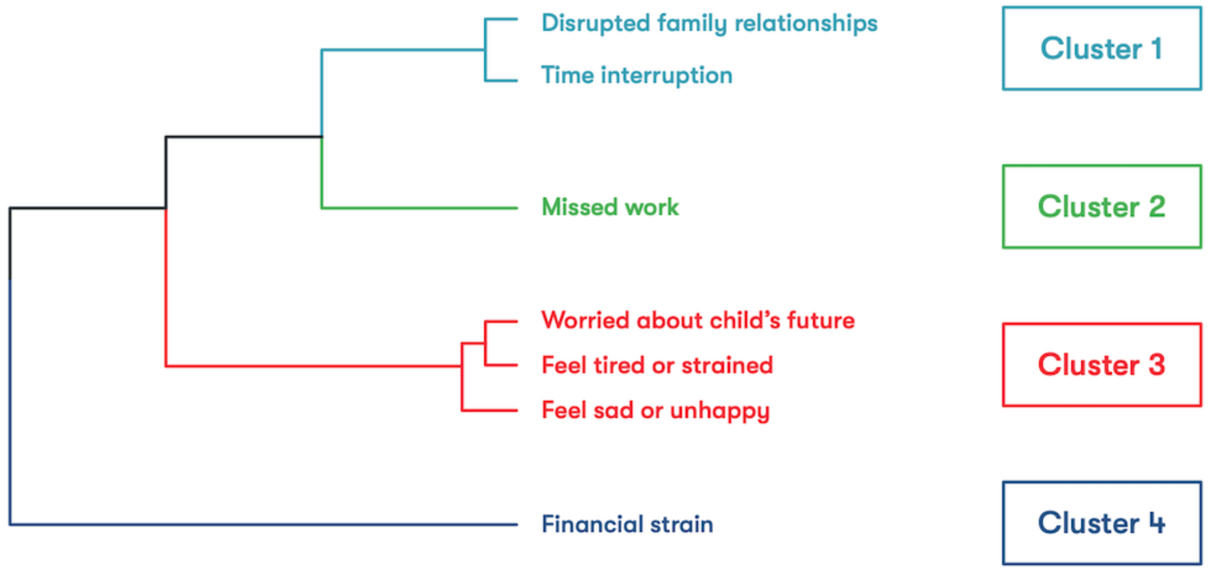
Caregiver Strain Symptom Clusters

The structure of the dendrogram produced from the hierarchical agglomerative clustering procedure suggests that four symptom clusters fit the data well (Figure 1), with key drivers of caregiver strain being (1) disrupted family relationships and time interruption, (2) missed work, (3) worry about their child's future and who felt tired and sad, and (4) financial strain. At baseline, 71.4% (1176/1647) of caregivers experienced symptoms in Cluster 1, 61.0% (1004/1647) experienced symptoms in Cluster 2, 80.4% (1325/1647) experienced symptoms in Cluster 3, and 20.8% (342/1647) experienced symptoms in Cluster 4.

Figure 1. Caregiver strain symptom clusters among caregivers with a high Caregiver Strain Questionnaire-Short Form 7 at baseline. This figure shows the key drivers of strain for caregivers of children with mental illness.



The Euclidean distance at which the symptoms merged for Cluster 3 was small and aligned with the grouping of symptoms defined in the CGSQ-SF7 subjective strain subscale. Therefore, further analysis of Cluster 3 was not conducted. However, the financial strain and missed work symptoms merged with other clusters at large Euclidean distances, suggesting that these symptoms are distinct from each other. Consequently, we treated the financial strain and work symptoms as independent clusters. This observation is a departure from the CGSQ-SF7 objective strain subscale grouping that clusters financial strain, missed work, time interruption, and disrupted family relationship symptoms together [18].

Caregiver Strain

Overall, the highest baseline caregiver strain was in the group receiving psychiatry and lowest in the group receiving coaching (Table 3). Baseline subjective measures of caregiver strain were higher in all groups than objective measures of caregiver strain (Table 3). Among those with high strain, a reliable improvement in the CGSQ-SF7 total was demonstrated in 78.9% (90/114) caregivers in coaching, 68.5% (113/165) caregivers in psychotherapy, and 65.2% (15/23) caregivers in psychiatry (Table 4). Maintenance on the CGSQ-SF7 total was achieved among caregivers without high strain for (93.2% (645/692) caregivers in coaching, 90.4% (529/585) of caregivers in psychotherapy, and 83.8% (57/68) of caregivers in psychiatry (Table 4). Rates of reliable improvement and maintenance were high for CGSQ-SF7 objective and subjective scores (Table 4). CGSQ-SF7 total, subscale, and cluster scores decreased from baseline to follow-up across all programs (Table 5).

Table 3. Caregivers with high and low-to-moderate Caregiver Strain Questionnaire-Short Form 7 scores at baseline.

Child-enrolled program	Total			Objective			Subjective		
	Baseline, mean (SD)	High strain[a], n (%)	Low-to-moderate strain[b], n (%)	Baseline, mean (SD)	High strain[a], n (%)	Low-to-moderate strain[b], n (%)	Baseline, mean (SD)	High strain[a], n (%)	Low-to-moderate strain[b], n (%)
Coaching	5.0 (1.7)	114 (14.1)	692 (85.9)	2.1 (0.8)	127 (15.8)	679 (84.2)	2.9 (1.0)	171 (21.2)	635 (78.8)
Psychotherapy	5.5 (1.7)	165 (22.0)	585 (78.0)	2.3 (0.8)	180 (24.0)	570 (76.0)	3.2 (1.0)	235 (31.3)	515 (68.7)
Psychiatry	5.8 (1.7)	23 (25.3)	68 (74.7)	2.4 (0.9)	25 (27.5)	66 (72.5)	3.4 (1.0)	37 (40.7)	54 (59.3)

[a] High strain was defined by having a total score of 7.0 or more, an objective score of 3.0 or more, or a subjective score of 4.0 or more at baseline.

[b] Low-to-moderate strain was defined as having a total score less than 7.0, an objective score less than 3.0, or a subjective score less than 4.0.

Table 4. Rates of reliable improvement and maintenance among caregivers on the Caregiver Strain Questionnaire-Short Form 7.

Child-enrolled program	Total		Objective		Subjective	
	Reliable improvement[a], n (%)	Maintained[b], n (%)	Reliable improvement[a], n (%)	Maintained[b], n (%)	Reliable improvement[a], n (%)	Maintained[b], n (%)
Coaching	90 (78.9)	645 (93.2)	93 (73.2)	633 (93.2)	119 (69.6)	596 (93.9)
Psychotherapy	113 (68.5)	529 (90.4)	114 (63.3)	506 (88.8)	160 (63.8)	477 (92.6)
Psychiatry	15 (65.2)	57 (83.8)	17 (68.0)	58 (87.9)	18 (48.6)	48 (88.9)

[a] Reliable improvement was determined among caregiver-child dyads with high strain and defined as having a minimum detectable change of −1.13 or lower on the total score, −0.66 for the objective score, and −0.76 for the subjective score.

[b] Maintained was determined among caregiver-child dyads with nonelevated strain and defined as having a minimum detectable change no less than −1.13 on the total score, −0.66 for the objective score, and −0.76 for the subjective score.

Table 5. Caregiver Strain Questionnaire-Short Form 7 total, subscales, and cluster scores among caregivers at baseline and follow-up.

Child-enrolled program	Baseline, mean (SD)	Follow-up, mean (SD)	Paired mean difference (95% CI)	Percent change (%)	*t* test (*df*)	*P* value[a]	Cohen *d*
Coaching							
Total	7.8 (0.8)	5.3 (1.6)	2.5 (2.2-2.8)	–32.1	16.8 (113)	<.001	1.9
Objective	7.5 (1)	5.3 (1.7)	2.2 (1.9-2.5)	–29.3	14.9 (126)	<.001	1.6
Subjective and Cluster 3[b]	7.3 (1)	5.1 (1.6)	2.2 (1.9-2.4)	–30.1	17.0 (170)	<.001	1.6

Objective	7.5 (0.9)	5.7 (1.9)	1.8 (1.5-2.1)	−24.0	13.1 (179)	<.001	1.2
Subjective and Cluster 3[b]	7.3 (0.9)	5.5 (1.9)	1.8 (1.6-2.0)	−24.7	15.2 (234)	<.001	1.2
Cluster 1[c]	6.7 (1.6)	5.8 (1.7)	1.0 (0.8-1.2)	−13.4	10.2 (373)	<.001	0.7
Cluster 2[d]	2.7 (0.8)	2.0 (1.1)	0.7 (0.6-0.8)	−25.9	15.0 (491)	<.001	0.8
Cluster 4[e]	2.7 (0.9)	2.0 (1.1)	0.7 (0.5-0.9)	−25.9	7.5 (186)	<.001	0.7
Psychiatry							
Total	8.1 (0.8)	6.1 (1.8)	2.0 (1.3-2.7)	−24.7	5.9 (22)	< .001	1.2
Objective	7.9 (1.0)	6.3 (1.7)	1.6 (0.8-2.2)	−20.3	4.5 (24)	<.001	1.1
Subjective and Cluster 3[b]	7.4 (1.1)	5.7 (1.8)	1.7 (1.2-2.3)	−23.0	6.4 (36)	<.001	1.1
Cluster 1[c]	6.8 (1.6)	6.0 (1.7)	0.8 (0.3-1.3)	−11.8	3.3 (54)	<.001	0.5
Cluster 2[d]	2.9 (0.9)	2.2 (1.1)	0.7 (0.5-1.1)	−24.1	5.5 (65)	<.001	0.8
Cluster 4[e]	2.8 (1.0)	1.9 (0.8)	0.9 (0.5-1.4)	−32.1	4.1 (23)	<.001	1.0

[a] *t* test *P* value is significant at .008 after adjusting for multiple comparisons using Bonferroni correction.

[b] Cluster 3 is made up of the same items as the Caregiver Strain Questionnaire-Short Form 7 subjective subscale.

[c] Cluster 1 includes disrupted family relationships and time interruption items.

[d] Cluster 2 includes the missed work item.

[e] Cluster 4 includes the financial strain item.

Association Between Caregiver Strain and Child Behavioral Health Severity

There was a strong positive association between baseline CGSQ-SF7 total score and PSC-17 total score (coaching: $\beta=.16$, $P<.001$; psychotherapy: $\beta=.13$, $P<.001$; and psychiatry: $\beta=.14$, $P<.001$; Table S1 in Multimedia Appendix 1). There was also a strong positive association between the change in CGSQ-SF7 total score and PSC-17 total score from baseline to follow-up (coaching: $\beta=.14$, $P<.001$; psychotherapy: $\beta=.13$, $P<.001$; and psychiatry: $\beta=.09$, $P=.01$; Table S1 in Multimedia Appendix 2).

Discussion

Principal Findings

Although there is a growing literature supporting digital mental health models for the adult population [25-27], there is far less research evaluating specific digital mental health models for children, teens, and their families [28]. In this study, we evaluated the effect of a web-based, multitiered pediatric mental health care intervention on caregiver strain and identified symptom clusters of caregiver strain measured within the CGSQ-SF7 associated with caring for a child with a mental health condition.

This analysis has 2 key findings. First, overall caregiver strain as measured by the CGSQ-SF7 total score, which is highly associated with their child's symptom severity, can improve with a mix of clinical interventions for the child and caregiver including coaching, psychotherapy, and psychiatry delivered on the web. Our results were consistent with previous studies that demonstrated that the severity of the child's problems is a key predictor of caregiver strain [29]. By matching patients and their families to the appropriate care pathway (ie, coaching vs psychotherapy vs psychiatry) based on both the child's symptom severity and family preference, this study suggests that these sources of caregiver strain can be improved. Not surprisingly, given their baseline acuity, families in coaching required fewer sessions and could be cared for in a shorter timeframe than families receiving the most intensive psychiatric care, which suggests that lower-intensity interventions may be an important part of the overall care landscape for families. Although other authors have found caregiver strain to vary by race and ethnicity in the adult mental health literature [6], we did not. This would be worth evaluating in a future analysis of caregivers for children.

Second, the drivers of caregiver strain measured within the CGSQ-SF7 vary among families with children in need of behavioral health services. While providing care focused on the child is beneficial for caregiver outcomes, it may also be valuable to target additional care to the specific needs of the caregiver. Targeted interventions may be more possible with the identification of key drivers of caregiver strain, which may be overlooked when relying on the CGSQ-SF7 total, objective, or subjective subscales alone. Specifically, disrupted family relationships and time interruptions, missing work, and financial strain are distinct caregiver strain symptoms within the CGSQ-SF7 that independently clustered in our population. Despite these symptoms being objective measures of caregiver strain, it may be insightful for providers to not only administer the CGSQ-SF7, but also to individually evaluate these distinct symptom clusters within the CGSQ-SF7 objective subscale, and include these considerations in care planning, as they may provide insights into the specific action plan and supportive interventions for each family. For example, for those caregivers for whom disrupted family relationships and time interruption were key drivers of caregiver strain, whole-family counseling or marital counseling may be warranted [30]. Similarly, those caregivers most worried about their child’s future who feel tired and sad may benefit from individual care or respite programs [31]. In addition, employers may have a role in mitigating strain among caregivers of children with mental illness. For caregivers for whom missed work was a key driver of strain, a more flexible work schedule may be helpful, and a robust benefit offering of no and low-cost mental health solutions may be particularly helpful for caregivers for whom the financial strain of caring for their children was the key driver of their strain. Future research should specifically evaluate additional interventions for caregivers, and whether those are most impactful delivered separately for caregivers or embedded within care for the family.

Limitations

Our analysis had several limitations; the first being our retrospective, observational design that did not include randomization or a control group. The second limitation is driven by our limited demographic data on each dyad which only included the age, gender, and race and ethnicity of the child. This lack of broad demographic data meant we were unable to control other important demographic variables, such as socioeconomic status, rurality, and family structure, since users are not currently required to provide this information to receive care. Third, while uncommon, it is possible for multiple caregivers to be involved in care. Fourth, we do not account for the number of care sessions completed by each dyad and how dose may moderate outcome estimates. Finally, this analysis aggregated all mental health diagnoses and concerns into one group. Specific diagnoses and concerns may have varying outcomes to web-based behavioral health programs and have different sources of caregiver strain. Future studies will address these limitations.

Conclusion

This analysis of a web-based, multi-tiered pediatric mental health care model demonstrates a positive impact on caregiver strain among a privately insured population with access to a computer or smartphone. We also identified common sources of caregiver strain measured within the CGSQ-SF7 among parents caring for a child with a mental health condition. We hope this work will inform the ongoing development of web-based pediatric mental health models and the designs of health benefits for commercially insured populations.

Data Availability

The data sets generated during and/or analyzed during this study are not publicly available but are available from the corresponding author on reasonable request. STROBE guidelines were adhered to and submitted as Multimedia Appendices.

Abstract

Background: The Singapore integrated 24-hour activity guide for children and adolescents was introduced to promote healthy lifestyle behaviors, including physical activity, sedentary behavior, sleep, and diet, to enhance metabolic health and prevent noncommunicable diseases. To support the dissemination and implementation of these recommendations, a user-friendly online resource was created to help children and adolescents adopt these behaviors in Singapore.

Objective: This study aimed to assess the acceptability of the online resource in the adoption of healthier lifestyle behaviors, and the change in the users’ behaviors with the use of this online resource.

Methods: Participants aged 7-17 years were required to log their activity levels of the past 7 days at the beginning and at the end of a 3-month period using the browser-based online resource, including information on the duration and frequency of moderate-to vigorous-intensity physical activity (MVPA), length of sedentary behavior, duration and regularity of sleep, and food portions. User satisfaction, on the length, ease of use, and relevance of the online resource, was also recorded using a 10-point Likert scale. Descriptive statistics and statistical analyses, including the Wilcoxon signed rank test and McNemar test, were carried out at baseline and at the end of 3 months.

Results: A total of 46 participants were included for analysis. For physical activity, the number of days of MVPA increased from a median of 3 (IQR 2 - 5) days to 4 (IQR 2 - 5) days (P=.01). For sedentary behavior, the median daily average screen time decreased from 106 (IQR 60 - 142.5) minutes to 90 (IQR 60 - 185) minutes. For sleep, 10% (5/46) more participants met the recommended duration, and the number of days with regular sleep increased from a median of 6 (IQR 5 - 7) days to 7 (IQR 5 - 7) days (P=.03). For diet, there was a decrease in the portion of carbohydrates consumed from a median of 42% (IQR 30 - 50) to 40% (IQR 30 - 48.5; P=.03), and the number of days of water and unsweetened beverage consumption remained stable at a median of 5 days but with a higher IQR of 4 - 7 days (P=.04). About 90% (39-41/46) of the participants reported that the online resource was relevant and easy to use, and the rating for user satisfaction remained favorable at a median of 8 with a higher IQR of 7 - 9 (P=.005).

Conclusions: The findings support the development of a dedicated online resource to assist the implementation of healthy lifestyle behaviors based on the Singapore integrated 24-hour activity guide for children and adolescents. This resource received favorable ratings and its use showed the adoption of healthier behaviors, including increased physical activity and sleep, as well as decreased sedentary time and carbohydrate consumption, at the end of a 3-month period.

KEYWORDS

online; physical activity; sedentary behaviour; sleep; diet; 24-hour activity; child; adolescent

Introduction

The World Health Organization (WHO) has identified the adoption of healthy lifestyle behaviors as a key preventive strategy against noncommunicable diseases (NCDs), such as cardiovascular diseases, cancers, and diabetes [1]. This strategy is best implemented when one is young, as children are not immune to the adverse health effects of suboptimal lifestyle behaviors [1]. Local longitudinal studies have also shown that children suffer adverse health effects from suboptimal lifestyle behaviors, including higher BMI from a lack of physical activity [2], longer screen time [3,4], and insufficient sleep [5]. Shorter sleep was also associated with decreased body length in the first 2 years of life [5]. This is even more concerning given the rise in the percentage of local overweight school-going children from 11% in 2013 to 17% in 2021 [6], and that less than half of these children are achieving the recommended amount of physical activity [7].

To improve the metabolic health of Singaporean children and adolescents aged 7-17 years, Singapore integrated 24-hour activity guide for children and adolescents was introduced to provide up-to-date and evidence-based recommendations on physical activity, sedentary behaviors, sleep and eating habits, framed within a 24-hour period [7]. During the development of this guide, Quah et al [8] surveyed 100 parents of school-going children revealing that they were concerned about the lack of physical activity and excessive screen-viewing time in their children, but only about half of these parents were aware of what the recommendations are for these activities. The findings from this study also highlight the importance of dissemination and implementation of the guide, including the development of resources to improve the awareness and adoption of this guide in the community [8].

Therefore, the aim of this pilot study was to create a user-friendly online resource to assess a child's or adolescent's activity levels based on the guide, with advice on improving or maintenance of the respective behaviors. The objectives were to assess the acceptability of the online resource in the adoption of healthier lifestyle behaviors, and the change in the user's behaviors with the use of this online resource.

Methods

Study Sample

The participants were recruited using a convenience sampling method via posters and social media advertisements. Eligible participants had to be of school-going age from 7 to 17 years, have access to electronic devices with an internet connection, and be able to participate in physical activity. Participants were required to log their activity levels using the online resource at the beginning and the end of a 3-month period (ie, baseline entry during the first week and final entry during the 12th week of the 3-month period).

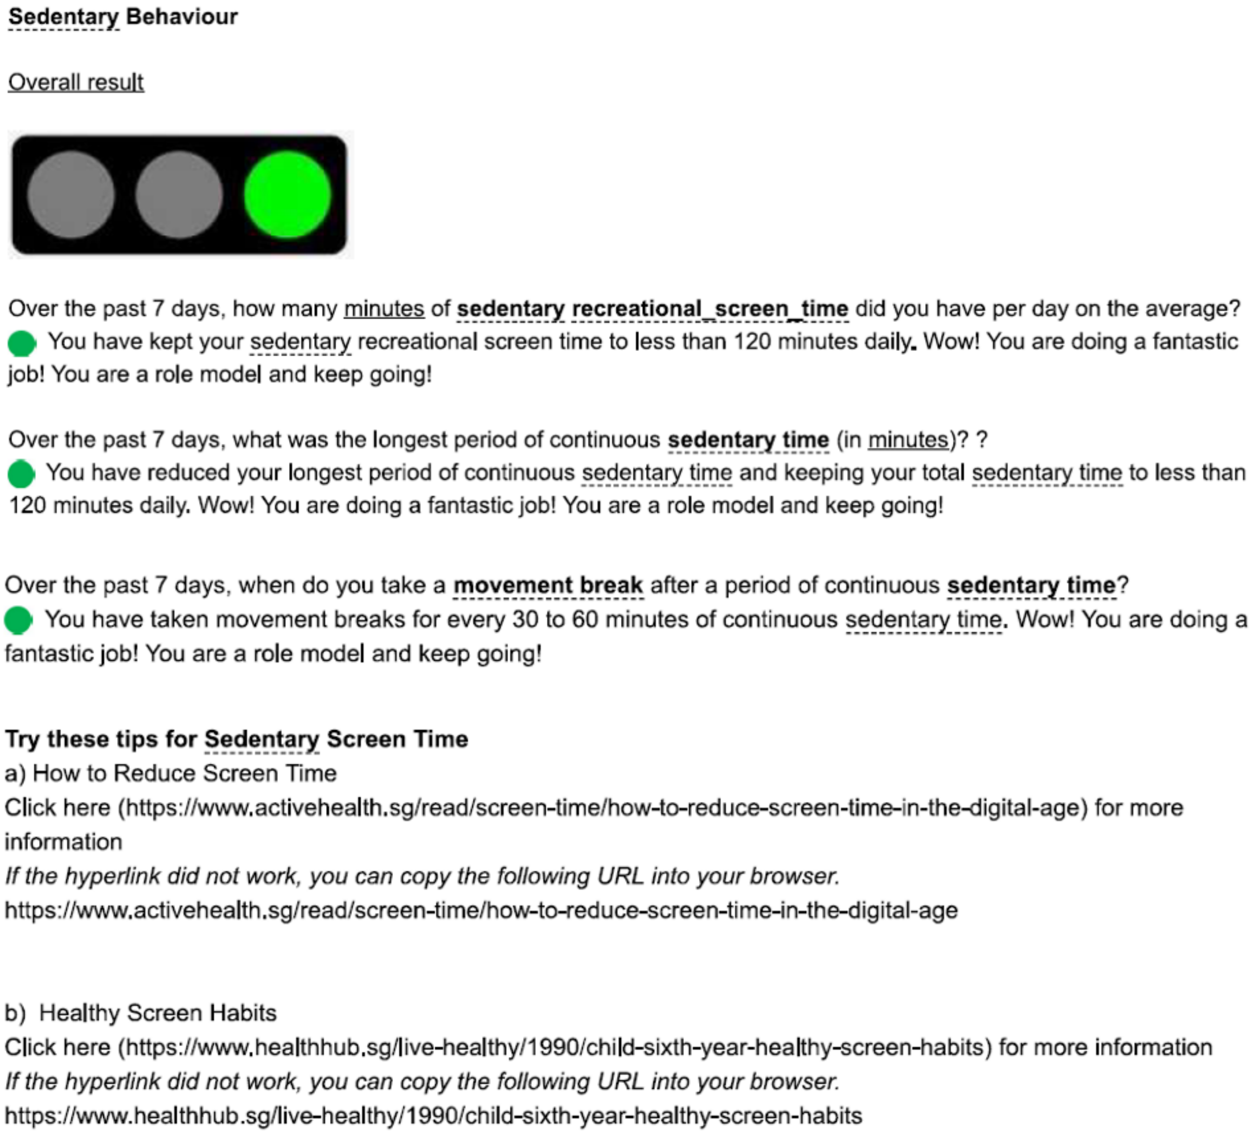
Ethical Considerations

This study obtained ethics approval with an exempt review from the SingHealth Centralised Institutional Review Board (reference number 2021/2403). Informed consent from parents and assent from participants were obtained before using the online resource, and they were allowed to withdraw from the study at any time. All data were de-identified using unique study IDs. All participants received SGD 20 (US $15.07) upon completing each survey as compensation for their time.

Resource Design and Data Collection

The online resource was designed as a browser-based activity diary. This resource was accessed via both computer and mobile devices. Each participant was assigned a unique username and a random password was generated for each entry. To improve the user interface and to minimize incomplete or missing data, participants were required to key in their information or activity level using a drop-down list or along a numerical bar. The questions for each activity domain were presented on a single page and were in sequential order (ie, all questions for physical activity were on the first page and all questions for sedentary behavior were on the next page). After entering all required data, the participant proceeded to the report page and was prevented from returning to edit the entered data. The resource was programmed to generate a report based on the data for each activity domain in the form of traffic light colors. Green was shown when the participant had met all recommendations for that domain, yellow if he or she met some, and red if none of the recommendations was achieved. Following the report, messages of encouragement and advice were displayed to help the participants maintain or improve their lifestyle behaviors (refer to Figures 1-3 for samples of reports, messages, and advice generated). Several links to recommendations and resources including the Singapore integrated 24-hour activity guide were also provided [7].

Figure 1. Sample of report, messages and advice generated in the online resource tool (green color shown) when recommendations are met for sedentary behavior.



Sedentary Behaviour

Overall result

Over the past 7 days, how many minutes of **sedentary recreational_screen_time** did you have per day on the average?
● You have kept your sedentary recreational screen time to less than 120 minutes daily. Wow! You are doing a fantastic job! You are a role model and keep going!

Over the past 7 days, what was the longest period of continuous **sedentary time** (in minutes)? ?
● You have reduced your longest period of continuous sedentary time and keeping your total sedentary time to less than 120 minutes daily. Wow! You are doing a fantastic job! You are a role model and keep going!

Over the past 7 days, when do you take a **movement break** after a period of continuous **sedentary time**?
● You have taken movement breaks for every 30 to 60 minutes of continuous sedentary time. Wow! You are doing a fantastic job! You are a role model and keep going!

Try these tips for Sedentary Screen Time
a) How to Reduce Screen Time
Click here (https://www.activehealth.sg/read/screen-time/how-to-reduce-screen-time-in-the-digital-age) for more information

Figure 2. Sample of report, messages, and advice generated in the online resource tool (yellow color shown) when some recommendations are met for sleep.

Sleep

Overall result

Over the past 7 days, how many hours of **sleep** did you have per night on the average?
🔴 This seems really tough but every effort counts. Let's try with a little more this week and progress towards having 6/7/8 hours or more of daily sleep. We are cheering for you!

Over the past 7 days, how many days did you have a **regular_sleep_and_wake_up_time**?
🟢 You have had a regular sleep and wake up time daily. Wow! You are doing a fantastic job! You are a role model and keep going!

Over the past 7 days, how many days of **uninterrupted_sleep** did you have?
🟢 You have had uninterrupted sleep daily. Wow! You are doing a fantastic job! You are a role model and keep going!

Try these tips for Sleep
a) Having Good Sleep
Click here (https://www.healthhub.sg/programmes/117/goodsleep) for more information
If the hyperlink did not work, you can copy the following URL into your browser.
https://www.healthhub.sg/programmes/117/goodsleep

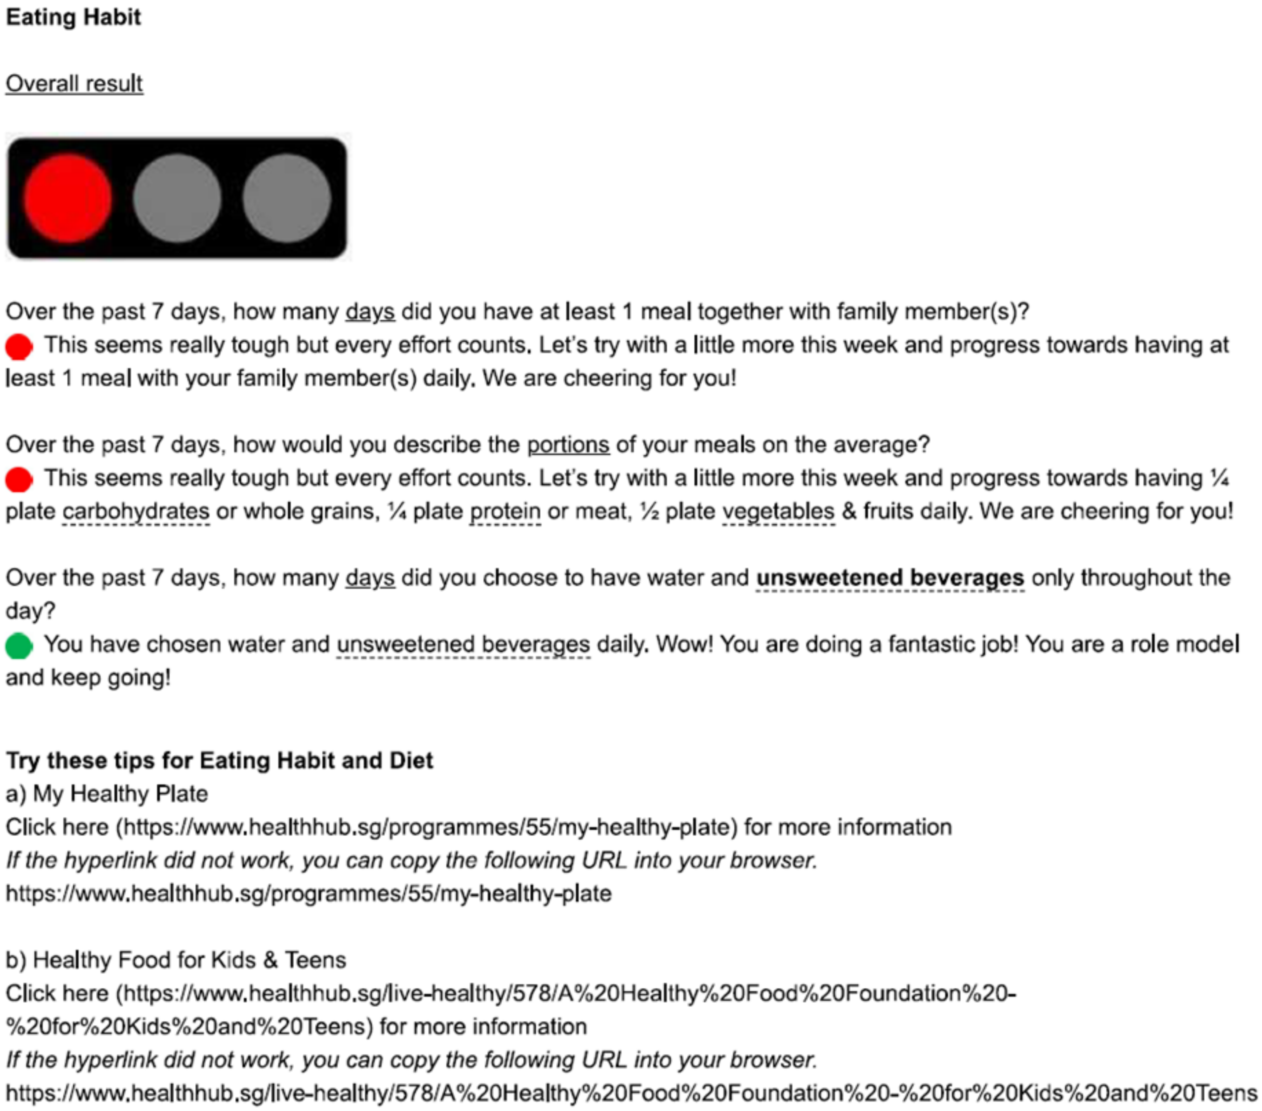
Figure 3. Sample of report, messages, and advice generated in the online resource tool (red color shown) when recommendations are not met for eating habits.



Eating Habit

Overall result

Over the past 7 days, how many days did you have at least 1 meal together with family member(s)?

🔴 This seems really tough but every effort counts. Let's try with a little more this week and progress towards having at least 1 meal with your family member(s) daily. We are cheering for you!

Over the past 7 days, how would you describe the portions of your meals on the average?

🔴 This seems really tough but every effort counts. Let's try with a little more this week and progress towards having ¼ plate carbohydrates or whole grains, ¼ plate protein or meat, ½ plate vegetables & fruits daily. We are cheering for you!

Over the past 7 days, how many days did you choose to have water and **unsweetened beverages** only throughout the day?

🟢 You have chosen water and unsweetened beverages daily. Wow! You are doing a fantastic job! You are a role model and keep going!

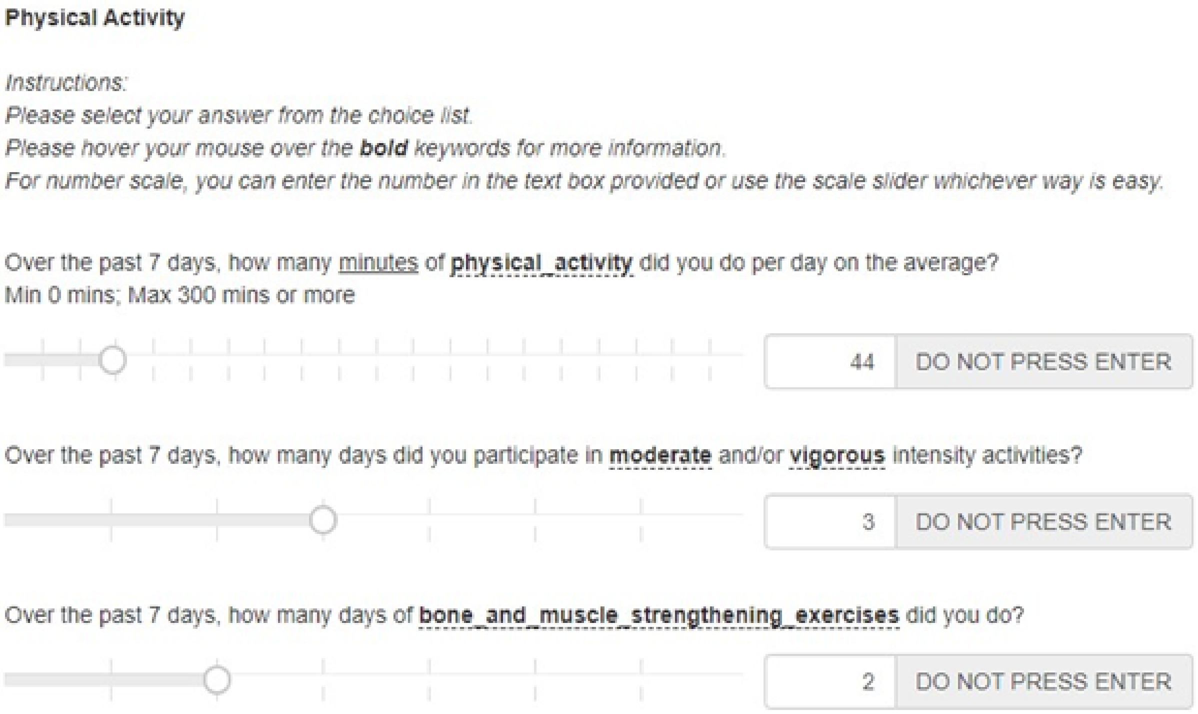
Question Design and Content Validation

A total of 27 questionnaire items garnered data on demographics, physical activity, sedentary behavior, sleep, eating habits, and user satisfaction. Participants aged 9 years and younger were recommended to enter the data together with their parents, and those older than 9 years did by themselves and sought their parent's guidance as needed. The participants were required to answer the activity questions based on their lifestyle activities over the past 7 days. Demographic information was solicited only when the participants used the resource for the first time, which included age, gender, ethnicity, height, and weight. The level of motivation for exercise of the participants was assessed using 4 questions adapted from Exercise Is Medicine, Australia [9]. In total, 3 questions were created for each activity domain based on the recommendations stated in the Singapore integrated 24-hour activity guide for children and adolescents. As there was no prior resource tool developed on the basis of this guide, all questions were created de novo by the guide developers. To improve the understanding and acceptability by local participants, the questions were written using similar language and styles used in the guide, and local resources were quoted whenever applicable. These questions were content validated qualitatively and quantitatively (content validity index of 0.94) for relevance and representativeness by two independent content experts using the response process validation procedure–an advocated best practice procedure outlined by Yusoff [10]. The content validity index of 0.94 is within the recommended acceptable range of at least 0.80 [10].

Assessment of Physical Activity and Sedentary Behavior

To assess the quantity of physical activity participation in the past 7 days, the participants were asked about the number of minutes of physical activity (inclusion of all intensities) engaged per day on average, the number of days they participated in activities of moderate to vigorous intensity, and the number of days they participated in muscle- and bone-strengthening exercises (refer to Figure 4). The recommended amount of physical activity is to engage in 420 minutes or more of moderate- to vigorous-intensity physical activity (MVPA) and to participate in 3 or more days of muscle- and bone-strengthening activities in a week [7].

Figure 4. Questions asked and sample response in the online resource tool for physical activity.



Physical Activity

Instructions:
Please select your answer from the choice list.
*Please hover your mouse over the **bold** keywords for more information.*
For number scale, you can enter the number in the text box provided or use the scale slider whichever way is easy.

Over the past 7 days, how many minutes of **physical_activity** did you do per day on the average?
Min 0 mins; Max 300 mins or more

44

Over the past 7 days, how many days did you participate in **moderate** and/or **vigorous** intensity activities?

3

Over the past 7 days, how many days of **bone_and_muscle_strengthening_exercises** did you do?

2

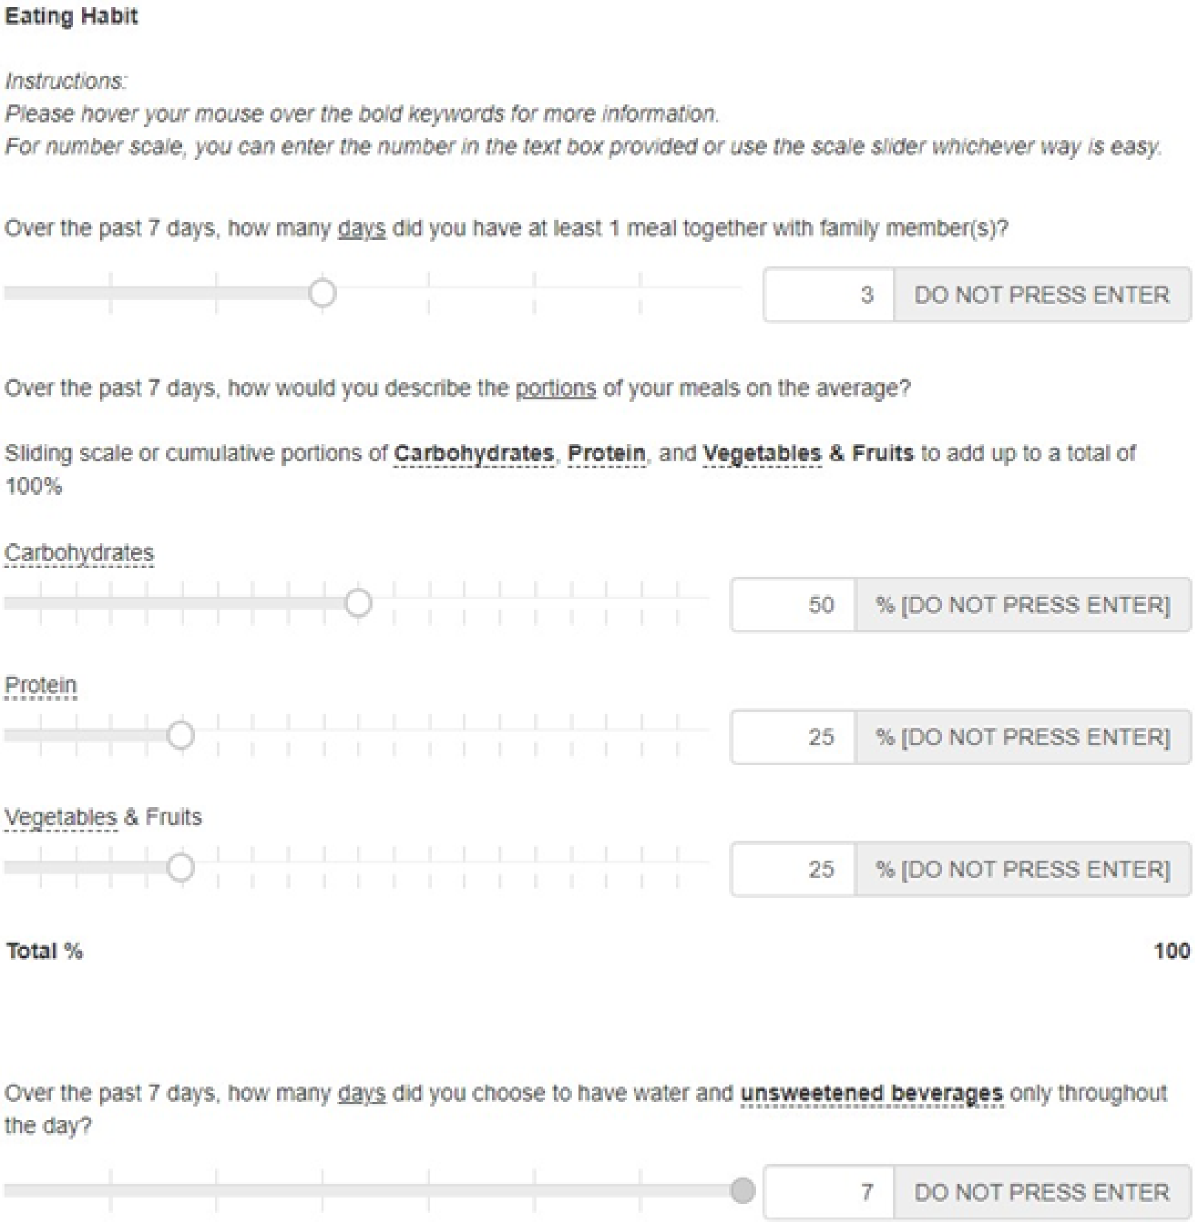
To assess the amount of sedentary behavior over the past 7 days, the participants were asked the daily average of sedentary recreational screen time, the longest period of continuous sedentary time, and when they took a movement break after a period of sedentary time. All these periods were participant-reported in minutes. The recommended average amount of screen time and continuous sedentary time is 120 minutes or less, and the recommended movement break is after every 60 minutes or less of sedentary time [7].

Assessment of Sleep and Eating Habits

To assess the quantity and quality of their sleep in the past 7 days, the participants were asked the average number of hours of sleep per night, the number of days they had regular sleep, and the number of times they woke up from sleep as well as the number of days of uninterrupted sleep. The recommended duration of sleep is according to the participant's age group (9-11 h for 7-13 y and 8-10 h for 14-17 y), and they are recommended to have regular and uninterrupted sleep daily (ie, 7 d per week) [7].

To assess the characteristics of their eating habits over the past 7 days, the participants were asked the number of days they had at least one meal with their family members, the average portions of carbohydrate, protein, vegetable and fruit consumed per meal (adding to a total of 100%), and the number of days they drank water and unsweetened beverages (refer to Figure 5). The recommended portion of food is 25% of carbohydrate, 25% of protein, and 50% vegetables and fruit, and it is recommended to have at least one meal with their family members and to choose water and unsweetened beverages daily (ie, 7 d per week) [7].

Figure 5. Questions asked and sample response in the online resource tool for eating habits.



Eating Habit

Instructions:
Please hover your mouse over the bold keywords for more information.
For number scale, you can enter the number in the text box provided or use the scale slider whichever way is easy.

Over the past 7 days, how many days did you have at least 1 meal together with family member(s)?

3 DO NOT PRESS ENTER

Over the past 7 days, how would you describe the portions of your meals on the average?

Sliding scale or cumulative portions of **Carbohydrates**, **Protein**, and **Vegetables & Fruits** to add up to a total of 100%

Carbohydrates 50 % [DO NOT PRESS ENTER]

Protein 25 % [DO NOT PRESS ENTER]

Vegetables & Fruits 25 % [DO NOT PRESS ENTER]

Total % **100**

Over the past 7 days, how many days did you choose to have water and **unsweetened beverages** only throughout the day?

7 DO NOT PRESS ENTER

User Satisfaction

The participants were asked about their opinion of the length of the survey (too short, just right, or too long), if the questions were easy to understand and if the online resource was easy to use (yes or no), if they thought that the questions were relevant to their health (important, somewhat important, not sure, somewhat not important, or not important), and their user satisfaction of the online resource using a 10-point Likert scale rating (1=very poor; 10=very good).

Statistical Analyses

Data analyses were conducted using the IBM SPSS Statistics for Windows (version 28.0). Continuous variables were presented as median and IQR and categorical variables as numbers and percentages. The Wilcoxon signed rank test and McNemar test were used to compare continuous variables and categorical variables, respectively, between the baseline and 3-month follow-up responses. Statistically significant results were determined at two-sided *P* values of less than .05. Effect size was measured using probability superiority with a value of more than 0.5 indicating a large effect for the 3-month follow-up assessments when compared with baseline assessments.

Results

Study Participants

A total of 57 participants were recruited from July to December 2022 and 11 participants were excluded due to incomplete data entry (ie, N=46). The details of the participants included are presented in Table 1. The mean age of the participants was 9.9 (SD 2.6) years with 52% (24/46) males, and the majority being Chinese (40/46, 87%). Most of the participants (37/46, 81%) reported that they have been physically active for the past 6 months (ie, maintenance phase in the 5 stages of change), and 9% (4/46) in the preparation phase with the remaining in the contemplation or precontemplation phase of exercise motivation [9].

Table . Characteristics of participants including their level of motivation (N=46).

Characteristics		Included participants (N=46)
Age (years), mean (SD)		9.9 (2.6)
Sex, n (%)		
	Male	24 (52)
	Female	22 (48)

Survey Satisfaction

A survey of participants' first-time usage of the online resource showed that 89% (41/46) agreed that the survey length was just right, and 85% (39/46) found the online resource easy to use. Almost 90% (41/46) of the participants reported that the questions were at least somewhat important to their health and 94% (43/46) found the questions easy to understand. The user satisfaction rating of the online resource was favorable at a median of 8 (IQR 6 - 8), based on a 10-point Likert scale. The results of the participants' 3-month follow-up rating showed that all aspects remained consistent and the rating was still favorable at a median of 8 with a higher IQR of 7 - 9 (P=.005). The survey rating was statistically significant (refer to Table 2).

Table . Rating of online resource tool at baseline and 3-month follow-up.

Domain		Baseline	3-month follow-up	*P* value[a]
Length of survey, n (%)				
	Too short	1 (2)	0 (0)	.56
	Just right	41 (89)	42 (91)	
	Too long	4 (9)	4 (9)	
Easy to understand, n (%)				
	Yes	43 (94)	43 (94)	>.99
	No	3 (7)	3 (7)	
Easy to use, n (%)				
	Yes	39 (85)	43 (94)	.12
	No	7 (15)	3 (7)	
Questions that are relevant to health, n (%)				
	Important	20 (44)	23 (50)	.53
	Somewhat important	21 (46)	17 (37)	
	Not sure	1 (2)	4 (9)	
	Somewhat not important	4 (9)	2 (4)	
	Not important	0 (0)	0 (0)	
User satisfaction rating of tool, median (IQR)				
	Median rating	8 (6 - 8)	8 (7 - 9)	.005

[a] *P* values are calculated using Wilcoxon signed rank test and McNemar test for continuous variables and categorical variables, respectively.

Baseline Activity Assessment

The duration of physical activity per day (for the past 7 d) recorded was a median of 60 (IQR 30 - 120) minutes, and the number of days of MVPA (for the past 7 d) and muscle- and bone-strengthening activities (for the past 7 d) were a median of 3 (IQR 2.0 - 5.0) days and 2 (IQR 1 - 3) days, respectively. The daily sedentary screen time per day (for the past 7 d) recorded was a median of 106 (IQR 60 - 142.5) minutes, and 21.8% (10/46) reported that their longest period of continuous sedentary behavior was above 120 minutes. The median period of daily sedentary behavior when the participants would take a movement break was 52.5 (IQR 30 - 60) minutes.

In terms of sleep, the number of hours slept per day (for past 7 d) was a median of 8 (IQR 8 - 9) hours, with 36.9% (17/46) meeting the recommended duration. The number of days with regular and uninterrupted sleep (for past 7 d) was a median of 6 (IQR 5 - 7) days and 7 (IQR 5 - 7) days, respectively. Just over 80% (37/46) of the participants reported having meals with their family daily over the past 7 days, and the median portions of carbohydrate, protein, and vegetable and fruit were 42% (IQR 30 - 50), 30% (IQR 28 - 35), and 30% (SD 20 - 32.8), respectively. The number of days of drinking water and unsweetened beverages in the past 7 days was a median of 5 (IQR 1 - 6) days with 20% (9/46) of the participants reporting doing so daily.

3-Month Follow-Up Activity Assessment

In a pre-to-post context, the average daily physical activity for the past 7 days remained stable at a median of 60 minutes but with a smaller IQR of 30 - 62.5 minutes (P=.03), while the number of days of MVPA and muscle- and bone-strengthening activity increased to a median of 4 (IQR 2 - 5.3) days (P=.01) and 3 (IQR 1 - 5) days (P=.02), respectively. There was a decrease in the daily average sedentary screen time to a median of 90 (IQR 60 - 185) minutes (P=.54), and fewer participants (14.3%, 7/46) reported their longest continuous period of sedentary time was more than 120 minutes. The median period of sedentary time before the participants took a movement break was also reduced to 30 (IQR 18.8 - 60) minutes (P=.08). The changes in the average physical activity duration, number of days of MVPA, and number of days of muscle- and bone-strengthening exercises were statistically significant (refer to Table 3).

Table . Level of physical activity, sedentary behavior, sleep and eating habits over the past 7 days–baseline and 3-month follow-up assessments using the online resource tool.

Domain	Baseline	3-month follow-up	*P* value	Probability superiority
Physical activity, median (IQR)				
Daily average amount (min)	60 (30-120)	60 (30-62.5)	.03	0.40
Moderate to vigorous physical activity (days)	3 (2 - 5)	4 (2 - 5.3)	.01	0.66
Muscle- and bone-strengthening activity (days)	2 (1 - 3)	60 (30 - 62.5)	.02	0.70
Sedentary behavior (min), median (IQR)				
Daily average screen time	106 (60 - 142.5)	90 (60 - 185)	.54	0.58
Longest continuous period	90 (60 - 120)	90 (60 - 120)	.79	0.52
Period of sedentary time before taking a break	52.5 (30 - 60)	30 (18.8 - 60)	.08	0.58
Sleep, median (IQR)				
Daily average amount (h)	8 (8 - 9)	8 (8 - 9)	.003	0.63
Regular sleep (days)	6 (5 - 7)	7 (5 - 7)	.03	0.60
Uninterrupted sleep (days)	7 (5 - 7)	7 (6 - 7)	.02	0.59
Eating habits, median (IQR)				
Meals with family members (days)	7 (0)	7 (0)	.34	0.48
Average portion of carbohydrate (%)	41.5 (30 - 50)	40 (30 - 48.5)	.03	0.64
Average portion of protein (%)	30 (28 - 35)	30 (28.8 - 36.3)	.22	0.40
Average portion of vegetable (%)	30 (20 - 32.8)	30 (20 - 35.3)	.10	0.62
Water and unsweetened beverages (days)	5 (1 - 6)	5 (4 - 7)	.04	0.66

The sleep duration remained stable at a median of 8 (IQR 8 - 9) hours (*P*=.003) but the increase in the minimum number of hours from 5 to 6 hours and the mean from 8.09 (SD 1.1) to 8.46 (SD 1.0) hours (data not shown) likely accounted for the significant *P* value. The percentage of participants meeting the recommended duration also increased to 48% (22/46; data not shown). The number of days with regular sleep increased to a median of 7 (IQR 5 - 7) days (*P*=.03) while the number of days with uninterrupted sleep improved to a median of 7 (IQR 6 - 7) days (*P*=.02). In terms of diet, there was a decrease in the percentage of participants having meals with their family daily (36/46, 78%). The median proportion of carbohydrate decreased to 40% (IQR 30 - 48.5*;* *P*=.03), whereas the proportions of protein and fruit and vegetable remained stable at 30% (IQR 28.8 - 36.3*;* *P*=.22) and 30 (IQR 20 - 35.3*;* *P*=.10), respectively. The number of days of water and unsweetened beverage consumption also remained stable at a median of 5 days but with a higher IQR of 4 - 7 days (*P*=.04). The average duration of sleep, number of days of regular sleep, number of days of uninterrupted sleep, portions of carbohydrate, and number of days of water and unsweetened beverage consumption were statistically significant (refer to Table 3).

Discussion

Principal Findings

This pilot study demonstrated that the novel online resource for improving lifestyle behaviors received consistent favorable ratings from the participants, with 87% to 89% agreeing that it was relevant to their health, and 85% to 94% agreeing that it was easy to use. These results help to reinforce the usefulness of online resources in assisting lifestyle behavioral changes and these may be in the form of a web-based tool [11,12], mobile app [13], or a combination of both [14]. van der Weegen et al [14] demonstrated that incorporating mobile and web-based tools in clinical practice increased the amount of participants' physical activity and the effect was still evident after 3 months. Online dietary tools were also developed in the United States and the United Kingdom as a part of their strategy to intervene in dietary habits at the population level. However, most of these tools focus only on a single lifestyle behavior and there is a paucity of available online resources that support the contemporary 24-hour activity approach. Therefore, it is imperative to develop an online resource to support the Singapore integrated 24-hour activity guide for children and adolescents as a concerted effort to improve the lifestyle behaviors in this pediatric population.

The assessment of the participants' activities also revealed that a significant proportion was unable to meet the recommendations in each activity domain. For instance, the calculated duration of MVPA in a week was 180 minutes (median average physical activity duration multiplied by median MVPA days – 60 min multiplied by 3 d), which was less than the recommended 420 minutes per week. Similarly, 63% (29/46) of the participants did not achieve the recommended sleep duration, and yet, the median sedentary screen time was close to 120 (IQR 60-142.5) minutes. Although the current recommendation on sedentary screen time is to be as low as possible, many parents might still be familiar with the previous recommendation of less than 120 minutes per day by the American Academy of Pediatrics [15]. In terms of their diet, the mean proportions of the main food groups also fell short of the recommended 25% of carbohydrate and protein, respectively, and 50% vegetable and fruit. These findings are consistent with studies in recent years, highlighting similar concerns that many children and adolescents in Singapore are not meeting these recommendations and hence not adopting healthy lifestyle habits [8,16,17]. Therefore, there is an ongoing need to educate the public on these recommendations and provide resources to aid them to adopt these lifestyle behaviors more easily.

Improvements in most lifestyle behaviors were observed when comparing the participants' 3-month follow-up activity assessments with their baseline assessments. In terms of physical activity, the number of days engaging in MVPA and muscle- and bone-strengthening activities increased from a median of 3 (IQR 2.0-5.0) days and 2 (IQR 1.0-3.0) days to 4 (IQR 2.0-5.3) days and 3 (IQR 1.0-5.0) days, respectively. Consequently, the calculated median duration of MVPA for the week also increased to 240 minutes. The average sedentary screen time decreased from a median of 106 (IQR 60.0-142.5) minutes to 90 (IQR 60.0-185.0) minutes, and the participants were taking earlier movement breaks after a median sedentary period of 30 (IQR 18.8-60.0) minutes as compared with the initial 52.5 (IQR 30.0-60.0) minutes. There were also improvements seen in sleep and dietary habits. The number of days with regular sleep increased from a median of 6 (IQR 5.0-7.0) days to 7 (IQR 5.0-7.0) days, and their carbohydrate intake decreased from a median of 41.5% (IQR 30.0%-50.0%) to 40% (30.0%-48.5%). Other components showed consistent results, such as the average daily amount of physical activity, the daily average amount of sleep, and the number of days consuming water and unsweetened beverages when compared with their baseline assessments; no deteriorating trend was found. These results showed the promising potential of using the online resource to tackle multiple lifestyle behavior domains of a subgroup within a population, and the effects could be enhanced by combining its use with clinical services and extending its adoption over a longer period [14].

The current movement guidelines toward an integrated 24-hour activity approach are built upon the evidence that similar health benefits can be achieved by meeting the recommendations of various combinations of activity domains [18,19]. Children and adolescents who meet all the recommendations have been shown to receive the best health benefits [20,21]. With the inclusion of dietary recommendations in the Singapore integrated 24-hour activity guide, a more comprehensive and holistic behavioral guidance approach of eating, moving, sleeping, and sitting is adopted. At the start of the pilot study, only 1 participant reported meeting the 3 movement recommendations (ie, physical activity, sedentary behavior, and sleep) but none met all recommendations including the dietary ones. These data improved by the end of the 3-month pilot study with 5 participants meeting the 3 movement recommendations and 2 meeting all, including the dietary recommendations. This improvement was likely because of improved participant and parental awareness of current recommendations and monitoring of their activities.

The next phase includes expanding this online resource to other age groups and developing it as a mobile app to improve user accessibility and community penetration. Leveraging on the experience of Singapore Paediatric Activity–Related Evaluation (SPARE) tool development, current team members have joined another work group to develop a similar digital resource for children aged 0 to 2 years. The eventual aim is to integrate all these resources into the institution's mobile health app so that a wider community can access and use these resources for themselves or their children.

Strengths and Limitations

This study is the first pilot on a single online resource that integrated multiple lifestyle behavior domains based on the latest 24-hour recommendations for Singaporean children and adolescents. The strength of the study lies in the assimilation of multiple lifestyle behavior activities in a single resource, and with the survey questions adapted to the local context. The limitations of the study include selection bias from the convenience sampling method and recall bias as participants were required to report their past activities. The decision for a 7-day recall was because it is a standard duration to capture habitual behaviors across weekdays and weekends. The small sample size and short timeframe of this study limit the generalizability of the findings to the national population and observations of long-term behavioral changes. Another limitation is the expectancy effects with self-reporting measures, which may influence participants' reporting toward socially acceptable norms.

Conclusions

This study showed that there were consistent favorable ratings from participants on its use. There was also the adoption of healthier lifestyle behaviors when comparing the participants' 3-month follow-up activity assessments with their baseline assessments after using the online resource, including increased physical activity and sleep while decreased sedentary time and carbohydrate consumption. The findings from this pilot study therefore support the role of developing a dedicated resource for the Singapore integrated 24-hour activity guide to assist in the promotion and implementation of the guide in children and adolescents [8]. Building a single resource catering for all activities provided easy access and likely catalyzed the awareness and adoption of these recommendations. The next phase would be to scale up the online resource in order to provide more convenient access, such as a mobile app, and to incorporate it into daily clinical practice.

Acknowledgments

This study received seed grant funding from the National Medical Research Council (NMRC) Centre Grant (grant reference number CGAug16C008). The funding body is not involved in the study design, collection or analysis of data, or the writing of the manuscript. The authors thank Nur Liyana Johari for her assistance in this study.

Authors' Contributions

All authors contributed to the design of the study. BKGL and FF collected the data. BKGL and SHT analyzed the data. BKGL provided the first draft of the manuscript; all authors provided critical reviews of the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Despite accessibility and clinical benefits, open access trials of self-guided digital health interventions (DHIs) for young people have been plagued by high drop-out rates, with some DHIs recording completion rates of less than 3%.

Objective: The aim of this study was to explore how young people motivate themselves to complete an unpleasant task and to explore perceived motivators and demotivators for engaging with a DHI.

Methods: In this qualitative research study, 30 children and adolescents aged between 7 and 17 years were recruited to participate in 7 focus groups conducted over a 3-month period. Focus group activities and discussions explored sources of motivation to complete tasks and engage in a hypothetical 6-week DHI for anxiety.

Results: Children (aged 7-11 years) reported greater reliance on external motivators such as following parent instruction to complete unpleasant tasks, while adolescents (aged 12-17 years) reported greater internal motivation such as self-discipline. Program factors, such as engaging content, were the most commonly mentioned motivators for engaging with a DHI across both age groups. After that, internal sources of motivation were most commonly mentioned, such as perceived future benefits. External factors were the most commonly mentioned demotivators across all ages, with time commitment being the most frequently mentioned.

Conclusions: The study’s findings have implications for enhancing adherence in future DHIs targeted to children and adolescents. Recommendations include the need for supportive parental involvement for children, while adolescents would likely benefit from mechanisms that promote autonomy, establish a supportive environment, and align with personal interests and values. Belief that a DHI will provide short-term benefits is important to both children and adolescents, as well as having confidence that future benefits will be realized.

Introduction

Self-guided digital health interventions (DHIs) represent a potential pathway to improve the mental well-being of children and adolescents [1,2]. DHIs use technology to deliver health care and support well-being. DHIs can be fully self-guided (eg, apps and web-based programs) or clinician supported (eg, helplines or web chat) and fulfill a range of purposes such as psychoeducation, cognitive behavioral therapy, self-assessment, or monitoring [3]. Compared to traditional face-to-face therapy, DHIs are inexpensive and widely available; approximately 86% of young Australians have access to DHIs delivered through internet services [4]. However, despite their accessibility and therapeutic appeal, open access trials of DHIs for children and adolescents have been plagued by high drop-out rates, with some DHIs recording completion rates of less than 3% [5].

Posttrial evaluations of DHIs have identified a range of factors that may explain why children and adolescents drop out and fail to complete prescribed web-based treatments. Common reasons include perceived low quality of content, usability issues, lack of support, and privacy concerns [2,6,7]. Although these studies provide useful insights, they tend to focus on program factors such as design, usability, and content, rather than individual factors such as motivation for engagement more broadly [8,9].

From a theoretical perspective, self-determination theory [10] suggests motivation is driven by an interplay of internal and external sources. Applied to motivation to complete DHIs, internal motivators may include engaging in a web-based program because it is enjoyable (eg, “I enjoy the activity”), while external motivators cover a range of motives outside the self, which may or may not interact with internal sources. These include participating in the program to avoid punishment (eg, “If I don’t do it I will get in trouble”), to receive a reward (eg, “I’m doing this to earn a certificate”), or because the program aligns with a partially or fully integrated value (eg, “This program is important to me”) [11]. Previous research has found that higher internal motivation, expressed as treatment readiness, predicted DHI adherence in adults treated for alcohol misuse [12] and completion of a 12-week DHI for anxiety [13]. However, to our knowledge, no previous study has explored how external and internal factors may influence children’s and adolescents’ motivation to complete a DHI. Factors that contribute to “loss of motivation” have also received limited research attention. Described as the “negative counterparts of motives” [14], demotivators represent influences that subtract from an ongoing action [15]. The aim of this study was to explore factors that motivate and demotivate children and adolescents to complete tasks. This knowledge could inform future strategies to enhance motivation for children and adolescents to engage in and complete DHIs.

Methods

Study Design

This qualitative study utilized focus group methodology to explore factors that motivate and demotivate young people to complete tasks. This was examined in two contexts: (1) while completing a task in their general life that they find unpleasant or boring, and (2) during hypothetical engagement in a self-guided DHI for anxiety. A focus group methodology was chosen due to the exploratory nature of the research questions.

Recruitment

Children and adolescents aged between 7 and 17 years were recruited to participate in focus group sessions. The potential for developmental differences in comprehension and expression across the age spectrum [15] was addressed by separating participants into age-based groupings that spanned a maximum of 3 years. Participants were recruited by posting advertisements and news posts on Facebook targeting users residing within 15 kilometers of the university precinct. Study information was also sent to faculty staff throughout the university. Communication material was directed at parents and included both parent and child study information.

Measures

Demographic Questions

Demographic data were collected prior to participation in focus groups. Adolescents (aged 12 years and older) and guardians (for children under 12 years) completed a brief questionnaire containing items on age, gender, year level at school, and history of mental health problems (“Has your child/have you ever experienced an emotional health problem?”).

Qualitative Questions

To support expression and mitigate the risk of groupthink [16], participants were encouraged to draw or write their ideas in response to stimulus material presented by the moderator (Textbox 1).

Textbox 1. Question guide.

Part A: Motivating Self

Think about something that you have to do each week that you really don’t like doing, but have to do anyway. Something you have to get done by yourself without help from anyone else.

1. Draw yourself doing it.
2. Put some feeling stickers on there.
3. Draw or write what it is that makes you get it done.

Part B: Engaging with Digital Health Interventions

I want you to imagine that you have signed up for this program, because you’ve been feeling scared, worried, or sad. To do the program, you have to log in on your computer every week for 6 weeks.

1. Start by putting some feeling stickers on there.
2. What do you think about having to keep going with it? Are there any reasons you don’t want to keep doing the program each week? What are the thoughts going through your head about that?
3. What are some things in your life that might get in the way of you logging on and doing the program?
4. What are some reasons why you would keep doing the program every week, even if you didn’t feel like doing it?
5. Draw or write down some things that might help you keep going with the program, even if you don’t feel like doing it?

Procedure

Eligible participants self-referred to the study by completing a web-based registration form. They were then contacted by email by a member of the research team and offered a place in a focus group based on availability specified during registration. Focus groups were held at a Brisbane, Australia, university campus between October and December 2021. On arrival, written consent was obtained from parents or guardians of participants under 16 years while those aged 16 and 17 years provided their own written consent. The demographic survey was completed by parents or guardians of children younger than 12 years, while adolescents aged 12 years and older completed their own. Participants were seated evenly around a large table, accompanied by a moderator (CC) who steered the discussions, as well as a supporting investigator (JC or SC, both clinical psychologists) responsible for note-taking and offering assistance to any child requiring attention during the focus group session. Participants were grouped together with children and adolescents of comparable ages to facilitate a conducive environment for interaction and sharing.

Parents were invited to remain in the room at a distance from the group or return at the conclusion of the session. Each focus group included two creative activities. In the first task, participants were provided with a blank piece of A4 paper, a set of 12 feeling/emotion stickers, and a pack of colored pens. They were invited to draw or write about a regular task they dislike doing and to then indicate how they felt about doing it using the stickers provided or by drawing their own. They were then asked to draw or write what it is that makes them get the task done. After completing their sheet, participants were invited to share their picture with the group if they were comfortable doing so (see Figure 1 for sample outputs).

For the second task, participants were provided with an A3 piece of paper featuring a color graphic of a young person facing a computer screen with thought bubbles to the side, a second set of 12 feeling/emotion stickers, and a pack of colored pens. Participants were introduced to a hypothetical DHI and shown a sample image of the dashboard of a web-based program for youth anxiety currently under development. We purposefully maintained a level of ambiguity regarding the application to prevent any potential biasing of participants' responses. Participants were asked to imagine they had signed up for the program because they had been feeling anxious. Participants completed 5 activities to draw out internal and external motivators and demotivators. They first indicated how they felt about doing the program using the sheet of stickers. They were then asked to write in one of the thought bubbles what they thought about doing it and any reasons why they would not want to continue with the program. Following this, they wrote or drew any things that would get in their way. Next, they were asked to use another thought bubble on the other side of the page to write down any reasons why they would keep doing the program even if they did not want to do it. Finally, they were asked to write or draw some things that would help them keep going with the program and get it done (see Figure 2 for an example output). The procedure for sharing and discussion was similar to the first task. All focus group sessions were audio-recorded and lasted between 60 and 80 minutes (including a break). A pilot test was conducted with 3 children to test engagement with drawing activities and general task comprehension. No changes to the guide were considered necessary; pilot group responses were not included in the analysis.

Figure 1. Examples of participant drawings about motivating self. (A) The left drawing was created by a 7-year-old female participant. (B) The right drawing was created by a 15-year-old female participant.

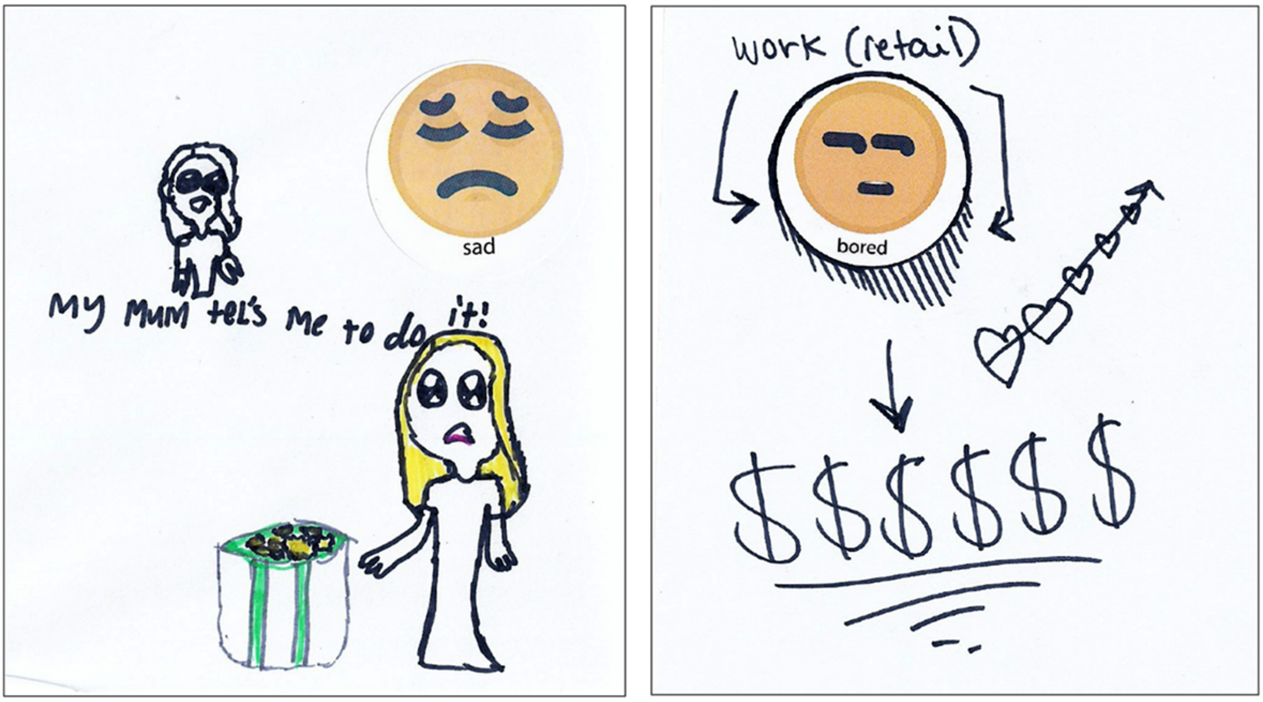

Figure 2. Example of a participant's drawings about engaging with a digital health intervention, created by a 12-year-old female participant.

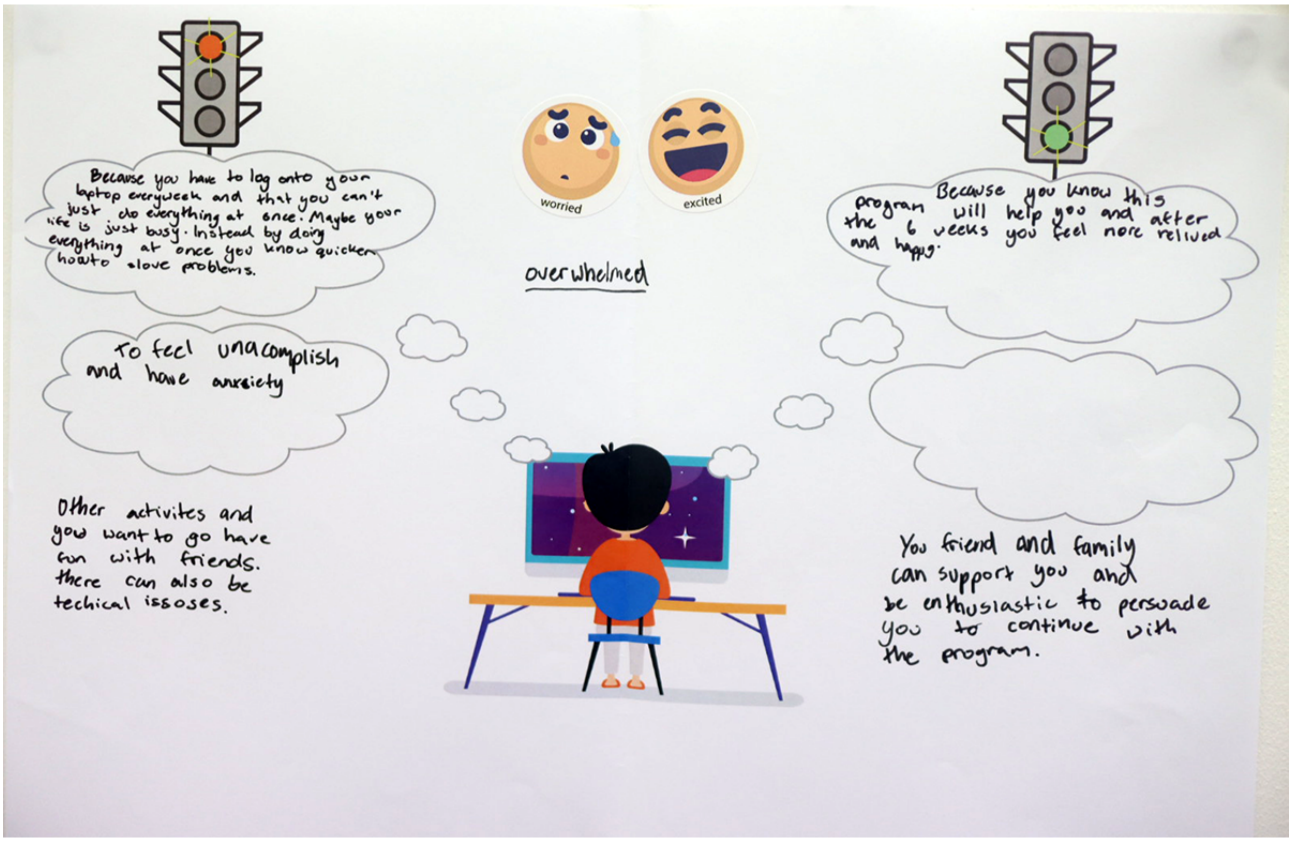


Data Analysis

Audio recordings from each focus group were transcribed and entered into QSR NVivo computer software (version 13; Lumivero). Thematic analysis [17] was used to analyze the data. Research team member CC initially reviewed and coded the transcripts. These codes were reviewed by a second researcher (SA) and both researchers independently generated preliminary themes. Any theme discordance was reconciled in discussions with a third researcher (JC). The final step involved all authors reviewing the theme labels and quotes for consistency and relevance and grouping subthemes.

Ethical Considerations

The study was approved by the Queensland University of Technology University Human Research Ethics Committee (Reference 4312-HE31). Written consent was provided by guardians of children under 16 years while those aged 16 and 17 years provided their own written consent. Participant responses were deidentified prior to analysis. Participants and their guardian were compensated with gift cards valued at Aus $30 (US $20.30) and Aus $40 (US $27.07), respectively.

Results

Participant Characteristics

A total of 31 participants were recruited; however, one (female, 16 years) was excluded due to inability to participate in the focus group due to severe anxiety. The final sample consisted of 30 children (18/30, 60% female) in 7 focus groups, with group sizes ranging from 3 to 6 participants (mean 4.3, SD 0.96). The age range within each group spanned 1-3 years. Specifically, the groups were conducted with participants aged 7-9 years, 7-10 years, 8-10 years, 10-13 years, 11-14 years, 14-16 years, and 16-17 years. Demographic characteristics are presented in Table 1.

Table . Participant characteristics.

	Children (7-11 years)	Adolescents (12-17 years)	Total (N=30)
Participants, n (%)	17 (57)	13 (43)	30 (100)
Female, n (%)	11 (65)	7 (54)	18 (60)
History of emotional problems, n (%)	8 (47)	7 (54)	15 (50)

Motivation to Complete Unpleasant Tasks

Home-based chores and routines (eg, unloading the dishwasher, taking a bath) were the most common unpleasant task type identified by children (12/17, 70%). In contrast, the majority of adolescents (9/13, 70%) chose tasks that originated out of the home (eg, homework or a part-time job).

Emotions

Participants selected an average of two stickers to represent their feelings about doing the task (mean 1.8 stickers, SD 0.8). Feeling bored (16/30, 53% of participants) and annoyed (15/30, 50%) were the most commonly selected feelings associated with things they did not like doing but had to do anyway. The popularity of these two emotions was common to both children and adolescents.

Motivational Sources

As shown in Table 2, children and adolescents identified a range of internal and external sources that underlie their motivation to complete unpleasant tasks. Adolescents were generally more expressive than children, identifying an average of 2.8 (SD 1.2) versus 1.1 (SD 0.9) sources, respectively. Internal motivation sources outnumbered external sources for adolescents, while external sources were more frequently mentioned by children.

Table . Internal and external motives experienced by children and adolescents during an unpleasant task.

	Number of responses from children (n=15)	Number of responses from adolescents (n=13)	Total (n=28)[a]
Internal motivational sources	4	28	32
Self-discipline	2	14	16
Sense of achievement	1	6	7
Fear of negative consequences	0	6	6
Making it fun	1	2	3
External motivational sources	12	9	21
Receive a reward	7	2	9
Avoid parental disapproval	1	4	5
Follow parent instruction	4	0	4
Social desirability	0	3	3
Total	16	37	53

[a] The data represent participant responses. Two children did not share motivational sources.

Internal Motivational Sources

The most common internal motivation source across all focus groups was self-discipline (16 responses). Included in this theme were reflections on responsibility and strategies that young people use to stay on task, including the use of self-talk and choosing to focus on the moment, as shown in the following comments.

> *I'll be like, "Come on man, you've committed to these subjects, You need to do it." And so I feel like that's a bit of my discipline.* [4R-17]
>
> *Yeah, you kind of just have to, so you force yourself to.* [6J-15]
>
> *Just kind of thinking, like, "This is my responsibility and it's helping me by doing it.* [5G-13]

A sense of achievement derived from completing the task was another common theme, expressed in comments from 6 adolescents and 1 child in the focus group discussions.

> *But when I have managed to finish it, then I've actually spent my time doing something useful, like I've achieved something.* [3Z-13]
>
> *It feels rewarding, so then sometimes I use a bit of that, like I tell myself, oh come on, just get it done and then you'll feel better afterwards that you've just done it.* [4R-17]

In addition, 6 adolescents (46% of adolescent participants) stated they were motivated by considering the negative consequences of not completing the task. For several participants, this appeared to be linked to a previous unpleasant experience (their own or observed in others). There was one adolescent that mentioned fear of failure and demonstrated the use of positive reappraisal as their language changed from fear of failure to focusing on the positive in order to motivate themselves to complete a difficult task.

> *So basically, I just remind myself of examples of people around me and just kinda kick myself up the pants.* [6L-16]
>
> *I'm just like, "If I don't do this, then it'll lead to this." So, it's just kind of, "Do it so that stuff doesn't happen.* [6E-14]
>
> *And then fear, I don't wanna get a bad end result, year 12. I need to put in a lot of effort into these things if I wanna do well…* [4R-17]

There were 3 participants who mentioned using various methods to make the task fun, such as thinking about other things or using music, either by listening to it or singing.

> *One thing that just pushes me to make sure I do it is I just think about other things while I do it.* [3E-13]
>
> *We make up a little song and then it helps us like, and then we like, sing it and then we get it done really quickly.* [7A-9]

External Motivational Sources

The most frequent external motivation was to receive a reward. For children, this often represented the opportunity to do other things (7 responses), while adolescents referred to financial rewards for unpleasant jobs (2 responses).

> *After I do it I can play.* [2E-10]
>
> *And something that helps me get through it is that I realize what I could do after I'm done, like, something good I can do it after I'm done.* [5S-11]
>
> *Obviously motivated by money 'cause yeah, that's the only reason people work.* [6J-15]

Parent or guardian influence on a child's motivational decision-making was evident in several responses, including inclination to follow parental instructions (4 responses).

> *Well, I normally ask my mom: "What do I have to do?", I do it.* [7E-9]
>
> *My mom told me to, so I have to do it.* [1H-10]

Avoiding parental disapproval from parents or guardians was mentioned by 4 adolescents and 1 child.

> *I sometimes don't have time to do it, which makes like my dad or my mom mad because I haven't done my chore.* [3E-13]
>
> *…and the thing that motivates me to do it is my parents will get mad at me if I don't do it.* [3L-14]
>
> *I don't get in trouble, so I have to do it.* [1J-8]

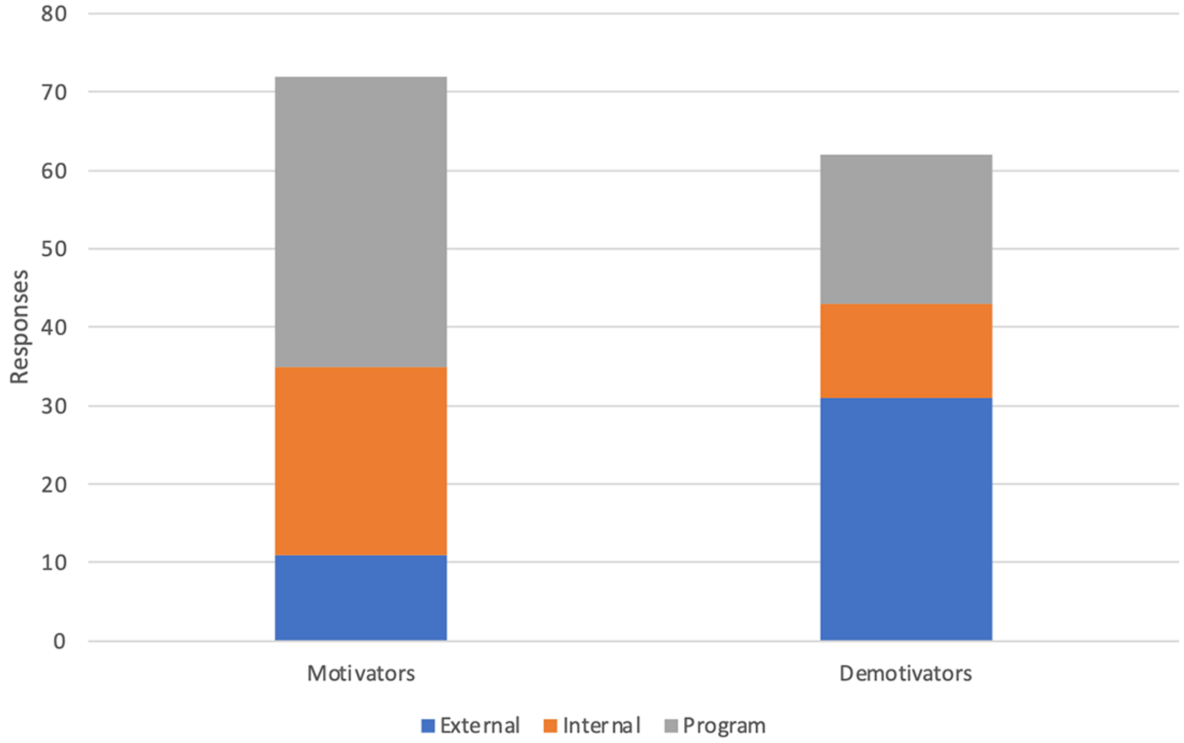
Social desirability was mentioned by 3 adolescents, 2 of whom highlighted peer comparison, while the third was motivated by a desire to meet the expectations of their parents and people around them.

> *I'm quite competitive and I know if I'll get a bad mark or compared to other people I'll get pretty sad so I just make myself do what I can.* [6E-14]
>
> *I'll say with me, my friend group is also pretty academic, so you think, "Oh, if I don't get a good mark, then other people are gonna be, "Oh, why are they friends with her? She's not as smart as them." You see.* [6V-15]
>
> *Of course, (I'm concerned about) my parents and then the people around me.* [6E-14]

Engaging With a DHI

Participants identified a range of motivating (72 responses) and demotivating (62 responses) sources that were categorized into internal, external, and program factors. As shown in Figure 3, program factors were the most frequently mentioned motivators (34 responses), while external sources were the most frequently mentioned demotivators (31 responses).

Figure 3. Motivation sources to engage in digital health interventions.



Emotions

Participants selected an average of 3 emotions to represent how they would feel about completing a 6-week DHI (mean 3.1, SD 1.3). The 5 most common emotions reflected a mix of negative emotions (15/30, 50% were worried; 10/30, 33% anxious; 9/30, 30% scared) and positive emotions (13/30, 43% excited; 12/30, 40% happy).

Motivating Sources That Support Engagement in DHIs

As shown in Table 3, participants identified a range of motivational sources they perceived would help them complete a 6-week DHI. The highest number of responses were program-specific factors (37 responses), followed by internal sources (24 responses) and external motivational sources (11 responses). Across all categories, perceived future benefits (14 responses), engaging content (10 responses), and gamification (7 responses) were the most commonly mentioned motivators.

Table . Sources of motivation to engage with digital health interventions.[a]

	Number of responses from children (n=17)	Number of responses from adolescents (n=13)	Total (N=30)
Internal	7	17	24
Perceived future benefits	5	9	14
Sense of accomplishment	1	4	5
Commitment	1	4	5
External	4	7	11
Social pressure	0	4	4
Social support	1	3	4
Rewards	3	0	3
Program factors	11	26	37
Gamification	0	7	7
Program reminders	2	3	5
Rewards in the program	0	6	6
Incremental benefit from each component	3	2	5
Engaging content	5	5	10
Program design features	1	3	4
Total	22	50	72

[a] The data represent participant responses.

Internal Motivators

Perceived future benefits of the program were the most commonly cited motivating factor. This theme covered several related concepts, including expectations of improved mental health, a sense of confidence they will be happier in the long run, improved coping self-efficacy, and a desire for self-improvement. Although most responses were from adolescents (9/14, 64%), participants as young as 9 years old expressed a relatively long-term view. Notably, child responses expressed confidence (denoted by the use of words such as “you know”), while adolescents appeared to temper belief (“there is a chance it could work”).

> *And you know you’ll be much happier after and you feel loved and safe.* [1A-10]
>
> *I might not like this, (but) it will help me in the long run.* [7A-9]
>
> *The desire of better mental health, that’s self-motivated. I wanna get that kind of thing self-improvement.* [4E-17]
>
> *Probably the chance it could actually work. So, obviously after the first one, if I feel like maybe there is a chance it will work out, I’ll be more committed to keep doing it.* [4R-17]

Among all participants, 5 suggested that thinking about the DHI as an accomplishment would help motivate and inspire them to complete the program.

> *Accomplished feelings, I guess, like your mental health is kind of improved, and if it feels kind of easy to keep going, then it makes it a whole bunch easier to keep going.* [5G-13]
>
> *I would be proud of myself for actually sticking to the program. It would make my parents happier, and I would have achieved something.* [3Z-13]

Classified under the theme of commitment, 4 adolescents and 1 child stated they felt obligated to finish what they started.

> *And then like think just guilt of giving up. I feel like I would just let myself down and then probably, just my…. Just discipline…. Oh, I made a commitment, I need to do it.* [4R-17]
>
> *Since it’s like a program. I think I’d kinda feel obligated to finish it so afterwards* [6V-15]
>
> *Just like five weeks to go or something, like…* [3C-11]

External Motivators

External influence from others, expressed as social support (eg, encouragement from family) or social pressure (eg, pressure to meet expectations from parents), represented the most commonly mentioned external motivator by participants. A total of 4 participants identified family members or therapists as a source of social support to complete a DHI, as highlighted in the following responses.

> *Friends and family that can help support you and keep you…keep enthusiasm up.* [5A-12]

> *Having your parents motivate you.* [3L-14]

There were 4 adolescents who identified aspects of social pressure from parents and therapists would influence them to complete the DHI.

> *Parents making me, therapists making me. If they're like, "You have to," then I'm like, "Okay, I have to.* [6J-15]
>
> *And then there's the external pressure, I guess it's like no external pressure, but wanting to make others happy.* [4E-17]

Rewards for participation, including games and tangible treats, were identified by 3 children as potential sources of motivation to complete the DHI.

> *Like getting a reward afterward. Like getting to play games or something.* [2E-10]
>
> *Food.* [3C-11]

Program-Specific Motivators

Engaging content was the most common program-specific motivator mentioned by participants. Participants believed that a DHI program that was fun (3 responses), enjoyable to use (3 responses), and interesting (2 responses) would encourage them to complete the assigned program. Almost one-third (5/17, 29%) of child participants made a comment about engagement, making this the most common facilitator within the younger age group.

> *You could have enjoyed last time, so you can't wait to come back.* [1A-10]
>
> *If you see something exciting you will have a go at it. It might be really exciting, so you'll just keep doing it.* [2V-8]

A program that offered tangible rewards for completion was recognized by adolescents (6 responses) as something that would help them complete a multisession DHI over 6 weeks.

> *Well, maybe if it was in the actual thing. Each one you get completed, that could be like, not necessarily a real-life reward but something in the game.* [6E-14]
>
> *Probably if I felt like there was a reward. If I wasn't doing it just for my own personal gain. If I felt like there was actually some kind of tangible thing at the end that I get.* [4R-17]
>
> *A voucher. If you finish a full six weeks.* [6J-14]

Gamification elements (eg, integrated games, end goals, and customizable avatars) were identified by 7 adolescents as program features that could support engagement. This theme was not mentioned by children.

> *Just more games to engage in, then maybe a couple more things during the week. Just so it can keep your mind off the mental illness* [6J-14]
>
> *People like avatars, customizing avatars. That was a thing when I was a kid.* [6J-15]

A total of 5 participants mentioned that they would persist with a DHI that demonstrated incremental benefits from what is learned in each component. Although one adolescent explicitly described the benefit as a "feeling of progress," other participants explained they would be willing to continue if the program was teaching them something or providing strategies they could immediately use to improve their mental health.

> *It might be helpful, so it can teach me something.* [1J-8]
>
> *I will have…. After doing the first week of the program, if I find it fun to do and I find the topics interesting and I'm learning about it, I'd be willing to continue doing it and have fun at it.* [4A-16]
>
> *And you know that it helps relieve stress, and they give strategies to manage your anxiety.* [5S-11]
>
> *Feeling of like progress. Like I'm actually getting somewhere.* [4R-17]

There were 4 participants who identified that program design features, including easy access and short session duration (one participant suggested a 15-minute time frame), may increase engagement in a DHI.

> *Just easy to access on your computer and stuff.* [5G-13]
>
> *I don't really know too much about it but if it's a small time like 15 minutes at a time or whatever then I'm like, "Okay, well, I might as well."* [6J-15]
>
> *Stuff like maybe an easy URL to type up or something.* [5G-13]

A DHI program that reminded users to log in was identified as a potential motivator by several adolescents and 1 child.

> *Something that might help me keep on doing it is gentle reminders, to do it throughout the week, or encouraging messages.* [3Z-13]
>
> *The things that can motivate you, like a word on motivation, reminders, like it being fun to people, encouraging phrases.* [3C-11]

Demotivating Sources

As shown in Table 4, time commitment (25 responses) was the most commonly mentioned demotivator. Other demotivators typically mentioned were apathy toward continuing (7 responses), concerns about effectiveness (7 responses), and content engagement (6 responses).

Table . Sources of demotivation to engage with digital health interventions.[a]

	Number of responses from children (n=17)	Number of responses from adolescents (n=13)	Total (N=30)
Internal	5	7	12
Anxiety	1	1	2
Negative emotions	2	1	3
Apathy toward continuing	2	5	7
External	12	19	31
Access to equipment	0	2	2
Lack of social support	0	4	4
Time commitment	12	13	25
Program factors	4	15	19
Concerns about effectiveness	1	6	7
Content engagement	1	5	6
Length of program	0	2	2
Privacy concerns	2	2	4
Total	21	41	62

[a] Data represents a count of responses, not participants.

Internal Demotivators

Apathy toward continuing was identified in focus groups with both adolescents (5 responses) and children (2 responses). Children described apathy in terms of “can’t be bothered” or “you don’t want to do it,” while adolescents used the term “motivation” and reflected on a sense of disregard for the program.

> *And then just again…. Just my own motivation, how much I’d care.* [4R-17]
>
> *And then just generally your own self-motivation to do it.* [6J-14]

Several adolescents linked lack of motivation to depressive symptoms, as shown in the following comments.

> *General mental illness, a lack of motivation, if I’m physically not able to do it, I’m not up to it, then I’m mostly not going to.* [6J-15]
>
> *Or maybe just your feelings or thoughts, ‘cause if you have depression in the first place you might not be very happy.* [3L-14]

Comments from 3 participants indicated that negative emotions connected to needing help could act as potential barriers to completing a DHI. These feelings included shame and hopelessness.

> *On the red side, the emotions could be like ashamed at yourself...* [3C-11]
>
> *Disappointed at the fact that they need this extra support, if it’s something.... If it’s obvious enough that this is a mental health thing.* [4E-17]
>
> *You don’t believe anything will make you feel better.* [1A-10]

Recognizing that the hypothetical DHI would be used by people with anxiety, 2 participants highlighted that participation in the program may exacerbate their anxiety, which could be a barrier to completion.

> *The kind of thoughts that would stop me would be lots of anxiety about it, like feeling unaccomplished, like I haven’t kind of done anything, and if it feels really hard to keep going.* [5G-13]
>
> *And you are worried about sharing your ideas.... Thinking about the past. If something’s happened in the past, something like anxiety.* [5S-11]

External Demotivators

Concerns about time was the most common reason participants would not engage with the program. Time commitment encompassed a range of related obligations that impacted young people’s perceived available time, including schoolwork, part-time work, social activities, household chores, and fatigue resulting from these tasks, as highlighted in the comments below.

> *Because you can be really busy, and...because you said how it’s every six weeks, and maybe a person doesn’t have that much of time.* [5A-12]
>
> *It takes time away from me. It might not even help me, and it’s a waste of energy.* [3Z-13]
>
> *I swim. I’m really busy. I do athletics and I’m really tired after school.* [1A-10]
>
> *Just school and work and just stuff outside like extracurriculars and stuff.* [6V-15]

Mirroring the motivating factor of social support identified above, lack of social support was identified as a demotivator faced by adolescents (4 responses).

> *Peer groups, I guess, if they're not that supportive. That could be peer pressure.* [5G-13]
>
> *There's a lack of support from family, well that's I think the main thing that would get them doing this in the first place. So, if that support begins to wear off then they are just not gonna keep doing it.* [4E-17]

Concern about access to equipment that was perceived to be necessary to complete the program was identified in 2 comments by adolescents.

> *And then objective things like access to an electronic device and access to the internet.* [4E-17]
>
> *So it's just a bit more of a hassle if I'm having to do that at my dad's, I'd be more discouraged to do it.* [4R-17]

Program-Specific Demotivators

The most common program-specific demotivator was concerns about program effectiveness. Responses from 7 participants suggested that any doubts about perceived effectiveness of the program would undermine their motivation to complete a DHI.

> *Probably doubt, like "Is this actually gonna work? Is this worth my time?"* [4R-17]
>
> *That I've had to do this kind of stuff before, and it never really does anything so what's the point? And then I'm not sure 'cause obviously I haven't done it.* [6J-15]

Similar to concerns about effectiveness, young people highlighted the importance of content engagement (6 responses), suggesting that repetitive, uninteresting, unenjoyable, or patronizing content would diminish motivation to complete DHIs.

> *If it just feels it's sort of the same thing again every five weeks, I'll lose motivation to keep doing it. If I feel.... It's not like...getting anywhere.* [4R-17]
>
> *Most likely not keep doing the program. If I was not learning anything I find interesting. So, I'd probably be bored and I wouldn't wanna come again.* [4A-16]
>
> *If it's too childish then I'll feel kind of patronised and annoyed so that's a hypothetical based on what it's actually like.* [6J-15]

Comments from adolescents highlighted that privacy is crucial to users of DHIs, and anxiety related to potential privacy breaches could be a major demotivator for users.

> *That's a massive problem with people who have anxiety and depression, 'cause they don't want people to know.* [6J-14]
>
> *Yeah they start panicking that it's gonna get leaked or something, yeah.* [6J-15]

The length of program was identified as a potential demotivator by 2 adolescents who felt that young people with symptoms of anxiety or depression may find it difficult to commit to ongoing, web-based therapeutic sessions.

> *And why am I spending so much time on it? It's like five weeks is a long time.* [6E-14]
>
> *If you know of anxious children, I'm sure something like being on a computer for maybe like an hour at a time, would be a daunting task.* [4E-17]

Discussion

Principal Findings

This study aimed to investigate factors that motivate and demotivate children and adolescents in completing challenging tasks with the goal of informing future strategies to enhance engagement in DHIs. We found that when faced with a task they do not want to do, children (7 - 11 years old) tended to be motivated by external sources. Short-term extrinsic rewards were the most common source, evidenced by children's desire to get the task done so they can do other things. In comparison, internal sources were more commonly reported by adolescents, who commonly spoke about the importance of self-discipline and a sense of accomplishment.

There are several factors that may explain the difference in motivational source between children and adolescents. First, it is likely that as children age and gain autonomy, they have more opportunities to face challenges, develop coping strategies, and derive internally regulated motivation, while younger children have limited experience beyond seeking support from caregivers [18,19]. Another factor that may explain the differences between age groups was task context, such that most adolescents chose a learning task, which offered potentially greater rewards for effort (ie, attainment value) compared to household chores, which were the common choice for children.

The findings from this study suggest that adolescents draw equally on positive motivations (achievement and reward) and negative motivations (fear of negative consequences and punishment) to persist with everyday unpleasant tasks. Although previous research tends to suggest that positive motivations are associated with greater long-term well-being, the findings from discussions with adolescents show that negative motivations can lead to positive outcomes. This is consistent with several studies that have shown that negative motivation (ie, fear of failure) can support positive change in children and adolescents [20,21].

Turning to the challenge of completing a hypothetical 6-week DHI program, perceived future benefits of the program was the most frequently mentioned motivation theme across both age groups, though the theme was more commonly mentioned among adolescents. This aligns with educational studies that have observed that differentiation between interest in and importance of academic tasks grows with age, as adolescents see beyond immediate desire for engagement ("will I enjoy it?") and may be more motivated by attainment value ("will this help me?") [22].

According to expectancy-value theory of achievement [22], persistence requires that young people not only recognize future benefits, but also believe that those outcomes are achievable. In this study, belief in a positive outcome was expressed in child and adolescent focus group discussions. Closely linked to the concept of success expectancy [22], belief is widely recognized as a predictor of adherence in therapeutic settings [23]. Previous research suggests that success expectancy—the belief that one will be successful in achieving a desired outcome—may be amplified by personal interaction [24], a factor that is not offered in self-guided DHIs. This underlines the challenge faced by DHIs to build belief in an online environment where personal contact with therapists or counselors is not available. Although therapist support is exogenous to self-guided DHIs, social support provided by family and friends may inspire belief. Social pressure was also mentioned as an external motivational source among adolescent participants. This is consistent with developmental studies that have shown social influences (positive and negative) are amplified during adolescence, when young people become increasingly exposed to a range of contextual factors, including social comparison in peer relationships, school culture, and family involvement [25]. Previous reviews have investigated the use of social platforms as a DHI program feature (ie, texting, social networking, web-based message boards, discussion forums) to support engagement [2]. However, our findings suggest that young people value support from family members as an important external motivation source rather than a feature embedded in the DHI. Family support strategies have shown to be effective for addiction recovery [26] and eating disorders [27] in adolescents, therefore a similarly designed family-based social support strategy may assist adolescents to complete self-guided DHIs.

Consistent with previous research [2,9], our findings highlighted that engaging content was considered an important motivator for both children and adolescents. For children, engaging content was the most mentioned motivator to stay engaged in a multisession DHI. Although also important, adolescents valued other program features more highly, including gamification and tangible rewards (such as certificates and rewards outside the DHI). However, given the nature of this study, it is not possible to make inferences about the relative importance of content versus gamification, although the observed difference between age groups may be explained by children having less exposure to games-related content online compared to older participants.

Time commitment was the most frequently mentioned demotivator in both child and adolescent groups. This result corresponds with previous DHI reviews where “lack of time” [28], “inability to find time” [9], and “time constraints” [29] were raised as issues by young people. This suggests that the benefits of convenience and accessibility offered by DHIs compared to traditional therapies [30] may not be valued by young users. Outside of time commitment, adolescents also expressed concerns about effectiveness. This is in line with a recent systematic review of DHIs, which identified “credibility” in relation to evidence of the intervention’s effectiveness as a common contributor to high retention rates for children and young adults [2].

Implications for the Development of Youth DHIs

Our focus group findings led to a number of recommendations for improving adherence in future DHI developments for children and adolescents. For children, engaging content combined with immediate, extrinsic rewards are important motivators to complete a DHI. Children also demonstrated a capacity to seek attainment value in a difficult task, however this needs to be nurtured with developmentally appropriate language as the majority of children did not consider the future benefits of a DHI in our discussions. Another implication for DHI designers is that children seek pleasurable online experiences at each point of engagement, while adolescents may respond more effectively to strategies designed to reinforce attainment value of the therapy goal (such as progression charts). The involvement of parents/guardians also appears to be a motivator valued by children, who identified parental instruction, approval, and reward-seeking in our focus group discussion. This highlights the importance of continuous parental engagement [31] in DHIs for children, which may include coaching-style support and the administration of rewards upon completing each step of a multisession program.

For adolescents, a sense of achievement was an important internal motivator for completing tasks they do not want to do. Recognizing that sense of achievement is closely linked to an adolescent’s sense of personal control [32], future DHIs can benefit from strategies designed to provide autonomy, create a supportive environment, and connect with adolescents’ interests. Granting autonomy can increase engagement with DHI tasks. This can be achieved by allowing them to select topics aligned with their interests. Strategies designed to provide social support from family and friends may help to amplify attainment value and buffer against concerns they may express about program effectiveness. Youth DHIs should also seek to incorporate interests into the content whenever possible, and tailor sessions and homework to align with their extracurricular interests. By making the program personally relevant, adolescents are more likely to see the value in completing the program.

Another implication for DHI designers is that negative motivations are frequently expressed by adolescents. In particular, fear of negative consequences was used for completing tasks they do not want to do. Negative motivations can provide initial drive; however, available evidence suggests that negative motivations may not sustain longer-term engagement [20]. Although acknowledging the importance of consequences for nonadherence, DHI programs need to provide mechanisms for adolescents to address these negative motivations in positive ways while also building self-confidence. Strategies could include providing mechanisms for adolescents to set their own deadlines, inviting others to hold adolescents accountable, or establishing tangible repercussions for inaction.

Finally, DHI developers also need to consider practical strategies to address concerns that both children and adolescents have about time required to complete a DHI. The issue of time commitment could be addressed in several ways, including providing brief, targeted content that can be quickly consumed on a regular basis. DHIs should also consider ways to integrate content with other applications and smart devices (eg, wearables) that children and adolescents access regularly to reduce learning time and support busy lifestyles, in and out of the home.

Limitations

Several limitations need to be acknowledged. First, while having a history of mental health or emotional problems was common in our sample, they were not a DHI-seeking population.

Generalization of results must therefore be approached with caution. Another limitation was that participants were not required to have previous experience with DHIs. Some responses from children reflected limited understanding of DHIs and web-based programs more generally. This implies that differences in responses from older participants may reflect online experience rather than developmental differences. Future work should assess children's and adolescents' perspectives in the context of their prior DHI and online experience more generally. Another potential limitation was group structure. Some children chose not to share their story about their artwork and so there was some potential loss of data. Although the moderator actively redirected conversation to younger participants, older participants were the predominant voices in most groups, and this may have contributed to a lack of sharing.

Conclusions

Results of this study indicate that engagement strategies that engender belief that a DHI will provide short-term benefits are important to both children and adolescents. Additionally, confidence that future benefits will be realized was also articulated by adolescents, but this appeared to be less important to children, reflecting potential age-related responses and online experience. The study also found that social support may be an effective source of engagement for young people; however, more research is required to explore how persuasion from family members can nurture belief and confidence in future benefits from DHIs. Finally, future research should consider how engagement strategies can be used to shift children's and adolescents' perception that self-guided DHIs are time-consuming.

Abstract

Background: The pandemic brought unprecedented challenges for child and youth mental health. There was a rise in depression, anxiety, and symptoms of suicidal ideation.

Objective: The aims of this knowledge synthesis were to gain a deeper understanding of what types of mental health knowledge translation (KT) programs, mental health first aid training, and positive psychology interventions were developed and evaluated for youth mental health.

Methods: We undertook a literature review of PubMed and MEDLINE for relevant studies on youth mental health including digital and hybrid programs undertaken during the pandemic (2020-2022).

Results: A total of 60 studies were included in this review. A few KT programs were identified that engaged with a wide range of stakeholders during the pandemic, and a few were informed by KT theories. Key challenges during the implementation of mental health programs for youth included lack of access to technology and privacy concerns. Hybrid web-based and face-to-face KT and mental health care were recommended. Providers required adequate training in using telehealth and space.

Conclusions: There is an opportunity to reduce the barriers to implementing tele–mental health in youth by providing adequate technological access, Wi-Fi and stationary internet connectivity, and privacy protection. Staff gained new knowledge and training from the pandemic experience of using telehealth, which will serve as a useful foundation for the future. Future research should aim to maximize the benefits of hybrid models of tele–mental health and face-to-face sessions while working on minimizing the potential barriers that were identified. In addition, future programs could consider combining mental health first aid training with hybrid digital and face-to-face mental health program delivery along with mindfulness and resilience building in a unified model of care, knowledge dissemination, and implementation.

Introduction

Background

The COVID-19 pandemic and resultant closures of schools during lockdowns worldwide brought on major challenges for child and youth mental health [1-3]. A systematic review found that, as a result of school closures, there was a rise in depression, anxiety, emotional and behavioral problems, stress, and suicidal attempts in children and teenagers during the pandemic period [4]. Many teenagers reported challenges with coping with their mental health due to isolation from staying at home and a lack of social contact with peers [2]. In particular, there were unique challenges for children and teenagers with existing mental health problems when it came to accessing timely basic mental health care services during the pandemic. This was due to pandemic-related closures of medical clinics [5] and school-based health services [2], limited capacity of medical doctors, and prioritization of patients with COVID-19, which left many patients with chronic health problems with lower levels of accessibility to care [6]. A study in the United Kingdom found that 26% of teenagers felt that they had reduced access to mental health care [1]. Furthermore, a study in Italy found reduced emergency department admissions for mental health problems as patients remained at home and socially isolated distanced themselves to reduce their risk of infection [7]. However, it should be noted that not all studies found that everyone had been equally impacted by COVID-19 and had experienced mental health challenges, with some studies finding improvements in some individuals, particularly those without a preexisting mental health condition [8]. Nevertheless, child and youth mental health was a critical public health challenge during the pandemic for many.

As a result of the mental health crisis in youth during the pandemic, medical doctors had to quickly transition to digital tele–mental health care services to meet the pressing mental health needs of children and teenagers and increase their accessibility to care [9]. Many service providers had to implement digital mental health care for the first time, which came with its unique challenges [9]. Before the COVID-19 pandemic, tele–mental health was less prevalent and often used in rural and remote patient settings [10]. However, as medical providers adjusted to the “new normal,” tele–mental health and other digital mental health approaches became more mainstream [11]. Nevertheless, it is also important to examine what other mental health programs, including face-to-face or combined digital programs, were implemented during the pandemic to better understand differences in program preferences and experiences.

Understanding the key challenges and experiences with these different approaches and models of psychiatric mental health care is essential to make recommendations for future best practice guidelines and pandemic preparedness. Understanding the facilitators of effective implementation of youth mental health services in clinical medical settings and how to overcome barriers is necessary for making recommendations for effective tele–mental health and in-clinic program implementation. Moreover, it is important to understand implementation challenges, including barriers to implementation, considering determinant frameworks that assess barriers to implementation rather than solely examining structural process models of implementation that describe how the program was implemented and the specific procedural steps [12]. Analyzing studies that used both structural and process frameworks and the models used when implementing studies during the pandemic will provide deeper insights into what was specifically developed, the processes that were undertaken, and the challenges that were experienced.

In addition to implementing psychiatric programs in clinical settings that are administered through clinical mental health professionals, there is also a need to better understand what mental health programs were implemented in the community setting, such as in schools through school-based officials and in charities, and understand and what efforts by key stakeholders to promote youth mental health and build resilience in children and youth (preteenagers, teenagers, and young adults). It is of particular interest to investigate whether stakeholders working to support children (eg, community-based organizations such as the YMCA) and mental health–specific organizations implemented youth mental health programs during the pandemic in schools and the general community setting. It is also of interest to understand any key program implementation challenges to make recommendations for implementation and policy research.

Furthermore, there is a need to evaluate the barriers to and facilitators of psychological programs, including self-guided ones in the home setting that taught youth how to manage their emotions during isolation and times of crisis and uncertainty. In particular, positive psychology and especially mindfulness-based approaches have been found to foster greater gratitude and well-being in children and youth [13-15], and it is of interest to evaluate what approaches were used to assist youth during pandemic times of crisis from the perspective of adoption and uptake challenges. In addition, there is a need to evaluate the implementation and knowledge dissemination efforts associated with mental health supportive aid programs such as mental health first aid [16].

Within the context of youth mental health, including psychiatric and psychological supportive programs, little is known about what knowledge translation (KT) strategies and theories were used to educate key stakeholders, including mental health practitioners when they transitioned to new models of care and implemented digital technology. Research is needed to evaluate what KT theories and models were used when disseminating knowledge to key stakeholders. Effective KT is a fundamental element of the public health research process [17]. Without effective translation of evidence into practice, research remains simply an academic area without real-world community health impact [18]. Understanding the key challenges and facilitators of KT, including implementing evidence-based mental health programs and interventions, is necessary. This way, future recommendations may be made for best practice guidelines during crisis times and for future pandemic preparedness. Given that there was an unprecedented rise in mental health issues during this time, it is important to know whether there were any KT strategies for parents, schools, and medical providers.

Aims and Objectives

The purpose of this literature review was to gain deeper insights into strategies, programs, and services for child and youth mental health during the pandemic period. Recommendations for future program and intervention implementation, research, and best practice guidelines were made.

This review had the following aims:

1. To better understand the experiences, barriers, and facilitators regarding youth mental health service delivery, including telehealth, face-to-face, hybrid (combined face-to-face with digital), and school-based mental health service implementation, as well as psychological supportive services during the pandemic.
2. Secondary aims were to better understand what types of pediatric and youth mental health programs were implemented, including digital, face-to-face, and hybrid programs; the key stakeholders involved; and what KT theoretical models and strategies (if any) were applied during their implementation throughout the pandemic.

Methods

Overview

A literature review using PubMed and MEDLINE was undertaken to identify relevant studies on youth mental health programs and services, including school-based and hospital-based telehealth or hybrid implementation (combined in-person with digital services), and psychological supportive studies undertaken during the pandemic. Google Scholar and manual hand searches were also undertaken. We included studies that were undertaken during the pandemic period between March 2020 and October 2022. The studies must have mentioned that they were undertaken during the pandemic. The search was then updated and rerun with refined and more specific search terminology after consulting with a medical librarian to include studies that may have been undertaken during the pandemic but published at a later time up until December 31, 2023. Studies that were undertaken before the pandemic but continued throughout the pandemic were also included. The studies must have been published in the English language with public full-text accessibility. The rationale for including studies undertaken during the pandemic was to gain a greater understanding of key implementation challenges specifically during pandemic times of crisis and uncertainty. Google Scholar and manual hand searches were also undertaken to identify any additional studies. General studies on mental health service use or program trends without an assessment of experiences, preferences, and barriers were excluded. Psychological supportive studies were only included if they were part of a mental health service program or service implementation that assessed barriers, perceptions, and recommendations for implementation. Psychological studies that evaluated the effectiveness of the intervention on mental health outcomes rather than primarily focusing on stakeholder or user perspectives on the implementation of mental health services or overall telehealth experiences were excluded as they were outside the scope of this review. We included general positive psychology studies including mindfulness-based, cognitive behavioral, acceptance-based, emotional regulation, and behavioral activation strategies from stakeholder and user perspectives. Studies on the provision of mental health first aid training were only included if they evaluated implementation experiences or KT specifically. Studies that focused on framework development or development of implementation or KT models were included, but reviews or general opinion pieces were excluded.

The keywords included word variations of “knowledge translation” or “dissemination” or intervention and “mental health” or “resilience” or “stress” and “young adult” or “teenager” or “youth” or “child” and “health services” or “implementation” or “telehealth” or “psychological services,” among others.

An example of the search strategy is detailed in Textbox 1.

Screening and Data Extraction

Titles were screened for relevance followed by screening of abstracts against the inclusion and exclusion criteria. The full texts of abstracts meeting the inclusion criteria were further screened. If the full-text articles met all the inclusion criteria, they were included in the literature review.

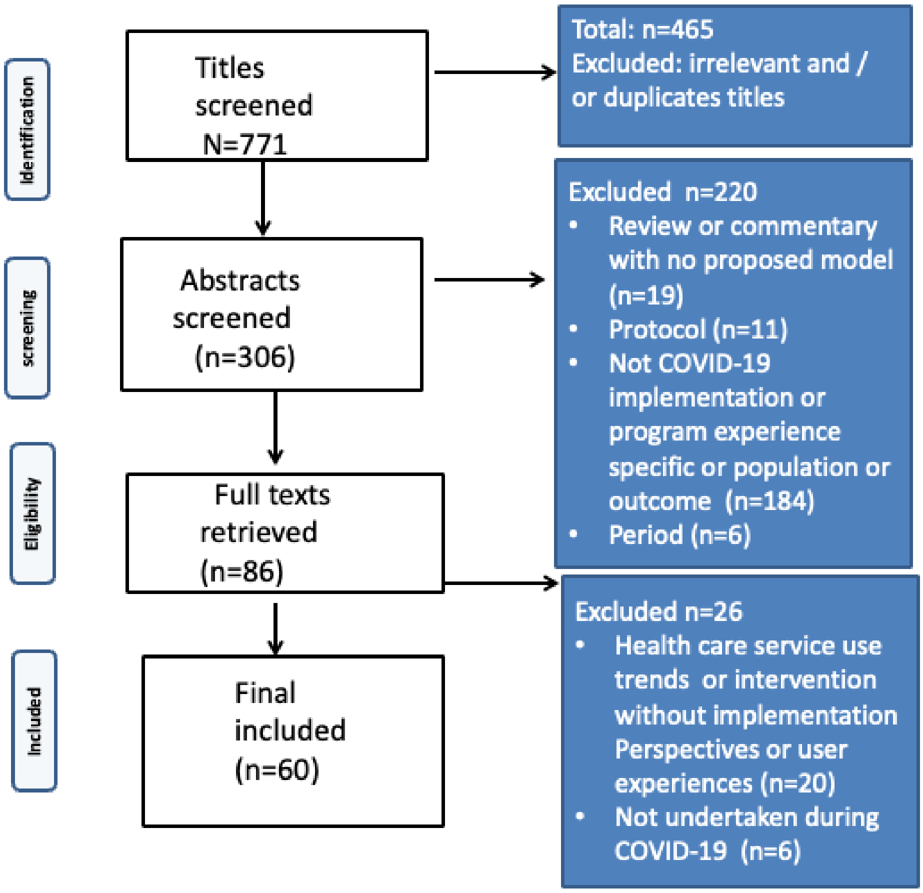
To ensure that the studies were undertaken during the pandemic period, we screened titles with the words “COVID-19” followed by checking the full texts to ensure that the programs were implemented within a COVID-19 context or with relevance to the pandemic, where lessons could be learned. Where it was unclear, authors of selected papers were contacted directly to confirm.

Data were extracted and summarized in tabular format. This included the study general characteristics, measures, outcomes (mental health, knowledge, and program implementation), KT media, and KT theories and behavior change theories.

Results

A total of 60 studies on youth mental health service or program implementation were included in the final review [9,19-77]. Figure 1 illustrates the search and screening process.

Figure 1. Flowchart.



Mental Health Outreach Services and Programs for Children and Teenagers With Mental Health Problems

Youth Mental Health Service Implementation

We identified and included 60 studies on mental health program initiatives to promote child and youth mental health during the pandemic that focused on the delivery and implementation of a wide range of mental health services, programs, and supports as well as knowledge dissemination during the pandemic. The results are summarized in Table 1. The study types were qualitative studies, case studies, and cross-sectional studies, as well as studies with mixed methodology. The countries spanned Canada, the United States, and Australia. One large study was undertaken in Europe across 8 countries: Austria, Germany, the Netherlands, Slovenia, Switzerland, Italy, Sweden, and the United Kingdom [29].

Table 1. Child and youth mental health knowledge translation (KT) tools, strategies, and interventions among stakeholders.

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Zbukvic et al [46], 2022	Australia; case study on workforce development KT	4400 MH workers	Teenagers with depression, anxiety, psychosis, trauma, borderline personality disorder, and self-harm (needs before and especially during the COVID-19 pandemic)	Work with stakeholders such as GPs[c], psychiatrists, psychologists, social workers, peer support workers, teachers, the legal justice system, police, and addiction specialists	Training in person and web-based (also outreach visits to clinical practice areas to change practice based on best practice evidence); diverse media: fact sheets, videos, webinars, web-based modules, and games to enhance engagement; focused on sharing knowledge from research; used behavior change theory; used the i-PAR-IHS[d] model (usability, context, innovation, facilitation, and recipients)	Orygen—youth MH organization focused on KT; primary, secondary, and tertiary health service delivery; offers professional development and continuing education support to enhance MH youth outreach	Difficulties with web-based e-MH care during the pandemic; levels of readiness across different organizations and adaptability; need for advice and recommendation and frameworks for implementation in a digital world using digital media
Parrot et al [37], 2022	Canada; focus groups and surveys	—[e]	Depression, anxiety, and germaphobia (pandemic related); kids (aged 6-16 years)	Work with key stakeholders at schools: parents (mean age 40 years; families), teachers, retired school board staff, retired teachers, and MH practitioners	Training in person and on the web on the DREAM[f] program—founded on the Knowledge Transitional Integration Framework (4 pillars: sustainability, accessibility, credibility, and feasibility; developing a digital program and a social literacy program, and creating meaning through creative engagement [eg, music and arts]); online classes founded on positive concept; new learning mindset or beginner mind and gratitude; incorporated rational emotive behavioral therapy and rational emotional logotherapy (identifying emotions)	KT and dissemination; stakeholders actively engaged (addressed needs of stakeholders) and participated in the research process and in the KTA[g] process—development, implementation, and evaluation stages; stakeholders were involved in surveys, focus groups, and interviews	Grounded theory informed; evaluated the credibility (hybrid program for those who do not agree with web-based methods), acceptability (stakeholders tried the web-based technology, and exposure increased positive perceptions; need for diverse music options with lyrics), accessibility, feasibility (ensuring extra teachers offer e-version in addition to the school-based version), and sustainability (memory aids, booklets, reminders, and program games based on key emergent themes from the interviews); recommendations for a hybrid in-person and web-based model for all students; the implementation stage of the aforementioned recommendations is still underway
Hou et al [30], 2022	Canada; cross-sectional survey	94; 84% female	Impact of COVID-19 on MH: depression, anxiety, and PTSD[h]; teenagers and young adults aged 13-39 years (cancer survivors)	Lived experience—childhood cancer survivors	Young adult cancer survivors had worse MH during the COVID-19 pandemic; infographic with information on meeting the needs of cancer survivors for MH during the COVID-19 pandemic (after a preliminary survey on MH); KT on coping strategies	Provided the infographic to those with lived experience with statistics on MH during the COVID-19 pandemic as well as coping strategies that were evidence based: increase sleep, improve diet and activity, and practice mindfulness	Infographic is just one medium; more research is needed on feasibility and the use of diverse media or resources for KT and dissemination; recommendation of personalized interventions with enhanced accessibility; more context research is needed (qualitative)

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Hanson et al [29], 2022	Europe; mixed methods—country case studies, analyses, implementation of KT, and implementation of a prevention intervention (clinical trial in 6 countries in the EU[i])	9437	AYC[j] of family members aged 15-17 years; promote MH, well-being, and resilience	8000 stakeholders at national and international levels: health care professionals, schools, teachers, nurses, psychologists, politicians, social workers, and researchers across Austria, Germany, the Netherlands, Slovenia, Switzerland, Sweden, the United Kingdom, and Italy; expert panel on AYC	Intervention founded on ACT[k] and the Discoverer, Noticer, Advisor model (derived from ACT); diverse media: in person, over Zoom, and using an app	ME to WE project involved several stages: knowledge synthesis via reviews, surveys of those with lived experience (needs), prevention intervention, qualitative interviews, and understanding of national policies and laws; participatory design with evaluation and impact of KT; KT and dissemination targeted stakeholders at meetings and networking efforts centered on raising awareness, engaging stakeholders, and involving them in the policy process	Key messages: identify young carers and offer supportive services, apps for support, peer and family support, and respite
Nicholas et al [35], 2021	Australia; cross-sectional survey	308 youths aged 12-25 years; 92 clinicians	General youth MH	Youth with lived experience and physicians	Telehealth implementation	Strategies to implement and improve the implementation of telehealth or tele-MH during the COVID-19 pandemic	Telehealth was not viewed as negative by young people in terms of attendance and perceptions of willingness to attend MH care relative to MH practitioners; technology issue barriers reported in 31% of cases; accessibility to e-MH and privacy were important
Eapen et al [25,78]	Australia; lexical analysis	6	Children with MH issues	Clinicians	e-MH service implementation	Strategies to ameliorate the implementation of e-MH by assessing the barriers and facilitators	Barriers to implementing e-MH included space, privacy, and technology (including internet accessibility); recommendations included a hybrid model with face-to-face interaction for real-life clinical assessment and web-based assessment to increase accessibility
Barney et al [20], 2020	United States; case analysis of the young adult medicine clinic telemedicine intervention implementation	—	General MH and addiction in teenagers and young adults	Clinicians (informing clinical practice) and MH practitioners (nurses, students, social workers, and administrative staff)	Telemedicine consultation implementation	Implementation of telemedicine	Increase in use by 97% during the COVID-19 pandemic; benefits were being feasible and acceptable, but barriers included privacy and technological barriers (eg, accessibility to devices); Zoom was preferred for privacy; need for clear guidelines for effective implementation

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Al-Rasheed et al [19], 2022	United States; survey	285	Children and teenagers; depression, anxiety, trauma, and behavioral issues	Telehealth practitioners and children and youth with lived experience	Telehealth implementation	CBT[l]+psychology telehealth implementation barriers and acceptability	Difficulties interacting with children; privacy issues (teenagers less willing to speak about discrete matters at home); high acceptability among clinicians (78.2%)
Carretier et al [22], 2022	France; qualitative interviews	20	Depression, anxiety, and PTSD	Telehealth practitioners, parents, and youth with lived experience	Telehealth implementation	Tele-psychiatry implementation barriers and facilitators	Hybrid method recommended: face-to-face with web-based methods; practitioners felt that nonverbal communication could be a challenge; the quality of the therapeutic relationship influenced care and the severity of their patients' MH problems; preference to select phone versus video calls; teenagers appreciated having their parents involved
Conradi et al [9], 2022	United States; case study implementation of telehealth at a children's advocacy center	—	Children; general MH and trauma	Telehealth providers and children at a children's advocacy center and their families	Informed by the Consolidated Framework for Implementation Research; online telehealth media	Implementation of telehealth; 3 areas: agency requirements, the needs of the telehealth professionals and training, and use of technology+effective communication strategies	Challenges included health professional burnout and need for support; need for clear communication and effective planning; patients should receive a virtual tour+"welcome kit"+frequent feedback on the sessions; ameliorate body language in front of technology; provide families with technology and adequate internet connection and play kits for the children; kids had "Zoom fatigue"; implementation of team managers for creativity+innovation; technology needs a consideration of space
Craig et al [23], 2021	United States; case study Affirm we-based group session	1 transgender youth	General MH in youth	Telehealth practitioners and LGBTQ[m] youth social workers	Implementation of affective CBT; AFFIRM[n] behavioral approaches; cognitive restructuring approaches; affirm social support networks; online and app support media	Evaluate the implementation of AFFIRM by engaging with LGBTQ youth	Recommendations: adapt to using Zoom (eg, chat and screen sharing) and become experienced with technology, include frequent check-ins and icebreaker questions to reduce virtual awkwardness, implement document sharing and Microsoft PowerPoint for engagement and dissemination, integrate calming strategies, and facilitate social networking via social apps for support

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Doan et al [24], 2021	Canada; framework development proposal analysis of the 6 Pillars framework at the Hospital for Sick Children	—	General MH; children+teenagers	Clinicians, children, teenagers, and families	Implementation of virtual MH care for children	Implementation of the telehealth 6 Pillars framework at the Hospital for Sick Children, Toronto, Ontario, Canada; plan to do act assisted clinicians to come with guidelines for virtual care (2 weeks of meetings)	The physical space is important—private and clean for training and practice; providers should be accepting and ready to use technology; need for a safety plan in virtual meetings for emergencies or unexpected events; parents must be present during consultations; patients must find telehealth acceptable, and the environment must be suitable (eg, safe, technology, accessible, and private); patients need adequate physical space for privacy; clinicians must follow and adhere to clinical practice standards and laws during telehealth
Gorny et al [27], 2021	United Kingdom; case analysis of London ward	36 hospitalized during the first-wave lockdown in March 2020	General MH problems, depression, and anxiety	Physicians, politicians, the national health care regulator (Care Quality Commission), hospital staff, social workers, children, parents, and leadership representatives from MH trusts	Implementation of a child and youth MH ward; —	Ward was created for child and youth MH to meet the COVID-19 challenges with a change in organizational structure and leadership; multidisciplinary team morning meetings to plan and work on patient cases	Challenges with implementing a young people and children MH ward in a pediatric setting; plan to set up a new ward involved integrating physical+MH care; MH nurses and child psychiatrists were allocated to one place in proximity to patients; dynamics changed with a multidisciplinary team and new managerial or leadership approaches for managing MH; tailoring treatment to patient needs
Lal et al [32], 2022	Canada; cross-sectional	51	General MH	Young adults	Telehealth implementation	Assess implementation barriers and experiences with youth telehealth	Main barriers included technological (technological support needed for the preliminary sessions) and privacy (secure private connections) barriers; overall, those with lived experience or knowledge users found the telehealth platform to be acceptable
Moorman [34], 2022	United States; analysis of practice data	100; 40 clinicians and 60 families	General MH	Practitioners, children and teenagers, and parents	Telehealth implementation (digital media)	Assessment of implementation challenges and experiences	Benefits of telehealth included higher attendance and access to MH; challenges with younger kids; difficult to understand body language web-based (nonverbal communication); privacy concerns

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Palinkas et al [36], 2021	United States; qualitative interviews via Zoom	21 state MH authorities	Range of MH problems in children+teenagers	State MH authorities	MH care provision, including telehealth	Rapid assessment procedure used to analyze key implementation themes regarding youth MH service delivery	Barriers to telehealth: technology+internet, privacy issues, challenges with using telehealth with younger children, and need for greater training of health professionals and an integrated system of reimbursement of costs of treatment
Power et al [39], 2022	Ireland; toolkit design	—	General MH promotion via+MH	Children and primary and secondary MH practitioners	Print resources (leaflet) for KT for promotion+MH; coping strategies; mindfulness; positive psychology; hand model of the brain	KT; happiness toolkit of essential MH resources created; KT of 6 evidence-based techniques for MH and resilience building; kids had to build an actual box; includes advice on social support or building healthy relationships; mindfulness; positive visualization—smile a vision; gratitude; hugs; hand model of the brain to identify emotions	Focused on the development of a model for MH care; the MH needs of children (pediatric MH population) are not met when physicians are not adequately trained; the toolkit may enhance mental well-being as a model of MH care
Randall et al [40], 2021	Australia; mixed methods—health data sets and surveys	140	General MH	Children and teenagers with MH problems and MH clinicians	Digital telehealth (psychiatry)	Challenges and opportunities in the implementation of telehealth	Barriers: technological issues identified as barriers, lack of human contact, and younger kids preferred face-to-face over video consultations; benefits were convenience; provider challenges included adequate training—developing skills for interviewing
Sharma et al [42], 2020	United States	57 faculty members and 97 clinicians in need of training	General MH in children and teenagers	MH clinicians at Seattle Children's Hospital: nurses, psychologists, psychiatrists, and behavioral therapists	Telehealth; tele–group training	Tele-psychiatry implementation involved phone consultations as a bridge before the full transition; took 6 weeks to implement tele–group training for MH practitioners; TeleMed Home scheduling visits and administrative staff trained	Clinicians have limited training in tele-psychiatry; tele-MH has barriers: need for special training for the DTC[o] virtual platform; privacy issues regarding using third-party applications for consultations; technological issues with the DTC platform crashing
Skar et al [43], 2022	Norway; clinical treatment data analysis	382 therapists treating 1240 patients	Children and teenagers with trauma	MH practitioners; 66 clinics	Trauma-focused CBT implementation	Issues with the implementation of CBT	Adequately trained (high intense) therapists linked with patient response and continued attendance; leadership training also important (secondary) to intense training for higher fidelity and nondropout; nonresponse linked to older children

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Somaiya et al [44], 2022	Australia; qualitative focus groups	44	General MH; youth	Youth with MH problems	Digital telehealth	Experiences with implementation of telehealth	Successful implementation of telehealth, acceptable+feasible; preference for face-to-face as an option after the pandemic in youth; benefits included accessibility, convenience, and web-based social interaction; barriers with technology, internet issues, lack of human contact and privacy, space, comfort with being on the internet, and meeting time or scheduling problems
McMellon and MacLachlan [33], 2021	Scotland; case or policy analysis	Aged 10-18 years	General MH	Observatory of Children's Human Rights in Scotland, Children and Young People's Commissioner Scotland, and children	Impact analysis of MH legislation for children during the COVID-19 pandemic	Recommendations by the ICRA[p] made for KT and implementation for the government	Increase resources for children's MH, including in schools (eg, training more staff to meet capacity and enhance access or reduce barriers to e-MH via technology and internet access for kids); offer in-person support for special groups who need it; undertake more research on special needs in diverse groups
Zickafoose et al [47], 2022	United States	29,000 surveys; 400 randomly selected who undertook trauma-informed training interventions	Children and teenagers; MH trauma	MH America schools and MH professionals	Dissemination and training for trauma-informed classroom practices	Implementing informal MH training and help via schools combined with formal professional medical help	Trauma-informed classroom practices can be implemented with effective dissemination via professionals and school staff; there were no differences in knowledge acquired when school staff versus health professionals delivered the MH material in trauma-informed classroom discussions; requirements include quality training
Rodriguez-Quintana et al [41], 2021	United States	982 trainees for the session; 155 needs assessment surveys	Ages from kindergarten to 12th grade; general MH	TRAILS[q] program	Group manual for school-based health professionals for youth MH; coping skills; promotes CBT+mindfulness (includes emotion recognition and gratitude); implementation of TRAILS program in schools; digital media: virtual support and information or tools; informed by therapeutic principles	Handbook or manual for knowledge dissemination and training for youth MH website with materials or information; 3-hour virtual training	The study focused on the development and early implementation; overall satisfaction among health professionals with the training materials; overall acceptability; some providers reached out for support with using virtual meetings and interactive web-based material; lack of internet may be a barrier for students and providers

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Podar et al [38], 2022	Germany; mixed methods—semistructured qualitative interviews+longitudinal data	12 gatekeepers and 216 adolescents	General MH; teenagers (refugees and migrants)	YOURCARE research project participants; schools+teachers, teenagers, parents, and psychologists	Needs assessment and case analysis of COVID-19 MH; media: —	Implementation and dissemination needs and barriers	Lack of integrated MH care in schools; segregation and stigma among young refugees; barriers to accessing MH care; need for antidiscrimination policies in schools; COVID-19 perpetuated inequalities; diversity is needed in implementation and research by including migrants
Weineland et al [45], 2020	Sweden; qualitative semistructured interviews	14	General MH in youth	Primary care therapists; youth MH centers in Sweden	Internet implementation of CBT	Implementation experiences with iCBT[r] training and program delivery	Barriers included motivating patients and the therapeutic relationship when communication is not in person
Goddard et al [26], 2020	United States; qualitative case analysis	308	General MH in youth	Listening and Learning attendees from the School-Based Health Alliance; school-based health centers	KT strategies to adjust to the pandemic on the Listening and Learning platform; digital implementation of telehealth (general); MH as a topic; digital media: Zoom, Skype, and online platform	Listening and Learning KT platform developed to help providers during the COVID-19 pandemic; experiences with implementing telehealth and strategies; physical art supplies and kits for children for MH (eg, dialectical therapy mailed to their homes)	Most providers adapted to virtual MH care using Zoom, Skype, FaceTime, Google Classroom and Voice, and Doxy; most barriers were technological issues such as troubleshooting; benefits included greater parental involvement; concerns about the privacy of the teenagers
Khan et al [31], 2021	United States; development of training and dissemination	—	General MH in children and teenagers	American Academy of Child and Adolescent Psychiatry, American Psychiatric Association, and directors of psychiatric training websites	6-stage model of curriculum development by Kern	Web-based curriculum for KT on pediatric tele-psychiatry; implementation addressing patient needs; 6 areas of competency; resources; evaluation tools for practitioners	Currently available on the internet for training; further results will come
Birkenstock et al [21], 2022	United States; virtual MH workshop implementation, community-based participatory research study	11	Immigrant youth with MH problems	Refugee immigrant center; youth with lived experience; university+art and health collective; Sanctuary Philadelphia Independent Cultural Youth project	Art workshops for MH; developing strategies for youth MH based on needs or planning	Implementation of an MH project for youth migrants on the web from face-to-face due to COVID-19	Issues with implementation due to COVID-19; challenges with switching to a digital system; fatigue from web-based meetings; more complex artwork was not possible on the web; alternative expression included photos, videos, and memes; activities mainly centered on virtual discussions; care packages sent to participants; program terminated early due to lack of participation

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Haliwa et al [28], 2022	United States; qualitative	191	General MH in school-age youth	—	Mindfulness on the web	Kidding around; yoga; implementation of a school-based digital training of teachers mindfulness program; knowledge, attitudes, and perceptions regarding implementation of mindfulness in schools	Misperceptions of mindfulness may act as barriers to implementing it in schools; cultural acceptance issues potentially; benefits for emotions and coping skills
Danseco et al [54], 2021	Canada; multilevel mixed methods implementation research—surveys+focus groups	192 youth and 97 agency leaders (surveys only)	General youth MH (virtual)	Families and youth, agency leaders, and MH service providers	Virtual care platform	Implementation of a virtual care platform for youth; adapted the Consolidated Framework for Implementation Research	Common barriers to implementation: privacy, internet connection, resources (eg, laptops and phones), and safety (sudden disconnection and unknown risk to the patient or a connection issue); less engaging than face-to-face for some (eg, children)+nonverbal cues harder to assess than face-to-face; work-life balance between home and the office and loneliness for MH practitioners; facilitators: engaged with adequate training and leadership as well as collaboration and good relationships with patients
Davenport et al [55], 2020	Australia; proposal for a model of care[h]	—	General MH	Tailored to MH for youth	Web-delivered care; digital toolkit	Brain and Mind Centre model of care; health IT for model deliverance; web-delivered care; Innowell platform	Need to implement necessary technological infrastructure for this model of care (implementation experiences not described)
Dhonju et al [57], 2020	Nepal; implementation of a multitier platform	100 health care professionals; 1206 parents, teachers, and caregivers	General MH	MH care professionals, teachers, and parents	Web-based platform with the use of apps for training, such as Zoom, Microsoft Teams, and Google Hangouts	Implementation of an MH platform or telehealth with face-to-face in-person programs	Challenges with participation (finding MH professionals to engage with); remote issues; connection issues with the internet and resources (access to technological devices); challenges with learning how to use Zoom for de novo users; barriers with timing and scheduling virtual sessions; resource issues: not all remote schools have access to the technology for virtual sessions and fewer interactional possibilities on the web versus in person; stigma is also a barrier
Havewala et al [75], 2023	United States	35	MH first aid training	Youth	Digital MH training	MH first aid training implemented virtually	Improvements in MH literacy, knowledge, confidence in MH first aid, help-seeking attitudes, and stigma

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Hawke et al [61], 2021	Canada; survey+open-ended questions	491	General MH in youth	Youth with and without lived MH experience	Explored use of virtual care, including web-based video sessions, phone calls, and use of messages	Not a specific implementation study but one on general experiences with accessing virtual care	Youth preferred MH virtual services that involved web-based video sessions, followed by phone calls; messages were the least preferred; technology had to run smoothly, including preferences for quality internet connection and technology; ease of booking and free MH care preferred; privacy and ability to mute were important; desired content on mindfulness and fitness and engaging content with education; preference for one-on-one over group sessions; need for human personal connection
Markoulakis et al [65], 2022	Canada; qualitative study, semistructured interviews	46	General MH	Youth and caregivers (from the standpoint of carers)	General virtual care and face-to-face services	Not implementation specific but about experiences with MH services, including digital ones, in Ontario, Canada	Fragmented MH services with difficulty accessing them; virtual care benefits included accessibility without the need to travel; issues with engagement with virtual (being easily distracted and it feeling less personal) versus in-person care; barriers with technology issues, including Wi-Fi
McQueen et al [66], 2022	Australia; qualitative (3 participant groups)	167 health care professionals and 68 parents	General MH	Parents and MH care providers	General MH services and virtual care	Not implementation specific but about experiences with MH services	Telehealth barriers included privacy; technology issues with Wi-Fi, sound, and camera (image quality); benefits of telehealth included accessibility; preferences for a hybrid on the web+in-person approach
Meininger et al [77], 2021	Germany; survey	561 therapists and 227 parents	General MH	Parents and MH professionals	Telehealth	Not implementation specific; general experiences with MH services and telehealth at an outpatient unit	One-quarter transitioned from in-person care to telehealth; high satisfaction+acceptance of telehealth; 47% of therapists preferred in-person care over telehealth (over returning to the latter); technology requirements were a barrier in 19% of cases (did not undertake telehealth)
Purtle et al [68], 2022	United States; surveys	159 state officials	General MH	State officials	General MH services+telehealth	Not implementation specific; general experiences with nationwide MH services+telehealth	Main barriers to telehealth were due to remote location, access to technology, and internet connection

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Rudnik et al [69], 2021	Poland	—	General MH	Students	Psychological support delivered via email+Skype; video calls; self-care behaviors; relaxation	Academic Psychological Support Centre in Gdańsk, Poland; applied the pandemic management theory; psychoeducation	Proposed model of care; initial challenges concerned a lack of clear guidelines
Brahmbhatt et al [49], 2021	United States and Canada	22 hospitals	General pediatric MH	Hospitals and MH practitioners	Tele-psychiatry; use of Zoom, WebEx, FaceTime, Microsoft Teams, Epic, Google, phone calls, video consultations, and a combination of media	Tele-psychiatry implementation	Rapid transition to tele-psychiatry used in 16/22 practices (PCLPs[s]); challenges with resources, including access to technology in 75% of cases; access to essential technology rose later on in the pandemic; quality of care not a challenge during virtual as well as hybrid delivery of MH services; lower levels of preference for virtual MH care among primary care providers; challenges faced due to a lack of continuity between primary care physicians and psychiatry in their use of tele-psychiatry
Campbell et al [50], 2023	Canada	48 for the semistructured interviews and 1300 for the mixed methods survey	General MH	MH practitioners, caregivers, and patients	Telehealth	General telehealth implementation experiences	Telehealth is helpful, but hybrid models are preferred; there was diversity in preferences; preference for in-person care for stronger therapy cases; need for private, safe space for consultations and access to technology; usefulness of telehealth included accessibility and no need to travel+social distancing; personal factors need to be considered when deciding the treatment modality and setting; facilitation of telehealth enabled through technological assistance guided by MH care providers

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Campos-Castillo and Laestadius [51], 2022	United States; cross-sectional	532	General MH; teenagers (AmeriSpeak Teen panel)	Teenagers	Telehealth and chat-based messages	Experiences with using the MH care system; not specific to one implemented program	Support from the teenagers' parents critical for enabling access to telehealth, including the provision of space; barriers to equitable access to in-person care among Black teenagers with preferences for in-person support; greater use of messaging and chat-based approaches for ethnic minority groups; need to ensure racial equity in MH diverse digital service accessibility
Childs et al [53], 2020	United States; observational implementation study at a psychiatric hospital	—	General MH	MH care providers at a psychiatric hospital managing teenage patients with MH problems	Zoom, Epic, video group-based psychotherapy, and Telephonic	Telehealth, including Telephonic, MyChart, and video consultation; implementation of youth psychotherapy at the hospital	Telehealth is feasible for group-based psychotherapy; need for an integration of telehealth with the electronic medical record for long-term sustenance
DeJong et al [56], 2022	United States; cross-sectional survey	138	General MH	Psychiatrists	Telehealth	Evaluation of telehealth training, education, and care	Large uptake of telehealth linked to a greater ability to manage the technology; fewer barriers in clinical care training using telehealth reported and greater training relative to prepandemic levels; barriers that remain need for greater equity in telehealth accessibility and funding
Garbutt et al [59], 2022	United States; qualitative interviews	19 pediatricians and 2 nurses	General MH	Pediatricians and nurses	—; provision of general MH support	Experiences with providing MH services; the Child Psychiatry Access Project	Discontinuity between care provided by pediatricians and MH specialists; need for greater accessibility to advice from colleagues on integrating MH care in the home setting; need for comprehensive MH care implementation for remote patients
Gorfinkel et al [60], 2023	Canada; cross-sectional survey	1928	General MH	Teenagers	Video, phone calls, chat-based support, and in-person support	Perspectives and experiences with receiving MH services	Preference for in-person MH care, followed by SMS text messages; phone calls were less preferred, second to video tele-MH consultations
Lal et al [63], 2023	Canada; longitudinal survey	26	General MH	MH care providers: clinicians, nurses, social workers, occupational therapists, and peer support	First-episode psychosis telehealth platform	Tele-psychiatry perspectives using the Reacts platform	Preliminary barriers that subsided with use included technology issues: sound, image quality, and internet connectivity; benefits: patient engagement+accessibility to continued MH care; benefits of Reacts: user centered and private

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Malik et al [64], 2023	India; mixed methods—survey+qualitative interviews	34	General MH	Teenagers and counselors	Digital behavioral problem-solving; tailored behavioral model; voice and video calls	Remote stepped-care model of mental health	Teenagers: preference for voice calls, which felt more private and required less technology; counselor barriers: timely remote support and need for teamwork from both the patient and provider to meet specific needs
Olson et al [67], 2020	—	—	Suicide prevention training	Families+caregivers	Zoom; Northwest Mental Health Technology Transfer Center	Involved patients with their families in the process; Northwest Interconnected Systems Framework; outreach efforts informed by Consolidated Framework for Implementation Research	Switching from in-person to web-based suicide prevention training resulted in greater participation levels than in prepandemic times; increases in knowledge+changes in behavior
Rusu et al [70], 2023	The Netherlands	1065	Cross-sectional survey on experiences	Psychiatrists	Telehealth	—; general experiences with telehealth	The stakeholders were more accepting of telehealth if they had previous training and clinical experience; recommendations to provide both for its successful implementation
Schriger et al [71], 2022	United States; mixed methods—survey and interviews	45	General MH	MH clinicians	Telehealth	—; general telehealth experiences	Training is essential for telehealth; need for resources; engagement is impacted during telehealth+discussion focus or topics; telehealth is not uniformly great for everyone and is contingent on patient characteristics and preferences; higher level of involvement, engagement, and creativity in some patients and families in virtual settings; barriers: privacy and internet accessibility
Stuart et al [72], 2023	Canada; cross-sectional survey+focus groups	29	General MH	ED[t] physicians	Telehealth	—; general telehealth experiences	Barriers to finding the time for telehealth and lack of resources or support from others; need for a greater level of training and comprehension on specific duties and roles in telehealth in the ED setting; benefits: value in providing services virtually for assessing MH

Study, year	Location and design	Sample size, N	MH[a] outcome and target group	Stakeholders	KT media—theory, BCT[b], and diverse media?	KT dissemination plan or efforts or implementation plan?	Key findings and messages
Sullivan et al [73], 2022	Semistructured interviews	207 (121 school-based health centers)	General MH	School-based centers	Zoom; School-Based Health Alliance (60-min session)	—; discussion over Zoom about school-based mental health support recommendations	Key barriers included limited availability of in-person support and staffing; community-based partnerships were important for the sustained provision of support; other barriers were language, cultural, privacy, and technology related (internet and Wi-Fi)
Williams et al [74], 2023	United States; pre- and posttest analysis of the electronic health record	—	General MH	Pediatric MH care providers at the hospitals	Telehealth	—; assessment of the electronic health record	Barriers and accessibility issues for pediatric telehealth in patients from racial minority groups
Kaar et al [62], 2023	Single-arm pilot study that transitioned during the pandemic from Colorado to Alabama (Ally)	—	General MH	Schools, students, and MH volunteers	Web-based delivery of Ally (advocates for all youth)	Health equity implementation framework—FRAME; use of volunteers	Adaptation to the new community setting and implementation required greater community support with volunteers to drive the program; 30-minute sessions each week; challenges with maintaining an equity perspective and health literacy level diversity; need for representation in group leaders from the same backgrounds; the benefit of virtual delivery was a greater reach
Banks [48], 2022	United States; open-ended survey	33	General MH	Teenagers	—	—; general health care use experiences	Financial problems were a main barrier for Black teenagers when it came to accessing MH services
Childs et al [52], 2021	United States; pretest-posttest analysis of attendance rates during the pandemic	—	General MH	Youth and adults (only youth information included)	Telehealth compared with in-person care	Telehealth implementation	Telehealth helped increase accessibility; benefits for group therapy during the pandemic; racial inequities in accessibility to telehealth in Hispanic and Latino youth
Bhat [76], 2021	United States; survey	6393	MH in patients with ASD[u]	Families	Web-based MH services	Experiences with web-based MH services for children with ASD	Web-based MH was not always suitable for many families with children with ASD; recommendations for hybrid (in-person and on the web) MH care

[r] iCBT: internet-based cognitive behavioral therapy.

[s] PCLP: pediatric liaison psychiatric consultation provider.

[t] ED: emergency department.

[u] ASD: autism spectrum disorder.

Stakeholders

Most programs engaged stakeholders, including politicians, not-for-profit organizations, schools, teachers, parents, youth with lived experience, health professionals including general practitioners, psychiatrists, psychologists, social workers, and the criminal justice system [20,25,29,30,35,37,46,79]. A study in Europe used the Knowledge to Action framework [80], with stakeholders involved in each stage of the research process from the development and implementation stages to the evaluation stage, including focus groups, surveys, and interviews [37].

COVID-19 Context

Most of the articles explicitly described that the study was implemented during the COVID-19 pandemic in their titles [9,19-22,24,26-28,30,32-42,44]. Others discussed their study relevance in relation to the COVID-19 pandemic in the abstract or main text [9,23,29,31,38,39]. Several articles described that they were undertaken during the COVID-19 pandemic in both the abstract and title as well as in the main text [48-74]. A few were undertaken before the pandemic but continued throughout the pandemic and had to adjust their implementation strategies, including transitioning from face-to-face programs to adapting to digital health or COVID-19–specific needs [43,45-47].

KT Media

Several but not all the programs delivered mental health KT interventions through diverse media to their various stakeholders [23,26,29,37,39,41,46]. Diverse media included combinations of fact sheets, webinars, Zoom meetings, videos, modules, infographics, and toolkits. For example, Orygen in Australia provided primary, secondary, and tertiary mental health services and education to mental health professionals both on the web and in person along with outreach visits to patients. Their KT media included fact sheets, webinars, videos, web-based modules, and games to increase engagement. Another large study across Europe integrated face-to-face KT using digital tools, including Zoom and a KT app [29]. Several studies used a hybrid method involving face-to-face and digital KT media [22,25,29,30,33,37,46]. However, most focused on implementing e–mental health programs exclusively on the web, usually through virtual mental health or telehealth [9,19,20,22,24,25,28,32,34-36,42,44]. One study focused on using 1 KT medium for translating information on self-care during the pandemic to young cancer survivors to promote their mental well-being using an infographic [30].

KT Theories

A few of the programs applied specific KT theoretical models and frameworks that informed their program implementation [9,31,37,46]. For example, the study by Zbukvic et al [46] in Australia used the Integrated Promoting Action on Research Implementation in Health Services model. The model is founded on usability, the context of the KT intervention, facilitation, and the recipients [46]. In addition, the DREAM KT program in Canada adopted the Knowledge Transitional Integration Framework. The framework is based on 4 pillars, namely, sustainability, credibility, accessibility, and feasibility.

In addition to established KT models, a few positive health psychology theories or models derived from this field were used [23,28,29,37,39,41,43]. For example, a large study across Europe by Hanson et al [29] was informed by positive psychology using acceptance and commitment therapy that informed the Discoverer, Noticer, Advisor model. The study by Zbukvic et al [46] in Australia also integrated the behavior change theory model into the KT program. The program in Canada also focused on developing resilience through emotions, attitudes, and meaning in their youth KT mental health program, whereby they sought to maximize positive experiences in youth with a beginner's mind and creative expression using means such as art, music, and gratitude [37]. They also integrated logotherapy through emotion identification into their program. Grounded theory further informed the first stage of their research at the stakeholder interview stage [37].

Barriers to and Facilitators of Digital and Face-to-Face Mental Health Service Program Delivery and Implementation for Youth During the Pandemic

Digital and Tele–Mental Health Implementation

Several studies reported barriers associated with technology and privacy [19,20,24,25,32,34-36,42,54,61,66,72,73]. Zoom was preferred for privacy reasons when conducting tele–mental health consultations in one study [20]. Accessibility issues included access to technological devices and adequate internet connection [9,25,33,36,54,57,61,63,65,66,68,72-74]. The studies recommended that parents should have adequate training and an orientation on the technology as well as increased accessibility to the internet. Technological support was also needed for the preliminary tele–mental health sessions [32], and technological issues were identified in 31% of users in one study [35].

Space was identified as a critical feature for the successful implementation and delivery of virtual mental health services and programs to children and teenagers [9,24,25,50,51]. For example, the study by Doan et al [24] at the Hospital for Sick Children in Canada, which adopted the 6 Pillars framework in their development of a framework for mental health practitioners, emphasized that the space needed to be clean and private for medical providers.

Body language or nonverbal communication cues were also identified as barriers in some studies [9,22,34,45]. One study found that it was difficult to motivate patients and that work was needed to build the therapeutic relationship when mental health consultations were virtual as opposed to face-to-face [45]. In addition to body language, there were challenges with implementing certain digital mental health interventions, including art therapy programs on the internet during the pandemic [21].

A few studies also found that tele–mental health service implementation was more challenging in younger children [9,19,22,34,36,40,54]. Children preferred face-to-face mental health consultations over virtual ones [40]. In addition, one qualitative study in France by Carretier et al [22] found that teenagers preferred phone calls over video consultations. "Zoom fatigue," feeling tired from using web-based technology for mental health care, was identified as an obstacle in one study in children. In total, 3% (2/59) of the studies made play or art kits for children to keep them engaged. One study recommended offering "play kits" to keep children interested and engaged with the technology [9]. Similarly, "art kits" were mailed out to children undergoing mental health therapy, including dialectical behavior therapy in adjunct to virtual telehealth appointments [26]. Thus, it seems that sending hands-on engaging resources to children may assist with their participation during web-based mental health sessions.

There were also challenges with managing and adapting to using the digital technology. For example, the case study by Zbukvic et al [46] on KT in workforce development (Orygen) involving 4400 mental health workers found that it was challenging to deliver digital mental health care during the pandemic and that there is a need for a framework with clear guidance on how to best deliver e–mental health care using digital media. They found that levels of readiness and adaptability varied across different stakeholder organizations [46]. Physician-level factors included the need for adequate training in tele–mental health [36,40,42,43] as well as readiness to partake in it [24].

A few studies found that physicians needed to be sufficiently trained in the technology when dealing with young patients with mental health problems. The study by Skar et al [43] found that there was higher patient attendance when they had adequately trained physicians. For example, this included leadership training [43] and learning how to undertake virtual interviews [40].

Actual hands-on training in using tele-psychiatry technology and the virtual platform was also emphasized in one study [42]. The study by Doan et al [24] also found that there is a need for a safety plan, with adequate preparation during emergencies or unforeseen events. The qualitative focus group study by Parrot et al [37] found that stakeholders who were not previously supportive of web-based mental health platforms found them to be acceptable after they had tried them, indicating that perceptions of digital mental health are more positive and willingness to try it increases if users learn how to apply it. The qualitative study by Goddard et al [26] involving the "Listening and Learning" platform for school alliances found that most providers adapted to using telehealth and virtual meetings on Zoom, Skype, and FaceTime. The study by Craig et al [23] found that there is a need for medical providers to be familiar with navigating digital technology, including screen sharing, implementing Microsoft PowerPoint for greater engagement and knowledge dissemination, and learning how to break social awkwardness on the web through things such as "icebreaker questions” when implementing cognitive behavioral therapy. They also found that there is a need to implement social apps for social networking [23]. Therefore, adequate knowledge dissemination on the use of digital health technology and its successful implementation through gaining interviewing skills and providing sufficient engagement for children and youth across diverse service providers is needed.

Overall, most of the studies that assessed acceptability and feasibility found that digital health and tele–mental health were viewed positively and there was a high uptake by youth during the pandemic [20,24,32,34,41,77]. The cross-sectional survey involving a needs assessment from the Transforming Research Into Action to Improve the Lives of Students implementation study (N=982 school-based health professionals who were trained) found that school-based mental health professionals were satisfied with the web-based manual that disseminated knowledge on youth coping skills [41]. Only one study found that medical providers experienced burnout from implementing telehealth [9]. The study by Moorman [34] that analyzed practice data from 40 health professionals and 60 families found that tele–mental health increased accessibility to mental health care for children and teenagers and resulted in a higher attendance.

School-Based and Nondigital Mental Health Approaches

A couple of studies examined the challenges with implementing mental health programs in face-to-face settings such as in schools and clinics. A large study in the United States with 29,000 stakeholders that analyzed data from 400 participants who undertook training in trauma-informed practices found that trauma-informed classroom practices could be successfully implemented through joint efforts between school-based professionals and mental health care providers [47]. The mixed methods qualitative interview study with 12 gatekeepers (with longitudinal data from 216 teenagers) by Podar et al [38] in Germany found that there is a need for an integrated mental health care system in schools and that inequities in accessibility exist among young refugees who experience stigma. They emphasized that there should be strong antidiscrimination policies when it comes to youth mental health in schools [38]. Thus, implementing programs in schools should maximize accessibility for all students. A case study analysis in the United Kingdom of youth in wards (N=36) found that it was challenging to implement a youth mental health ward in a pediatric setting, which required setting up a new ward and combining physical health with mental health [27]. They also found that it required joint efforts in a multidisciplinary team setting involving nurses and pediatric psychiatrists, which led to adopting new leadership and managerial approaches as well as tailoring treatments to individual patients [27].

Hybrid Mental Health Approaches

Some of the studies opted for hybrid approaches when implementing mental health services and programs for children and teenagers [22,25,29,30,33,37,46,76]. The case analysis by McMellon and MacLachlan [33] in Scotland recommended a hybrid program with enhanced access to digital mental health services and technology in schools combined with face-to-face in-person support through greater staff training. The lexical analysis study by Eapen et al [25] in Australia also made recommendations for a hybrid mental health care service delivery for youth in clinics and at home to increase accessibility, ensuring clinical assessment in person combined with web-based support. Another study in Australia (case study) by Zbukvic et al [46] found that diverse stakeholders, including mental health care providers, required web-based training and outreach in-person clinic visits, with KT and dissemination strategies involving videos, fact sheets, modules, and webinars to meet the mental health needs of youths. In addition, a large mental health mixed methods KT implementation study in Europe (ME to WE) involving 8000 stakeholders evaluated KT and dissemination strategies to meet the needs of youth who cared for someone [29]. Through extensive knowledge syntheses and a participatory design, they found that youth should receive support from both peers and family in addition to mental health supportive services and respite. They also made recommendations for a mental health app that would support young caregivers [29]. Raising awareness of the mental health needs of young carers was also brought up as a theme [29]. The focus group study by Parrot et al [37] recommended a hybrid model for in-class and web-based KT for youth mental health by ensuring that teachers offered both the in-class learning version and the web-based one. Behavior change techniques such as reminders to enhance memory were also recommended, including things such as games, booklets, and memory aids. They also found that students preferred a range of lyrics with music as part of a meaningful program [37]. To enhance accessibility and engagement, they also recommended more teachers who could offer the program on the web [37]. The study by Hou et al [30] found that an infographic, while informative, was only one medium for KT and dissemination for youth mental health and resilience and that other KT media should be explored in the future along with personally tailored interventions.

In addition, one study combined passive KT with active KT, a type of hybrid approach for disseminating knowledge. The study by Power et al [39] involved a KT leaflet for resilience building in children and teenagers combined with a happiness toolkit that required children to build a physical box, emphasizing the importance of real-life relevance for children in addition to a passive leaflet when it comes to participation and engagement. However, this was an early developmental study on a new model of care rather than an implementation study evaluating its barriers and acceptability.

Overall, support services should include a range of resources, including in-person social support and an app. All these studies with hybrid approaches found that accessibility to mental health supportive services or engagement was enhanced when diverse options were offered through in-person support, web-based support, digital applications, and support from family and friends in addition to professional help to accommodate diverse learning needs and preferences. As barriers were noted for digital delivery, hybrid methods were also recommended for accessibility from this perspective. It also appears that active versus passive methods may enhance participatory engagement; however, more research is needed to confirm these findings.

Mental Health First Aid

A couple of studies implemented mental health first aid through virtual platforms and found that knowledge improved [67,75]. The study by Olson et al [67] found that participation in suicide prevention training increased when they transitioned to a web-based delivery system due to COVID-19.

Summary of Findings

In summary, it seems that the successful implementation of mental health programs requires hybrid approaches involving both in-person (face-to-face) and web-based sessions. Digital mental health may be successfully implemented if barriers are minimized, such as providing children, teenagers, and their families with adequate access to the internet or providing them with stable Wi-Fi, maximizing privacy using encrypted servers, and finding a suitable space for these meetings. Ensuring adequate engagement by keeping younger children interested through sending them hands-on material to engage with during web-based sessions seems desirable. In addition, medical providers require adequate training with sufficient space and knowledge of web-based learning tools. Finally, a couple of studies noted racial inequities in accessibility to mental health programs [48,51,52,74], highlighting that this needs to be addressed to ensure successful and equitable mental health program and service implementation.

Discussion

Principal Findings

The objective of this literature review was to broadly gain a better understanding of the types of programs that were implemented during the pandemic for child and youth mental health along with a better understanding of implementation challenges and knowledge dissemination strategies, including KT theoretical models for program implementation. This included clinical programs in health care settings and community-based programs in schools. It also included individual- and family-level preventive strategies for early identification and referral through knowledge dissemination in mental health training programs. The implications of the results of each aim will be discussed in this section.

First, we aimed to better understand the key barriers and challenges regarding implementing child and youth mental health programs during the pandemic. Certain factors need to be taken into account, including internet accessibility, to ensure that everyone has equitable access and that there are no technological barriers to timely mental health care for youth. Privacy was also raised as an important barrier in e–mental health among youth, highlighting that secure digital media need to be used. There were issues with Wi-Fi accessibility, emphasizing that a stable internet connection is vital for implementing these programs for youth. Policies could consider funding Wi-Fi for families who may struggle financially with respect to purchasing high-speed, stable internet plans. In addition, having a secure and private space is important for both the practitioners and the patients. However, it is challenging for patients to make room for meetings if they do not have adequate space at home. Nevertheless, from a program implementation stance, it appears that mental health services via telehealth are acceptable for young adults overall. However, it seems that younger teenagers and children may require additional strategies to avoid “Zoom fatigue” and keep them interested and engaged. For these reasons, the programs opted for offering hybrid care to youth or combined media such as apps along with family supportive services, whereas children received art kits or play kits to enhance participatory engagement.

Second, we aimed to better understand what types of mental health programs were implemented during the pandemic by key stakeholders and what KT theoretical models and strategies were adopted during the implementation of these programs. We identified a few initiatives, particularly in Canada and Australia, that worked toward providing mental health care to young adults while engaging with critical stakeholders. Important stakeholders included schools, medical doctors, psychologists, the criminal justice system, families, young adults with lived experience, social workers, charities, and politicians, among others. Some offered training to the stakeholders, and others provided direct mental health support to those with lived experience.

We identified several programs that were implemented for youth during the pandemic, with most being telehealth and digital based, followed by hybrid (mixed face-to-face with digital) and in-person face-to-face programs. However, overall, many programs recommended a hybrid method for delivering youth mental health services, including the use of digital media and face-to-face sessions to increase accessibility and meet the learning pretenses of stakeholders. The digital media included apps, the use of Zoom, and other web-based tools or websites.

Some the initiatives used clear KT theories to inform their programs, and 7 of them had used psychological theoretical models. There is a need for more implementation programs to use KT models when training practitioners to use evidence-based methods. Some programs also used theories of behavior change and psychological theories to inform their interventions, such as facilitating positive experiences through meaningful expression and engagement [37].

The use of diverse media for KT rather than one medium appears to be important. In their review of KT interventions for parental knowledge of all childhood health problems published until 2015, Albrecht et al [81] found that most studies used one medium. Thus, the use of digital media in an increasingly digitalized world appears to be an important move toward enhancing accessibility for youth mental health. The pandemic has especially highlighted the urgent need for the transition to web-based methods to enhance accessibility despite different levels of stakeholder acceptability. However, more research is needed to better understand whether the programs and hybrid models are actually effective in improving youth mental health as this was not evaluated in the implementation studies.

Another aim was to understand what mental health first aid training interventions were developed for increasing knowledge of mental health support and understanding any challenges regarding their implementation or adoption. We did not identify many such studies that were undertaken during this period. Initially, we identified 6 studies that were published during the pandemic period, with many finding increased perceived self-efficacy for providing mental health first aid, but not all led to changes in behavior, including the actual provision of mental health support to someone in distress [82-87]. However, after following up and closer examination, the studies were not actually undertaken during the pandemic period itself.

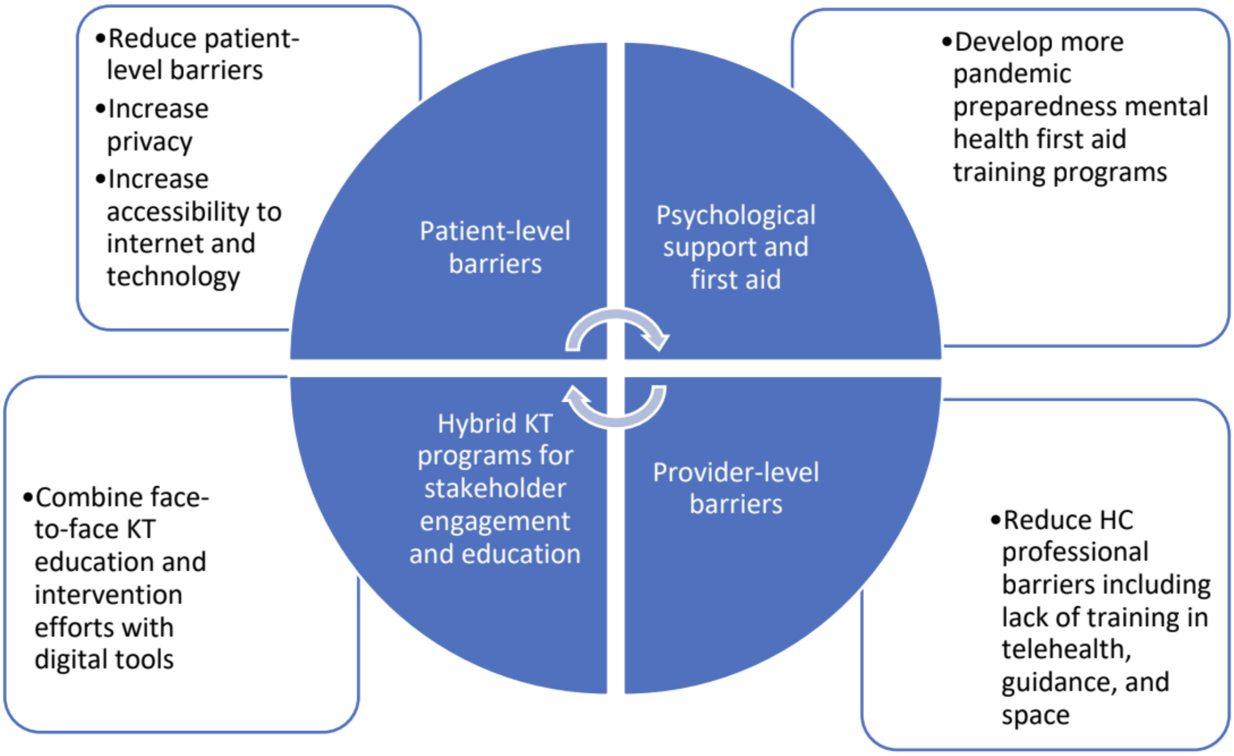
Recommendations

On the basis of the knowledge synthesized from this literature review, several recommendations can be made for youth mental health promotion in the postpandemic era and for future pandemic preparedness. A future youth mental health KT tool may also be developed based on these recommendations.

1. Evaluate more hybrid models of mental health for KT among various stakeholders.
2. Reduce the barriers to implementing tele–mental health in youth by providing adequate technological access, Wi-Fi and stationary internet connectivity, and privacy protection.
3. Enhance staff training and preparedness for a future pandemic by having the equipment, knowledge, and skills in place.
4. Undertake more research on youth mental health for future pandemic preparedness and first aid training, including the barriers to and facilitators of effective KT and implementation.

Figure 2 illustrates 4 levels of steps that could be taken for future child and youth mental health and pandemic preparedness.

Figure 2. Future pandemic preparedness regarding pediatric and youth mental health. HC: health care; KT: knowledge translation.



Limitations

One limitation of this review is that we undertook more of a narrative literature review as, ideally, we would have required 2 screeners for a full scoping review, which was not possible due to resource limitations. We included publicly accessible free articles due to resource limitations. We also did not search gray literature, which could have provided more data on rapidly implemented studies that were not published. There is a possibility that there were more studies on this topic given the breadth of the COVID-19 literature.

However, our overarching aim was to gain a better understanding of the common implementation challenges and KT strategies that were developed in general during the pandemic, and we broadly covered the literature in several key areas spanning KT; implementation; school-based programs; and health care, including telehealth programs. A strength of this review is that we structured our analysis around KT and provided practical “hands on” recommendations for implementation and policy that may be applicable to many future studies, especially when planning for a future pandemic.

We note that there were wide variations in terms of countries and policies during the pandemic, but the overarching implementation issues were common across the studies despite this. In addition, although the studies are generalizable to pre- and postpandemic times, the focus was on the pandemic period to ensure that we understood what the challenges were during times of uncertainty and crisis, when swift decisions had to be made regarding new implementation issues.

Conclusions

In summary, we aimed to better understand the implementation experiences, challenges, and facilitators of child and youth mental health program services during the pandemic. We found that, while many benefited from digital implementation strategies, hybrid in-person combined support was preferred.

Provider-related challenges were also identified with transitioning to telehealth and learning how to use the technology. Barriers for patients were mainly privacy related and technological, including access to the internet and devices and the ability to communicate efficiently through a screen.

We also aimed to gain a better understanding of the KT intervention strategies, programs, and positive psychology interventions that were developed to promote youth mental health during the pandemic period. We identified KT programs that engaged with a wide range of stakeholders during the pandemic, and a few were KT theory informed. Future studies should focus on hybrid systems of KT and youth mental health program delivery and address technological and privacy barriers linked to the implementation stage of youth mental health e-services.

Abstract

Background: Social anxiety disorder (SAD) is a common mental disorder in adolescents and young adults. Early intervention and support could help prevent the development of full-blown SAD. Considering that adolescents with social anxiety symptoms do not prefer face-to-face sessions due to their fear of communicating with therapists, internet-based cognitive behavioral therapy (ICBT) was implemented.

Objective: This study aimed to examine the effectiveness of complete self-help ICBT for subthreshold SAD in high school and college students with no history of mental disorders.

Methods: A multicenter randomized controlled trial designed to demonstrate the objective was conducted from December 2022 to October 2023. Participants were students enrolled at 6 universities and 1 high school. The intervention was a complete self-help ICBT and consisted of 10 text-based sessions that taught cognitive behavioral therapy techniques for social anxiety in youths and young adults. The comparison was a no-treatment condition (control group), which was randomly assigned in a 1:1 ratio by a computer program. A total of 2 psychological scales were used to assess the severity of social anxiety, and 1 psychological scale each was used to measure symptoms of depression, general anxiety, and quality of life.
