Results: In total, 77 students were enrolled as study participants. Through the randomization procedure, 38 participants were included in the intervention group, and 39 patients were included in the control group. Results from the analysis of covariance with depression as covariates showed that the participants in the intervention group had significantly reduced symptoms of social anxiety, depression, and general anxiety compared to the control group. The response rate was 61% (19/31) in the intervention group and 24% (9/38) in the control group: odds ratio (OR) 4.97 (95% CI 1.61-16.53; *P*=.003) in the Fisher exact test. The recovery rate was 68% (21/31) in the intervention group and 34% (13/38) in the control group: OR 3.95 (95% CI 1.32-12.56; *P*=.008). The OR for the remission ratio was 2.01 (95% CI 0.64-6.60; *P*=.20) and for the risk of worsening was 0.23 (95% CI 0.002-1.33; *P*=.10), but no significant difference was observed.

Conclusions: The results of this randomized controlled trial show that fully unguided ICBT improves subthreshold SAD in adolescents and young adults. Interpretation of the effectiveness in preventing SAD that meets the diagnostic criteria is limited by sample size and the follow-up period. Future studies should include more extended observations and larger sample sizes in high-risk populations.

Introduction

Background

Social anxiety disorder (SAD) is a mental disorder characterized by excessive anxiety and embarrassment in social situations and fear of being negatively evaluated [1]. The lifetime prevalence of SAD is 4% [2], with a prevalence of 2.1% in adolescents and young adults [3]. Anxiety disorders, including SAD, are the most common psychiatric disorders [4], and mild (subthreshold) forms are common and cause significant disability [5]. The onset of SAD often occurs in the early to midadolescent years [6], with most of the patients having the disorder before their 20s [7]. The adolescent years represent a life stage where interpersonal relationships become more complex, leading to a heightened susceptibility to anxiety in social situations. Quite a few young individuals, even those who do not meet the diagnostic criteria, are aware of experiencing social anxiety at levels below the threshold for diagnosis. For example, a previous study reported 280 high school students in Japan found that approximately 20% experienced moderate social anxiety over a period of 3 years [8]. Another research focused on social fears and SAD among Portuguese youth, and 26% reported with intense self-reported social fear [9]. The presence of subthreshold anxiety disorders increases the risk of full-blown anxiety disorders by more than 3-fold [10]. Treating subthreshold anxiety disorders in a timely manner may prevent the onset of full-blown anxiety disorders [11]. When adolescents develop SAD, it can negatively affect their interpersonal relationships, academic achievement, and career development [12]. Intervention for subthreshold SAD is crucial, as it holds the potential to prevent these issues from arising in the first place.

Cognitive Behavioral Therapy for SAD

Cognitive behavioral therapy (CBT) is one of the most effective treatment approaches for SAD [13]. By modifying the cognitive behavioral cycle that sustains social anxiety [14], a strong therapeutic effect can be achieved [15]. The effectiveness of face-to-face individual CBT has been established not only for adults but also for children and adolescents [16]. However, low rates of in-person CBT and poor access make it challenging to provide long-term treatment [17]. The low prevalence of CBT in Japan (6.2%) can be attributed to a shortage of cognitive behavioral therapists and its high costs in terms of time and finances [18]. Barriers to mental health treatment have been identified via interviews of patients with SAD. These barriers include a lack of awareness of available treatment facilities, fear of self-disclosure, and financial constraints due to a lack of insurance coverage [19]. Additionally, approximately 80% of adults with SAD developed the condition during adolescence [20]. Adolescence is a period of establishing autonomy, and as the scope of social responsibilities expands, young people tend to hesitate to seek support from others [21]. Access to appropriate treatment remains limited, as many youth do not seek help [22]; this problem is further exacerbated by the shortage of mental health services available worldwide [23]. In resource-limited situations, therapeutic approaches must be refined to improve access to treatment. An early intervention to address the mental health needs of youth could lead to rapid recovery or prevent relapse of mental health problems [24].

Internet-Based CBT for SAD

Internet-based CBT (ICBT) is a promising solution that can overcome physical barriers and time constraints. Many ICBT programs have been implemented, and recently, countries with high smartphone penetration and internet use have begun to validate the effectiveness of self-help ICBT [25,26]. Self-help programs usually have high dropout rates, but the feature of not having to interact with the therapist has been reported to help reduce the dropout rate of patients with SAD and lead to satisfactory treatment completion rates [27,28]. A previous study including individuals with nonclinical anxiety disorders has also confirmed a significant reduction in anxiety symptoms through complete self-help ICBT: 50 cases underwent a web-based ICBT for SAD [29]. Furthermore, conducting ICBT through mobile devices such as smartphones or tablet PCs, as opposed to desktop computers, may enhance therapeutic effects. Social situations eliciting social anxiety are often present outside the home or private spaces, and intervention through mobile devices facilitates the immediate recall and implementation of CBT techniques when confronted with these situations. Unguided ICBT for individuals with SAD using mobile devices has demonstrated a high effect size with a range of Cohen *d*=0.81 when compared to a waitlist group using the Leibowitz Social Anxiety Scale (LSAS) total score [28,30].

ICBT for Subthreshold SAD

However, there is currently no study examining the effectiveness of unguided ICBT for subthreshold SAD treatment providers. Due to not meeting the diagnostic criteria, individuals with subthreshold SAD may have lower motivation and potentially higher dropout rates in self-help treatment. Moreover, adolescents with mild to moderate symptoms of social anxiety may show a small or limited treatment response. On the contrary, subthreshold SAD may exhibit a higher average treatment response rate, potentially surpassing the 53.6% observed in diagnosed SAD [31], as it lacks the functional impairments such as depression and avoidance frequently observed in patients with SAD [32]. Due to these remaining areas of uncertainty, it is inappropriate to simply extrapolate evidence from diagnosed SAD when considering the applicability of unguided ICBT to subthreshold SAD.

Objective

The aim of this study was to assess the effectiveness of intervening in widespread subthreshold SAD during adolescence and evaluate the acceptance of unguided, completely self-help ICBT, taking into consideration dropout.

Methods

Ethical Considerations

The research protocol underwent review and was approved by the ethics review board of the Clinical Research Management Center at Kagoshima University Hospital (ID 220196). Participants received both oral and written explanations of the study and were enrolled upon expressing their voluntary written consent. For high school participants, written consent was obtained from both the participants and their guardians. The data collected in this study were anonymized and required a code to identify specific individuals.

Study Design

This study reports based on the CONSORT (Consolidated Standards of Reporting Trials) Statement for Randomized Trials of Nonpharmacologic Treatments [33]. The CONSORT eHEALTH checklist is presented in Multimedia Appendix 1. A multicenter randomized controlled trial (RCT) was conducted from November 2022 to October 2023 in Japan. A research team (KM, MN, and SH) at Kagoshima University Hospital and the University of Fukui designed this RCT. A total of 6 universities and 1 high school were registered as implementation sites in this study. This clinical trial is registered in the University Hospital Medical Information Network Center, and an overview of the research protocol is publicly available (UMIN000050064).

Participants and Recruitment

Participants were recruited from 6 universities and 1 high school in Japan. In total, 89 students gave informed consent, and the eligibility criteria were confirmed. Of them, 77 students met the eligibility criteria, and they were enrolled in this clinical trial. The participants were randomly assigned to an intervention group (ICBT) and a control group (no treatment). Participants received coupons worth JP ¥5000 (equivalent to US $31.30) as compensation for each of the 2 data submissions. Participants assigned to the intervention group received compensation at baseline and at the start of the intervention. Those assigned to the control group received compensation at baseline and at 10 weeks. High school participants did not receive remuneration, in accordance with their school’s educational policy.

Eligibility and Exclusion Criteria

High school or college students between the ages of 15 to 25 years, with a total LSAS score≥30 or higher [27], and with their own smartphone were eligible. The exclusion criteria were diagnosis of psychiatric disorders such as depression, history of CBT within 2 years, IQ<85, imminent suicidal risk, and the presence of advanced diseases such as cancer.

Intervention

Participants assigned to the intervention group were instructed to complete a specific ICBT program entirely through self-help, using their own smartphones. Participants could contact the research team if they had any specific questions. It was recommended to complete 1 module per week, with automatic email reminders sent every Monday morning, prompting participants to engage in the program. If a module was not completed by Friday, participants received an automatic email reminder on Saturday at noon. The first author (KM) developed an unguided ICBT program for subthreshold SAD in adolescents and young adults. The ICBT program was built on an e-learning platform (learningBOX; learningBOX Inc). The ICBT program is based on the Clark and Wells [14] model. The ICBT program consists of 10 sessions of training on effective CBT components for social anxiety. Table 1 shows the treatment modules. The participants in the control group received no treatment; they also were asked to refrain from accessing information about CBT.

Table 1. The modules and tasks of the treatment course.

	Module	Task
1	Psychoeducation and case-formulation	Developing an idiosyncratic version of the formulation
2	Examine the function of safety behaviors and self-focused attention	Manipulating safety behaviors and self-focused attention with behavioral experiments
3	Video feedback to correct negative self-image	Updating negative distorted self-images by video feedback in participant's smartphone
4	Attention training in photographic social situations	Shifting the focus of attention to external information during a conversation or communication
5	Behavioral experiments to test negative predictions and assumptions	Observing the reactions of others immediately after behavioral experiments
6	Opinion survey to follow-up behavioral experiments	Updating negative assumptions about failures in social situations
7	Handling anticipatory worry and postevent rumination	Exploring the advantages and disadvantages of worry and rumination
8	Image description	Updating negative self-images and impressions
9	Schema work	Addressing dysfunctional negative beliefs and assumptions
10	Prevent relapse	Summarizing coping strategies for social anxiety and reflecting on the progress of the treatment course

Outcomes

Primary Outcome

The primary outcome was the severity of social anxiety, as per the self-rated LSAS score. The LSAS was developed to measure social anxiety [27]. The LSAS contains 24 social situations related to "fear or anxiety" and "avoidance" that the participants are asked to rank on a 4-point scale, with 0=never and 4=severe. The Japanese version of the LSAS has demonstrated reliability and validity and is widely used in clinical and research settings in Japan [34]. Response to the ICBT was defined as a decrease in the LSAS by 28% or more [35]. Remission was defined as an LSAS total score<35, as specified in a previous ICBT study of SAD conducted in Hong Kong [36]. Conversely, to assess the risk of exacerbating social anxiety, we defined worsening as an increase in LSAS of 28% or more.

Secondary Outcomes

The secondary outcomes were the scores on 4 self-administered scales: the Social Phobia Inventory (SPIN) is a self-rating scale that measures 3 characteristic aspects of SAD: fear, avoidance, and physiological arousal [37]. In the Japanese version of the SPIN, 17 questions are answered on a 5-point scale, with 0=not applicable at all and 4=strongly applicable [38]. The Patient Health Questionnaire-9 (PHQ-9) was developed to measure depressive symptoms [39,40]. The first 9 items of the PHQ-9 assess how often various depressive symptoms have occurred in the last 2 weeks. The Generalized Anxiety Disorder-7 (GAD-7) scale was developed to measure anxiety levels [40,41]. The first 7 items of the GAD-7 assess how often various anxiety symptoms have occurred in the last 2 weeks. The EQ-5D-5L measures the quality of life (QOL) values for calculating quality-adjusted life years (QALYs) in the economic evaluation of medical technologies [42,43]. In the EQ-5D-5L, the responder answers questions on 5 dimensions directly related to QOL (mobility, self-care, usual sensitivity, pain or discomfort, and anxiety or depression). Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems, and extreme problems. The QALY ranges from 0 to 1.0, with 0=dead and 1.0=in perfect health. We also calculated the recovery rates of the Improved Access to Psychotherapy program and improvement (recovery) rates considering total scores in SPIN<19 and PHQ-9<10, simultaneously for comparison with a UK sample [44].

Sample Size

The sample size was calculated to be 78 using G*Power (version 3.1.9.7; The G*Power Team), which is a free statistical analysis software [45,46]. The required sample size of this RCT was estimated to be 52, considering a 2-tailed significance level of .05, a power of 80%, and an estimated effect size of 0.8 [30]. The required sample size above was calculated considering the 50% dropout rate of previous studies with unguided ICBT [47].

Randomization

Randomized allocation was conducted by the minimization method with a randomization generator [48]. In randomization, LSAS total score <50 or ≥50, sex (male or female), and facilities were used as adjustment factors.

Blinding

Blinding was not implemented.

Statistical Analyses

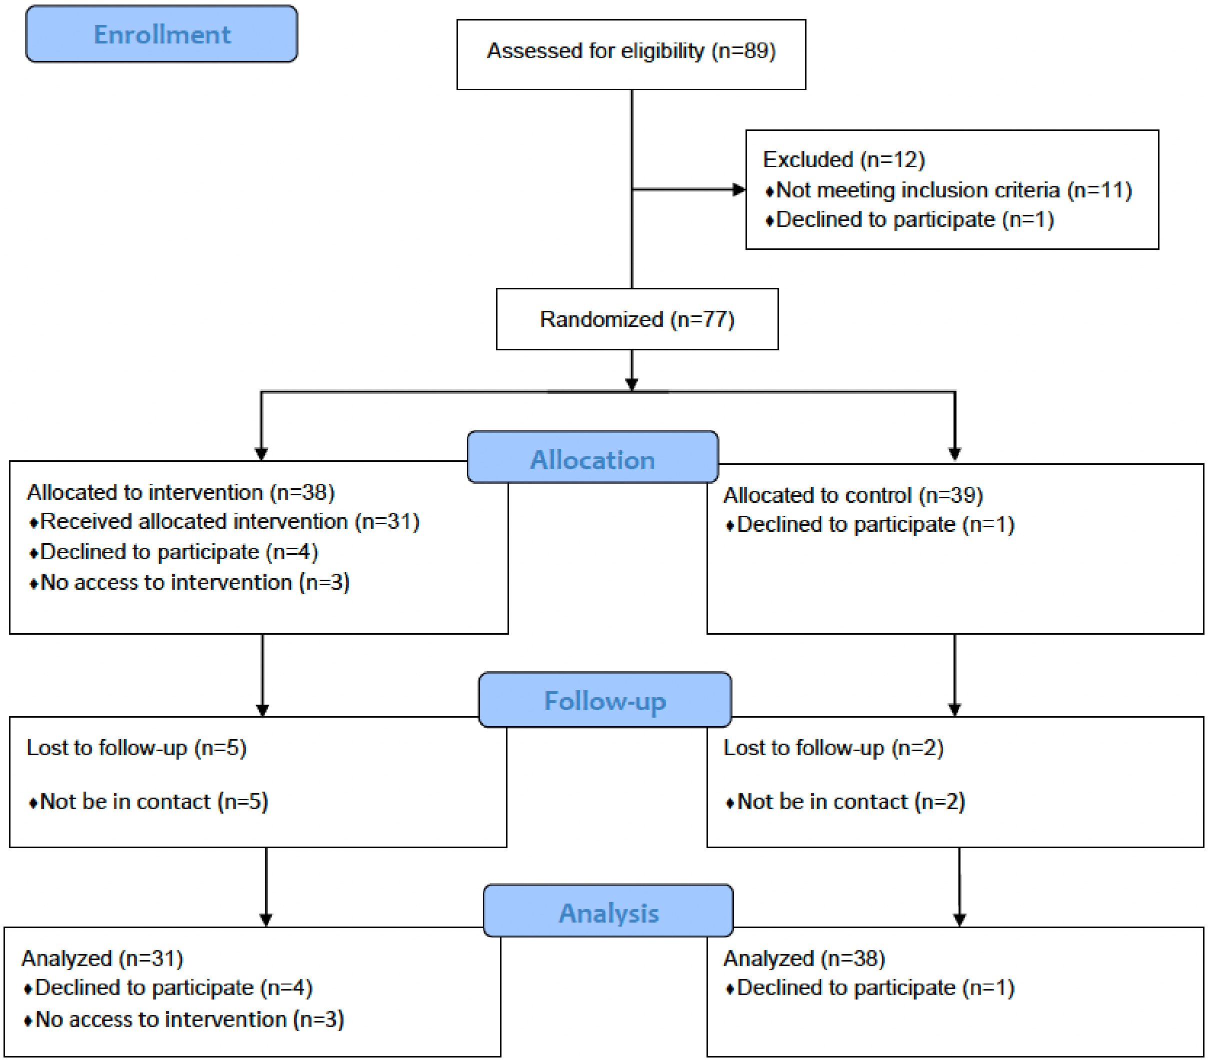
Missing values were imputed using the *mice* package in R (version 4.3.2; R Foundation for Statistical Computing), a free statistical software package [49]. Demographic data at baseline were described, and between-group characteristics were analyzed using independent sample 2-tailed *t* tests. To investigate significant differences in the change of scores between groups for both the primary and the secondary outcome measures, an analysis of covariance (ANCOVA) was conducted. A covariate factor was the severity of depression determined by measuring the PHQ-9 total score at baseline. For treatment response ratio, remission ratio, and recovery ratio, Fisher exact test was performed, and odds ratios (ORs) with 95% CIs were calculated. Analyzing the risk of worsening social anxiety measured in LSAS involved the calculation of risk ratio, relative risk reduction (RRR), absolute risk reduction (ARR), and number needed to treat (NNT). Statistical analyses were implemented by using R (version 4.3.2). A significance level of .05 was used for all analyses.

Results

Recruitment

Among the 38 participants assigned to the intervention group, 4 declined research participation after the preintervention assessment. A total of 31 participants completed the ICBT program at least once, while 3 did not access the intervention program at all. Therefore, the dropout rate from this ICBT program was 9% (3/34), the implementation rate of ICBT was 91% (31/34), and the completion rate was 65% (22/34). Of the 39 participants assigned to the control group, 1 declined research participation, and data on outcomes could not be obtained for 2 students due to unavailability. Following the predetermined analysis plan, the statistical analysis included data from 31 participants in the intervention group and 38 in the control group. Figure 1 shows the participant flow diagram.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.



Demographical and Characteristic Data

Table 2 shows the demographics, clinical characteristics, and baseline outcomes of the participants included in the analyses. The level of depression, measured by the PHQ-9, in the control group, was significantly higher than the intervention group at baseline; however, clinically, both groups fell within the range of “mild depressive symptoms” (total score 5-9) [50]. No significant differences were observed in other outcomes.

Table 2. Demographical and characteristic data, and the total scores of outcomes at baseline.

Demographical and characteristic data	ICBT[a] group (n=31)	Control group (n=38)	*P* value (unpaired *t* test)
Sex (female), n (%)	20 (65)	25 (66)	N/A[b]
Age, mean (SD)	21.61 (2.06)	21.39 (2.32)	.68
LSAS[c], mean (SD)	58.38 (19.17)	59.08 (20.77)	.88

Outcomes and Estimation

Primary Outcome

The reduction in LSAS total score from baseline to postintervention assessment was significantly greater in the intervention group compared to the control group by 11.62 (95% CI 1.67-21.56; $F_{1,66}$=3.91; *P*=.02). Figure 2 presents the change in LSAS total score from baseline to postintervention assessment. The change in LSAS total score from preintervention to postintervention assessment in the intervention group was significantly larger than that in the control group by 9.39 (95% CI 1.31-17.48; $F_{1,66}$=4.65; *P*=.01).

[a] ICBT: internet-based cognitive behavioral therapy.

[b] ANCOVA: analysis of covariance.

[c] LSAS: Liebowitz Social Anxiety Scale.

[d] N/A: not applicable.

[e] SPIN: Social Phobia Inventory.

[f] PHQ-9: Patient Health Questionnaire-9.

[g] GAD-7: Generalized Anxiety Disorder-7.

The reduction in SPIN total score from baseline to postintervention assessment was significantly greater in the intervention group compared to the control group by 8.05 (95% CI 3.02-13.08; $F_{1,66}$=5.39; *P*=.007). The change in SPIN total score from preintervention to postintervention assessment in the intervention group was significantly larger than that in the control group by 8.26 (95% CI 3.75-12.78; $F_{1,66}$=7.23; *P*=.01).

The reduction in PHQ-9 total score from baseline to postintervention assessment was greater in the intervention group compared to the control group by 1.15 (95% CI 0.41-2.70; $F_{1,66}$=1.19; *P*=.31), not significantly. The change in PHQ-9 total score from preintervention to postintervention assessment in the intervention group was larger than that in the control group by 1.75 (95% CI 0.28-3.23; $F_{1,66}$=2.96; *P*=.06), not significantly.

The reduction in GAD-7 total score from baseline to postintervention assessment was greater in the intervention group compared to the control group by 1.24 (95% CI –3.05 to 2.79; $F_{1,66}$=1.66; *P*=.21), not significantly. The change in GAD-7 total score from preintervention to postintervention assessment in the intervention group was significantly larger than that in the control group by 1.81 (95% CI 0.31-3.33; $F_{1,66}$=4.15; *P*=.02).

The reduction in QALY measured by EQ-5D-5L from baseline to postintervention assessment was greater in the intervention group compared to the control group by –0.0388 (95% CI –0.09 to 0.008; $F_{1,66}$=1.41; *P*=.25), not significantly. The change in QALY measured by EQ-5D-5L from preintervention to postintervention assessment in the intervention group was larger than that in the control group by 0.0366 (95% CI –0.0120 to 0.0852; $F_{1,66}$=1.31; *P*=.28), not significantly.

Ancillary Analyses

Table 4 presents Fisher exact test results for treatment response rate, remission rate, recovery rate, and risk ratio. The treatment response rate in the intervention group was significantly higher at 61% (19/31) compared to the control group at 24% (9/38; *P*=.003; OR 4.97, 95% CI 1.61-16.53). The recovery rate in the intervention group was substantially higher at 68% (21/31) compared to the control group at 34% (13/38; *P*=.008; OR 3.95, 95% CI 1.32-12.56). Regarding the risk of deterioration, the intervention group had a higher but nonsignificant rate of 6% (2/31) compared to the control group 24% (9/38; *P*=.10).

Table 4. Results of Fisher exact test[a].

Result	ICBT[b] group (n=31), n (%)	Control group (n=38), n (%)	OR[c] (95% CI)	*P* value
Response	19 (61)	9 (24)	4.97 (1.61-16.53)	.003
Remission	12 (39)	9 (24)	2.01 (0.64-6.60)	.20
Recovery	21 (68)	13 (34)	3.95 (1.32-12.56)	.008
Worse	2 (6)	9 (24)	0.23 (0.02-1.23)	.10

[a] Definition of clinically significant change: response: a decrease in the Liebowitz Social Anxiety Scale (LSAS) by 28% or more; remission: an LSAS total score<35; recovery: total scores in Social Phobia Inventory<19 and Patient Health Questionnaire-9<10; and worse: an increase in LSAS of 28% or more.

[b] ICBT: internet-based cognitive behavioral therapy.

[c] OR: odds ratio.

Adverse Events and Harms

No severe adverse events were reported for this study period. Table 5 presents the relative risk, RRR, ARR, and NNT. The results of the RRR imply that ICBT reduces the occurrence of deterioration events by 73% compared to no treatment in the control group. The results of the ARR imply that ICBT can save 17% more adolescents and young adults from deterioration events of social anxiety compared to no treatment. The results of the NNT suggest that unguided ICBT could be required for 5.8 individuals with subthreshold SAD in adolescents and young adults to prevent deterioration in symptoms for 1 individual.

Table 5. Results of worse risk analyses[a].

Result	ICBT[b] group (worse=6%) and control group (worse=24%) (%)
RR[c]	26
RRR[d]	73
ARR[e]	17
NNT[f]	6

[a] Formula: RR=percentage of worse event ICBT group/control group; RRR=1–RR; ARR=percentage of worse event in control group–ICBT group; and NNT=1/ARR.

[b] ICBT: internet-based cognitive behavioral therapy.

[c] RR: relative risk.

[d] RRR: relative risk reduction.

[e] ARR: absolute risk reduction.

[f] NNT: number needed to treat.

Discussion

Principal Findings

This study evaluated the effectiveness of unguided ICBT for adolescents and young adults with subthreshold SAD through a multicenter RCT. The dropout rate in the intervention group was 9% (3/34), with an ICBT implementation rate of 91% (31/34) and a completion rate of 65% (22/34). The participants who conducted ICBT showed a significant reduction in social anxiety symptoms compared to those who did not receive treatment. Key indicators representing substantial symptom improvement, namely, treatment response rate (ICBT: 19/31, 61% vs control: 9/38, 24%; *P*=.003) and recovery rate (ICBT: 21/31, 68% vs control: 13/38, 34%; *P*=.008), demonstrated significant differences between the groups, with the intervention group showing better outcomes. No serious adverse events were observed in either group. Regarding deterioration events in social anxiety symptoms, there were 2 (6%) out of 31 cases in the intervention group and 9 (24%) out of 38 cases in the control group, but the difference was not statistically significant (*P*=.10). In summary, this study indicates that ICBT is an effective intervention approach for improving social anxiety symptoms in adolescents and young adults with subthreshold SAD.

Comparison With Prior Work

A systematic review and meta-analysis of outcomes from 20 RCTs on SAD meeting clinical diagnostic criteria demonstrated that ICBT is effective in improving social anxiety symptoms, with a moderate effect size (Hedge *g*=0.55) [51]. In this study, unguided ICBT was shown to be sufficiently effective for subthreshold SAD in adolescents and young adults. This expands the evidence on CBT studies for SAD from several perspectives. The first perspective is the absence of therapist guidance. Many conventional ICBT studies for SAD have included therapist guidance [26,30]. Our results suggest that providing unguided ICBT to students with subthreshold SAD significantly reduces social anxiety symptoms measured by LSAS compared to the untreated group with a moderate effect size (Hedge *g*=0.66-0.66). The moderate effect size calculated in this RCT was comparable to a meta-analysis of 10 RCTs on face-to-face CBT for SAD [15]. Most of the participants assigned to the intervention group in this RCT achieved the treatment course of the Clark and Wells [14] model. Therefore, it appears that, even without guidance, significant improvements in social anxiety symptoms can be achieved with sufficient engagement.

Another perspective is related to the acceptance of ICBT for adolescents and young adults who do not meet the diagnostic criteria of SAD but are at high risk. As an application in clinical psychiatric care, a longitudinal cohort study has reported that ICBT enhances treatment adherence and reduces social anxiety symptoms in adults at risk for the onset of SAD [52]. Since SAD tends to manifest in adolescence [6], similar effects for subthreshold SAD may be observed in student support services in high schools and universities. Given the high likelihood of anxiety disorders persisting into adolescence [53], preventing the onset of mental disorders through early intervention in high-risk individuals is an important endeavor. Therefore, future research on subthreshold SAD in adolescents should consider conducting longitudinal cohort studies within the context of ICBT studies. Additionally, 23.3% of adolescents and young adults experience some form of anxiety, and among them, 39.1% use some form of health care service [54]. Only 108 (39.1%) of the 277 individuals sought medical help for their mental health issues, while the remaining 169 (60.9%) did not access healthcare. Since young individuals with social anxiety tend to avoid seeking help and contacting others [55], unguided ICBT may have the potential to meet their needs.

A previous preliminary study involving 17 adolescents with SAD who underwent ICBT reported high satisfaction with unguided ICBT through web-based questionnaires and semistructured interviews [56]. Participants who received guided ICBT in this preliminary investigation particularly appreciated the ability to access the ICBT program multiple times, allowing for repeated self-help. In this RCT, among the 34 participants in the intervention group, the majority (n=31, 91%) performed an ICBT module at least once. While 65% (n=31) completed the full ICBT course, those who completed the entire treatment course—up to module 9, corresponding to the Clark and Wells [14] model—accounted for 82% (n=28). According to these results, unguided ICBT is probably more acceptable for adolescents and young adults with subthreshold SAD.

Preliminary findings from our results also indicate that receiving complete self-help ICBT reduced the worsening of SAD by 73%. In addition to its short-term efficacy, unguided self-help ICBT may potentially prevent deterioration—that is, inhibiting the onset of SAD—in youths with subthreshold SAD. Even in the absence of guidance from CBT therapists, implementing ICBT based on the Clark and Wells [14] model may be beneficial for young adults and adolescents with SAD symptoms.

Limitations

This study has several limitations that may increase the risk of bias. First, the primary outcome, the self-reported LSAS, was not blinded. The participants assigned to the intervention group may have positive expectations regarding the intervention, which could potentially affect the outcome. In the future, RCTs with blinded assessors should be conducted. Second, the control condition in this study was a no-treatment condition. To control for biases introduced by receiving the intervention or no treatment, future RCTs should consider using sham applications as psychological placebos to ensure blinding. Third, the evidence obtained in this RCT pertains to short-term effectiveness and cannot speak to the medium- to long-term effects. Particularly, to assess the effects on preventing the deterioration of social anxiety symptoms and preventing the onset of SAD, future intervention studies for subthreshold SAD should include a randomized cohort study with an observation period of several years.

Conclusions

This multicenter RCT, conducted in Japan, has demonstrated that unguided ICBT can reduce social anxiety symptoms in adolescents and young adults with subthreshold SAD. Unguided ICBT appears to be a user-friendly intervention approach for supporting subthreshold SAD. Complete self-help ICBT may be a practical treatment approach that prevents deterioration in adolescents and young adults at high risk of developing SAD. Future research should incorporate study designs measuring long-term outcomes and focus on conducting cohort studies aimed at assessing the risk of clinically diagnosed SAD.

Acknowledgments

This study was supported by the Platform for All Regions Kyushu and Okinawa for Startup-ecosystem 2022 of the Japan Science and Technology Agency. The 2023 Kagoshima University Young Researcher Support Grant (representative: KM) was supported for English proofreading and some manuscript subscriptions.

Abstract

Background: Youth suicide is a pressing public health concern, and transitions in care after a suicidal crisis represent a period of elevated risk. Disruptions in continuity of care and emotional support occur frequently. “Caring contacts” validating messages post discharge have the potential to enhance connections with patients and have been shown to improve outcomes. More recently, positive outcomes have been noted using caring contact text messages (SMS and MMS), which hold promise for engaging patients in a pediatric setting, but there are few studies describing the large-scale implementation of such an approach.

Objective: This study aims to describe the process of developing and implementing automated caring contacts within a quality improvement framework, using a standardized series of supportive texts and images, for adolescents discharged from high-acuity programs at a large midwestern pediatric hospital. We describe lessons learned, including challenges and factors contributing to success.

Methods: We implemented the caring contacts intervention in 3 phases. Phase 1 entailed developing supportive statements and images designed to promote hope, inclusivity, and connection in order to create 2 sets of 8 text messages and corresponding images. Phase 2 included piloting caring contacts manually in the hospital’s Psychiatric Crisis Department and Inpatient Psychiatry Unit and assessing the feasibility of implementation in other services, as well as developing workflows and addressing legal considerations. Phase 3 consisted of implementing an automated process to scale within 4 participating hospital services and integrating enrollment into the hospital’s electronic medical records. Process outcome measures included staff compliance with approaching and enrolling eligible patients and results from an optional posttext survey completed by participants.

Results: Compliance data are presented for 4062 adolescent patients eligible for caring contacts. Overall, 88.65% (3601/4062) of eligible patients were approached, of whom 52.43% (1888/3601) were enrolled. In total, 94.92% (1792/1888) of enrolled participants completed the program. Comparisons of the patients eligible, approached, enrolled, and completed are presented. Primary reasons for eligible patients declining include not having access to a mobile phone (686/1705, 40.23%) and caregivers preferring to discuss the intervention at a later time (754/1705, 44.22%). The majority of patients responding to the optional posttext survey reported that the texts made them feel moderately to very hopeful (219/264, 83%), supported (232/264, 87.9%), that peers would be helped by these texts (243/264, 92%), and that they would like to keep receiving texts given the option (227/264, 86%).

Conclusions: This study describes the successful implementation of automated postdischarge caring contacts texts to scale with an innovative use of images and demonstrates how a quality improvement methodology resulted in a more effective and efficient process. This paper also highlights the potential for technology to enhance care for at-risk youth and create more accessible, inclusive, and sustainable prevention strategies.

Introduction

Context

Youth suicide is a pressing public health concern and the third leading cause of death for individuals aged 10 to 19 years in the United States [1]. Suicide deaths among US youth increased during the COVID-19 emergency, with significantly more suicides than expected among male participants, non-Hispanic American Indian or Alaskan Native, and Black youth [2]. Regarding nonfatal suicidal behaviors, the percentage of youth presenting to pediatric hospitals for suicidal thoughts and attempts more than doubled between 2008 and 2015 [3]. A recent national study of emergency department (ED) visits in adolescents aged between 12 and 17 years reported significant increases in suicide attempts beginning in May 2020 and extending through March 2021, compared to corresponding periods in 2019 [4], with increases particularly elevated in females.

To address the needs of pediatric patients at risk of suicide more effectively, the behavioral health (BH) service line at our large Midwestern pediatric hospital adopted the Zero Suicide model, a comprehensive framework using a quality improvement (QI) approach to combine best practice tools and strategies to improve suicide care across health care systems with demonstrated reductions in patient suicides and suicidal behaviors [5-7]. Although identification and treatment of high-risk youth are core to Zero Suicide, transitions in care are also prioritized as vital points for system improvement. One potential means of improving outcomes for adolescents during care transitions is the use of caring contacts, now considered a best practice for transitions in care [8].

In this paper, we describe our hospital's process of developing and implementing an automated and scalable universal caring contacts texting system for adolescents being discharged from the Psychiatric Crisis Department (PCD), Youth Crisis Stabilization Unit (YCSU), Inpatient Psychiatry Unit (IP), and Consult Liaison Service (CL) using an iterative QI approach to improve efficiency and enrollment of eligible patients and enhance health care equity with respect to age, sex, gender identity, race, and ethnicity.

Problem Statement

While hospitalization or crisis care is often accessible for youth at imminent risk for suicide, the days and months after hospital discharge remain a high-risk period [9]. However, many youths receive limited (or no) follow-up mental health care [8,10-12], which is particularly concerning as follow-up care within 7 days of discharge is associated with a decreased risk for suicide [13]. Indeed, studies suggest that 42% of adolescents who attempt suicide do not attend their first scheduled appointment posthospitalization, and 25% do not attend even one follow-up session [10]. These concerning statistics underscore the need to maintain connections with high-risk patients as they transition levels of care, often across multiple, fragmented health care systems.

Similar Interventions

Conceptualized by Motto [14] as validating, nondemand communications following a suicidal crisis, caring contacts are intended to enhance a patient's inherent sense of self-worth and connectedness to ongoing supports [15]. Caring contacts originally took the form of personalized letters expressing concern without placing demands on the recipients (eg, no requests to engage in services or self-care). Working with a high-risk population of adult patients who refused, or did not follow through with, ongoing treatment upon discharge from a psychiatric facility, Motto and Bostrom [15] found significant reductions in suicide for those receiving caring contacts during the first 2 years post discharge. Of note, this reduction was no longer significant after 5 years, and the suicide rates for the intervention and control groups converged by year 14. The first year post discharge is the highest risk period for suicide and also saw the highest frequency of caring contact letters. Although effects may be time-limited, implementation of caring contacts has since been shown to reduce suicidal behaviors and readmissions across communication modalities (eg, letters, postcards, and phone calls), clinical populations, and cultures [16-25]. A recent meta-analysis [26] found that caring contacts reduced self-reported suicide attempts at 1 year but did not find significantly reduced suicide rates or ED visits and hospitalizations. However, the number of studies included in the analysis was small due to the limited number of available randomized controlled trials.

More recently, the feasibility and acceptability of texting as a means of communicating with caring contacts have been demonstrated in adults [19,27,28] and adolescents [29,30]. Furthermore, a randomized controlled trial demonstrated that a brief contact intervention delivered through text messages significantly reduced hospital-related self-harm visits over a 24-month period [31]. Using text messages has significant benefits: texts are nonintrusive, easily accessible, can be stored for later viewing, and the receiver has control over whether to remain involved. However, the existing literature exclusively features text-based caring contacts without the use of images. In considering the pediatric population served by our hospital, we decided to implement caring contact text messages paired with hopeful images to support adolescents during transitions of care as most youth have a high comfort level with receiving text messages [23]. The nearly ubiquitous use of smartphones by adolescents, even in households earning less than US $30,000 a year [32], and the high overall retention rate for youth involved in digital health interventions [33] presented an opportunity to text hopeful and engaging images along with supportive language in a confidential, nonstigmatizing format to all eligible patients without significant concern that access to a smartphone might be a barrier to equitable care.

Methods

Aims and Objectives

The main goal of this paper is to describe the development and implementation of a scalable automated text-based caring contacts intervention using a QI methodology to support eligible youth aged 13 to 18 years being discharged from acute services at our hospital following acute BH interventions related to a suicidal crisis. As a secondary objective, this implementation included a posttext survey to evaluate the extent to which patients found the texts hopeful and supportive.

Blueprint Summary

Overview

In this study, caring contacts texts are supportive messages paired with hopeful images that include local and national youth crisis resources. Messages are unidirectional and do not serve as a text or chat service, although links are provided to youth who would like to access crisis support at any time.

There were three phases for this initiative: (1) phase 1: development and refinement of text messages (November 2018 to January 2019); (2) phase 2: piloting text messages and creating local workflows (February 2019 to February 2020); and (3) phase 3: full implementation with data collection across all 4 service areas (March 2020 to September 2021).

Phase 1: Development (November 2018 to January 2019)

The development of caring contacts message content began with the creation of validating, supportive statements and images aimed at promoting hope and a sense of inclusivity and connection to others while avoiding demanding or potentially emotionally intense or triggering content (Multimedia Appendix 1). An initial set of 16 images with supportive statements and information about crisis resources was developed by the hospital content experts in consultation with an adult former patient and member of the Zero Suicide implementation team, representing lived experience as a suicide attempt survivor. Messages were then reviewed by patient focus groups, representing diversity across race and gender, whose presenting concerns included suicidal ideation or behavior across inpatient and outpatient programs. Feedback from the focus groups indicated that the proposed texts were overwhelmingly viewed as positive and encouraging, were not emotionally triggering, and contained appropriate content. Feedback obtained from parent advocates, therapists, and suicide prevention experts also informed the development of 2 series of 8 caring contacts texts. Each text series was designed to be sent to individual patients over a 4-month period, starting the day after discharge, then weekly for 4 weeks, and monthly for the remaining 3 months. The second set of 8 texts was used for patients readmitted to the hospital.

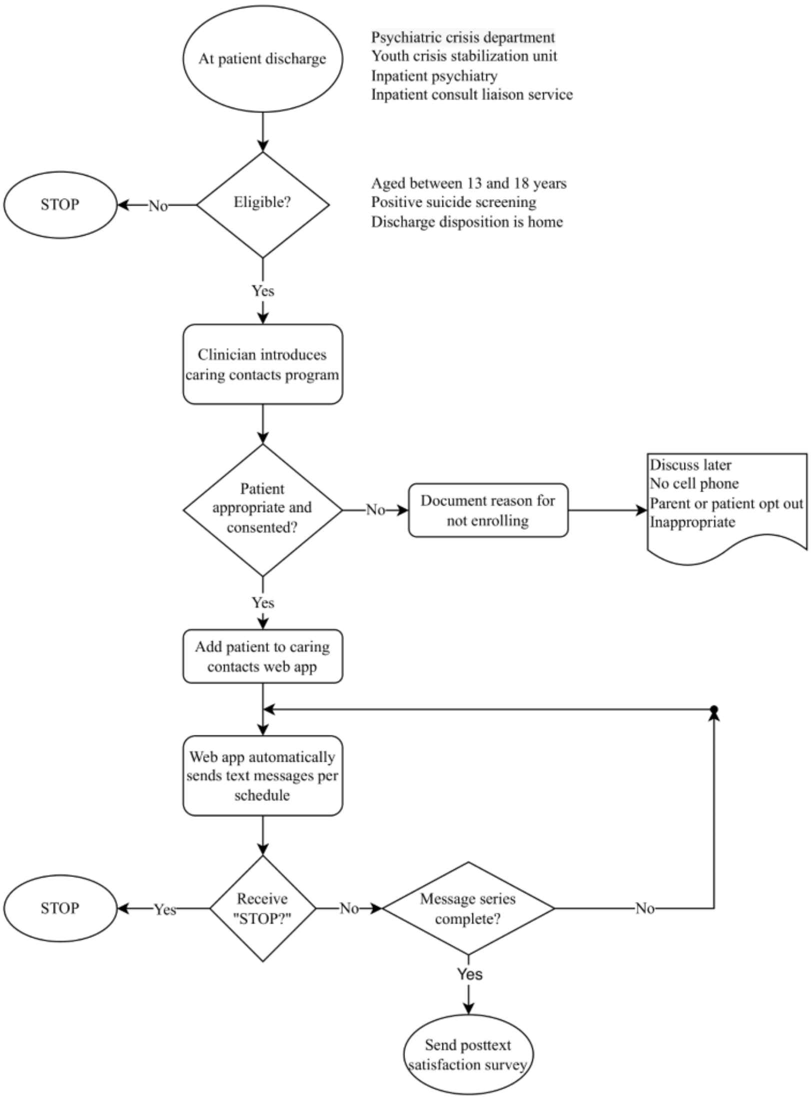
Phase 2: Pilots (February 2019 to February 2020)

As part of our continuous QI efforts, each of the participating services collaboratively developed workflows to identify, consent or assent to receive texts, obtain contact information, and enroll eligible participants. Staff were then trained in these processes, and the first pilots were held, which consisted of multiple plan-do-study-act cycles [34] initially focusing on a small number of clinicians (between 1 and 5) enrolling between 1 and 4 patients each. Barriers to enrollment proved to be using a paper workflow rather than electronic medical records (EMRs), clinicians inconsistently approaching families for consent, failing to provide resources and enrollment forms, and forgetting eligibility criteria.

In response to these barriers, changes were made to the patient enrollment process, which was built directly into the EMR (completed in March 2020). We consulted with hospital legal services, and, given that caring contacts was now the standard care for youth with suicidal thoughts and behaviors, the hospital amended the general consent to allow for texting directly to adolescents aged 13 years and older, consistent with the Children’s Online Privacy Act.

Early in phase 2, we hypothesized that the PCD would be the most effective site to enroll patients, as it serves as the point of entry for most hospital inpatient admissions to our system of care. However, low compliance rates and concerns that the discussion of care transition and caring contacts would fit better into the safety planning and discharge process led to the decision that each of the participating services would be responsible for enrollment at the time of a patient’s discharge. Toward the end of phase 2, all participating services were retrained in the new enrollment workflows. Figure 1 illustrates the final workflow.

Figure 1. Process flow for the caring contacts program.



Phase 3: Full-Scale Implementation With Data Collection (March 2020 to September 2021)

In March 2020, the responsibility for enrollment at the time of discharge was expanded to all participating services. A digital caring contacts enrollment form was implemented in the EMR, and we initiated automatic texting of the caring contacts through a web app. New participants were entered into the site as they were discharged from participating services, and their text sequence was initiated and scheduled automatically. In July 2020, the addition of a flag in the EMR reminding clinicians to enroll patients further increased the percentage of eligible patients approached.

Process Measures

A QI approach for implementation places significant focus on compliance with established protocol to iteratively drive system changes to achieve its aims. One of the goals of this initiative was to maximize the enrollment of youth being discharged from the 4 participating services, making it imperative to identify and approach all eligible patients. Initially, eligible participants were identified through a visit diagnosis, billing diagnosis, or discharge diagnosis. However, in July 2019 during phase 2, BH implemented the Zero Suicide framework, including the use of a well-validated suicide screener at first contact for all patients with the Asking Suicide-Screening Questions [35] and, where appropriate, further risk assessment with the Columbia Suicide Severity Rating Scale [36]. Eligible participants were then identified based on a positive suicide risk endorsement on either measure.

A monthly compliance report was generated to assess adherence to the process, with two metrics, that were (1) percentage of eligible patients approached by staff to enroll and (2) percentage of eligible patients enrolled. Eligible participants were identified based on a positive suicide risk endorsement on the Ask Suicide-Screening Questions [35] and Columbia Suicide Severity Rating Scale [36] tools. For patients declining, 1 of 4 reasons was indicated by the clinician: no mobile phone, patient or family preferring to discuss enrollment at a later time, parent declined, and patient is developmentally inappropriate to enroll (comprehension challenges, autism spectrum, or nonverbal). The compliance data reported in this study were collected in phase 3, for which all participating services enrolled participants. In phase 3, due to the automation of the entire identification, approach, and enrollment process, accurate data could be obtained to determine compliance (compliance data are not reported for phase 2 due to the challenges in accurately determining the number of eligible patients for each plan-do-study-act, but actual numbers of the first texts sent in phase 2 are displayed in Multimedia Appendix 2). Summary compliance data were sent to the clinical leaders of the participating services to review and resolve program barriers to enrollment.

Posttext Survey

Although focus groups suggested that automated texts and images were acceptable and affirming to patients, it was important to establish that this format was not problematic for participants and that they experienced a level of support and hopefulness by receiving them. A 4-question survey was sent to participants through a URL link in the final text. The survey used a Likert scale for the first two questions and yes or no for the last two questions: (1) On a scale of 1-5, how hopeful did these text messages make you feel? (2) On a scale of 1-5, how supported did these text messages make you feel? (3) Do you think other kids like you would be helped by these text messages? (4) If given the option, would you like to keep receiving text messages in the future?

Data and Analysis

Data were extracted from 2 key sources—the EMR (ie, Epic) and the caring contacts web-based app database. Statistical process control methods were used to monitor compliance and analyze improvements over time. Specifically, c-charts allowed the study team to track the percentage of eligible patients approached and the percentage enrolled in caring contacts on a monthly basis for any special cause variation. Standard statistical process control rules were used to establish the control limits and identify special cause variation using the c-chart [37]. Tracking caring contacts enrollment compliance by unit was important as it allowed managers to provide feedback to individual clinicians and identify potential implementation barriers, which facilitated process improvement.

Psychiatric service areas and demographic factors (race, ethnicity, gender, and age) were retrospectively retrieved for all eligible patients based on the daily discharge list. Descriptive statistics of the demographic data and service areas for patients eligible for the program, patients approached about the program, patients enrolled in the program, and patients who completed the program, were generated. The approach rate is defined as the proportion of eligible patients who the clinical team approached to introduce the program. Enrollment rate is defined as the proportion of patients enrolled among patients approached, while completion rate is defined as the proportion of enrolled patients who completed the caring contact program fully. Point estimates of these rates were calculated for each demographic factor value and psychiatric service area, together with their corresponding 95% CIs. These data were examined in a pairwise fashion within each demographic factor or service area to see whether there were statistically significant differences in introduction, enrollment, and program completion rates. When the CIs of rates are nonoverlapping for a pair of factor values within the same category, such as 2 age groups or 2 different race values, then we can conclude the 2 factor values have statistically significant differences.

Technical Design

In phase 2, all caring contacts texts were sent manually through a dedicated mobile phone. However, the large volume of texts per patient over time necessitated the development of an automated process through a web-based app. This required upfront investment but ensured scalability to additional hospital services, reduced the chances of human error, and reduced the administrative burden of a manual process, resulting in long-term savings.

The web-based app was developed to track patient enrollment, automatically send the programmed series of texts to participants, and update enrollees' program progress and status. The app was built on an internal machine server behind the hospital firewall to maximize controls over security and privacy protection. Only patient phone numbers and nonpatient-specific message contents are passed to the messaging service provider, which stores the phone numbers for a limited time to ensure delivery. In turn, the hospital only receives the time of the message sent, the delivery status, and whether patients choose to opt out. Only hospital staff enroll patients to eliminate the inclusion of unnecessary details in the EMR. Youth attempting to reply to the text messages receive an auto-generated response validating their outreach and providing reminders of the different crisis options and links available around the clock.

Target

This QI initiative addressed the use of caring contacts with high-risk adolescents between the ages of 13 and 18 years discharged from our highest acuity BH services at Nationwide Children's Hospital, which serves as a regional hub for pediatric services in Ohio.

Interoperability

The web-based app for caring contacts and the EMR system were designed to not communicate to protect patient health information and minimize risk.

Participating Entities

A brief description of participating services is provided as follows: (1) PCD: a walk-in psychiatric ED for youth and families that serves as an entry point to higher levels of hospital-based care. (2) YCSU: crisis stabilization unit for voluntary admissions with a strong emphasis on individual and family therapy. (3) IP: inpatient psychiatry service with psychiatric unit milieu. (4) CL: psychiatric consult-liaison services provided to youth admitted for medical reasons who present with BH challenges during their admission.

Budget Planning

Although grant-funded, startup costs for this initiative and resources were required to develop process flows and integrate these processes into the EMR. Some ongoing resources are also required to maintain the system. The overall budget for the development and maintenance of the caring contacts program was approximately US $102,560 across the 31-month study time frame. The research and development costs of US $27,720 included the technical design, creation of wireframes, application programming interface integration, testing, implementation, and maintenance to support the startup of automated caring contacts. Vendor fees were US $285 per month (US $3420 per year) throughout the study period. The cost of educational materials provided to families and staff was approximately US $300 per year. In addition, the management of caring contacts typically involves a percentage of the time of a bachelor's-level staff member corresponding to program volume. Given the very high volume of acute care at this pediatric hospital, 50% of the effort was dedicated to personnel costs, equating to approximately US $25,250 per year and US $65,230 over the study period. Costs were covered by grant funding from the Ohio Suicide Prevention Foundation. In terms of replication, it is important to note that costs for new sites would be lower as startup and monthly fees are significantly lower due to a collaboration with a new vendor who offers startup to new sites using our design for US $2500 and a monthly text service fee of US $99 per month.

Sustainability

Nationwide Children's Hospital has made a significant commitment to reducing the pediatric suicide rate in the region and has significant resources devoted to data management and QI. Once grant funding for this initiative ends, we will allocate resources to support and sustain it.

Ethical Considerations

The hospital's Institutional Review Board (IRB) reviewed our proposal to implement caring contacts as a QI initiative and determined that this initiative did not constitute human subjects research under 45 Code of Federal Regulations part 46 or 21 Code of Federal Regulations part 50. Participants were not offered or provided with any form of compensation.

Results

Coverage

This initiative was implemented at Nationwide Children's Hospital, the second-largest children's hospital in the United States, which provides 38 licensed inpatient psychiatric beds and an additional 16 beds in the YCSU. Annually, it facilitates over 2000 discharges from these units. The PCD manages approximately 8000 visits each year. Furthermore, over 240,000 BH outpatient visits occur annually, underscoring its substantial regional role in pediatric mental health care.

Outcomes

From March 2019 to September 2021, a total of 4062 adolescent patients were eligible to receive caring contacts text messages. The total number of youths approached for the caring contact program (n=3601), total number enrolled (n=1888), and total number of youths having completed the program (n=1792) are listed in Table 1, together with summary statistics breakdowns by demographic factors and psychiatric service areas for these patient cohorts.

While compliance data for phase 2 could not be calculated, Multimedia Appendix 2 displays the actual number of texts sent by month during the pilots before automation. Once phase 3 began in March 2020, it took 3 months to consistently achieve an approach rate of over 90% (Multimedia Appendix 3). The enrollment rate by month is reflected in Multimedia Appendix 4. The overall patient approach rate for the 19-month period was 89% (95% CI 88-90), with an enrollment rate of 53% (95% CI 51-54), and a completion rate of 95% (95% CI 94-96; Figure 2). The table on the left of each panel in Figure 2 shows the total number of patients eligible, approached, enrolled, and completed, stratified by demographic factors and psychiatry service areas. The point estimates of approach rates, enrollment rates, and completion rates are listed, along with the associated CIs. Point estimates and 95% CIs of these rates are also visually represented on the right of each panel in Figure 2.

We assessed differences in age, gender, and race or ethnicity in an initial effort to identify whether approach rates were conducted equitably. There were no significant differences in approach rates between male and female patients. However, the approach rate for the White patient group (513/1189, 89.67%) was significantly higher than for the Black patient group (647/756, 85.6%). The approach rate for the patient group with another or unknown ethnicity was significantly lower than the other patient groups. The approach rate for the 13-year-old patient group was significantly lower than all other age groups, while the approach rate for the 18-years-old patient group was significantly higher than the other age groups. The pairwise approach rates were all statistically different between any 2 service areas in CL, PCD, IP, and YCSU, ordering from the lowest to the highest. The program enrollment data show that females enrolled in the caring contact program at a significantly higher rate than males (54% vs 48%). There were no significant differences in enrollment by race or ethnicity. The 13-year-old patient group had a significantly lower enrollment rate than older groups. YCSU had a significantly higher enrollment rate than the other service areas.

The reasons for declining the caring contact program are summarized in Table 2. The "no cell phone" option was chosen at a significantly higher rate for females (513/1189, 43.15%) than for males (173/516, 33.5%), while "inappropriate" was chosen at a significantly higher rate for males (55/516, 10.7%) than for females (65/1189, 5.5%). "No cell phone" was selected at a significantly higher rate for 13-year-olds (91/168, 54.2%) than for 16- (142/377, 37.7%), 17- (101/299, 33.8%), and 18-year-olds (71/210, 33.8%). "Inappropriate" was selected at the significantly highest rate for inpatient consultation or liaison, while "inappropriate" was selected at the significantly lowest rate for YCSU among all service areas. "Discuss at a later time" was selected at a significantly higher rate in the PCD (442/947, 46.7%) than the CL (30/93, 32%) and inpatient (79/217, 36.4%).

Program completion data indicated that females also completed the caring contact program at a significantly higher rate than males (1360/1418, 95.9% vs 432/470, 91.9%). There were no significant differences in program completion by race, ethnicity, age group, or service area.

[a] The proportion is statistically significantly different than at least another value in the demographic category, for example, proportions of “no cell phone” among females and males are statistically significantly different.

[b] Cell value of “—” is used to avoid the disclosure of cell counts less than 11.

[c] CL: Consult Liaison Service.

[d] PCD: Psychiatric Crisis Department.

[e] YCSU: Youth Crisis Stabilization Unit.

A total of 1961 optional posttext satisfaction surveys were sent, of which 264 (13.46%) were completed. A total of 219 (83%) respondents reported that the texts made them feel moderately to very hopeful, 232 (87.9%) respondents reported feeling moderately to very supported, 243 (92%) respondents reported that peers would be helped by these text messages, and 227 (86%) respondents reported they would like to keep receiving texts in the future if given the option.

Lessons Learned

Success Factors

As expected for any large-scale implementation initiative, engaging staff across disciplines and hierarchy was a critical factor in successful implementation. Service areas with actively engaged leaders and champions facilitated smooth integration of the initiative into existing workflows and demonstrated greater adaptability and flexibility throughout the process. Embedding these new procedures seamlessly into the EMR and daily workflows of clinicians also contributed significantly to successful implementation.

Challenges

High volume periods, especially when combined with low staffing levels, negatively impacted compliance and may have contributed to clinicians checking the "discuss later" reason for declining the intervention instead of taking the time to educate and enroll families. Staff turnover and program workflow changes led to a need for regular updated training. Furthermore, the data suggest implicit bias may have impacted approach rates.

Discussion

Overview

This paper describes the process of developing and implementing automated caring contacts, containing both text and images, for adolescents receiving acute services in a large BH service line using a QI methodology, with the ultimate goal of decreasing suicide risk during transitions in care. We were able to demonstrate that an automated system can be delivered at scale and that data obtained from the system can be leveraged to provide rapid improvement in adherence to established protocols. Moreover, the addition of images to the texts appears to be acceptable to an adolescent population. Consistent with the initial implementation of caring contacts letters by Dr Jerome Motto, these texts and hopeful images were expressions of care and validation. However, using a pre-established series of texts for all patients deviates from the original concept of sending personalized letters. The low dropout rate and posttext survey results suggest this was not a barrier to our patients. Youths receiving caring contacts reported that they felt supported and hopeful and that they thought this intervention would help others. Not personalizing the content of texts ensured that communication minimized the potential for exposure to protected health information and allowed us to significantly expand capacity. This has improved efficiency and, arguably, the cost-benefit ratio of this initiative. Further analyses will examine whether there has been a reduction in return visits to the PCD and psychiatric readmissions and whether this varies by participating service unit.

Our intent was to scale up this initiative through an iterative QI process. This approach enabled us to refine enrollment procedures, seamlessly integrate the initiative into the EMR, and enhance recruitment strategies. As a result, we relatively quickly achieved over 90% of eligible patients being approached monthly, with a consistent enrollment rate exceeding 50%. The potential benefits of implementing caring contacts to scale are significant—decreased loss to suicide, decreased suicide contagion, improved hospital readmission rates, decreased costs, and decreased pressure on an already overburdened mental health system.

Our process outcomes reflected some significant differences by age group in approach, enrollment, and completion rates. The 13-year-old patient group was less likely to be approached and had a lower enrollment rate than the other age groups, which may be due to a lower rate of mobile phone access. The lower approach rate is also potentially a reflection of lower perceived autonomy and clinician perceptions of lower risk in younger patients. In general, the enrollment rate increased with age, and the 18-year-old group had a significantly higher enrollment rate than the younger age groups. In addition, females were more likely than males to enroll in and complete this initiative, possibly reflecting an increased openness to accessing mental health support and to emotional information processing.

Approach rates differed by service type. Specifically, the approach rate was higher for the YCSU than for other service areas, and their patients were also more likely to enroll than patients in the other services. The YCSU was also less likely to endorse the "discuss at a later time" reason for declining the intervention. These differences may reflect the unit's relatively high acuity, focus on intensive therapy, including family therapy, favorable clinician-to-patient staffing ratios, and patient population (older youth admitted voluntarily and without significant disruptive behaviors). The CL service had a significantly lower approach rate than the other participating services and also had the highest use of the "inappropriate" decline reason. This likely reflects the nature of the CL service, which is spread across medical units rather than being on a single unit, and possibly lower engagement with the CL clinicians. As might be expected with a real-world QI implementation, there were external pressures that impacted staff compliance over time, such as high-volume periods that decreased the likelihood eligible patients would be approached.

We posited that a large-scale suicide prevention intervention made available to a broad population would increase health care equity as all eligible participants would be identified and approached. However, Black youth were less likely to be approached to participate than their White peers (647/756, 85.6% vs 2430/2710, 89.67%), possibly reflecting implicit bias on the part of clinicians. To further examine this difference by race, we analyzed the approach rates by race for each service area separately but found no statistically significant differences, which could be due to smaller cell sizes. There were no differences in enrollment or completion by race or ethnicity. The percentage of patients without access to a smartphone was higher than expected, but there were no statistically significant differences by race.

A limitation of this study is that demographic data were not collected for the focus groups, and it is unclear whether feedback was obtained at similar rates from youth of color as from White youth. However, the data reflect no significant differences in completion rates based on race or ethnicity. There were also no follow-up data collected for families who declined because they preferred to discuss the initiative at a later time. Another limitation was the relatively low rate of response to the survey and the potential for selection bias; our results may not be representative of all youth enrolled. As this implementation was a QI initiative rather than a research study, all data were aggregated, and there was no control group.

Based on the literature suggesting the year after discharge is a high-risk period, we moved to sending a set of 19 texts over the course of a year, starting in September 2021. Future enhancements include implementing caring contacts in other languages (Spanish, Somali, Arabic, and Nepali) to ensure cultural inclusivity. In addition, as the hospital expands the larger Zero Suicide framework across departments beyond the BH service line, we have also expanded caring contacts, starting with primary care and several intensive outpatient programs. We have begun the dissemination of our caring contacts content and processes to other health care systems in Ohio as well. Through this effort, we have standardized our processes and workflows, which will ultimately make implementation easier and more cost-efficient for our health care partners. Notably, during the initial manual phase, caregivers frequently expressed interest in receiving caring contacts and additional resources. This highlights the potential value of additional support for those caring for at-risk youth. Therefore, we are developing a set of caring contacts specifically tailored to support caregivers.

Future research could focus on identifying an optimal number and duration of texts and whether the addition of images impacts outcomes. As we plan to expand the program to include multilingual support and adapt to broader health care contexts, subsequent research will be essential in evaluating these adaptations' effectiveness, the stability of outcomes across diverse groups, and ensuring that the interventions remain culturally sensitive and equitable. There is preliminary support suggesting that cultural adaptations to caring contacts are acceptable across diverse populations [38]. Furthermore, this study lays the groundwork for future studies to explore the long-term impacts of automated messaging on suicide prevention outcomes for youth, the nuances of its acceptability across different demographic groups, and its integration into various health care settings.

Conclusions

In summary, this study describes the implementation of a scalable, automated caring contacts intervention integrated into a larger suicide prevention QI framework, in our case the Zero Suicide model, within a large health care system that is sustainable over time. An innovative component of our implementation was the use of images to engage participants. Consistent with other studies, our data suggest that this is an acceptable approach to intervening with adolescents at risk for suicide. The scalability and acceptability emphasize the potential for implementing automated supportive interventions on a broader scale, offering a viable pathway to enhancing postdischarge care for at-risk youth. This study highlights the growing potential for leveraging technology in mental health interventions and shifting toward more accessible, inclusive, and sustainable suicide prevention strategies.

Acknowledgments

We would like to acknowledge Amber Moore for her support with QI processes, Lindsey Kegler for support with the electronic medical records (EMRs), and the clinical managers and clinicians of the Psychiatric Crisis Department (PCD), Youth Crisis Stabilization Unit (YCSU), Inpatient Psychiatric Unit (IP), and Consult or Liaison Services. Funding for this project was made possible (in part; SM062894) by the Substance Abuse & Mental Health Services Administration (SAMHSA) in partnership with the Ohio Suicide Prevention Foundation. The views expressed in written training materials or publications and by speakers and moderators do not necessarily reflect the views, opinions, or policies of Center for Mental Health Services, Substance Abuse & Mental Health Services Administration, or the United States Department of Health and Human Services, nor does mention of trade names, commercial practices, or organizations imply endorsement by the US Government.

Abstract

Background: The rise in internet addiction, including web-based gaming and social networking services, is a serious concern. Even with access to medical institutions and counseling services, individuals with internet addiction, particularly adolescents, often refuse medical treatment or counseling. Parent-focused psychological intervention may lead to positive outcomes by improving the parent-adolescent relationship and helping parents identify and modify their adolescent’s problematic behaviors, including internet addiction.

Objective: This study was a pilot randomized controlled trial to test the feasibility of remote cognitive behavioral therapy via videoconferencing for parents of adolescents with internet addiction.

Methods: A total of 13 parents of adolescents aged 12-20 years with internet addiction were recruited and randomly assigned to either 12 sessions of the videoconference-delivered cognitive behavioral therapy (vCBT) group (n=6, 46%) or the waitlist control group (n=7, 54%). The study period was from March 1, 2018, to March 31, 2022. The primary outcome was the scores of the Young Internet Addiction Test reported by the adolescents. The secondary outcomes were adolescents’ hours of internet use per day (Internet Addiction Test), reported by the adolescents and by their parents; the Young Diagnostic Questionnaire, completed by the parents; and the quality of life of the adolescents and the parents, measured by the EQ-5D-5L. These were evaluated at weeks 0 and 13.

Results: As the primary outcome, the mean total Internet Addiction Test score decreased from 67.7 (SD 18.3; 6/13, 46%) at week 0 to 56.2 (SD 25.1; 5/9, 56%) at week 13 in the vCBT group, compared to an increase from 66.9 (SD 21.9; 7/13, 54%) to 68.0 (SD 18.7; 4/9, 44%) in the control group. For all outcomes, no significant differences were found between the 2 groups (all $P>.05$).

Conclusions: This study suggested the practical feasibility of vCBT for parents of adolescents with internet addiction. Further large-scale, multicenter randomized controlled trials are necessary to examine the effectiveness.

Introduction

The invention of the internet changed the world in unimaginable ways. With the internet, instantaneous and comprehensive exchange of large amounts of information with the rest of the world is possible. In the information age, the internet directly and indirectly impacts various aspects of people's lives; it is used, among other things, for information gathering, entertainment, communication, and buying and selling products and services [1]. However, with its continual development, its negative aspects, such as fraud, crime, cyberbullying, and wasteful spending, have come to the front; the problem of internet addiction is one such issue that has received considerable scholarly attention [2-5].

Research on internet addiction has been ongoing since the 1990s; studies have aimed to address the serious consequences associated with growing internet use, such as low grades, withdrawal, disordered eating habits, and lack of sleep [6-8]. Internet addiction can lead to depression, aggression, exacerbation of general psychiatric symptoms, and a decline in self-esteem, which can affect a person's career prospects and social support [9-15]. However, while studies have highlighted the importance of providing ongoing support for individuals with internet addiction, the number of medical and educational institutions that provide support remains limited [16-18]. In addition, even when a parent or guardian (hereafter referred to as a parent) of a person with internet addiction has access to medical institutions and counseling services to overcome the same, individuals with the addiction often refuse treatment, leaving them struggling with the addiction. In many cases, parents lack continuous access to medical institutions and counseling services; thus, the entire family is unable to receive the necessary support.

Parental factors have a significant impact on their children's risk of developing internet addiction [19,20]. In addition, many adolescents with internet addiction may be reluctant to receive treatment or have difficulty attending the intervention sessions. Therefore, researchers recommend designing interventions focusing on parents. Such parent-focused interventions can lead to positive outcomes for the entire family by improving the parent-child relationship and helping parents identify and modify their child's problematic behaviors using evidence-based methods.

Cognitive behavioral therapy (CBT) is a psychotherapy that helps thoughts and behaviors that have become rigid and narrow due to emotional stress to be more flexible and open. It is effective in treating a wide range of mental disorders, including depression and anxiety, and also in helping prevent recurrence [21]. In addition to face-to-face CBT, videoconference-delivered CBT (vCBT) is known to be effective in treating many mental disorders. Videoconferencing systems transmit audio and video signals over the internet and are used in treating mental health problems [22-24]. Research has demonstrated the effectiveness of vCBT for anxiety disorders [25] and chronic pain [26].

In this study, we administered CBT to the parents of adolescents with internet addiction, based on Community Reinforcement and Family Training (CRAFT) [27-29], a cognitive-behavioral program designed to get individuals who abuse substances and refuse treatment to enter treatment by teaching family members how to support a clean or sober lifestyle [30-33]. In Japan, CRAFT has also been used for families of youth in withdrawal [34].

This study aimed to conduct a pilot randomized controlled trial (RCT) to examine the feasibility of vCBT for parents of adolescents with internet addiction. Questionnaires and other surveys were administered to adolescents with internet addiction; however, the adolescents themselves did not receive any direct interventions in the form of vCBT.

Methods

Participants

The inclusion criteria of adolescents with internet addiction and their parents were as follows: (1) parents of adolescents with internet addiction (aged 12-20 years at the time of the survey) who provided consent; (2) parents who were aged at least 20 years and living with the adolescent with internet addiction at the time of providing consent; (3) adolescents and parents who were adequately informed, fully understood, and had given their free and voluntary written consent to participate in this study; (4) adolescents who were able to complete the self-administered questionnaire; (5) adolescents with internet addiction who scored 40 or higher on the self-administered Internet Addiction Test (IAT); and parents who were healthy enough to receive continuous CBT counseling support once a week for 12 weeks at home, using a videoconferencing system, and who had no physical or mental illness or disability that would interfere with counseling support.

Exclusion criteria for adolescents with internet addiction and their parents were as follows: (1) those who had difficulty obtaining ongoing counseling support due to problem behaviors, such as severe self-injurious behaviors, including cutting wrists or experiencing domestic violence; (2) those who had complications, such as a severe psychotic disorder, bipolar disorder, drug dependence, or alcohol-dependence, that are likely to interrupt CBT due to worsening of these symptoms; (3) those who were at an imminent risk of suicide, exhibited repeated antisocial behavior, or had progressive illness, thereby consequently discontinuing CBT; (4) those who had difficulty contacting the investigator; and (5) those deemed by the principal investigator or subinvestigator to be unfit for the safe conduct of this study.

Participants were recruited through posters on the Chiba University website; the Chiba University Hospital and its affiliated hospitals; and educational institutions in the Chiba Prefecture in Japan. During enrollment, adequate written and oral explanations were provided to the adolescents and their guardians. Only those who provided written and oral consent of their own free will were enrolled. However, if it were difficult for the participants to visit Chiba University (eg, because of COVID-19), an initial diagnostic evaluation was conducted remotely via videoconferencing.

Randomization

Parents of adolescents with internet addiction who agreed to the study design were asked to come to the hospital once—for the diagnostic evaluation; they were examined directly by the physician, and then divided, by random assignment, into a vCBT group (research treatment intervention group) and a waitlist control group. Participants who were unable to visit Chiba University Hospital due to COVID-19 restrictions were offered the option of completing the web-based initial diagnostic assessment for this study (to determine their eligibility to receive CBT counseling), so that they could participate in the clinical trial as soon as possible.

The case registration system was centrally administered at the Clinical Research Data Center (Department of Clinical Trials, Chiba University Hospital). The case registration was performed by issuing subject identification codes in the electronic medical record using the clinical trial system, creating a correspondence table, and performing linkable anonymization. For case registration, subject identification codes were issued, correspondence tables were created, and linkable anonymization was performed. The screening period was no longer than 8 weeks.

Sample Size

Considering this was a pilot study, the target number was calculated to ensure that the safety and feasibility of conducting a large-scale RCT in the future could be verified. Subsequently, 20 patients were targeted for analysis (CBT group: n=10, 50%; waiting list group: n=10, 50%). The main hypothesis of this study was to verify the superiority of the symptom-improving effect of the combined CBT group on patients with internet addiction.

Study Design

This study was an RCT (2 parallel groups) and a prospective intervention study. As mentioned above, parents were randomly assigned to either the vCBT group (the intervention group) or the control group.

In the vCBT group, for each parent, sessions were held weekly for 50 minutes each, over 12 weeks, either remotely or in person. The primary efficacy and safety outcomes were assessed before the intervention began (week 0), at the end of the intervention (week 13), and during the follow-up period (week 24).

In the control group, the parents and adolescents waited without intervention. The primary efficacy and safety outcomes were assessed only before the start of the intervention (week 0) and at the end of the intervention (week 13), but not during the follow-up period (week 24).

Intervention: vCBT for Parents

As mentioned above, CBT was administered to the parents of adolescents with internet addiction, based on CRAFT [23,24]. The program was designed to reduce the burden on family members of addicted individuals, improve family relationships, and promote the use of medical treatment services for individuals with addiction. The content and objectives of all 12 sessions are listed in Table 1 [27,29-33].

Sessions were held weekly for 50 minutes each over 12 weeks focusing on a specific theme. Parents completed the homework presented after the session and aimed to solve their communication problems with their adolescents. In the waiting list control group, parents and adolescents waited without receiving any intervention. Tests related to the primary outcome for evaluating efficacy and safety were to be conducted only before the start of the intervention (week 0) and at the end of the intervention (week 13), but not during the follow-up period (week 24). The waiting list control group then received CBT similar to the vCBT group.

Table 1. Content of each session.

Times	Contents	Purpose
1	Assessment interview	Conduct specific interviews with the adolescent with internet addiction about their daily life and set treatment goals.
2	What is internet dependence? (psychoeducation)	Parents gain a better understanding of internet addiction and cognitive behavioral therapy.
3	Understanding problematic behaviors	Categorize the adolescent’s desirable and undesirable behaviors in daily life.
4	Case formulation (functional analysis)	Parents learn how to conduct a functional analysis of problem behaviors and recognize external and internal triggers.
5	CRAFT[a] (problem solving)	Parents understand the CRAFT problem-solving method. They also practice the RIBEYE[b] and score evaluation methods. RIBEYE is one of the problem-solving techniques in CRAFT.
6	CRAFT (assertion)	Encourage parents to acquire positive communication skills. Additionally, parents undergo assertion training.
7	Effective praise	Parents learn strategies to encourage positive behaviors in adolescents with internet addiction, while also addressing their own actions and taking a proactive approach to reduce negative behaviors.
8	What the family does first?	In order to enrich the lives of the whole family, parents reconsider their roles and rebuild their relationships with their children.
9	How to treat children?	Parents understand “6 ways to protect adolescents from internet addiction.”
10	Stability of the whole family	Parents understand ways to prevent violent behavior and learn the importance of improving the whole family's overall stability to help address the problem of their adolescent’s internet addiction.
11	Treatment of internet addiction	Review and generalize previous treatment sessions.
12	Relapse prevention	Approach appropriate counseling institutions.

[a] CRAFT: Community Reinforcement and Family Training.

[b] RIBEYE: relax, identify, brainstorm, evaluate, yes to one, encourage yourself. This is a method in which the therapist (supporter) helps the client solve the problems they are facing. It is said that by mastering this method, the range of thinking will be broadened, and the client will be able to respond calmly and flexibly.

Outcomes

Primary Outcome: Young IAT

The primary outcome was the scores of the Young IAT [34] reported by the adolescents. The 20 items were rated on a 5-point Likert scale, ranging from 1=not at all to 5=frequently, to indicate the extent to which internet use interfered with their daily life, family relationships, social life, personal health, and state of mind. The score ranged from 20 to 100, with higher scores indicating greater problems caused by internet use. Young IAT defines a score between 20 and 49 as an average user who is in control of their internet use, a score of 50 to 79 as an addicted user with occasional or frequent problems with their internet use, and a score of 80 to 100 as an addicted user with major problems with their internet use.

For adolescents with internet addiction, the primary outcome was the change in IAT scores at week 13, compared to week 0 (baseline).

Secondary Outcomes

For adolescents with internet addiction, the following secondary outcomes were included to measure the effectiveness of the intervention: (1) daily hours of internet use as reported by adolescents; and (2) the Japanese version of the EQ-5D-5L [35-39] questionnaire, a self-reported quality-of-life index.

EQ-5D-5L Questionnaire

The EQ-5D-5L is a self-management questionnaire and rating system comprising 5 dimensions (mobility, self-care, usual activities, pain or discomfort, and anxiety or depression), each with 5 levels of severity (no problems, mild problems, moderate problems, severe problems, and extreme problems). The 5 dimensions of responses can be combined into a 5-digit number describing the health status of the respondent (11111=no problem at all and 55555=extreme problems). This defines a total of 3125 possible health states, which can be converted into a single health index by applying a formula that assigns a value to each response. To obtain the EQ-5D-5L index, the Japanese version of the EQ-5D-5L was used.

For the parents, the secondary outcomes included: (1) daily hours of internet use by adolescents as reported by parents; (2) parent-administered Japanese version of the EQ-5D-5L; and (3) Young Diagnostic Questionnaire (YDQ).

YDQ Instrument

To assess problematic internet use, the parents answered the YDQ [40,41]. The YDQ consists of 8 items (binary response format: 0=no, 1=yes). By summing up the values of all 8 items of the questionnaire, a YDQ sum score (range 0-8) was calculated with a higher sum indicating a higher risk of problematic internet use among adolescents.

Ethical Considerations

The Research Ethics Committee of Chiba University Hospital approved this study (IRB: 607). Written informed consent was obtained from all participants. Data were anonymized and participants in this study were not compensated. The study registration is UMIN000032483. This study was funded by Grants-in-Aid for Scientific Research (C) 20K10350.

Statistical Analysis

The distribution and summary statistics of subject background data were calculated in each analysis. For nominal variables, the frequency and proportion of categories are shown for each group. For continuous variables, summary statistics (number of cases, mean, SD, minimum, median, and maximum) were calculated for each group. Comparisons between groups were performed using the Pearson chi-square test for nominal variables, the Fisher exact probability test when more than 20% of cells had expected frequencies fewer than 5, and 2-tailed *t* tests for continuous variables. The significance level was set at 5%.

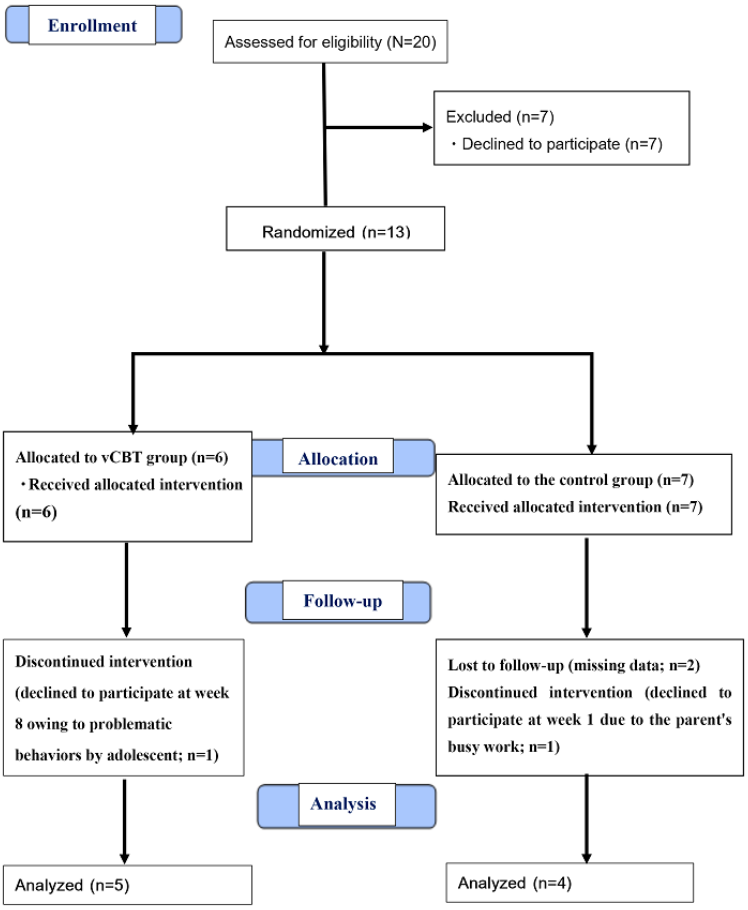
For the primary outcome, the adolescents' IAT score at the start of the study was used as the baseline value, and statistical analyses were performed to determine the change at the end of treatment. The 2-sided significance level for hypothesis testing was set at the 5% level, and the 2-sided 95% CIs were calculated. The primary objective of the study was to determine whether the vCBT group showed significant improvement over the control group at week 13, based on the adolescents' IAT scores. The null hypothesis posited no significant difference in the changes of IAT scores between the 2 groups in the primary analysis, which was tested using analysis of covariance. The covariates included in this analysis were factors used for allocation adjustment: sex, age less than 16 years, and age 16 years and older [34]. To complement the results of the primary analysis, secondary outcomes, briefly described here, were analyzed using both analysis of covariance and linear mixed-effects models, without adjustment for multiplicity. The significance level for hypothesis testing was set at a 2-sided 5%, and corresponding 2-sided 95% CIs were calculated. All statistical analyses were executed using R (version 4.2.1, R Foundation for Statistical Computing), with a significance level set at *P*<.05.

Results

Participants

The study period was from March 1, 2018, to March 31, 2022. Figure 1 shows the characteristics of the participants. Of the 20 participants who were assessed for eligibility, 7 declined to participate. Finally, 13 participants and their adolescents (vCBT group: n=6, 46%; control group: n=7, 54%) provided informed consent, and were randomized to receive the intervention (Multimedia Appendix 1).

Figure 1. Flow diagram of the participant selection process based on Consolidated Standards of Reporting Trials (CONSORT) guidelines. vCBT: videoconference-delivered cognitive behavioral therapy.



During the follow-up, 1 patient in the vCBT group discontinued the intervention. This youth withdrew from participation in week 8 due to behavioral problems. In the control group, 2 patients were lost to follow-up due to missing data, and 1 patient discontinued the intervention because their parents refused to participate in the first week due to work reasons. Finally, 5 patients in the vCBT group and 4 in the control group were analyzed.

Adverse Events

One of the participants in the intervention group declined to participate in this study at week 8 due to her adolescent's problematic behaviors. After that, the problem behavior disappeared. Table 2 shows the characteristics of participants. There were 0 male and 6 female participants in the vCBT group and 1 male and 6 female participants in the control group. The mean age of the participants was 47.33 (SD 4.6) years in the vCBT group and 50.29 (SD 5.2) years in the control group. As for adolescents, 5 were male and 1 was female in the vCBT group and 6 were male and 1 was female in the control group. The mean age of the adolescents was 15.00 (SD 2.2) years in the vCBT group and 15.57 (SD 2.1) years in the control group.

Table 2. Characteristics of the participants.

Participant and characteristics	vCBT[a] group (n=6)	Control group (n=7)	*P* value[b]
Parent			
Sex, n (%)			
Male	0 (0)	1 (14)	≥.99
Female	6 (100)	6 (86)	≥.99
Age (years), mean (SD)	47.33 (4.6)	50.29 (5.2)	.30
Adolescent			
Sex, n (%)			
Male	5 (83)	6 (86)	≥.99
Female	1 (17)	1 (14)	≥.99
Age (years), mean (SD)	15.00 (2.2)	15.57 (2.1)	.64

[b] 2-tailed *t* test.

Primary Outcome

The primary outcomes are shown in Table 3. As assessed by the IAT for youths, the vCBT group scored 67.7 (SD 18.3; 6/13, 46%) points and the control group 66.9 (SD 21.9; 7/13, 54%) points at week 0. At week 13, the vCBT group scored 56.2 (SD 25.1; 5/9, 56%) points and the control group scored 68.0 (SD 18.7; 4/9, 44%) points. The change from baseline was –7.80 (SD 17.3) points in the vCBT group and 1.75 (SD 16.6) points in the control group. There was no significant change of IAT between the 2 groups (*P*=.43; Table 3).

Table 3. Primary outcome.

Time point and outcome	vCBT[a] group	Control group	*P* value[b]	*P* value[c]
Week 0 (n=13)			.94	N/A[d]
Participants, n (%)	6 (46)	7 (54)		
Internet Addiction Test score, mean (SD)	67.7 (18.3)	66.9 (21.9)		
Week 13 (n=9)			.46	N/A
Participants, n (%)	5 (56)	4 (44)		
Internet Addiction Test score, mean (SD)	56.2 (25.1)	68.0 (18.7)		
Change from baseline			.43	.57
Participants, n (%)	5 (56)	4 (44)		
Internet Addiction Test score, mean (SD)	–7.80 (17.3)	1.75 (16.6)		

[a] vCBT: videoconference-delivered cognitive behavioral therapy.

[b] 2-tailed *t* test.

[c] ANCOVA.

[d] N/A: not applicable.

Secondary Outcomes

As shown in Table 4, the change from baseline in adolescents' hours of internet use per day was –2.30 (SD 1.86) hours for the vCBT group and –0.50 (SD 1.00) hours for the control group. There was no significant difference of change in internet use time reported by the adolescents between the 2 groups (*P*=.33).

Table 4. Secondary outcomes.

Change from baseline	vCBT[a] group (n=5)	Control group (n=4)	*P* value[b]	*P* value[c]
Internet usage time (hours) reported by adolescents, mean (SD)	–2.30 (1.86)	–0.50 (1.00)	.33	.71
Adolescent's EQ-5D-5L index score (QOL[d]), mean (SD)	0.04 (0.28)	0.06 (0.18)	.45	.38
Internet usage time (hours) reported by parent, mean (SD)	–2.00 (3.81)	0.25 (1.26)	.14	.84
Parent's EQ-5D-5L index score (QOL), mean (SD)	0.20 (0.30)	–0.06 (0.18)	.01	.84
Parent's Young Diagnostic Questionnaire scores, mean (SD)	–0.20 (1.30)	0.50 (1.73)	.70	.09

[a] vCBT: videoconference-delivered cognitive behavioral therapy.

[b] 2-tailed *t* test.

[c] ANCOVA.

[d] QOL: quality of life.

For the EQ-5D-5L in adolescents, the change from baseline was 0.04 (SD 0.28) points for the vCBT group and 0.06 (SD 0.18) points for the control group. There was no significant change in the QOL of the adolescents between the 2 groups (*P*=.45).

The parent-reported change from baseline in the adolescents' daily internet use time was –2.00 (SD 3.81) hours for the vCBT group and 0.25 (SD 1.26) hours for the control group. There was no significant difference of internet use time reported by the parents between the 2 groups (*P*=.14).

For the EQ-5D-5L, a parent QOL index, the change from baseline was 0.20 (SD 0.30) points for the vCBT group and –0.06 (SD 0.18) points for the control group. The change of QOL of the parents in the vCBT group was significantly higher than that in the control group (*P*=.01).

For the YDQ, the change from baseline was –0.20 (SD 1.30) points for the vCBT group and 0.50 (SD 1.73) points for the control group. There was no significant difference in change of YDQ between the 2 groups (*P*=.70).

Discussion

Overview

We conducted vCBT for parents of adolescents with internet addiction and tested its effectiveness in improving the symptoms of internet addiction in adolescents. In this study, the change in the IAT from the start of intervention week 0 to the end of intervention week 13 was –11.5, from 67.7 (6/13, 46%) to 56.2 (5/9, 56%) in the vCBT group, and 1.1, from 66.9 (7/13, 54%) to 68.0 (4/9, 44%) in the control group. We did not find a statistically significant difference between the vCBT group and the control group in this study. In the completed analysis, the change in the IAT in the vCBT group was –7.8, from 64.0 (5/9, 56%) to 56.2 (5/9, 56%), and the change in the IAT in the control group was 1.75, from 66.3 (4/9, 44%) to 68.0 (4/9, 44%).

A systematic review of meta-analyses of treatments for internet addiction shows that CBT is generally effective [42,43]. For the primary outcome, Bernstein et al [44] conducted a 2-arm RCT of a digital health intervention in 130 people with internet use disorders. An intervention group of 65 participants received 7 of their CBT-based sessions and were compared to a waitlist control group of 65. The results showed the IAT of the intervention group decreased by 7.99, from 63.46 to 55.47, and the waitlist control group decreased by 3.09, from 63.89 to 60.8. This was statistically significant (*d*=0.54, 95% CI 0.19-0.89).

Similarly, Yang et al [45] conducted an RCT comparing an intervention group and a control group to examine the effects of a short-term intensive CBT intervention on internet addiction among Chinese university students. Intensive CBT comprised 5 sessions of 90 minutes each, totaling 7.5 hours. The intervention group received an intervention program in addition to an internet addiction training course. By contrast, the control group received only an internet addiction training course. Consequently, from baseline to posttreatment assessment, the IAT decreased by 7.3 from 59.6 to 52.3 in the intervention group, and by 1.1 from 59.9 to 58.8 in the control group.

Compared to the studies by Bernstein et al [44] and Yang et al [45], our study showed similar reductions in the CBT intervention group. However, these studies directly intervened with individual internet addicts, whereas our study differed in that the target of intervention was the parents of adolescents with internet addiction.

For the secondary outcomes, regarding the amount of time adolescents use the internet per day, Wölfling et al [46] conducted a 2-arm RCT of a CBT called short-term treatment for internet and computer game addiction; it consisted of 15 weekly group and up to eight 2-week individual sessions in 143 people with internet addiction, compared to a waitlist control group of 71. As a result, the amount of time spent on the internet a weekday decreased by 3.1 hours for the intervention group, from 6.5 to 3.4 hours and remained unchanged for the waitlist control group at 5.8 hours. The amount of time spent on the internet on weekends decreased for the intervention group by 4.3 hours, from 8.4 to 4.1 hours, and for the waitlist control group by 2.0 hours, from 7.6 to 5.6 hours. They showed that the intervention group was statistically significant on both weekdays and weekends ($P \leq .001$).

In this study, the amount of change in youth-reported internet usage time in the intervention group decreased by 2.30 hours, from 11.4 to 9.1 hours, and that in the control group by 0.50 hours, from 9.25 to 8.75 hours (*P*=.33). Although our study did not distinguish between weekdays and weekends, the values in Wölfling et al [46] study and ours were similar. Taken together, these results suggest that CBT may help patients with internet addiction reduce internet usage time.

Zhu et al [47] conducted a systematic review of 3538 internet addicts and a total of 57 RCTs to examine the effectiveness, benefits, and drawbacks of various treatments used alone or in combination. Their network meta-analysis of 13 interventions showed that the top 4 were repetitive transcranial magnetic stimulation+CBT, drugs+other, repetitive transcranial magnetic stimulation, and electroacupuncture+CBT. Cañas and Estévez [48] conducted a systematic review of intervention or prevention programs for excessive internet use among adolescents and considered 14 programs that met inclusion criteria. Both systematic review studies were regarding interventions for internet-addicted adolescents themselves; no study about CBT for parents of adolescents with internet addiction was identified.

Concerning family therapy as the intervention, Liu et al [49] conducted multifamily group therapy for each family with an adolescent with internet addiction (aged 12-18 years) and a parent (aged 35-46 years). They showed that the intervention group was significantly better than the control group on the adolescent pathological internet use scale, the internet use time, the parent-child communication scale, and the parent-child intimacy scale.

In addition to the previous studies about CBT for adolescents with internet addiction themselves or family therapy, this study suggested the feasibility of vCBT for parents of adolescents with internet addiction.

Limitations

A few limitations of this study must be acknowledged. First, although the implementation plan called for 20 participants (vCBT group: n=10, 50%; control group: n=10, 50%), the final analysis included a smaller number of 9 respondents (vCBT group: n=5, 56%); control group: n=4, 44%). The sample size for this study was examined to determine what sample size would be needed to show a significant difference; based on the results of this exploratory RCT, statistical analysis indicated that the ideal sample size would be 108 cases for vCBT (n=54) and control group (n=54) combined. This was substantially larger than the current sample size.

Second, the waiting list group was used as a control group because of ethical reasons. As the waitlist control may be inappropriate for evaluating treatment outcomes, alternative treatments should be used as a control group in future large-scale RCTs. Third, this was a single-center RCT and not a multicenter study, which affects its generalizability. Fourth, since there are no data on follow-up after the vCBT intervention in this study, future efforts should focus on collecting follow-up data and implementing efficient strategies to ensure a higher response rate. Fifth, for the primary outcome, we used the Young IAT. In the systematic review by meta-analysis, the IAT was the most used measure of internet addiction; however, other measures should be considered as well. Specifically, data should be collected by objective machines, such as tablets, on the time spent on the internet by addicts. Additionally, other evaluation measures that have emerged since the IAT, such as the Compulsive Internet Use Scale, should be examined [50,51].

Conclusions

This study suggested the practical feasibility of vCBT for parents of adolescents with internet addiction. Further large-scale, multicenter RCT is necessary to examine the effectiveness.

Abstract

Background: In 2021, the United States experienced a 14% rise in fatal drug overdoses totaling 106,699 deaths, driven by harmful opioid use, particularly among individuals in the perinatal period who face increased risks associated with opioid use disorders (OUDs). Increased concerns about the impacts of escalating harmful opioid use among pregnant and postpartum persons are rising. Most of the current limited perinatal OUD studies were conducted using traditional methods, such as interviews and randomized controlled trials to understand OUD treatment, risk factors, and associated adverse effects. However, little is known about how social media data, such as X, formerly known as Twitter, can be leveraged to explore and identify broad perinatal OUD trends, disclosure and communication patterns, and public health surveillance about OUD in the perinatal period.

Objective: The objective is 3-fold: first, we aim to identify key themes and trends in perinatal OUD discussions on platform X. Second, we explore user engagement patterns, including replying and retweeting behaviors. Third, we investigate computational methods that could potentially streamline and scale the labor-intensive manual annotation effort.

Methods: We extracted 6 million raw perinatal-themed tweets posted by global X users during the opioid epidemic from May 2019 to October 2021. After data cleaning and sampling, we used 500 tweets related to OUD in the perinatal period by US X users for a thematic analysis using NVivo (Lumivero) software.

Results: Seven major themes emerged from our thematic analysis: (1) political views related to harmful opioid and other substance use, (2) perceptions of others' substance use, (3) lived experiences of opioid and other substance use, (4) news reports or papers related to opioid and other substance use, (5) health care initiatives, (6) adverse effects on children's health due to parental substance use, and (7) topics related to nonopioid substance use. Among these 7 themes, our user engagement analysis revealed that themes 4 and 5 received the highest average retweet counts, and theme 3 received the highest average tweet reply count. We further found that different computational methods excel in analyzing different themes.

Conclusions: Social media platforms such as X can serve as a valuable tool for analyzing real-time discourse and exploring public perceptions, opinions, and behaviors related to maternal substance use, particularly, harmful opioid use in the perinatal period. More health promotion strategies can be carried out on social media platforms to provide educational support for the OUD perinatal population.

KEYWORDS

X; Twitter; opioid use disorder; thematic analysis; pregnancy; perinatal care; women and child health; maternal health; COVID-19; opioid epidemic

Introduction

In 2021, it was reported that fatal drug overdoses accounted for 106,699 deaths in the United States, which marks a 14% increase in fatal drug overdose rates compared to the rates in the previous year [1]. Notably, harmful opioid use was a major contributor, implicated in 75.36% of these drug overdose fatalities [1,2]. The ongoing opioid epidemic persists as a significant public health challenge in the United States, particularly affecting individuals of reproductive age. It is estimated that 70% to 80% of women with substance use disorder (SUD) have concurrently endured physical abuse, sexual harassment, and severe mental health conditions—factors that exacerbate morbidity and mortality rates in this demographic [3]. Moreover, in 2019, about 20% of birthing individuals reported their opioid misuse during pregnancy based on their self-reported data [4]. According to self-reported data from 2019, disseminated by the Centers for Disease Control and Prevention [4], approximately 7% of surveyed individuals indicated they used prescription opioid pain relievers while pregnant, with one-fifth of them reporting opioid misuse. These findings underscore the prevalence and detrimental impact of opioid use disorders (OUDs) among pregnant and postpartum individuals, making it one of the most prevalent and pernicious forms of SUD in the United States.

In the context of perinatal care, opioid medications are often prescribed for pain relief (analgesia). Nonetheless, the prolonged use of these prescription opioids can cause dependency, tolerance, and addiction, collectively characterized under OUD. Data from 2017 to 2018 indicate that approximately 42.5% of opioid overdose fatalities among women in the United States were associated with prescription opioids [3]. Given their efficacy in pain management, a significant proportion of women diagnosed with OUD are more inclined to persist in their opioid consumption throughout pregnancy. The excessive prescription of opioids during this critical period not only heightens the susceptibility to OUD in new mothers but also escalates the likelihood of postpartum depression [5]. Furthermore, the deleterious impacts of opioid use extend to fetuses, notably increasing the risk of neonatal opioid withdrawal syndrome [6], seizures, and respiratory complications in neonates [5]. Despite the progress in medication-assisted treatments designed to enhance maternal and fetal health outcomes by mitigating the fetal stress associated with OUD, the ramifications of opioid use during prenatal and postpartum phases persist as a significant societal concern [5].

The ubiquity of social media plays a key role in facilitating public discourse and fostering connections, thereby making these platforms invaluable for real-time public data collection and capturing public sentiment, increasingly recognized as vital for public surveillance. X, formerly known as Twitter, emerged as a preeminent social media platform for its expansive global reach, enriched by its user engagement features and capabilities for users to rapidly disseminate information through retweets. By 2023, X had attracted more than 450 million active users monthly [7], highlighting its significance in global digital communication. In addition, research also reveals that X is among the foremost platforms used by individuals for stress management through constructive and detrimental practices, as well as expressing views, concerns, and insights about diverse health issues [8]. Furthermore, X represents a cost-effective and efficient medium for the dissemination of public health communications, providing a rich vein for researchers to identify consumer health interests and concerns [8-10]. Its user engagement functions, such as retweets, likes, and user follow-up conversations, enable the dynamic assessment of public sentiment, facilitate the real-time exchange of personal health perspectives, and enhance public education through the accessible presentation of scientific findings [9,11,12].

The exploration of linguistic patterns within X conversations related to opioids unravels intricate insights into harmful opioid use trends and societal perceptions of this substance. Graves et al [13] analyzed 84,023 opioid-related tweets in the United States, delineating discussions on opioid issues across diverse geographic regions. Their analysis indicated that ongoing monitoring of X data could facilitate the detection of emerging opioid trends. Moreover, this study highlighted that linguistic analyses may yield valuable insights into public reactions to dynamic opioid markets and identify intervention opportunities for targeted high-risk populations and areas [13].

Existing literature, primarily using qualitative methodologies and randomized controlled trials with limited samples, has predominantly focused on risk factors associated with opioid use during pregnancy, perceptions of treatment for OUD, and health care–seeking experiences of women with OUDs [14-16]. Scarce studies used X data to explore widespread perception related to OUD, its treatments, and naloxone [16]. To the best of our knowledge, there is a void in social media research examining perinatal OUD to gauge public sentiment. As such, in this study, we address this gap by analyzing tweet content on opioid use in the perinatal period during the opioid epidemic from 2019 to 2021. Through classical thematic analysis, a methodology extensively used in qualitative research for identifying, analyzing, and reporting data patterns [17] along with the latest machine learning models for initial testing the feasibility of scaling up the annotations and improving labeling accuracy, we aim to uncover emerging perinatal OUD trends and user engagement reflected in social media discourse [18-20]. More specifically, the objective of this study was to unravel X users' disclosure and communication patterns concerning public opinions, personal experiences, and challenges associated with OUD and OUD care during pregnancy and postpartum periods, with a view of enhancing health promotion strategies for this vulnerable population on social media platforms. Consequently, this study provides a more detailed overview and insightful implications on public health policy and services, aiming to enhance OUD treatment options for women in the perinatal period. As such, our three primary research questions (RQs) to guide this study are as follows:

- RQ1: What are key themes and trends in perinatal OUD discussions on X from 2019 to 2021?
- RQ2: What user engagement patterns, including disclosure frequency, retweeting and replying tweet behaviors, emerged in perinatal OUD–related discourse on X?
- RQ3: Considering the labor-intensive process of manually coding qualitative data, even for a small sample of tweets, are there any computational methods to streamline and scale this annotation effort?

Methods

Ethical Considerations

The University of South Carolina's Institutional Review Board (Pro00113240) has reviewed this study's data collection and analysis approach. Since we extracted public data from X, this study was deemed as nonhuman participant research and exempted from review. Furthermore, we also cleaned and de-identified anonymous tweets before our data analysis process.

Data Collection

We gathered 6 million raw tweets from X related to general perinatal OUD guided by a set of keywords provided by our clinical team, spanning from May 2019 to October 2021. This data set underwent a refinement process using English keywords pertinent to OUD in English, encompassing terms such as "opioid," "heroin," "codeine," "oxycodone," "Vicodin," "fentanyl," and "Percocet," among others. The full list of these keywords is listed in Multimedia Appendix 1. Additionally, we applied a geolocation filter to narrow down the data to tweets within the United States. This filtering process yielded a narrowed pool of 3290 perinatal opioid use–related tweets. Then, we further identified and removed 85 duplicate tweets to 3205 unique tweets. A random sample of 500 was then extracted for thematic analysis, a sample size aligned with prior qualitative research methods that have analyzed Twitter data sets of similar scope [21,22]. Figure 1 outlines the sequential steps of data collection, cleaning, and sampling processes used in this study.

Figure 2 illustrates the trends of the number of monthly perinatal OUD-related tweets from May 2019 to October 2021. The highest volume of tweets was recorded in July 2019. Subsequently, from August 2019 to February 2020, there was a significant decline in the number of tweets. In March 2020, coinciding with the COVID-19 period, the tweet volume surged nearly 7-fold.

Figure 1. Flowchart of data collection, cleaning, and sampling process. OUD: opioid use disorder.

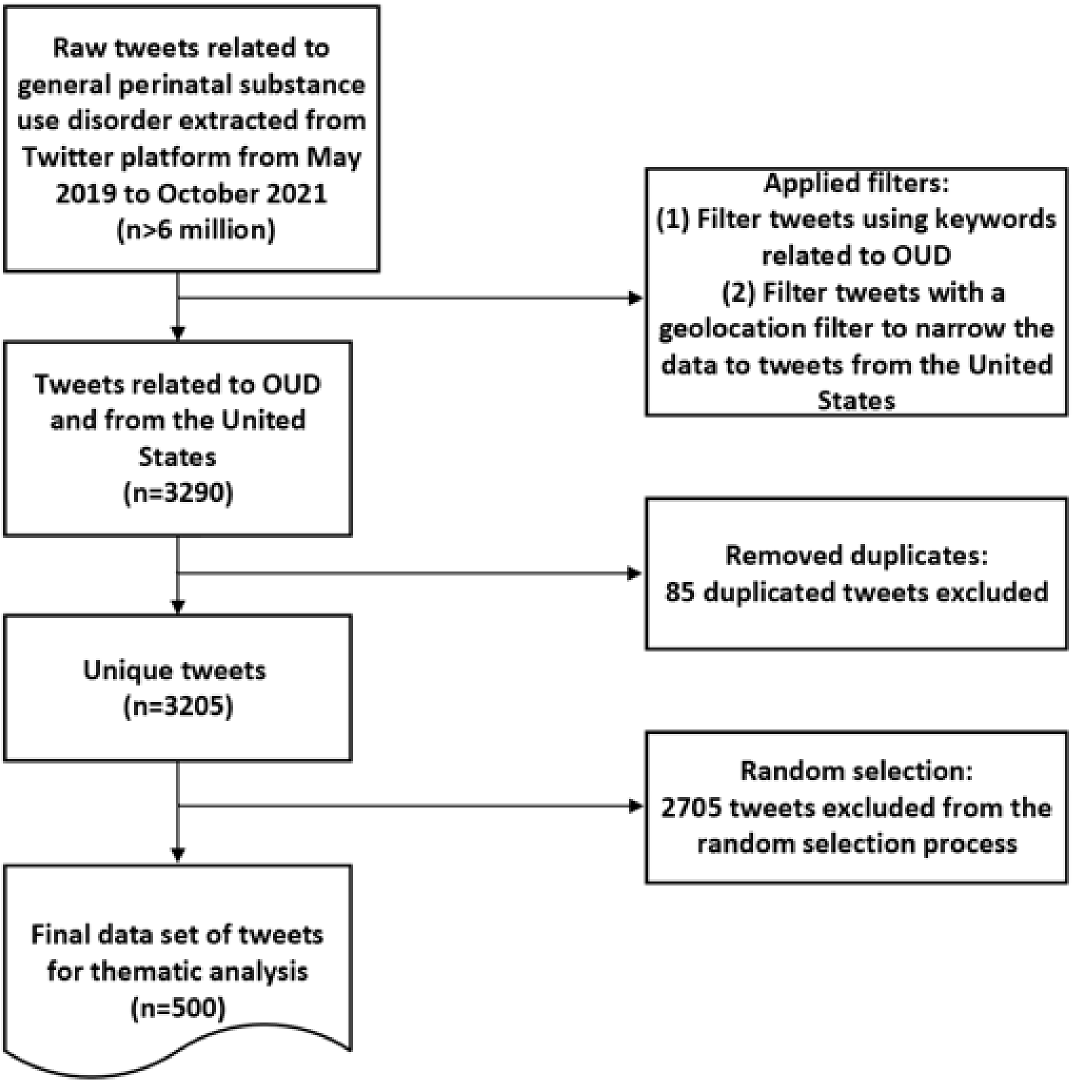

Figure 2. Number of monthly perinatal opioid use disorder–related tweets from May 2019 to October 2021.

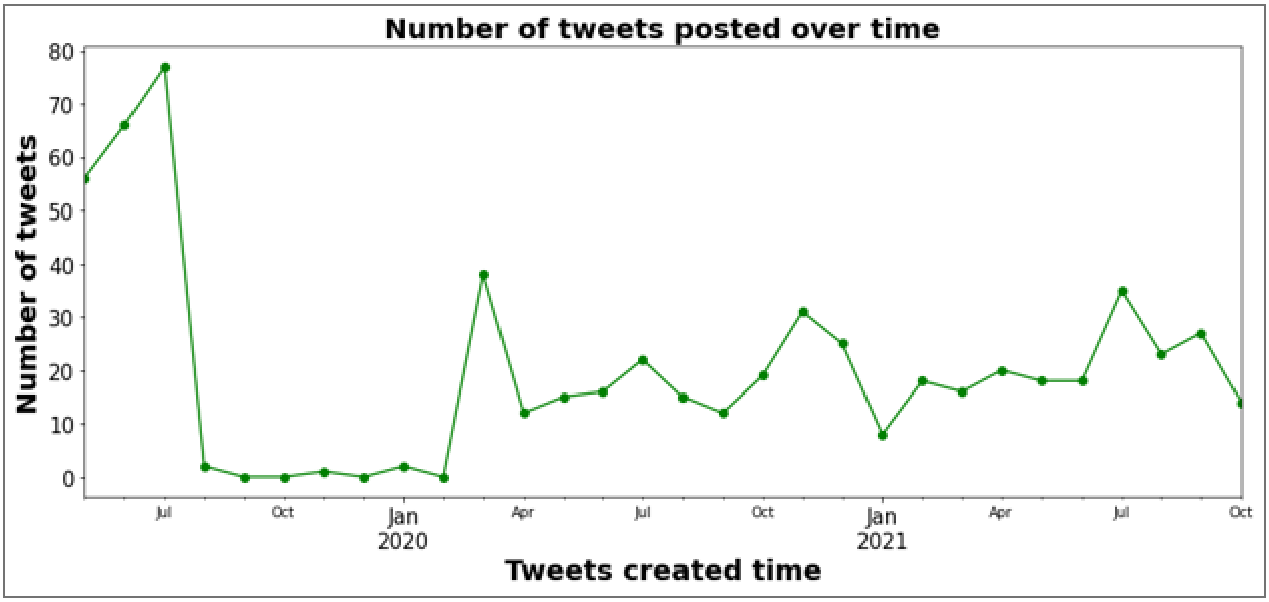

Thematic Analysis

Two trained researchers independently conducted the thematic analysis on the 500 randomly selected tweets, achieving a satisfying κ score of 0.82. NVivo (version 12; Lumivero) software was used in analyzing the tweet data set through a manual coding process, such as labeling and categorizing specific sections [23]. Using open-coding techniques, the researchers identified themes in the X discourse on opioid use and labeled codes based on the content and context of the tweet. Each tweet was coded independently, and the main themes identified were further divided into subthemes. These subthemes provided specificity and helped address the tweet's context and information. The occurrence of thematic overlap was notable, necessitating multiple categorizations per tweet to encapsulate the breadth and complexity of themes articulated [24]. In total, the analysis of the 500 tweets resulted in the identification of 7 main themes. The researchers deployed 174 unique codes throughout this process, accounting for 1307 references across the selected tweets.

Results

Identified Themes of Perinatal OUD

Table 1 provides a brief description of the 7 main themes, the number of references for each theme, and their sample tweets. The number of references in NVivo refers to the number of times a passage of text was coded to each theme and subtheme. The seven primary themes we identified include (1) political views related to harmful opioid and other substance use, (2) perceptions of others' substance use, (3) lived experiences of opioid and other substance use, (4) news reports or papers related to opioid and other substance use, (5) health care initiatives, (6) adverse effects on children's health due to parental substance use, and (7) topics related to nonopioid substance use. We described each main theme and its subthemes in the following subsections.

Table 1. Seven main themes identified with opioid use disorder in the perinatal period.

Main themes	Description	Sample tweet	References (n=457), n (%)
Political views related to harmful opioid and other substance use	Opinions or perceptions on the influence of politics and other governmental structures on substance use	• "@***a@real*** @*** @*** was born in Detroit! ***, you need to go back to Pennsylvania and, those suburban Opioid addicts in your old neighborhood."	101 (22.1)
Perceptions of others' substance use	Opinions or perceptions on other people's use of substances	• "@***a @***a @***a @***a @***a Can we talk seriously about opioid addiction in pregnant mothers? How We the PEople can write law to PROactively PROtect our women & children? @***a @***a @***a Get to the core"	91 (19.9)
Lived experiences of opioid and other substance use	Personal substance user's experiences including individual's experience or an individual's family or friends	• "I Am: An Un-apologetic Opioid Patient – National Pain Report ..." • "Chronic pain is a disease. Do we have to start a mea culpa for every disease? Cancer, MS, polio, broken bones, DDD, dystonia, strokes, Parkinsons, IBS, kidney stones, childbirth w/o a spina"	70 (15.3)
News reports or papers related to opioid and other substance use	Published information regarding a recent event, change, or situation related to substance use	• "Rate of women addicted to opioids during pregnancy quadrupled in 15 years, CDC says"	48 (10.5)
Health care initiatives	Information and methods for either educational purposes or to address current health needs	• "Opioid exposure following vaginal delivery appears to be a trigger for future persistent opioid use and misuse, independent of confounding factors #***a #SOAPAM2019 #BestPaper #OBAnes #OpioidCrisis #OpioidEpidemic"	37 (8.1)
Adverse effects on children's health due to parental substance use	The consequences that children face due to their parents ' use of substances	• "Not to be stupid but does that go for heroin crack marijuana ok to put as much in your body as you want. My wife had an abortion we regret it now you have to live with it"	24 (5.3)
Topics related to nonopioid substance use	Tweets comparing other substances or ideas to opioids or about nonopioid drugs	• "Booking holidays and city breaks - that's my heroin. Edinburgh, Brussels, Manchester & Berlin done! Roll on Vegas, Portugal & Spain! See the world, have great fun with great friends and family! Get her booked! #***"	86 (18.8)

[a] ***: Reaction from a private Twitter user account.

Political Views Related to Harmful Opioid and Other Substance Use

Tweets were categorized under the theme "political views or criminalization of behaviors related to opioid and other substance use" if the content referred to an individual's beliefs or opinions on a political or governmental topic related to opioids or other substances. Within this theme, the researchers identified 2 major subthemes, as shown in Table 2, with "opioid epidemic" being the most common (n=68). Under the "opioid epidemic" subtheme, tweets frequently referenced opioid addiction (n=11), followed by illegal drug importation (n=10), and companies that manufacture opioids (n=8). Meanwhile, tweets categorized under the "multifactorial perspectives" subtheme mentioned the topic of abortion most often (n=7), followed by drug addiction (n=4) and human trafficking (n=4).

Table 2. Subthemes of political views related to opioid and other substance use.

Subthemes	Description	Sample tweet	References (n=89), n (%)
Opioid epidemic	Political opinions regarding the opioid crisis	"Why don't we look at maternal health disparities the way we do the opioid epidemic? We don't blame that community for addiction, we look at other factors and causes (prescribing, etc). What are risk factors in the community leading to maternal disparities?"	68 (76)
Multifactorial perspectives (abortion, child abuse, drug addiction, homelessness, human trafficking, and imprisonment)	Tweets that contain multiple components within one tweet in relation to politics	"@***[a] @*** NYC is becoming a #[obscenity] $15 coffee, gangs running some neighborhoods, illegals [obscenity] taxpayers money dry, reduction in services for residents, homelessness, drug addiction, human trafficking, child abuse #ToxicLiberals advocating 4 everything but values integrity and Americans"	21 (24)

[a] ***: Reaction from a private Twitter user account.

The 21 tweets categorized under the "multifactorial perspectives" subtheme were further categorized into 4 sublevels: individual, general public, health care provider, and policy. The result is presented in Table 3. The analysis revealed policy-level tweets as the most frequently occurring with a count of 14, followed by general public-level tweets (n=7). However, no tweets were at the health care provider (n=0) or individual (n=0) levels. Policy-level tweets were defined as tweets referring to specific governmental regulations or policies, with most tweets about abortion and domestic terrorism. General public tweets were defined as tweets on the general public, with no particular attention on governmental policies. Within this category, most tweets were about drug addiction and homelessness. Coding for the general public tweets that target no specific audience is important, as it facilitates researchers in comprehending the perspectives and beliefs on current issues, thereby suggesting potential solutions.

Table 3. Sublevels of multifactorial perspectives.

Levels	Description	Sample tweet	References (n=21), n (%)
Policy level	Tweets referring to specific governmental regulations or policies	"i can't believe this people haven't been prosecuted for domestic terrorism yet. what a [obscenity] corrupted [obscenity] system. a child molester walking amongst the children and a [obscenity] heroin addict/porn star acting as a journalist. [obscenity] white people"	14 (67)
General public level	Tweets on the general public, with no particular attention on governmental policies	"this is their concern when homeless line streets of major cities, when illegals flood our country, when infrastructure needs repair, when babies left to die after birth if unwanted, when illegal voting plagues the system, when hundreds die from opioid addiction, etc. really?!"	7 (33)

Perceptions of Others' Substance Use

Tweets were classified under the "perceptions of others' substance use" theme when their content demonstrated an individual's opinions regarding another person's substance use or general use in the larger population. The researchers identified 5 major subthemes. The most common subtheme was "opioid use" (n=34), followed by "children exposure" (n=21), "substance use during pregnancy" (n=20), "polysubstance use" (n=8), and "religious beliefs" (n=6), as shown in Table 4.

Table 4. Subthemes of perceptions of others' substance use.

Subthemes	Description	Sample tweet	References (n=89), n (%)
Opioid use	The use of opioids, prescribed or illicit use	• "@***a is surprised by the prevalence of Opioid prescribing after a vaginal delivery: 30%; 87% after C Section. Most patients rate pain at 0 at D/C and do not use all the opioids they are prescribed."	34 (38)
Children exposure	Children being exposed to substances, intentional or unintentional	• "First, how dare you even think of giving a baby Morphine?!! I'm beyond [obscenity]."	21 (24)
Substance use during pregnancy	The use of substances during which a fetus is developing in the mother's womb	• "@***'d rather have 95% of your profits..." • "Momma's got baby number seven on the way and has an opioid craving she needs to take care of ..."	20 (22)
Polysubstance use	The use of more than one substance simultaneously	• "Forgot to mention: his default state is 'vapes maximum strength THC 24/7' recovering opioid addict still on prescription opioids, also 'occassionally' does coke" • "His drug problem is clearly SKY HIGH atm so yeah, baby intervention tonight"	8 (9)
Religious beliefs	Tweets regarding an individual's religious views or beliefs	• "PRAYER REQUEST: 100 percent disabled vet in his last moments from mesothelioma (service related-asbestos exposure.) He is a warrior born/bred." • "He's in great pain; being kept on morphine to keep him comfortable. He can't speak, eat or move." • "Pray for a peaceful transition. Amen"	6 (7)

[a]***: Reaction from a private Twitter user account.

Lived Experiences of Opioid and Other Substance Use

Tweets that described an individual's experience or experience of family and friends related to opioid and other substance use fell under the main theme of "lived experiences of opioid and other substance use." There were 2 main subthemes, "opioid use" (n=65) and "polysubstance use" (n=5), identified under this category, as shown in Table 5.

Table 5. Subthemes of lived experiences of opioid and other substance use.

Subthemes	Description	Sample tweet	References (n=67), n (%)
Opioid use	The use of opioids, prescribed or illicit use	"It's been a year since I lost my baby brother to dumb ass heroin and my heart still hurts just the same. I miss you so much"	62 (92)
Polysubstance use	The use of more than one substance simultaneously	"What'chu want? I got ketamine, MDMA, Adderall, Bromo-Dragonfly, heroin, coke, crack, codeine, oxys, percs, vikes, PCP, LSD, Dilaudid, mescaline, mushrooms, bath salts, cortisone, Toradol. I got molly. I got her sister Sandra. I got big Frank. I got birth control, I got Plan B."	5 (8)

Most of the tweets under "opioid use" were related to the loss of loved ones, predominantly due to harmful opioid use leading to fatal overdose (n=24), followed by opioid use for pain management (n=17). When further stratified by opioid type mentioned under both subthemes combined, heroin was the most common (n=17), followed by morphine (n=10), codeine (n=10), fentanyl (n=9), oxycodone (n=5), and hydrocodone (n=2).

News Reports or Papers Related to Opioid and Other Substance Use

Tweets that referred to published news reports or papers concerning opioid and other substance use were placed under "news reports or papers related to opioid and other substance use" theme. Five subthemes were identified, as shown in Table 6, with "opioid use" being the most common (n=30), followed by "substance use during pregnancy" (n=11), "unintentional drug exposure" (n=2), "child neglect" (n=2), and "concurrent use of alcohol and opioids" (n=2).

Table 6. Subthemes of news reports or papers related to opioid and other substance use.

Subthemes	Description	Sample tweet	References (n=47), n (%)
Opioid use	The use of opioids, prescribed or illicit use	"***[a] hospital shut down as revelations emerge that a dangerous dose of morphine killed 7-month-old baby Ethan. We tell you more on #K24EveningEdition"	30 (64)
Substance use during pregnancy	Prenatal substance use during fetus development	"The opioid crisis comes to the classroom as soaring numbers of children born in drug withdrawal reach school age | The Seattle Times"	11 (23)
Unintentional drug exposure	Accidental exposure of children to substances	"highlights problems: Baby was exposed to 87 micrograms, 4% of the therapeutic dose. Codeine level tho was 'stratospherically high': 50x higher than would be expected. Opioid poisoning could not be the cause of death. Neonatal opiod toxicity hard to envision."	2 (4)
Child neglect	A form of abuse in which the caregiver fails to meet the child's basic need	"Police arrested Edwardo Zepeda after he lost his daughter when he went on a late-night alcohol run. The 4-year-old was later found sleeping in between two power boxes. He is now charged with child abuse @KTNV"	2 (4)
Concurrent use of alcohol and opioids	The use of opioids and alcohol simultaneously	"Radle was born in Tulsa, Oklahoma, and died in May 1980 from a kidney infection, exacerbated by the effects of alcohol and narcotics; he was 37."	2 (4)

[a] ***: Reaction from a private Twitter user account.

Tweets were also stratified by the news media outlets in which they were published and categorized by national outlet, state outlet, community, health news, international, and unknown source. News reports or papers generated at the national level included CNN, USA Today, New York Times, Fox News, and ABC News, which provide information and reports on the United States overall. State-level news outlets included Oklahoma News, Seattle Times, Tennessean, and San Antonio Express-News. Community-level news outlets, such as Vox News, are privately owned, publish opinionated journals and cover American news. Tweets listed under health news are news outlets that specifically publish medically related information and reports, such as *Science Daily*, *Medical Press*, and *JAMA Network*. International-level news is international news outlets, which include Irish News, Irish Times, and United Press International. Finally, tweets were coded as "unknown" if the user-generated content referred to a news report or paper but did not specify its source. Among these 6 categories, national-level news and unknown were the most common (n=13), followed by state-level news (n=9), international-level (n=5), health news (n=5), and community-level news (n=2).

Health Care Initiatives

Tweets were categorized under "health care initiatives" theme if they contained information to educate the public and address current societal health needs. Four main subthemes were identified under this category as shown in Table 7. The most common subtheme was "speaker presentations" (n=20), followed by "government initiatives" (n=6), "research" (n=6), and "addiction treatment services" (n=3).

Table 7. Subthemes of health care initiatives.

Subthemes	Description	Sample tweet	References (n=35), n (%)
Speaker presentations	Individuals or a group of individuals who educate others and raise awareness based on current data and information	"Important #***[a] findings by @*** on the risk of persistent opioid use after childbirth, especially after c-sections and when getting prescriptions before delivery."	20 (57)
Government initiatives	Government-funded programs or policies to assist with substance use	"During Health, Welfare Family Services cmte, Senate Committee Chairman @***Senate discusses @*** HEAL opioid research grant working in 16 counties, two of them in his district."	6 (17)
Research	Ongoing investigation or discoveries regarding substance use	"PROMISE and MOTHER studies debunked lots of myths—dose of #buprenorphine and #methadone not related to neonatal withdrawal severity and methadone was associated with more #opioid need than bup Hendree Jones #CPDD19"	6 (17)
Addiction treatment services	Treatment programs with the objective to assist people with drug addiction	"Great tour and presentation from the staff at *** Addiction and Family Services. We were impressed with the organizations no wait time screening and triage as well as the Rapid Access Opioid Treatment program. Providing services to those when they need it most is crucial"	3 (9)

[a] ***: Reaction from a private Twitter user account.

Tweets placed under "speaker presentations" were further divided into national, state, and clinician levels. National presentations were cited most frequently (n=10), followed by clinician speaker presentations (n=5), and finally, state-level presentations (n=3).

All sample tweets coded under "health care initiatives" were also stratified in relation to opioid use during prenatal care, pregnancy period or delivery, postpartum or breastfeeding, and childcare or maternal health to determine the prevalence of perceptions and opinions about opioid use across the different stages of pregnancy. The results showed tweets were most commonly about childcare and maternal health (n=11), followed by the quality of care received during pregnancy and delivery period (n=7), care quality postpartum and during the breastfeeding period (n=4), and finally, prenatal period (n=1).

Adverse Effects on Children's Health due to Parental Substance Use

Tweets that described the outcomes of children's health due to parental use of opioids and other substances were listed under "adverse effects on children's health due to parental substance use" theme. Table 8 indicates the most common subtheme under this category was "multifactorial perspectives" (n=22), followed by opioid orphans (n=1).

Table 8. Subthemes of adverse effects on children's health due to parental substance use.

Subthemes	Description	Sample tweet	References (n=23), n (%)
Multifactorial perspectives (neonatal abstinence syndrome, abortion, miscarriage, foster care, and deaf)	Tweets that contain multiple components within one tweet in relation to adverse effects on children	"Was born in withdrawal to heroin. Had 2 ab, tubes tied after 3rd child. Have company spons ins, still can't afford to go to dr even though have afib, so went strict vegan, quit weed, liquor, etc. Have been on welfare b4, but now help family, but I'm happy and grateful!"	22 (96)
Opioid orphans	Children who became parentless due to parental opioid use	"15-year-old ***[a] calls himself an opioid orphan, which is a child who has lost one or both parents to the opioid crisis whether it's to rehab prison or death. Part of Steven's path to healing is his plan to help other kids."	1 (4)

[a] ***: Reaction from a private Twitter user account.

Under "multifactorial perspectives," tweets related to neonatal abstinence syndrome were the most frequent (n=9), followed by abortion (n=5), foster care (n=2), miscarriage (n=1), and deaf (n=1). There was 1 specific tweet about opioid orphans, which is a term describing children who become parentless due to parent's use of opioid (n=1).

Topics Related to Nonopioid Substance Use

Tweets were coded as “topics related to nonopioid substance use” if the content was not related to opioid use. There were references to other drugs, abstract ideas about opioids, and mentions of opioids in pop culture, music, and television. There were 3 major subthemes under this category, with the most common being nonopioid drugs (n=43), followed by pop culture (n=28), and Norco, California (n=6), as listed in Table 9.

Table 9. Subthemes of topics related to nonopioid substance use.

Subthemes	Description	Sample tweet	References (n=77), n (%)
Pop culture	Entertainment that is enjoyed by the general public	• “Book your tickets to see our Grad Show ‘Darknet’ . 10/13July at The Union Theater.” • “Computer hacking, Heroin overdosing, Methadone Selling, The rise of Robots and Artificial Intelligence, Family conflict and Big tech ... ”	28 (36)
Nonopioid drugs	In relation to drugs that are not opioids	• “A few people have asked about the #surgery I had.” • “It was a #laparoscopic #hysterectomy with a #chemo flush. I have three incisions in my #stomach and they took my #cervix #FallopianTubes and #uterus out through my #vagina. #no #narcotics #cannabis only!”	43 (56)
Norco, California	In relation to the city in California with the same name as the brand name of hydrocodone or acetaminophen	• “***a going away party. It [obscenity] that one of my best friends is moving so far away. But I wish nothing but the best for him and his family. I owe a lot to him. A real to friend! @ Norco, California”	6 (8)

[a]***: Reaction from a private Twitter user account.

Table 10 presents the distribution of various identified topics or themes across 3 time periods: before COVID-19 in 2019, during the COVID-19 pandemic period without COVID-19 vaccination (year 2020), and during the COVID-19 pandemic period with COVID-19 vaccination (year 2021). Notably, in the pre–COVID-19 era, the predominant theme among tweets pertained to “political views related to substance use.” Throughout the duration of the COVID-19 pandemic, “lived experiences of opioid and other substance use” emerged as the theme with the highest frequency of tweets, closely followed by “political views related to substance use.” In the COVID-19 pandemic period after launching the COVID-19 vaccination in 2021, “lived experiences of opioid and other substance use” continued to dominate the thematic landscape of the tweets.

Table 10. Comparison of various theme distributions during 3 time periods of before and during the COVID-19 pandemic with and without COVID-19 vaccination.

Themes	Time period (n=600)		
	Pre–COVID-19 tweets, n (%)	COVID-19 without vaccination tweets, n (%)	COVID-19 with vaccination tweets, n (%)
Political views related to opioid and other substance use	63 (10.5)	54 (9)	46 (7.8)
Perceptions of others’ use	28 (4.7)	26 (4.3)	22 (3.7)
Lived experiences of opioid and other substance use	30 (5)	71 (11.8)	72 (12)
News reports or papers related to opioid and other substance use	19 (3.2)	14 (2.3)	24 (4)
Health care initiatives	13 (2.2)	13 (2.2)	10 (1.6)
Adverse effects on children’s health due to parental	17 (2.8)	14 (2.3)	14 (2.3)
Topics related to nonopioid substance use	30 (5)	8 (1.3)	12 (2)

To understand user engagement dynamics on X, we further analyzed additional users' retweet and reply tweets to examine user interaction behaviors. Table 11 summarizes the mean counts and percentages of retweets and replies associated with tweets across the identified thematic categories. Analysis of user engagement in terms of retweeting behavior reveals that "health care initiatives" emerges as the preeminent theme, recording the highest mean retweet count, closely followed by "news reports or papers related to opioid and other substance use." In terms of tweet replies, "lived experiences of opioid and other substance use" was ranked the highest replied theme, with other thematic categories lagging significantly.

Table 11. Average retweet and reply count based on themes.

Themes	Theme retweet count, mean (SD)	Tweet reply count, mean (SD)
Adverse effects on children's health due to parental substance use	0.98 (3.26)	0.51 (0.99)
Health care initiatives	1.61 (2.28)	0.31 (0.47)
Lived experiences of opioid and other substance use	0.47 (1.83)	1.72 (5.05)
News reports or papers related to opioid and other substance use	1.47 (4.68)	0.40 (0.96)
Topics related to nonopioid substance use	0.32 (0.77)	0.34 (0.89)
Perceptions of others' substance use	0.26 (0.79)	0.53 (0.92)
Political views related to harmful opioid and other substance use	0.62 (2.81)	0.46 (1.16)

Table 12 presents the distribution of tweets across various themes as percentages. Importantly, the themes "lived experiences of opioid and other substance use" and "political views related to harmful opioid and other substance use" were ranked a higher percentage of the perinatal OUD tweet data set compared to the others.

Table 12. Thematic breakdowns of perinatal opioid use disorder tweets in percentages.

Themes	Tweet count (n=600), n (%)
Political views related to harmful opioid and other substance use	163 (27.2)
Perceptions of others' substance use	76 (12.7)
Lived experiences of opioid and other substance use	173 (28.8)
News reports or papers related to opioid and other substance use	57 (9.5)
Health care initiatives	36 (6)
Adverse effects on children's health due to parental use of substances	45 (7.5)
Topics related to nonopioid substance use	50 (8.3)

Discussion

Principal Findings

Overall, public health researchers and public health authorities can potentially use these social media platforms as a communication and monitoring tool to promote public health awareness and positively influence public health behavioral changes in all pregnancy stages [25,26]. This study leveraged the expansive reach of X with a set of tweets pertinent to perinatal SUD as informed by relevant keywords curated by our clinical team, ranging from May 2019 to October 2021. This corpus underwent a rigorous refinement procedure to result in a set of 3205 unique perinatal OUD-related tweets in the United States, among which we randomly selected 500 tweets for in-depth thematic analysis, forming the foundation for our data analysis.

Our thematic analysis unveiled several key trends: the consequences of harmful opioid use in the perinatal period, shared experiences and published newspapers on opioid use, perspectives on the opioid epidemic, and current protocols and practices that are put in place to combat the opioid epidemic. As one of the first such studies to explore perinatal OUD disclosure patterns on social media, we identified seven major themes from 500 random tweets related to OUD in the perinatal period: (1) political views related to harmful opioid and other substance use, (2) perceptions of others' substance use, (3) lived experiences of opioid and other substance use, (4) news reports or papers related to opioid and other substance use, (5) health care initiatives, (6) the adverse effects on children's health due to parental substance use, and (7) topics related to nonopioid substance use.

This study also revealed the potential of social media platforms such as X for public health surveillance. For example, before the COVID-19 pandemic, the dominant theme about OUD in the perinatal period was "political views on substance use." However, during the prevaccination period in the pandemic, tweets about "lived experiences of opioid and other substance use" and "political views related harmful opioid and other to substance use" surged among tweets related to OUD in the perinatal period, and they remained prominent even after COVID-19 vaccinations became available. This study further provides support that social media data can provide valuable insights and trends regarding public concerns and opinions during public health crises. Policy makers can leverage these insights and trends emerged from social media platforms to understand evolving public concerns and opinions and further develop public health policies and interventions accordingly.

Overall, these themes collectively identified socioecological factors at the individual, interpersonal, environmental, community, and national levels (including policies and structures that can promote or hinder treatment), underscoring the multifaceted nature of OUDs and their treatment within the perinatal population. Addressing 3 issues necessitates a multitiered treatment strategy that fosters substantial and sustainable changes, advocating a systematic approach for collective action among key stakeholders. Notably, the analysis highlighted the prominence of "health initiatives" conducted by health welfare, family services, senate committees, local addiction treatment services, and other legislative bodies. The health promotion strategies funded by government health programs can be used to increase public awareness on social platforms about adverse effects caused by OUD and disseminate information on safe nonpunitive networks where pregnant and postpartum women can safely access treatment. There are also opportunities to disseminate targeted research discoveries, especially to and for families and children. This study underscores the potential of government-initiated health promotion strategies through social media platforms, such as X, particularly for families and children impacted by OUD to enhance the quality of OUD care during the perinatal period.

Given the labor-intensive nature of the human manual annotation process, to elevate the scalability and precision of thematic analysis within perinatal opioid–related tweets, we also initially explored support vector machine (SVM), random forest (RF), and extreme gradient boosting (XGBoost) algorithms in tandem with the Word2Vec model, creating binary weak labeling models for each identified theme. These models were trained on 80% (n=400) of the manually annotated tweet data, using the derived themes as labels, and their performance was evaluated on the remaining 20% (n=100). The comparative analysis across 7 thematic categories revealed distinct strengths among the models: XGBoost demonstrated superior accuracy in themes concerning adverse effects on children's health due to parental substance use, SVM excelled in analyzing health care initiatives and lived experiences of opioid and other substance use, and RF was significantly effective in interpreting politically charged content. This machine learning approach is promising to facilitate the processing of a larger data set but also enabling nuanced analysis across various dimensions, underscoring the potential of enhancing text analysis efficiency.

Limitations

This research study had several limitations and challenges. First, key term ambiguity sometimes led to the inclusion of irrelevant data, such as tweets referring to Norco, California, coincidentally captured as the brand name of hydrocodone or acetaminophen. We had to manually exclude these irrelevant terms for our content analysis. Second, the anonymous nature of X posed challenges in consistently delineating the demographic and geographical details of users. Finally, the user-generated content provided limited insights into ethnic and racial disparities and maternal disparities in our small sample, which could be expanded with a much larger tweet sample in future studies.

Discussions and Future Research

Addressing harmful opioid use in the perinatal period remains a public health imperative in the United States. Researchers have turned toward using X, a popular social media platform, to dissect health perceptions and behaviors, offering a lens on the opioid epidemic's evolving discourse. Our study findings suggest a universal opioid screening in perinatal care, destigmatization, enhanced care access, and a preference for treatment over penalization to combat the epidemic effectively, especially among pregnant individuals. Using X as a valuable social media platform, we were able to analyze real-time public perceptions and behavior as well as current trends on the opioid epidemic and opioid use during the perinatal period. As such, this study provides important implications on perinatal OUD treatment policies, services, and potential ways of using social media as a platform to facilitate and promote healthy and impactful initiatives and community support to the vulnerable perinatal OUD population at large.

With many more identified relevant and touching themes, we significantly enriched the overall understanding of the complexity of OUD use in the perinatal care domain and associated pressing issues in a much broader way, calling for more research and services in this specific domain. First, this study highlights the need to establish more comprehensive initiatives and universal screening, as they were recommended by the American College of Obstetricians and Gynecologists and Centers for Disease Control and Prevention. Universal screening and assessment of all pregnant individuals for substance use are crucial during pregnancy, and targeted support for child welfare and maternal health, especially given that there are fewer initiatives on postpartum or breastfeeding and prenatal period, and thus there is room for expanding this area of care services, health promotion initiatives, and research. Second, we advocate for a collaborative and resource-adequate approach to mitigate OUD's impacts on maternal and child health [4,27,28]. Likely, social media platforms can be used as a medium to promote such universal screening, reduce stigma, and increase assisted treatment programs for these disadvantaged vulnerable populations through government agencies, public health–related organizations, and communities. Third, more government initiatives and services to address the health concerns of pregnant individuals with OUD delay in health seeking, an emphasis might need to be placed on treatment rather than criminalization of child abuse and loss of child custody [10]. Fourth, additional studies assessing racial and ethnic maternal disparities and maternal disparities are needed due to significant racial and ethnic disparities with reported higher maternal morbidity and mortality rates for Black women compared to non-White Hispanic women due to pregnancy-related causes [29] and postpartum depression driven by increased substance use of alcohol and illicit drug use during pregnancy [30]. As a result, further research is essential to address racial and ethnic disparities, emphasizing more the important role of social media platforms in broadening outreach and support for vulnerable populations, guiding policy changes, and fostering stakeholder engagement for systematic solutions in OUD-related perinatal care.

Moreover, to improve the labeling accuracy and scalability, our future research will also aim to integrate large language models to refine the labeling technique, leveraging large language models' advanced text comprehension for improved feature extraction and more accurate predictions, thereby streamlining the analysis of complex thematic data within social media discourse.

Overall, as topics related to perinatal OUD discussed on social media platforms evolve, more systematic investigation is needed to capture the full spectrum of perinatal opioid misuse and disparities. Larger samples in different geolocations from more diverse social media platforms may provide greater insights on current health perceptions and public response on opioid use in perinatal care for practical public health policy implications.

Conclusions

Given the prevalence and detrimental impact of OUD among pregnant and postpartum individuals, this study aims to enhance our understanding of opioid use patterns during the perinatal period by analyzing related tweets on the X platform. We randomly sampled 500 tweets from May 2019 to October 2021 and conducted a thematic analysis.

Our analysis, thematic analysis, identified 7 key themes in perinatal OUD discussions, with "lived experiences of opioid and other substance use" and "political views related to harmful opioid and other substance use" among the most frequently discussed on X. Our user engagement analysis revealed that "health care initiatives" and "news reports or papers related to opioid and other substance use" received the highest average retweet count, and "lived experiences of opioid and other substance use" received the highest average tweet reply count. Given the labor-intensive nature of manual annotation, we investigated machine learning models to improve the scalability and precision of thematic analysis. We found that different computational methods excel in analyzing different themes: XGBoost for identifying adverse effects on children's health due to parental substance use, SVM for analyzing health care initiatives and lived experiences of substance use, and RF for interpreting politically charged content.

Abstract

Background: Social media have shown the potential to support type 1 diabetes self-management by providing informational, emotional, and peer-to-peer support. However, the perceptions of young people and health care professionals' (HCPs) toward the use of social media for type 1 diabetes self-management have not been systematically reviewed.

Objective: The aim of this study is to explore and summarize the experiences and views of young people with type 1 diabetes and their HCPs on using social media for self-management across qualitative findings.

Methods: We searched MEDLINE, Embase, PsycINFO, and CINAHL from 2012 to 2023 using Medical Subject Heading terms and text words related to type 1 diabetes and social media. We screened and selected the studies according to the inclusion and exclusion criteria. We quality appraised and characterized the included studies and conducted a thematic synthesis.

Results: We included 11 studies in our synthesis. A total of 9 of them were qualitative and 2 were mixed methods studies. Ten focused on young people with type 1 diabetes and 1 on HCPs. All used content analysis and were of moderate to high quality. Thirteen descriptive themes were yielded by our thematic synthesis, contributing to five analytic themes: (1) differences in how young people interact with social media, (2) characteristics of social media platforms that influence their use and uptake for type 1 diabetes self-management, (3) social media as a source of information, (4) impact on young people's coping and emotional well-being, and (5) impact on support from and relationships with HCPs and services.

Conclusions: The synthesis suggests that we should consider leveraging social media's peer support capabilities to augment the traditional services for young people with type 1 diabetes. However, the patients may have privacy concerns about HCPs' involvement in their online activities. This warrants an update of existing guidelines to help young people use social media safely for self-managing their diabetes.

KEYWORDS

adolescents; health care professionals; social media; thematic synthesis; type 1 diabetes; type 1 diabetes mellitus; T1DM; young people

Introduction

Type 1 diabetes mellitus (T1DM) is the most common form of diabetes diagnosed in children and young adults, with a global prevalence of 5.9 per 10,000 people per year [1,2]. Children with T1DM have a 12-year reduced average life expectancy, mainly as a result of acute and chronic complications (eg, hypoglycemia, as well as cardiovascular and cerebrovascular diseases) [3-5].

Reducing the incidence of complications and improving diabetes-related quality of life relies on effective self-management [6,7]. This includes psychosocial acceptance of living with T1DM and tasks such as home blood glucose monitoring and adhering to complicated medical regimens [8]. Yet, many young people struggle to self-manage effectively and find it overwhelming [9], while also often enduring depression, anxiety, stigma, discrimination, and inadequate support [10-13]. Moreover, traditional health care services may not fully meet their needs because of long waiting hours, scheduling problems, and a fear of being judged [14].

Social media platforms have shown potential to support self-management for several long-term conditions, including T1DM [15-19]. For example, Meade et al [20] suggested that social media could help build diabetes-related skills and knowledge by providing patients and health care professionals (HCPs) access to information and means to interact with each other. In addition, social media platforms can be a source of emotional support [14] by facilitating contact with peers for validation and sympathy, which can increase their sense of normality and belonging [21,22]. Finally, the anonymity offered by social media (eg, use of pseudonyms) can enable young people to discuss sensitive topics with less fear of embarrassment or judgment [23-25].

At the same time, however, information shared on social media can be inaccurate, inappropriate, or misrepresented [8,26], and there are concerns about privacy and security when sharing personal health information online [27,28]. Given the presence of both potential benefits and risks, it is important to further understand young people's and HCPs' experiences, views, and concerns about using social media to self-manage T1DM. Previous qualitative studies explored this [14,25,28] but were limited to a particular time, geography, demographic group, and context [29]. A review and summary of findings across qualitative studies is still lacking.

We, therefore, aimed to address this gap by (1) identifying and characterizing the studies that examined young people's and HCPs' experiences and views of using social media to self-manage T1DM and (2) exploring and synthesizing these experiences and views, as well as the reasons for young people to use or not to use, or for HCPs to recommend or to not recommend social media for self-managing T1DM.

Methods

Thematic Synthesis

Thematic synthesis is a way of integrating findings from multiple qualitative studies and providing a wide range of perceptions of people in different time, space, population groups, and contexts [30] by synthesizing quotations and findings from each study. We used a thematic synthesis approach for summarizing young people's and HCPs' experiences and perceptions of using social media to self-manage T1DM as reported in previous qualitative studies. With this, we aimed to produce a new, higher-level understanding of this phenomenon beyond the original findings of individual studies.

The design of this review was informed by Thomas and Harden's [29] guidelines and reported in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [31], where relevant. We registered this review on PROSPERO [32], which is an international prospective register platform for systematic reviews.

Identifying Relevant Studies

Search Strategy

We searched MEDLINE, Embase, and PsycINFO via Ovid, as well as CINAHL on February 16, 2023, using Medical Subject Heading terms and text words related to T1DM and social media (see Multimedia Appendix 1). We selected search terms based on previous reviews on related topics (eg, Elnaggar et al [8] and Faulds et al [26]) and refined them with the support of a librarian. The search was restricted to studies published in English since 2012, which was when social media became more mainstream. To complement our electronic search strategy, we manually searched reference lists of included studies.

Inclusion and Exclusion Criteria

Our criteria for selecting papers, structured according to population, phenomenon of interest, and context [33] are mentioned in Table 1.

Table 1. Inclusion and exclusion criteria.

Inclusion criteria
Population
People aged 10-24 years diagnosed with T1DM[a]
This age range aligns with the definition of young people by the World Health Organization [34]
Studies with mixed age or disease groups were included if we were able to check if quotes were from people who met our criteria
HCPs[b], ie, doctors, nurses, and allied HCPs, providing care for young people with T1DM
Phenomenon of interest
Studies that addressed experiences and views of young people with T1DM and HCPs of using social media platforms for self-management. As social media platforms, we considered messaging platforms (eg, WhatsApp), mainstream social networks (eg, Facebook, Instagram, Twitter, and Reddit), and disease-specific web portals and online communities (eg, diabetes.uk [35])
Studies or data from young people and their HCPs were included if they shared their views and perceptions about social media platforms for T1DM self-management regardless of whether they had personal experience of using it as such
Context
Any health care context
This will include self-management activities that young people undertook outside of clinic settings in the context of their daily lives
Study type
Any study with qualitative data
For example, studies reporting findings from interviews or ethnographic research, survey studies reporting free-text comments from questionnaires, studies qualitatively analyzing posts from social media platforms, and mixed methods studies presenting qualitative data or findings (eg, a randomized controlled trial with a nested qualitative process evaluation)
Publication type
Original research published in peer-reviewed journals
Language
English
Time of publication
2012-current
Exclusion criteria
Population
People outside the 10-24–year age range or without a diagnosis of T1DM
Informal caregivers or parents; HCPs providing T1DM care solely for adults
Phenomenon of interest
Experiences and views about self-management of T1DM but without references to the role of social media within that, or about social media in general but not in relation to T1DM self-management
Context
None
Study type
Study only reporting quantitative data (eg, survey studies without analysis of free text comments)
Publication type
Reviews, books, conference papers, opinion pieces, commentaries, and gray literature
Language
Other languages
Time of publication
<2012

[a] Type 1 diabetes mellitus.

[b] Health care professional.

Screening

At least 2 reviewers independently conducted 2 rounds of screening (round 1: title or abstract [YM, LH, and KL]; round 2: full text [YM and KL]) to assess papers against the criteria in Table 1. Discrepancies between reviewers were solved through discussion.

Quality Assessment

We used the Critical Appraisal Skills Programme Qualitative Studies Checklist [36] to assess the quality of included qualitative studies (consisting of 10 criteria) and the Mixed Methods Appraisal Tool (MMAT; 17 relevant criteria) [37] for mixed methods studies. Each study was assessed independently by 2 researchers (YM and KL), with disagreement resolved through discussion. We reported how many criteria each study met as an indicator of their quality. In line with methodological guidance [36,37], we did not remove or assign lower importance to quotations from lower-quality studies, but left it to readers to judge the accuracy of the quotations in reflecting the participants' viewpoints and perceptions.

Data Extraction and Synthesis

For objective 1, we extracted information on publication (authors, year of publication, and country), study method (study design, recruitment setting, and data collection), study population (sample size, age, gender, ethnicity, and social media experience), and social media platform (name and type, target users, and purpose). We synthesized information using counts and percentages.

For objective 2, we extracted and thematically synthesized all text labeled as "findings" or "results," as well as related participants' quotes [29]. We also extracted participants' sex and age, if reported at quote level. One researcher (YM) extracted data for all studies, with another (KL) doing this in duplicate for a random 20% (n=3) of studies. Data were exported to NVivo (Lumivero) for further thematic synthesis in 3 steps [29]. First, line-by-line coding in duplicate by 2 researchers (YM and KL) using an inductive approach—the researchers extracted and tabulated all quotes and applied codes that reflected the meaning of the quote. The researchers met regularly to discuss and compare codes, solving disagreements through discussion and with input from another researcher (SvdV) where needed.

Second, developing descriptive themes—once no new codes were identified and data saturation was achieved, 2 researchers (YM, and KL) grouped the final codes into descriptive themes based on their differences or similarities and underlying relationships.

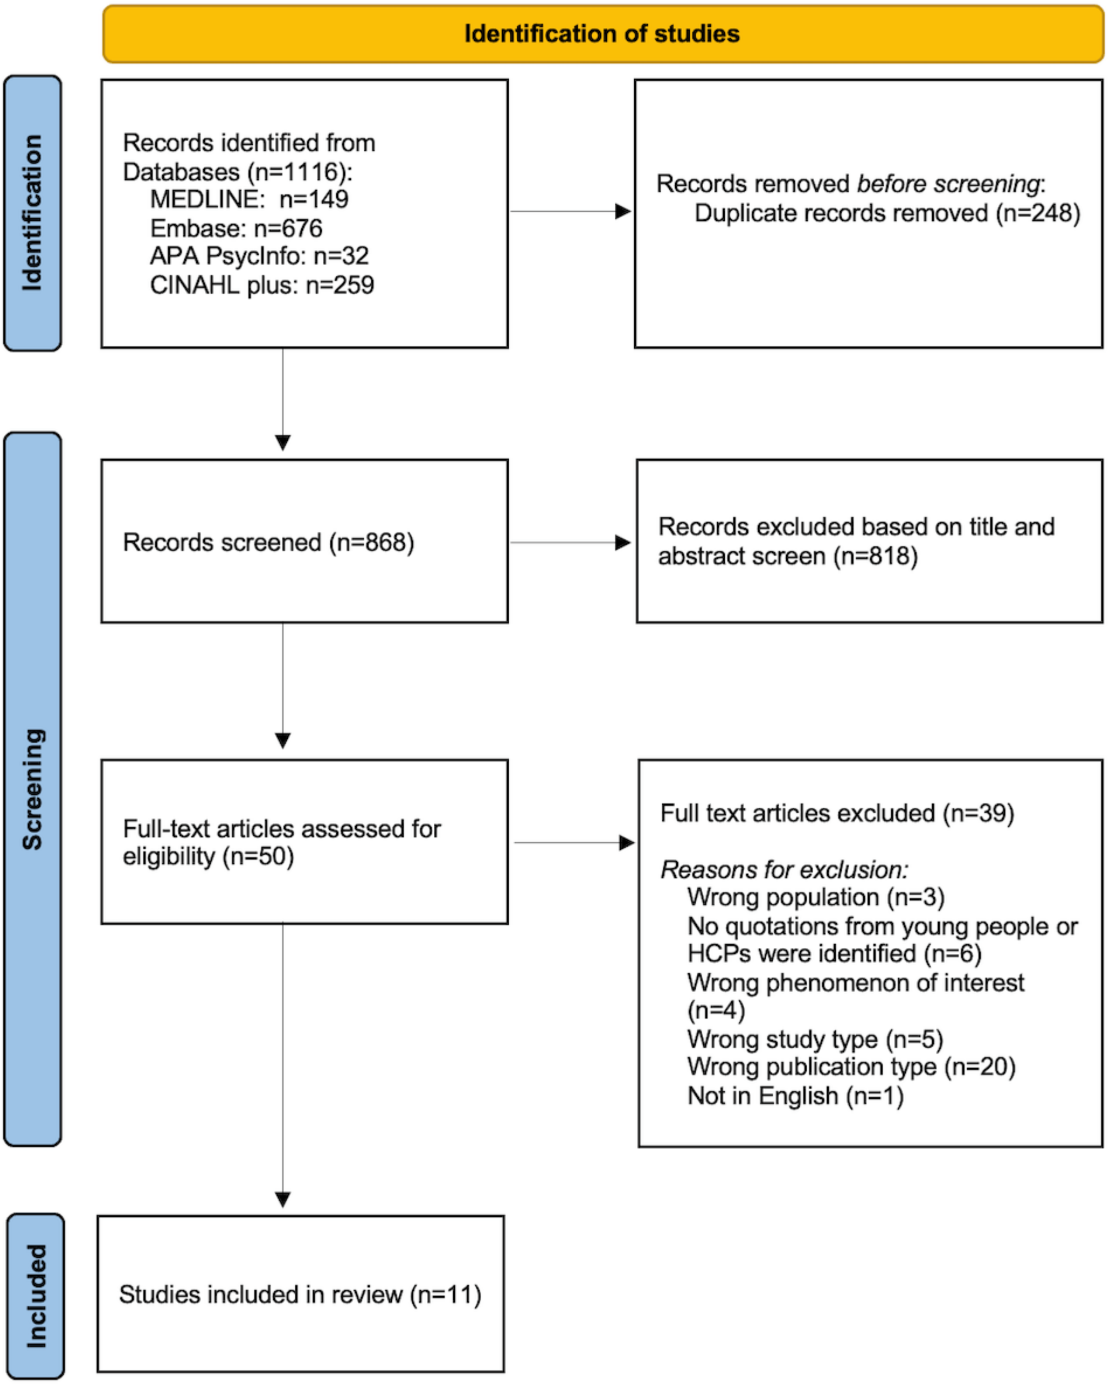
Third, generating analytical themes through a series of discussions within the team to explore how the descriptive themes related to our research aim and objectives, while endeavoring a novel interpretation and insights that expanded beyond simply summarizing the findings of individual-included studies.

Results

Overview

Figure 1 shows our search yielded 1116 studies, of which we ultimately included 11 [22,23,38-46]. The main reason for excluding papers based on full text was "wrong publication type" (n=20).

Figure 1. PRISMA flow diagram of the study selection process. HCP: health care professional; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Study Characteristics

The characteristics, aim, and main results of the included studies were summarized in Multimedia Appendix 2. Of the 11 included studies, the majority were qualitative studies [22,23,38-40,43-46] and conducted in the United States [22,39,41,45,46]. All used content analysis. Most studies focused on young people with T1DM, with only 1 focusing on HCPs [43]. A total of 4 studies used moderated platforms [41-43,46]. All studies met most quality criteria, except 1 that failed to meet 3 out of 10 criteria [38]; Multimedia Appendix 3 contains our detailed quality assessment for each study.

Synthesis

Table 2 shows how we identified 13 descriptive themes that contributed to 5 analytic themes, with Figure 2 showing to what extent studies contributed to each of the themes (see Multimedia Appendix 4 for the underlying study-level information).

Table 2. Analytic and descriptive themes with additional illustrative quotations.

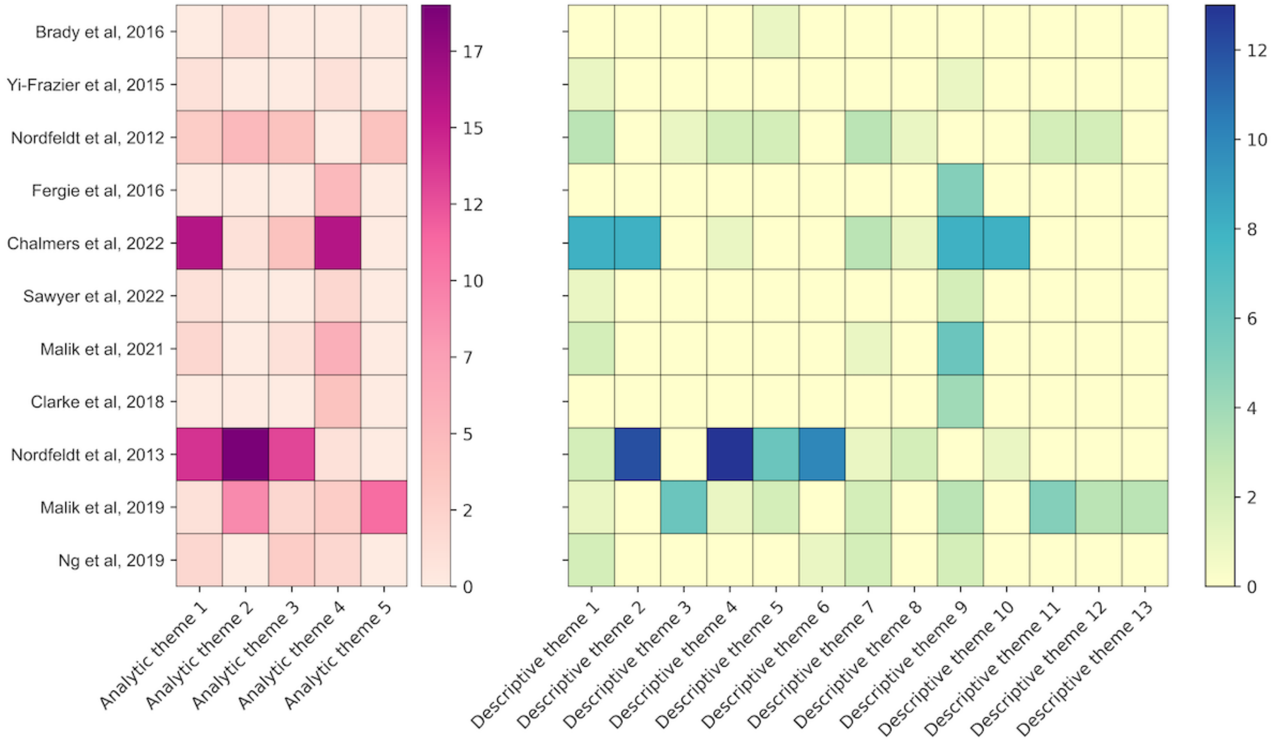
Analytic and descriptive themes	Additional illustrative quotations
Analytic theme 1: differences in how young people interact with social media (differences in how young people with T1DM[a] interacted with social media, including different levels of engagement and willingness to disclose information about their condition).	
Descriptive theme 1: passive versus active user engagement	• "I also read blogs, but don't post anything myself." [HCPs[b]], [43] • "I've made posts about going to camp with other diabetics or that I'm with my 'dia-besties.'" [Female participant aged 16 years], [39]
Descriptive theme 2: levels of T1DM disclosure	• "A girl I went to middle school with has [information about the fact that she has diabetes in] her Instagram handle. some people have their handles as their real names and then have type 1 in their bio." [Female participant aged 18 years], [39] • "[Y]ou see most websites, if you're creating a website which you don't want everybody to see...only just friends, then you can arrange it with passwords" [44] • "People don't understand. Most people think you have to be overweight to have diabetes and they're like, 'How do you have diabetes? You're not fat'" [Female participant aged 14 years], [39]
Analytic theme 2: characteristics of social media platforms that influence their use and uptake for T1DM self-management (characteristics of social media that influenced their use and uptake for T1DM self-management, including easier access to information and peer support, platform design, and trustworthiness).	
Descriptive theme 3: easier access to information and peer support	• "The advantages are that it is handy if you need to look something up, accessible information, and that it is easy to search" [HCPs], [43] • "I get a lot of emails and it's really hard to distinguish what is spam and what is not [since] sometimes it doesn't go into the spam box" [22]
Descriptive theme 4: platform design	• "I feel like a social media page would be a lot better because depending on how it would be set up, it would be organized" [22] • "I want like...I want it to be colourful and funny..." [Girls, 10-11 years], [44]
Descriptive theme 5: trustworthiness	• "The website here looks serious, if it should be some strange person, or for instance a paedophile, I don't think that he would enter a diabetes website and look there. I rather think that those who enters a diabetes website are those interested in diabetes as a subject" [Girls, 14-15 years], [44] • "If it comes across as reasonable and educational, you know, you kind of trust in it. rather than someone who types 'lyk dis'" [18-25 years], [38] • "If you feel certain about what kind of website it is, who's behind it, then you can trust that there's no false things there" [Girls, 12-13 years], [44]
Analytic theme 3: social media as a source of information (social media had the potential to cater to diverse information needs and provided an avenue to learn from peers and educate others).	
Descriptive theme 6: catering for diverse information needs	• "And there is news, what happens in the body, sexuality, and lots of different things...about insulin and medical devices, and about food and how you're affected by things...what you ought to think about, not to smoke, and with diabetes, don't drink and such stuff" [Girls, 14-15 years], [44]
Descriptive theme 7: learning from peers' experience	• "It was so helpful to be able to ask questions and see the questions asked by others to learn from their experiences and gain knowledge of how others manage their diabetes" [Female participant aged 23 years old], [42]
Descriptive theme 8: educating others	• "School and preschool staff can visit the site to prepare themselves prior to our visits" [HCPs], [43]
Analytic theme 4: impact on young people's coping and emotional well-being (positive and negative effects social media could have on young people's coping and emotional well-being).	
Descriptive theme 9: emotional support from peers	• "Have friends who you know are also going through the same problems and who you know understand what you are feeling" [Female participant aged age 22], [23] • "I think if you have something as big as diabetes in common then like you could probably bond really fast" [22]
Descriptive theme 10: humor and hope	• "I just post like jokes and relatable stuff for diabetics...When it comes to my diabetic page, I just hope it makes someone laugh...It's just a bunch of memes." [Female participant aged 14 years], [39] • "It would be fun to know just, yes, that there will be the remedy for diabetes within 15 years and...it is...they have been talking a lot about finding a certain remedy to regain your insulin production" [Boys, 14-15 years], [44]
Analytic theme 5: Impact on support from and relationship with HCPs[b] and the health care service (how social media might affect the support from and relationship with HCPs and the health care service) support from and relationship with HCPs and the health care service.	

Analytic and descriptive themes	Additional illustrative quotations
Descriptive theme 11: more direct support from HCPs	- "If it's a question that affects your care during those three months [between clinic visits], or it does something to help what you're doing within diabetes, then that could be helpful because you get the answer then and not have to wait" [22]
Descriptive theme 12: better HCP-patient relationships	- "By doing so I learn how the patients think, which can be useful in working with them (HCPs) [43], [Through social media] they would know more about me, and what I like and what kind of foods I like, so that could also factor into insulin pump settings" [22]
Descriptive theme 13: potential privacy concerns	- "In a DM [conversation] it's only going to me...[but] I feel like if it was me and [care team member] in a DM, I could add anyone at any time, or [the care team member] could add anyone at any time, and then it's no longer private" [22] - "I think it would be a little weird [engaging over social media] at first" [22]

[a] T1DM: type 1 diabetes mellitus.

[b] HCP: health care professional.

Figure 2. Heat map visualizing the extent to which studies contributed to analytic and descriptive themes. Darker colors indicate more substantial contributions and the numbers beside the color bars refer to the number of quotations coded under each theme [22,23,38-46].



Analytic Theme 1: Differences in How Young People Interact With Social Media

Descriptive Theme 1: Passive Versus Active User Engagement

Young people exhibited different levels of engagement on social media. Some could be categorized as "content consumers" or "lurkers" who tended to be more passive observers [39,43]. They might consume content, such as reading blogs and following forums, to stay informed about the others' experiences, but they rarely contributed content or engaged with the other users [39,43]. This might be due to a lack of time, having other priorities, or not being interested in posting [41,42,44]. For example [39],

> *There's nothing for me to like post about, I don't do like blood sugar updates on my story or anything.* [Male participant aged 13 years]

On the other hand, there were "active participants" who actively contributed to the social media community. They regularly shared content related to their diabetes journey, interacted with T1DM peers, offered insights to raise awareness, and fostered connections within the diabetes community [39]. Some "active participants" also worked as "role models" to motivate fellow users by showing a positive attitude toward T1DM management and sharing how they combatted their condition [44,45]. For example [39],

> *[I]t's second nature. That's the mood I would want [my followers] to get out of [my posts]. Show it who's boss.* [Male participant aged 16 years]

Descriptive Theme 2: Levels of T1DM Disclosure

Young people expressed different opinions toward diabetes disclosure on social media. Some were comfortable being open and outspoken about having T1DM, freely disclosing their condition in their posts and even profile descriptions on public-facing platforms such as Instagram (Meta Platforms) and Twitter (Twitter, Inc), thus appearing to consider it part of their online identity [39]. For example [39],

> *When you have an Instagram [account], you set your profile...and I put that I'm diabetic on there.* [Female participant aged 18 years]

Others selectively shared their T1DM-related activities in more inclusive platforms such as Facebook (Meta Platforms) group and Snapchat (Snap Inc), appreciating the features that allowed them to choose audiences or block unwanted viewers to keep themselves safe and protected from unwanted strangers accessing personal information [39,44]. For example [39],

> *Snapchat has a feature where you can block people from seeing your story and stuff, so I am comfortable [discussing T1D] because I can control who sees what.*

Additionally, some young people chose not to share their T1DM-related activities possibly due to previous bad experiences or concerns about potential misunderstanding or judgment from others [39]. For example, one female participant aged 18 years explained [39],

> *I have always gotten bullied for it (T1D), so I keep it on the down low on social media.*

Analytic Theme 2: Characteristics of Social Media Platforms That Influence Their Use and Uptake for T1DM Self-Management

Descriptive Theme 3: Easier Access to Information and Peer Support

Social media were perceived by young people of T1DM and HCPs to be easier and more timely means of communication and to have quicker access to information compared with traditional methods such as email and phone calls [22,43]. For example, unlike the complexities of searching through emails and distinguishing spam, it was "just at the tip of your fingers" [22] to flip through information and communicate with others.

Social media also provided an alternative online channel for seeking peer support compared with in-person interactions. This online support complemented face-to-face interactions, offering individuals a sense of autonomy to access social support whenever they felt ready and comfortable [41]. At the same time, however, others felt in-person meetings could offer a chance to better understand personalities and foster deeper connections [41].

Descriptive Theme 4: Platform Design

The platform's user interface design and how content was presented influenced young people's and HCPs' choice of using social media in T1DM self-management [22,43,44]. Young people and HCPs expressed a preference for well-organized platforms that simplified the process of finding specific information [22]. Platforms that appeared messy and overwhelming with excessive information might deter users' exploration and engagement [43,44]. Additionally, young people preferred regularly updated content that aligned with their needs—they found it difficult to feel engaged or interested if platforms did not offer anything new or relevant to their experiences [39,44]. Younger participants further expressed a preference for colorful platforms that provided age-specific information on a wide range of topics [39,44].

Descriptive Theme 5: Trustworthiness

Trustworthiness was another important part that affected young people's use and HCPs' recommendation of social media for T1DM self-management.

First, young people with T1DM and HCPs tended to trust platforms with well-presented facts [44], using formal and professional language rather than casual language such as "lyk dis" (18-25 years) [38].

Second, young people were more likely to use platforms that were recommended by sources they perceived as reliable, such as HCPs and peers [22,43], while HCPs felt more comfortable offering information via sites that were developed with or moderated by HCPs to ensure accurate information was given [43]. One HCP explained [43],

> *What feels safe for me...is that the information they can read here is the information we have provided. We know that we have critically reviewed it together.*

Third, young people trusted transparent platforms where they knew who was allowed to join and use the platforms as users. Otherwise, they might feel unsafe or concerned about interacting with malicious or deceptive individuals [44].

Analytic Theme 3: Social Media as a Source of Information

Descriptive Theme 6: Catering for Diverse Information Needs

Social media could provide diverse diabetes-related information, such as food and sports tips, insulin and pump instructions, information about drugs and medicine, advice on healthy habits (eg, abstaining from smoking or drinking alcohol), and insights on long-term complications and future expectations about life quality [39,44]. Moreover, social media provided information tailored to different groups of people, such as age-specific information for children and young people and diabetes management guidance tailored to the needs of caregivers and school staff [44].

Descriptive Theme 7: Learning From Peers' Experience

Social media also served as a valuable platform for young people with T1DM to learn from the experiences of their peers who openly discussed different treatment options and gave advice based on their experience [39,43]. This real-life experience complemented the more standardized advice from HCPs and clinical services [39,44], bringing pros and cons of treatment to life. As such, it better informed young people's understanding of different treatment options [22,40,41,44]. One female participant aged 18 years explained [42],

> *...through the website and seeing how other people manage their health to see what could work better for me.*

Descriptive Theme 8: Educating Others

Social media offered opportunities for others to learn and stay up-to-date about T1DM. For example, caregivers and school staff could equip themselves with knowledge involving T1DM management to provide more appropriate and informed support to young people with T1DM [43]. Additionally, the knowledge shared on certain types of public-facing social media (eg, YouTube videos and hashtag campaigns on Instagram and Twitter) played a vital role in raising public awareness and reducing misunderstandings [44], such as the misconception that T1DM was associated with being overweight as shown in the quote "...Most people think you have to be overweight to have diabetes." (female participant aged 14 years) [39].

Analytic Theme 4: Impact on Young People's Coping and Emotional Well-Being

Descriptive Theme 9: Emotional Support From Peers

T1DM self-management has the potential to be an overwhelming process, often leading to mental health issues, such as anxiety and depression [10,48]. While social media could be a source of emotional support to help them manage these [22,40,42,46], there were examples in the literature of it being associated with negative feelings, for example, diabetes-related stigma [39] and sometimes increasing feelings of loneliness [42].

First, social media provided a platform for young people with T1DM to openly share their feelings and seek comfort and understanding from other users [23]. When they did so, it was very common to receive positive and encouraging responses [39]. These positive responses from their peers could validate their condition and uplift their spirits, making them realize they were not alone in the journey of managing T1DM and gradually accepting the condition as "second nature" [39]. For example [41],

> *Just feeling like you're not the only one going through it...and that you can still lead like a normal life and still have diabetes.*

At the same time, however, others felt that despite the positive feedback they received, those without T1DM could not fully comprehend their challenges [39]. This sense of disconnection further intensified their feelings of isolation [39]. One female participant aged 17 years explained [39],

> *[Other social media users] would be like, "Do your best" or "You're doing wonderful!" But a lot of people don't know, and I feel like that makes you feel a little bit more alone.* [Female participant aged 16 years]

The conflicting views above highlighted the importance of emotional support from peers with shared experiences and who truly understood the challenges. This shared understanding could give young people a sense of belonging and normalization, creating a safe space where they could freely express their emotions and struggles. Furthermore, shared experiences could easily foster strong bonds and friendships with others [22]. For example, young people tended to use social media to reconnect with peers after attending a face-to-face diabetes camp [45]. This was particularly important for young people who lacked family support, as it could provide supplementary information and emotional help [40,44].

Descriptive Theme 10: Humor and Hope

Humor and hope were 2 important strategies that young people used to cope with T1DM [39,44]. By joking about their condition on social media, they could reduce the stress associated with it and treat it as "less of a big deal and kinda normalize it" (male participant aged 15 years) [39]. Additionally, some young people used humor to defend themselves against potential bullying and negative comments. For example, 1 person explained, "I just have to eliminate that chance [of bullying] by like making fun of me before they do" [39]. Moreover, some young people posted jokes and humor and had a positive outlook on social media to inspire their peers to take on a more optimistic approach to deal with their long-term conditions [39]. Finally, young people also expressed hopes of a cure for T1DM on social media [44]. This outlook could fill them with hope and excitement, igniting a sense of optimism for the future.

Analytic Theme 5: Impact on Support From and Relationship With HCPs and the Health Care Service

Descriptive Theme 11: More Direct Support From HCPs

Social media changed the way how young people with T1DM received support from HCPs [22,43]. In some cases [22], young people reported that their parents communicated with HCPs about their diabetes and felt their parents were not fully informed about their condition. Social media enabled young people with T1DM to communicate directly with their HCPs, promoting greater engagement in self-management and empowering them to take control of their condition [22]. For example [22],

> *My parents are normally the ones who would talk with the doctors and stuff. and so with social media it would be like I'm taking more control over what's happening.*

Young people also valued the timeliness of communication via social media in between clinic visits. For example, when wanting to contact HCPs, young people with T1DM could send direct messages to their HCPs, rather than going to clinics, sending emails that were lost or never replied to, or trying to get in contact through a phone [22,43].

Descriptive Theme 12: Better HCP-Patient Relationships

Engaging with HCPs through social media offered the potential to cultivate a more personalized HCP-patient relationship [22,43]. By sharing insights with HCPs about their lifestyle and preferences, HCPs could better understand young people's conditions and adopt a more patient-centered approach to care. Young people with T1DM and HCPs believed this resulted in better and more tailored support [22,43]. For example, "you would probably get to know each other a bit more and you would be more knowledgeable about things going on" [22].

Descriptive Theme 13: Privacy Concerns

Despite the benefits mentioned above, some young people felt awkward when they engaged with their HCPs through social media [22]. They expressed privacy concerns about the potential inspection and judgment if their HCPs were a part of their personal social media platforms or if their HCPs inadvertently invited someone they did not know into their private conversation, potentially leaking their personal information to others [22]. For example [22],

> *...it might be awkward at the same time, like, if your doctor's following you on Instagram and they can see everything you're posting and all that stuff.*

Discussion

Summary of Findings

This synthesis systematically reviewed the qualitative data on experiences and views of young people with T1DM and their HCPs regarding the use of social media for self-management. We included 11 studies in our synthesis, 10 of which focused on young people with T1DM. All used content analysis and met most quality criteria.

A total of 5 analytical themes and 13 descriptive themes were yielded by the synthesis. It revealed varying levels of engagement and comfort among young people with T1DM in using social media for self-management, with greater levels of trustworthiness given to professionally designed platforms recommended by HCPs or peers. Social media facilitated young people's access to a wide range of information and peer support and enabled easier and more direct communication with HCPs. Privacy and safety concerns were the main barriers preventing the use of social media for T1DM self-management.

Relation to Other Studies

Several of our findings were in accordance with previous research on the role of social media for self-managing T1DM in young people. For example, consistent with other reviews [8,14,27,49,50], we identified that young people with T1DM used social media to enhance their diabetes management knowledge and skills and to provide and receive emotional peer support. Similarly, we confirmed that social media could complement traditional health care services by providing direct communication with HCPs, complemented with tailored insights from online peers. Beyond these studies, we additionally identified the supplementary role of social media in complementing family and face-to-face support [41]. Overall, our findings reinforced the established understanding of the supplementary supportive potential of social media for T1DM self-management.

In contrast to previous research [8,27,49], we did not find many concerns related to misinformation. This may be explained by young people's trust in the experiences and tips shared by their online peers [22,43]. However, these individualized experiences may not be a suitable source for everyone and may contain information that is not necessarily accurate [22,37]. Furthermore, privacy and safety concerns were the main risks identified in the synthesis, often preventing young people from using social media [22,39]. These risks were linked to disclosing excessive personal information online, which in turn might lead to things such as online bullying, harassment, and encountering malicious individuals [22,27,44]; these risks and issues are common in any online activity and can be minimized by using social media safely [27].

Finally, our synthesis revealed novel insights into HCPs' role in using social media for T1DM self-management. We found that HCPs encouraged patients to connect with peers on social media to gain diverse perspectives on T1DM treatment and to use HCP-moderated online platforms, while other research found that HCPs might advise against patients' social media use [50,51]. Also, where previous reviews and studies indicated HCP involvement in self-management could improve HCP-patient relationships and health care delivery more generally [8,50-52], our synthesis found more diverse patient attitudes, ranging from beliefs that HCP involvement would enable tailored support to worries about potential scrutiny of their social media posts.

Implications for Practice and Research

Implications for Social Media Platforms and HCPs

The supplementary role of online peers' experiences identified in our synthesis, which was confirmed by other studies [8,14,27,49,50], implies that HCPs should consider integrating customized peer-to-peer mechanisms into traditional services to provide better health care. For example, moderated social media online forums and Facebook groups such as Diabetes UK [35] and Diabetes Yes [42] have created online communities that provide professional-reviewed knowledge and real-life experiences from peers that complement medical care. HCPs could recommend that their patients access these platforms to get information and peer support between clinic visits. Meanwhile, they could participate in moderated online groups to communicate with and support their patients.

However, the reliability and applicability of information and experiences exchanged online cannot be assured [22,37], social media platforms and HCPs should educate young people on how to identify credible online health information about their T1DM, for example by providing evidence-based knowledge and contrasting it against misleading content [22,43].

Furthermore, our synthesis showed that young people have different comfort and engagement levels in sharing their T1DM-related content online. This may warrant further refinement of available functionality within social media platforms to give users more control over what they share with whom, such as features allowing selective audiences or restricted profile access.

Implications for Health Policy Makers

Our synthesis identified that young people had privacy and safety concerns about using social media and involving HCPs for T1DM self-management [22,39,44]. Existing guidelines [27,53,54] provided a broad and comprehensive framework for safe social media use and appropriate HCP involvement, but these did not incorporate patient and HCP input, and may be outdated given the rapidly evolving social media landscape.

Furthermore, protections for patients regarding inappropriate HCPs' involvement were insufficiently addressed.

Recommendations could be enhanced by developing updated and evidence-based guidelines that incorporate input from patients and HCPs. Informed consent procedures could be added to existing guidelines to protect patients by (1) informing patients on the risks and best practices of using social media for T1DM self-management; (2) emphasizing patients can opt out of HCPs' involvement in their social media T1DM self-management; (3) providing clear conduct guidelines for HCPs; and (4) establishing formal reporting channels for patients' concerns over uncomfortable interactions, boundary violations, or privacy issues.

Implications for Future Research

The participants in the included studies were mostly social media users; only 1 study in our synthesis [22] included a small proportion of participants who did not have social media experience. This may have introduced a potential bias toward more positive views, especially as several studies interviewed young people involved in developing a social media platform. To gain a more holistic perspective and inform platforms and guidance suitable for a broad range of young people with T1DM, future research could include input from nonsocial media users.

The first-order qualitative data included in our synthesis consisted of participants' quotations about their experiences and opinions. Future studies could analyze young people's social media posts to gain additional insights into their actual (instead of reported) online behaviors, attitudes, and topics of interest.

Limitations

One limitation of our synthesis came from the exclusion of non-English studies, which means we may have missed insights from non-English studies on this topic. Widening the scope beyond English could enrich our findings by uncovering different cultural perspectives from non-English speaking contexts that were not captured in our synthesis.

Another limitation arose from solely analyzing qualitative data from original studies published in peer-reviewed journals. This excluded potentially valuable inputs from gray literature and text from social media platforms that may have provided additional real-world practices, patient experiences, and emerging trends relevant to this topic. Incorporating these wider sources in future analyses could lead to a more comprehensive synthesis of diverse qualitative evidence.

Conclusions

Our synthesis identified the experiences and views of young people and HCPs using social media for T1DM self-management. It reinforced social media's role in providing peer support, supplementary information, and emotional support. In addition, privacy and safety concerns were identified as key barriers preventing young people from engaging with social media for support and information.

The synthesis suggests we should consider leveraging social media's peer support capabilities to augment traditional services for young people with T1DM. However, patients may have privacy concerns about the HCPs' involvement in their online activities. This warrants an update of existing guidelines to help young people use social media safely for self-managing their diabetes.

Abstract

Background: Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disorder with no cure. Most children are prescribed several medications aimed at controlling disease activity, managing symptoms, and reducing pain. Physical activity is also encouraged to retain musculoskeletal function. The primary determinants of treatment success are maintaining long-term adherence, ongoing monitoring by a pediatric rheumatologist, and involvement of an interdisciplinary team. To support these goals, a new digital intervention was developed, InteractiveClinics, which aimed to prompt children to take their medications, report pain levels, and increase their physical activity.

Objective: This study aims to evaluate the usability of InteractiveClinics among children with JIA.

Methods: As part of this pediatric cross-sectional study, 12 children were asked to wear a smartwatch for 2 weeks, which was synchronized to the InteractiveClinics phone app and web-based platform. Personalized notifications were sent daily to the watch and phone, to prompt and record medication adherence and pain level assessment. Physical activity was automatically recorded by the watch. At the end of the study, all children and parents completed a postintervention survey. Written comments were also encouraged to gain further feedback. Descriptive statistics were used to summarize the survey results, and all qualitative data underwent thematic analysis.

Results: Twelve children aged 10 to 18 years (mean 14.2, SD 3.1 years; female: n=8, 66.7%) and 1 parent for each child (n=12; female: n=8, 66.7%) were enrolled in the study. Based on the highest and lowest agreement areas of the survey, most children and parents liked the smartwatch and web-based platform; they found it easy to learn and simple to use. They were also satisfied with the pain and physical activity module. However, usability and acceptability barriers that hindered uptake were identified in the phone app and medication module. Children required a unique in-app experience, and their suggestive improvements included more personalization within the app; simplification by removing all links not relevant to antirheumatic medications; flexibility in response times; improved conferment through gamification; additional comment fields for the input of more data, such as medication side effects or pain-related symptoms; more detailed graphical illustrations of the physical activity module, including a breakdown of metrics; and importantly, interconnections between modules, because medication adherence, pain levels, and physical activity can each influence the other. They were, overall, improving usefulness for children and parents.

Conclusions: The usability of InteractiveClinics was positive. Children and parents liked the watch and web-based platform and were satisfied with the pain and physical activity module. However, children wanted a unique in-app experience through more personalization, simplification, flexibility, conferment, comment fields, graphical illustrations, a breakdown of metrics, and interconnections. Certainly, inclusions are needed to promote user adoption and advancement of new validated digital health interventions in pediatric rheumatology, to support the delivery of integrated care.

Introduction

Overview

Globally, more than 3 million children are currently living with the autoimmune disorder juvenile idiopathic arthritis (JIA) [1,2]. JIA is the broad term used to describe a heterogeneous group of 7 inflammatory disorders, all of which have an unknown origin that begins in children younger than 18 years [3,4]. The commonality between these disorders is joint inflammation and pain [5,6]. Prolonged exposure to this inflammation can cause serious widespread complications for a child, such as impaired growth [7,8], delayed pubertal development [8,9], premature cardiovascular disease [10], and organ damage [11]. Ongoing exposure to pain can induce permanent changes in the nervous system, increasing pain sensitivity and the continuance of persistent pain in adulthood [6,12]. Regrettably, there is no cure. Instead, a "treat to target" approach is used to induce clinical remission or lower disease activity [13]. The aim is to normalize and preserve joint function, prevent growth retardation, maintain physical function, and avoid permanent disability [7,14], ultimately improving the child's quality of life [15].

Background

Medications

For most children, the first line of treatment includes the aggressive use of medications, for a prolonged period of time, because the therapeutic response to gain disease control and symptom relief is slow [16,17]. Typically, these medications include disease-modifying antirheumatic medications (such as methotrexate, sulphasalazine, and leflunomide) in combination with corticosteroids to target inflammation. In addition, ibuprofen and naproxen can ease the pain and further calm the swelling [14,16,18]. However, adhering to a strict medication schedule can be difficult for many children due to the need to take multiple medications of varying doses, by different routes of administration (oral, intravenous, and intra-articular) [14,16,19] and on different days at different times, to limit the medications' side effects on well-being [20]. An example is administering disease-modifying antirheumatic medications on a Friday night, to ensure the associated nausea and brain fog do not interfere with school performance. Therefore, reliable monitoring of a child's medication adherence by a pediatric rheumatologist is crucial to ensure they are gaining the full therapeutic response and alleviating any side effects they may experience [21].

Pain Level Monitoring

Pain is often one of the first JIA-related symptoms experienced by a child. Pain begins at an early stage of the disease trajectory when a child's joints begin to swell and become restricted. It is at this early stage that a child's pain perception can be permanently altered [6,12] because pain activates changes in the central and peripheral neural pathways, decreasing a child's pain threshold [22] and increasing sensitization [12]. This means pain can persist despite good disease control [6,23] and become widespread throughout the body, such as in both the affected and unaffected knee [24]. Understandably, it is essential that pain fluctuations for JIA are meticulously monitored, and appropriate treatments quickly initiated to achieve pain-free remission [12,15].

Physical Activity

Exercise is prescribed for children with JIA because of the abundant health benefits [25]. Exercise helps to retain musculoskeletal function and muscle strength [26], cardio-respiratory health, a healthy weight, and good mental health [27]. Yet, children are often not motivated to exercise because of their symptoms, such as chronic synovial joint inflammation, erythema, pain, stiffness, limited range of movement, and fatigue [28]. However, this motivation does not change when there is no pain and good disease control [29]. Perhaps this is because many children and parents are under the belief that exercise will exacerbate symptoms [25], when the reverse is true, exercise can promote alleviation. In fact, a recent systematic review reported no adverse events related to exercise [25].

Importantly, there are also many non–JIA-related reasons why children do not exercise. They simply do not enjoy it, have too little time, or need parental support to attend exercise programs [30] or pay for the ongoing costs associated with attending [31]. Undeniably, in order to improve the current low adherence rates for children with JIA (40% - 47%) [32,33], a new, cost-effective way is needed to promote and maintain a regular exercise regime.

Interdisciplinary Team

To achieve the best possible outcomes for children with JIA, children need access to a diverse interdisciplinary team that works in conjunction with the pediatric rheumatologist, child, and parents [34-36]. Services from allied health can include physiotherapy, occupational therapy, and podiatry to support physical function and pain [36-38], while nursing can support medication adherence through education and demonstration of injection techniques [36]. Importantly, this support also needs to be maintained for an extended period of time [39], and ongoing monitoring of the child is needed to ensure treatment success [37].

Digital Health

Recent advances in smart technology have the potential to support chronic disease management [40,41] by improving treatment adherence, recording symptoms, and monitoring health behaviors [42]. For JIA, digital health innovations could be adopted to prompt medication adherence, record pain levels, and improve physical activity. These are 3 key areas that can lead to poor outcomes. Research to date on eHealth and mobile health (mHealth) interventions for JIA has predominantly focused on electronic pain diaries and web-based programs [43]. These electronic pain diaries have used personal digital assistants [44], Apple iPods, and computers [45], while web-based programs have focused on providing education and skills to promote chronic disease management, cognitive behavior [46], physical activity [47], peer support [48], and improved quality of life [49]. Overall, feasibility and usability studies have revealed that these forms of interventions are readily accepted by children [45,46]. They find this technology easy to use and navigate [50] and need little training because they are already using the internet and mobile technology in their day-to-day life [51,52]. In fact, in Australia, 81% of children over 14 years and 55% between 10 and 13 years own a mobile phone [53,54]. Internationally, 18% - 43% of children aged between 13 and 17 years and 7% - 45% of children aged 6 - 12 years own a smartwatch [55], with a predicted rate that will substantially increase over the next few years [56].

InteractiveClinics

InteractiveClinics is an innovative digital health web-based platform aimed at supporting digital health research. It was developed by academics from the University of Newcastle, Australia, and the University of Manresa (Catalonia) Spain, with IT support from BitGenoma Ltd Digital Solutions. For JIA, InteractiveClinics was used to prompt and monitor the 3 modifiable risk factors associated with poor JIA-related outcomes—medication adherence, pain levels, and physical activity—by using a commercially available smartwatch, a customized phone app, and a password-protected Australian web server. To further address the ethical and privacy issues related to data safety, all data collected by the app and web-based platform was managed in accordance with the University of Newcastle's Information Security Data Classification and Handling Manual, and the Privacy Management Plan. The cost of development for the platform, app, and important server protection was approximately Aus $75,000 (US $48,000).

Objectives

The aim of this study is to evaluate the usability and acceptability of InteractiveClinics among children (aged 10 - 18 years) by determining if the intervention is (1) easy to use, (2) acceptable, and (3) useful [57,58].

Methods

Study Overview

This study was part of a cross-sectional study, following the World Health Organization's 6-stage step-up approach to develop a digital health intervention. These steps start from monitoring the intervention's functionality and fidelity through to evaluating feasibility, usability, efficacy, and effectiveness [58], allowing improvements to be put into place after each stage of testing and improving the quality of the intervention [59].

This study focuses on evaluating InteractiveClinics' usability to support the development of a user-centered design, because the success of an intervention is dependent on whether intended end users engage with the intervention [58]. For 2 weeks, children and parents gained hands-on experience using InteractiveClinics and then completed a postintervention survey. To ensure detailed analysis, survey questions were based on a quantitative descriptive and qualitative design, to invite participants to answer questions in their own words [60].

Recruitment of Participants

As part of this pediatric cross-sectional study, children were recruited through 2 pediatric rheumatology outpatient clinics within 2 tertiary children's hospitals in Australia. The eligibility criteria included an age range of 10 to 18 years, a diagnosis of JIA, and good comprehension of the English language. The exclusion criteria included a cognitive impairment, physical disability, or visual impairment that would affect the child's ability to understand or use smart technology.

Ethical Considerations

Ethics approval for this study was granted by the Hunter New England Research Ethics Committee (approval no: 2019/ETH01035). To ensure informed consent, all potential participants were provided with an information sheet, explaining the study's purpose, expectations, and how all data collected will be deidentified. Additionally, all study participants were informed that they could withdraw from the study at any time, without discrimination, by simply not completing the survey. In total, 12 children and 12 parents agreed to participate in the study, provided signed consent, and completed the anonymous survey between September and November 2022 (Table 1).

Table . Participants' demographics.

Demographics		Values
JIA subtype [a] , n (%)		
	Polyarthritis (rheumatoid factor [Rh] negative)	5 (41.7)
	Oligoarthritis	4 (33.3)
	Enthesitis related	1 (8.3)
	Polyarthritis (Rh positive)	1 (8.3)
	Psoriatic	1 (8.3)
Medications, n (%)		
	DMARDs[b]	5 (41.7)[c]
	bDMARDs[d]	2 (16.7)
	NSAIDs[e]	5 (41.7)
	Corticosteroids	3 (25)
	Pain relievers	7 (58)
	Folic acid	1 (8.3)
Disease duration (years), mean (range)		4.9 (5 months to 10 years)

[a] Juvenile idiopathic arthritis (JIA) subtypes based on the International League of Associations for Rheumatology criteria [3].

[b] DMARD: disease-modifying antirheumatic drug.

[c] One participant was prescribed both DMARDs and bDMARDs.

[d] bDMARD: biological disease-modifying antirheumatic drug.

[e] NSAID: nonsteroidal anti-inflammatory drug.

Intervention

InteractiveClinics aims to motivate children to take their medication, record their pain, and increase their participation in physical activity. Personalized notifications were sent daily to the smartwatch and phone, to prompt and record medication adherence (Figure 1) and complete a pain level assessment within the app (Figure 2). Physical activity was automatically recorded by simply wearing the watch.

InteractiveClinics presents these 3 key areas of monitoring as 3 modules—medication adherence, pain level, and physical activity level—which can be monitored daily, weekly, or monthly by the child within the app (Figures 1 and 3) or on a secure, password-locked, web-based platform by the child, parents/caregiver, pediatric rheumatologist, and health care team (Figure 4).

Pain levels were recorded on the validated electronic visual analog scale (eVas) module [61-63]. eVas uses a simple horizontal line with defined pain limits. The left end point indicates "without pain," and the right end point indicates "worst possible pain" (Figure 2). This reporting scale has been found to be highly reliable and consistent with the original paper-based visual analog scale [61-63].

Figure 1. Weekly example of medication adherence responses.

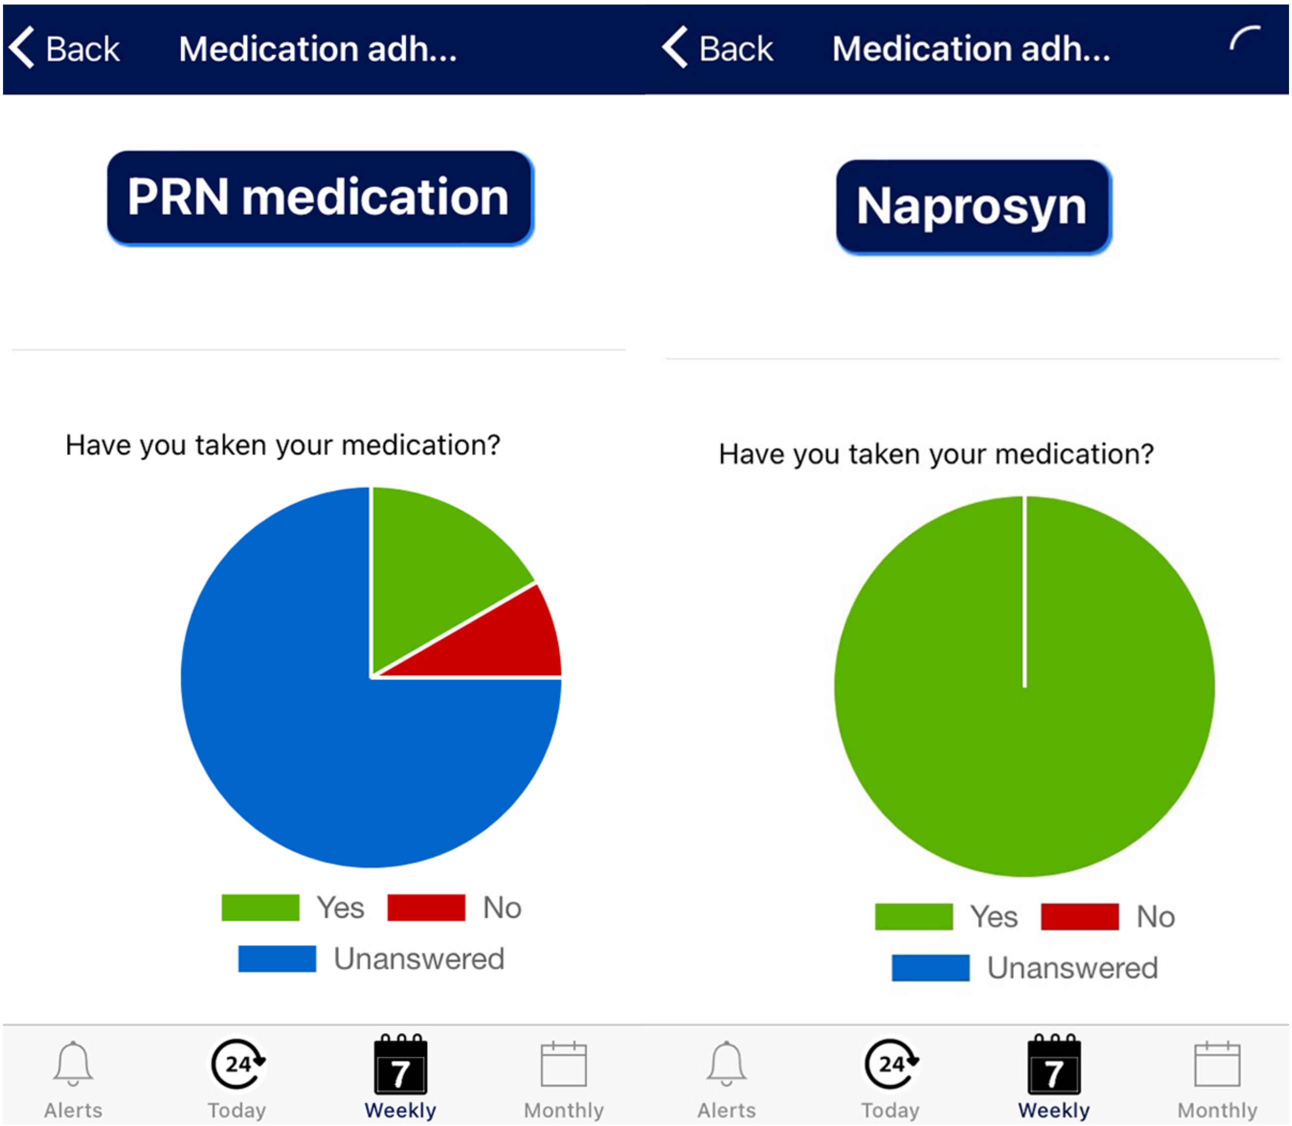

Figure 2. Recording pain level on the electronic visual analogue scale module.

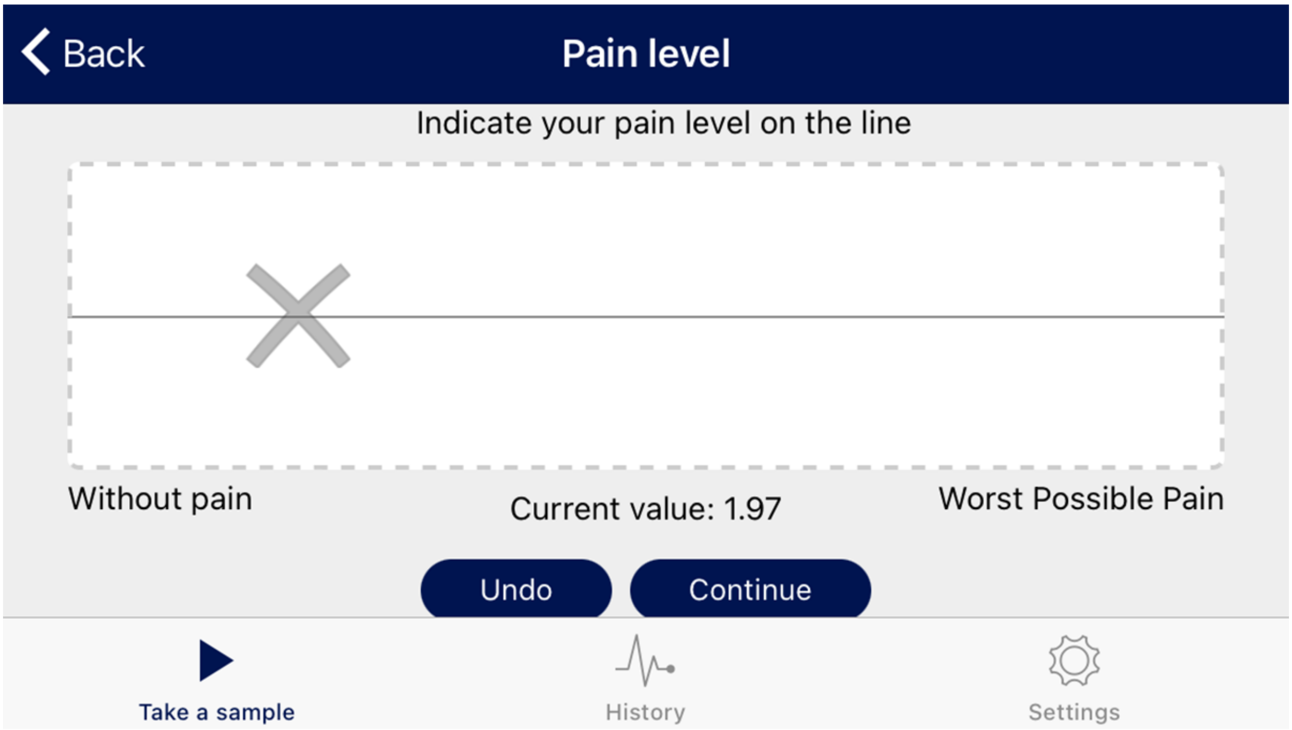
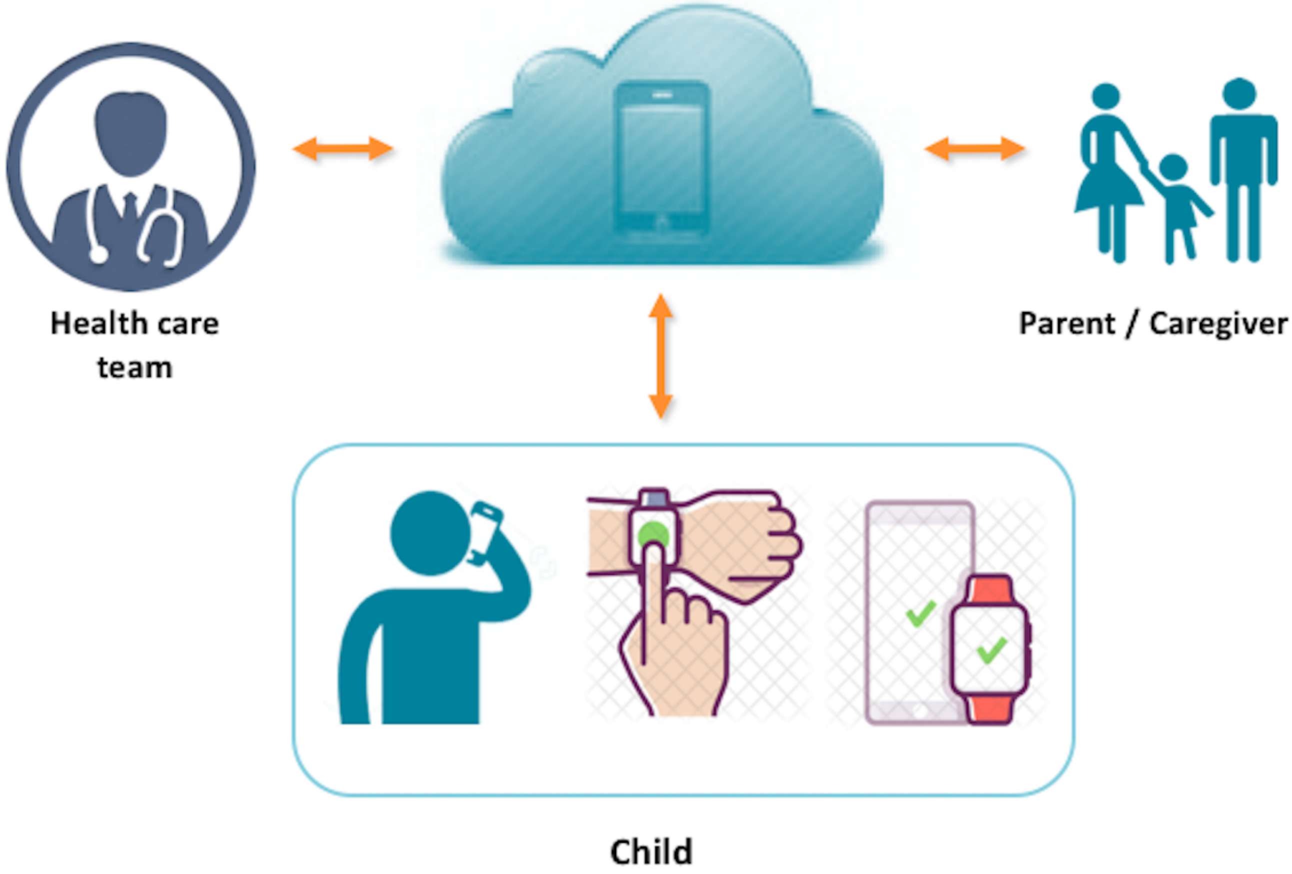


Indicate your pain level on the line

Current value: 1.97

Figure 3. Weekly example of real-time pain levels.

Figure 4. Data communication supporting an integrative model of care for juvenile idiopathic arthritis.



Materials

The materials supplied to support participation in the intervention were as follows: a smartwatch (Apple Watch series 3, with a water-resistance rating of 50 meters, to support low-intensity activities such as swimming [64]), a smartphone (Apple iPhone, SE, 2016, loaded with Aus $30 [US $20.01] worth of pre-paid credit), the InteractiveClinics app (preset on the iPhone), and a personal password (to access the data collected on the secure web-based platform).

The persuasive influences used to promote the adoption of the intervention were as follows [43]: training (for 15 minutes on how to use the smartwatch, InteractiveClinics app, and web-based platform), an instruction manual, ongoing technical support, ongoing human communication (researcher contact details [SB] were placed in the phone), goals set by the user (for the physical activity module), personal reminders (daily personal notification sent to the watch and phone, at a time preselected by child, to prompt and record medication administration and pain level assessment), and a reactive feedback loop (for the physical activity module).

A more detailed description of InteractiveClinics has been provided in an earlier feasibility study [59].

Data Collection

InteractiveClinics' usability and acceptability were measured through a postintervention survey. Two surveys were developed to collect feedback from children and their parents after they used the digital intervention for 2 weeks. Survey questions were adapted from the System Usability Scale [65,66], to ensure the survey questions encompassed the unique multimodal approach being used by InteractiveClinics. Further, to enable younger children to complete the survey without help from their parents, age-appropriate language was used.

For the parents, survey responses were based on the 1-to-5 Likert scale (1=strongly disagree, 2=disagree, 3=unsure, 4=agree, and 5=strongly agree). For children, survey responses were based on the visual face scale [66].

Written comments were also encouraged by children and parents throughout the survey, in a free-text format, to identify any unmet inclusions; to illustrate important points; and, importantly, to facilitate a user-friendly design.

Data Analysis

Quantitative Data Analysis

Descriptive statistics were used to summarize participants' demographic characteristics. For the survey results, a percentage agreement was used to place the data into 2 independent judgments, to allow the examination of either agreement or disagreement [67]. Commonly agreed included the responses "strongly agree" and "agree," and commonly disagreed included the responses "unsure," "disagree," and "strongly disagree." This form of data analysis focuses on reporting the proportion of answers that agree, by calculating them as a percentage [68]. These percentages can then be easily compared because there is a common denominator.

Qualitative Data Analysis

For all the qualitative data, this study used thematic analysis. This is an inductive approach used to examine themes and patterns within the data [69]. Coding began by clustering together small descriptive segments to expose both the strengths and weaknesses of InteractiveClinics. Then collectively, mutual patterns emerged forming latent themes, allowing the child's and their parent's experience to be heard.

To ensure rigor at all stages of interpretation, codes were continually checked to ensure they retained their original meaning, and trustworthiness and clinical relevance were enhanced by all members of our research team. Final results were internally reviewed, and data saturation was reached, drawing no more conclusions.

Results

Child Survey Feedback

The response rate to the survey among children was 100% (12/12). Most children (9/12, 75%) also completed the survey without any help from their parents. The results of the quantitative section of the survey are presented in Table 2.

Table . Quantitative survey results: child version (n=12).

Child survey questions		Smartwatch, n (%) agree	App, n (%) agree	Web-based platform, n (%) agree
Usability				
	Easy to learn	12 (100)	6 (50)	7 (58.3)
	Simple to use	12 (100)	8 (66.7)	9 (75)
	Felt comfortable using the…	11 (92)	8 (66.7)	8 (66.7)
	Quick to use	9 (75)	9 (75)	10 (83.3)
	Information clear and well organized	8 (67)	6 (50)	7 (58.3)
Acceptability				
	I liked the…	9 (75)	3 (25)	8 (66.7)
	Was fun	9 (75)	0 (0)	2 (16.7)
	Was useful	10 (83)	5 (41.7)	6 (50)
	Satisfied with…	9 (75)	6 (50)	6 (50)
	Would recommend to other young people with arthritis	10 (83)	5 (41.7)	5 (41.7)

Smartwatch

Based on the highest and lowest agreement areas of the survey, the results support using a smartwatch as part of the intervention. The watch was easy to learn (12/12, 100%) and simple to use (12/12, 100%), and the information was useful (10/12, 83%). However, only 8 children reported the information was clear and organized (8/12, 67%). Written feedback also identified children were "expecting the App to open in the watch." Instead they "could not answer anything on the watch." Children wanted an expandable notification with a reply action, to allow their medication administration and pain levels to be directly recorded from the watch.

Phone App

In comparison to the smartwatch, problems were identified within the phone app.

Although the perceived usability of the app was reported as simple (8/12, 66.7%) and quick (9/12, 75%), only half of the participants found learning to use the app easy (6/12, 50%). Furthermore, only a small number of children liked the app (3/12, 25%), and none described the app as fun (0/12, 0%), impairing acceptability. Written feedback revealed participants were seeking a unique in-app experience through demographic "personalisation."

Web-Based Platform

The usability of the web-based platform was reported as simple (9/12, 75%) and quick (10/12, 83.3%). However, only 7 participants reported it was easy to learn (7/12, 58.3%). Similar to the app, only half of the participants reported the platform as useful (6/12, 50%) or were satisfied (6/12, 50%). Further, only 2 participants reported the platform to be fun (2/10, 16.7%). Written feedback resulted in the following theme: interconnections. Participants wanted to see a comparison between the 3 modules, medication adherence, pain levels, and physical activity, to explore if any relationships exist. A participant explained the following: "has the potential to be helpful if I could access the physical activity [and medication adherence] results in line with my pain" (child 7).

Parent Survey Feedback

The response rate to the survey among parents was 100% (12/12). The results of the quantitative section of the survey are presented in Table 3.

Table . Quantitative survey results: parent version (n=12).

Parents survey questions	Smartwatch, n (%) agree	App, n (%) agree	Web-based platform, n (%) agree
Easy to learn	11 (91.7)	8 (66.7)	7 (58.3)
Simple to use	11 (91.7)	9 (75)	8 (66.7)
Comfortable in supporting my child	11 (91.7)	11 (91.7)	10 (83.3)
Supporting my child was quick	10 (83.3)	8 (66.7)	8 (66.7)
I did not need to prompt my child	7 (58.3)	5 (41.7)	3 (25)
My child was independent	9 (75)	8 (66.7)	5 (41.7)
Information is clear and well organized	10 (83.3)	8 (66.7)	7 (58.3)
The system is error-free	10 (83.3)	3 (25)	10 (83.3)

Smartwatch

Most parents' responses supported the usability and acceptability of the smartwatch. Parents reported the watch was easy to learn (11/12, 91.7%) and simple to use (11/12, 91.7%). However, only 9 parents reported children could independently use the watch (9/12, 75%), and 7 parents did not need any prompting (7/12, 58.3%). No written feedback for improvement was recorded.

Phone App

Most parents felt comfortable supporting their child (11/12, 91.7%) and agreed using the app was simple (9/12, 75%). However, only a small number of parents did not need to prompt their child to use the app (5/12, 41.7%), or found the system error-free (3/12, 25%).

> *I don't think the app is working properly. [parent 5]*

To improve the app, written feedback suggested simplification, to ensure the app directly aligned with their child's needs. A parent explained the following: "simplified interface by removal of unnecessary buttons" (parent 6).

Web-Based Platform

Parents reported that they were comfortable in supporting their child when using the platform (10/12, 83.3%), and found the system to be error-free (10/12, 83.3%). However, less than half reported that their child could independently use the platform (5/12, 41.7%), and only 3 parents did not need to prompt their child (3/12, 25%). Suggested improvements included "improving the activity rings [for the physical activity module]" (parent 3).

Modules Within the App

Medication Adherence Module

Child Usability

Half of the participants agreed medication reminders were helpful (6/12, 50%), sent at the right time (6/12, 50%), and not bothersome (7/12, 58.3%). There were also no reported adverse events (12/12, 100%).

Child Acceptability

Less than half of the participants were satisfied with the medication module (5/12, 41.7%). Even less agreed that the response list was clear (2/12, 16.7%). Only 3 children would continue to use the medication module (3/12, 25%). Suggestions for improvement included flexibility. Rather than asking the research team to update their medications, children wanted to "self-change medication times [within the app]" (child 2) and "add or remove medications [within the app]" (child 12).

Parent Satisfaction

Parents were also not satisfied with the medication module (5/12, 41.7%), resulting in the following theme: comment fields. They wanted to see a broader range of data collected that aligned with their child's needs. For example:

> *add comment fields to record medication symptoms such as nausea from Methotrexate, headaches from Humira, exhaustion and brain fog. [parent 9]*

Pain Level Module

Overview

Children agreed recording pain was helpful (8/12, 66.7%), how to record their pain was clear (10/12, 83.3%), and responding to the pain reminders was not bothersome (7/12, 58.3%). There were also no adverse events reported (12/12, 100%). However, less than half were satisfied (4/12, 33.3%) and would continue using the pain module (6/12, 50%). Children were underwhelmed by the eVas response to their pain. When they entered their pain level on the numerical line and pressed confirm, only the numerical value between 0 and 10 emerged, describing their pain.

> *When you put your pain in nothing happens. [child 1]*

This resulted in the following theme: conferment. Children suggested that the pain score should include gamification or the use of "visual aids, which may be of benefit."

Similar to the feedback from the medication module, children also wanted flexibility. Although pain scores could be added at any time in the app, children wanted to be able to self-adjust their pain-reporting notification time within the app.

> *I wanted to change my pain time. [child 5]*

Parent Satisfaction

Most parents were satisfied with the pain module (8/12, 66.7%). However, parents expressed, again, wanting to "record" additional information. Further supporting the comment fields theme, this would allow them to document “joint/s the pain is in” (parent 3) and “potential contributing factors for pain such as weather, over-exertion” (parent 9).

Physical Activity Module

Child Usability

Children were overall satisfied with the physical activity module (9/12, 75%). Most followed (8/12, 66.7%) and understood their physical activity levels (8/12, 66.7%) and agreed that the module increased their physical activity (7/12, 58.3%).

Child Acceptability

Half the children agreed that recording their physical activity was helpful (6/12, 50%) and would like to continue using the physical activity intervention (6/12, 50%). No adverse events were reported (12/12, 100%).

Written feedback suggesting how to improve this module included a graphical illustration. Children reported they needed more graphical representation of their daily and weekly physical activity levels.

> *Have the physical activity show more details [child 1]*

Parent Satisfaction

More than half of the parents were satisfied with the physical activity module (7/12, 58.3%), and their feedback on improvements aligned with children, suggesting more details, such as “a break-down of metrics” (parent 7).

Overall Satisfaction With InteractiveClinics

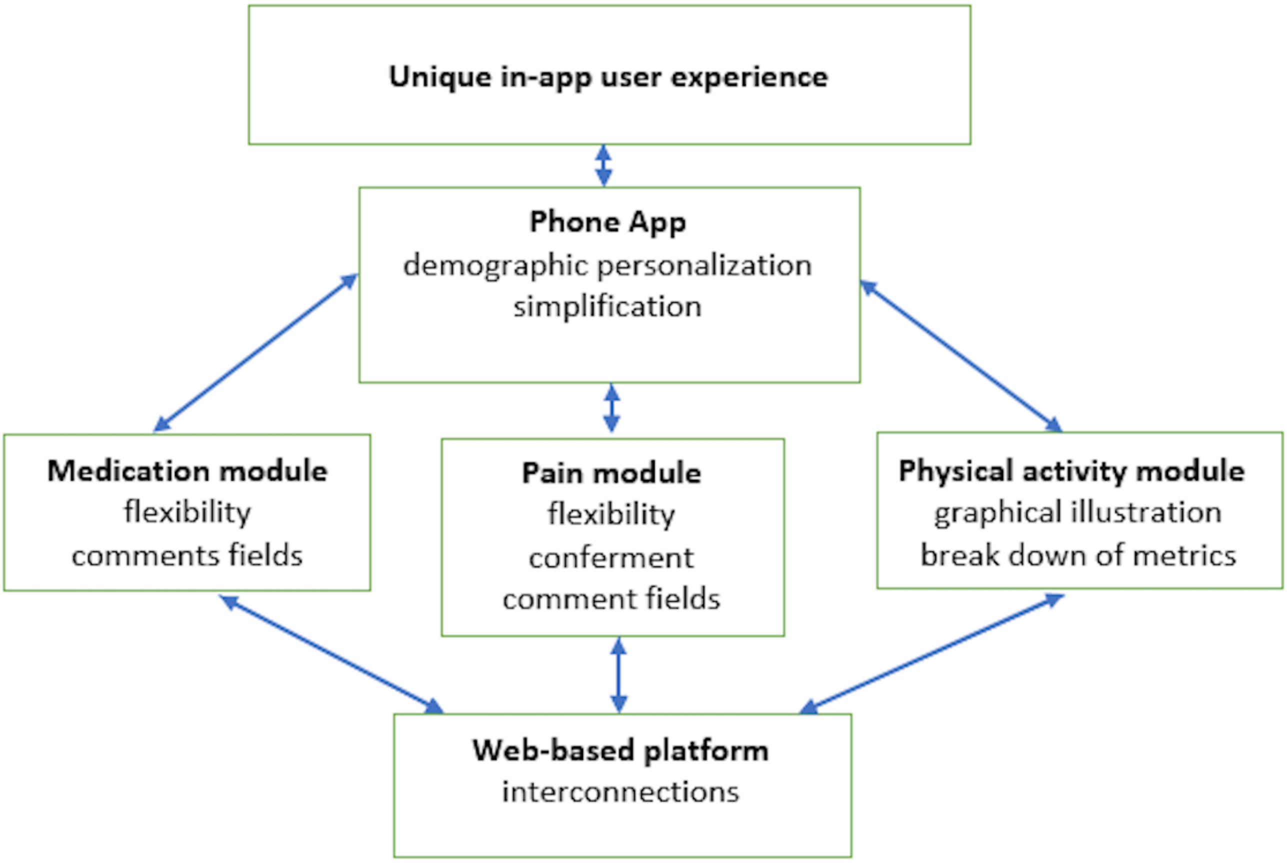
Overall, most children found all the information on InteractiveClinics easy to understand (9/12, 75%). However, only 5 children reported that the information collected met their needs (5/12, 41.7%), and 4 children reported that it would support their doctor with their care (4/12, 33.3%).

In contrast, most parents felt InteractiveClinics was appropriate to address their child’s needs (10/12, 83.3%). They found the information useful (8/12, 66.7%) in supporting their understanding of the effects JIA had on their child (8/12, 66.7%) and would use InteractiveClinics again (6/12, 50%). Importantly, 7 parents reported that InteractiveClinics would support their child in their next pediatric rheumatology consultation (7/10, 58.3%).

> *We found the App very useful. My child required no prompting to record her pain levels and it was good for me to understand her level of pain.* [parent 6]
>
> *I think it will be very useful in the future.* [parent 4]

Summing up the feedback on all key areas in InteractiveClinics, participants wanted a unique in-app experience (Figure 5).

Figure 5. Coding tree representing the analyzed content.



Discussion

Principal Findings

This study sought to evaluate the usability and acceptability of InteractiveClinics for children (aged 10 to 18 years) living with JIA. A unique feature of InteractiveClinics is the multimodal approach it uses to support the 3 key management areas in JIA treatment: medication adherence, pain, and the retention of physical activity. InteractiveClinics was supported through a commercial smartwatch, customized phone app, and web-based platform.

This study exposed both the strengths and weaknesses of InteractiveClinics. Most children and their parents liked the watch and web-based platform, finding it easy to learn and simple to use. They were satisfied with the pain and physical activity module, and no adverse events were reported. However, there was also the need for improvements. Children identified usability and acceptability barriers that hindered uptake, particularly in the phone app. This finding is important because user feedback can be vastly different from how the intervention was planned to be used [70]. To improve InteractiveClinics, children wanted a unique in-app experience through more personalization, simplification, flexibility, conferment, comment fields, graphical illustrations, a breakdown of metrics, and interconnections.

Suggestive Improvements

The importance of personalization is that it provides children with choice, autonomy, and ownership when using technology [71]. This is achieved by enabling children to customize the app features to suit their needs [72] and providing more feedback, on an individual level [73].

Parents also requested more simplification by removing all the buttons that were not relevant to their child. Other studies have also requested removing any complexities. DeForte et al [74], for example, reported children only wanted simple buttons. This would also support a child with a disability or low level of literacy, improving their ability to navigate the app [75].

In addition, the app needed to be more flexible. Children wanted to be able to change their medication response times within the app, earlier or later than the previously selected notification times given to the research team (SB). Rather than being reliant on the research team to update their medications, they wanted to adjust the response times to work around their activities. Interestingly, a systematic review of medication apps for adults, reported that the main components that foster medication adherence were reminders and importantly, medication-tracking histories [76]. Therefore, future changes will be made to InteractiveClinics to provide users control over their notification reminders, to ensure an accurate medication history is recorded.

Further, children wanted more from the pain module; instead of the numerical scale confirming their pain recording, they wanted more exciting conferment. In contrast, children with cancer pain in a phone app study requested the numerical scale instead of the pediatric face scale using smiley faces [77]. Therefore, it was not surprising then when children suggested more engaging gamification. Yet, very few studies have considered gamification mechanics as part of their pain assessment, despite the evidence suggesting they are liked and can increase motivation [78]. Indeed, this is certainly an area in need of further research.

There was also an overwhelming response from parents to include comment fields to record additional information such as medication-induced side effects. This is important because a recent study identified that two-thirds of children with JIA, within 1 year of diagnosis, experience side effects that have an impact on their life [79]. Understandably, concerns about these side effects can result in the termination of their treatment, posing the risk of increasing disease activity [80]. Therefore, it is imperative for InteractiveClinics to collect detailed input from children on what occurs between pediatric rheumatology appointments, to gain a more comprehensive overview of disease activity and adverse events [81], enabling timely re-evaluation and mitigation strategies to be put into place, rather than merely relying on the assessment of pain and active joint count at each visit [82]. Permitting suitable changes to treatment such as prescribing folate to reduce methotrexate-induced nausea [17,83,84] or brain fog [85], changing the route of administration [17,84], splitting doses, or altering the rate of absorbency [20] can reduce the risk of disease burden and further polypharmacy in adulthood [19].

For the physical activity module, children reported wanting more graphical illustrations representing their physical activity. According to the World Health Organization, children between the ages of 10 to 18 years are in a phase of life between childhood and adulthood where health behavior can be greatly influenced. Therefore, they are in need of age-appropriate comprehensive information [86], as they are active agents in their own development [87]. A similar study that used an activity tracker, app, and web-based profile also reported the need for more detailed feedback. Children, instead of a similar traffic light system, wanted the see the actual step count [88] (in other words, the breakdown of metrics).

To improve the app and web-based platforms' usefulness, children also wanted to see interconnections between the medication adherence module, pain level module, and physical activity module to, for example, determine the impact pain or medications may have on physical activity levels. This is important because each of these modifiable risk factors can affect another [15,49]. Demonstrating a correlation between this information could also be useful for the pediatric rheumatology team to better understand disease progression or remission, therefore facilitating adjustments to treatment accordingly, and also to avoid the impact JIA can have on development, physical function, and health-related quality of life [15,49].

Clinical Importance

An important clinical finding in this study was parental endorsement. Parents, in contrast to children, felt InteractiveClinics was useful in addressing their child's problems by helping them understand the effects JIA had on their children. This is an important finding because parents' narratives of their child's condition often remain unmet [89]. By gaining self-awareness, the parent may gain a more insightful understanding of their child's status on treatment that may be interfering with their progress [89]. In addition, parents then examine their own views and behaviors that can also contribute either positively or negatively to their child's health outcomes, because children are observational learners [90]. For example, a parent's fear and catastrophizing can result in protective behaviors and avoidance of treatments, therefore impairing their child's functional ability [90], suggesting the importance of digital health care in educating and empowering parents.

Overall, the children and parents included in this study, through their own lived experience, were incredible collaborators in improving the usability of InteractiveClinics, greatly extending our understanding of the unique needs of children with JIA. This is important, as there is criticism toward the current "treat to target" approach used in JIA management. Children and their parents are often not included when formulating treatment plans [82]. Yet, their goals of treatment are often different from those of the Pediatric Rheumatology teams because they are focused more on the present, rather than the long impact of the disease [82], emphasizing the importance digital health care can have in supporting child-centered and family-centered care [91].

Limitations

There are several limitations that need to be considered when interpreting this study's findings. First, this study only recruited a small convenience sample of 12 children and 12 parents, limiting generalizability. Although a small sample size (>10 participants) is typically used for usability testing[58], the suggestive inclusion to improve InteractiveClinics may not be representative of all children with JIA. Therefore, to overcome sampling bias, a larger, more diverse participant sample is needed across different demographic and geographical locations in the next stage of testing.

Also, due to the nature of this usability and acceptability study, consenting participants were actively prompted to be critical and provide written feedback on how the proposed digital health intervention could be improved. This may have limited the provision of any positive attributes.

In addition, the written feedback they provided may have not been as detailed as expected for thematic analysis. Patterns did emerge, and data saturation was reached; however, there was still a risk of research bias [69], so all authors internally reviewed and rereviewed emerging codes and themes against the original text during all stages of analysis.

Further Research

Further research is now needed to examine the potential challenges and limitations of incorporating InteractiveClinics into clinical practice. First, this research needs to focus on device access and digital literacy, because this study supplied all the equipment needed to participate and provided ongoing technical support. Second, the level of engagement and length of adherence among participants using the intervention needs to be considered, to clearly understand whether digital health care is an effective and sustainable intervention to support chronic disease management for children and their families.

A comparative analysis is also needed to compare InteractiveClinics to other digital health interventions targeting pediatric chronic disease. This would help with positioning the intervention within the broader digital health landscape and identifying any unique benefits that may be offered over existing tools, in order to find supportive and effective digital health solutions.

Interestingly, for JIA, 2 recent systematic reviews identified no similar digital health interventions that have used a multimodal approach to support chronic disease management [43,92]. In fact, most interventions were still at an early stage of development [43], and heterogeneity exists, making it difficult to compare their effectiveness [92]. Instead, the findings of these reviews helped to identify 3 specific areas that are needed in JIA management—symptom monitoring, physical activity promotion, and self-management development [92]—which were used to support the development of the 3 modules included in InteractiveClinics: pain level, physical activity level, and medication adherence. It is also important to note that no studies directly targeted medication adherence [43,92], yet early aggressive pharmacological treatment and the monitoring of side effects are keystones in JIA treatment [91].

Now, the future direction of InteractiveClinics is to use the feedback gained from the children and parents within this study to improve the usability of the intervention. The World Health Organization clearly reinforces the importance of doing this before commencing costly trials [58]. Then, the next step is to test the intervention's efficacy and effectiveness [58]. This will be achieved through conducting a pilot randomized controlled trial, which will remove the sampling bias identified in this study and determine the intervention's effectiveness on health outcomes for children with JIA and children living with other chronic conditions.

Conclusion

Most children and their parents liked using the smartwatch and web-based platform; they found it easy to learn and simple to use. They were also satisfied with the pain and physical activity modules. However, usability and acceptability barriers that hindered uptake were identified in the phone app and medication module. Children sought a unique in-app experience, and their suggestive improvements included more personalization within the app; simplification by removing all nonrelevant links; flexibility in response times; improved conferment through gamification; additional comment fields for the input of more data, such as medication side effects or pain-related symptoms; more detailed graphical illustrations of the physical activity module, including a breakdown of metrics; and importantly, interconnections between the modules, because medication adherence, pain levels, and physical activity can each influence the other. Further research is now needed to ensure these inclusions are combined with standardized comprehensive assessments and evidence-based behavior change strategies to promote user adoption and advancement of new, validated digital health interventions in pediatric rheumatology clinical care.

Abstract

Background: Studies have highlighted significant challenges associated with the transition from pediatric to adult health and social care services for youth living with childhood-acquired disabilities and their caregivers. Patient navigation has been proposed as an effective transitional care intervention. Better understanding of how patient navigation may support youth and their families during pediatric to adult care transitions is warranted.

Objective: This study aims to describe the preferred adaptations of an existing web-based platform from the perspectives of youth with childhood-onset disabilities and their family caregivers to develop a web-based peer-patient navigation program, Compassionate Online Navigation to Enhance Care Transitions (CONNECT).

Methods: A qualitative descriptive design was used. Participants included youth living with childhood-acquired disabilities (16/23, 70%) and their caregivers (7/23, 30%). Semistructured interviews and focus groups were conducted, digitally recorded, and transcribed. Thematic analysis was used to analyze the data and was facilitated through NVivo software (Lumivero).

Results: Participants desired a program that incorporated (1) self-directed learning, (2) a library of reliable health and community resources, and (3) emotional and social supports. On the basis of participants' feedback, CONNECT was deemed satisfactory, as it was believed that the program would help support appropriate transition care through the provision of trusted health-related information. Participants highlighted the need for options to optimize confidentiality in their health and social care and the choice to remain anonymous to other participants.

Conclusions: Web-based patient navigation programs such as CONNECT may deliver peer support that can improve the quality and experience of care for youth, and their caregivers, transitioning from pediatric to adult care through personalized support, health care monitoring, and health and social care resources. Future studies are needed to test the feasibility, acceptability, usability, use, and effectiveness of CONNECT among youth with childhood-onset disabilities.

Introduction

Background

Young people with childhood-onset disabilities (eg, acquired brain injury and cerebral palsy) are living longer than previous generations owing to advances in medical knowledge and clinical management [1,2]. Research and advocacy efforts have focused on ensuring continuous access to health, education, and social services for youth transitioning from pediatric to age-appropriate and developmentally appropriate adult health care services, to support autonomy and maximize independence in society for capable youth [3-7]. Many youths who age out of pediatric services experience a gap in services designed to meet their adult health and social needs [6,8-12]. Furthermore, finding and accessing the appropriate adult care providers and services is often challenging [8,12,13]. Adult health care providers often lack training related to aging with a childhood-onset disability and supporting the unique health and psychosocial needs of young adults [7,14-16].

Youth and young adults living with disabilities acquired in childhood often have chronic health issues that require frequent health care visits, and yet, few receive the comprehensive services and support they need [8,12,17]. Without seamless, accessible, and appropriate services, health concerns may remain poorly managed or undetected, increasing the risk of preventable secondary health complications and comorbidities in young adulthood [18-21], which may lead, in turn, to increased or inappropriate reliance on acute health services (eg, hospitalizations) [7,13,22]. For example, young adults with disabilities aged between 19 and 27 years, including cerebral palsy, spina bifida, and acquired brain injuries, visit physicians and are admitted to the hospital, on average, 9 times more than that among the general population [17,23]. Results from studies conducted in Alberta, Canada, indicate that individuals providing care for children or adolescents with complex care requirements frequently experience feelings of being overwhelmed, fearful, and isolated [24]. Collectively, this evidence highlights gaps in appropriate care for a growing population of transition-age young adults with disabilities (eg, aged 18-30 y) and their caregivers [7]. Closing this gap and ensuring the successful transition from pediatric to adult services is vital to improve the health and well-being of youth and young adults living with disabilities.

Despite the critical importance of successful transition, there is limited evidence about effective transitional care interventions for young adults with childhood-onset disabilities. Most evaluation studies have been descriptive in nature [7], lack rigor in design [25], and often do not use instruments that are valid and reliable for meaningful evaluation [26]. Furthermore, high variability across practice settings and the siloed nature of health and social services have led to issues with transferability to practice settings and community contexts [7]. Previous evidence syntheses in this area, including a systematic review [25], and clinical guidelines [27] have focused mainly on managing chronic medical diagnoses and failed to address the specific and additional needs of the youth with disabilities. It is important to address this gap, as young adults with disabilities may have diverse requirements as they prepare to transition to adult care settings [28,29]. Thus, there exists a pressing need to develop and implement culturally sensitive, accessible, effective, and fiscally sustainable approaches to youth transition. Cost-effective transitions for young adults with childhood-onset disabilities can be expected to have positive, far-reaching impacts on health and social care systems [30].

Although case navigation is a recognized effective transition intervention [31], a recent systematic review found no studies of peer navigation for transition-age youth with childhood-acquired disabilities [7]. Patient navigation emerged in the 1990s as a model of transitional support across health care settings [32,33]. Patient navigation has been defined as a partnership among the patient; family; members of the care team; and patient navigator, who facilitates timely access to health or community resources and fosters self-management and autonomy through education and emotional support [34]. Patient navigators can be peer (lay) navigators (eg, peers with lived experience) or professional navigators (eg, nurses) [32]. Although patient navigation has historically been implemented in the context of adults with cancer, recent programs have focused on children and youth with complex, chronic conditions [35,36]. Patient navigation has been posited as an intervention for youth and young adults with disabilities by reducing barriers to access and integrating various services in a timely, coordinated manner, thus facilitating seamless transitions in care [37]. For example, NaviCare/SoinsNavi is a professional patient navigation center in Canada that is specifically designed to provide support and assistance to children, youth, and their families who are dealing with complex care needs [38]. Patient navigation centers such as NaviCare/SoinsNavi play a crucial role in helping individuals and families navigate the complex health care system by offering guidance, information, and coordination of care [38]. Peer navigation is generally defined as an advantageous interaction between a peer navigator and a patient and traditionally involves a trained peer who provides education and support to a patient to promote recommended health care use behaviors (eg, health screening, attending the recommended care events, and adhering to treatment or follow-up care) with the goal of optimizing care [39,40]. Specifically, through the provision of emotional, informational, and appraisal support, peer navigators can increase patient self-efficacy and, consequently, promote the achievement of recommended health behaviors. However, so far, it is not well known whether and how peer navigation can contribute to the delivery of integrated care for youth with childhood-acquired disabilities transitioning to the adult health care system and community services. Thus, studies of the role that patient navigators may have in assisting during these transitions and specific components of such an intervention are needed.

The NexJ Health Wellness Platform is a web-based platform that has been previously used to build peer navigation programs for adults with chronic illness (eg, cancer [41]). The profile and dashboard display users' personal information that they wish to share with their circle of care members (eg, peer navigators, health care providers, and families). The profile also includes contact information such that the youth or care team can connect with one another via the platform. The dashboard is adaptable, such that the youth can personalize it with their own background or goals. Points are assigned as individuals meet their goals. The care plan is also where navigators can note any action item that youth should be taking to manage their health (eg, medications to take). Related to this aspect, there is a scheduling feature on the program, which is very similar to a digital calendar, where the clients can set up an appointment with their care team members, who will receive this request and schedule the appointment. Reminders of appointments will be facilitated through the scheduling feature. The health library contains resources provided by the study team that are verified by health care professionals and organized into different categories according to conditions, disabilities, mental health, socialization, mindfulness, and health needs. In phase 1, we received initial ideas about how the platform should be modified to build the Compassionate Online Navigation to Enhance Care Transitions (CONNECT) platform, which are presented as part of phase 2, as described in the following sections.

Objective

This study aimed to describe the preferred adaptations of this existing web-based platform from the perspectives of youth with childhood-onset disabilities and their family caregivers to develop a web-based peer-patient navigation program called CONNECT. CONNECT aims to be a web-based tool in peer-patient navigation for youth with childhood-acquired disabilities transitioning to adult health care and community services. The development of an evidence-based, patient and family–informed, web-based peer navigation intervention for young adults with childhood-onset disabilities holds the potential to improve transitional care experiences and outcomes [42].

Methods

Study Design

We conducted a qualitative descriptive study using semistructured interviews and web-based focus groups [43,44]. Qualitative description is a commonly used methodology in health care research, whereby the primary goal is to describe a complex construct by staying close to the data elicited from the perspectives and in the words of participants with lived experiences [45]. A qualitative descriptive approach is based on individuals' experiences and points of view—in this case, on peer navigation [38]. We have reported our methods as per the COREQ (Consolidated Criteria for Reporting Qualitative Research) [46].

Ethical Considerations

The protocol for this study was approved by the (University Health Network Research Ethics Board REB 22-5023). Informed verbal and written consent were obtained from all participants.

Setting

The study was conducted in Ontario, Canada, where peer navigation has recently emerged as a novel model of pediatric care provincially [47] but where little is known about patient navigation in the context of transition-age youth with disabilities.

Sampling and Recruitment

A convenience sampling strategy that combined criterion and snowball sampling was used to recruit English-speaking youth, aged between 19 and 30 years with cerebral palsy, intellectual disabilities, or acquired brain injury, and their caregivers [48]. Individuals who were unable to communicate in English were excluded from the study. The recruitment process primarily involved 2 health care organizations that maintain email lists of clients interested in research projects related to youth living with disabilities. The research coordinator used the email list to send invitations to individuals, and in addition, administrators at these organizations verbally promoted the study during group support sessions. Furthermore, social media advertisements were used to reach a wide audience of eligible participants. As part of the snowball sampling approach, at the end of the interview, participants were encouraged to actively inform their peers about the study, facilitating the expansion of our participant network. Eligible participants were subsequently contacted by a study coordinator to obtain informed verbal and written consent. It is important to note that none of the participants had previous affiliations or associations with the research team, ensuring impartiality in data collection.

We initially set a predetermined sample size goal of 15 to 25 participants, which was informed by existing guidance for qualitative research, where the aim is to reach a point of saturation at which new data no longer significantly contribute to the emergence of additional themes or insights [49,50].

Data Collection and Analysis

Overview

Data collection and analysis occurred in 2 phases. Phase 1 aimed to obtain insight about the initial, desired characteristics of a web-based patient navigation program. Before phase 2, we incorporated the findings from phase 1 into the CONNECT program. Phase 2 aimed to obtain feedback about the preferred adaptations of an existing web-based platform to further develop the CONNECT intervention. We also collected information about sociodemographic characteristics to help contextualize the interview data.

Phase 1

Semistructured interviews were conducted using an interview guide developed by the research team (refer to Textbox 1 for a sample interview guide). Before the interview, participants were provided with a definition of patient navigation to help orient them to the topic area. Then, 2 experienced qualitative researchers (KMK and TSJL) conducted all interviews over the phone. Each participant completed a single interview ranging between 30 and 75 minutes. Interview were audio recorded and professionally transcribed verbatim. Immediately following each interview, the interviewer wrote reflexive memos about the interview. In total, 61% (11/18) of youths and 39% (7/18) of caregivers participated in the interviews (phase 1).

Textbox 1. Sample interview questions.

If money/resources were no object, what would the "ideal" patient navigation intervention look like to you?

- Not applicable

Thinking about your experience as you transitioned from pediatric to adult health and social care services, how might a patient navigation program have been helpful when you/your family member transitioned (ie, to adult healthcare, community resources/services)?

- What benefits do you think such a program would provide to patients and family caregivers that current support, training, resources, programs, services, etc. you receive do not?

From your perspective, what are the ideal components of a patient navigation intervention?

- In what ways, specifically, do you think a patient navigator could help provide education and support?
- What can/should the navigator do?
- What information can/should the navigator provide?
- What information about the program is needed to inform people who are taking part in the intervention?
- What kind of training is needed for the navigators?

Interview data were thematically analyzed, whereby preliminary themes were derived from ongoing data collection and analysis through a coding process [51,52]. First, all transcripts were reviewed for accuracy by author, KMK, who compared the audio files with the transcript. During this process, any preliminary thoughts about the data were recorded. Next, all transcripts were reviewed independently by 3 investigators (KMK, TSJL, and SEPM) and coded using open coding procedures. Discussions around key ideas and codes in the data occurred through a series of weekly meetings to reach consensus on a codebook [51]. This codebook was then applied to the transcripts by 2 researchers (KMK and TSJL), under the guidance of the senior author (SEPM). The coded data were reviewed by the research team, who met at least once weekly to discuss similarities and differences across and within the coded data. This process occurred until preliminary themes were identified. Full-team meetings helped to refine the themes and their content [51]. The full research team comprised content and methodological experts (ie, experts in disabilities, health care transition research, health system research, and qualitative methods). Interviews were stopped when theme saturation was believed to have been achieved, as consistent redundancy was evident in the themes derived from participant experiences [51,53,54]. Data from these interviews were shared with technology developers of the NexJ Health Wellness program to inform the customization of the existing program. An existing web-based program, NexJ Health Wellness, was previously designed to support the monitoring and coaching of chronic diseases in adults.

Phase 2

Web-based focus groups were conducted where participants were introduced to the initial features of CONNECT that had been incorporated based on the feedback provided in the interviews (ie, phase 1). However, owing to scheduling difficulties (ie, unable to gather participants on the same day), we also offered participants individual interviews if they preferred. Of the 18 participants who were interviewed and had consented to be contacted for focus groups, 3 (17%) participated in the focus groups and 2 (11%) participated in individual interviews. Some participants who participated in the initial interviews did not participate in the follow-up focus groups or interviews; reasons included the following: their phone or email was not working, and thus, they were unreachable by the research coordinator, and time constraints (eg, work schedules and family obligations). Then, 6 new participants (ie, individuals who did not participate in the original interviews; n=1, 17% caregivers and n=5, 83% youths) were also recruited. Of these 6 participants, 3 (50%) participated in a focus group and 3 (50%) were interviewed individually. These individuals also completed the sociodemographic questionnaires. Overall, 2 focus groups, with 3 participants per focus group, and 5 individual interviews were conducted.

The focus groups lasted approximately 90 minutes and were facilitated by 2 experienced qualitative investigators (KMK and SEPM). A focus group guide (Textbox 2), informed by the preliminary analysis of and reflexive memos from the interviews, was developed by the first and senior authors. During the focus groups, the qualitative investigators strived to ensure that participants had equal opportunity to share their thoughts by using probes to ask individuals their own thoughts. A research assistant took field notes and memos during and after the focus groups [55]. As in phase 1, the research team explored the emergence of new themes as we conducted additional interviews and focus groups. When we reached a point where new interviews did not yield substantially new insights or themes and, instead, reinforced the existing ones, we made the informed decision to conclude the data collection phase.

Textbox 2. Sample focus group guide.

From your perspective, what qualities make an effective peer navigator (especially with the view to promoting quality of life and increased participation/integration in the community)? We are defining effective as a program that would help you in promoting quality of life and increased participation/integration in the community.

- What training should a peer navigator have to be effective?
- How often should the touch-points with peer navigators be?

Now thinking about the platform you've just seen/reviewed, what components/features here would you like/be helpful in your peer navigator program (or the program for your family member)? Why?

- What components would you dislike/not be helpful (and be helpful to you as a family member)? Why?
- Has the platform captured the issues that are important to you (ie, that you described before)?
- Are there any components not included that you would like to see?

We are interested in building an online peer navigation program that focuses on compassionate care. Do the features presented here promote the description of compassionate care you hold? Why or why not?

- If not, what could be added/amplified?

Is the platform easy to use and understand in terms of its eg, wording and the interface? Why or why?

- Are there ways that we could improve on these areas?

The individual interviews were conducted by the same 2 interviewers who led the focus groups, using the same guide. All focus groups and interviews were audio recorded and transcribed verbatim. Phase-2 data (ie, interviews and focus groups) were analyzed using the same thematic analysis process as the interviews [51,52]. Following this process, a more critical review of both the interview themes and focus group themes was conducted. Similarly, the coded data from both data sets were combined. Once completed, a side-by-side comparison of the individually coded transcripts was conducted during a team meeting. To help identify the major themes across the data, 3 research team members (KMK, TSJL, and SEPM) led the analysis by individually reviewing the coded transcripts, meeting minutes, and memos. The full investigation team then reviewed the preliminary major themes to reflect about salient ideas, which resulted in full-team discussion and subsequent follow-up discussions to clarify ideas. Hence, investigator and data triangulation were used to ensure the trustworthiness of the data [56,57].

Positionality of the Research Team

Qualitative researchers are urged to consider how their background and position affect the design, analysis, and reporting of their study [58]. The research team consisted of Canadian researchers with various backgrounds (eg, cultural) and education (eg, trainees, health care professionals, and researchers). Throughout the data collection and analysis process, the research team had frequent discussions to remain cognizant of their own positions and reflect about how these could influence the design of the intervention and the findings. This was the first time the research team had worked with the technology partner. None of the investigators experienced living with cerebral palsy. Throughout the data collection process, we upheld reflexivity by consistently engaging in critical self-reflection and modifying our interview and focus group guides accordingly. This iterative approach empowered us to enhance our questioning techniques and remain responsive to the emergence of new themes and valuable insights.

Results

Overview

In total, 24 participants participated in this study, with 5 (21%) participating in both phase 1 and phase 2. Of these 24 unique participants, 8 (33%) were caregivers (all women) and 16 (67%) were youths (n=11, 69% young women; n=5, 31% young men). Most of the caregivers (7/8, 88%) were mothers to a youth with a childhood-onset disability, and a participant was an aunt. Characteristics of the youths and caregivers are reported in Table 1. To secure anonymity, quotations include only the participants' group (ie, youth or caregiver), sex, diagnosis, and participant ID number. We have synthesized the findings from phase 1 and phase 2 in Figure 1 and Table 2.

Table 1. Characteristics of the participants (N=24).

Characteristics	Youths (n=16), n (%)	Family caregivers (n=8), n (%)
Sex		
Female	11 (69)	8 (100)
Male	5 (31)	0 (0)
Age (y)	3 (23)	7 (58)
Living environment		
Urban	15 (94)	8 (100)
Rural	1 (6)	0 (0)
Highest level of education		
Obtained high school	9 (56)	4 (50)
Obtained college or university	7 (44)	4 (50)
Ethnicity		
Asian	4 (25)	2 (25)
White	11 (69)	4 (50)
South Asian	1 (6)	0 (0)
Southeast Asian	0 (0)	2 (25)
Primary diagnosis		
Intellectual disability	8 (50)	N/A[a]
Cerebral palsy	5 (31)	N/A
Acquired brain injury	3 (19)	N/A
Primary diagnosis of care recipient

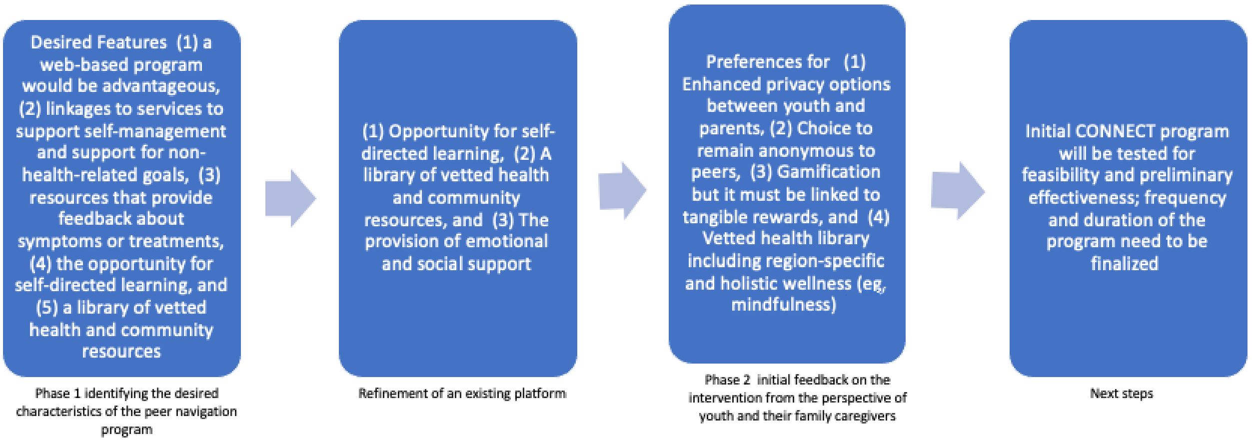
Figure 1. Summary of key findings categorized based on the phase. CONNECT: Compassionate Online Navigation to Enhance Care Transitions.



Desired Features (1) a web-based program would be advantageous, (2) linkages to services to support self-management and support for non-health-related goals, (3) resources that provide feedback about symptoms or treatments, (4) the opportunity for self-directed learning, and (5) a library of vetted health and community resources

Phase 1 identifying the desired characteristics of the peer navigation program

(1) Opportunity for self-directed learning, (2) A library of vetted health and community resources, and (3) The provision of emotional and social support

Refinement of an existing platform

Preferences for (1) Enhanced privacy options between youth and parents, (2) Choice to remain anonymous to peers, (3) Gamification but it must be linked to tangible rewards, and (4) Vetted health library including region-specific and holistic wellness (eg, mindfulness)

Phase 2 initial feedback on the intervention from the perspective of youth and their family caregivers

Initial CONNECT program will be tested for feasibility and preliminary effectiveness; frequency and duration of the program need to be finalized

Next steps

Table 2. Summary of themes.

Phases and themes	Description
Phase 1	
Advantages of web-based programs	• In this theme, participants expressed the advantages of a web-based program over in-person support, citing time-saving benefits and independence in navigating web-based resources. Some participants, especially caregivers, acknowledged limited technology knowledge and concerns but saw the potential for enhanced accessibility, particularly for non–health-related goals, through a web-based program.
Benefits of peer support	• Participants highlighted the benefits of peer support within the proposed program. They emphasized the importance of the peer navigator being trained in individualized, client-centered care and possessing knowledge about regional health and social services. Furthermore, participants stressed the significance of training the navigator in mental health support to aid in transitions from pediatric to adult services.
Core components of a navigation program	• Participants expressed their desires for several core components of a navigation program: • Patient education: Participants emphasized the importance of patient education to enhance their understanding of their condition and treatment options. They believed that this knowledge would empower them with the confidence to actively engage in shared decision-making regarding their health care. • Care coordination: Participants stressed the need for care coordination to enable collaborative, patient-centered, and team-based care across various health care settings. This aspect was seen as essential for ensuring seamless transitions in care. • Monitoring and coaching: Participants desired remote and mobile support for self-management of their health conditions. They expressed the need for ongoing monitoring and coaching from the research team to help them navigate their health care effectively.
Phase 2	
Logistical considerations for CONNECT[a]	• Participants discussed various logistical considerations for the CONNECT program. They emphasized the importance of specific aspects: • Navigator characteristics: Participants expressed a preference for peer navigators with similar life experiences and disabilities. • Value of appraisal support: Participants highlighted the need for the navigator to provide appraisal support, including feedback and evaluation. They suggested regular opportunities for participants to provide feedback and suggestions, with input reviewed by trained health care professionals to enhance the program. • Necessary infrastructure for accessibility: Participants discussed the importance of accommodating the differences in abilities when using CONNECT.
Balancing youth confidentiality with caregiver involvement	• Both youth and caregivers highlighted the importance of personalized control over the information shared via CONNECT. Participants believed that navigators could help facilitate discussions with caregivers. Caregivers also wanted control over specific platform functions to prevent unintended actions, suggesting additional confirmation steps for certain actions owing to concerns about unintentional changes.
Value of multimodal communication	• Participants valued the program's multimodal communication options, including phone calls, instant messaging, email, and video calls, with the ability to initiate contact themselves. Digital text-based communication was seen as providing fast access to psychosocial support and enhanced privacy for sensitive discussions.

Holistic and developmentally appropriate care needs	• Participants emphasized the importance of holistic and developmentally appropriate care within the CONNECT program:
	  • Developmentally appropriate care: Participants believed that receiving care through CONNECT should consider their unique developmental stages, life events, and personal goals, making their participation in the program meaningful.
	  • Point system: Many youth participants did not find value in the point system incorporated into the generic program, especially if points were not linked to tangible outcomes or rewards.
	  • Health library: Participants responded positively to the health library, viewing it as a trusted and credible source of health information and comparing it with a more reliable version of a Google search.
	  • Forums: Regarding the community forum, participants discussed the issue of anonymity and its impact on their ability to connect with peers. They believed that not remaining anonymous could lead to the potential for meaningful peer connections, providing additional opportunities for mentorship during transitions in care.

[a] CONNECT: Compassionate Online Navigation to Enhance Care Transitions.

Phase 1: Development

Overview

During the phase-1 interviews, participants described their desires for a web-based patient navigation program. The research team worked with participants during the interviews to identify features for the first iteration of the novel, web-based CONNECT program. Phase 1 consequently identified themes related to the advantages of a web-based patient navigation program facilitated by peer support and the core categories desired in a web-based peer navigation program.

Phase 1—Theme 1: Advantages of Web-Based Programs

Several participants explained that a web-based program would be advantageous in comparison with in-person support owing to time-saving benefits related to not needing to travel. Many participants indicated that they would feel comfortable in navigating the web-based navigation program, whereas some caregiver participants highlighted having limited knowledge about technology and associated worries of being unable to support their care recipient:

> *I think if you can, implement the program using technology as best as you can because that way, I can do it on my own time without finding a drive and I can do all the things that I need to do online independently without assistance. If I do need help, then it's okay, but I always do it independently when tech. issues come up.* [Youth 10; female; cerebral palsy]
>
> *I guess, not too many families struggle with technology I have, but I don't know how to fix things. Like, as a single mom, working full-time, I have a child with very, very severe disabilities, not really able to use technology like this. So, I'll need to learn how to use it to help him.* [Caregiver 2; female; cerebral palsy]

Although participants reported working with various care providers to support and maintain their health during transitions in care, many were unfamiliar with opportunities for self-management and support for non–health-related goals. Youth believed that that a web-based program would make such services more accessible:

> *I wish the services, specifically life skills and things like that were more easily accessible, because they're only in a couple of places right now and you have to have the time available to go to certain sessions wherever they're happening. And I wish they were more frequent or accessible maybe online and just to be able to talk to people even just for five minutes if you have a question about a goal rather than having to book an appointment a year in advance to see five different people at the same time. It's not always the best way to get the help that you need, so the program should help with that by being online with one peer.* [Youth 8; female; cerebral palsy]

Phase 1—Theme 2: Benefits of Peer Support

Participants noted that, in addition to being a peer, the navigator should be someone who is trained in individualized, client-centered care with knowledge about the existing health and social services in the region, if possible. Participants also highlighted the importance of training the navigator in mental health support to facilitate the transitions from pediatric to adult services.

Participants highlighted numerous components to be considered for the program. Considerations included resources that provided feedback about disability-related symptoms or treatments; opportunity for self-directed learning; library of vetted health and community resources; and ability to allow for human connection including ongoing communication, compassion, and understanding. Participants validated the notion of peer navigators as being ideal to provide compassionate, appropriate care because they can provide information and emotional support and facilitate health care navigation from a lived experience perspective. Participants also highlighted a general need for support from their navigator with managing personal goals of care and nonmedical transitions (eg, desire to find employment).

Despite consensus on these preferences, participants highlighted that a degree of personalization would be required in the navigator's approach. Participants believed that the peer navigator is uniquely positioned to provide this individualized support. There was no consensus among participants about the duration for or frequency in which an individual would want to interact with their peer navigator or use the CONNECT program. Thus, participants highlighted that the program should be available for as long as the individual felt that they needed to be enrolled, as transitions can range in time. A participant shared the following:

> *But maybe 6-12 months or 12-18 months for 2 hours. The reason I say two hours is because there are a lot of things that you have to learn and express, right? If people get the hang of it somewhere, I guess they can go on their own. But if they still have problems with it, or like accessing it even, they can stay longer. Every individual is different, so I would like to see it tailored to their own individual needs.* [Youth 2; male; cerebral palsy]

Phase 1—Theme 3: Core Components of a Navigation Program

Participants described desiring the following: education to improve the understanding of their condition and treatment options for confidence in shared decision-making; care coordination to enable collaborative, patient-centered, team-based care across multiple care settings; and monitoring and coaching to provide remote and mobile support to help self-management, until they were built into a functioning prototype. Participants also described desiring multiple channels and modes of communication to support participants in achieving their health and wellness goals, whereby the peer navigator is the first point of contact for participants.

Phase 2: Feedback About the Features of the Initial CONNECT Program

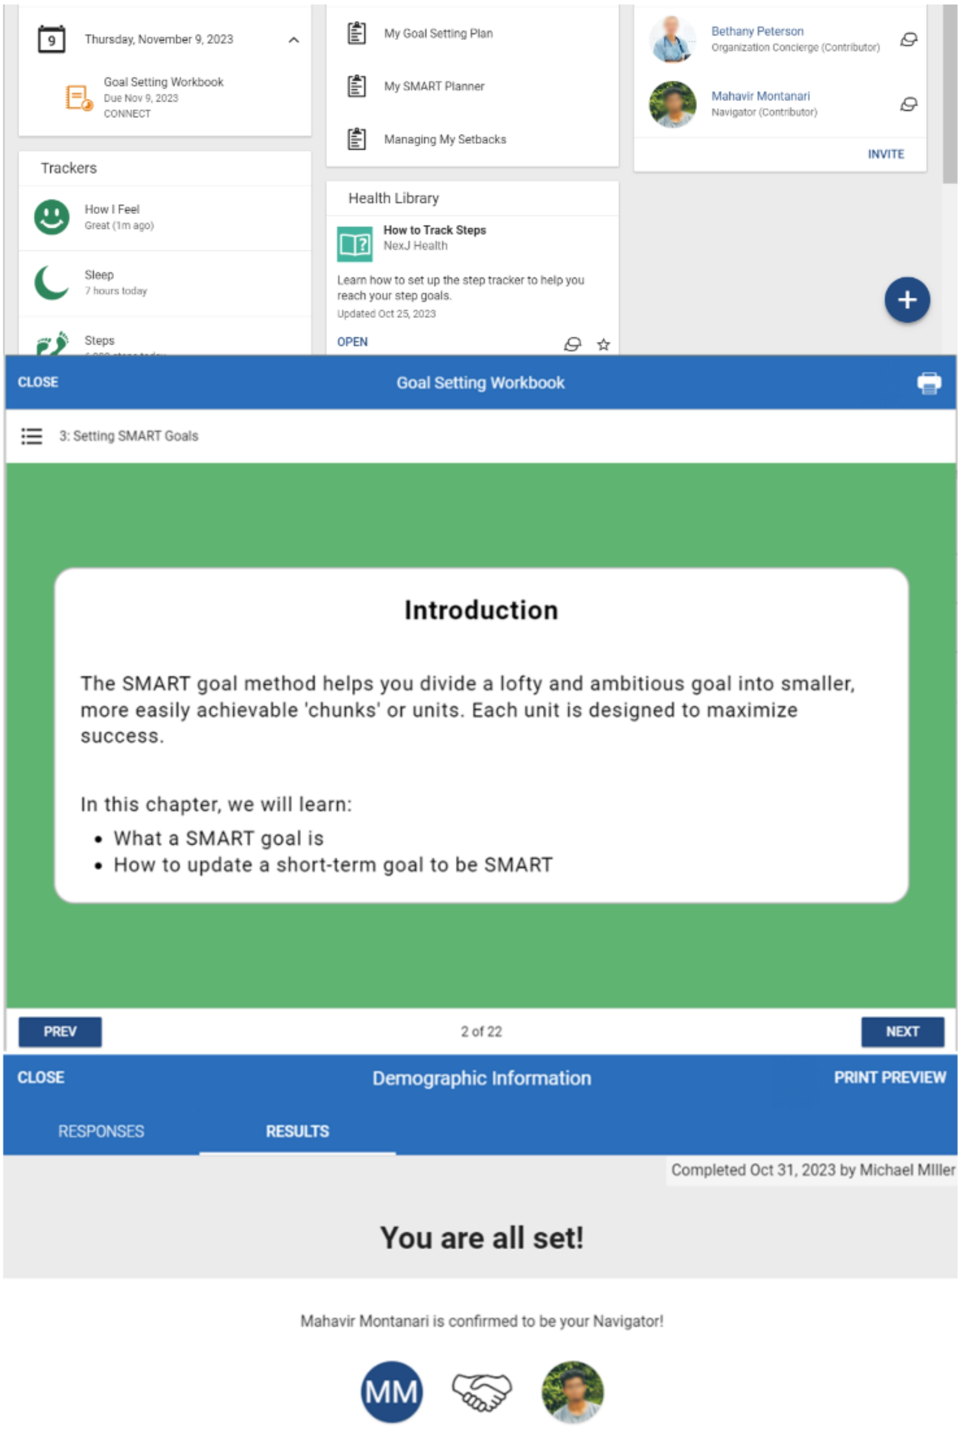
In this section, we have outlined the key themes related to the logistics, parental control, multimodal communication, and varied needs for support regarding the use of CONNECT. Figure 1 presents the collective learnings across phase 1 and phase 2.

Phase 2—Theme 1: Logistical Considerations for CONNECT

Overview

Participants described a wide range of logistical considerations related to the CONNECT program. These included the training of the patient navigator, value of appraisal support, and infrastructure needed for CONNECT. We have illustrated these changes in an updated image of the CONNECT system in Figure 2.

Figure 2. Updated Compassionate Online Navigation to Enhance Care Transitions platform.



Learn how to set up the step tracker to help you reach your step goals.

Introduction

The SMART goal method helps you divide a lofty and ambitious goal into smaller, more easily achievable 'chunks' or units. Each unit is designed to maximize success.

In this chapter, we will learn:

- What a SMART goal is
- How to update a short-term goal to be SMART

Completed Oct 31, 2023 by Michael Miller

You are all set!

Mahavir Montanari is confirmed to be your Navigator!

Subtheme 1: Navigator Characteristics

Participants described their ideal peer navigator as someone with similar life experiences and disabilities. Participants described that they would prioritize someone with these similar experiences over someone of the same age or sex. An individual shared the following:

> *As a person of colour, and as a self-identifying woman, I would feel more comfortable if someone my age and my demographic were to provide me information, compared to, let's say just purely an example, of a cis white man.* [Youth 19; female; intellectual disability]

Another youth participant described this by sharing the following:

> *It's just nice to have a person who lived through that experience, and know that somebody has been through it. Actual lived experience is very good versus just a doctor telling you some theoretical things, versus a real person.* [Youth 14; male; acquired brain injury]

Another caregiver shared the following:

> *I prefer my son connect with a person who has the same condition. Especially in my son's case, it's a little bit different because he's underweight, he is suffering from dysphasia and he has a G-Tube inserted in his stomach....So, when you have these resources and connect with other persons who have the same condition, it would be very helpful for me and my son both in critical and non-critical situations.* [Caregiver 7; female; cerebral palsy]

Having time to meet the navigator before receiving care or advice from them was reported as an important facilitator to developing a trusting relationship.

Subtheme 2: Value of Appraisal Support

Participants also highlighted the importance of and need for the navigator to assist with appraisal support (ie, evaluation and feedback), particularly in providing feedback to the navigator and other health care providers. A participant shared the following:

> *I think also maybe just giving them the option to provide feedback and suggestions as needed so maybe having it once a week, or two weeks, or something where a form goes out for them to provide feedback or if they would provide any suggestions. I guess that would be helpful on your side as well when creating it and making the program a bit better so having that going out once every month or so, just so that they know that their suggestions are being heard.* [Youth 5; female; intellectual disability]

Participants shared that this feedback could be reviewed with trained health care professionals who could provide the navigator with strategies for improvement. Many youths suggested that these strategies should be provided by someone who is trained in mental health care. A youth shared the following:

> *I think counsellors and therapists, for example, are a very good role model to draw upon these professional qualities from. I think people who are trained in mental health aspects do hold the qualities it takes to create an environment where the participant would feel safe talking about their issues.* [Youth 19; female; intellectual disability]

Subtheme 3: Necessary Infrastructure for Accessibility

Upon reviewing the existing platform, participants highlighted that owing to accessibility concerns, different hardware may be needed to accommodate the differences in abilities when using CONNECT. Examples of hardware mentioned included laptops, desktops, iPads or tablets, and cellular phones. A caregiver described the following:

> *[My son] cannot use a computer because both of his are closed. Even now, he uses the computer, but I have to open it and set everything up and put the camera in front of him. But also, the iPad, yeah, sometimes is much better because he has hand control movement, so yeah, the iPad is much better for my son, but it's different for other people.* [Caregiver 1; female; has a son with cerebral palsy]

Regardless of the technology, almost all participants noted that the device should allow for features such as control over the size of font, brightness, and speech-to-text functions. To serve the multicultural population of Canada, participants emphasized that the program had to be available in English, French, and other languages that may be spoken by users.

Some participants identified the barriers to the use of CONNECT for individuals who may not have access to internet. A participant said the following:

> *I would say that perhaps having the program in an online program might not work for everyone. They might not be able to access a computer or access the internet. But I think it's really important to figure out a way to make sure that these individuals are still included in the program and are still able to be supported through the program.* [Youth 13; female; acquired brain injury]

Phase 2—Theme 2: Balancing Youth Confidentiality With Caregiver Involvement

Many youths raised concerns over their parents accessing the information they shared via CONNECT. Youth described that all aspects of the program (ie, communication among the care team and progress posts) should be personalized such that the youth can control who can view their personal health information. Confidentiality came up as an important factor regarding youth feeling comfortable with using CONNECT, particularly in the context of discussing sexual and reproductive health issues or medical concerns with the navigator (eg, impact of the disability on reproductive health). Moreover, youth thought that the navigator could help them with discussions with their caregivers about their role in their care. A youth shared the following:

> *Thinking of sexual health concerns and like if someone wants their parents to know. Because I know that there are youths who are already basically independent at a very young age, and so they can easily bring up this conversation with their parents because they just have that type of dynamic. Some other youths might have a different dynamic with their parents, such that it's like, they've relied upon them for medical issues and things like that, so they don't really know how to go about bringing conversations other than, hey, I kind of want to do this. I think in that case, having a navigator would definitely help to express next steps to the youth.* [Youth 19; female; intellectual disability]

At the same time, caregivers wanted to be able to control the functions their care recipient could access. A caregiver shared the following:

> *My point is some of the features I don't want him to play with like canceling appointments. I want to prevent him from doing that on his own. All the features we have on the platform will be absolutely necessary. It's like in the bank account you have to have it joint with certain people so you can do it. Because if he makes it, sometimes I can't change it or something, I have to make up the time to make it right back, right? So, that's what I worry about.* [Caregiver 7; female; has a son with cerebral palsy]

Another caregiver described that owing to the nature of some disabilities, many of the features on the program should have "an extra layer of clicks or click/confirm options" such as a need to click a second button or confirm button to make the action happen:

> *My son is 20 years old and he has uncontrolled movement for his hand. Sometimes he pushes the button and makes a mistake. So, what should I do in this case? For my son, he clicks very fast. So, the thing is I want a lock, so both of us to be there, so we can make it available.* [Caregiver 1; female; cerebral palsy]

Phase 2—Theme 3: Value of Multimodal Communication

All participants appreciated that the program allowed for multiple modes of communication. Participants responded favorably to having the option to communicate with the navigator on one's own terms (ie, phone call, instant messaging, email, and video call), with the contact being initiated by the youth. Simultaneously, participants believed that digital communication (ie, SMS text message) could lead to fast access and more prompt management of their psychosocial issues. Some youths found that not having to communicate verbally provided an added sense of privacy, for example, if they were discussing issues that they did not want others to hear (eg, in the community forum or through messaging their patient navigator). Moreover, caregivers noted that this option may help accommodate youth with nonverbal communication abilities.

Moreover, youth believed that being able to contact the navigator when they wanted could help them better access services for a variety of health and nonhealth issues. For example, a participant shared the following:

> *My main goal is to be able to be in a place where I can live in an apartment and go to work every day and not necessarily have to think about how my disability will impact me after I've already troubleshot it for long enough that I have a routine. So I also just want to talk about that and get support with that. Just living life when something comes up.* [Youth 8; female; cerebral palsy]

Participants emphasized that the navigator should be available to the youth, caregivers, and care providers beyond standard business hours (eg, Monday to Friday from 9 AM to 5 PM), through a toll-free number, email, or messenger functions on the platform. Participants described wanting to reach a navigator that they trusted with a specific concern or a general need for emotional support during a crisis. Participants suggested having alternative navigators available to support the provision of 24/7 care. A participant stated the following:

> *Like, because people that will go through health issues, and they need support, but you don't know when they need the support. You can't just have it, have someone that's a registered person be present only from nine to five, or like, I don't know, eight to four, or something like that. Sometimes going through something right now, like my...like, I'm talking fine right now, but at night I'll be like, crying in my bed. So, you need to have people there, and someone to talk to at all times. Even at two in the morning, three in the morning. That's the key, I believe, when you're building something to support someone. Because our struggles happen all the time, not just during the day and sometimes we have no one who understands us to talk to....So, having a main person from nine, from eight, or whatever, and then having a couple of people at night to, just to...you know, just there. Even though people...even if people don't need it, you know, you want to be there in case someone wants it, right?* [Youth 15; female; intellectual disability]

Phase 2—Theme 4: Holistic and Developmentally Appropriate Care Needs

Overview

Participants indicated that the CONNECT program should provide health education and support that is developmentally appropriate. Youth perceived that receiving care through CONNECT should account for their unique developmental needs, life events, and personal goals, therefore making participation in the program meaningful. Participants operationalized developmentally appropriate care as care that could be personalized to their abilities including up-to-date health information that was written in lay terms and care that could promote self-management.

Subtheme 1: Point System

Many youth participants did not value the point system that is a part of the generic program, especially if the points were not linked to outcomes such as a prize. A participant described the following:

> *I don't know, a little reward or something tangible, that is motivational, but just having the points itself might not be worth anything to someone who isn't a child.* [Youth 18; female; intellectual disability]

Subtheme 2: Health Library

Participants responded positively to the health library, often comparing the program with a Google search that was more trusted or credible. A participant described the following:

> *So, if I had someone recommending things to me that would be incredible. When it's on an app for healthcare, it's already you would trust it a lot more as a rule I would think.* [Youth 16; female; intellectual disability]

However, participants noted that the health library should be expanded beyond physical health, to include mental health and information about accessible hobbies (eg, sport centers), restaurants, and transportation options.

Subtheme 3: Forums

Regarding the community forum, participants discussed the issue of anonymity. By not remaining anonymous, participants felt that there would be the potential to meet other peers. The potential to meet more peers with lived experiences was an attractive possibility to many of the youths as it would provide additional opportunities for mentorship through transitions in care. A participant described the following:

> *I feel like people can actually make friends out of this. Because some people might be going through the same thing, and they might be, eventually, buddies down the road. So, I feel like definitely this is something...especially patient-to-patient. There will be a connection. Like, oh, she or he is going through the same thing as I am. And they will feel like they're not alone, in case they want to make a decision. I definitely understand why you guys did anonymous, and it's definitely a good option to still keep anonymous, but there should be...if people want to share their name, it's okay to share their name, so that they can make friends that way.* [Youth 15; female; intellectual disability]

Participants appreciated the information vetting (eg, using peer navigators as moderators) that would occur in the forums, such that the advice provided by peers would likely be considered legitimate and safe.

Discussion

Principal Findings

We have presented the findings from the development process of a web-based patient navigation program that highlighted the preferred adaptations of an existing web-based platform from the perspectives of youth with childhood-onset disabilities and their family caregivers that will be incorporated into a web-based peer-patient navigation program called CONNECT. Participants desired a program that included (1) information about disabilities, (2) self-directed learning, (3) a library of reliable health and community resources, and (4) emotional and social supports. Upon obtaining feedback, we found that participants perceived that CONNECT could help support holistic and developmentally appropriate care needs. Participants also desired a program that was accessible to people with various physical disabilities. Moreover, as with other peer support literature [59-61], we found that for peer navigation to be most meaningful, the navigator should have similar life experiences as the user.

Our findings suggest that youth wanted their personal health information to remain confidential and preferred options of personalized caregiver involvement. Confidentiality is a major factor affecting youth's decision to access health care services [62]. When health care professionals can assure confidentiality and a trusting relationship, youth are more likely to communicate regarding their needs, engage with follow-up, and develop skills to navigate the health care system [62]. Having a navigator with the same disability and similar life circumstances was viewed as important by participants, as it can help foster trusting relationships. A study of an existing web-based peer navigation program for adult cancer care also found that participants wanted to be matched with a peer navigator who shared common characteristics, particularly the same language and sexual orientation [41]. Optimal Matching Theory, a well-cited theory in the peer support literature that informed CONNECT, suggests that living with a disability or illness creates the need for social support across many aspects of care (eg, physical and occasional) [63]. Matching the support desired with the support provided can enhance outcomes including improved friendship formation, reduced social isolation, and improved mental health [63]. Incorporating simple screening questions regarding language, disability, and sexual orientation may be helpful. It may also be helpful to incorporate specific areas where youth are seeking support, such as emotional, informational, or practical support; their preferred mode of communication; specific modes of web-based delivery; and when and how much the intervention should be delivered. Taken together, these considerations or adaptations may serve to enhance the overall benefits of the CONNECT intervention.

Although there are many definitions of patient navigation [64], implicit in most definitions is the notion that a patient navigator works to meet the health needs of individuals and their families [32]. Our study found that patient navigation should address psychosocial, educational, recreational, and vocational considerations and physical health considerations. In addition to health information, participants also desired information that could facilitate their day-to-day lives such as locating restaurants that are accessible for people with disabilities. Moreover, an important finding from this study was that despite the positive views about having peer support offered in various ways (eg, forum and via the navigator), participants also wanted the information shared and discussed to be vetted by a trained professional. Thus, opportunities for peer navigators to routinely work alongside health care professional navigators may be worth considering in future studies and programs, as current interventions often include solely lay or professional navigators, rather than both [65,66]. For example, youth desired emotional support during times of crises, indicating an example of where care can be better facilitated through trained professionals. Future studies should begin to explore navigation programs that include a combination of professional and peer support and programs that have professional oversight of peer navigators to determine whether and how they can be effectively integrated into transitional support interventions to optimize peer navigation delivery for youth with childhood-acquired brain injury, intellectual disabilities, and cerebral palsy and their families. Our findings provide the preferred requirements for a web-based peer navigation program for youth with childhood-acquired disabilities transitioning from pediatric to adult care. Future studies focused on refining the CONNECT program have the potential to improve the transitional experiences and outcomes of youth living with childhood-acquired disabilities and their families. The age and developmental variations among youth with complex care needs complicate the logistics of patient engagement with the intervention, as tailored approaches are essential owing to diverse cognitive and communication abilities [67,68]. Therefore, addressing these logistical challenges while maintaining a patient-centered, coproduced approach is paramount in the refinement of the CONNECT program.

In a meta-analysis of randomized controlled trials to determine the effects of patient navigation on health care use outcomes, Ali-Faisal et al [69] determined that compared with usual care, patients who received patient navigation were significantly more likely to access health screening and attend a recommended follow-up. Peer-patient navigation was also associated with increased adherence to cancer care follow-up treatment and obtaining early diagnoses [69]. Moreover, data from published studies reporting telehealth solutions for people living with illness or disability suggest the delivery of patient-centered care, relationship building between professionals and patients [68], and supporting medication adherence and health system cost savings [70]. Future directions for this program of research will include evaluating the effectiveness and health economic impacts of an optimized CONNECT intervention in a large-scale, pragmatic, randomized controlled trial. Benefits of the CONNECT program could include increasing participants' knowledge, skills, and confidence in managing health care transitions and health-related quality of life. The results of a future randomized controlled trial may help determine the potential of CONNECT for wide dissemination and public health impact, if it demonstrates effectiveness.

We acknowledge that implementing CONNECT in real-world clinical practice entails multifaceted challenges. Successful implementation of patient navigation programs within health care systems necessitates planning, funding, multidisciplinary engagement, workflow establishment, communication mechanisms, knowledge user support, appropriate caseload management, and in-kind resource allocation [71]. Thus, to ensure a fit with existing health and social care systems, careful consideration must be given to how the CONNECT system aligns with established health care workflows, processes, and roles [72,73]. Future implementation studies are required to determine who will provide the initial instructions to both users and administrators and are essential for successful adoption. In addition, addressing the provision of ongoing technological support is vital to resolving any technical issues promptly and ensuring seamless operation of CONNECT in the community setting (ie, home) [74]. Thoughtful planning regarding these aspects will play a pivotal role in the effective implementation and sustainability of the system within the complex landscape of health care practices.

Limitations

This study had some limitations. Most notably, participant selection was biased toward individuals who had high-speed internet and telephone service, as they were more likely to participate in the interviews and focus groups. As such, the needs of individuals living in rural and remote areas, who may be without high-speed internet, and individuals without access to necessary hardware should be considered [75]. Moreover, our study was limited to individuals who could verbally communicate in English, excluding youth with certain communication impairments or disabilities. Moreover, we only recruited individuals with cerebral palsy, acquired brain injury, and intellectual disabilities. All participants in this study were from Ontario, Canada. As such, the preferences and perceptions of the participants may not be transferable to the desires and perceptions of a broad community of youth living with childhood-acquired disabilities [76]. Beginning our intervention development with an existing platform (ie, iterating on an existing platform) may have limited the opportunity to meaningfully co-design the CONNECT program. Finally, our participants explored the existing platform without actual interactions with the peer navigator. By deploying the patient navigation intervention, future studies could also assess its ecological validity [77].

Conclusions

This study describes the development of CONNECT, a web-based peer-patient navigation intervention for youth with childhood-acquired disabilities to support transitions from pediatric to adult care. Our findings reveal that youth desire receiving peer support from an individual with similar life experiences through multimodal communication techniques and with assurance of confidentiality. At the same time, participants highlighted that for web-based patient navigation to be age appropriate and developmentally appropriate, it must involve trusting relationships and vetted information. Future studies are needed to further refine CONNECT before determining its effectiveness in real-life settings. To the best of our knowledge, this study is the first to explore the desires of youth and their caregivers regarding web-based patient navigation and a codeveloped potential technology solution; however, additional studies are needed to expand the knowledge about the benefits of web-based patient navigation for youth with childhood-acquired disabilities to support transitions from pediatric to adult care.

Abstract

Background: Web-based patient portals are tools that could support adolescents in managing their health and developing autonomy. However, informatics administrators must navigate competing interests when developing portal access policies for adolescents and their parents.

Objective: We aimed to assess the perspectives of informatics administrators on guiding principles for the development of web-based health care portal access policies in adolescent health care.

Methods: We interviewed informatics administrators from US hospitals with ≥50 dedicated pediatric beds. We performed a thematic analysis of guiding principles for developing and implementing adolescent portal access policies.

Results: We interviewed 65 informatics leaders who represented 63 pediatric hospitals, 58 health care systems, 29 states, and 14,379 pediatric hospital beds. Participants described 9 guiding principles related to three overarching themes: (1) balancing confidentiality and other care needs, (2) balancing simplicity and granularity, and (3) collaborating and advocating. Participants described the central importance of prioritizing the health and safety of the adolescent while also complying with state and federal laws. However, there were differing beliefs about how to prioritize health and safety and what role parents should play in supporting the adolescent's health care. Participants also identified areas where clinicians and institutions can advocate for adolescents, especially with electronic health record vendors and legislators.

Conclusions: Informatics administrators provided guiding principles for adolescent portal access policies that aimed to balance the competing needs of adolescent confidentiality and the usefulness of the portal. Portal access policies must prioritize the adolescent's health and safety while complying with state and federal laws. However, institutions must determine how to best enact these principles. Institutions and clinicians should strive for consensus on principles to strengthen advocacy efforts with institutional leadership, electronic health record vendors, and lawmakers.

Introduction

Web-based patient portals are widely available tools that can improve patients' sense of control [1-4], adherence [1], and medical understanding [2,3,5]. Portals represent an opportunity to engage adolescents in health care and support their developing autonomy. However, adolescents could experience emotional distress or frustration when reviewing results or clinical notes through the portal, especially if they receive difficult news such as a cancer diagnosis. These portals also risk divulging confidential information to parents that an adolescent has shared with a clinician [6,7]. Adolescents are less likely to communicate transparently with clinicians if they have concerns about confidentiality [8,9]. These concerns could lead adolescents to forgo sensitive medical care that could result in serious health repercussions, such as sexually transmitted infections, unplanned pregnancies, or poor mental health. However, parents often play an important role in managing the adolescent's health, and US public opinion supports parental access to adolescents' health care records [10]. Additionally, most adolescents rely on their parents' support to manage or comanage their health care, especially if the adolescent has a chronic illness [11]. To provide ethical and effective access to adolescent portals, institutions must strive for ideal strategies that balance confidentiality and usefulness [12-14].

The 21st Century Cures Act mandates that US health care systems allow patients access to their electronic health record (EHR) data, typically through web-based patient portals [15]. We previously found that pediatric institutions have used widely varying policies for adolescent portal access across the United States [16]. Although most studies of adolescent portal use have been performed in the United States [17], other countries are similarly providing portal access to adolescents and their parents [18,19]. Variations in portal policy are driven, in part, by adolescent confidentiality laws that vary by state [20]. Each state has unique confidentiality laws with categories of protected information that generally include information about reproductive health, substance use, sexually transmitted illnesses, and mental health [21,22]. However, even within states, health care systems have interpreted the same laws differently, leading to different access policies [16]. Similarly, regulations vary in other countries. For example, the General Data Protection Regulation of the European Union requires a patient to be 16 years old to provide digital consent. The 21st Century Cures Act mandate for transparency has encouraged institutions to further reevaluate these adolescent portal access policies and their interpretation of laws.

Few studies have engaged administrators to understand their perspectives on guiding principles for developing and implementing adolescent portal access policies following the 21st Century Cures Act. Several professional medical societies have published guidelines and policy statements about adolescent portal policies and focused mainly on preserving confidentiality [13,14,23,24]. However, it is essential to understand the perspectives of administrators who are charged with developing and implementing these policies because they have rich experiential insights into the challenges of administrating adolescent portal access in the US health care system. In the United States, these administrators often work in teams that include technical staff and clinicians with informatics expertise. These groups also collaborate with risk management and legal counsel to develop adolescent portal access policies that they perceive to be compliant with state and federal laws. We interviewed 65 informatics administrators from multiple health systems across the United States. Our prior analysis of these interviews characterized the varying adolescent portal policies across the United States [16], as well as approaches to engaging adolescents in using the portal [25]. In this analysis, we aimed to identify guiding principles to inform the development of these policies in the future.

Methods

Overview

We report these findings following the Standards for Reporting Qualitative Research (SRQR) checklist [26] (Multimedia Appendix 1).

Participants and Recruitment

We performed structured interviews with informatics administrators who oversaw adolescent portal access policies. Informatics administrators were eligible if they were involved in developing or implementing adolescent portal policies and if they oversaw a US children's hospital with ≥50 dedicated pediatric beds. Specialty and rehabilitation hospitals were ineligible. We identified children's hospitals using the Children's Hospital Association (CHA) database in January 2022. Of 232 children's hospitals, we excluded specialty or rehabilitation hospitals (n=37), non-US hospitals (n=7), and hospitals with <50 pediatric beds (n=9), yielding 179 eligible hospitals. We recruited participants through 2 email groups of informatics administrators and simultaneously identified contact information for informatics administrators through publicly available data. These email groups included informatics administrators across the United States who opted into the list to communicate with fellow informatics leaders. After initially sending recruitment materials through these email groups and receiving some responses, we then sent targeted emails to administrators at each remaining children's hospital listed in the CHA database. We emailed administrators at every eligible children's hospital to request interviews. We also included administrators from US hospitals with which the authors were affiliated, given the importance of capturing representative data across the United States.

Data Collection

We identified the number of pediatric beds from the CHA database, supplemented with information from hospital websites. We developed a structured interview guide that explored adolescent portal policies, factors influencing the development and implementation of policies, and approaches to engaging adolescents through portals (Multimedia Appendix 2). We specifically asked for advice from other informatics administrators and guiding principles for developing adolescent portal access policies. This interview guide was developed through a literature review and engagement with informaticists. We revised the interview guide with a stakeholder advisory board and 3 informatics administrators. This advisory board included 4 physicians with expertise in informatics, primary care, adolescent medicine, and endocrinology, as well as an adolescent with chronic illness and their parents. In the interview guide, we indicated which questions were essential and which questions could be skipped if insufficient time. However, we were able to ask each pertinent question for the current analysis in every interview. BAS conducted interviews between February and July 2022 via telephone or videoconferencing software. Interviews were audio-recorded and professionally transcribed. Interviews ranged from 12 to 43 minutes.

Data Analysis

Our overall qualitative analysis adhered to the Total Quality Framework, a comprehensive approach that ensures the accuracy, credibility, analyzability, transparency, and usefulness of qualitative findings [27,28]. We used thematic analysis [29] of guiding principles for developing and implementing adolescent portal policies. BAS and ALA developed the codebook. BAS is a pediatric oncologist, ethicist, and communication researcher with training in qualitative research. ALA is an organizational psychologist and ethics researcher with experience and training in qualitative research. Coding involved multiple iterative steps: (1) read transcripts to familiarize themselves, (2) descriptively coded 5 transcripts to formulate preliminary codes, (3) grouped codes into categories and collapsed categories into representative themes, and (4) refined definitions for themes through 3 cycles of independent coding and consensus meetings. After reviewing 25 transcripts, we reached saturation for representative themes. Using this final codebook, BAS, CB, and ME independently coded all transcripts, using these codebook definitions to ensure consistent and reliable application of codes. These authors then reviewed the other's application of codes, marked disagreements, and resolved disagreements through discussion. We used Dedoose (SocioCultural Research Consultants) qualitative software.

Ethical Considerations

The institutional review board at Washington University determined this study was exempt. We obtained verbal informed consent. All transcripts were deidentified prior to analysis.

Results

Participant and Health Care System Characteristics

We identified 179 eligible pediatric hospitals and contacted an informatics administrator at every eligible center. We interviewed 65 informatics experts representing 63 hospitals across 58 health care systems. Thus, participants represented 35% of all US children's hospitals with more than 50 dedicated pediatric beds. EHRs from all participating health systems had web-based health portals in pediatrics. The number of dedicated pediatric beds in participating hospitals ranged from 51 to 664 (median 189, IQR 107-313) beds. In total, participants represented systems with 14,379 dedicated pediatric beds across 29 states plus Washington, District of Columbia (Table 1). The majority of health care systems used Epic EHR systems.

[a] Includes 1 participant who identified as a director of health information systems.

[b] Other roles included pediatric service line lead, director of nursing informatics, director of quality, certified analyst, adolescent physician, director of clinical analytics, medical director of informatics, chief medical officer, and clinician champion.

[c] EHR: electronic health record.

Guiding Principles and Advice for Developing Adolescent Portal Access Policies

Overview

Participants described 9 guiding principles related to three overarching themes: (1) balancing confidentiality and other care needs, (2) balancing simplicity and granularity, and (3) collaborating and advocating. We describe each of these themes and principles in Table 2 and subsequent sections.

Table 2. Subtheme definitions for guiding principles for developing and implementing adolescent portal policies.

Themes and subthemes	Representative excerpts
Balancing confidentiality and other care needs	
Provide appropriate transparency while complying with state and federal laws	Compliance with laws and regulations was noted as an essential requirement for any portal policy. The overarching goal of improving transparency was shared by nearly all administrators, but there were differences in how to achieve this transparency in ethically and legally acceptable ways. Administrators described the vagueness of these laws and several instances with state and federal laws are in conflict. As a result, administrators described the importance of developing a productive, collegial working relationship with the institutional compliance office and legal counsel.
Prioritize adolescent health and safety	Administrators strongly believed that all policies should aim to ensure the health and safety of the adolescent. However, health and safety could sometimes be in conflict. For example, some adolescents might need parental involvement to help them manage complex disease. Other adolescents might be unsafe if their parents see sensitive information, such as drug use, gender identity, or sexual activity.
Preserve clinician-adolescent relationship	Administrators highlighted the importance of ensuring that portal policies support rather than strain the clinician-adolescent relationship. Clinicians especially needed to honor their promises of confidentiality or they would risk losing the adolescent's trust.
Support adolescent's developing autonomy	Although administrators had disagreements about what level of access is appropriate or mandated for parents, most administrators expressed that adolescents should have access to as much of their own information as possible. Not only do adolescents have a right to learn about their own health, but administrators believe that this access could support the adolescent's development into adulthood and self-management.
Balancing simplicity and granularity	
Strive for appropriate granularity in the differential sharing of health information	Administrators generally agreed that some granularity in the ability to determine which information is shared with parents versus adolescents is ideal. Some described an ideal in which adolescents could determine each type of information that is shared with their parents. However, technological limitations created barriers for differential sharing, especially at centers with smaller pediatric populations.
Ensure the end product is useful for families	Administrators urged vendors and institutions to ensure the user interface was user-friendly and provided meaningful information for parents and adolescents. They also described how it was important to make sure information was understandable to families. Simply providing access was not sufficient. Additionally, administrators urged against the view of the portal as a panacea for all communication and information challenges.
Collaborating and advocating	
Engage key stakeholders within the institution	Administrators emphasized the importance of engaging with leadership, informatics workforce, legal or compliance officers, clinicians, frontline staff, parents, and adolescents in developing and implementing access policies. Additionally, they encouraged the ongoing engagement of these parties after implementation to ensure the system continues to meet all parties' needs.
Collaborate with colleagues at other institutions	Given the uncertainty and vagueness of state and federal laws, administrators encouraged other administrators to communicate with colleagues at other institutions to understand the variety of approaches to adolescent portal access. This collaboration was especially important to understand how other hospitals in the same state were interpreting the laws.
Advocate with external parties for adolescent and pediatric issues	Many of the conditions influencing adolescent policies originated outside of the institution, especially state laws, federal policies, and EHR[a] functionality. It is imperative for health care institutions to advocate with these external parties to support safe and transparent sharing of adolescent medical information through portals.

[a] EHR: electronic health record.

Balancing Confidentiality and Other Care Needs

Provide Appropriate Transparency While Complying With State and Federal Laws

State-level confidentiality laws varied widely across states, leading to policies that varied in the amount of authority parents have to access their child's medical information through the portal. The federal mandate against information blocking did not specify how this mandate applied to adolescent health, and the federal law specifically defers to state laws in these matters. Furthermore, federal and state laws were written vaguely, and some perceived the state and federal laws to be in conflict. For a detailed analysis of state-by-state variability, see Sharko et al [22]:

> *It was a lesson learned how really poorly written state laws are. Whether it's state or federal or regulations, you think it would spell out exactly what you need to do, but it's not that way at all. That 1,250-page*

> *behemoth that [Office of the National Coordinator for Health Information Technology] produced only muddied the waters even further. We really don't know what they're really expecting and they're not.* [Participant #181, chief medical information officer]

Participants described how adhering to state laws was a critical foundation for any portal access policy for adolescents:

> *We have an affirmative requirement to protect certain information and not violate the state laws of [our state]. That is, obviously, something we take extremely seriously.* [Participant #176, chief medical information officer]

Given the complexity, variation, and vagueness of state laws, participants expressed the essential role of institutional legal and compliance officials:

> *There are many regulations that are conflicting, and it's really important to ensure that you are looping in your compliance and legal folks...because ultimately, there's just laws that are in conflict.* [Participant #26, chief information officer]

However, the recommended approaches to complying with confidentiality laws varied. While participants described the need to balance transparency and confidentiality, some participants emphasized the importance of prioritizing the adolescent's confidentiality over transparency and limiting access for both parents and adolescents because this was the "path of least resistance" (participant #78, clinical informaticist), technically easier, and satisfied the concerns of legal and compliance administrators. Additionally, some participants expressed their beliefs that state laws provided protection if they opted to restrict information from both parents and adolescents:

> *We have not increased access for adolescents...We would defend it based on state laws about confidentiality. If there's state laws that supersede some of the Cares Act, we can seek protection behind those.* [Participant #78, clinical informaticist]

Conversely, others emphasized the importance of transparency:

> *I think that the default assumption should be that teens can access all their own information, and that parents can access all of their kids' information, except that that's protected by adolescent health laws.* [Participant #153, chief medical information officer]

Some participants also described the "importance of parents knowing what's going on with their [adolescent]" (participant #93, chief medical information officer).

> *We can't disconnect the parents from the non-confidential information. I think it's so important and key for them to be able to continue to meaningfully provide care and safely provide the care that's required for their adolescent. Disconnecting them from that information, I think, is just the wrong thing to do.* [Participant #172, chief medical information officer]

However, this point was discussed less frequently than the importance of preserving transparency. Some participants recommended that adolescents should be empowered to determine this balance of transparency and privacy by determining what level of access their parents are permitted: "I think having it be in the adolescent's hands to determine what their parents have access to and to be the ones in control of that I think is the right approach" (participant #119, chief medical information officer). Participants in other states, however, explained that such an approach might conflict with their state laws that provided parents with rights to access these data.

Prioritize Adolescent Health and Safety

In addition to adhering to the law, participants described how the adolescent's health and safety must be the other central guiding principle for portal access policies: "To me, the guiding principle is always what's the safety of the patient and what's in their best interest" (participant #26, chief information officer). Furthermore, some participants described the need to prioritize the adolescent's health needs over the legal concerns of the institution:

> *Focus on the patient, not on the lawyers. If we can, again, try and stay focused on what is gonna help us take care of the patients, why do we want to be transparent with this information, understand that nobody is out to get us...Frankly, the government doesn't have the resources to do any kind of investigation anyway.* [Participant #112, chief medical information officer]

However, there were differing beliefs about how to prioritize health and safety. For some participants, supporting health requires transparent disclosure of high-quality information to both adolescents and their parents.

> *Information is powerful. Information helps improve communication, helps improve health outcomes, helps improve quality.* [Participant #57, chief medical officer]

Additionally, some participants reiterated the need to incorporate parents in the adolescent's health care, especially for adolescents with serious illness:

> *I do think for other health conditions, we want to be careful not to set barriers to where the parents can be helpful in helping that adolescent manage those conditions. It's very much a balancing act.* [Participant #176, chief medical information officer]

Others, however, described how limiting parental access might be necessary to ensure the adolescent's safety, for example, if they were at risk of abuse from parents following disclosure of sensitive information:

> *At the very top of the pyramid is patient. All of our decisions, we try to keep that in mind. That's where, even though I may get frustrated that sometimes there's access that's decreased for my parents, if it means that it's providing the actual patient a little bit more security and privacy, then I'm able to appreciate that this is really what's best for them.* [Participant #38, chief medical information officer]

Still, others were uncertain about how to determine what portal policy is best for adolescents:

> *Yeah. I think it should be about patient—what's best for the patient. I think that should be—to me, it's pretty simple. Now, that's a complex part, right? How much information do you divulge? What do they keep from their parents? What's the right thing to do? The more ethical issues there, which I don't have an answer to but, I think, at the end of the day, what's gonna promote the best health for child and adult?* [Participant #140, chief medical information officer]

Preserve Clinician-Adolescent Relationship

Participants advised clinicians to recognize that adolescents have a right to their own relationship with their clinician:

> *At the end of the day, we wanna protect their information and their relationship with their provider...I struggle because, as a parent, I want to have access to my child's information, but I also realize it's their relationship as well, so, I guess, just protecting their—I don't know—right to have that relationship with a provider.* [Participant #167, chief medical information officer]

The trust established in this relationship is essential to engaging adolescents in their care and bolstering the long-term clinical relationship: "I think if [trust is] fractured, then it's difficult to have an ongoing good relationship with that teenager" (participant #20, chief medical information officer). This trust relies on clinicians honoring their promises of confidentiality:

> *If we tell them that a conversation is private, it truly is private and that we honor that, and that there is a mechanism for that to truly be information that we do not share without their consent. Otherwise, they're just never going to trust us. They're not gonna trust giving us that information or really feeling comfortable engaging with a portal.* [Participant #172, chief medical information officer]

Support Adolescent's Developing Autonomy

Supporting and developing the adolescent's autonomy were also goals of many participants:

> *Patient access to patient portals has a lot of positives, and I think one that gets overlooked is patients taking ownership of their own health care because the portal allows them to learn about themselves at an earlier age, learn what their diagnoses are, what their medications are, who their providers are...I think it'll help patients understand more about themselves, communicate better with health care professionals, and make them an active participant in their health care.* [Participant #57, chief medical officer]

They viewed portals as a teaching tool to support the independence of the adolescents:

> *The portal, I think for the adolescent group, is a way to increase engagement and to, hopefully, teach some of these skills that are going to be lifelong skills. This is like a really pivotal time, and I think we're missing the opportunity, from that perspective.* [Participant #10, clinical informaticist]

However, the role of the adolescent must be adapted to their level of development and interest:

> *We can't expect a 14-year-old to manage their Type I Diabetes or their own Inflammatory Bowel Disease, but I do think that by giving them access, it does kind of help them take that next step in owning the management of their current diseases.* [Participant #138, clinical informaticist]

In addition, policies should not force responsibilities on the adolescent if they are not ready or willing to manage their health:

> *For adolescents that truly want to manage their own health care and want to be engaged to that degree, then they should be the primary user of the portal, with the parent being in a supporting role. On the flip side, if you have a parent and a child relationship where the parent really is managing everything, then they need to retain that.* [Participant #181, chief medical information officer]

Some participants described the importance of guidance and guardrails to ensure adolescents remain safe. For some participants, the ideal guardrail is comanagement of care between the parent and adolescent, with graduated responsibility for the adolescent over time. Without this support, adolescents might be unable to sufficiently manage their health care:

> *Is a 13-year-old ready to make their own medical decisions? There's probably a handful who are, but there's probably a lot more who struggle with that. I know certainly my kids at 13 wouldn't have been able to manage their own care.* [Participant #133, chief medical information officer]

Balancing Simplicity and Granularity

Strive for Appropriate Granularity in Differential Sharing of Health Information

Many participants described the need for technological advancements that will permit differential sharing of information between the parent and adolescent:

> *Technology needs to evolve so that parents can be engaged, and teens have the ability to actively, through portals, decide what they're gonna share and not share because every relationship between a teen and their parents is different and can change on a moment's notice.* [Participant #176, chief medical information officer]

The adolescent would ideally control this access, perhaps through widgets on their portal that do not require clinician actions:

> *I would put the widgets for access right on the portal for the adolescent to control in addition to reupping having an active process for re-upping. I would also make it more autonomous that they can manage the access independently. They don't have to go through us.* [Participant #60, chief medical information officer]

Some participants believed that adolescents with complex needs might need different or modified privacy settings to ensure that the child's medical problems are sufficiently managed:

> *I think that we try to make it as simple as possible, and this is a rather complex issue. I think that we probably need another type of access for those patients with chronic medical care needs, or if we could pick and choose more easily which things a child was letting their parent see, I think that would make it a little bit easier, and I think I would be more satisfied with it.* [Participant #38, chief medical information officer]

With this granular sharing, however, some participants worried that allowing the adolescent to censor certain health information might be considered information blocking or might conflict with state laws that consider the medical record to be the parent's property: "When you cross over into that world where you're now blocking certain elements from the parent, then you possibly fall into information blocking" (participant #98, clinical informaticist). Another participant further elaborated:

> *I think that to be fully compliant with the Cures Act and the need to prevent information blocking, we should really only be selectively not sharing that information with the proxy, the third party [and adolescents should retain access to this information]. Right now, at least in our system, we only really have the ability to either have it appear in the portal or not appear in the portal [for both the adolescent and proxy]...That seems unfair to adolescents 'cause those may be the things they most care about.* [Participant #119, chief medical information officer]

Conversely, other participants worried that more granular sharing was required to comply with the Cures Act because many health care systems were withholding information from adolescents. To achieve this granularity, a participant encouraged other administrators to "figure out your needs, and then design backwards from that" (participant #52, chief medical information officer).

Ensure End Product Is Useful for Families

In addition to the focus on portal access and privacy issues, participants also emphasized the importance of focusing on the user experience to ensure the portal is useful. Participants noted that registration processes needed to be simplified and streamlined to encourage portal use:

> *Making our consent form electronic. Instead of having to come in and sign a piece of paper, that process is now online. You can sign up for a patient portal account through an electronic form. You can upload a picture of your driver's license, and that has made all the difference in helping people get enrolled with a patient portal account.* [Participant #167, chief medical information officer]

However, many of the barriers to streamlined enrollment were related to identity verification to ensure parents were not registering for their adolescent's account. Furthermore, some participants described the need to engage adolescent end users to ensure the interfaces are user-friendly:

> *In general, I'm not sure if people have set about to do studies from the patient perspective, on how difficult or easy it is to use any of these personal health records or the portals that they have, so there's a lot of improvement that could be done in terms of making these user-friendly.* [Participant #116, chief medical information officer]

Collaborating and Advocating

Engage Key Stakeholders Within the Institution

When developing policies, participants stressed the importance of engaging multiple stakeholders within the health care institution, clinical teams, and families to ensure the policies were responsive to the needs of these parties and as broadly acceptable as possible: "Communication, communication, communication, get everybody involved early and speak to all the people who were involved" (participant #121, clinical informaticist). Stakeholders included teens, parents, legal and compliance teams, clinicians, informaticists, information technology support staff, and other frontline staff involved in registration and enrollment. Participants advised multiple approaches to engaging families, including advisory boards, open forums, and satisfaction surveys:

> *If you don't have a family advisory board or a teen advisory board, that is really key. Then I also think just having open forums to hear what people say because we're not perfect.* [Participant #167, chief medical information officer]

Yet, some participants felt that the adolescent voice was lacking at their institution:

> *I don't think there's any adolescent voices being represented. I think there's a lot of parental voices being represented, but I don't think in our situation, I don't think that there's any—there's ever been a teen at the table in adolescent practices even in creating clinic culture.* [Participant #144, clinician]

Within the clinical team, participants advised administrators to consider differences in practice patterns and patient populations when developing and implementing policies:

> *We had to have a working group with legal, with experts in adolescent care, and really with care providers from different venues. Outpatient versus ED, versus urgent care, versus inpatient are all very different sets of episodes of care, and information types. The needs and perspectives, the providers are also gonna be different.* [Participant #153, chief medical information officer]

One participant described the need to continue tracking the expected and unexpected outcomes of policies after implementation:

> *Put this on your agenda regularly. How are we accomplishing this, and what are our gaps? For our organization, I feel like we—and how are we gonna*

> *continually assess it? We are not successfully doing that.* [Participant #163, chief medical information officer]

Another important aspect was collaborating with hospital administration to understand organizational priorities to most effectively advocate for adolescents:

> *Know what your state laws are but also know what are your guiding principles as an organization with respect to adolescent health. Those might be in conflict. Then you have to determine what is your risk tolerance when it comes to that.* [Participant #20, chief medical information officer]

Collaborate With Colleagues at Other Institutions

Given the multiple challenges inherent in developing and implementing portal policies for adolescents, participants emphasized the importance of collaborating and sharing best practices with colleagues. Additionally, some participants noted how institutions within the same state are implementing very different policies. As such, some participants called for institutions within states to strive toward consensus on a common approach, even though consensus would be difficult to reach:

> *I would say that to the extent you can within your state, come together across institutions and try to at least discuss a common approach...I think some uniformity agreements which is straight in will never get there, but it's great to strive for.* [Participant #180, chief medical information officer]

Furthermore, institutions should share their best practices with other institutions:

> *Then I would encourage institutions to share best practice. If something's working put it out there so that other people that are using the same EHR can see what you're doing and learn from it as well.* [Participant #37, clinical informaticist]

Finally, a participant from an integrated health system advised informatics leaders from major academic pediatric hospitals to consider smaller pediatric centers with fewer resources when recommending standards and policies:

> *The big pediatric institutions in the country, I would ask that they really think about where and how a lot of pediatric care is delivered in the country...How do we help the great work that's happening at some of the big, pediatric centers from that standpoint really get into these other places in the country that are providing lots of pediatric care?* [Participant #36, clinical informaticist]

Advocate With External Parties for Adolescent and Pediatric Issues

Participants described the need to pressure EHR vendors to develop necessary technical functions in the EHR, especially related to granular differential sharing of content between adolescent and proxy portals. Currently, each health system has to modify its EHR instance to meet these unique sharing needs, and the capacity to differentially share information between proxy and adolescent portals is limited:

> *I think the other thing is to continue to pressure the vendors to make this easier to do out of the box, and that's really where the CEOs have the ear of the leads of the vendor, EHR vendors, and so really to push that this is something that needs to be really addressed at the vendor level. It's crazy for us all to be doing our own build on this.* [Participant #155, chief medical information officer]

Additionally, participants described the need to advocate and lobby legislators to improve laws and regulations by adding specificity around the type of sharing required, age of adolescence, and parental and adolescent rights: "Encourage Uncle Sam [United States Government] to write rules that make sense specific to the pediatric population" (participant #109, chief medical information officer). One participant described the importance of engaging with legal counsel that was external to the hospital, to avoid being "stuck in an institutional echo chamber" (participant #158, clinical informaticist). To support these advocacy efforts, 1 participant called for guidance from national organizations:

> *It would be really great if one of our professional organizations would come forward, like the [American Academy of Pediatrics] and say like, "This is what we believe," in the context of information blocking and the Cures Act...If you could refer to some external expert body...I think it would really lend that extra weight.* [Participant #90, chief medical information officer]

Discussion

Informatics administrators described guiding principles that aimed to maximize transparency while complying with laws, respecting parental roles, protecting the adolescent's health and safety, and ensuring that the portal remains a useful tool. These overarching guiding principles align well with prior policy statements from professional organizations, providing an evidence base to support these statements. For example, the American Academy of Pediatrics advised health care institutions to ensure medical teams are "aware of state and federal requirements and to assist them in complying with standards, rules, and regulations" [23]. The Society for Adolescent Health and Medicine described the crucial importance of institutions determining which information will be shared with patients and proxies, as well as ensuring this information sharing complies with the 21st Century Cures Act Final Rule. This organization specifically recommended that clinicians and institutions know and abide by state and federal laws and advocate on behalf of the adolescent with key stakeholders within and outside of the institution [24]. The American College of Obstetrics and Gynecology similarly called for awareness and compliance with pertinent laws, while ensuring adolescents have the ability to have private, confidential communication with their obstetrician-gynecologists. Additionally, they advised clinicians to be aware of their institution's policies and capabilities regarding confidentiality when they are documenting sensitive information [14].

While we observed general agreement on many of these overarching principles, these goals can be conflicting when put into practice. For many adolescents with chronic illness, for example, providing parents with information is essential to support that child's complex care needs. Yet, technological limitations and interpretations of state laws led many institutions to limit parental access to information that is essential to support the adolescent [16]. Furthermore, the usefulness of portals is greatly diminished when institutions limit available information. For example, we previously found that some institutions shut down the portal completely during adolescence for parents and adolescents, and other institutions only provide minimal information such as vaccination status and vital signs [16]. Contrarily, other adolescents might need information withheld from their parents to protect them from abuse or harm. Inadvertent disclosure of sensitive information can subvert the adolescent's right to privacy, diminish trust in clinicians, and decrease the adolescent's transparent engagement with the health care system [6,8,9,30]. Furthermore, some adolescents might forgo sensitive care (ie, sexually transmitted infections, pregnancy, and drug abuse) if they are not guaranteed confidentiality. Some participants described how adolescents should be empowered to decide on this balance between confidentiality and usefulness by determining how much access they will permit their parents. Yet, some institutions considered this practice to be in conflict with their state's laws.

While it is important to ensure adolescent's confidentiality, the role of parents in supporting adolescents must not be ignored. Most adolescents rely on their parents for medical management, insurance and financial support, transportation, assistance in decision-making, emotional support, and consent to treatment [11]. Furthermore, some adolescents have limited interest in using portals, scheduling appointments, filling prescriptions, and managing other aspects of care. For adolescents with serious or debilitating illness, this reliance on parents can be even greater. Depending on each adolescent's unique situation, protecting privacy can either be essential to providing safe and effective health care or a major barrier to health and safety. When developing policies, the beneficial role of parental involvement must be weighed against the potential harms of inadvertent disclosure. To the extent possible, administrators should leverage available technology to minimize these disclosures while also allowing adolescents to involve parents in their health care to the extent desired or required by law.

These data highlight several targets for ongoing advocacy efforts, further supporting prior calls for advocacy in this area [24]. Within each institution, pediatricians can advocate with institutional leaders to ensure policies are informed by the adolescent's best interests and the voices of key stakeholders. To address technological limitations, institutions can advocate with EHR companies to develop tools and workflows to permit differential sharing of information to the adolescent and proxy. Pediatricians and pediatric institutions can also advocate with lawmakers at the state and federal levels to support legislation that is informed by the experiences of adolescents, parents, and clinicians. Future studies should aim to capture the perspectives of adolescents and parents to better inform these advocacy efforts. To strengthen these advocacy efforts, health care institutions within and across states should attempt to align policies and priorities to the extent possible. While many participants described myriad challenges to gaining a national consensus, intrastate consensus should be more feasible, since all institutions are responding to the same state laws.

This study has limitations that should be considered. We limited enrollment to hospitals with at least 50 dedicated pediatric beds, which could underrepresent the challenges of hospitals in integrated health systems with a smaller pediatric presence. Our results could be biased toward larger pediatric hospitals, which could limit the representativeness of our data. Also, participants could have moderated their responses during interviews due to social desirability bias. Furthermore, we did not design this study to evaluate specific characteristics of different EHR platforms, which could have provided additional practical information.

Informatics administrators provided guiding principles for adolescent portal access policies that aimed to balance the competing needs of adolescent confidentiality and the usefulness of the portal. As bedrock principles, these policies must prioritize the adolescent's health and safety while complying with state and federal laws. The main limiting factors in balancing these priorities were technological limitations and institutional interpretations of laws. Although most participants agreed on broad principles, we observed disagreements about how to specify the principles into policies. Institutions and clinicians should strive for consensus on principles to strengthen advocacy efforts with institutional leadership, EHR vendors, and lawmakers.

Abstract

Background: Tuberculosis (TB) remains a major cause of morbidity and death worldwide, with a significant impact on children, especially those under the age of 5 years. The complex diagnosis of pediatric TB, compounded by limited access to more accurate diagnostic tests, underscores the need for improved tools to enhance diagnosis and care in resource-limited settings.

Objective: This study aims to present a telemedicine web platform, BITScreen PTB (Biomedical Image Technologies Screen for Pediatric Tuberculosis), aimed at improving the evaluation of pulmonary TB in children based on digital chest x-ray (CXR) imaging and clinical information in resource-limited settings.

Methods: The platform was evaluated by 3 independent expert readers through a retrospective assessment of a data set with 218 imaging examinations of children under 3 years of age, selected from a previous study performed in Mozambique. The key aspects assessed were the usability through a standardized questionnaire, the time needed to complete the assessment through the platform, the performance of the readers to identify TB cases based on the CXR, the association between the TB features identified in the CXRs and the initial diagnostic classification, and the interreader agreement of the global assessment and the radiological findings.

Results: The platform's usability and user satisfaction were evaluated using a questionnaire, which received an average rating of 4.4 (SD 0.59) out of 5. The average examination completion time ranged from 35 to 110 seconds. In addition, the study on CXR showed low sensitivity (16.3%-28.2%) but high specificity (91.1%-98.2%) in the assessment of the consensus case definition of pediatric TB using the platform. The CXR finding having a stronger association with the initial diagnostic classification was air space opacification (χ21>20.38, *P*<.001). The study found varying levels of interreader agreement, with moderate/substantial agreement for air space opacification (κ=0.54-0.67) and pleural effusion (κ=0.43-0.72).

Conclusions: Our findings support the promising role of telemedicine platforms such as BITScreen PTB in enhancing pediatric TB diagnosis access, particularly in resource-limited settings. Additionally, these platforms could facilitate the multireader and systematic assessment of CXR in pediatric TB clinical studies.

Introduction

Tuberculosis (TB) is a communicable disease caused by *Mycobacterium tuberculosis*. According to the World Health Organization (WHO), TB remains one of the leading causes of death globally from a single infectious agent, with over 1.6 million TB-related deaths reported in 2021 [1]. Alarmingly, most children who succumb to TB are never diagnosed or treated [2]. The risk of death is notably high (44%) among children under 5 years with untreated TB, while less than 1% of children receiving recommended treatment die [3].

The diagnosis of TB in children is complex, especially in infants and young children, where the risk of rapid disease progression and mortality is higher than in any other age group [4,5]. The paucibacillary nature of TB in this age group and the absence of highly sensitive point-of-care diagnostic tests to microbiologically confirm pediatric TB make diagnosis challenging [4]. Chest x-ray (CXR) remains a valuable diagnostic tool for TB in children, especially when laboratory testing is unavailable, infeasible, or yields negative results. Most children with pulmonary TB exhibit radiographic changes indicative of TB. For children under 5 years, anteroposterior (AP) and lateral (LAT) views are recommended, while posteroanterior (PA) CXRs are preferred for older children and adolescents [6]. The LAT radiograph is particularly useful in children under 5 years for the optimal evaluation of hilar or mediastinal lymphadenopathy [7]. CXR findings in children with pulmonary TB may lack specificity [8], and CXR alone is insufficient to determine the appropriate treatment for the child. Instead, CXR can support the clinical diagnosis of pulmonary TB when TB is presumed and microbiological testing is negative.

Screening tests using symptoms or CXR may be useful in children who are TB contacts or living with HIV [2]. According to Vonasek et al [2], any abnormality identified on CXR appears to be the most accurate screening test for pulmonary TB in children, although this accuracy can be influenced by the quality of the CXR and interreader variability. In a recent study [9] involving a cohort of HIV-negative children, the majority of whom (92%) were under 5 years old, a treatment-decision algorithm was proposed for low-resource countries. In these settings, CXRs are reserved to confirm diagnoses in patients lacking sufficient clinical evidence to initiate treatment. The WHO guidelines underscore the necessity for further research concerning integrated treatment-decision algorithms [6]. This highlights the crucial importance of promoting research aimed at improving and validating these tools within the pediatric context, thus facilitating informed recommendations in this area [9,10].

Assessing disease severity in children is essential for determining their eligibility for the recommended 4-month treatment regimen for nonsevere TB in children and adolescents aged 3 months to 16 years. CXRs serve as a valuable tool for this purpose. Furthermore, recent WHO guidelines [6] emphasize that CXRs can assist in evaluating treatment response and identifying alternative diagnoses in children who do not respond to TB treatment.

The limitations in accessibility and sensitivity of available diagnostic tests for childhood TB are probable reasons for the gap between the estimated 1.17 million annual incident child TB cases, of which less than half are diagnosed or reported to the WHO [6]. This gap is even more pronounced for children under 5 years old. Additionally, the COVID-19 pandemic has decreased access to TB diagnosis and treatment, particularly affecting children and young adolescents, resulting in a significant decrease in notifications for younger age groups. To address these challenges, the End TB Strategy outlined by the WHO emphasizes the importance of leveraging enhanced digital health tools for more efficient delivery, monitoring, and evaluation of TB patient diagnosis, treatment, and care [11,12]. Telemedicine tools could play a crucial role in enhancing accessibility for diagnosis and treatment. Previous studies have shown that telemedicine can be beneficial in optimizing the care of multidrug-resistant TB in resource-limited settings [13]. Moreover, providing specialist expertise directly through telemedicine tools in low-resource settings has not only improved patient management but also provided additional educational value to local physicians, thereby benefiting other patients as well [14].

In this paper, we introduce a novel telemedicine web platform called BITScreen PTB (Biomedical Image Technologies Screen for Pediatric Tuberculosis), designed for the assessment of pediatric TB using digital CXR images and clinical information. The platform aims to facilitate remote interpretation, streamlining, and standardizing the clinical evaluation of pediatric TB cases, particularly in resource-limited settings where access to expert readers may be limited. The platform underwent functional evaluation in a pilot study conducted by 3 independent expert readers (RSJ, JLR, and HSS). This evaluation involved a retrospective assessment of a data set comprising 218 examinations of children under 3 years of age, selected from a previous study conducted in Mozambique [5,10]. Furthermore, based on the results of the evaluations conducted through the platform in the pilot study, we present new insights into its performance, the agreement among evaluators, and the challenges associated with the assessment of pediatric TB using CXR images, considering various radiological findings.

Methods

BITScreen Platform

BITScreen is a store-and-forward telemedicine platform built using a Model-View-Controller (MVC) design pattern, implemented on open-source frameworks and tools by JJGV. The MVC design pattern offers a modular and scalable structure for organizing and building software applications, facilitating efficient development, maintenance, and expansion of the platform. In an MVC application, the "View" is responsible for presenting information to the end user, while the "Controller" manages the user's interaction using the data stored and organized in the "Model." The primary functional requirement of the platform is to facilitate asynchronous medical evaluation of pediatric TB studies. This involves assessing clinical data and CXR images, optionally including corresponding clinical symptoms. The global requirements identified in the design of the system are listed in Textbox 1.

Textbox 1. Global requirements identified in the system design.

- Multistudy

The capacity to perform multiple clinical projects simultaneously.

- Multicenter

The system must allow the participation of multiple medical centers and admit many-to-many relationships between medical centers and projects/studies.

- Multidevice

Web-based access to the views of the platform, which allows its use in different devices through an internet browser.

- Security

The platform must warrant security in terms of authentication, confidentiality, and integrity in compliance with European regulations.

- Cloud Storage

The system must enable the secure storage of images, tests, and reports associated with the project in a remote environment.

Figure 1 illustrates the unified modeling language use case diagram, which delineates the interaction between users and the system. The user roles include the examiner, responsible for patient management and creating new examinations; the evaluator, tasked with assessing studies by identifying potential TB-related findings in CXR images; and the administrator user, responsible for managing user and medical center access. Additionally, the administrator defines examiners (individuals who examine patients) and evaluators (individuals who assess CXRs) and monitors the progress of evaluations.

Figure 1. Use case diagram of the BITScreen PTB (Biomedical Image Technologies Screen for Pediatric Tuberculosis) platform with the 3 roles considered (examiner, evaluator, and administrator) and the operations associated with them. All the “Manage” operations included the suboperations new, edit, and delete.

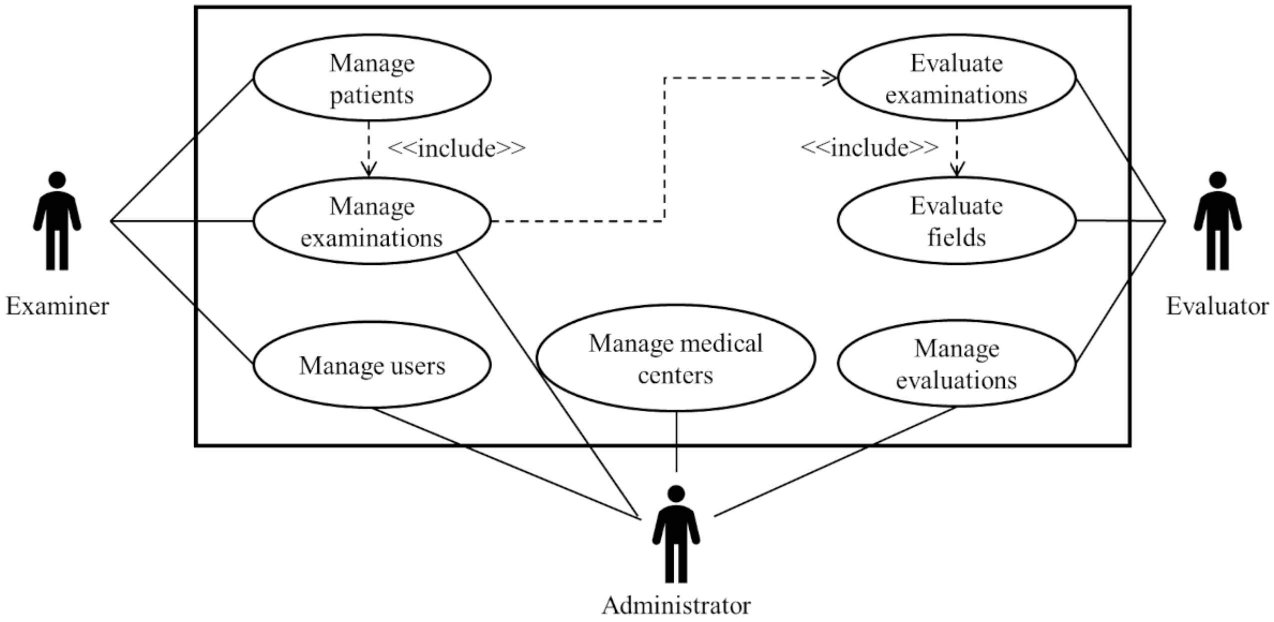

Figure 2 displays the activity diagrams designed to illustrate the process of uploading a new examination to the platform by an examiner, incorporating clinical information and CXR images, as well as the subsequent transmission of the corresponding examination to be evaluated by an evaluator user. The input fields included by the examiner to create a new examination were month and year of birth, date of the examination, cough, fever, malnutrition, HIV status, BCG (Bacillus Calmette-Guérin) vaccine scar, tuberculin skin test, TB diagnosis, TB contact, TB treatment, treatment starting date, and the CXR images (AP or PA and LAT views). In our pilot study, only the CXR images were presented to the evaluators. The patient’s age was determined based on the month and year of birth in relation to the acquisition date of the CXR. The examiner is required to upload at least one AP or PA view CXR image, with the LAT view being optional if available. In this pilot study, only evaluators were granted access to the CXR images. In the evaluation process, the platform was designed to include the assessment of the image quality of the CXR images; the identification of pulmonary TB radiological findings in various regions of the lungs, considering different types of findings; and a global evaluation of the CXR examination. In Figure 2, only 1 evaluation is depicted, but the platform allows for multiple evaluations (in our platform validation, we included 3 evaluations for each examination). If more than 1 evaluation is configured, the evaluation process of the examination will not conclude until all evaluators have completed their assessments within the platform.

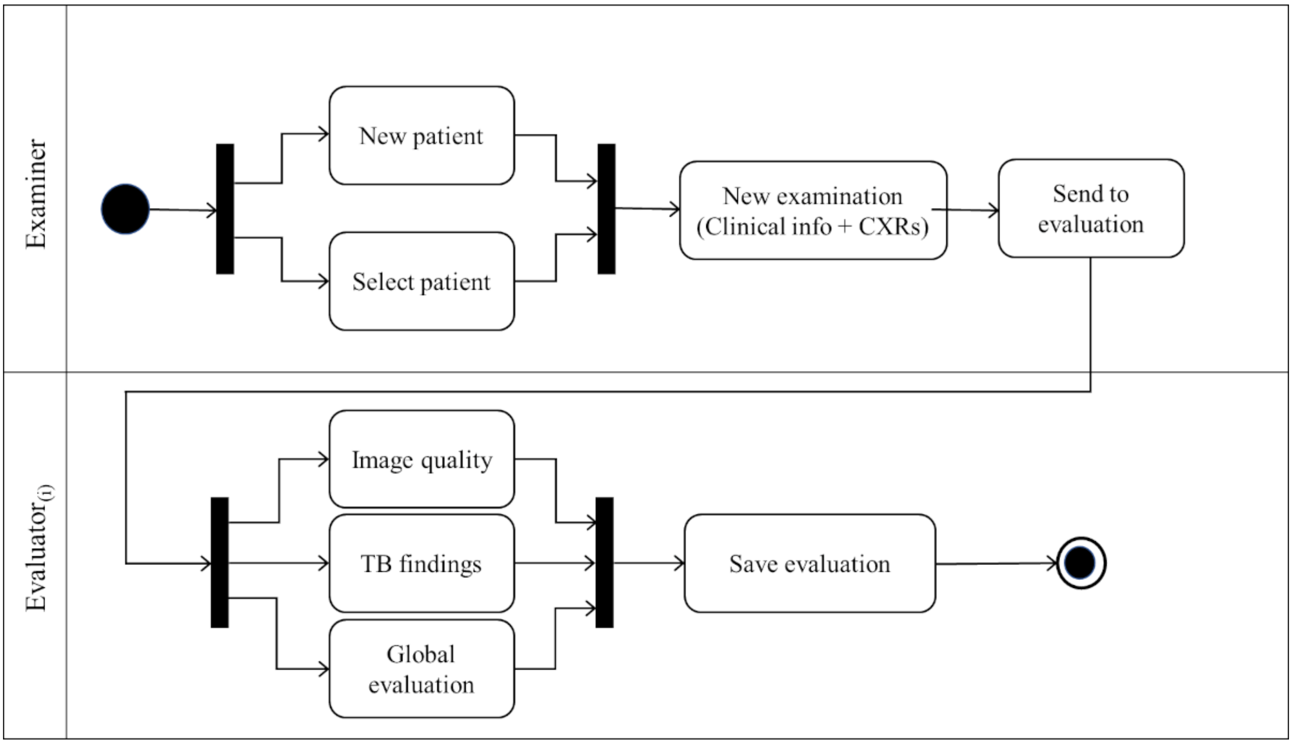
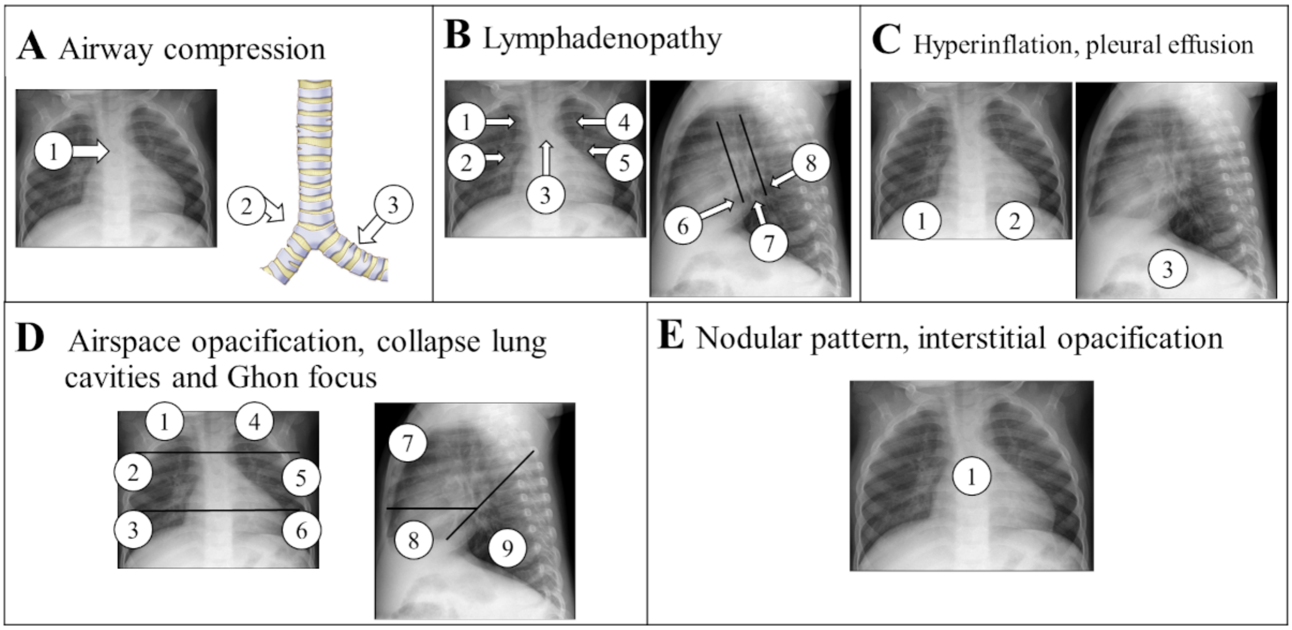
Figure 2. Activity diagram of the process for creating and evaluating a new examination including the clinical information about the patient and the chest x-ray (CXR) images (anteroposterior or posteroanterior and lateral views). TB: tuberculosis.



The evaluation of CXR images is pivotal for identifying presumed patients with TB and constitutes a primary focus of the platform’s design. To ensure a comprehensive and rigorous assessment of the CXR images, evaluators are required to indicate “yes” or “no” to assess the presence or absence of various radiological TB findings across different thoracic locations. For this purpose, we divided the assessment into 10 sections corresponding to different types of findings, resulting in a total assessment of 55 independent observations, with 36 from the AP/PA view and 19 from the LAT view. The 10 sections of pediatric CXR TB findings corresponded to airway compression or tracheal displacement, soft tissue density suggestive of lymphadenopathy, hyperinflation, pleural effusion, air space opacification, collapsed lobe or lung, cavities, calcified parenchymal lesions, nodular pattern, and interstitial opacification. Figure 3 depicts the templates provided to the evaluators, highlighting the specific locations of the features to be assessed. These locations and types of findings were determined based on previous recommendations in the literature, including the “Diagnostic CXR Atlas for Tuberculosis in Children” [15] and the CXR review tool developed by Andronikou and the South African Tuberculosis Vaccine Initiative (SATVI) and used in Graham et al [16].

Figure 3. Evaluation templates with the location of the specific findings that should be assessed by the evaluators with "yes" or "no" for each of the 10 sections. (A) Locations for the evaluation of possible airway compression or tracheal displacement. (B) Locations for the assessment of soft tissue density suggestive of lymphadenopathy. (C) Locations for the assessment of hyperinflation and pleural effusion. (D) Locations for the evaluation of air space opacification, collapsed lung, cavities, and calcified parenchyma. (E) Location for the assessment of nodular pattern, either miliary or larger widespread and bilateral nodules, and interstitial opacification. Based on [15,16] and chest x-ray review tool developed by Andronikou and the South African Tuberculosis Vaccine Initiative and used in Graham et al [16].



For the back-end implementation of the platform, we used PHP's Laravel framework (version 6.2; PHP Group). Laravel offers a range of built-in tools and features, which were leveraged in the project, including routing, authentication, authorization, database connection management, and the Blade templating engine. For data storage, we opted for the MariaDB database (version 10.1.38; MariaDB plc/MariaDB Foundation), a fork of the MySQL database management system. We chose MariaDB because of its efficiency, customization options, portability, reliability, open-source nature, cost-effectiveness, and widespread adoption by a large and active community. The front end of the platform was built using the Bootstrap framework (version 4.3.1; Bootstrap Core Team), which offers a plethora of predesigned components that can be seamlessly integrated into a website. Indeed, Bootstrap's responsive design ensures that the application can be easily accessed and used across a wide range of devices and screen sizes. As for the server configuration, it operates on Debian 4.9 (Debian Project) and is equipped with 2 virtual central processing unit cores (Intel Xeon), 4 GB of RAM, and 100 GB of hard disk space. This setup provides a stable and efficient environment for hosting the platform and handling user interactions.

Data Set Pilot Study

The data set used to evaluate the platform in our pilot study was sourced from a previous prospective descriptive study called ITACA [5]. This study focused on young children under 3 years of age presumed to have TB and was conducted at the Manhiça Health Research Center (CISM), situated in Southern Mozambique [5,10]. For our evaluation, we collected a total of 218 examinations. This included all microbiologically confirmed and "probable" cases, as well as a random selection of 113 additional cases from the unlikely TB cases subset. The cases were confirmed using Ziehl-Neelsen staining, rapid tests, and Xpert MTB/RIF, with identification through mycobacterial molecular identification (HAIN GenoType Mycobacterium CM/AS; Hain Lifescience) [5]. Table 1 presents their demographic data. To enhance comparability between studies and encourage the standardization of diagnostic procedures, we adhered to the case definition classification for research reporting based on diagnostic evaluation studies of intrathoracic TB in children proposed by Graham et al [17]. In this update from the previous case definitions presented in 2012 and 2013 [16,18], the authors established 3 case definitions: confirmed TB, unconfirmed TB, and unlikely TB. The collected cases were retrospectively classified [5] according to these definitions, using the information gathered from the previous study [10]. Table 2 displays the TB diagnosis categories identified alongside the corresponding clinical data for each case. The symptom definitions considered were as follows [5]: cough for 14 days or more not responding to a course of antibiotics; fever greater than 38°C for 14 days or more; malnutrition defined as under 60% weight for height, failure to gain weight for more than 2 months, or any loss of weight not responsive to nutritional intervention; and TB contact in the last 12 months.

Table 1. Patient demographic characteristics of the data set of the pilot study.

Demographic characteristics	Male (n=122), n (%)	Female (n=96), n (%)	Total (N=218), n (%)
Age range			
<12 months	18 (14.8)	19 (19.8)	37 (17.0)
12-23 months	54 (44.3)	43 (44.8)	97 (44.5)
24-35 months	50 (41.0)	34 (35.4)	84 (38.5)

Table 2. Diagnostic categories and corresponding clinical characteristics considering the definitions from López-Varela et al [5] and Graham et al [17].

TB[a] category	Confirmed (n=10), n (%)	Unconfirmed TB (n=95), n (%)	Unlikely TB (n=113), n (%)
Sex			
Female	6 (60.0)	44 (46.3)	46 (40.7)
Age range (months)			
<12	3 (30.0)	21 (22.1)	13 (11.5)
13-23	3 (30.0)	42 (44.2)	52 (46.0)
24-35	4 (40.0)	32 (33.7)	48 (42.5)
Cough			
Yes	5 (50.0)	17 (17.9)	14 (12.4)
Fever			
Yes	4 (40.0)	6 (6.3)	5 (4.4)
Malnutrition			
Yes	5 (50.0)	81 (85.3)	104 (92.0)
HIV status			
Positive	2 (20.0)	35 (36.8)	4 (3.5)
BCG[b] scar			
Yes	10 (100.0)	94 (98.9)	113 (100.0)
TB contact			
Yes	2 (20.0)	11 (11.6)	4 (3.5)

[a] TB: tuberculosis.

[b] BCG: Bacillus Calmette-Guérin.

Ethics Approval

The ITACA study protocol received approval from both the Mozambican National Bioethics Committee (15/CNBS) and the Hospital Clinic of Barcelona Ethics Review Committee (HCB/2009/4682). Written informed consent was obtained from the parents/legal guardians of all study participants. Additionally, the substudy focusing on the digital processing of the CXR images was approved by the Mozambican National Bioethics Committee.

Evaluation Protocol

The 218 baseline examinations, conducted at the time of evaluation for presumptive TB, were uploaded by the administrator user using the platform's automatic importing feature. This was done via a CSV file containing the input fields outlined in Table 2, along with the location of the CXR files featuring the AP view (in all participants) and the LAT view (in 207 participants). The platform automatically assigned all cases to 3 pediatric CXR expert readers, each possessing extensive experience in assessing TB imaging in endemic settings of low-income, resource-limited countries [5,19]. These 3 evaluators conducted a blind evaluation of the 218 examinations using the platform, relying solely on the CXR views and reference templates (Figure 3), without any additional information. The evaluation encompassed the following components: (1) assessment of CXR image quality, categorized as "acceptable," "poor but readable," or "not acceptable not readable"; (2) evaluation of 55 observations across 10 sections, with responses marked as "yes" or "no"; and (3) a final global evaluation of the case, categorized as "suggestive of TB," "not suggestive of TB," or "not evaluable."

Performance Metrics

To evaluate the performance of the evaluations, we used the metrics sensitivity, specificity, positive predictive value (PPV), F_1-score, and accuracy. We defined sensitivity or recall as the number of true-positive cases with x-ray findings suggestive of TB divided by the sum of true positives and false negatives.

We defined specificity as the number of true negatives divided by the sum of true negatives and false positives. The PPV is the proportion of true-positive predictions out of all positive predictions (true positives + false positives). It measures how many of the positive predictions are actually correct. The F_1-score serves as a measure of a model’s accuracy by blending both the PPV and recall. It is commonly used to assess the effectiveness of a classification algorithm. Ranging between 0 and 1, an F_1-score of 1 indicates flawless PPV and recall, while a score of 0 signifies the poorest performance achievable. Accuracy, by contrast, is calculated as the sum of true positives and true negatives divided by the sum of true positives, true negatives, false positives, and false negatives. A true-positive case is identified when an evaluator marks a case as “suggestive of TB” in the global evaluation, and the examination is classified as either “confirmed” or “unconfirmed TB.” Conversely, a true-negative case occurs when the evaluator designates “not suggestive of TB,” and the examination is labeled as “unlikely TB.” An examination is considered a false negative if the evaluator indicates “not suggestive of TB,” yet the case is classified as “confirmed” or “unconfirmed TB.” A case is classified as false positive if an evaluator marks it as “suggestive of TB,” while the examination is categorized as “unlikely TB.” Furthermore, we examined the relationship between TB features identified in the CXRs and the global evaluation (“suggestive of TB” and “not suggestive of TB”) concerning the initial diagnostic classification, combining “confirmed” and “unconfirmed TB.” Statistical significance was determined by a chi-square P value <.05. Finally, we used Cohen kappa to assess the interreader agreement across all evaluations conducted by the evaluators, including CXR image quality, TB feature assessments, and TB global evaluations. Kappa scores were categorized as follows: ≤0 for no agreement, 0.01-0.2 for slight agreement, 0.21-0.4 for fair agreement, 0.41-0.6 for moderate agreement, 0.61-0.8 for substantial agreement, and 0.81-1.00 for almost perfect agreement.

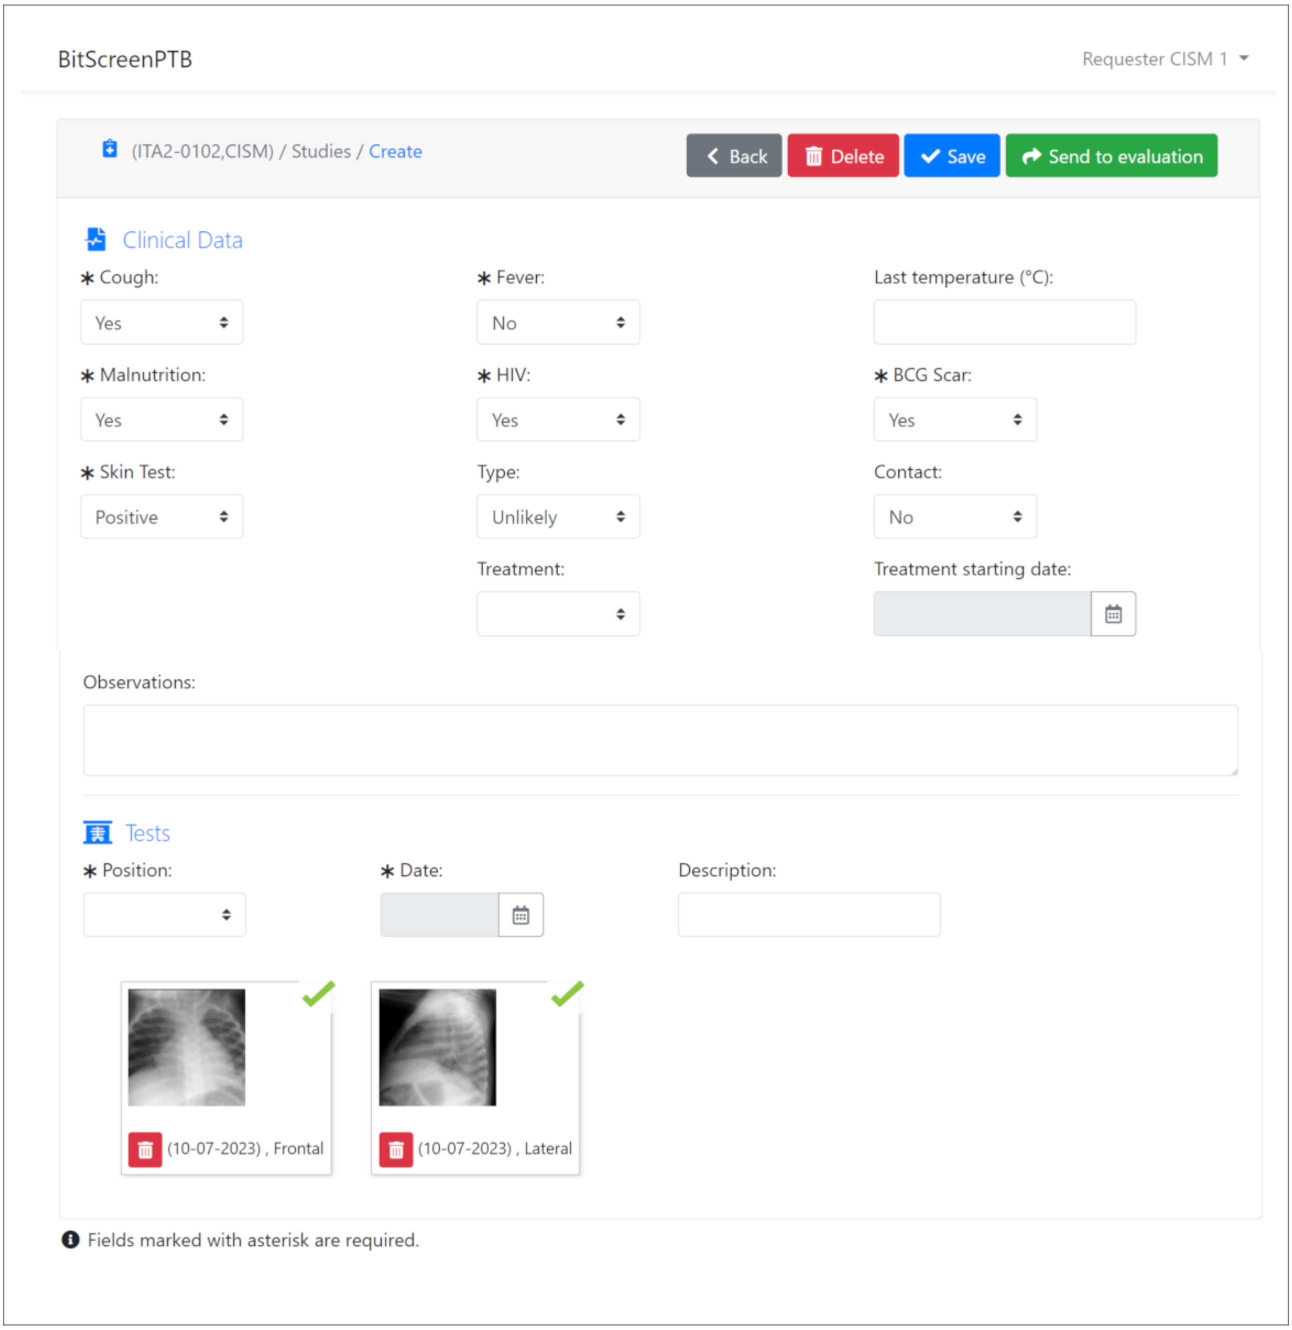
Platform Usability Evaluation

We developed a comprehensive questionnaire comprising 5 sections and 15 items to thoroughly assess the usability of the platform. This questionnaire was adapted from the Telehealth Usability Questionnaire (TUQ) proposed by Parmanto et al [20], a well-established tool for evaluating telemedicine services [21]. Our questionnaire addresses various crucial usability aspects, encompassing usefulness (3 items), ease of use and learnability (2 items), interface quality (4 items), reliability (2 items), and global satisfaction (2 items). A detailed breakdown of the questionnaire components and associated items is presented in Table 3. Additionally, we conducted an analysis to ascertain the duration of the evaluation process for each examination. We precisely measured the duration from the initiation of a new examination request to the submission of the evaluator’s final evaluation into the system. By computing the time difference between these 2 events, we obtained a precise and dependable estimate of the time taken by the expert to conduct a comprehensive evaluation of an examination.

Results

The 2 primary views of the new BITScreen platform are illustrated in Figures 4 and 5: the input form utilized by examiner users and the evaluation form used by evaluator users, respectively. In the top section of the input form (Figure 4), examiners input details such as cough, fever, last temperature, malnutrition, HIV status, BCG scar presence, tuberculin skin test result, TB category, contact with a TB source patient, treatment status, treatment starting date, and any observations. In the bottom section, examiners have the option to upload CXR images for evaluation by the evaluators.

Figure 4. Example of the BITScreen PTB (Biomedical Image Technologies Screen for Pediatric Tuberculosis) examiner user view of a new examination with the 2 different areas: Clinical data and Images.



∗ Cough: Yes
∗ Fever: No
Last temperature (°C):
∗ Malnutrition: Yes
∗ HIV: Yes
∗ BCG Scar: Yes
∗ Skin Test: Positive
Type: Unlikely
Contact: No
Treatment:
Treatment starting date:
Observations:

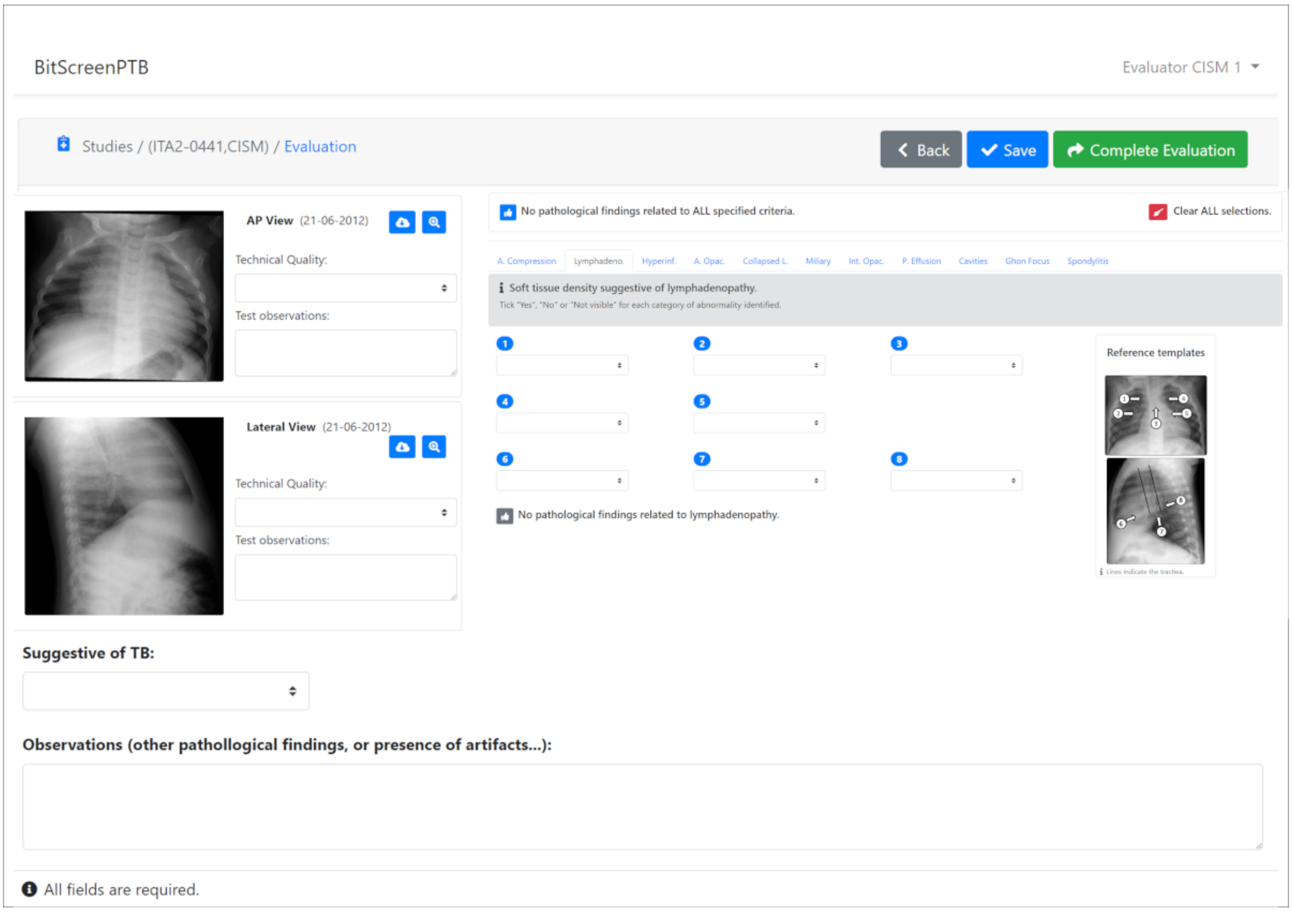
∗ Position:
∗ Date:
Description:

(10-07-2023) , Frontal
(10-07-2023) , Lateral

Fields marked with asterisk are required.

In the case of the evaluation form (Figure 5), the view used by the evaluators displays the CXR images on the left side of the screen, allowing them to download or zoom in on each image for detailed examination. Evaluators are tasked with assessing the quality of each CXR image. On the right side of the screen, the 10 sections described previously are presented as separate tabs. Within these tabs, evaluators are required to assess all 55 different observations. The templates depicted in Figure 3 remain consistently visible in the view to aid evaluators in their tasks. Readers are provided with the option to mark all locations without pathological findings as “no” for all criteria at once or for all locations of a specific criterion, streamlining and expediting the evaluation process. At the bottom of the view, the global evaluation field for the examination is displayed. All fields are mandatory, except in cases where the CXR images are deemed not evaluable.

Figure 5. Example of the BITScreen PTB (Biomedical Image Technologies Screen for Pediatric Tuberculosis) evaluator user view with 3 different areas: quality image assessment, identification of the presence of findings in the different locations presented in the templates, and a global evaluation of the case.



No pathological findings related to ALL specified criteria.

Soft tissue density suggestive of lymphadenopathy.

Tick "Yes", "No" or "Not visible" for each category of abnormality identified.

No pathological findings related to lymphadenopathy.

Lines indicate the trachea.

All fields are required.

The results of the usability questionnaire administered on the telemedicine platform are outlined in Table 3. The overall score for all questions averaged 4.4 (SD 0.59) out of 5. Users rated the platform positively in terms of usefulness, with an average rating of 4.42 out of 5; ease of use and learnability, receiving an average rating of 4.47 out of 5; and interface quality, which garnered positive feedback with an average rating of 4.13 out of 5. The platform was also perceived as reliable, with an average rating of 4.26 out of 5 and a high level of variability (SD 0.82). Additionally, all 3 evaluators expressed a high level of satisfaction with the platform, giving it an average rating of 5.0 out of 5.

Some specific questions received lower ratings, particularly item 4 in the interface quality dimension (The system is able to do everything I would want it to be able to do) and item 1 in the reliability dimension (Whenever I made a mistake using the system, I could recover easily and quickly). Conversely, items with higher feedback included item 1 in the ease of use and learnability section (It was simple to use this system), as well as questions related to global satisfaction and future use, where “I would use the platform again” and “Overall, I am satisfied with the platform” received maximum feedback from all evaluators.

Table 3. Results of the Usability Questionnaire (1=strongly disagree to 5=strongly agree).

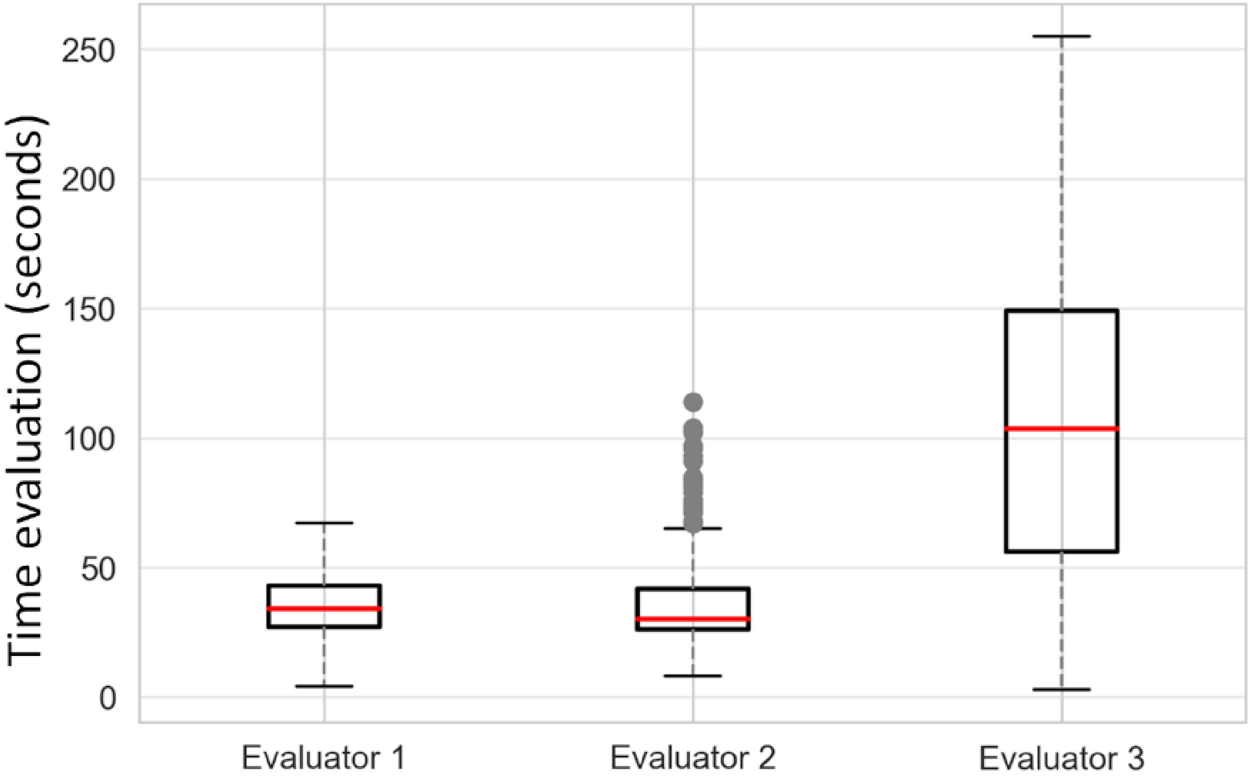
Section	Mean (SD)
Usefulness	4.42 (0.53)
1. It facilitates the assessment of CXRs[a] in pediatric TB[b] studies	4.64 (0.58)
2. It saves me time assessing CXRs in pediatric TB studies	4.31 (0.58)
3. It includes all the items I need to evaluate pediatric TB studies	4.31 (0.58)
Ease of use and learnability	4.47 (0.52)
1. It was simple to use this system	5.00 (0.00)
2. It was easy to learn the system	4.31 (0.58)
3. The templates with the location of the findings facilitate the assessment of the cases	4.31 (0.58)
4. I believe I could become productive quickly using this system	4.31 (0.58)
Interface quality	4.13 (0.58)
1. The way I interact with this system is pleasant	4.00 (0.00)
2. I like using the system	4.31 (0.58)
3. The system is simple and easy to understand	4.31 (0.58)
4. The system is able to do everything I would want it to be able to do	3.91 (1.00)
Reliability	4.26 (0.82)
1. Whenever I made a mistake using the system, I could recover easily and quickly	3.91 (1.00)
2. The system gave error messages that clearly told me how to fix the problems	4.64 (0.58)
Satisfaction and future use	5.0 (0.00)
1. I would use the platform again	5.0 (0.00)
2. Overall, I am satisfied with the platform	5.0 (0.00)

[a] CXR: chest x-ray.

[b] TB: tuberculosis.

Figure 6 presents the completion times of the evaluators. Evaluator 2 demonstrated the shortest completion time, averaging 35.3 (SD 13.2) seconds. Evaluator 1 followed with an average time of 37.8 (SD 19.2) seconds, while evaluator 3 recorded the longest completion time, averaging 110.3 (SD 63.2) seconds. Despite evaluator 3 taking more time, their superior performance and identification of more observations justify the additional time spent. A previous study [22] has indicated that radiologists typically spend an average of 2 minutes and 9 seconds (129 seconds) evaluating and reporting neonatal CXR images, a duration longer than what was observed in our study. However, it is crucial to highlight that our reviewers were tasked solely with marking specific findings' locations, assessing image quality, and delivering a global assessment, without the need to compose a report or dictate findings. In any case, our findings suggest that the platform could serve as a valuable tool for swiftly evaluating cases and annotating findings in CXR images.

Figure 6. Evaluation time in seconds by the 3 evaluators of the 218 examinations.



Next, we present the results from the assessment of 218 examinations in this pilot study. The evaluation of the CXR AP views revealed that 195/219 (89.0%), 167/193 (86.5%), and 150/219 (68.5%) images were rated as "acceptable" by evaluators 1, 2, and 3, respectively. Additionally, 23/219 (10.5%), 26/193 (13.5%), and 65/219 (29.7%) were rated as "poor but readable." However, for the LAT views, the image quality was lower. Specifically, 160/209 (76.6%), 109/161 (67.7%), and 128/208 (61.5%) images were rated as "acceptable" by the 3 evaluators, while 42/209 (20.1%), 46/161 (28.6%), and 59/208 (28.4%) were rated as "poor but readable." Additionally, 7/209 (3.3%), 6/161 (3.7%), and 21/208 (10.1%) LAT views were deemed "not acceptable, not readable." Notably, only evaluator 3 rated all views of the CXRs as "not acceptable, not readable" in 2 examinations, and there was only 1 image that received this rating from all 3 evaluators. The number of images classified in each category by each expert is presented in Figure S1 in Multimedia Appendix 1, while Figure S2 in Multimedia Appendix 1 provides examples of images and their corresponding ratings.

Table 4 displays the performance metrics of the global evaluation. Among the 3 evaluators, evaluator 3 exhibited the highest sensitivity (28.2%), F_1-score (40.8%), and accuracy (60.9%). However, evaluator 3 had the lowest specificity (91.1%), indicating a potential tendency to classify more unlikely TB cases as suggestive of TB compared with the other evaluators. Evaluator 2 demonstrated the highest specificity (98.2%), suggesting proficiency in accurately identifying unlikely TB cases. However, the evaluator displayed the lowest scores for sensitivity (12.4%) and F_1-score (21.7%), indicating challenges in correctly identifying both confirmed and unconfirmed TB cases. Evaluator 1's scores were intermediate across all metrics, except for PPV, which exhibited the lowest score (73.9%). This suggests that while evaluator 1 did not excel in any specific metric, the performance was consistently average across all metrics. To further illustrate the results, Figure 7 showcases the confusion matrices with the corresponding counts of true negatives (top left), true positives (bottom right), false positives (top right), and false negatives (bottom left), while Table S1 in Multimedia Appendix 1 provides the evaluation for each TB diagnostic class.

Table 4. Performance metrics considering sensitivity, specificity, positive predictive value, $F1$-score, and accuracy (N=218)[a].

Metrics	Evaluator 1	Evaluator 2	Evaluator 3
Sensitivity (95% CI)	16.3 (10.5-24.6)	12.4 (7.4-20.0)	28.2 (20.4-37.5)
Specificity (95% CI)	94.6 (88.8-97.5)	98.2 (93.8-99.5)	91.1 (84.3-95.1)
Positive predictive value (95% CI)	73.9 (50.3-63.4)	86.7 (62.1-96.3)	74.4 (58.9-85.4)
F_1-score (95% CI)	26.8 (19.8-35.1)	21.7 (15.2-29.9)	40.8 (33.1-49.1)
Accuracy (95% CI)	56.9 (50.3-63.4)	56.9 (50.2-63.3)	60.9 (54.3-67.2)

[a] All values are in percentages.

Figure 7. Confusion matrices of the 3 evaluators. TB: tuberculosis.

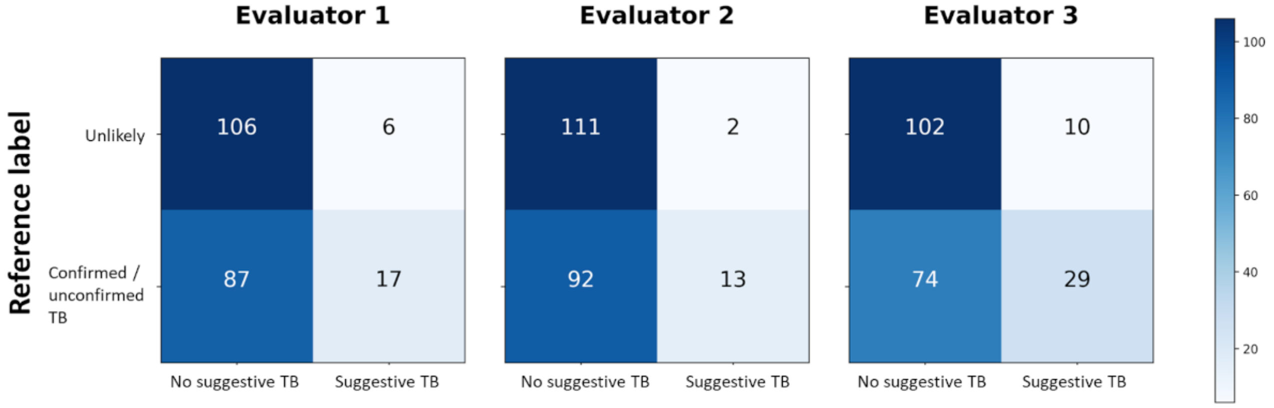


Table 5 displays the number of observations recorded by each of the 3 evaluators in the 3 diagnostic categories, namely, confirmed TB, unconfirmed TB, and unlikely TB, across the 10 examination fields. The total number of observations recorded by the 3 evaluators was 64, 59, and 150, highlighting a substantial difference between evaluator 3 and the other 2 evaluators. This difference was particularly noticeable in the unconfirmed TB and unlikely TB categories. Air space opacification emerged as the category with the highest number of observations by all evaluators, notably in the unconfirmed TB category, where it ranged from 22 to 33, totaling 95 cases. Following closely, lymphadenopathy was the second most frequently observed area, with evaluator 3 recording this finding in 34 examinations across all categories, 22 of which were in the unconfirmed TB category. Additionally, a notable number of observations were recorded in the interstitial opacification field, with evaluator 3 being particularly active in marking this finding in 16 examinations. By contrast, the areas of cavities and calcified parenchyma were only identified by evaluator 3, who marked 4 and 6 examinations, respectively. It is also worth noting that evaluator 3 recorded observations for all examination areas, whereas evaluators 1 and 2 did not record any observations in the cavities and calcified parenchyma areas. Finally, Figure 8 showcases examples of observations for 4 different patients with detailed marking of their findings.

Table 5. Results of the evaluation of the findings by the 3 experts considering the AP[a] and lateral CXRs[b] without additional clinical information. Each data point of the table represents the number of patients where the evaluators reported 1 or more times the presence of the finding. The last row includes all the patients with any of the previous abnormalities. The order of the data comes from the assessment of the findings by evaluators 1/2/3 (N=218).

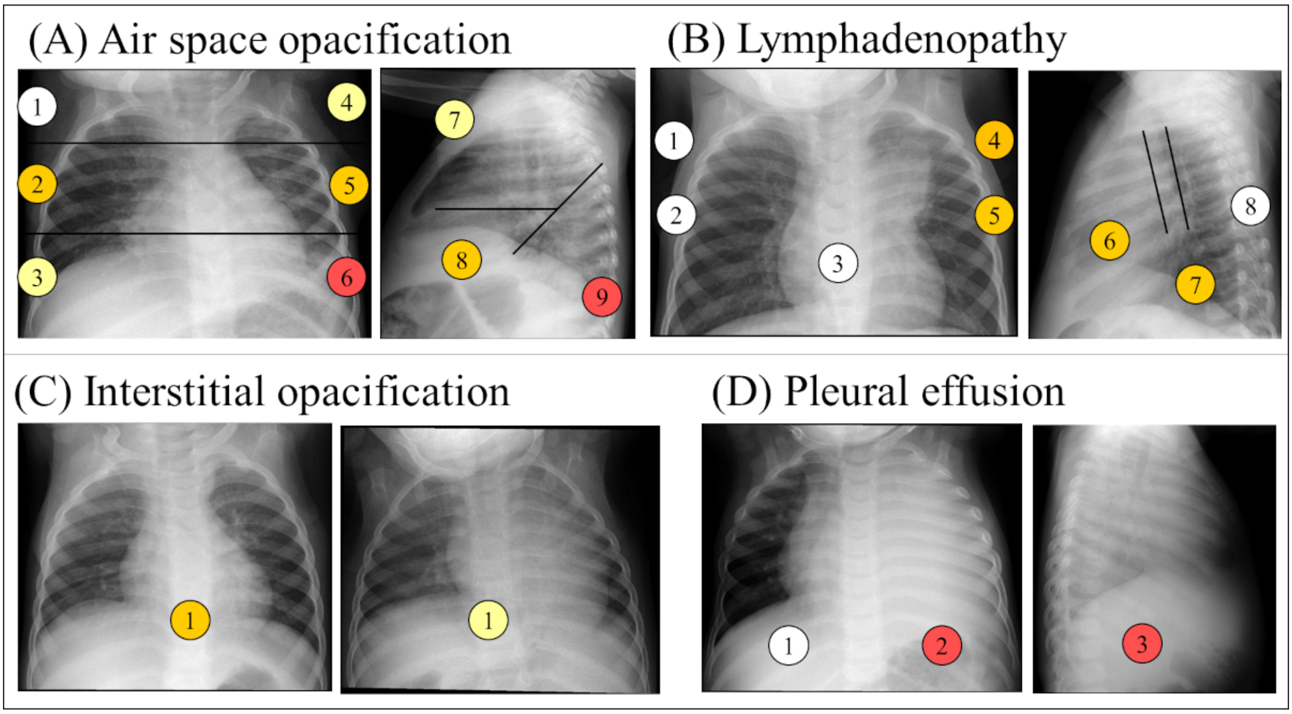
Results	Overall, n	Confirmed, n	Unconfirmed TB[c], n	Unlikely TB, n
Number of patients	218	10	95	113
Airway compression or tracheal displacement or both	4/0/7	2/0/0	2/0/4	0/0/3
Lymphadenopathy	7/7/34	3/1/4	4/4/22	0/2/8
Hyperinflation	4/0/3	2/0/0	2/0/2	0/0/1
Air space opacification	31/42/52	7/7/7	22/30/33	2/5/12
Collapsed lung	5/1/9	0/0/2	4/1/6	1/0/1
Nodular picture	1/2/3	0/0/1	1/2/2	0/0/0
Interstitial opacification	7/1/28	1/0/2	5/1/16	1/0/10
Pleural effusion	5/6/4	0/0/0	5/6/4	0/0/0
Cavities	0/0/4	0/0/0	0/0/3	0/0/1
Calcified parenchyma	0/0/6	0/0/0	0/0/4	0/0/2
Any abnormality	41/46/92	8/7/9	30/33/54	3/6/29

[a] AP: anteroposterior.

[b] CXR: chest x-ray.

[c] TB: tuberculosis.

Figure 8. Example of evaluations of findings in different studies. The locations of the findings are defined in Figure 3. The color of the locations represents the number of evaluators that identified the presence of the finding in that location, being 0 evaluators for white, 1 evaluator for yellow, 2 evaluators for orange, and 3 evaluators for red. (A) Presence of air space opacification in the anteroposterior (AP) and lateral chest x-ray (CXR) views of an examination of a female patient of 11 months classified as unconfirmed tuberculosis (TB) and as suggestive of TB by 1 out of the 3 evaluators. (B) Presence of lymphadenopathy in the AP and lateral CXR views of an examination of a female patient of 11 months classified as confirmed TB and as suggestive of TB by the 3 evaluators. (C) Presence of interstitial opacification on AP CXR views of 2 studies, the one on the left is from a male patient of 1 year and 4 months of age. Both studies were classified as unconfirmed TB and not suggestive of TB. The AP view on the right corresponds to a patient of female of 11 months of age. The examination was classified as unlikely TB and 1 out of 3 evaluators assessed it as confirmed TB. (D) Presence of pleural effusion in the AP and lateral view of an examination of a male of 2 years and 2 months of age classified as confirmed TB and evaluated as suggestive of TB by the 3 evaluators.



To gain a deeper understanding of how various evaluations influence the final diagnosis of TB, we examined the association between the assessments made by each evaluator, including the final evaluation and the initial diagnostic classification. The results of the chi-square test (see Table S2 in Multimedia Appendix 1) indicated that the most significant association for the CXR features was observed with the identification of air space opacification, yielding χ^2_1>20.38 and *P*<.001 for all evaluators. The second most noteworthy finding was the significant association of lymphadenopathies with the initial classification for evaluator 1 (χ^2_1=5.79, *P*=.02) and evaluator 3 (χ^2_1=11.88, *P*<.001). Additionally, the final evaluation showed a significant association with the initial classification, with *P* values of .02, .005, and <.001 for evaluators 1, 2, and 3. These findings are consistent with those presented in Table 5, which highlighted that these fields had the highest number of observations among the rest.

Finally, we investigated the agreement between evaluators using the Cohen kappa score for the interreader agreement for image quality, the global evaluation, and all the different findings (see Table S3 in Multimedia Appendix 1). Concerning image quality, we observed substantial agreement between evaluators 1 and 2 (κ=0.65), but only fair agreement between evaluators 1 and 3 (κ=0.33) and 2 and 3 (κ=0.31), primarily due to evaluator 3 assessing many more images as “poor quality.” The agreement for the global evaluation was very similar, with fair agreement ranging from 0.26 to 0.32. However, for the findings, we found that air space opacification exhibited a moderate to substantial Cohen kappa index, ranging from 0.54 to 0.67. The number of observations identified by the evaluators (as shown in Table 5) and the association with the initial classification (as demonstrated in Table S2 in Multimedia Appendix 1) underscored the significance of air space opacification as a crucial finding. Its large number of observations, strong association, and consistency between different evaluators emphasize its importance in the diagnosis process. Another field demonstrating moderate to substantial agreement was pleural effusion, with Cohen kappa scores ranging from 0.43 to 0.72. However, despite this strong agreement, there were fewer observations and a weaker association with the initial classification. Lymphadenopathies also emerged as an important finding in terms of observation and association, but the agreement was only slight, ranging between 0.13 and 0.21.

Discussion

Principal Findings

Store-and-forward telemedicine has emerged as a valuable solution for improving access to specialist and primary health care advice, leveraging technological advancements to overcome barriers in low-resource settings [13,14]. Our work showcases the potential application of this approach in assessing TB in young children in underserved areas, where the shortage of specialists and the challenges associated with TB assessment in this population may have a greater impact. The positive assessment of the telemedicine system, coupled with the reduced time needed for evaluation, further bolsters the case for utilizing telemedicine in diagnosing pulmonary TB. This not only ensures timely intervention but also promotes efficient health care delivery.

The low sensitivity of x-rays in identifying positive cases in our pilot study corroborates the challenges reported in diagnosing TB in children, as documented in other studies [23-27]. Limited research has offered detailed insights into the global sensitivity and specificity of CXR in young children for TB diagnosis. Kaguthi et al [24] reported sensitivities ranging from 50% to 75% and specificities between 72.9% and 85.2%. However, they acknowledged the imprecision in measuring sensitivity due to the limited number of definitive cases. Berteloot et al [27] reported higher sensitivities (71.4%) and lower specificities (50.0%), although the evaluation process involved a consensus and an older age group of children. Other studies [25,26] have also investigated the performance of TB diagnosis using CXR but focused on the most relevant findings to support the diagnosis [25,26]. Similar to those findings, in our results, lymphadenopathies, opacifications, and pleural effusions were the findings having the strongest association with positive evaluation (as indicated in Table S2 in Multimedia Appendix 1). Integrating a treatment-decision algorithm that incorporates clinical evidence, CXR findings, and the Xpert MTB/RIF assay (or its current version, Xpert MTB/RIF Ultra), as proposed by several studies [2,9], could enhance the performance of the diagnostic process and streamline treatment decisions. This approach could be considered in future developments.

Comparison With Other Studies

In terms of interreader agreement, our findings align, to some extent, with other studies that have also reported slight to moderate agreement [24,25,28]. Kaguthi et al [24] reported poor agreement on abnormalities consistent with TB (κ=0.14) and moderate agreement (κ=0.26) on lymphadenopathy. However, their lower agreement results compared with ours could be attributed to the variability in expertise among the readers. Our results are more closely aligned with other studies in terms of the reader profile [25,27,28]. For instance, Palmer et al [25] reported a moderate agreement (κ>0.4) on specific features such as alveolar opacification, pleural effusion, expansile pneumonia, and enlarged perihilar lymph nodes. Similarly, Berteloot et al [27] reported a κ value of 0.36 between a radiologist and a pediatric pulmonologist. Lastly, Andronikou et al [28] presented a κ value of 0.5 among trained pediatric radiologists, although their data set included older children with a mean age of 9 years.

Limitations

Our pilot study has several limitations. First, the number of confirmed cases is small, and the presence of some important features relevant to diagnosis by CXR, such as airway compression or tracheal displacement, nodular pattern, cavities, or calcified parenchyma, is also limited. This may explain the lack of a stronger association with the TB classification highlighted in other studies [23]. The evaluators’ performance was compared with the case definition, which includes abnormal CXR as one of the criteria for unconfirmed TB. As observed in analogous studies [27,28], our research was constrained by the limited number of studies and readers. Broader validation, including a wider range of studies and readers, may provide more robust insights into the agreement and performance of the evaluations. The expertise of our readers may not fully reflect the typical skill set available in resource-limited settings; however, this challenge can be overcome through the implementation of consensus classifications. Moreover, the approach of conducting double assessments by both nonexperts and experts has been successfully tested in other projects [29,30], suggesting its potential effectiveness in enhancing diagnostic accuracy. By incorporating these methods into our telemedicine platform, we can overcome limitations related to reader expertise and enhance the overall diagnostic process for pediatric TB in resource-limited settings.

Besides the current utilization of the platform as a diagnostic tool for remote evaluation of CXR examinations, we have planned its future use for the systematic assessment of data sets in clinical studies and as a labeling tool for TB findings present in CXR. This will facilitate the training of artificial intelligence segmentation and classification models. The inclusion of new data sets from multiple settings and the expansion of the number of readers will enable a comprehensive validation of the platform. Additionally, it is essential to view CXR as part of a broader diagnostic algorithm for pediatric TB, which includes assessing symptoms; signs of TB; exposure to a TB source patient; results from tests for *M. tuberculosis* infection (eg, tuberculin skin tests or interferon-gamma release assays), microbiological tests (eg, Xpert MTB/RIF, microscopy, or culture for *M. tuberculosis*), and any other relevant supporting tests [15]. Following this approach, we are considering leveraging the platform with a treatment-decision algorithm that incorporates clinical evidence and artificial intelligence models to enable automatic CXR scoring. This integration has the potential to significantly enhance the accuracy and efficiency of TB diagnosis in young children.

Conclusions

TB remains a significant global health challenge, particularly among children, and the COVID-19 pandemic has intensified the situation. CXR imaging is crucial for diagnosis, severity assessment, and treatment response evaluation. In this study, we introduced a novel telemedicine web platform, BITScreen PTB, which utilizes CXR images and clinical information. Its purpose is to streamline remote reading and standardize pediatric TB examinations in resource-limited settings.

Our platform received positive feedback from users, and while there may be room for further improvements to address concerns about reliability and interface quality, it shows promise for future use. Our study underscores the potential of telemedicine platforms such as BITScreen PTB to enhance access to TB diagnosis in children, especially in low-resource settings. Additionally, the platform has the potential to serve as a labeling tool for CXRs to develop and integrate artificial intelligence models, which could enhance the accuracy and speed of TB diagnosis in children, particularly in resource-limited settings.

Acknowledgments

The authors acknowledge the support of Ministerio de Ciencia e Innovación, Agencia Estatal de Investigación (grant PDC2022-133865-I00), cofinanced by the European Regional Development Fund (ERDF), “A way of making Europe,” and from the H2020-MSCA-RISE-2018 INNOVA4TB (EU) project (ID 823854) and the ADVANCETB Cost Action (EU) project (ID CA21164). DCM’s PhD fellowship is supported by Universidad Politécnica de Madrid. The telemedicine platform will support the STool4TB project funded by EDCTP2 (grant number RIA2018D-2511) and the nested TITANA ancillary study. We thank the collaborators from this project for their fruitful discussions and feedback.

Abstract

Background: Digital health interventions are increasingly used to deliver health-related interventions for children and young people to change health behaviors and improve health outcomes. Digital health interventions have the potential to enhance access to and engagement with children and young people; however, they may also increase the divide between those who can access technology and are supported to engage and those who are not. This review included studies that reported on the access to or engagement with digital health interventions among children and young people.

Objective: This review aims to identify and report on access and engagement in studies involving digital health interventions among children and young people.

Methods: A systematic review following the Joanna Briggs Institute methods for conducting systematic reviews was conducted. An electronic literature search was conducted for all studies published between January 1, 2010, and August 2022, across sources, including MEDLINE, CINAHL, and PsycINFO. Studies were included if they examined any aspect of access or engagement in relation to interventions among children and young people. The quality of the included papers was assessed, and data were extracted. Data were considered for meta-analysis, where possible.

Results: A total of 3292 references were identified using search terms. Following the exclusion of duplicates and review by inclusion criteria, 40 studies were independently appraised for their methodological quality. A total of 16 studies were excluded owing to their low assessed quality and flawed critical elements in the study design. The studies focused on a variety of health conditions; type 1 diabetes, weight management and obesity, mental health issues, and sexual health were the predominant conditions. Most studies were conducted in developed countries, with most of them being conducted in the United States. Two studies reported data related to access and considered ethnicity and social determinants. No studies used strategies to enhance or increase access. All studies included in the review reported on at least 1 aspect of engagement. Engagement with interventions was measured in relation to frequency of engagement, with no reference to the concept of effective engagement.

Conclusions: Most digital health interventions do not consider the factors that can affect access and engagement. Of those studies that measured either access or engagement or both, few sought to implement strategies to improve access or engagement to address potential disparities between groups. Although the literature to date provides some insight into access and engagement and how these are addressed in digital health interventions, there are major limitations in understanding how both can be enhanced to promote equity. Consideration of both access and engagement is vital to ensure that children and young people have the ability to participate in studies.

KEYWORDS

access; engagement; digital health technology; mobile phone; children

Introduction

Background

Worldwide, access to many public services including health information and service provision is available through digital platforms [1]. The COVID-19 pandemic has accelerated the digital shift and highlighted the value it can bring to enabling access to health services and enhancing social connectedness [2]. However, equitable distribution of resources crucial for engaging with digital platforms—such as access to equipment, financial support for connectivity, and digital literacy—is uneven among populations. Consequently, certain groups have greater access to digital services than others [3,4]. It is crucial to focus on equity concerning access to digital health services, ensuring that the gap between those who can and cannot access these services is not widened further [5].

A plethora of literature exists on equity in health and health care; however, the key principles remain the same: that there should be equal access to health care for those in equal need of health care; equal use of health care for those in equal need of health care; and equal (equitable) health outcomes, for example, quality-adjusted life expectancy [6,7]. Equal access for equal need requires horizontal equity, conditions whereby those with equal needs have equal *opportunities* to access health care [8].

Health care providers are increasingly using digital technologies such as smartphones, websites, or SMS text messaging to communicate information to address health needs and in the delivery of health interventions [9]. Digital health interventions are programs that provide information and support for physical and mental health using digital technologies [10,11]. These interventions can be automated, interactive, and personalized, using user input or sensor data to shape feedback, treatment decisions, and treatment delivery [12].

Digital health interventions for children are increasing because of rapid technological advancements and the increasing interest of children and young people in technology [13]. Digital health interventions have been proposed to create opportunity to increase access to health care [14-16]. However, unless access to health care is equitable so that children and young people as consumers of health care within wider communities can use appropriate services in proportion to their need, inequities will create a divide in outcomes [17,18].

Although there is evidence for the effectiveness of digital health interventions developed for children and young people [19,20], understanding how issues related to access and variations by individuals, families, and communities are areas that have not been reviewed and require further discussion.

Objective

This review aimed to identify the reports of access to, and engagement with, digital health interventions among children and young people. The review includes a report of data on access and engagement in studies that report on the effectiveness of digital health interventions as well as evaluations of strategies to increase access and engagement.

Methods

The review followed the Joanna Briggs Institute (JBI) methodology for systematic reviews [21] in design and was conducted according to the PROSPERO protocol (CRD42020170874). The review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement.

Search Strategy

A scoping search was conducted to identify key papers and search terms to inform the search strategy. This included the key terms and medical subject headings engagement or equity of access or access to health care and digital health or mobile health or electronic health.

The search strategy was reviewed and refined by a research librarian. The base search strategy was developed on CINAHL. A total of 4 web-based databases, including CINAHL, MEDLINE, PsycINFO, and Embase, were searched for English language publications between January 2010 and August 2021 and updated in August 2022. A manual search in Google Scholar was also conducted. Gray literature sources including OpenGrey, ProQuest Dissertation and Theses (ProQuest), and Google and Google Scholar were also searched to identify unpublished studies. Multimedia Appendix 1 provides the full search strategy. EndNote (Clarivate) was used to remove duplicate citations before screening.

Inclusion and Exclusion Criteria

The review included studies that reported data on access or engagement when reporting the effectiveness of digital health interventions for children and young people. The participants included school-aged children and young people aged 5-18 years. Parents or caregivers of children receiving health services were also included; however, studies that only reported the parent experience were excluded. Studies reporting on health interventions involving 1-way and 2-way communication including web-based platforms, mobile apps, videoconferencing, and SMS text messaging on access or engagement outcomes were included. Qualitative and quantitative studies were included in this review.

Studies that included children aged ≤4 years and ≥19 years were excluded. Studies that reported health professionals, such as nursing staff, medical personnel, health care management and administrators, or researchers, as the primary users of the digital health intervention were excluded. Studies reporting a telephone-based intervention with no additional technological function or where the intervention focused on health records such as patient portals or personal health records were excluded.

Screening

The titles, abstracts, and full papers of the selected records were screened independently by 2 reviewers (SR and MJ) using the abovementioned inclusion and exclusion criteria. Any discrepancies were discussed, and disagreements were resolved by a third reviewer (LW). The reference lists of all included studies were reviewed to identify relevant papers that were not found in the electronic search.

Assessment of Methodological Quality

The quality of the screened papers was critically appraised independently by reviewers (SR and LW) using the appropriate standardized critical appraisal instruments from JBI, including the Checklist for Randomized Controlled Trials, Checklist for Quasi-Experimental Studies, Checklist for Cohort Studies, Checklist for Analytical Cross Sectional Studies, and the Checklist for Qualitative Research [21].

Data Extraction

Data were extracted from the included studies using an adapted version of the standardized data extraction tool from JBI [22]. Two reviewers (SR and MJ) extracted the data from the included papers, and a third reviewer (LW) verified the accuracy of the extracted data, with any disagreement resolved through discussion.

The extracted data included specific details about the study setting and context; the aim and objectives of the study; study design; the sampling of participants, sample size, and the characteristics of the study sample; and details about the interventions and engagement and access outcomes. All data were extracted following a thorough reading of the text to identify qualitative or quantitative findings relevant to the objectives and questions for the review. A second reviewer checked all the data extracted from each paper to enhance certainty.

Data Synthesis

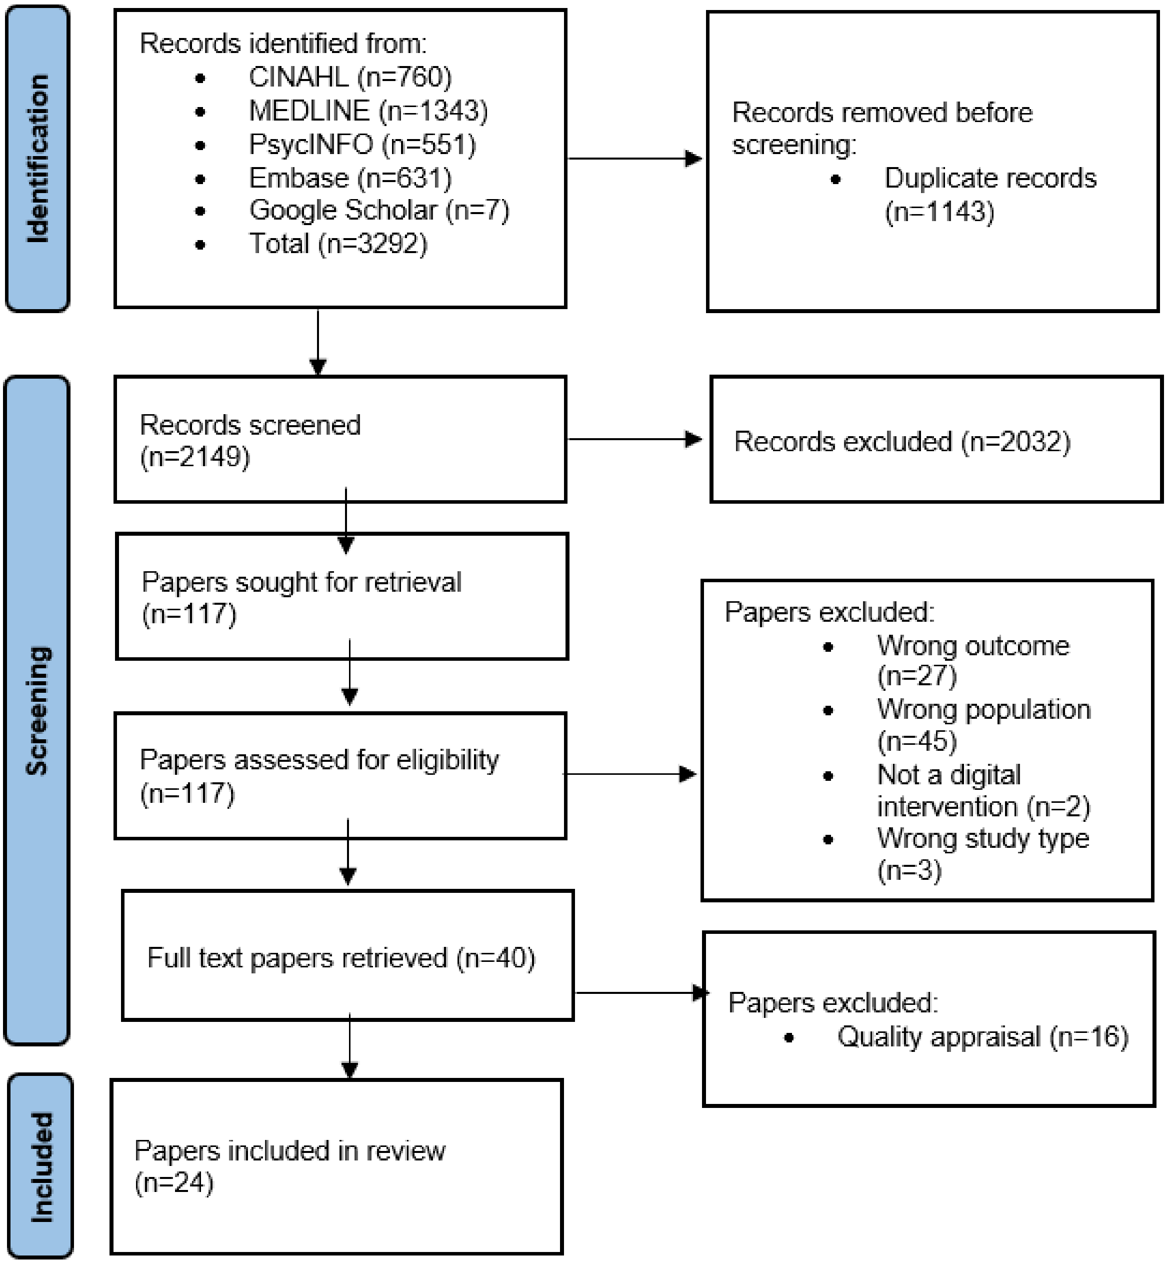
Owing to the heterogeneity between the studies on outcome measures, research design, and the intervention, a meta-analysis was not possible. The findings have been presented in narrative form including tables and figures to aid in data presentation. The process of data synthesis followed the JBI approach of meta-aggregation. The meta-aggregative approach is sensitive to the practicality and usability of the findings extracted and does not seek to reinterpret these findings. A strong feature of the meta-aggregative approach is that it enables the generation of statements in the form of recommendations that can guide researchers, practitioners, and policy makers. In this way, meta-aggregation contrasts with meta-ethnography or the critical interpretive approach to qualitative evidence synthesis, which focuses on reinterpretation and theory generation rather than aggregation.

Results

Study Inclusion

In total, 3292 references were identified using the search terms. The addition of secondary searches of reference lists and gray literature resulted in the identification of no further references. The exclusion of 1143 duplicates resulted in 2149 references. The titles and abstracts of the references were independently reviewed to determine if they met the inclusion criteria, and 2032 references were excluded. The remaining 117 references were retrieved in full text papers and reviewed by 3 reviewers (SR, MJ, and LW) using the inclusion criteria. A total of 77 studies were excluded as they did not meet the inclusion criteria. Of the 77 studies, 45 (58%) were excluded because the age of the child was outside the inclusion range, 27 (35%) did not report on access or engagement, 2 (3%) did not include a digital intervention, and 3 (4%) were opinion pieces or letters to the Editor. A total of 40 studies met the inclusion criteria (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of the study selection and inclusion process.



Methodological Quality

A total of 40 studies that met the inclusion criteria were independently appraised for their methodological quality. A total of 16 studies were excluded where the quality of the studies was assessed as low and critical elements of the study design were flawed (Tables 1-5). A cutoff was applied for each research design. A total of 5 randomized controlled trials (RCTs) were excluded because they were unclear or did not report on ≥6 items out of 13 items (Table 1). In addition, 7 quasi-experimental studies were excluded because they were unclear or did not report on ≥4 out of 9 (Table 2). All qualitative studies were retained (Table 3). The 1 cohort study was excluded because it did not meet 5 of the 11 items (Table 4). One cross-sectional study was excluded because it did not meet 4 of the 8 criteria (Table 5). Of note, the mixed methods study was assessed using the criteria for RCTs and qualitative studies for the relevant sections as per JBI guidance.

Table 1. Quality assessment. Randomized controlled trials.

Study	Randomization used for assignment of participants to treatment groups	Allocation to treatment groups concealed	Treatment groups similar at the baseline	Participants blind to treatment assignment	Those delivering treatment blind to treatment assignment	Outcomes assessors blind to treatment assignment	Treatment groups treated identically other than the intervention of interest	Follow-up complete and if not, were differences between groups adequately described and analyzed	Participants analyzed in the groups to which they were randomized	Were outcomes measured in the same way for treatment groups	Were outcomes measured in a reliable way	Was appropriate statistical analysis used	Was the trial design appropriate, and any deviations from the standard randomized controlled trial	Percentage of items assessed as met

Characteristics of the Studies

Of the 24 studies included in the review (Table 6), 7 (29%) used an RCT design, 12 (50%) were quasi-experimental studies, and 3 (13%) used a qualitative study design. One study used an analytical cross-sectional study design and 1 used a mixed methods design.

Table 6. Study characteristics.

Study	Health condition	Aim and objectives	Country	Study setting	Study design	Type of digital intervention	Age	Gender
Anderson et al [33], 2018	Sickle cell disease	To examine the feasibility of the Intensive Training Program (ITP), a mobile health intervention for youths with sickle cell disease to promote disease knowledge, adherence, and patient-provider communication.	United States	Pediatric sickle cell disease clinic	Quasi-experimental	Mobile app	Children: mean age of children 13 (SD 3.33) years	Children: 16 (50%) children were female
Beaudry et al [34], 2019	Children transitioning from pediatric to adult care with chronic illness	To test the feasibility of a texting platform aimed at increasing engagement among teenagers while teaching essential self-care skills while transitioning to adult focused care	United States	Pediatric inflammatory bowel disease, cardiology, and type 1 diabetes specialty clinics	Quasi-experimental	Text message	Children: mean age of children 15 years; 2 aged 14 years; 1 aged 15 years; 9 aged 16 years; and 1 aged 17 years	Children: sex of children not provided
Bergner et al [22], 2018	Type 1 diabetes	To evaluate the acceptability and feasibility of Check It! a positive psychology intervention to improve adherence in adolescents with T1D[a]	United States	Outpatient pediatric diabetes clinic	Mixed method (RCT[b] and qualitative)	Text message	Children: mean age of adolescents 14.8 (SD 1.5) years	Children: 63 (52.5%) female participants and 57 (47.5%) male participants
Brown et al [35], 2016	Sexual health	To evaluate a behavior change intervention targeting sexual health service uptake among young people delivered using digital media	United Kingdom	Secondary schools	Quasi-experimental pretest posttest design	Website and mobile app	Children: mean age at baseline 15.7 (SD 1.51) years	Children: at baseline 158 (55%) female and 129 (45%) male participants; at follow-up 94 (41%) female 134 (59%) males
Bunnell et al [23], 2017	Mental health	To examine access and completion of a web-based disaster mental health intervention in adolescents and their caregivers affected by the spring 2011 tornadoes in Missouri and Alabama	United States	Community	Quasi-experimental; pretest posttest design	Website	Children: mean age of rural children was 14.5 (SD 1.76) years; mean age of urban children was 14.6 (SD 1.74) years; parents or caregivers: mean age of rural caregivers was 45.0 (SD 9.54) years; mean age of urban caregivers was 45.4 (SD 9.38) years	Children: 329 (49%) rural female participants and 347 (51%) rural male participants; 658 (50%) urban females and 663 (50%) urban males; parents or caregivers: 493 (72.9%) rural caregivers were female and 183 (27.1%) were male; 980 (74.2%) urban care givers were female and 341 (25.8%) were male
Galy et al [37], 2019	Overweight and obesity	To investigate a technology-based program combining education, objective measures of PA[c]), and self-assessment of goal achievement delivered to Pacific adolescents	New Caledonia	School	Quasi-experimental pilot study	Mobile app and wearable tracker device	Children: mean age of children 11.9 (SD 0.57) years; age ranged from 12 to 14 years	Children: sex not provided
Hilliard et al [25], 2020	T1D	To evaluate the feasibility and acceptability of a behavioral intervention delivered to parents of adolescents with T1D via mobile-friendly web app	United States	Diabetes clinic in the hospital	RCT	Mobile app	Children: mean age of children 15.3 (SD 1.5) years; parents: not provided	Children: 47 (59%) female participants and 33 (41%) male participants; parents: 64 (80%) female and 16 (20%) male

Study	Health condition	Aim and objectives	Country	Study setting	Study design	Type of digital intervention	Age	Gender
Kosse et al [40], 2019	Medication self-management asthma	To explore the use and the effective engagement of adolescents aged 12-18 years with the Adolescent Adherence Patient Tool	The Netherlands	Community	Quasi-experimental	Mobile app	Children: mean age of children 15.0 (SD 2.0) years	Children: 48 (55%) female participants and 39 (45%) male participants
LeRouge et al [51], 2016	Weight management (overweight)	To investigate the use of animated avatars and virtual agents to deliver computer-based interventions for chronic weight management ins adolescents	United States	Camp Jump Start	Qualitative	Virtual avatars	Children: mean age of adolescents not provided	Children: sex of children not provided
Lopez et al [52], 2020	Substance use and HIV	To evaluate a technology-based approach to delivering culturally tailored, integrated substance use disorder and HIV risk behavior prevention programs to African American female youths	United States	School and community	Qualitative	Telemedicine	Children: age ranged from 13 to 18 years	Children: all (100%) female participants
March et al [42], 2018	Mental health (anxiety)	To examine program adherence, satisfaction, and changes in anxiety with a publicly available online, self-help iCBT[d] program (BRAVE Self-Help)	Australia	Community	Quasi-experimental	Website	Children: mean age of children 12.9 (SD 2.97) years	Children: 2938 (66.4%) female participants and 1406 (31.8%) male participants; 81 (1.8%) participants identified as another gender category
McGill et al [44], 2019	Diabetes type 1	To evaluate an SMS text messaging intervention in teenagers with T1D assessing factors associated with text responsiveness and glycemic benefit	United States	Outpatient clinic	Quasi-experimental	Text message	Children: mean age of children 14.9 (SD 1.3) years	Children: 76 (52%) female participants and 70 (48%) male participants
Palermo et al [24], 2020	Chronic pain	To evaluate effectiveness and implementation of a digital health delivered psychological intervention for children aged 10-17 years with chronic pain	United States	Pain clinics	Stepped-wedge cluster randomized trial	Mobile app	Children: mean age of children 14.5 (SD 1.9) years	Children: 117 (81.8%) female participants and 26 (19.2%) male participants
Piatkowski et al [56], 2020	Obesity	To examine user characteristics and parenting practices associated with adolescents' initial use of the Aim2Be app; a health behavior modification intervention	Canada	Community	Analytical cross-sectional study	Mobile app	Children: mean age of children 14.9 (SD 1.5) years	Children: 184 (49.6%) female participants and 187 (50.4%) male participants
Sousa et al [47], 2015	Overweight and obesity	To evaluate the effectiveness of an e-therapeutic platform (Next.Step), aiming to promote weight management skills and the adoption of health-promoting lifestyles	Portugal	Pediatric obesity clinic	Quasi-experimental	Website	Children: mean age of children 14.2 (SD 1.51) years	Children: 48 (51.1%) female participants and 46 (48.9%) male participants
Tolou-Shams et al [53], 2019	Mental health and substance abuse	To examine the acceptability of a dyadic (youth and caregiver) SMS text messaging intervention to enhance treatment engagement of the youths attending face-to-face community-based treatment, as referred by probation staff	United States	Community-based Juvenile Probation Department and community-based provider organization	Qualitative	Text message	Children: mean age of children was 17.0 years; caregiver: age ranged from 35 to ≥65 years.	Children: 6 (75%) female participants and 2 (25%) male participants; caregiver: 4 (80%) female and 1 (20%) male

Study	Health condition	Aim and objectives	Country	Study setting	Study design	Type of digital intervention	Age	Gender
Tu et al [48], 2017	Overweight and obesity	To determine whether adolescent and parental adherence to components of an e-health intervention resulted in change in adolescent BMI and waist circumference (WC) z-scores in a sample of overweight/obese adolescents	Canada	Children's Hospital Endocrinology and Diabetes Clinic and Center for Healthy Weights program in British Columbia and by other sources	Quasi-experimental	Website	Children: mean age of children 13.2 (SD 1.8) years; parents: mean age of parents 45.8 (SD 6.2) years	Children: 91 (57.2%) female participants and 68 (42.8%) male participants; parents: 135 (84.9%) female participants and 24 (15.1%) male participants
Voss et al [28], 2019	Autism	To evaluate the efficacy of Superpower Glass, an artificial intelligence–driven wearable behavioral intervention for improving social outcomes of children with ASD[e]	United States	Home environment	RCT	Wearable glasses	Children: mean age of 8.4 (SD 2.46) years	Children: 8 (11%) female participants and 63 (89%) male participants
Whittemore et al [29], 2013	Type 1 diabetes	To compare the demographic and clinical characteristics of young people with T1D on recruitment, participation, and satisfaction with eHealth programs	United States	Clinical sites	RCT	Website	Children: mean age of 8.4 (SD 2.46) years	Children: 177 (55.3%) female participants and 143 (44.7%) male participants
Widman et al [30], 2017	Sexual health	To assess the feasibility and acceptability of Project HEART providing sex education focusing sexual communication skills to reduce the risk of HIV/STDs[f] and unplanned pregnancy among youths	United States	High schools	RCT	Website	Children: mean age of 12.3 (SD 1.1) years	Children: 107 (100%) female participants
Wingo et al [49], 2020	Children with physical disabilities	To test the usability and preliminary efficacy of an eHealth and telecoaching intervention compared with telecoaching alone	United States	Pediatric rehabilitation medicine clinics	Quasi-experimental	Website	Children: mean age of 11.3 (SD 3.3) years; parents: mean age of parents not provided	Children: 29 (58%) female participants and 21 (42%) male participants; parents: 45 (90%) female participants and 5 (10%) male participants
Ybarra et al [31], 2019	HIV prevention	To determine whether technology is an appropriate delivery mechanism for adolescent-focused HIV preventive programing in South Africa	South Africa	Schools	RCT	Text message	Children: mean age of 17.5 (SD 1.2) years	Children: 647 (63.7%) female participants and 368 (36.3%) male participants

Study	Health condition	Aim and objectives	Country	Study setting	Study design	Type of digital intervention	Age	Gender
Zhang et al [32], 2018	Diabetes type 1	To investigate adolescents with T1D engagement with an SMS text messaging intervention	United States	Diabetes clinic	Randomized pilot study	Text message	Children: mean age of 15.0 (SD 1.3) years	Children: 25 (52.1%) female participants and 23 (47.9%) male participants

[a] T1D: type 1 diabetes.

[b] RCT: randomized controlled trial.

[c] PA: physical activity.

[d] iCBT: internet-based cognitive behavioral therapy.

[e] ASD: autism spectrum disorder.

[f] STD: sexually transmitted disease.

The studies focused on a variety of health conditions; type 1 diabetes (4/24, 17%), weight management and obesity (5/24, 21%), mental health issues (4/24, 17%), and sexual health (3/24, 13%) were the predominant conditions (Table 6). Most studies (23/24, 96%) were conducted in developed countries. Most studies (15/24, 63%) were conducted in the United States.

Of the 24 studies included in the review, 10 (42%) recruited participants from outpatient clinics, 1 (4%) recruited from the hospital setting, 4 (17%) recruited in schools, and 8 (33%) within community settings. One study recruited participants from both a school and a community setting.

In more than half of the studies (16/24, 67%), more females were recruited than males. In 3 studies, the gender of the child was not provided [23,33,51].

Type of Digital Interventions

Overall, 38% (9/24) of the digital health interventions were web based, 21% (5/24) of the interventions were mobile apps, 29% (7/24) of the interventions used SMS text messaging, 4% (1/24) of the interventions used a website and a mobile app, 4% (1/24) of the interventions were a telemedicine intervention with participants logging in on their home computer or tablet, and 8% (2/24) of the digital interventions combined a website and digital wearable glasses and an app and wearable tracker (Table 6).

Access and Engagement

Access to Digital Health Interventions

The 2 studies that reported access and digital health interventions included 1 that reported on access related to race and ethnicity and access by income and 1 that reported on gender differences in accessing services (Table 7).

Table 7. Report of access and engagement.

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
Anderson et al [33], 2018	32 children completed the baseline survey	90 days (6 weeks) participants to enter medication daily	No data reported	28 (87%) participants logged in	Participants logged in average 18 of the 30 days (60% of participants logged in each day)	37% tracking daily entry	27 (84%) participants completed track an entry of medication each day	Ranged from 41.7% to 91.7%
Beaudry et al [34], 2019	13 children enrolled	24 weeks—weekly text messages sent	No data reported	13 (100%) children responded to the chatbot	97% responded to weekly text message	Responses rates ranged from 85% to 100% response to the text message each week	13 children, 100% responded to the last text of the study period. 12 (92%) children completed the final survey	Satisfaction was not measured on the survey. Children reported being motivated to respond to the texts because of its “ease of use” and because they were “friendly.”
Bergner et al [22], 2018	120 parent child dyads enrolled	8 weeks; intervention group to answer weekly text message	No data reported	Information not provided	14% teenagers answered weekly phone reminders (control group) vs 67% in the text (intervention) group (*t*=7.97; *P*<.001)	No other measurement provided	89% of the adolescents and 92% of the parents completed the 3-month follow-up survey	Adolescents and their parents were satisfied with the study, with >87% noting a positive experience.
Brown et al [35], 2016	287 children enrolled at baseline	6 weeks	A digital intervention approach had a significant positive effect on psychological barriers to and antecedents of service access among females. Males reported greater confidence in service access than females.	100%	No measured	At follow-up, all participants reported having accessed the website or web app at least once. 45% had visited ≥2 main intervention pages. 36% indicated that they had not visited any of the core website pages and 21% indicated that they had visited only one of the 19 main intervention pages.	Not measured	Not measured
Bunnell et al [23], 2017	2000 families (parent child dyad)	Intervention period not provided	No data reported	485 (36.7%) urban adolescents and 223 (33.0%) rural adolescents accessed the resource. 503 (38.1%) urban caregivers and 233 (34.5%) rural caregivers accessed the resource.	Not measured	Not measured	384 (79.2%) urban adolescents and 170 (76.2%) rural adolescents completed the course. 313 (62.2%) urban and 128 (54.9%) rural caregivers completed the course.	Not measured

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
Galy et al [37], 2019	24 adolescents	4 weeks to 8 one-hour modules	No data reported	24 (100%) adolescents used the electronic tracking device	24 (100%) adolescents wore the electronic tracking device daily	Not measured	21 (84%) adolescents competed the program.	95% of the adolescents rated their satisfaction with the modules as “fun.”
Hilliard et al [25], 2020	80 families enrolled. At baseline randomized to 55 family’s intervention and 25 families usual care control	3 to 4 months	No data reported	All 55 (100%) intervention arm families (parents) downloaded the app and logged in at least one time	53 participants (parents; 96%) logged in at least 1 additional time. 91% of parents used the app ±2 days per week on average. 79.9% of parents logged in each day.	96% of the participants used the strengths tracking section of the app. 90% of the participants viewed the strengths summaries.	78 families (98%) completed follow-up	Intervention participant responses (n=50) on the USE[a]. questionnaire indicated high acceptability of the intervention. Feedback from 48 parents was positive.
Lopez et al [52], 2020	58 African American adolescents	S 11 weekly; 1-hour group sessions with youth participants and 1 20-minute individual session with each parent of participants at some point between weeks 5 and 9 (totaling 12 weeks)	No data reported	53 (91%) adolescents completed the baseline	—[b]	—	39 (67%) completed the intervention	100% would recommend the program to a friend
Kosse et al [40], 2019	103 patients enrolled	6 months	No data reported	87 (84%) patients logged in to the app. 16% of the patients did not download the app.	86 adolescents used the app 1975 times between October 2015 and April 2017. The median app use per person was 17 times.	51% watched at least 1 movie. 65 (75%) adolescents sent or received ≥3 chat messages. 18 adolescents used the peer chat.	26 (weekly) reminders sent to complete the app—individually completed the app 10 times.	Not measured

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
LeRouge et al [51], 2016	70 adolescents	Intervention period not provided	A structured protocol of questions including general background questions (ie, age, technology access questions, level of avatar, or virtual agent experience) and then reviewed midfidelity mock-ups of 7 types of graphical embodiments of the character, for the virtual self-avatar or virtual agent.	70 (100%)	Not measured	Not measured	Not measured	Not measured
March et al [42], 2018	4425 young people enrolled	20 weeks with 10 sessions	No data reported	3467 (78.4%) completed the first session	Not measured	48.05% (2126/4425) of the registered participants completed only 1 or 2 sessions. 24.75% (1095/4425) of the participants completed at least 3 sessions.	3.6% (163/4425) completed all 10 sessions	The mean total satisfaction rating was 17.72 (SD 5.16) out of a maximum 25
McGill et al [44], 2019	151 young people enrolled	18 months	No data reported	147 (97%) young people received the SMS text messaging intervention. Received a daily text message to check blood glucose levels.	Over 18 months, 49% of young people responded with ≥1 blood glucose result on ≥50% of days. Declined over time (0 to 6 months 60% response—7 to 12 months 50% daily response); 13 to 18 months 43% daily response	Not measured	Not measured	Not measured
Palermo et al [24], 2020	143 youths enrolled: 73 youths assigned to the treatment group and 70 youths to the control group	8 weeks	No data reported	68 (97%) youths downloaded the app and 54 youths (74%) completed at least 1 module of the intervention.	Not measured	Youths completed an average of 3.1 modules; range 5 (0 to 8)	20 (27%) youths completed the intervention program.	85.7% of youths and rated the WebMAP program as moderately to highly acceptable on the Treatment Evaluation Inventory

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
Piatkowski et al [56], 2020	371 adolescents and parent dyads enrolled and completed the baseline assessment	Not provided	No data reported	294 (79.2%) adolescents used the app	Not measured	Not measured	Not measured	Not measured
Sousa et al [47], 2015	94 adolescents enrolled (48 adolescents enrolled in the experimental group and 46 adolescents enrolled in the control group)	24 weeks	No data reported	25 (52.1%) adolescents in the experimental group logged in to the website.	On average, accessed the platform 10.68 times (SD 18.92)	On average analyzed 7.9 (SD 9.25) resources and read 31.8 (SD 47.56) messages from the forums during the 24-week period.	13.7% of the adolescents in the experimental group completed the activities.	Satisfaction was not measured.
Tolou-Shams et al [53], 2019	8 youths	6 months	No data reported	Not measured	Not measured	Not measured	7 (87.5%)	Not measured
Tu et al [48], 2017	159 (90%) adolescent parent dyads participated	8 months	No data reported	15 (9.4%) adolescents and 50 parents (31.5%) did not log in to the intervention website during the entire study period.	Over the 33-weeks intervention adolescents logged into the website an average of 13.4 weeks, and parents logged into the website an average of 7.5 weeks	Adolescents mean percentage of web pages viewed per week, where a total of 83 and 78 pages could be viewed in the first and last 4 months, respectively (typically there were 4-5 pages per week to view).	On average, adolescents and parents completed 28% of the web pages viewed.	Satisfaction was not measured
Voss et al [28], 2019	71 families enrolled; 40 (56.3%) were randomly assigned to the treatment and 31 (43.7%) to the control group	6 weeks; 20-minute sessions at home 4 times a weeks	No data reported	27 (67.5%) of the 40 treatment families engaged with the Superpower glasses.	Families used the glasses 12.1 times over the 6 weeks.	27 (67.5%) families used each of the 3 engagement activities at least once, used the device at home for 20 min 3 times per week. Participants played guess the emotion in 39.8%, capture the smile 23.8%, and unstructured free play 36.4%.	24 (60%) families completed the intervention	Satisfaction was not measured

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
Whittemore et al [29], 2013	320 youths enrolled: 167 were allocated to TeenCope intervention and 153 were allocated to managing diabetes intervention.	5 sessions	Black, Hispanic, or mixed-race and -ethnicity youths with type 1 diabetes were less likely to enroll in digital health interventions than White and higher-income youths	148 (90.3%) youths who received the intervention logged in	Not measured	Not measured	250 (78.1%) youths completed at least 4 of 5 sessions. The mean number of sessions completed was 4.08 (SD 1.64) across both groups. 39 (12.2%) completing 1 to 3 sessions, and 31 (9.7%) completing no sessions.	Satisfaction was high with mean satisfaction score was 3.97 (SD 0.71) for TEENCOPE (1 is not at all satisfied and 5 is very satisfied)
Widman et al [30], 2017	107 participants randomly assigned to the intervention group and 115 participants assigned to the control group.	1 session; 45 minutes to complete	No data reported	107 (100%) participants interacted with the website	Not measured	Not measured	107 (100%) participants completed the intervention	Participants found the program to be highly acceptable with 79% of participants reported they would come back to the website again, 88% would recommend the program to a friend, and 94% plan to use the information they learned in the future
Wingo et al [49], 2020	65 parent and child dyads consented and randomized and a total of 32 dyads randomized to the eHealth group and 33 to the telephone only group.	12 weeks	No data reported	24 (75%) eHealth group received the intervention; 26 (78.7%) telephone only group received the intervention.	Not measured	Mean days journal entry: 45.6 food, 46.1 water, and 42.1 physical activity	17 (67%) in the eHealth group compared with 23 (92%) of telephone only group completed the intervention.	Parents indicated they valued phone calls more than the eHealth platform
Ybarra et al [31], 2019	303 youths; 150 intervention and 153 control	8-10 daily text messages sent over 5-week period	No data reported	98% of the intervention participants sent or received a text message	Not measured	Not measured	Not measured	93% of the intervention participant said they somewhat or strongly agreed that they liked the program
Yen et al [50], 2019	20 (83%) adolescents enrolled	4 weeks	No data reported	100% responded	On average, participants responded to text prompts on 72.4% of days	Not measured	19 adolescents completed the intervention.	The intervention was described as good or excellent by >90% of the parents and 100% of the adolescents

Study	Number of participants enrolled	Intervention period	Data reported on access	Engagement; logged in; or interacted at least once	Engagement; frequency; average per day or week	Engagement; intensity of engagement	Engagement; completion of the course	Engagement; acceptance satisfaction
Zhang et al [32], 2018	48 adolescents were enrolled. 24 adolescents and their caregivers in intervention group and 24 in the education group.	8 weeks	No data reported	87% responded	The mean response rate was 76 to the 4 to 5 text messages per week overall. Responses waned over the 8-week period, from 87% in week 1 to 81% in week 5 and 62% in week 8.	Not measured	Not measured	Not measured

[a] USE: Usefulness, Satisfaction, and Ease of use.

[b] Data not reported.

Race and Ethnicity

Equity of service use based on race and ethnicity was explored in 1 study. Whittemore et al [29] reported that Black, Hispanic, or mixed-race youths with type 1 diabetes were less likely to enroll in digital health interventions than White and high-income youths. However, once enrolled, youths of diverse races and ethnicities with type 1 diabetes were as highly satisfied with the eHealth programs as White youths. The results suggest that eHealth programs have the potential to reach diverse youth groups and to be relevant to them; however, considerations relating to access need to be addressed in the study design.

One study reported on access related to gender. Brown et al [35] reported that the digital intervention had a significant positive effect on psychological barriers to and antecedents of service access among females. Males reported greater confidence in service access than females and significantly increased service access by the second follow-up.

Equity of service use based on income was explored in 1 study. Whittemore et al [29] reported that low-income youths were less likely to participate, possibly because of access. However, once enrolled, youths of diverse races and ethnicities and low-income youth with type 1 diabetes were as highly satisfied with the eHealth programs as White youths and those with higher income.

Engagement With Digital Interventions

Overview

Engagement with the digital health intervention was measured by the frequency and intensity of engagement, satisfaction with the digital health intervention, and changes in knowledge or behavior. Of the studies that reported on engagement, most used system use data to capture how the intervention was used by each participant. The studies reported on various aspects of use data including initial log-in, frequency, intensity, and duration of engagement with the program, as described in Table 7.

Initial Log-In

Once enrolled in a digital health intervention, most participants logged in and engaged with the intervention. The percentage of enrolled participants logging in at least once to the digital intervention ranged from 35.6% [23] to 100% [30,34,35,37,50]. One study did not provide this information [22]. In 16 studies, more than three-quarters of the participants logged on at least once to the digital intervention (Table 7).

Frequency of Engagement

Frequency of engagement was measured by the log-in data, number of log-ins recorded per participant, average log-ins per unit of time or total for intervention duration, visits to the site, number of visits per participant, average per unit of time, or total time of visits. Overall, 42% (10/24) of the studies reported the average number of log-ins per unit of time. The measurement of frequency varied across the studies with either daily or weekly measurement with the unit of measurement dependent on the study aims and the frequency of the delivery of the intervention.

Overall, 21% (5/24) of the studies reported on engagement on a daily basis with between 49% [44] to 100% [37] of the participants engaging daily with the intervention. Moreover, 29% (7/24) of the studies reported weekly engagement with the digital health intervention, 13% (3/24) of the studies reported the percentage of participants engaging weekly, and 17% (4/24) of the studies reported the average weekly engagement with the website or app.

The most frequent measurement of the frequency of engagement was daily or weekly response to text messages by participants as reported in 6 studies.

Zhang et al [32] found that adolescent sex was significantly related to engagement (t=2.42; P=.02), with boys demonstrating higher response rates (88%) than girls (67%). However, Whittemore et al [29] found no significant gender difference in enrollment and participation in an eHealth program for adolescents with type 1 diabetes.

Intensity of Engagement and Type of Behavior

The intensity of engagement was measured by pages viewed, modules viewed, number of emails sent, number of posts, and number of experts accessed. Three studies measured the number of log-ins per participant and reported the number of times an app or web page was visited. Zhang et al [32] reported that race and ethnicity were significantly related to engagement (t=3.48; P=.04), with White, non-Hispanic youths responding to more messages (80%) than youths in racial and ethnic minority groups (45%).

One study measured functions used stating the number and percentage of participants who used the 5 functions within the intervention platform [40].

Completion of Modules and Courses

Most studies measured either completion of modules or completion of the course, with completion rates ranging from 3.6% to 100%, with most studies reporting >80% of participants completing modules or the course. Completion of modules, web pages, and courses were measured in 16 studies. In the study with the lowest completion rate [42], completion of all 10 sessions was low (3.6%), but 48% of the participants completed some sessions [40]. Although completion rates were reported in 16 studies, understanding whether these were higher or lower than expected or in direct comparison to face-to-face or other nondigital intervention approach was not clear. Completion of the intervention sessions was high in several studies (Table 7); for example, 84% of the participants completed the intervention in 2 studies [33,37], 95% of the participants completed the intervention in another study [50], to 100% of the participants completing the intervention [37]. The results did not provide insight into whether the digital nature of the intervention increased, decreased, or had a neutral impact on completion rates.

Satisfaction

Satisfaction was measured in 14 studies, with satisfaction measurement methods varying across the studies (Table 7). Of the 14 studies that assessed satisfaction, participants were generally satisfied with the digital intervention, and in 1 study [49] participants were more satisfied with telephone calls than the digital alternative. When reported, satisfaction rates were high, ranging from 42% [33] to 93% [31].

Discussion

Principal Findings

This review found that few studies have reported on how they addressed access and engagement of children and young people in digital health interventions. Most studies (23/24, 96%) included in the review were conducted in developed countries, mainly the United States. Only 2 studies reported data related to access, and no study reported the use of strategies to enhance or increase access. All studies included in the review reported on at least 1 aspect of the engagement of children and young people in interventions. Engagement was assessed in relation to frequency but did not consider whether the level of engagement achieved could be considered effective.

Access to health care includes both the availability of services and the ability of individuals and populations to access services. Inequities in access to health care tend to affect the most susceptible people in our communities and those with the most complex health care needs [17,57]. Until now, the examination of young people's access to digital health interventions has primarily focused on reviewing their engagement after enrollment in the study. However, there has been minimal consideration of equity issues regarding access before enrollment or engagement after enrollment among different groups. There is much work to be done in carefully mapping the factors that may affect access within a population during the conception of a study and planning for how to improve equity in relation to access before recruitment begins. The World Health Organization [58] has developed a framework for planning, developing, and implementing youth-centered digital health interventions. The framework provides guidance on the key considerations at each stage, including whether a digital solution is the best approach and consulting with young people. Examples of considerations for researchers and others to deliberate include ownership of, and access to, digital devices; connectivity in a geographical area; and community consultation to understand the cultural, social, family, and individual beliefs and behaviors related to technology, health, and behavioral change to create a user-centered designed intervention.

Variability in the measurement of engagement with digital health interventions reflects the diversity, complexity, and multiple aims of the digital health interventions. Although there is variability in the measurement of engagement, most young people in the studies included in this review engaged with the digital health interventions once enrolled. The measurement of engagement with interventions was based on use data, frequency and intensity of engagement, and user satisfaction data. There has been no exploration of the relationship between engagement with the digital intervention and the outcome measures. The concept of “effective engagement” [19] was not explored in the papers included in the review. The concept of promoting effective engagement rather than simply more engagement is an area that could yield valuable insights into how to support young people to achieve the goals and intended outcomes of a digital health intervention. Exploring and recognizing the combination of measures to promote and support “effective engagement” is an area for development with the potential to test multidimensional models of engagement [1,59].

The digitalization of health has the potential to improve health outcomes by empowering young people to become active custodians of their own health. There is the potential to improve access and health outcomes for traditionally underserved groups where smartphone ownership and use are higher than the general population [60,61]. However, caution has been advised regarding the digitalization of health, as it tends to favor certain groups while potentially having negative impacts on others. Although there has been exponential growth in the use of the internet, access to health information remains unequal [61].

Equal use for equal need requires conditions whereby those who have an equal need for health care make equal use of health care. Compared with equal access for equal need, this equity principle requires more proactive efforts. Areas related to fiscal and social policy, that influence education, housing conditions, and nutrition, are highly influential and speak to fundamental determinants of health. To promote access and engagement, researchers must first recognize the importance and value of considering these factors and preempt, plan, and document their efforts to make progress.

The limitations of this review include the search for, and inclusion of, papers published in English only. The heterogeneity of the papers meant that a meta-analysis was not possible and a narrative summary was completed. The review included studies that reported on either access or engagement or both; however, improving or addressing these concepts was not the primary aim of the studies. Where the 2 concepts are fundamental to the design and effectiveness of digital interventions, a strength of the review lies in the inclusion of all studies that report on the consideration of access and engagement.

Conclusions

The review identified several gaps and raised important questions for further investigation. Most of the studies reporting on access or engagement, did not seek to improve access to digital technology and focused on the frequency of engagement. Future work should explore how access and engagement can be considered preemptively and assessed throughout the intervention, with the goal of improving the equity of access and effective engagement with digital interventions.

Acknowledgments

The authors would like to acknowledge Lisa Munro, a subject librarian at Edith Cowan University, for her support with the search strategy. Funding to support the research assistant role was provided by the School of Nursing and Midwifery, Edith Cowan University. The funder had no role in the design of this study and did not have any role in its execution, analyses, interpretation of the data, or preparation of the manuscript.

Data Availability

Data are presented in the manuscript and Multimedia Appendix 1.

Authors' Contributions

LW, EM, and DA were involved in conceptualization, methodology, screening, and bias assessment and wrote the review. MJ and SR were involved in study methodology, literature search, screening, data extraction, data analysis, and bias assessment and wrote the review.

Abstract

Background: There is limited understanding of the concept of the digital identity of young children created through engagement on social networking sites.

Objective: The objective of this scoping review was to identify key characteristics of the concept of digital identity for children from conception to the age of 8 years on social networking sites.

Methods: This scoping review was conducted using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. The key databases searched were EBSCO, Web of Science, ProQuest ERIC, and Scopus. Gray literature sources (National Grey Literature Collection, ProQuest Dissertations and Theses, and Google Scholar) were also searched to identify unpublished studies. Articles were selected if they were published in English and reported data on the digital identity of children in relation to social networking sites.

Results: The key terms used in the literature were *sharenting*, followed by *digital footprints* and *children's identities*. Our study revealed 2 approaches to the creation of digital identity: *social digital identity* and *performative digital identity*. The articles in this review most commonly used the term *sharenting* to describe the behavior parents engage in to create digital identities for children on social networking sites. Motivations to post information about children differed among parents; however, the most common reasons were to share with friends and family and create digital archives of childhood photos, termed *social digital identity*. The second motivation was categorized as performative digital identity. The risk of digital kidnapping and identity theft associated with the creation of digital identities also influenced parents' behaviors.

Conclusions: The creation of a digital identity for children is an emerging concept. Our review develops a deeper understanding of sharenting behaviors that can be used to better support parents and their children in creating a digital identity with children and awareness of the potential future impact. We recommend that future studies explore the perspectives of children as key stakeholders in the creation of their digital identity.

KEYWORDS

digital identity; children; social networking sites; sharenting; scoping review; perspectives

Introduction

Background

Every post made on social networking sites contributes to the development of a digital identity. For some, this occurs naturally through their engagement with social networking sites, and for others, the process is planned or curated. Children and vulnerable populations can be represented on social networking sites without control over the creation of the digital identity developed on their behalf [1-7]. Children's digital identities are often created before the child is born [8,9]. The creation of a child's digital identity can start with parents sharing information about their soon-to-be-born or newly born child on social networking sites [3,10-12]. Digital identity development continues beyond the initial post as images, events, and milestones are shared with or without the permission of the child.

One of the major limitations of the literature on children and social networking sites is the underrepresentation of the voice of the younger child. There is little information available on social networking sites and their use and impact on children and even less from the perspective of children [13-16]. The lack of research with children is mainly attributed to the minimum age requirement for a child to register an account. Each social media site and app has its own criteria for minimum age requirements, which range from 13 to 16 years (13 with parental consent). It is common for parents to either post on behalf of their children or post (knowingly or unknowingly to the child) about their children between conception and the age of 8 years [17].

Although literature on the digital identity of children is emerging [8,12,18,19], evidence on the digital identities of adults has grown rapidly over the past 2 decades [20-25]. Despite the increase in the literature that explores adults' digital identity, the key concepts related to processes and outcomes have not been established [1,20]. Approaches to define digital identity often draw on existing theories, such as the theory of self-presentation by Goffman [26,27]. Goffman [26] describes identity as performative and the world as a stage on which the act is taking place. The performance cannot take place without an audience who is there to validate the social performance [26]. Social networking sites are often seen as a stage in which one is actively trying to manage their impression or performance to be liked by others [28].

Research on adolescents' digital identity (development) also draws on the theory by Goffman [26] and identity development theories such as the stages of psychosocial development were developed by Erikson [29], the identity status theory by Marcia [30], and the concept of networked publics by Boyd [31]. Identity development theories describe the adolescent years as the most important phase of identity development, and little is theorized about young children's identity development [20,29,32]. However, Schachter and Ventura [33] argue that identity formation starts before adolescence and that parents play an active role in their children's identity formation and later identity development. This aligns with the early formation of "digital" identities, which often starts with parents posting about their children on social networking sites.

Objectives

There is limited understanding of the concept of digital identity for young children [21,34]. The purpose of this scoping review was to explore key characteristics in the literature on the concept of digital identity for children from conception to the age of 8 years on social networking sites. The review question was as follows: "What are the key concepts, definitions, and characteristics related to the concept of digital identity as generated through engagement with social networking sites for children from conception to the age of 8 years?"

Methods

Overview

A preliminary search of the Cochrane Database of Systematic Reviews and *JBI Evidence Synthesis* was conducted, and no current systematic or scoping reviews on the topic were identified. The updated methodological guidance for conducting a Joanna Briggs Institute scoping review was used in tandem with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) to guide this review [35]. The completed PRISMA-ScR checklist can be found in Multimedia Appendix 1. A scoping review was assessed as the most appropriate method, where the purpose of this review was to identify and clarify concepts [36] regarding the digital identity of children. The scoping review protocol was registered with the Open Science Framework and can be retrieved via the web (see the reference for a link to the protocol) [37].

Search Strategy

Relevant databases were searched using a constructed Boolean strategy with subject headings and keywords to reflect the inclusion criteria (the search strategy can be found in Multimedia Appendix 2). The first search was conducted between July 2022 and September 2022, and the second search was conducted between February 2023 and April 2023. The strategy was developed in conjunction with a specialist librarian. The search strategy, including all identified keywords and index terms, was adapted for each included database or information source. The databases EBSCO, Web of Science, ProQuest ERIC, and Scopus were searched. The reference lists of the included studies were cross-checked with search outcomes to identify studies not previously identified. Gray literature sources such as the National Grey Literature Collection, ProQuest Dissertations and Theses, and Google Scholar (the first 200 results) were also searched to identify unpublished studies.

The search terms were as follows: *child* OR *children* OR *infant* OR *toddler* OR *preschooler* (population) AND (*digital* AND *identity*) OR *"digital identity"* OR (*online* AND *profile*) OR *"online profile"* OR (*social* AND *presence*) OR *"social presence"* OR *sharenting* (concept) AND *social media* OR *Facebook* OR *Instagram* OR *Twitter* OR *Snapchat* OR *Tumblr* OR *"social networking"* (context).

Inclusion and Exclusion Criteria

Overview

Studies of any research design that included the presentation of findings on digital identity in relation to children from conception to the age of 8 years on social networking sites were included if a full text could be retrieved. The viewpoint within the studies could be of the young person, family, health professionals, peers, and others. Further inclusion criteria were articles that were peer reviewed, written in English, and published between January 2000 and April 2023 inclusive. Gray literature was included if research findings were reported. No restrictions on the inclusion of studies were applied in relation to the geographic location or setting of the studies except for the generation of the data on social networking sites.

Participants

Social media related to children from conception to the age of 8 years was included. Data related to family members who posted about their children were also included.

Concept

The concept explored was digital identity on social networking sites in relation to children from conception to the age of 8 years. This review focused on web presence on social networking sites, and therefore, literature on digital identity that was purely data generated was excluded. Data-generated identities include, for example, log-ins, personal information saved on websites for identification purposes, and data saved while using apps and playing games. This type of digital identity is discussed elsewhere [38].

Types of Sources

This scoping review included both qualitative and quantitative studies. Quantitative study designs including experimental and quasi-experimental study designs, randomized controlled trials, nonrandomized controlled trials, before-and-after studies, interrupted time-series studies, analytical observational studies (prospective and retrospective cohort studies), case-control studies, and analytical cross-sectional studies were considered for inclusion. This review also considered descriptive observational study designs including case series, individual case reports, netnography, and descriptive cross-sectional studies for inclusion.

Screening

Following the search, all identified references were imported into EndNote (version 20.1; Clarivate Analytics) for the identification and removal of duplicates and then exported to the Joanna Briggs Institute System for the Unified Management, Assessment, and Review of Information (Ovid) for a second identification of duplicates and the independent screening of titles and abstracts against the inclusion criteria by 2 reviewers [39]. Any differences between the reviewers regarding the inclusion or exclusion of articles for full-text review were discussed, and if not resolved, they were referred to a third reviewer. The full texts of the retained articles were independently assessed by 2 reviewers. Any differences between the reviewers were discussed and, if not resolved, they were referred to a third reviewer. The reasons for excluding studies at the full-text review stage were recorded. The study selection, screening, and reasons for exclusion at the full-text review stage are reported in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram [35] in Multimedia Appendix 1.

Charting the Data

Data extraction tables were developed with the team and used to ensure a uniform data extraction process. Data extraction was undertaken by a minimum of 2 reviewers. The selected studies were analyzed to identify the key characteristics, such as study design, aim, country of study, setting and context, participant characteristics (the age and gender of the children and their families), and sample size. Key terms and concepts related to children's digital identity were identified, and themes and trends were charted. Where required and possible, the authors of the papers were contacted to request missing or additional data for clarification.

Analysis and Presentation of Results

All articles in this scoping review were searched for key terms used in relation to the concept of digital identity. If the term was mentioned ≥2 times, it was included in the count. Key terms were included if they appeared in the main text, titles, abstracts, or keywords but not in references, footnotes, or headers.

Where variations of the term existed, all variations were analyzed as related to the core term. For example, for the core term *children's identities*, variations such as *children's identity*, *child's identity*, *the identity of the child*, or *their (children's) identity* were included. Similarly, variations of *sharenting* such as *oversharing*, *anti-sharenting*, and *grand-sharenting* [40] were analyzed as related to the core term *sharenting*.

The search was carried out using the PDF reader Nitro (Nitro Software, Inc), and words were copied and pasted into the search bar to avoid spelling mistakes. The search strategy included terms such as *identit* to quickly identify all terms related to identity, such as *online identity*, *digital identity*, and *social identity* (*identity* on its own was not counted).

Data were presented in tabular form, which allows for easy comparison between articles. A graphic was chosen as a way to demonstrate the relationships between key terms. Quantitative and qualitative data were extracted into tables to compare the studies, and qualitative data were sorted into key themes. Key trends are discussed in the Results and Discussion sections.

Results

Overview of Results

The search produced a total of 2573 abstracts, 1764 references from database and register searches, and 809 references from searches using other methods (refer to Multimedia Appendix 1 for the PRISMA flowchart [40]). Of the 1764 references, 652 (36.96%) were identified as duplicates, leaving 1112 (63.04%) references. There were no duplicates in the 809 references from other search methods. After title and abstract reviews were completed on all remaining references, 93.53% (1040/1112) of the articles were excluded from the database references and 99% (801/809) were excluded from the references from other search methods. This left 72 articles, of which 1 (1%) was excluded as there was no way to retrieve the full text and there were no contact details for the corresponding author [41]. Of the remaining 71 articles, after the full-text review, 50 (70%) were excluded, with the most common reasons being ineligible phenomena of interest (n=20, 40%), age (n=14, 28%), and the article not being about the child or children (n=8, 16%). This resulted in 21 articles. An additional hand search in March 2023 and April 2023 identified 7 articles for full-text review, of which 6 (86%) were included and 1 (14%) was excluded as it was not about the child or children. This resulted in a total of 27 articles included in this scoping review [7,9,10,17-19,40,42-61].

Characteristics of the Studies

Participants

Overview

The total reported number of participants in this scoping review was 8643, comprising mothers (n=1768), fathers (n=585), grandparents (n=1), and participants reported collectively as parents (n=1841). In total, 4% (1/27) of the articles reported data from child participants (n=68) [59]. The remaining 4263 participants were not identified further. Overall, more female participants (n=4158) than male participants (n=1753) were reported in the articles.

The sample size of the included studies ranged from 1 [18] to 3472 [57] participants. Notably, 30% (8/27) of the articles did not provide sample characteristics [7,43-45,47,48,52,54]. This was due to the study context (eg, content analyses of social networking site posts and photos) [7,43-45,47,48,52,54] and the nature of the articles, such as books or reviews [54] (Table 1).

Table 1. Characteristics of the included studies.

Study, year	Study aim	Study design	Country	Setting and context	Identity type	Participants	Age	Sex
Ammari et al [19], 2015	To investigate how parents decide what to disclose about their children on SNSs[a]	Qualitative	United States	Sharenting and the shared responsibility of parents in managing their children's online identities	SDI[b]	102 parents	Data unavailable	Male and female
Bare [43], 2020	To provide an overview of the images of children being posted to Instagram by parents under the hashtag #letthembelittle	Qualitative	United States	Content analysis of Instagram posts of children with the hashtag #letthembelittle.	SDI and PDI[c]	Unspecified	Data unavailable	Data unavailable
Benevento [44], 2022	To understand how photographs shared on social media connect and express values regarding childhood	Narrative inquiry	Not specified	Analyzing Instagram postings and comments on photos of children on 2 hashtags—#letthekids and #fashionkids	SDI	Not specified	Data unavailable	Data unavailable
Bezakova et al [45], 2021	To identify the extent of the problem of sharing content on minors with family members on social media (*sharenting*), identify legal solutions to the problem, and point out the importance of adequate social mechanisms (media and marketing) to raise awareness of the issue	Analytical-synthetic and comparative research methods	Not specified	Analyzing sharenting of sensitive data on social media, comments, reviews, blogs, web portals, and emails. Identifying legal solutions to protect children.	SDI	Not specified	Data unavailable	Data unavailable
Briazu et al [46], 2021	To investigate how the risks and benefits alongside psychosocial variables affected the Facebook sharenting behavior of mothers of young children	Mixed methods	United Kingdom	Facebook sharenting behaviors of mothers	SDI	190 mothers of young children	62.6% were aged between 25 and 34 y	Female
Brosch [10], 2016	To learn about parents' habits regarding their children on Facebook, especially how much and what kind of information about their children they share	Social media ethnography	Poland	Sharenting on Facebook. Exponential nondiscriminative snowball recruiting.	SDI	168 parents with a child or children aged <8 y	Data unavailable	Data unavailable
Choi and Lewallen [47], 2018	To examine how children are represented on Instagram and how children are depicted in relation to traditional stereotypes	Mixed methods	United States	Content analysis of 510 photos of children on Instagram on children's gender and racial representations on social media	SDI and PDI	Not specified	Data unavailable	Data unavailable

Study, year	Study aim	Study design	Country	Setting and context	Identity type	Participants	Age	Sex
Cino and Dalledonne Vandini [40], 2020	To investigate how boundaries of children's social media presence are understood and experienced within interacting systems regarding the relationship between MILs[d] and DILs[e]	Literature review and qualitative study	United States	Digital dilemmas on their children's digital footprints, privacy, and social media presence created by members external to the family, such as the child's teacher. Analysis of parents' posts on a BabyCenter community, a web-based parenting forum.	SDI	300 parents	Most were female. Specific data are unavailable.	Data unavailable
Dobson and Jay [18], 2020	This paper explored the representation of children and family life, with an emphasis on the "image of the child" that exists on Instagram.	Qualitative	Australia	Perspectives and experiences of an influencer parent sharenting photos on Instagram	SDI and PDI	1 mother	Data unavailable	Female
Er et al [48], 2022	To investigate *sharenting* during the early COVID-19 pandemic and quarantine periods	Qualitative	Turkey	Sharenting during the pandemic and quarantine period. Descriptive content analysis of the Instagram profiles of the parents—401 posts from Instagram	SDI	Unspecified	Data unavailable	Data unavailable
Fox et al [50], 2022	To explore first-time fathers' vulnerabilities and decisions to engage in sharenting, especially given that marketers seek to connect with new parents on social media via engagement tactics that prompt sharenting	Mixed methods	United States	First-time fathers' willingness to sharent on social media and their level of perceived sensitivity to their children's information. Web-based survey on Amazon Mechanical Turk using Prime Panels and grounded theory.	SDI	75 first-time fathers	Aged 20 to 40 y	Male
Fox and Hoy [49], 2019	Study 1: to explore mothers' expressions of vulnerability and how these relations can be linked to their motivations for sharing children's PII[f] on social media. Study 2: to explore mothers of young children in a Twitter chat and the extent to which they post children's PII, as well as the mother's vulnerability.	Mixed methods	United States	Qualitative: interaction of consumer vulnerability of the mother and the reasons and decision to post about their children on social media. Quantitative: interaction of a brand—Carter's, Inc and Children Apparel—with the engagement of mothers on Twitter.	SDI	Study 1: 15 mothers; study 2: 122 participants	Study 1: aged 24-40 y; study 2: data unavailable	Study 1: female; study 2: data unavailable
Hashim et al [51], 2021	To investigate the trends, motives, or purposes behind sharenting by Malaysian parents and their awareness (or lack thereof) of its related privacy issues	Qualitative	Malaysia	Mothers' motives to sharent and the type of content they post frequently and like to update their status with or post on social media	SDI	40 mothers	52.5% were aged between 31 and 40 y	Data unavailable
Holiday et al [52], 2022	To identify how parents self-present in their sharenting posts	Qualitative	United States	Self-representation on Instagram posts about their children	SDI and PDI	Unspecified	Data unavailable	Data unavailable

Study, year	Study aim	Study design	Country	Setting and context	Identity type	Participants	Age	Sex
Jorge et al [17], 2022	To explore how Cristiano Ronaldo, his partner, and his mother shared information about his children on Instagram between 2018 and 2020	Qualitative	Portugal	Sharenting of a celebrity, Cristiano Ronaldo, and his family members. The digital identity of Cristiano Ronaldo's children analyzed through sharenting by Ronaldo, his partner, and his mother on Instagram.	SDI and PDI	3 participants (mother, father, and grandmother)	Data unavailable	Data unavailable
Kopecky et al [53], 2020	To investigate the type of content that parents publish about their children and compare this behavior between Czech and Spanish parents	Quantitative study	Czech Republic and Spain	Comparing sharenting content, extent, and behaviors in 2 countries. The study was conducted on the web (Google Forms distributed through Facebook, Instagram, email, and WhatsApp channels)	SDI	1093 Czech parents and 367 Spanish parents	Czech parents aged 25 to 64 y; Spanish parents aged 21 to 61 y	Men and women
Kumar and Schoenebeck [9], 2015	To gather mothers' narratives and experiences about sharing baby photos on Facebook. To show how identity performance allows mothers to enact—and receive validation of—good mothering.	Qualitative study	United States	Attitudes, opinions, and experiences of sharing baby photos on Facebook and mothers' perceptions of Facebook and other sites	SDI	22 mothers	Aged 25 to 39 y	Female
Kumar [54], 2021	To investigate how power works through 3 fields of discourse that govern parents' social media conduct	Review and qualitative study—"thinking with theory" method	United States	Governmentality and parents' conduct in sharenting	SDI	Unspecified	Data unavailable	Data unavailable
Latipah et al [55], 2020	To describe the sharenting model by millennial parents as a process of exchanging information between parents in parenting, mentoring, education, and child development	Phenomenological approach	Indonesia	Motives, impact, and ways of sharenting. Interview was completed via the web.	SDI and PDI	10 parents	Aged 24 to 35 y	5 female and 5 male
Leaver [7], 2020	To investigate how exactly the digital communication and sharing of and by parents about their children can be balanced with children's rights to privacy both in the present and, more challengingly, in the future	Critical review of parenting practices through examples	Australia	Sharenting children's sensitive information on Instagram, Facebook, wearables, and apps (Owlet Smart Sock and Peakaboo Moments); web safety; and children's rights to opt out	SDI and PDI	Unspecified	Data unavailable	Data unavailable
Marasli et al [56], 2016	To investigate the use frequency and the content of social media sharing and investigate the information a group of parents shared on the web about their children via content analysis	Mixed methods	Turkey	Sharenting on Facebook	SDI	219 parents	41.7% were aged 31 to 40 y	Data unavailable

Study, year	Study aim	Study design	Country	Setting and context	Identity type	Participants	Age	Sex
Mascheroni et al [62], 2023	To investigate the patterns of sharing among a nationally representative sample of parents of children aged 0 to 8 y. To identify the presence of recurrent sharenting styles. To examine the relationship between sharenting styles and parents' sociodemographic information and between sharenting styles and parental practices of privacy management adopted to govern their children's social media presence.	Quantitative	Italy	Sharenting styles, extent of sharenting, and parents' privacy management practices	SDI	1000 Italian parents	Aged 18 to 54 y	Male and female
Minkus et al [57], 2015	To measure adults' sharing of children's PII in web-based social networks, namely, Facebook and Instagram	Mixed methods	United States	Analysis of images shared on Facebook and Instagram	SDI	2383 Facebook users and 1089 Instagram users	≥18 y	Women and men
Morris [58], 2014	To provide insights into the types of child-related content that mothers of infants and toddlers are willing to share on SNSs	Mixed methods	United States	How mothers of young children use Facebook and Twitter and mothers' perceptions on the appropriate site on which to share photos of their children. Survey was completed on the web.	SDI	412 mothers	Aged 19 to 46 y	Female
Sarkadi et al [59], 2020	To investigate children's thoughts about sharenting	Quantitative	Sweden	Children's views on sharenting. Survey was completed on the web.	SDI	68 children	Aged 4 to 15 y	Two-thirds were boys, and one-third were girls
Turgut et al [60], 2021	To investigate what factors affect what parents share on social media about their children	Qualitative study	Turkey	Sharenting and its associated factors and parents' views on legal liability	SDI	88 parents	Aged 22 to 45 y	Data unavailable
Wagner and Gasche [61], 2018	To investigate what factors parents consider when disclosing personal information about their children on SNSs and what strategies they apply	Qualitative	Germany and Austria	Parents' thoughts on drivers and inhibitors of disclosing children's photos on SNSs	SDI	220 mothers	Data unavailable (mean age 31.1 y)	Data unavailable

[a] SNS: social networking site.

[b] SDI: social digital identity.

[c] PDI: performative digital identity.

[d] MIL: mother-in-law.

[e] DIL: daughter-in-law.

[f] PII: personally identifiable information.

Study Origin

Of the 27 studies, 11 (41%) were conducted in the United States [9,19,40,43,47,49,50,52,57,58], 3 (11%) were conducted in Turkey [48,56,60], and 2 (7%) were conducted in Australia [2,18], followed by 1 (4%) study conducted in both the Czech Republic and Spain [52], 1 (4%) conducted in Germany and Austria [61], and 1 (4%) from each of the following countries:

the United Kingdom [46], Malaysia [51], Poland [10], Sweden [59], Italy [62], Indonesia [55], and Portugal [17]. The remaining 7% (2/27) of the studies did not name the country of data origin [44,45].

Context

The main social networking sites used were Instagram and Facebook. A total of 26% (7/27) of the studies focused on Instagram [17,18,43,44,47,48,52], and 15% (4/27) of the studies focused on Facebook [9,10,46,56]. The remaining studies focused on social media more broadly.

Study Design

In total, 48% (13/27) of the studies used a qualitative approach [9,10,17-19,43,44,48,51,52,55,60,61]. A total of 26% (7/27) of the studies used a mixed methods approach [46,47,49,50,56-58]. In total, 11% (3/27) of the studies used a quantitative design [30,53,59]. A total of 7% (2/27) of the studies used both qualitative and literature review methodologies [40,54], and 4% (1/27) of the articles were book chapters [7].

Key Terms and Concepts Used to Describe Digital Identity

In this first part of the *Results* section, we explore key terms and concepts used in relation to the concept of the digital identity of children on social networking sites. We then explore the concept of digital identity in relation to 2 types of behaviors that underpin the development of young children's digital identity.

The Key Term Sharenting

Overview

The term *sharenting* was the most commonly used term in the literature (21/27, 78% of the articles) on the development of children's digital identities [7,10,17,40,44-54,56,59,60]. Of the 27 studies, 5 (19%) studies discussed the term in more detail and provided a definition of *sharenting* [40,45,47,49,50]. Bezakova et al [45] explained the term *sharenting* as "the overuse of social media by parents or legal guardians who share photos or various home videos of minors with the virtual community," whereas Brosch [10] defined *sharenting* as "the practice of a parent to regularly use the social media to communicate a lot of detailed information about their child" and drew on the Collins dictionary definition. All authors appeared to share a similar understanding of the term *sharenting*. Thus, the definition of *sharenting* is widely accepted and used frequently in the context of the digital identities of children on social networking sites.

Digital Footprint

A total of 48% (13/27) of the articles referred to the concept of digital footprint(s) [7,9,10,19,40,45,46,48,50,53,54,60,62]. The term *digital footprints* was sometimes used interchangeably with the term *digital identity*. It often came down to the authors' preference for wording to describe the creation of digital identities for children. For example, Brosch [10] and Bezakova et al [45] explained that children's digital footprints are mostly created by parents early in their child's life, sometimes before or just after the birth of the child or during infancy [10,45]. Brosch [10] further explained that 10.7% of Polish parents in their sample created digital footprints for their unborn children by posting sonogram images, and 8.3% shared photos of the expectant mother on Facebook. As illustrated by this example, the term *digital footprints* was used synonymously with the term *digital identity*.

When the risks of sharing children's content on the web were discussed, the term *digital footprints* was often chosen. Kumar and Schoenebeck [9] discussed the risk of mothers creating digital footprints for their children in relation to the benefits of receiving validation. Mothers in their study were hesitant and uncertain about how their photo-sharing behavior might affect their children's online identity later and restricted their sharing to pictures that were cute and funny and showed milestones. Nevertheless, they found that the benefits of receiving validation via shared content outweighed the mothers' concerns about digital footprints and oversharing. The authors introduced a new term, *privacy stewardship*, to describe "the responsibility mothers take on as they consider what kinds of baby photos are appropriate to share and the implications for their children's digital footprint." In line with this, Cino and Dalledonne Vandini [40] described the pressure and responsibilities of motherhood as mothers are eager to and expected to actively manage their children's digital footprints. The literature suggests that the management of children's digital footprints and identities is mostly considered to be the responsibility of parents, especially mothers [7,9,40,62].

The Use of the Term or Concept of Identity

The different types of identities that were mentioned in relation to children's digital identities on social networking sites are discussed in the following sections.

Children's Identities

The term *children's identities* or variations of this term (eg, *child's identity*) was used in 44% (12/27) of the articles [7,9,17,19,43,44,48,52-54,56]. The term *children's identities* was used to represent a broad concept that often encompassed other subterms or concepts related to identity. A total of 26% (7/27) of the articles that included the term *children's identities* further discussed the concept of *online identity* [9,17,19,43,45,53,60], and 15% (4/27) of the articles discussed the term *digital identity* [17,54,60,62].

Online Identity

All articles that used the term *online identities* discussed how parents were the creators of their children's identities on the web [9,17,19,43,45,53,60]. Similar to the other concepts related to the digital identity of children, *online identity* could often be used interchangeably with the term *digital identity*. However, the context in which *online identity* was used differed from that in which the other terms were used. Of the 27 studies, 5 (19%) studies discussed children's online identities in the context of children's rights and agency over their online identity and the missing consent from children to allow their parents to post about them on the web [17,19,43,45,53].

Digital Identity

The literature did not generate an accepted definition of digital identity; however, some authors briefly discussed the concept and its relationship with *sharenting*. Kumar [54] linked the concepts of digital identity and sharenting: "sharenting is potent thanks to the concept of a 'digital identity,' also called a digital persona, profile, legacy, trail, footprint, or presence" and "Sharenting discourse portrays the creation of a digital identity as a choice, one best left to the child."

Mascheroni et al [62] also linked the 2 terms by discussing the consequences of sharenting on children's digital identity: "Generally speaking, almost half of the parents are reportedly aware of the consequences of sharenting for children's digital identity, but regular sharers show a lower average value, suggesting a lower degree of awareness."

Jorge et al [17] discussed the term *digital identity* in more detail by exploring how celebrity sharenting contributes to the construction of children's digital identities. They found that the parents shared information and photos that aligned with the theme of happy and grateful parenthood and that the family posts represented the children as the extended selves of the father, stepmother, and grandmother.

Thus, there is an understanding that the digital identities are created by parents through sharenting. Here, sharenting is seen as the action (sharing information about the child), and the digital identity is described as the consequence or outcome of the sharenting behavior. Although sharenting was well defined, definitions for children's digital identity were not provided in the articles.

Other terms or concepts that included the word *identity* were used less frequently; for example, *relational identity* was mentioned in 7% (2/27) of the articles, whereas the terms *identity performance*, *mediated identity*, *private identity*, *social identity*, *social media identity*, and *moral identities* only appeared each in 4% (1/27) of the articles. Overall, most articles (19/27, 70%) in this review discussed some form of identity in relation to children's presence on social networking sites.

Sharenting is the behavior that parents engage in when sharing information about their children on social networking sites. This creates long-lasting *digital footprints* on the web that form children's *digital identities*. The literature has identified a number of risks related to the creation of children's digital identities on social networking sites, such as *digital kidnapping* and *identity theft*, especially if the information that was shared contained *personally identifiable information*. These areas will be explored in relation to the concept of the digital identity of young children.

Safety: Digital Kidnapping

A total of 11% (3/27) of the articles in this review discussed the concept of digital kidnapping [43,48,51]. The terms *identity theft*, *personally identifiable information*, and *privacy stewardship* were used in 7% (2/27) of the articles in this review [9,46,49-51,54]. The term *digital kidnapping* is defined as "people who steal a child's identity and photo on social media and pass the child off as their own" [48]. Digital kidnapping is described as one of the risks of creating digital identities for children by sharing images, especially those that include personal information about the child and reveal the child's face [43,48]. Hashim et al [51] found that Malaysian mothers were concerned about digital kidnapping and identity theft and, therefore, were conscious of not sharing locations in their posts and actively hid information regarding places and their children's names and dates of birth.

Children's Digital Identity as an Extension of Parents' Digital Identities

A total of 7% (2/27) of the articles discussed the concept of extended self [17,52]. These 2 articles also discussed the term *relational identity*. In the article by Holiday et al [52], the authors discussed the theory of the "extended self" and applied it to the concept of sharenting. The authors described parents' engagement in sharenting as fundamental to their identity as parents, which the authors argued says more about the parent as an individual than about the depicted child. Following this thought, sharenting is seen as a form of parents' self-presentation that includes children as a component in the definition of the self.

Jorge et al [17] also described parents' representation of children on social networking sites as the extended selves of family members. When children's digital identities on social networking sites are interpreted as extensions of their parents' or family members' identities, parents' and family members' identities form part of the child's digital identity. Accordingly, some articles in this review (4/27, 15%) discussed the digital identity of parents, mothers, and families in relation to the child's digital identity [9,49,54,62].

Overall, the review of the key term and concepts related to digital identity shows that there is limited research defining key terms such as children's *digital identity* and *digital footprints*, whereas *sharenting* is a commonly used and widely accepted term that is clearly defined.

Content and Image Analyses

The Development of Social and Performative Digital Identities

The synthesis of the data generated through content and image analyses generated 2 types of digital identity: "social digital identity" and "performative digital identity." Children's social digital identity creation involves parents who create their children's digital identity by sharing information such as everyday activities and milestones without links to commercial products or promotion of their children. Parents' motivation to create social digital identities for their children is most often to share with family and friends and keep a digital diary [9,10,51,52,54,61], whereas children's performative digital identity is created when parents promote or market their children, often for their own benefit, for example, to promote their clothes and brands [18,44,52]. This means that parents post information and photos of their children to convey a picture of the child that can deviate from the actual identity of the child. These posts often present the child in a neat and fashionable way and can include links to products that parents obtain a financial share of. For example, "mummy" or fashion bloggers (eg, #fashionkids) create performative digital identities for their children that mostly benefit them and often disregard the needs of the child [18,63].

The Use of Social and Performative Digital Identities in the Literature

Overview

Most articles (18/27, 67%) discussed social digital identities exclusively [9,10,19,40,42,45,46,48-51,53,54,56-58,60,61], whereas 30% (8/27) discussed performative digital identities [7,17,18,43,44,47,52,55]. Social digital identities were mostly created on Facebook or discussed in a social media context in general, whereas performative digital identities were mostly created on Instagram. A summary of the types of posted content is presented in Table 2. The percentages indicate the proportion of articles that discussed the different topics.

Table 2. Analysis of posted content related to children on social networking sites (N=27).

Content	Total articles, n (%)	Activity or leisure time, n (%)	Events (birthdays or family), n (%)	Posing or influencer or making income, n (%)	Developmental stages or milestones, n (%)	Family holidays or outings, n (%)	Embarrassing or cute, n (%)	Face visible, n (%)	Name or DOB[a], n (%)	Nudity, n (%)
Social DI[b]	18 (67)	11 (61)	13 (72)	1 (6)	6 (33)	3 (17)	8 (44)	6 (33)	7 (39)	5 (28)
Performative DI	8 (30)	7 (88)	2 (25)	6 (75)	1 (12)	1 (12)	2 (25)	3 (38)	2 (25)	3 (38)

[a] DOB: date of birth.

[b] DI: digital identity.

Social digital identities were often created through images of events such as birthdays and family gatherings, whereas most of the studies that demonstrated a performative digital identity (8/27, 30%) included images and descriptions of children posing for photos, and in some cases, the family made an income from these posts [7,17,18,43,44,47,52,55].

In the following sections, we explain what information (including text and photos) parents typically share when creating social and performative digital identities for children and what motivates them to share this information.

Social Digital Identities

What Parents Share When Creating Social Digital Identities for Their Children

Most studies (10/27, 37%) reported that parents created social digital identities for their children by sharing their happy moments. Brosch [10] found that these happy moments were often recorded during daily life activities, outings, and special events (95.6%). Similarly, most of the mothers in the study by Briazu et al [46] shared information about special days (72.7%) or social activities (52.6%), and some shared information about health (6.7%) or educational issues (5.2%). Brosch [10] found that many parents revealed private information about their children by sharing posts containing images of their children's birthday parties (23.2%), baby videos, birth certificates, kindergarten diplomas, or art (32.7%), as well as sonogram images (10.7%). Information about the child was also shared via posts containing information such as the child's name and date of birth (48.2%). Brosch [10] also found that some of the posts contained embarrassing photos (eg, nude or seminude pictures of the child during bathing or at the beach), photos in which children were in distress (eg, crying or angry), or photos in which children were covered in food after dinner (eg, chocolate on their faces).

Kopecky et al [53] surveyed parents from the Czech Republic and Spain and found that these parents shared photos of celebrations, family moments, holidays, important milestones, and photos that parents considered to be cute or funny. Most parents reported sharing content in which the child could be identified (by face) but did not include sexual content (81.7%). One-fifth of parents shared photos in which the child was partially exposed to the extent that the identity of the child could be determined. A small proportion (3.5%) of parents from the Czech Republic reported sharing nude photos of their young children.

Er et al [48] investigated sharenting behaviors at the beginning of the COVID-19 pandemic. They found that mothers posted more often than fathers and that most posts contained photos and some contained videos of the children. Of the 226 posts they analyzed, 207 included the children's faces, with a limited number of parents blurring their children's faces (n=17). In line with the other studies, the posts were generally happy, for example, expressing the joy of spending time with children and love toward children and showing how children and the family happily played games, cooked, or learned together. The daily lives of the children were also posted, including birthdays, vacations, and anniversaries. A smaller proportion of posts expressed unpleasant situations during the COVID-19 pandemic, such as boredom, complaints, and unhappiness with quarantine.

Cino and Dalledonne Vandini [40] explored the digital identities that are created for children by the mothers' mothers-in-law and the conflict that this raises with the mothers. The content is either shared before the birth of the child (eg, pregnancy status of the mother, gender reveal, or labor) or afterward (eg, daily life activities) and usually against the will or knowledge of the mother.

Fox et al [50] investigated first-time fathers' sharenting behavior and found that fathers tried to avoid posting sensitive information (eg, their naked child). However, they did post about everyday activities such as going to the park, playing, birthdays, and firsts (eg, first tooth). Fathers were aware of security risks and, therefore, hid their children's faces and names.

Hashim et al [51] found that parents mostly shared social events (eg, vacations, events, family activities, and outings; 29.3%), moments (eg, good, funny, happy, important, or special moments; 25.3%), day-to-day activities (13.3%), memories of their children (12%), school activities (10.6%), food (4%), antics (2.6%), and milestones (2.6%) about their children.

Kumar and Schoenebeck [9] interviewed mothers about their sharenting experiences. Mothers described the photos that they shared about their children as cute and funny and explained that the photos often contained family or friends and developmental milestones of the children.

Marasli et al [56] found that the most common theme parents shared about on Facebook was special days (81.4%), such as birthdays, graduations, and year-end shows, followed by social activities (54.98%) and educational issues (30%). Less commonly shared themes included sports and arts activities (18.96%), play activities (17.54%), health issues (12.8%), and recommendations about products for children and informatics (12.32%). Most parents in this study (63.77%) also reported that they liked sharing pleasant things about their children.

Minkus et al [57] used a web-based application programming interface called Face++ to analyze Facebook and Instagram photos. The software identified children via age estimates based on the faces in the photos. Over 25% of the photos on Facebook and 16% of the photos on Instagram with children aged 0 to 7 years had comments that revealed the children's names, and 2.7% (Facebook) and 5% (Instagram) included the word *birthday*. The authors were also able to infer the children's last names from the parents' last names. Overall, 5.6% of Facebook accounts and 19% of Instagram accounts with child photos revealed the name and date of birth of the children, which is enough information to identify them. By further linking the parents' Facebook accounts with public records (eg, voter registration records), the authors were also able to identify the address of the parents and children.

Parents' Motivation to Create Social Digital Identities for Their Children

In this section, we explore mothers', fathers', and mothers-in-law's motivations for creating social digital identities for their children on social networking sites. Briazu et al [46] found that mothers' motivations or perceived benefits of posting about their children were to build connections, gain practical benefits such as asking for parenting advice, gain emotional benefits (eg, pride and joy from their children), and help others, and some mothers did not identify any benefits.

Fox and Hoy [49] found that the desire to be a "good" mother motivated mothers' sharenting behavior. Mothers used sharenting as a coping strategy. They shared their experiences as mothers and information about their children to seek affirmation and social support from others. The authors also explored mothers' motivations *not* to post about their children. Mothers focused on portraying the "right" image of the child and avoided posts that potentially could have made them look like a "bad" parent. It was also important to mothers in this study that their children would not be upset or embarrassed by their posts later in life.

Kumar and Schoenebeck [9] found that most mothers in their study used Facebook as an archive for their children's photos. It was important to these mothers to portray their children and themselves in a favorable light and to receive validation and support as mothers.

Wagner and Gasche [61] investigated German and Austrian mothers' decision-making processes and strategies when sharing about their children. Most mothers indicated that the costs of sharing photos of their children on the web outweighed the benefits, and therefore, more than half of the mothers (60%) never shared photos of their children on social networking sites. The mothers' main motivation to share was social participation (to inform others, to keep others up to date, and to document the children's development), followed by showing how proud they are of their children and the need to be liked, approved of, and accepted by others.

Fox et al [50] found that fathers' motivation to share was not to gain support from others but rather to express humor or spotlight themselves as fathers. Overall, fathers made fewer sharenting decisions, and the main responsibility of sharenting most often lay with the mothers [50].

Hashim et al [51] found that the most common motivation (42.8%) for Malaysian parents to share about their children was to save memories of them. Social networking sites served as an archive or journal for them to refer to at a later stage. The second most common motivator (31.6%) was the desire to share their experiences, information, activities, and feelings about raising children. Other motivations included being influenced by other social media users; staying connected and engaged with others; and motivating, encouraging, and inspiring other parents. In line with this, Turgut et al [60] described parents' motivation to post about their children as related to keeping in touch with others (eg, relatives and friends) and recording and memorizing their children's development. Brosch [10] found that the number of Facebook friends was a significant predictor of sharenting.

Cino and Dalledonne Vandini [40] investigated the motivation of mothers-in-law to post about their grandchildren. They reported that grandmothers' motivation stemmed from a desire to show excitement for the grandchild, which was often at the cost of the parent's desire for agency over their children's digital identities. However, it was noted that grandparents might be less knowledgeable about the internet and web safety and are potentially naiver about sharing information about their grandchildren on the web.

Performative Digital Identities

What Parents Share When Creating Performative Digital Identities for Their Children

Posts that contribute to a child's performative digital identity creation are usually well planned out to present the child in a fashionable or favorable way. Benevento [44] investigated posts with the *#letthekids* and *#fashionkids* hashtags. These are often used by parents who create performative digital identities for their children by sharing well-prepared posts that have been planned out. The hashtag *#letthekids* emerged as a counter to the more established hashtag *#fashionkids*; it stands for "let the kids dress themselves." The author found that *#fashionkids* photos often show the child alone during structured activities outdoors. Children are often displayed smiling or with still expressions posing with their possessions (eg, clothing and accessories). The attention is drawn to the child and their outfit rather than the location or activity. The background locations include well-maintained spaces such as parks, backyards, and playgrounds as well as home settings (eg, bedrooms and kitchens). Although children are often presented as posing with a focus on their clothes, these are most often casual.

In contrast, *#letthekids* photos often show the child during unstructured activities, such as during play, eating in their home environment, or in nature (eg, forest). This hashtag often displays children acting on their own, for example, while playing with their toys in their room, but also sometimes includes family members. The children in the *#letthekids* hashtag often look away or are shown from behind, as if they are not aware of the photo being taken. Interestingly, *#letthekids* posters upload more professional photographs than *#fashionkids* posters and more naked or seminaked pictures of their children than *#fashionkids* posters [44].

Choi and Lewallen [47] investigated children's gender representations on Instagram and found that parents posted more about their female children than about their male children and generally presented both their female and male children with positive emotions in white or gender-typical (ie, pink and blue) clothes. Children on Instagram were often displayed as playing or having fun in indoor settings by themselves. Girls were found to be frequently displayed as engaging in fashion.

Holiday et al [52] explored how parents self-presented in their children's presentation on Instagram. The authors identified 3 presentational categories: *polished*, *promotional*, and *intimate*. Photos in the *polished* category displayed children as visually appealing and suggested that parents invested time and effort in the post to portray an idealized image of the child. The parents were presented as favorably themselves, with possessions including the child. The attention was often directed toward the parents, not the children (via the text or image). Children in this category served as accessories (eg, in the parents' arms or on the side of the photo). Parents typically presented themselves as their "ideal self" in this category. The *promotion* category included posts in which parents used their children to promote their own skills, competencies, services, or products. Finally, the *intimate* category portrayed children more realistically without perfectioning of the image. With a strong focus on the child in the *intimate* category, more information is revealed about the child, which adds to the child's digital identity [52].

Jorge et al [17] explored celebrities' creation of their children's digital identities through sharenting. The authors analyzed Cristiano Ronaldo's family's sharenting practices and the portrayal of the children as the parents' extended selves. The results showed that celebrity sharenting contributes to digital identities through the themes of happy and grateful parenthood and the representation of children as the extended selves of the father, stepmother, and grandmother. Finally, Latipah et al [55] found that millennial parents shared content about their children related to everyday activities that are perceived as fun and that are often displayed as esthetically pleasing, with some posts including the promotion of products.

Parents' Motivation and Motives for Creating Performative Digital Identities for Their Children

Parents who engage in performative digital identity creation for their children have several motives for sharenting. Some parents want to pass on knowledge and educate other parents by providing advice, products, and insights into their daily life activities [18,55], whereas others' motive is to primarily promote their products or clothes [44,52]. In the *promotion* category in the study by Holiday et al [52], the motivation behind posting was often to promote products or services to other parents, whereas parents' motivation in the *intimate* category was often to preserve memories, which is in line with our findings on the motivation to create social digital identities.

Dobson and Jay [18] found that the motive of their case study was to connect with others as the family lived in a rural area. The mother reported that she had made friendships on the web and that followers empathized with her posts and offered support and a sense of community.

In the study by Latipah et al [54], parents' motivation to share about their children was to receive affirmation and social support and to demonstrate the ability to care for their children, social participation, and documentation.

The only study that included children as participants could not be classified as either "performative" or "social" digital identity. In this study, children were asked for their opinion on sharenting [58]. Children aged 4 to 15 years indicated that it is not OK for parents to post photos of their children (them) on social networking sites, whereas sending the photos to relatives was more accepted by the children in the study. The lowest (least acceptable) scores were found among the youngest children (aged 4-6 y) in the study. Irrespective of the participants' age, children wanted to be asked before their parents took or shared photos of them, and they wanted their answers to be listened to.

Discussion

Summary of Principal Findings

Overview

This scoping review identified 27 studies. Participants included mothers and fathers (collectively reported as parents) and grandparents. On the basis of the analysis of the key terms and concepts used in the literature, the following description of how these relate to one another was developed. The creation of a child's digital identity is developed through the behaviors of parents, most referred to as *sharenting*. The behavior of parents through the decisions on the web they make creates a digital identity that can be described as social digital identity or performative digital identity. We found that much of the literature on the concept of the digital identity of children reports on parents, especially mothers, and their sharenting behavior on social networking sites. The most used terms related to digital identity in the literature are *sharenting*, followed by *digital footprint* and *children's identity*. The term *sharenting* is well defined and popular among researchers and the media, whereas the term *digital identity* was less commonly used. We found that the term *digital footprint* was more commonly used than *digital identity*; however, clear definitions were also lacking in the articles in this review. Common across all terms was parents making decisions about what to share about their children, mostly without the children's consent.

The term *digital identity* is more commonly used in the literature on adults [20-25,64,65]. However, we expect a rise in the term digital identity in relation to children in the coming years as there has been a steep increase in research that focuses on the consequences and risks of sharenting [50,66,67]. The use of digital identity terms often depends on authors' preference for words. We found that *digital footprints*, *children's identity*, *online identity*, and *digital identity* were used interchangeably by authors. Together with *sharenting*, these 4 constructs were the most used terms across the articles, suggesting that they are closely related.

Digital Identity Creation: What and Why

We found that most of the content shared by parents was related to *social digital identity* and included sharing special events such as birthdays and family gatherings, as well as everyday activities and leisure time. In the *performative digital identity* category, posts also included content about everyday activities and leisure time but with a focus on children who were posing for a photo, with some posts contributing to the posters' income (eg, influencers). In the *performative digital identity* category, the motives of some parents were to sell products or promote themselves and their children. The content posted appeared carefully prepared and polished. The literature on the digital identity of children frequently made reference to the concepts of safety on the internet and the rights of the child, and these 2 areas will be explored further with reference to the findings of this review.

Safety Risks: Digital Footprints

Although some awareness among parents of the potential risks of creating digital footprints via sharenting and the creation of their children's digital identities was noted, there is still uncertainty about the exact impact and consequences of parental sharing behavior. One of the potential risks, digital kidnapping, was considered by some parents; however, the benefits of sharing were described as outweighing the risks of creating digital footprints and identities [9]. The perceived risks of sharenting may differ depending on the parents' cultural background. For instance, in the study by Wagner and Gasche [61], 60% of German and Austrian mothers reported never having shared a photo of their children on the web. In an Australian study, participants refrained from posting about their children on social media as a strategy for privacy [68]. Other researchers suggest that parents who perceive web-based social networks as a source of support are highly likely to sharent [69,70].

To make an informed decision about whether to share children's content on the web, parents need to receive information and guidance. Researchers and policy makers have started to develop new policies and guidelines for parents. Although there is a need to update existing policies to reflect the addition of online identities [71-73], the focus of many of these guidelines and policies is on children's screen time exposure and not on children's digital identity development or children's right to their digital identity and footprints [71,74,75]. Therefore, we recommend more rigorous research on parents' attitudes toward privacy and the factors influencing their sharing of children's photos and information on the web. Findings from such studies could inform efforts and emerging policies directed at mitigating sharenting behaviors that are associated with web-related risks.

Children's Rights and Privacy

The process of children's digital identity creation most often takes place without the child's permission or input [10,17-19,43,45,52-54,62]. No studies in this review investigated young children's creation of their own digital identities on social networking sites. A study in this review asked children for their opinion on their parents' sharenting behavior [59], and very few of the studies in this review (4/27, 15%) addressed the agency of the child [18,19,54,59]. When digital identities are created early for the child without the input of the child, their right to create their own digital footprint or identity is taken away, leaving them without a voice and choice [45,54,60]. Where possible, children should be involved in the development of their digital identity. Research to identify how this can be achieved and to give voice to the experiences of young children is needed to better understand this important and fast-moving area [19]. Future studies should explore the perspectives of children as key stakeholders in the creation of their digital identity [19,76].

Strengths and Limitations

To our knowledge, this is the first scoping review to map out the literature published on the creation of digital identities among young children through social networking sites. We strove to apply rigorous methods to search and select articles and chart the data. Owing to our strict age range exclusion criteria, we did not review articles that discussed the digital identity of children aged ≥9 years on social networking sites. The use of search terms and the selected databases may not have been exhaustive, and the omission of social networking sites such as YouTube is a limitation. The search was only valid up to April 2023. In the same vein, most of the included studies were conducted in the Western world, with only 7% (2/27) of the studies conducted in Asia and none conducted in Africa or South America. The interpretation of the findings should consider this geographical bias.

Conclusions

Digital identities on social networking sites are created when photos and information about a person are shared. The digital identities of children on social networking sites from conception to the age of 8 years are most often created by their parents (without the children's permission). Children's digital identities can be grouped into 2 categories: social and performative. Parents use the web environment to capture moments that matter to them while also creating positive narratives around the child's life. The content that is shared for each type of identity and the motivation behind the creation of such identities differ. Research into young children and the digital world has focused on areas such as the effects of screen time and child development and digital safety [77-81]. We urge greater attention to the important area of how the digital identity is created, the impact of this, and how young children can be involved in important decisions that affect their lives.

Abstract

Background: Internet addiction is an emerging mental health issue in this digital age. Nowadays, children start using the internet in early childhood, thus making them vulnerable to addictive use. Previous studies have reported that the risk of internet addiction tends to be higher in lower-income regions with lower quality of life, such as Indonesia. Indonesia has high risks and prevalence of internet addiction, including in children. Digital interventions have been developed as an option to combat internet addiction in children. However, little is known about what parents and therapists in Indonesia perceive about these types of interventions.

Objective: This study aims to investigate the experiences, perceptions, and considerations of parents and therapists regarding digital interventions for combating internet addiction in young Indonesian children.

Methods: This study used a qualitative exploratory approach through semistructured interviews. We involved 22 parents of children aged 7 to 11 years and 6 experienced internet addiction therapists for children. The interview data were transcribed and analyzed using thematic analysis.

Results: Participants in this study recognized 3 existing digital interventions to combat internet addiction: Google Family Link, YouTube Kids, and Apple parental control. They perceived that digital interventions could be beneficial in continuously promoting healthy digital behavior in children and supporting parents in supervision. However, the existing interventions were not highly used due to limitations such as the apps' functionality and usability, parental capability, parent-child relationships, cultural incompatibility, and data privacy.

Conclusions: The findings suggest that digital interventions should focus not only on restricting and monitoring screen time but also on suggesting substitutive activities for children, developing children's competencies to combat addictive behavior, improving digital literacy in children and parents, and supporting parental decision-making to promote healthy digital behavior in their children. Suggestions for future digital interventions are provided, such as making the existing features more usable and relatable, investigating gamification features to enhance parental motivation and capability in managing their children's internet use, providing tailored or personalized content to suit users' characteristics, and considering the provision of training and information about the use of interventions and privacy agreements.

Introduction

Background

Digital devices and the internet have useful functions for supporting our daily lives and work. Multiple studies have reported that, nowadays, children start using digital devices in early childhood [1-5]. Digital device ownership has also increased rapidly among young children [6,7]. Providing children with access to the internet can be beneficial for them and their parents, especially for learning and entertainment purposes [8,9]. However, increasing internet use in young children is followed by increasingly urgent risks that they will not be able to self-manage their digital behavior wisely. The addictive use of the internet and digital devices has emerged as one of the most anticipated concerns related to internet use in young children [7,10].

Internet addiction (IA) is defined as a behavioral disorder caused by the excessive and uncontrolled use of the internet and digital devices that can have negative impacts on mental, physical, and social health [11]. Behavioral addiction related to the internet and gaming has been recognized as a diagnosable mental health condition that needs further research in the *International Statistical Classification of Diseases and Related Health Problems, 11th Revision*, and the *Diagnostic and Statistical Manual of Mental Disorders, 5th Edition* [12,13]. IA can have harmful consequences for young children, such as speech delay, physical disorders, personality disorders, aggressive behavior, eating disorders, self-isolation, decreased academic performance, and decreased vision [14-19]. Young children are vulnerable to IA due to their limited self-control, limited digital literacy, incomplete cognitive development, and influence from family and their environment [20-23].

According to the Interactional Theory of Childhood Problematic Media Use (IT-CPU), the development of IA risks in young children (aged <12 years) could be defined from combined psychology, communication, and human-computer interaction perspectives [7]. On the basis of the IT-CPU, the problem in children is jointly influenced by distal factors (eg, the family’s socioeconomic condition, the family’s dysfunction, and the digital environment), proximal factors (eg, children’s behavior and emotion; the family’s behavior, attitude, literacy, and media use; and peers’ technology access), and maintaining factors (eg, parent-child relationships, children’s media use engagement and motivation, and peer influence) [7].

Some approaches to combat IA in young children include education, therapy, digital parenting, strategic physical activity, and digital intervention [24,25]. Although digital interventions are sometimes seen as an effort to “fight fire with fire,” previous studies have reported that they might have the potential to combat IA due to the ability to use technology to promote healthy digital behavior with lower effort [25-27]. Multiple studies have also reported that digital interventions show promising efficacy for combating smartphone addiction in adolescents or adults [28-31].

Some types of digital interventions are common to promote healthy digital behavior, such as parental control and digital well-being software. They offer various functions, such as screen time monitoring and limitations, app management, content restrictions, and location tracking. Parental control software aims to support parents in monitoring and regulating children’s devices remotely (eg, Google Family Link and Apple parental control) [32]. Digital well-being software supports the user in self-monitoring and self-limiting the use of the internet and digital devices [26]. Digital well-being systems are available in stand-alone apps (eg, ActionDash and StayFree) or integrated within operating systems (eg, Android and iOS), devices (eg, Samsung and Oppo), and apps (eg, TikTok, Facebook, and YouTube).

The research and development of digital interventions for young children is still in its infancy [25]. A previous study in South Korea reported that the efficacy of parental control software was not promising in terms of reducing addictive behavior in children [25,33]. In addition, it is not known how digital interventions are currently being used to combat IA in young children. This raises questions about the perceptions and considerations of the people involved in efforts to combat IA in young children and their views on the use of digital interventions. Parents play a vital role in using digital interventions to manage their children’s behavior. IA therapists may also recommend digital interventions to their clients or recommend using them to support IA treatment [34].

Multiple studies have reported that people in lower-income regions (eg, the Eastern Mediterranean, Southeast Asia, and Africa) with a lower quality of life tend to have a higher prevalence of IA [35,36]. In line with those studies, Indonesia is among the countries in Southeast Asia with a high prevalence of IA, including in children [36,37]. Indonesia is a lower-income country with >212 million active internet users, and >30 million of them are children [38,39]. Therefore, this study investigated the use of digital interventions in the Indonesian context as a lower-income country with high risks and prevalence of IA.

Some digital interventions for children are available in Indonesia, such as Google Family Link, Apple parental control, Norton Family, FamiSafe, and Safe Lagoon. However, little is known about the perceptions on digital interventions of children’s stakeholders in Indonesia who are involved in efforts to combat IA. Therefore, this qualitative exploratory study aimed to investigate the experiences, perceptions, and considerations of parents and child IA therapists regarding the use of digital interventions for combating IA in young Indonesian children. We formulated 3 research questions (RQs) to achieve this objective:

1. What are the experiences of parents and therapists in Indonesia with digital interventions to combat IA in young children? (RQ 1)
2. What are the limitations perceived by parents and therapists in Indonesia of digital interventions to combat IA in young children? (RQ 2)
3. What functions are recommended by parents and therapists in Indonesia for digital interventions to combat IA in young children? (RQ 3)

This study contributes to extending the knowledge from parents’ and therapists’ perspectives on the current state, existing perceptions, and future implications of digital interventions to combat IA in young Indonesian children. The findings of this study will be valuable considerations in evaluating the existing interventions and developing better interventions in the future.

Theoretical Framework

The theoretical framework that underlies the RQs in this study is related to the development and evaluation of digital interventions to combat IA in children. This includes digital behavior change interventions (DBCIs), parental mediation, and the Unified Theory of Acceptance and Use of Technology (UTAUT).

According to DBCIs, digital technologies can be used to support health-related behavior change and promote healthy behavior [40]. Using behavior change theories, models, and frameworks in developing digital health interventions can help the design team address the problem effectively [41]. The use of DBCIs can also be beneficial to combat addictive behavior related to the internet and digital devices [27]. Therefore, this approach may be applied to develop digital interventions for combating IA in young children.

Parental mediation theory emphasizes the parents' role in communicating about digital media use with children to mitigate negative impacts [42]. This theory suggests active mediation, restrictive mediation, and coviewing as parental strategies to prevent the harmful effects of digital media on children [42]. The original strategy was refined into 4 mediation activities to adapt to the rapid development of the digital media landscape: gatekeeping (regulation), discursive (discussion), investigative (monitoring), and diversionary (alternative activities) [43]. This theory can be used to support parents in combating IA in their children through digital interventions.

The UTAUT model suggests factors that influence the acceptance of the use of digital health interventions [44]. The UTAUT model is a modification of the technology acceptance model that focuses on digital health interventions [45]. According to this model, performance expectancy, effort expectancy, social influence, facilitating conditions, and internet anxiety can jointly influence the acceptance of an intervention [46]. This model underlies the need to investigate the experiences and perceptions of potential users and health practitioners to increase the acceptance of digital interventions for combating problems.

Methods

Study Design

This study used a qualitative exploratory approach through semistructured interviews to conduct a detailed exploration of the experiences, perceptions, and considerations of digital interventions to combat IA in children [47]. This approach is commonly used to explore stakeholders' perspectives on digital health care interventions [48-50]. Previous studies on IA interventions have also emphasized the need to explore the potential, needs, and considerations regarding digital interventions to improve our efforts to combat problematic internet use in children [51-53]. It is essential to investigate this from the perspectives of children's stakeholders who may have a significant contribution or influence in combating IA in children, such as parents and IA therapists for children. However, little is known about their perceptions and experiences regarding the use of digital interventions to combat IA in children. Therefore, this study contributed to an in-depth investigation of their perspectives through a qualitative exploratory approach to fill the gaps.

This study was systematically reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [54]. This checklist consists of 32 items to report important criteria in qualitative research, such as interviews or focus group discussions (Multimedia Appendix 1 [54]). The researchers of this study comprised a PhD candidate and senior researchers (PhDs) from Australia and Indonesia from various cultures and interdisciplinary backgrounds (eg, human-computer interaction, social science, and product design). We have previous experience in digital intervention research for special populations (eg, children, older adults, and people with mental health conditions).

Participants

This study involved 2 stakeholders who have important roles in combating IA in young children, including parents as the primary guardians of their children and IA therapists for children. Parents are typically the main actors who provide digital devices and supervision to their children [55,56]. Therefore, they are responsible for ensuring their children's digital health and well-being. Child addiction therapists in Indonesia are psychologists or psychiatrists who have expertise and experience in working with children with IA risks. They also have a duty to promote the prevention of addictive use. Involving parents and child therapists provided valuable and comprehensive insights into the experiences and considerations of using digital interventions to combat IA in young children.

A total of 28 participants (n=22, 79% parents and n=6, 21% experienced therapists) took part in this study. The inclusion criteria for parents were (1) being the primary guardians of children aged 7 to 11 years, (2) both parents and children being active internet users, and (3) residing with their children. If the parents had more than one child, we asked them to focus on one child who met our inclusion criteria when participating in this study. This was to ensure their consistency in sharing their experience with their children. They were recruited using a convenience sampling strategy through parenting communities in Indonesia. We sent invitations to 20 parenting communities in Indonesia to participate in this study through web-based platforms such as Facebook, Instagram, and WhatsApp. We provided the researcher's contact details (YT) on the invitation so that parents could express their willingness to participate. Of the 33 parents who were initially interested in participating, 11 (33%) refused to participate for personal reasons after knowing the procedure and goals of this study. At the beginning of data collection, we conducted a preliminary test using the Parent-Child Internet Addiction Test (PCIAT) to obtain previous knowledge about whether their children might have a normal, mild, moderate, or severe risk of IA [57]. The PCIAT is a 20-item validated questionnaire to assess children's IA risks through their primary guardian's perspective [58].

Similar to the parents, we recruited therapists through a convenience sampling strategy. The inclusion criteria for the therapists were (1) psychologists or psychiatrists with expertise in IA therapy for children and (2) formally recognized therapists with >4 years of experience. We contacted 10 prominent hospitals and psychology bureaus in Indonesia that offer services related to IA treatment for children. This aimed to obtain information about potential therapists that might meet our inclusion criteria. Initially, we invited 12 therapists, but 6 (50%) refused to participate for personal reasons. The characteristics of the participants in this study are shown in Tables 1 (parents) and 2 (therapists).

Data Collection

Data collection for this study was conducted from September 2023 to November 2023. As the participants were located in different cities in Indonesia, we conducted the interviews on the web using Microsoft Teams (Microsoft Corporation). Each interview session was conducted by the first author (YT; male) in Bahasa (the national Indonesian language) and lasted 30 to 60 minutes. There was no previous relationship between the interviewer and the participants in this study. Before the interview session, the interviewer explained the objective and scope of this study to each participant. The main topic discussed in the semistructured interviews was the experiences, perceptions, and recommendations regarding using digital interventions to combat IA in children. If the participants were no longer using the digital interventions, they could also share their past experiences and why they stopped using them. The probing questions of the interviews are shown in Multimedia Appendix 2.

We recorded the audio of each interview session. The recordings were transcribed in Bahasa using Google Speech-to-Text and then manually refined by a researcher (YT) who is a native speaker of Bahasa. The interview transcripts were returned to each participant for checking and correction. After that, we translated them into English for data analysis and reporting purposes.

Data Analysis

The data analysis was conducted qualitatively using thematic analysis through five main stages: (1) transcribing, reading, and understanding the data; (2) coding the data; (3) identifying meaningful patterns within the data; (4) defining and grouping the themes; and (5) reporting the findings according to the themes [59]. The NVivo (version 12.0; QSR International) software was used to support coding the data and identifying meaningful patterns within the data. Although the thematic analysis did not rely on quantifiable measures, we presented the frequency of themes, subthemes, or issues discussed as additional information to describe the findings and increase reporting transparency [60,61].

To ensure the quality of the data analysis, we followed the 15 criteria for good thematic analysis proposed by Braun and Clarke [60]. The criteria include the transcription (1 item), coding (5 items), analysis (4 items), overall (1 item), and reporting (4 items) processes [60]. The interview transcripts were checked by the interviewer (YT) and participants to ensure their accuracy. The codes and themes were identified and checked rigorously to ensure the validity and consistency of the analysis. The methods, data, and findings of this study were described and reported with adequate details and transparency. We also provided a good balance between narrative explanations and participants' quotes or stories to report the findings of this study.

We started coding the participants' experiences with digital interventions to combat IA in young children. We analyzed their experiences based on three themes: (1) interventions they recognized to combat IA in young children (eg, "Google Family Link"), (2) interventions used by parents or recommended by therapists to their clients (eg, "Apple Parental Control"), and (3) features used or recommended by the participants and how they used them (eg, "device use monitoring").

The participants' perceptions of digital interventions were coded and grouped into 3 main themes: advantages, limitations, and recommended functions. We coded the advantages they perceived from the interventions they had known (eg, "filtering inappropriate content"). The limitations came from their experiences using or recommending digital interventions (eg, "complicated to use"). In addition, the limitations were expressed as part of the reasons why some participants chose not to use the existing digital interventions (eg, "data privacy issue"). The recommended functions were analyzed based on the functions or features considered useful by the participants (eg, "suggesting substitutive activities").

Ethical Considerations

Ethics approval for this study was obtained from the Swinburne University Human Research Ethics Committee (reference: 20237278-16490; approval date: August 24, 2023). Written informed consent was granted by all participants involved in this study. We did not collect the personal identity of the participants, such as their names or addresses. Each participant was assigned a unique identification number to ensure their anonymity. Each participant in this study was given a voucher for 300,000 Indonesian rupiah (Aus $30 or US $20) in recognition of their participation.

Results

Overview of the Internet Use by the Children of the Participating Parents

The parents who participated in this study had given their children access to the internet since early childhood (age of 1-5 years). However, children started using the internet routinely when entering preschool or primary school (age of 5-7 years). Most children (18/22, 82%) had their own mobile devices (eg, smartphones or tablets), whereas the others had to borrow them from their parents or use them collectively with their siblings. All children of the participants were active users of mobile devices, such as smartphones or tablets, and some of them also actively used televisions (18/22, 82%) and nonmobile devices such as laptops or PCs (6/22, 27%) and PlayStation consoles (2/22, 9%). Their favorite digital activities were watching videos (eg, YouTube, TikTok, and television channels) and gaming (eg, Minecraft, Roblox, Mobile Legends, and Free Fire). All parents agreed that the internet can be beneficial for their children in terms of education and entertainment. Most parents (17/22, 77%) also said that digital devices helped them fill their children's free time and keep the children calm and quiet at home. In addition, parents said that some primary schools had started teaching internet technology and delivering school materials through web-based media.

In general, parents showed awareness of the fact that the excessive and uncontrolled use of the internet could bring harmful consequences to their children. Parents whose children had mild to moderate IA risks based on PCIAT scores conveyed various negative impacts of excessive use on their children. This included decreased school performance or creativity (10/22, 45%), inappropriate use of language (8/22, 36%), aggressive behavior (8/22, 36%), procrastination of other activities (7/22, 32%), self-isolation (6/22, 27%), anxiety when not using the internet (5/22, 23%), poor communication with the family (4/22, 18%), eating problems (eg, food intake avoidance; 4/22, 18%), and eye problems (eg, decreased vision, swollen eyes, and red eyes; 3/22, 14%).

Experiences With Digital Interventions

Parents and therapists generally showed diverse experiences with the use of digital interventions (Table 3). Participants in this study mentioned 3 parental control software they had known to combat IA in young children: Google Family Link, YouTube Kids, and Apple parental control. Google Family Link and Apple parental control offer similar parental control features at the operating system level. A total of 68% (15/22) of the parents and 83% (5/6) of the therapists mentioned Google Family Link, whereas Apple parental control was only mentioned by 17% (1/6) of the therapists. In August 2023, approximately 88% of Indonesian internet users used Android devices, and only 11% used iOS devices [62,63]. This might explain why the participants were more familiar with Google Family Link. In addition, this app is widely available on both the Google Play Store and Apple App Store, whereas Apple parental control is only available for devices with the iOS operating system. One parent said the following:

> *During the pandemic, I gave my child a Samsung tablet because she needed to study online. Since then, I have also tried using that application [Google Family Link]. The app has been available on her tablet since we bought it, so I can use it immediately.*

On the basis of parents' experiences, 18% (4/22) of parents actively used Google Family Link and perceived it as a useful mechanism to manage children's digital behavior. In total, 50% (2/4) of these parents (whose children had a normal IA risk) used most app features, including monitoring, screen time limitations, and app management. They and their partners were working parents, so they used the features to supervise their children remotely because they could not always be home. They felt that the app was helpful for supporting them in monitoring and limiting their children's interaction with technology easily. They communicated the rules about the use of the app clearly to their children so that their children could understand the purpose of using those features. One of the parents said the following:

> *I usually restrict her screen time using Family Link from Google. I've been using this app for a long time because it's been available on my child's tablet since the beginning. Usually, I use it to set the duration of the application she can use and what time the application can be used. I also set the total duration for her to use the tablet in a day so the tablet will be locked after reaching the limit. I think it's quite useful because it can help me organize my daughter, mainly because my husband and I are both working, so we can't monitor her screen time continuously.*

In total, 50% (2/4) of these parents (whose children had mild and moderate IA risks) only used the screen time monitoring and download management features. Through the download management feature, they have to provide parental permission if their children want to download a new app. They used screen time monitoring to understand what apps their children accessed and how much time children spent on each app. However, they only used the feature occasionally (eg, once a week or once a month), and they did not make essential decisions based on screen time monitoring. One of them said the following:

> *I use the one from Google. It's called Family Link, as I remember. I organized it so my child had to ask me for permission whenever she wanted to download a new application...I never knew and never used the other features.*

Another 14% (3/22) of the parents had used Google Family Link in the past but no longer used it because they found it difficult to make appropriate rules for their children and set them up consistently.

YouTube Kids is a child-friendly version of YouTube that features content for children and has some parental control features (Table 3). However, those features can only be used within the YouTube environment. A total of 45% (10/22) of the parents mentioned and used this app, and 33% (2/6) of the therapists mentioned this app as a way to filter inappropriate videos for children. Among the existing digital interventions, YouTube Kids was one of the most popular because all participants' children spent most of their screen time watching videos on YouTube or playing games. They perceived that filtering inappropriate videos on YouTube was one of the most important things to prevent deviant behavior in their children. One parent said the following:

> *She consumes some inappropriate content in YouTube Shorts, even though she doesn't need that information or content. Some explicit pornographic content also appears in videos, even if it's intended for children. I really appreciate features on YouTube to filter such videos. This is really important because I can't always see what my daughter watches.*

Some parents actively used parental control features on YouTube to filter inappropriate videos for children (10/22, 45%) and limit access to YouTube (3/22, 14%). However, 18% (4/22) of the parents said that sometimes their children did not like the available child-friendly videos on YouTube Kids, so they tended to find content on other apps such as Google or social media (eg, TikTok and Instagram). One of them said the following:

> *My child now doesn't want to use YouTube Kids because he can't find interesting videos there. Maybe he doesn't like videos for children anymore. Now, he is more interested in short videos from YouTube shorts or TikTok. He often watches short videos on TikTok using my account because I don't allow him to create his own account.*

In total, 50% (3/6) of the therapists actively recommended the use of parental control software to help parents control their children's internet use. One of them said the following:

> *I think it can help parents. In my opinion, parents need help to make their job easier in supervising their children. Such software can be utilized if parents are willing and capable of learning how to use it.*

However, they did not recommend it to all clients because they thought that some parents may not have the adequate willingness, capability, or life circumstances to use it. While they knew about Google Family Link and YouTube Kids, they did not recommend which app to use specifically. The other 50% (3/6) of the therapists reported that they sometimes mentioned parental control software as an option for parents to control their children's behavior but they never recommended it. One of them said the following:

> *I tell them there are such apps [parental control software]. However, I don't really understand what applications can be used because I don't understand technology well. I just advise parents to try such applications, but personally, I never try it myself.*

Parents perceived that the digital interventions mentioned in Table 3 could be beneficial in supporting the supervision of their children remotely (11/22, 50%) and filtering inappropriate content for their children (15/22, 68%). Similarly, 67% (4/6) of the therapists also expressed those benefits. One of them said the following:

> *This [digital interventions] can make it easier for families to monitor how long their children play [digital devices] or what kind of applications are safe*

> *to be used. It’s very useful, but many people don’t know about this. We need to let them know so they can monitor their children remotely.*

In total, 50% (3/6) of the therapists also perceived the benefit of digital interventions in providing continuous supervision. One of them said the following:

> *Sometimes parents are limited and busy with their own business, so they cannot control their children for 24 hours a day. Applications like this [parental control apps] will definitely help parents control their child continuously.*

In addition, the therapists believed that digital interventions could provide creative ways to educate parents and children on healthy internet use and support the work of IA practitioners such as themselves. With a limited number of mental health workers and low awareness of healthy internet use in Indonesia, this type of intervention may help their work in raising awareness and promoting healthy digital behavior in Indonesian children. One therapist said the following:

> *In the app, we may provide education about parental digital literacy that can help our work. Interesting education via digital devices will be more popular and exciting than conventional education like seminars or classes that we usually do.*

Table 3. Summary of the digital interventions known and used by parents and therapists.

Attribute	Parents	Therapists
Interventions known	• Google Family Link[a] • Key features: • Screen time monitoring • Screen time limitations • App management • App restrictions • Content restrictions • Location tracking • YouTube Kids[b] • Key features: • YouTube content filtering • YouTube access limitation	• Google Family Link[c] • Key features: • Screen time monitoring • Screen time limitations • App management • App restrictions • Content restrictions • Location tracking • YouTube Kids[d] • Key features: • YouTube content blocking • YouTube access limitation • Apple parental control[e] • Key features: • Screen time monitoring • Screen time limitations • Download management • App restrictions • Content restrictions
Interventions used by the parents or recommended by the therapists	• Google Family Link[f] • Features used: • Screen time monitoring[g] • Screen time limitations[h] • App management[f] • App restrictions[h] • Content restrictions[h] • YouTube Kids[b] • Features used: • YouTube content filtering[b] • YouTube access limitation[g]	• Parental control apps in general[i] • Features recommended to their clients: • Screen time monitoring[i] • Screen time limitations[d] • App restrictions[d] • Content restrictions[i]
Perceived advantages of digital interventions	• Supporting parents in monitoring and supervising their children remotely[j] • Filtering inappropriate content[a]	• Supporting parents in monitoring and supervising their children remotely[k] • Filtering inappropriate content[k] • Providing continuous supervision[i] • Providing creative ways to educate parents and children[d] • Overcoming the lack of internet addiction practitioners in Indonesia[d]

[a] 68% (15/22) of parents.

[b] 45% (10/22) of parents.

[c] 83% (5/6) of therapists.

[d] 33% (2/6) of therapists.

[e] 17% (1/6) of therapists.

[f] 18% (4/22) of parents.

[g] 14% (3/22) of parents.

[h] 9% (2/22) of parents.

[i] 50% (3/6) of therapists.

[j] 50% (11/22) of parents.

[k] 67% (4/6) of therapists.

Limitations of the Existing Digital Interventions

Although most participants recognized the existence of digital interventions to encourage healthy digital behavior in their children, the existing interventions were not highly used. Both parents and therapists perceived that digital interventions might be beneficial to encourage healthy internet use and combat IA in young children. However, they also highlighted some limitations with the existing interventions, which may discourage some of them from using the interventions (Textbox 1).

Textbox 1. Limitations of the existing interventions.

Parents

- Parents finding it difficult to use and set up the app (12/22, 55%)
- Parents being unable to set appropriate rules (9/22, 41%)
- Incompatibility with family culture (4/22, 18%)
- Jeopardized parent-child relationships (4/22, 18%)
- Data privacy issues (2/22, 9%)

Therapists

- Parents finding it difficult to use and set up the app (4/6, 67%)
- Parents being unable to set appropriate rules (3/6, 50%)
- Incompatibility with family culture (2/6, 33%)
- Functions not comprehensive (3/6, 50%)
- Children’s privacy issues (2/6, 33%)

The most frequent limitations expressed by the parents and therapists were associated with the parents’ capability and knowledge of how to use the software and create appropriate rules through the interventions. A total of 55% (12/22) of the parents expressed their limitations in using the software. One said the following:

> *The problem is that applications like that [parental control software] seem complicated. Honestly, I’m a mother who doesn’t really understand technology.*

Similarly, 67% (4/6) of the therapists perceived that some Indonesian parents might not be capable of using and willing to use parental control software. In total, 33% (2/6) of the therapists also had difficulties in learning how to use the digital interventions. One said the following:

> *I tell them [clients] that there is parental control software as an option. However, because I don’t really understand the technology well, I advise parents to try such applications, but I can’t teach them how to use it.*

A total of 41% (9/22) of the parents expressed their limitations in creating appropriate rules through the interventions. One said the following:

> *Even if I can control my child through the app, I have to learn what kind of restrictions should be applied to him* [her child]

Similarly, 50% (3/6) of the therapists were concerned that parents with low digital literacy and capability would find it difficult to use the features. Although the features are helpful, parents might still be confused about setting appropriate rules for their children. One of them said the following:

> *We might be able to limit screen time, but the application can only function well if parents set it properly. The question is whether the parents can use it correctly or not.*

Most of their clients were also confused about finding proper substitutive activities after limiting their children’s screen time.

A total of 18% (4/22) of the parents and 33% (2/6) of the therapists were also concerned about the apps’ incompatibility with family culture in Indonesia. They reported that some content and tips suggested by the existing interventions did not suit their social values and beliefs. For example, one parent said the following:

> *Once, I used the feature to filter child-friendly videos because my child really likes watching videos on his tablet. However, I found videos that, sorry to say this, promoting LGBT, which is completely unacceptable because it is not appropriate with our religion and culture.*

Parents shared other concerns about using digital interventions. A total of 18% (4/22) of the parents thought that the features of the existing interventions might make children uncomfortable, thus jeopardizing the relationship between parents and children. One parent said the following:

> *In the past, I wanted to use an application called [Google] Family Link, but my husband and I decided not to use it for some reasons. We want to give more trust to my daughter because she might feel pressured if she feels like she is always being watched.*

In total, 9% (2/22) of the parents said that they were worried about using parental control software because they had to synchronize multiple devices and input personal data. As some interventions have app management features, they also worried that the system could access and remove confidential data on their devices. One parent said the following:

> *I have to connect my device to my child's device, and that application can delete or move applications on my child's device. If they can do that, I'm afraid that they may also access or even delete my personal data.*

Therapists reported other limitations of the existing interventions in terms of limited functions and trust issues in children. They highlighted that some essential functions are needed in digital interventions. One said the following:

> *Many things must be improved to be truly helpful, and they [digital interventions] must be made functionally more holistic. For example, they can provide education for parents and children, personalized supervision for parents, and child-friendly content recommendations that are interesting.*

Related to the trust issues, one therapist said the following:

> *Parents might be over-worried and end up using the app excessively. For example, they spy and track a child's phone without proper communication. No matter what, children aged seven or above need to be given some privacy.*

Therapists also had concerns that some children might trick the system if their parents could not provide proper understanding and communication about the rationale behind their supervision through digital interventions such as parental control software. This would make the parents falsely feel that everything is under control.

Recommended Functions of Digital Interventions

The participants recommended some functions that may be useful in combating IA in young children (Textbox 2). Parents and therapists suggested some functions for a digital intervention, such as supporting parental supervision, suggesting substitutive activities, monitoring and limiting internet use, and suggesting child-friendly content. One parent said the following:

> *Many parents don't direct their children to do other activities, so the children will get bored if they don't spend time with their gadgets [digital devices]. Parents must be able to direct their children to other activities that are positive and interesting for children. It would be helpful if the app could help the parents with that.*

Textbox 2. Recommended functions.

Parents

- Supporting parental supervision (14/22, 64%)
- Suggesting substitutive activities (9/22, 41%)
- Monitoring and limiting use (9/22, 41%)
- Suggesting child-friendly content (8/22, 36%)
- Supporting parental decision-making in regulating children's digital behavior (4/22, 18%)

Therapists

- Supporting parental supervision (3/6, 50%)
- Suggesting substitutive activities (3/6, 50%)
- Monitoring and limiting use (3/6, 50%)
- Suggesting child-friendly content (3/6, 50%)
- Developing children's competencies to combat addictive behavior (5/6, 83%)
- Improving parental digital literacy (4/6, 67%)
- Supporting parents in communicating internet use rules (2/6, 33%)

One therapist also discussed the need for some functions:

> *In my opinion, parents need help to make their job easier in supervising their children. An application might help. For example, it can recommend good content for children, monitor the device use in real-time, and make children stop playing smoothly.*

Parents expected that the interventions would simplify their efforts in making essential decisions regarding education and rules for their children. This is because many parents were confused about regulating their children's internet use although they knew their children used the internet excessively. They were also afraid that their rules would make their children uncomfortable or offended. One said the following:

> *I'm often confused with the daily decision I should make about regulating my child. It's really difficult to handle. I want to give him the internet to make him happy, but I need a clue on how best to control him all the time.*

Therapists perceived that parental control software might help supervise children's digital activities to support behavior change in children. However, they said that parents and children cannot solely rely on screen time limitations or device restrictions to address the problem. One therapist said the following:

> *What is more important is how parents understand the rules, communicate the rules, and make children understand the rules. Therefore, I advise parents that we cannot completely depend on limitations and blocking through the apps.*

In total, 67% (4/6) of the therapists also suggested the need for digital interventions to have comprehensive coverage in managing their children's internet use, such as across devices or apps. One said the following:

> *I think it would be more useful if we could limit them at the device [operating system] level. Restrictions on single application become less effective because children can use more than one application.*

Therapists highlighted the need for other essential elements to combat IA in children: proactive parental supervision, developing children's competencies to combat addictive behavior, effective parent-child communication, proper education on healthy internet use, and enjoyable real-world activities. One therapist said the following:

> *I think a comprehensive intervention is needed. For example, there may be education, real-time measurement, and the ability to carry out addiction prevention over time.*

Another therapist had an interesting argument on developing children's competencies:

> *The family factors can prevent young children from addiction, like developing children's foundations [to combat addictive behavior], good communication, and happy life. We should realize that one similar software may cause a different response. Some children may be addicted to it, but not the others. Therefore, preventing addiction will be more powerful if the parents build their children's foundations from the beginning. With good foundations, children will not easily become addicted when given negative stimulus from the internet.*

Discussion

Experiences With Digital Interventions to Combat IA in Young Children

In this study, we explored the experiences, perceptions, and considerations of parents and therapists regarding digital interventions to combat IA in young Indonesian children. This study investigated multiperspective views from parents, who are the primary guardians of young Indonesian children, and child therapists, who have expertise and experience in working with children with IA risks. The participating parents and therapists generally perceived that digital interventions such as parental control software could increase parents' capability to promote healthy digital behavior in their children in the long term. This perception aligned with the DBCI concept that using behavior change principles in digital interventions could be useful to promote healthy behavior in their users [40]. In this case, promoting healthy digital behavior was considered beneficial to combat IA in young children. Other studies have also highlighted the similar potential of DBCI use for addressing the problem, and the current interventions primarily focus on screen time regulation [24,25].

The participants similarly perceived the advantages of using digital interventions for combating the problem, such as supporting parents in monitoring and supervising their children remotely (15/28, 54%) and filtering inappropriate content for children (19/28, 68%). In addition, the therapists perceived more benefits, such as facilitating continuous parental supervision (3/6, 50%) and supporting health practitioners' work to promote and educate parents and children on healthy internet use (2/6, 33%).

Almost all participants (26/28, 93%) highlighted the role of parents as the key to developing healthy or risky digital behavior in their children, especially in children aged <12 years. This is because parental influence and mediation significantly impact children's digital behavior [22,42,56]. In the context of young children, no one is more influential than parents, although other parties can also influence them (eg, siblings and peers). Parents provide their children with the internet, so they are responsible for managing their children's internet use [55]. In addition, children aged <12 years are generally still in the cognitive development phase [64], so they may not have good self-regulation and self-efficacy [65]. However, parents often, intentionally or not, expose their children to risky digital behavior [55,66]. The findings showed that many parents (13/22, 59%) were confused about educating their children and regulating their healthy digital behavior. As digital parenting is something new, they may not necessarily be able to regulate their children's internet use well even though various monitoring and restricting features are available [56]. Therefore, the interventions may not only intervene with children's use of technologies but also with parents' management of their children's technology use. The interventions should be able to support and educate parents on how to encourage their children's healthy digital behavior effectively.

Participants in this study recognized 3 digital interventions to combat IA in the form of parental control software: Google Family Link, Apple parental control, and YouTube Kids. Despite the positive sentiment on the potential of digital interventions, the use of the existing features of those systems among the participants was not convincing. This is because, of the 28 participants, only 4 (14%) parents actively used Google Family Link, 10 (36%) parents used YouTube Kids, and 3 (11%) therapists actively recommended using parental control software to their clients. In addition, the parental control features on YouTube Kids can only monitor and limit children's internet activities while watching YouTube content. Therapists argued that the regulations at the app level would be less effective because children typically interact with more than one app, device, or streaming service. This statement was supported by the findings that all children of the participating parents used more than one app daily (eg, YouTube, Minecraft, and TikTok) and many parents (18/22, 82%) gave their children access to more than one device (eg, smartphone, tablet, and television).

A total of 50% (2/4) of Google Family Link users used all features except location tracking. Their children had normal addiction risks based on the PCIAT score, and they reported the usefulness of the app in helping them supervise their children when the parents were busy with their activities. This may be initial evidence that the proper use of digital intervention features could be helpful for parents in combating IA in their children. However, we need further evidence on the mechanism of the app in preventing or reducing IA in children. Another 50% (2/4) of Google Family Link users only used 2 features of the app: screen time monitoring and parental permission to download new apps. However, they reported that they only monitored children's screen time occasionally (eg, once a week or once a month) and did not make essential decisions based on monitoring. Therefore, we could not explore their overall experiences with using the app.

Limitations of Digital Interventions to Combat IA in Young Children

The participants expressed some limitations that may underlie the lack of use of the existing digital interventions. The limitations might also decrease participants' motivation to use digital interventions. Both parents and therapists mentioned 3 similar limitations with these interventions: the parents' difficulties in using the apps, the parents' difficulties in setting appropriate rules through the apps, and the incompatibility of the features or content with family culture in Indonesia.

Parents and therapists highlighted that one of the most significant obstacles in combating IA in children are the parental limitations in terms of capability and time to educate their children and manage their digital behavior. This parental issue could be the main barrier to using digital interventions for supporting internet use parenting [67,68]. Therefore, the interventions should support and simplify parental efforts to manage their children's digital behavior, as suggested in the UTAUT model [46]. The capability of computer systems in digital interventions should be used to support, assist, and simplify parental efforts in sustainably educating their children and regulating their digital behavior. If the intervention requires many complex settings and actions, parents may feel that it will add load and complexity to their lives. No matter how good the features are, the intervention will be less practical if the potential users have no intention of using it and capacity to use it. We cannot assume that all parents have adequate digital literacy and capability [69]. Thus, it is essential to match the interventions to parents' digital capabilities, capacity to engage, and other limitations. In addition, the therapists were also worried that children would outsmart or work around the regulations or restrictions, leading parents to mistakenly feel that everything is under control. Therefore, the interventions should be designed to include a range of scenarios and conditions so that children cannot work around or override them [70].

A total of 21% (6/28) of the participants in this study perceived that the existing digital interventions might not suit some families' cultures in Indonesia. For example, they reported that some child-friendly content suggested on YouTube Kids was inappropriate based on their own cultures and beliefs. In other cases, parents felt that the screen time restriction feature might elicit the impression of distrust toward their children, so they felt uncomfortable using it. Considering the culture of the users is very important when developing digital health interventions for children [71-73]. Reflecting on such cases, it is crucial to consider the potential users' cultures in developing digital interventions to combat IA.

Parents expressed concern that using limitation or restriction features may lead to negative experiences for children and jeopardize parent-child relationships. Other studies have also highlighted that healthy parent-child relationships are essential in combating IA [74-76]. Therefore, it is important to consider that the interventions should not harm the relationship between parents and children. For example, the system may assist parents in communicating the rules appropriately so that their children can understand and accept them well. Providing a positive experience to the parents is also essential to avoid any frustration so that they can provide better supervision and communication to their children. For example, we could facilitate parents' experience of the benefits of their efforts through the interventions or create engaging gamification features that simplify evidence-based information and support parents in establishing rules for their children in novel and attractive ways (eg, short videos, animations, and role-playing).

Concerns about data privacy and security were also reported by 9% (2/22) of the parents due to the nature of parental control software systems. The software typically has privacy warnings and agreements presented to its users [77,78], but parents may still not understand or be confident in using it. In addition, related studies have reported privacy problems with the current parental control software, such as accessing personal data and sharing user data with third parties without appropriate consent and transparency [79,80]. Therefore, further studies are needed to investigate how the developers overcome this privacy concern and how those privacy issue warnings and agreements are delivered to ensure that the users feel confident and secure in using the software.

Therapists perceived other limitations in terms of functional and children's privacy issues. In total, 50% (3/6) of the therapists highlighted some essential functions not covered in the existing interventions, such as proactive parental supervision, children's competencies to combat addictive behavior, parent-child communication enhancement, proper education on healthy internet use, and enjoyable real-world activity suggestions. Other studies have also reported the absence of similar functions in the existing parental control software, such as maintaining family relationships, parental mediation, and social support [70,81].

A total of 33% (2/6) of the therapists also emphasized that the need for the use of digital interventions should not raise any privacy issues in children, which can jeopardize the parent-child relationship. Parents should be responsible for protecting children's privacy in web-based environments [82]. However, the therapists had experiences with parents becoming overprotective since using parental control software. They reported rare cases in which their clients (parents) seemed to be overmonitoring their children almost all the time, which could create other family relationship problems. This issue has not been discussed much in the context of digital health interventions for children. Therefore, we need further research studies to investigate how this issue affects children and how to address the issue appropriately.

Recommended Functions for Digital Interventions to Combat IA in Young Children

The participants in this study recommended several functions for digital interventions to combat IA in young children. They suggested some functions that were covered in the interventions discussed in this study, such as parental supervision (17/28, 61%), use monitoring and restrictions (12/28, 43%), and child-friendly content filtering (11/28, 39%). This means that those functions should be maintained and improved in the interventions. However, the participating parents expressed some suggestions to improve the implementation of those functions.

One of the main parental limitations identified in this study was the parents' confusion or inability to determine and enforce appropriate supervision for their children. In line with this problem, 18% (4/22) of the parents recommended decision-making support features to guide them in monitoring and creating appropriate rules for their children. This feature may complement and improve the monitoring and restriction functions that already exist in the interventions. We may adopt the concept of decision support system software in the context of promoting healthy digital behavior in young children [83]. The digital interventions may also capture and use some valuable data from the children (eg, screen time, web-based activities, and favorite content) as input to provide tailored or personalized decision-making suggestions for the parents [84].

Regarding use restrictions, both parents and therapists similarly expected the system not to jeopardize the relationship between parents and children. Providing digital interventions with proper education and suggestions may help parents communicate the rules better so that their children can understand and accept them properly. For the content filtering function, the participants expected that the suggested content would be appropriate for their culture, social values, and beliefs. Providing culture-specific or personalized features for the users may help address their expectations [85,86].

The participants also recommended functions that might not exist in the interventions discussed. In total, 41% (9/22) of the parents and 50% (3/6) of the therapists recommended the need to suggest substitutive activities for children. Parents often feel confused about providing proper and positive activities for their children apart from internet activities. Some parents also relied on the use of digital devices as an option to fill their children's free time. Therefore, to prevent internet overuse, it would be helpful if the system could suggest alternative activities that suit the needs and preferences of their children. The activities suggested should be attractive enough for children to shift from the virtual to the physical world [87].

Therapists highlighted that digital interventions should be used to develop children's competencies in understanding internet use properly to combat addictive behavior. According to the IT-CPU theory, children's behavior and attitude toward internet use can significantly influence their IA risks [7]. Therefore, developing children's competencies to combat addictive behavior may help prevent or reduce IA risks in young children. In total, 67% (4/6) of the therapists also emphasized the need to improve digital literacy levels in children and parents. This is supported by previous studies that reported the significant contribution of improving digital literacy through education to the success in combating IA in children and adolescents [69,88,89]. Digital interventions were seen as potential tools to provide education in more interesting ways (eg, gamified learning) and increased accessibility [90,91].

In this study, parents were concerned that regulating internet use through the system would jeopardize their relationship with their children. This is also supported by the IT-CPU theory that the parent-child relationship is one of the maintaining factors that influence the IA risk in children [7]. In line with this concern, 50% (3/6) of the therapists expressed the need for digital intervention features to support parents in communicating internet use rules to their children. It is important to consider how the interventions may help parents not only set the rules but also deliver and communicate them to the children properly. The use of gamification features (eg, turning the rules into missions with accomplishment rewards and using animated videos or avatars to explain the importance of the rules) may help make it easier for children to understand and accept the rules [42,92,93].

Implications for Future Digital Interventions

Reflecting on the findings of this study, some implications can be derived related to the design of digital interventions and other aspects that influence the use and acceptability of digital interventions to combat IA in young children. The participants in this study expressed some limitations of the key features of the existing interventions (eg, screen time limitation, screen time monitoring, and content filtering) that discouraged them from using the interventions. Nevertheless, they still perceived those features as helpful for combating IA in children. For example, parents may limit children's screen time through the system but still have difficulty providing substitutive activities. In other cases, parents can monitor children's screen time, but they may still be confused about creating and communicating the appropriate rules based on monitoring. Therefore, this study suggests the need to improve the existing features to be more usable and relatable for the parents to increase their motivation and capability to use the interventions.

According to the UTAUT model, the acceptability of the interventions will be better if we can provide functions that are perceived as beneficial by the potential users [46]. The findings of this and other related studies highlight that the existing features in digital interventions (eg, screen time monitoring and limitations) might not be sufficient to combat IA in young children [33,70]. Our findings suggest that digital interventions should focus not only on restricting and monitoring screen time but also on suggesting substitutive activities for children, developing children's competencies to combat addictive behavior (eg, attitude toward internet use and self-regulation), improving digital literacy in children and parents, and supporting parental decision-making to promote healthy digital behavior in their children. To provide continuous and comprehensive intervention, it is also essential to develop interventions that can cover all the devices or apps that children use. For example, we may develop the interventions to have control over the entire device (operating system) or across devices as children may use more than one app or device.

The appropriateness of the features or content provided by digital interventions could also determine the users' perception, engagement, and acceptability [46,94]. The findings of this and other digital health intervention studies report similar concerns that some features or content provided by the interventions might be inappropriate for the users' culture or beliefs [72,73]. Participants in this study recognized and used the existing interventions developed by big technology multinational companies (eg, Google, YouTube, and Apple). Therefore, the features or content provided by the digital interventions may need to be adjusted to suit their unique characteristics and culture.

To our knowledge, no digital intervention has been developed for the Indonesian context to date. Given the higher prevalence of IA in lower-income regions such as Indonesia [35,36], further studies may be needed to develop culture-appropriate digital interventions for vulnerable populations in these regions. In addition, we suggest adopting tailoring or personalization mechanisms to deliver suitable features or content based on the users' characteristics and culture. These mechanisms can also be beneficial to increase behavior change intention in combating addictive behavior [27,95].

Parents play an important role in supervising and educating children to combat IA [70]. This explains why existing digital interventions for young children typically involve parents in combating IA [52]. In this study, we found that parents perceived barriers to using the existing digital interventions due to their limitations in terms of capability, knowledge, and skills to use the interventions and create appropriate rules. These limitations emphasize the need to provide adequate training for parents to increase their motivation and capability to use digital interventions [96,97]. Collaborating with parents in designing digital interventions may also be beneficial to understand their limitations and suit their needs [98]. In addition, we may support parents through gamification features, such as goal setting, progress tracking, rewards and punishments, and visualization of the results of their supervision, to enhance their ability and engagement in supervising their children [99,100].

Privacy issues related to the use of digital interventions cannot be overlooked. The acceptability of digital interventions may decrease due to parents' distrust of data security and the findings of other studies that have reported privacy violation cases by parental control software [79,80]. Although the interventions typically have privacy warnings and agreements [77,78], we should ensure that the parents can understand and accept the provisions properly; otherwise, they will be reluctant to use the interventions. In addition, providing education on this issue may help parents feel more confident in using the interventions. Another privacy issue raised was related to children's privacy problems due to excessive parental supervision (eg, overmonitoring or being overprotective). Although there is a lack of discussion of this issue in the context of internet use, therapists emphasized the need to consider this in future interventions to avoid other family problems. We argue that improving parents' knowledge of digital parenting and assisting their decision-making through digital interventions may help address this issue.

Limitations of This Study

This study has several limitations. This study may have limited generalizability as we used a small number of participants and a nonrandom sampling strategy (convenience sampling). Therefore, reader discretion is needed in considering the context of this study when using or applying the findings.

In this study, we involved parents and therapists as the children's stakeholders in combating IA, but we did not collect data from children. Therefore, further studies may be needed to complement the results of this study by exploring children's experiences with and perceptions of related topics.

To achieve the objective of this study, we focused on exploring participants' experiences and perceptions regarding the digital interventions already available in Indonesia. Other digital interventions might have been developed in other contexts or regions, but we did not include them in this study. Further studies may be needed to investigate other interventions not included in this study.

Most participating parents (20/22, 91%) in this study were mothers or female individuals. This is because, in the culture of most Indonesian families, the mother typically has a role as the primary guardian of the children. As we required the participation of the primary guardians of children, we did not prioritize an equal proportion of mother and father participation. Nevertheless, the children of the participating parents had quite a balanced gender proportion (64% boys and 36% girls). In addition to this, we found no significant differences between mothers' and fathers' perspectives in this study.

Conclusions

This study shed light on the experiences, perceptions, and considerations of parents and therapists regarding the use of digital interventions for combating IA in young Indonesian children. Participants in this study perceived the benefits of digital interventions in continuously promoting healthy digital behavior in young children and supporting parents in regulating their children's internet use. However, the participants did not highly use the existing interventions due to some limitations. This includes essential issues such as the interventions' functionality and usability, parental capability, cultural incompatibility, parent-child relationships, and privacy.

Our findings suggest that digital interventions should focus not only on restricting and monitoring screen time but also on suggesting substitutive activities for children, developing children's competencies to combat addictive behavior (eg, attitude toward internet use and self-regulation), improving digital literacy in children and parents, and supporting parental decision-making to promote healthy digital behavior in their children. Suggestions for future digital interventions are provided, such as making the existing features more usable and relatable, investigating gamification features to enhance parental motivation and capability in managing their children, providing tailored or personalized content to suit users’ characteristics, and considering the provision of training and information on the use of interventions and privacy agreements.

This study contributes to extending the knowledge from parents’ and therapists’ perspectives on the current state, existing perceptions, and future implications of digital interventions to combat IA in young Indonesian children. The findings of this study will be valuable considerations in evaluating the existing interventions and developing better interventions in the future. For future work, we aim to collaborate with multiple stakeholders (eg, parents, children, teachers, peers, and therapists) to develop digital interventions to combat IA in young children by continuously encouraging healthy digital behavior and improving parental mediation of children’s internet use. The findings of this study will be the primary considerations for future work in developing digital interventions to prevent or reduce IA risk in children.

Acknowledgments

The authors would like to thank the Indonesia Endowment Fund for Education and the Indonesian Center of Higher Education Funding for funding the PhD project associated with this study. They also thank all participants who provided their time and effort to take part in this study.

Abstract

Background: Amid growing concern over children's access to online pornography, policy makers are looking toward new and emerging technological concepts for unexplored solutions including artificial intelligence and facial recognition.

Objective: This study sought to explore and ideate emerging technological interventions that are feasible, acceptable, and effective in preventing and controlling the exposure of young people to online pornographic material.

Methods: We conducted a series of qualitative co-design workshops with both adult (n=8; aged 32-53 years) and adolescent participants (n=4; aged 15-17 years) to ideate potential technological interventions that are feasible, acceptable, and effective at preventing and controlling the exposure of young people to online pornographic material. A story stem methodology was used to explore participants' attitudes toward two unique technological prototypes.

Results: Participants expressed a generally favorable view of the proposed technological concepts but remained unconvinced of their overall utility and effectiveness in preventing the intentional viewing of pornography by young people. Age-appropriate parent-child conversations remained participants' preferred approach to mitigating potential harms from pornographic material, with parents also expressing a desire for more educational resources to help them better navigate these discussions. User privacy and data security were a primary concern for participants, particularly surrounding the use and collection of biometric data.

Conclusions: Internationally, policy makers are taking action to use age assurance technologies to prevent children's access to online pornography. It is important to consider the needs and opinions of parents and young people in the use and implementation of these technologies. Participants in this study were generally supportive of new and emerging technologies as useful tools in preventing the accidental exposure of young people to online pornographic material. However, participants remained less convinced of their ability to avert intentional viewing, with substantial concerns regarding technological efficacy, adaptability, and user privacy. Further, co-design and prototype refinement are needed to better understand user acceptability and comfortability of these new technological interventions, alongside additional research exploring sociocultural differences in information needs and user experiences.

Introduction

Background

Internationally, the median age of first intentional viewing of pornography is around 13 years; however, the majority of young people are exposed unintentionally at an even younger age [1-5]. Accidental viewing may be more harmful than intentional access due to the shock and distress experienced upon unexpected or unwanted exposure to pornographic material [6]. Consultations by the Australian eSafety Commissioner found that it was widely considered that pornography is harmful for younger children, but that the balance between harm and benefit is more nuanced for older teens and adults [3].

In recent years, the use of restrictive technology, such as internet filters, has become a common approach to preventing children's early exposure to pornography [7]. However, these technologies are very unpopular with young people and their parents. A 2021 study, for example, found that only 22% of young Australians supported internet filters blocking pornographic content at a national level, while a 2014 study from the United States found that two-thirds of adults opposed censorship of pornography [8,9]. In research with parents in Australia, the United Kingdom, and the United States, very few had used internet filters [10-12]. A key barrier to use was the belief that the technology was ineffective and could be easily bypassed by young people, with other concerns including the impact on the parent-child relationship, data security and privacy, and a lack of perceived need [2,3,10-12].

But technology continues to evolve, with advances, including natural language processing and visual processing, and products, like age verification and kid-safe internet searches, gaining increased attention [13-17]. Technologies can also incorporate behavioral interventions, such as pornography literacy education or self-monitoring and metrification [18,19]. These technologies offer unexplored opportunities and barriers to families in keeping children safe. Furthermore, there have been renewed efforts from governments to implement policy solutions. For example, age verification for access to online pornography is legislated in Germany and France [20,21]. In 2023, the Australian eSafety Commissioner published the Age Verification Roadmap, which considered the feasibility of and evidence for mandatory age verification mechanisms for access to online pornographic content throughout Australia [3]. In 2024, the Australian Government announced an age assurance trial to explore technologies to prevent children's access to online pornography [22]. With these policies being implemented, it is vital to consult the community about how they could be applied. It is within this context, that our paper contributes to an emerging evidence base, and provides important insights into the acceptability and feasibility of new-age verification technologies.

Research Aims

This study seeks to gain a better understanding of user attitudes to emerging technology and policies relating to pornographic access and identify barriers and opportunities for implementing interventions. We used co-design methods to work with parents and young people to explore how these technologies could be used. This research project aimed to ideate technological interventions that are feasible, acceptable, and effective in preventing and controlling the exposure of young people to pornography.

Methods

Phase 1: Discovery and Concept Design

In the first phase of this study, the research team sought to establish what current and emerging technological solutions have been proven or have shown promising efficacy toward the prevention of young people from online sexual harm and exposure to online explicit material. Researchers from the Monash Sustainable Development Institute Evidence Review Service were engaged in July 2022 to conduct a rapid systematic review of contemporary literature and practice, with additional information collected via expert interviews and bibliographic analysis [23]. A final report was delivered to the research team in November 2022.

Following the discovery process, the research team evaluated the existing technological solutions, as well as emerging developments, contexts, and attitudes identified through the evidence review to create a series of speculative prototypes to be tested with research participants. Two of these technological concepts were developed and refined (Textbox 1). The purpose of these concepts is not to present the best possible prototypes but to generate critical discussion about different features of technology.

Textbox 1. Technological concepts.

"SafeAgeID"

This concept seeks to harness facial imagery processing techniques to analyze a user's facial profile and determine an approximate age. This may include measuring ratios between facial features, detecting the degree of wrinkling on a user's face, or measuring a range of points around the nose and eyes. It is proposed that, when installed on users' devices, the "SafeAgeID" app would require a facial scan validation prior to accessing explicit content. If a young person attempts to view restricted materials and fails a facial validation assessment, a notification will be sent to the young person's parent or guardian with information about the attempted access, and the material will be blocked from view on the young person's device.

"PornScreenPro"

This concept seeks to combine both parental monitoring software and internet filters into a single app. The "PornScreenPro" technology would allow parents or guardians to set certain restrictions and limits on the type of material available to view on each device and would also allow the active or passive monitoring of explicit content access, generating regular reports and notifications about trends and viewing activity. This technology could also be used by adults as a form of self-monitoring and reflection, similar to other forms of self-metrication, for example, step counting [18].

Phase 2: Co-Design Workshops

The second phase of the study involved generative co-design workshops. Data from these workshops was used to generate two outputs: (1) a thematic exploration of participant attitudes toward new technological interventions (described in this paper), and (2) a set of design principles and specifications for further development of potential low-fidelity technological prototypes (not described in this paper).

Recruitment

Participant recruitment was facilitated by an external research recruitment agency based in the Melbourne area. The agency sent a brief advertisement to an existing network of suitable participants, and those interested in participating were then directed to complete an online expression of interest survey through the REDCap (Research Electronic Data Capture; Vanderbilt University) platform. Respondents were eligible to participate if they were either adolescents aged between 13 and 18 years or a parent or legal guardian of an adolescent aged between 8 and 16 years. Participants were required to be proficient in English and experiencing economic hardship or social disadvantage, determined through self-reported access to a government-issued health care card or receipt of income support at the time of research. Socioeconomic disadvantage was included because of evidence that digital health interventions can exacerbate inequity when the “digital divide” is not addressed [24,25]. Therefore, we included those experiencing disadvantage to purposefully co-design interventions that met this group’s needs.

Research recruiters contacted suitable candidates following their expression of interest to confirm their eligibility and availability and to provide additional information about the workshop content and structure. Confirmed participants were then sent an email invitation with selected workshop times, along with participant information and consent forms. All participants provided informed written consent including informed parental consent for all participants younger than 18 years of age.

Participants

In total, 12 individuals took part in the research workshops: 8 parents and 4 adolescents. Parents were aged between 32 and 53 years, 75% (n=6) of parents identified as female, 50% (n=4) of parents had a tertiary education, and 38% (n=3) of parents spoke a language other than English at home. Adolescent participants were all aged between 15 and 17 years, and 75% (n=3) of adolescents identified as female. All were current high school students, with 25% (n=1) of adolescents speaking a language other than English at home.

Workshop Procedure

In mid-2023; two 90-minute workshops were held online via Zoom (Zoom Video Communications, Inc) with participating parents across consecutive weeks. A third in-person workshop was held over a 2-hour period with adolescent participants at an inner-city university campus.

Each workshop was facilitated by a multidisciplinary team including a public health researcher, a digital information researcher, and a design practitioner. Across all workshops, researchers used a story-stem completion methodology to explore participants’ perspectives toward the proposed technological concepts [26]. This relatively novel qualitative method presents participants with an incomplete hypothetical scenario and invites participants to complete the narrative by drawing on their own unique experiences, expectations, and mean-making processes [27]. This methodology was specifically selected by the research team as it not only allowed insight into the perceived acceptability and feasibility of the two technological concepts but also generated a greater understanding of each participant’s broader attitudes toward young people’s online interactions and themes of adolescent sexual development. As a speculative method, story-stem completion is particularly useful for exploring concepts or technologies that may not exist or that participants may not have experienced before [28]. As an approach that uses a third-person narrative, it is also excellent for eliciting participants’ knowledge, thoughts, and feelings about sensitive themes [29].

All participants were first given a brief overview of the technological concepts being evaluated including their proposed use and expected functions. A series of story stems were then presented one-by-one to participants, featuring two hypothetical, yet realistic scenarios (Textbox 2). The names in the story stems were deliberately chosen for their gender-neutral associations in Australian English, allowing participants to form their views and apply their gendered lenses to the story stems. Facilitators read aloud the first scenario (part A), and participants were then encouraged to continue the hypothetical story arc individually in a separate worksheet, drawing upon their own experiences and perspectives to complete the narrative. Each anonymous response was collected from participants, before being read aloud by the facilitators with group discussions and reflections to follow. In poststory discussions, facilitators prompted participants to consider and discuss the likelihood of the stories happening in real life, preferred outcomes of stories, how their responses would differ in different circumstances (eg, older or younger child), how the stories made them feel, modifications they would make to the concepts, and other unintended consequences of these technologies. Participants were then given a second related story stem (part B) that continued the first story arc to elicit further insights following slight changes in the hypothetical narrative. Once again, participant responses were collected and discussed as a group, with researchers prompting deeper discussions as needed. This process was repeated for the second technological concept, with new hypothetical scenarios used. Both parents and adolescent participants responded to the same story stem scenarios, with parents completing one concept per workshop, while adolescents completed all story stems in a single workshop.

Following the conclusion of each workshop, the research facilitators also participated in a collective debrief lasting between 20 and 40 minutes, in which key discussion themes and participant responses were further explored. This provided the opportunity for the research team to not only share their professional perspectives on the key insights gained from each workshop but also reflect on the workshop process and refine any minor issues for future sessions.

Textbox 2. Workshop story stems.

Technological concept 1: "SafeAgeID" facial scan recognition

- Part A
    - Harper is 8 years old. At lunchtime, Harper heard the term "threesome" being used by friends but did not understand what it meant. At home, Harper uses the family iPad and types "threesome" into Google.
    - Harper finds a video in the search results and clicks on the link. The iPad suddenly blurs everything on the screen and asks for a facial scan before being allowed to continue to view the explicit video.
- Part B
    - The age verification technology scans Harper's face and decides Harper is probably younger than 18 years and blocks the porn site. The SafeAgeID app instructs Harper to ask for an adult's help to proceed.
    - SafeAgeID app sends a notification to Harper's parents about an attempted porn site viewing, with the date, time, porn video's URL, and the image of Harper's face from the scan.

Technological concept 2: "PornScreenPro" monitoring platform

- Part A
    - Jo is 13 years old and uses the family computer to watch videos and games, and do schoolwork. Jo clicks on a link friends have shared for a porn video. A parenting app called "PornScreenPro" is installed on the computer, and it sends Jo's parents a notification that porn content has been detected as part of their child's internet activity.
    - Along with the notification message, PornScreenPro sends guidance to Jo's parents on how to talk to a 13-year-old about pornography and internet safety in an age-appropriate way.
- Part B
    - Jo is now 19 and watches porn fairly regularly. Lately, Jo has been watching more porn and finding that the content needs to be more graphic or extreme in order to "get off."
    - Jo's phone has a default activity monitor for activities like running and walking, time spent on social media, TV shows, movies, and porn. Jo gets a notification message, "You have watched porn for 36 hours this month, that is 22 hours more than last month."
    - Jo can look at the advice the app offers on reducing pornography use. It also has information about porn's impact on relationships and expectations around sex. It can also suggest pornography that is less extreme or violent.

Data Collection and Analysis

All data, including debrief discussions, workshop audio recordings, and story stem responses, were transcribed and checked for accuracy by researchers. A collaborative iterative thematic analysis approach was adopted to capitalize on the highly multidisciplinary perspectives of the research team [30]. This analysis process was undertaken by two researchers (JT and STK) from the public health and design and technology fields, respectively, with the aim of better integrating specific technological design implications alongside broader themes of young people's sexual health and development.

Following transcription, researchers first familiarized themselves with the data before creating an independent set of initial codes using NVivo 14 software (Lumivero) and the Miro online platform. The research team then met to discuss this preliminary analysis and to compare initial codes and emerging themes. A second, more extensive round of independent thematic analysis was then undertaken, with initial codes refined and developed into more distinct themes. The research team once again met to discuss the corresponding analyses, and following minor revisions, merged the datasets into a single thematic framework that is reflective of the collective perspectives and understandings of the research team [31].

Ethical Considerations

Ethics approval was granted by the Alfred Health Human Research Ethics Committee (ID 663/22). All participants gave informed consent. All adult participants were provided with an AU $100 (US $68) gift voucher as an appreciation for their time, while adolescent participants were provided with an AU $120 (US $81) gift card for their contributions and to compensate for the additional travel expenses. All data were deidentified.

Results

Overview

Three key themes were identified by researchers from the data, with several subthemes further explored. The key themes and subthemes are outlined in Textbox 3 below.

Textbox 3. Key themes and subthemes.

Theme 1: limitations of technology

- Workarounds and circumvention
- Perceived utility of self-monitoring technology

Theme 2: technology as a secondary tool

- First line of defense against accidental exposure
- Age-appropriate conversations remain paramount
- Additional support for parents and guardians

Theme 3: customizable and secure design

- Privacy and data security
- Configurable options for a diversity of users

Theme 1: Limitations of Technology

Workarounds and Circumvention

Throughout each workshop, participants readily identified limitations that the proposed technologies may encounter when applied to real-world conditions. Participants saw the clear potential for these technologies to prevent accidental exposure. However, most mentioned the inability of these technologies to prevent the intentional access of pornography and other online explicit content. Both adult and adolescent participants strongly believed that young people were likely to easily circumvent the restrictive barriers of the proposed technologies, especially when deliberately seeking to view explicit content.

> *It'd be pretty easy to get around the face IDs if you really wanted to see something.* [Adolescent]
>
> *The workarounds kind of rang true to me, that [young people] would try to get around the technology in some way.* [Parent]

Participants described the various ways in which young people were likely to bypass both technological concepts including gaining access through older or alternative devices, seeking access through older siblings or friends, or convincing parents to temporarily disable the technology. Further strategies to navigate the restrictive technologies included using alternative search terminologies such as slang words, emojis, or languages other than English.

> *...the other thing I did note that was interesting was how the child could then try another way of searching for the [explicit] word … for young teenage boys, an eggplant [emoji] signifies something different so, you know, it's the different connotations that people may use, and these technologies will not, or cannot really prevent.* [Parent]

Similarly, several participants also questioned the ability of both technological concepts to prevent harmful exposure through different mediums such as adult cartoons or anime, text-based content, and audio recordings. There was also concern that other forms of harmful online activities, such as sexting or acts of child grooming, would go uncensored, as they were not as easily identifiable as traditional image-based pornographic content.

> *I feel like we're a bit reliant on this technology and only the imagery, but not the text sort of content.* [Parent]
>
> *...you think you're providing this safe platform, whereas they could still go and look up a whole written story about what a threesome was, and that wouldn't be blocked.* [Parent]

Perceived Utility of Self-Monitoring Technology

When discussing the merits of the "PornScreenPro" concept, both adult and adolescent participants questioned the utility of such monitoring technologies, particularly when applied to older adolescents with a developing sexual identity and curiosity for pornographic content.

> *I think the whole concept of the [PornScreenPro] app to a teenager or young adult is not something that is suitable at that age, especially if it's a male. They've just finished high school, the world is their oyster, they're exploring, you know, their sexuality, meeting up with friends, learning different things, and I think the last thing they need or would pay heed to would be an app that sort of prevents them from doing that.* [Parent]

Participants also felt that older adolescents were unlikely to pause and reflect on their own behaviors and pornographic consumption at such an age, even when notified or provided with supportive resources. Consequently, many felt that the "PornScreenPro" app would quickly become a nuisance to users, leading to the technology either being ignored or disabled with enough time.

> *One thing that jumped out at me as being really consistent is that the majority of the [story stem] narratives talked about disregarding the [PornScreenPro] app. Young people didn't care about info on the app, turned off notifications, found them annoying.* [Parent]
>
> *I think if you're at that stage [of life] you're not going to see a notification about [harmful pornographic consumption] and be like "ah maybe I'll look at that," you'll just be like "I don't really care."* [Adolescent]

Theme 2: Technology as a Secondary Tool

First Line of Defense Against Accidental Exposure

Despite the limitations identified above, there was still an overarching agreement among both parent and adolescent participants that these novel technological interventions had a place in protecting young people from online harms, with general support for their further refinement and development. Participants discussed how these new technologies could still be beneficial tools, acting as a "first line of defense" against the accidental exposure of younger children to pornography and other explicit content.

> *Whether the child goes looking for answers when they're not ready, well hopefully this technology, once its released, it would screen out and block those because they're not of age yet, or they're not, you know, ready for it.* [Parent]

Age-Appropriate Conversations Remain Paramount

However, participants reiterated that these apps should not be seen as a "fail-safe" solution and that there was still an important need for close parental oversight and engagement. More specifically, both adult and adolescent participants overwhelmingly agreed that age-appropriate conversations remained the most suitable and preferred course of action for addressing concerns of online harm to young people.

> *I feel like there's a danger that people would think that it was a fail-safe technology … and that the most important aspect is that it shouldn't replace those ongoing conversations about being safe online.* [Parent]
>
> *[Jo's] parents get the link and are not sure what to do so they approach the situation carefully. They realise that it was an accidental mistake and so are cautious on talking to her but do make it a point in the future to educate her about porn in a safe way. Over the next few days its forgotten and Jo is careful not to click on random links again.* [Parent story stem response]

Indeed, many of the participant's hypothetical story-stem responses described an "ideal" outcome whereby parents avoided emotional responses and instead opted for a more empathetic and educational conversation.

> *[The parents] are glad that this technology has blocked their underage child's access. Next few days, the parents sit the child down to ask why she went searching and what would she like to know. Parents propose the next time the child is curious, she should approach the parents first.* [Parent story stem response]
>
> *Ideally, after some confusion and perhaps further failed attempts at accessing the content, Harper would feel comfortable enough to ask one of her parents about the definition of the term [threesome].* [Adolescent story stem response]

Some parents further suggested that adopting these technological apps in their homes would also act as a catalyst for them to have the necessary conversations about online safety with their children before any exposures occur.

> *...if this technology actually existed you would of kind of have to have some of those conversations already about these filters, like "these things exist, there's this app on the iPad that will help stop you from seeing inappropriate content."* [Parent]

Additional Support for Parents and Guardians

Yet, while participants placed significant importance on having these open and informed conversations with young people, several parents also expressed a lack of confidence in their own ability to do so. Many parents felt unprepared for what they described as "difficult" and "awkward" conversations and reflected that they felt less technologically literate in today's online world.

> *We [parents] have sort of I guess been brought up with a limited sort of technology and our children are obviously, it's a second language for them, you know, they understand sometimes more than we do so I feel at times they may be able to actually get around it more than we actually can.* [Parent]

Parents expressed a desire for more educational resources on how to discuss pornography and internet safety in age-appropriate ways and felt that this information must accompany any internet monitoring technology.

> *We understand our children but don't get a good sense of how to educate them in the proper way. They may not really listen.* [Parent]

Several parents also stated that these conversations remain a shared responsibility, with the school system and educators also needing to play a strong role in delivering appropriate cybersecurity and sexual health education.

> *Teachers still play critical role within the school to educate the children, the students, rather than the parent. Parents can play a supporting role.* [Parent]

Theme 3: Customizable and Secure Design

Privacy and Data Security

User safety and data security were a paramount concern for many participants. Several parents expressed a lack of confidence in the ability of third-party apps to protect user information, with numerous participants referencing recent large-scale cyberattacks on Australian organizations, and how these data breaches had further heightened their anxiety regarding online privacy.

> *So many sites have been hacked lately that we would normally think are really secure, like telecommunications and banking.* [Parent]

There was a particularly strong apprehension from parents toward the safe storage of biometric data, with facial scans and images of young people seen as especially sensitive. Some felt that the collection and storage of such sensitive biometric data would in fact attract greater attention from cyber-criminals, with the technology acting as a “beacon” for malicious actors to gain access to young users and their valuable personal data.

> *Having those photos of the children, are they going to be safe? That was my concern as well, just like how everyone mentioned, and too much information being out there so those were my two concerns that I’ve just been pondering about… in some way this technology would be a bit of a beacon for groomers and people wanting to access children.* [Parent]

While these privacy concerns did not undermine participants’ overall assessment of the utility of the technological interventions per se, participants did articulate a strong desire for further information on the safety mechanisms of the proposed technologies. Many felt that these concerns would need to be thoroughly addressed before they felt comfortable using the different apps.

> *I think mostly parents would be accepting of it, I think maybe, I think you’d hit the majority of parents, at least yeah, but I still think the biggest concern would be the face ID technology and the collection of data and identity and I think that yeah that would be the biggest concern.* [Parent]

Configurable Options for a Diversity of Users

Additionally, while participants were quite forthcoming with their own thoughts and reflections on the proposed technologies, many were also acutely aware of and frequently vocalized the need to consider alternative perspectives and value systems in the development process. Both parents and adolescents sought to highlight that each person, family, and sociocultural group may hold different attitudes toward sex, pornographic content, and young people’s sexual development more generally. Consequently, participants expressed a desire to see flexible and highly configurable options available within the proposed technologies to suit the individual needs of users and the unique sociocultural requirements of different family groups.

> *Yeah, because for different households, maybe we say ok I’ve got a 10-year-old, I think my 10-year-old is not ready for that but if another 10-year-old in another household goes “mum and dad, I want to learn about this” then they do the age verification and then its ok for them.* [Parent]

> *I hope that if this kind of technology comes out it would kind of help with acknowledging the fact people choose to [use the technology] for different reasons … it depends on why they’re using it, and how they’ve been brought up. I feel that a technology that addresses that kind of diverse range of people using it would be the most impactful like positively.* [Parent]

Discussion

Principal Results

Both adult and adolescent participants in this study expressed a general level of support for the use of age verification technologies in the regulation of pornography and other online materials for young people. This finding is consistent with other recently published studies, which have indicated similar levels of acceptance for such restrictive strategies aimed at safeguarding online environments. In 2021, the eSafety Commissioner surveyed 1200 Australian adults, with 78% of respondents supporting the use of age verification mechanisms as a means to verify minimum user age on pornographic websites [32]. In a similar survey conducted the following year, just 4% of young Australians believed that online pornography should remain unrestricted by age, with 59% also supporting the implementation of age verification technologies [33]. Comparable research conducted in both the United Kingdom and New Zealand has found similar levels of acceptance. Close to 83% of surveyed UK parents supported the introduction of age verification processes for access to pornographic websites [34], while 71% of young adults in New Zealand were in favor of restricting access to online pornography for teenagers and young children [35]. Our findings, therefore, add to a growing body of evidence suggesting sustained acceptance among the broader population for the use of such technologies within this context.

As a stand-alone strategy, however, these restrictive technologies have clear limitations, particularly in their ability to prevent young people from intentionally viewing explicit online content. In a survey of American high schoolers for instance, 98% of young participants stated that they had no difficulties in circumventing traditional internet filters in order to gain access to pornography [36]. Similarly, research from Australia, the United States, and the United Kingdom has consistently found a strong perception of inefficacy toward these restrictive filtering technologies among the general public [7]. It is unsurprising, therefore, that participants in this study echoed this perspective when discussing the merits of the two proposed technologies. While participants were generally supportive of the new technological approaches, few were convinced of their overall ability to prevent intentional exposure to explicit content. Both cohorts remained firm in their belief that young people were still likely to circumvent both the “SafeAgeID” and “PornScreenPro” apps. This skepticism may be attributed, in part, to the heavy reliance of both proposed technological concepts on traditional restrictive internet filtering practices to prevent exposure to online material. While novel features, such as facial imaging, may allow for a more streamlined and acceptable age verification process, both concepts remain similarly limited in their capacity to prevent intentional access due to the numerous perceived workarounds young people may exploit.

In isolation, restrictive strategies, such as age verification technologies, are therefore unlikely to provide sufficient online protection and support to young people, particularly as their sexual interests and preferences evolve. Instead, participants expressed a strong preference for informed and age-appropriate conversations as an additional and primary method for minimizing potential harm from online material. Yet crucially, participants also had a perceived deficit in their own knowledge and confidence when it came to initiating these conversations with their child, expressing a desire for additional resources to support them with this process. While comparable studies [9,35] have observed similar views from parents and caregivers toward the necessity of these conversations, there remains a dearth of literature exploring what “age-appropriate” exactly entails including the age and contexts in which these conversations should be undertaken. Acknowledging and supporting the essential role of parents and caregivers in guiding young people’s exposure to pornography is crucial, given that active parental mediation in online activities has been shown to diminish risky online behaviors and promote healthier sexual development [37-39]. Additional research is therefore required to enhance our understanding of the specific information parents require to facilitate these crucial conversations, along with determining the optimal timing and contexts for conducting these discussions with young people.

Finally, the findings of our co-design study have implications for future prototype design and development. Participants expressed a desire for more configurable options within the proposed apps to better suit their family’s needs and sociocultural understandings of pornographic content, including what types of media are screened, and to allow for families to select what they are comfortable with their children accessing. Future prototypes should also have the capability to adapt to different age groups, providing parents the ability to enforce stricter controls for younger users and gradually allow more autonomy as children mature, or as parents decide they are ready to access different content. The controls of future apps should ensure adults can watch pornographic content without being restricted or tracked unless voluntarily selected. The apps should be inclusive and accessible for all users, including those who do not speak, read, or write English, or people with disabilities. This could involve text-to-speech features, multilingual capabilities, easy-to-read fonts, and other accessibility features. Finally, supportive educational resources should be developed and provided in tandem with future technological applications to ensure better user acceptability, with a particular need for further information on user privacy and security, and broader information about the app’s design in easy-to-understand language.

Study Limitations

The findings of this study need to be considered in light of several limitations. Participant recruitment was undertaken via an external research recruitment agency, drawing from a network of individuals who had previously indicated a willingness to participate in research. This may have introduced a level of self-selection bias, with the views expressed by our participants potentially differing from those of disadvantaged parents and young people more broadly. Workshops were also carried out within a group setting, leaving the potential for social biases to influence participant responses (eg, social desirability). This bias may have been reduced somewhat by having participants individually complete written story stems, before discussing their thoughts with the group. We were able to analyze these written data in addition to what participants were willing to say in the group discussions. The use of story-stem methodology also brings additional methodological limitations, as story completion frequently replicates the conventional structure of Western storytelling [40]. This is particularly important to note when evaluating the narratives expressed within a culturally and linguistically diverse participant cohort, whereby cultural intricacies, alternative viewpoints, and diverse narrative structures may have been overlooked or misunderstood. Finally, while the novel technological concepts proposed to participants were developed through an extensive evidence review process, they remained speculative and hypothetical prototypes, and thus, participant opinions and feedback were formed based on incomplete information and may change with supplementary details (ie, participant concerns over app security and privacy).

Implications for Future Research

This study provides insights into the wants, needs, and concerns of parents and young people toward emerging restrictive age verification technologies. Further co-design and prototype development are needed to incorporate the findings from this study, with further iterative testing and consultation with key stakeholders to ensure user acceptability and user comfortability. Given the rapidly changing nature of the technological landscape, advances in age verification technology should be monitored closely for future relevance and application, particularly advancements in generative artificial intelligence-driven biometric systems such as facial image processing. Additionally, there is a need for the development of supportive resources for parents and other users of these proposed technologies to address concerns of privacy and user configurability. Further research is needed to better understand the information needs of parents when conducting age-appropriate conversations, including what “age-appropriate” means for different family units, and guidance on when and how to facilitate these discussions. Consideration must also be given to the sociocultural context of users, with further research needed to understand how differences in language, culture, and religion may influence parental information needs and the overall acceptability of the proposed technologies.

Conclusions

As policy makers continue to pursue age verification and other restrictive strategies to limit children’s and adolescents’ exposure to pornography, it is vital to understand how these tools are perceived by potential users. Parents and adolescents in this study agreed that such technology is useful as a “first line of defense” against the accidental exposure of young people to online explicit materials, but that these tools are less likely to be useful or acceptable for preventing intentional pornography access. Concerns over privacy, efficacy, and adaptability need to be considered when implementing future tools or policies. Most importantly, both parents and adolescents insisted that technology alone was not the answer; parent-child conversations and comprehensive sexual health and pornography education were the ultimate solutions to addressing the potentially harmful impact of pornography on young people.

Acknowledgments

The study was funded by a Westpac Foundation Safer Children, Safer Communities research grant. MSCL receives a Career Development Fellowship from NHMRC.

Data Availability

The datasets generated or analyzed during this study are not publicly available because it may be identifiable, but selected data can be made available from the corresponding author upon reasonable request.

Authors' Contributions

Study conception and design by MSCL, DM, and SC. Material preparation and data collection were performed by NC, STK, and DM. Data analysis was led by STK and JT. The first draft of the manuscript was written by JT and MSCL, and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

Abstract

Background: In many areas of health care, learning health care systems (LHSs) are seen as promising ways to accelerate research and outcomes for patients by reusing health and research data. For example, considering pregnant and lactating people, for whom there is still a poor evidence base for medication safety and efficacy, an LHS presents an interesting way forward. Combining unique data sources across Europe in an LHS could help clarify how medications affect pregnancy outcomes and lactation exposures. In general, a remaining challenge of data-intensive health research, which is at the core of an LHS, has been obtaining meaningful access to data. These unique data sources, also called data access providers (DAPs), are both public and private organizations and are important stakeholders in the development of a sustainable and ethically responsible LHS. Sustainability is often discussed as a challenge in LHS development. Moreover, DAPs are increasingly expected to move beyond regulatory compliance and are seen as moral agents tasked with upholding ethical principles, such as transparency, trustworthiness, responsibility, and community engagement.

Objective: This study aims to explore the views of people working for DAPs who participate in a public-private partnership to build a sustainable and ethically responsible LHS.

Methods: Using a qualitative interview design, we interviewed 14 people involved in the Innovative Medicines Initiative (IMI) ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now) project, a public-private collaboration with the goal of building an LHS for pregnant and lactating people. The pseudonymized transcripts were analyzed thematically.

Results: A total of 3 themes were identified: opportunities and responsibilities, conditions for participation and commitment, and challenges for a knowledge-generating ecosystem. The respondents generally regarded the collaboration as an opportunity for various reasons beyond the primary goal of generating knowledge about medication safety during pregnancy and lactation. Respondents had different interpretations of responsibility in the context of data-intensive research in a public-private network. Respondents explained that resources (financial and other), scientific output, motivation, agreements collaboration with the pharmaceutical industry, trust, and transparency are important conditions for participating in and committing to the ConcePTION LHS. Respondents also discussed the challenges of an LHS, including the limitations to (real-world) data analyses and governance procedures.

Conclusions: Our respondents were motivated by diverse opportunities to contribute to an LHS for pregnant and lactating people, primarily centered on advancing knowledge on medication safety. Although a shared responsibility for enabling real-world data analyses is acknowledged, their focus remains on their work and contribution to the project rather than on safeguarding ethical data handling. The results of our interviews underline the importance of a transparent governance structure, emphasizing the trust between DAPs and the public for the success and sustainability of an LHS.

Introduction

Background

In many areas of health care, learning health care systems (LHSs) are seen as a promising method for learning from real-world experiences [1,2]. In an LHS, health care and research are aligned to accelerate research and outcomes for patients and have the potential to develop scientific knowledge based on health information and research data by directly implementing new insights from analyses to the clinical practice [3].

For some patient populations, an LHS approach may be considered one of the most promising ways forward, for example, the group of pregnant and lactating people, who are often excluded from controlled clinical research studies and for whom there is still a poor evidence base for medication safety and efficacy. In real life, numerous medications, which are key to the health of the pregnant person, have been used safely and effectively in pregnancy with minimal risk to the fetus and pregnant person, but we do not systematically learn from these experiences [4-8]. Current information on medications used during pregnancy and lactation is fragmented and spread across different countries and data sources, including pregnancy or medicine cohorts, registries, research groups, and the pharmaceutical industry [9]. Examples of such data sources are the European system for the evaluation of safety of medication use in pregnancy in relation to risk of congenital anomalies (EUROmediCAT), the European Network of Teratology Information Services (ENTIS), and national population registries or regional cohorts. Accessing and analyzing these unique data sources in a system of continuous learning could help more effectively clarify how medications impact pregnancy outcomes.

In general, a remaining challenge of data-intensive health research, which is at the core of an LHS, has been obtaining meaningful access to data. A way to impact the field of pregnancy and lactation is through collaborations between various organizations (including public-public and public-private). These organizations, known as data access providers (DAPs), often possess or have access to vast amounts of routine (health care) data, which reflect routine health care encounters and processes, and they have valuable expertise in managing large data sets. Collaborating with private organizations can also be beneficial, as they also possess relevant data and resources. In addition, private organizations, such as medicines marketing authorization holders, require evidence on the effects of medications during pregnancy to comply with regulatory requirements and to update product information. Public-private partnerships present their own set of challenges, such as ownership, benefits and effectiveness, impact on public interest, and achieving a social license, all of which have been discussed in the literature on public-private partnerships [10,11]. In addition, frequently discussed in the context of LHS development is the challenge of establishing a sustainable collaboration capable of consistently facilitating the processes of data collection, analyses, and dissemination of research results [2,12-14].

At the same time, there is a growing expectation for these DAPs as data controllers and processors to extend their focus beyond regulatory compliance and actively safeguard the privacy and appropriate use of data. The General Data Protection Regulation (GDPR) includes various rules and principles for data controllers to ensure transparency and adherence to principles, such as fairness, purpose limitation, data minimization, accuracy, storage limitation, integrity and confidentiality, and accountability, while granting certain rights to persons whose personal data are being processed (GDPR, Articles 5 and 6) [15]. Ultimately, DAPs are viewed as moral agents who must respect ethical principles such as transparency, trustworthiness, responsibility, and community engagement [16].

To realize a sustainable and ethically responsible LHS, it is important to know whether people working for these organizations acknowledge their role and responsibility in safeguarding the responsible use of data and the dissemination of research outcomes to the public. Rising expectations with respect to DAPs' responsibility for the ethical use of data and data ownership do not necessarily mean that each of these organizations has a dedicated governance structure to safeguard these principles or that people working for DAPs feel as if they are a moral actor in an LHS. Moreover, apart from the obvious differences in management and reward systems among DAPs [17], these organizations may also have different motivations for collaborating in an LHS. Furthermore, their perspectives on the sustainability of an LHS and their roles once the project phase concludes may also diverge.

Objectives

In this study, we aimed to explore the views of people working for DAPs who participate in public-private partnerships to build a sustainable LHS. We were especially interested in the views of DAPs contributing to the Innovative Medicines Initiative (IMI) ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now) project, which aims to build an LHS for pregnant and lactating people [18]. Using a qualitative interview design, we hoped to identify, better understand, and juxtapose people's views and interests in collaborating in an ecosystem that uses routine health data to generate new knowledge for pregnant and lactating people and their doctors. By providing insight into the views and interests of people representing DAPs in this particular LHS, this study intends to inform a governance framework for LHSs and, in turn, to help facilitate the development of a sustainable LHS in which public and private organizations collaborate. Moreover, this study aims to contribute to the ongoing discourse on moral responsibilities associated with responsible data handling and dissemination of research findings, particularly by exploring whether DAPs themselves perceive and articulate this moral responsibility.

Methods

Design

We conducted a qualitative study to collect the views and interests of people who work for organizations and who act as a DAP in the ConcePTION project. This qualitative interview study is a substudy of the IMI ConcePTION project (Textbox 1). IMI ConcePTION was used as the primary case study during the interviews and as the source for participation selection. The study was reported following the COREQ (Consolidated Criteria for Reporting Qualitative Research) [19]. We conducted semistructured interviews with a topic list (refer to the general topic list in Textbox 2). The topic list was based on the topic list used for another qualitative interview study, in which we asked women during preconception, pregnancy, and nursing what they thought about an LHS for pregnant and lactating women [20]. The topic list was also based on an analysis of the challenges of public-private partnerships, LHSs, and responsible data sharing [1,10,21], as well as discussions among the research team. To mitigate the potential for socially desirable responses from our respondents, it was determined that the topic of moral responsibility regarding the use of data and the dissemination of research findings would not be included in the general topic list. Instead, an opportunity for spontaneous or organic discussion of the topic was provided during the course of the interview. Moreover, it was expected to be, for example, discussed under topic 2: “expertise and dual roles.” This topic provided an opportunity for DAPs to elucidate their roles and responsibilities concerning their primary organization; their involvement in the ConcePTION consortium; and in certain instances, their clinical obligations.

Textbox 1. Description of the initiation, aim, and composition of the Innovative Medicines Initiative (IMI) ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now) project.

In April 2019, the IMI ConcePTION project was launched, which aims to establish a trusted ecosystem that can efficiently, systematically, and in an ethically responsible manner generate and disseminate reliable evidence-based information regarding the effects of medications used during pregnancy and breastfeeding to women and their health care providers. The ConcePTION consortium consists of European public and private stakeholders, including national public health institutes, the European systems for the evaluation of safety of medication use in pregnancy in relation to risk of congenital anomalies (EUROmediCAT), the European Network of Teratology Information Services (ENTIS), research institutes, universities, and pharmaceutical companies. The ConcePTION consortium is currently a public-private partnership; however, the approach of ConcePTION to collect and learn from real-world data on the safety of medicines during pregnancy and breastfeeding is similar to what may also be called a learning health care system [6].

Textbox 2. General topic list used during the qualitative study to guide the interviews.

Topic list

- Willingness to participate
- Expertise and dual role
- Future (after consortium agreement ends)
- Conditions for working for the ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now) learning health care system
- Added value

Sample and Setting

To capture a wide range of interests and perspectives (contrast maximization), a variety of people from different types of organizations and different countries were identified. We aimed to include people working as DAPs in partnering organizations and third parties in the ConcePTION project. To be able to invite people working for different DAPs, we distinguished between private (pharmaceutical companies and private centers) and public organizations (universities, teratology information centers, public health services, and hospitals), countries, regions, collaborative partnerships, and occupations. Respondents were recruited using purposeful sampling with the help of colleagues from the ConcePTION consortium. The respondents were approached via email. Most of the interviews started with an introductory question related to the work of the respondent and the process of data collection, storage, and analysis within their organization. We then used the topic list to continue with the interview. Although the approach of ConcePTION is similar to that of an LHS, we used the terms ecosystem and network interchangeably. This is because the term ecosystem is commonly used within the consortium and is more familiar to the respondents. The interviewer (MJH) created a safe space for respondents and invited them to share their views and experiences by emphasizing (1) the privacy and confidentiality arrangements, (2) their autonomy during the interview (eg, regarding answering questions, stopping the interview, and asking for clarification), and (3) the option to review the transcript before analysis. These points were emphasized by the interviewer before seeking verbal consent. The interview allowed respondents to introduce or emphasize new issues that they considered relevant. Therefore, it is important to emphasize that the results reflect personal views and do not represent the views of the entire organization for which the respondents work.

Data Collection

The interviews were conducted by MJH (trained qualitative researcher, female) using the topic list. The topic list was refined after 2 pilot interviews. Furthermore, according to the technique of constant comparative analysis, the interview topics evolved as the interviews progressed alongside data analysis [22]. Data were collected from November 2021 to February 2022. The interviews were conducted in English and Dutch and took place via a secure communication platform. The interviews took 33 to 60 minutes, with an average duration of 43.8 (SD 75) minutes. In 12 out of 14 interviews, there had been no previous contact between the interviewer and the respondent. In 2 out of 14 interviews, the interviewer and the respondent had contacted each other before for project-related work. During and after the interview, MJH made notes to enhance the data and to provide a clear context for data analysis. The interviews were audiotaped, transcribed verbatim, coded, and stored anonymously. Verbal consent was obtained from all the respondents. One respondent requested to read the transcript before analysis.

Data Analysis

After transcription, we analyzed the interviews according to the thematic analysis method and by using a backward and forward approach between data collection and analysis to develop codes [22]. An initial coding list was developed based on the topic list. Subsequently, the transcripts were coded. The coding list was evaluated and adapted, and all interviews were coded using NVivo 12 software (Lumivero). To enhance the validity of our results, an intern (medical student, Bachelor of Science) also read and coded 8 randomly chosen interviews out of 14 pseudonymized interviews to check for consistency of the thematic framework and critically read the coding list. In the course of the analysis, codes were adapted, and additional codes were added to the coding list where necessary. A meaning pattern was identified across the data set, leading to the formulation of interpretative higher-order themes. The themes capture the views and interests of the DAPs regarding the ConcePTION ecosystem. The themes represent both topics that were often discussed by respondents and a variety of views that are helpful in the development of a sustainable ecosystem of continuous learning. The findings, including the coding list and formulated higher-order themes, were discussed by the complete research team (MJH, RvdG, MCJMS, and JJMvD). Thematic saturation was reached when additional data did not lead to any new emergent themes after 14 interviews [23]. Furthermore, a member check was executed during the last phase of data analysis. A draft version of the manuscript was sent to all respondents, inviting them to provide feedback and discuss the accuracy and interpretation of our results [24].

Ethical Considerations

The research protocol, including the procedure for obtaining informed consent, was reviewed by the institutional research support office at UMC Utrecht. As no intervention was imposed on the participants, this study was exempt from ethics review under the Dutch law. All participants were provided with a letter of information and gave their verbal consent for participation and recording as required under the Dutch law that implements the GDPR (*uitvoeringswet algemene verordening gegevensbescherming*). Each participant was assigned a study ID number to protect their privacy and confidentiality. Furthermore, their names, the names of their workplace, and other names of the consortium members mentioned in the interviews were redacted by the interviewer MJH. The participants were not compensated for participating in the study.

Results

Overview

Of the 23 DAPs that were approached, 14 agreed to participate in the study, 4 declined, and 5 did not respond. A total of 14 semistructured interviews were conducted with 18 people involved in IMI ConcePTION. A total of 2 DAPs were represented by 2 employees of the same organization or research collaboration. The interview respondents worked in different organizations, including universities, public health centers, hospitals, teratology information centers, pharmaceutical companies, and private centers. Table 1 shows the respondents' characteristics. We could not share all details to ensure the privacy of the respondents.

Because of the constant comparative analysis during the qualitative study, we enhanced our interview guide. During the first couple of interviews, the subject of (moral) responsibility was not (always) organically discussed. Therefore, we added to the second topic "expertise and dual roles," the possibility of asking DAPs directly about their sense of responsibility and to whom that responsibility was directed, if relevant. We still decided to leave the answers open and not steer too much in the direction of the sense of *moral* responsibility regarding the use of health data and dissemination of research findings to avoid socially desirable answers.

On the basis of the interviews, we formulated 3 main themes characterizing the views and reflections of DAPs on the development of a knowledge-generating ecosystem for pregnant and lactating people. These themes emerged consistently across all interviews. We provide representative quotations to illustrate these themes (Table 2).

Table 1. List of characteristics of the respondents, categorized based on the respondent number, type of organization, whether it is a public or private organization, and the general location of the organization.

Respondent number	Type of organization	Public or private organization	General location of the organization
R01	University	Public	Southern Europe
R02	Research institute	Public	Southern Europe
R03	Pharmacoepidemiologic research institute	Public	Central Europe
R04	Research institute	Public	Northwestern Europe
R05	Hospital	Public	Central Europe
R06	University	Public	Northern Europe
R07	University	Public	Western Europe
R08	Pharmaceutical company	Private	Central Europe
R09	Public health service	Public	Middle East
R10	Pharmaceutical company	Private	Western Europe
R11	University	Public	Northwestern Europe
R12	Hospital	Public	Northwestern Europe
R13	Health center	Private	Middle East
R14	University	Public	Northwestern Europe

Table 2. Representative quotations (Q) from the respondents (R) used to illustrate the identified themes.

Themes and quotation number	Quotation and respondent number
Theme 1: opportunity and responsibility	
Q1	"It was another opportunity for us to exchange data on a wider basis. ...share with one another might be an interesting experience." [R09]
Q2	"The first thing to remember, is that we want to be important. We want to continue being bold. Because at the end, it's big; ConcePTION. It has a lot of power. We want to be there. Not for, only for some type, scientific purposes. But the main one is, to include our data." [R02]
Q3	"Think it's two things. One is we feel the obligation, because we have a large database, so it's a moral obligation I think—or we think. And the other one is also because we like working in this team." [R03]
Q4	"I'm excited to be in this field, because you can help people improve their health whether it's women or children, doing this study, or in other types of study we do. I'm not sure I'd use the word responsible in that context, but definitely it's a motivating factor." [R14]
Q5	"Then we would have some safeguards that we are the ones who say 'Yes, this data can be used,' or the results. We have obligations to the data providers; we need that these are full in. So the problem is if we have like one day to review the results and then something is published, we will kind of have problems with our obligations." [R03]
Theme 2: conditions for participation and commitment	
Q6	"To be sure that at least we have one [person] working on this. And that it is a very stable income. Because otherwise we are looking for the calls [tenders] and running for them. And yeah, it takes a lot of time, and when we spend time on this, we don't spend time on thinking about the research we're performing." [R07]
Q7	"We are a research institute, and we get evaluated every seven years, and we are measured on publications mostly. So, research is a value for us and publications is important for us, and especially also first and last authorships. So we need to focus our resources on getting some publications." [R03]
Q8	"There needs to be some rules, an agreement about our participation and how much pharma can affect the processes and how much pharma can receive from this and every package actually, so it should be in some agreement written down." [R13]
Q9	"What I would want is to have more time to discuss things like double programming and also to decide like decisions implicitly made." [R03]
Theme 3: challenges for a knowledge-generating ecosystem	
Q10	"[In] the end, you're going to need a person who understands the data and to analyze [the data] how is the meaning of the data? Because if you are, at the end, just a numbers situation. You are not thinking about this biological play. Classical or not. Or if it makes sense with your kind of population." [R02]
Q11	"In many countries that are strict data privacy rules and when for a given observation, there are like less than four observations, the results are masked. ...that means that I cannot use the data when combining data from several studies. So one thing that I think would be beneficial is to see if there would be data privacy rules that would be lifted for pregnancy studies." [R08]
Q12	"So, but it's a big assumption. Because academia is involved, you know,..., taking care of [the governance; the data privacy]. And ...they will handle the trust part. I trust them or [when academia] are taking the lead in this project, I'm like: 'okay I think they will take care of everything.' ...They [academic partners] are extra careful, and that extra carefulness is making collaborating complex and difficult." [R10]
Q13	"But here one of the biggest questions is the sustainability. So how this platform will be, I'm saying platform and it's not the exact quote, but how this platform will be sustained after ConcePTION." [R08]

Theme 1: Opportunity and Responsibility

Most respondents wanted to contribute to the ConcePTION project because they viewed the project as an *opportunity* to (1) contribute to the goal of creating knowledge on the safety of medication used during pregnancy and lactation; (2) look at medication safety and birth defects in a larger context (European wide); (3) collaborate and share experiences with other registries, databases, and the like (quotation 1); (4) stimulate scientific research; (5) learn from others and their registries; and (6) showcase their databases and share expertise (quotation 2).

Respondents also emphasized the need to use real-world data. Some respondents mentioned that they feel it is their *responsibility*, or as 1 respondent expressed, *moral obligation* to contribute because of the database or resources they have access to. They felt that they, with their organization, were in a position to contribute to something important, and therefore, they must (quotation 3). Some have been working for a very long time on this specific topic and have already contributed greatly to solutions to close the knowledge gap regarding medication safety in pregnancy and lactation. Only a few mentioned that they felt responsible for helping these groups of people; others saw the lack of knowledge more as a motivation to contribute to the ConcePTION ecosystem (quotation 4).

Besides articulating a responsibility toward pregnant and lactating people, their offspring, and their doctors, the respondents of the private industry also explained that they need to generate knowledge because it is a requirement from the European Medicines Agency and Food and Drug Administration. As they are required to research medication safety among pregnant people, this was considered to be another type of obligation and, with that, a different type of willingness to participate.

A few respondents also expressed feeling a responsibility for enabling research and the quality of the data analyses, and because of that, they wanted to be involved in the decision-making regarding the development and testing of analytical scripts within the research ecosystem.

Finally, 1 respondent also mentioned their responsibility and obligations toward other *data providers*. Some organizations receive data from other organizations, such as health insurance providers. Because of these obligations, they wanted to remain in control of some of the review processes in terms of data programming and analyses (quotation 5). However, challenges in this regard were also discussed stemming from time and financial constraints as well as short research deadlines. None of the respondents discussed their role as data controllers, which involves the responsibility to determine the purpose and manner in which personal data are processed.

Theme 2: Conditions for Participation and Commitment

Respondents explained that their willingness to collaborate within the ConcePTION LHS depends on certain conditions that need to be in place.

Resources and Support

In all interviews, financial resources were discussed as an important condition. Interestingly, financial resources were mentioned as important for reasons beyond the immediate need to cover resource costs associated with participation in a project. Financial resources were discussed in the following ways: (1) as a stable flow of income, preferably contracted for an extended period and covering all the planned activities, and (2) as a source of funding. A stable flow of income is beneficial for attracting and training more employees in this area of work and will help with distributing tasks and becoming more specialized and efficient in the field of pharmacoepidemiology. Agreements on financial support are also necessary for planning and being less dependent on other sources to keep “the system running” (ie, tendering; quotation 6). Regarding sources of funding, some respondents specifically stated that they cannot receive funding from the private industry. They believe that because they are independent (public) institutions, there would be a conflict of interest.

Other respondents mentioned that besides financial resources, they also need IT and computational resources to perform the actual analyses and to ensure that they can keep up with the heavy computational work, which is necessary for sustaining the data analyses.

Some respondents mentioned that they are not used to writing certain types of protocols or experience challenges when receiving ethics approval for studies. Some respondents suggested that ConcePTION could benefit from having a permanent staff to provide support and address questions about timelines, deadlines, funding, ethics, and events.

Scientific Output and Motivation

The importance of scientific output was emphasized during the interviews. Some respondents worked in academic institutions whose aim was to produce scientific publications (quotation 7). Therefore, their willingness to participate in an ecosystem is also affected by whether they get to perform and design studies within the ConcePTION LHS and publish the results in scientific journals. Some respondents also emphasized the need to ask more scientific questions and implement more scientific methods within the network. They mentioned that working within the ConcePTION ecosystem should be different from tendering for projects from pharmaceutical companies. Finally, respondents also wanted to feel motivated to commit to the ConcePTION ecosystem. According to them, motivation is stimulated in different ways, but most importantly, by scientific interest in the project, autonomy regarding work, respect for expertise, and good working relationships. A few respondents also emphasized the importance of offering valuable and easily accessible knowledge to pregnant and lactating people as well as health care providers as a prerequisite for contributing to the ecosystem. They felt that generating valuable information for these stakeholders is the most important goal of an ecosystem such as ConcePTION.

Safeguards

Safeguards were also mentioned as a condition for working for the ConcePTION ecosystem. A few respondents were hesitant regarding the role of the pharmaceutical industry in the processes of formulating research questions, cowriting protocols, and analyzing results (quotation 8). According to them, industry involvement could conflict with the primary goal of the research, or they considered it challenging to align the goals of private and public industries. Other respondents, who worked for pharmaceutical companies, regretted this view and argued that collaboration is very much needed and possible because of independently determined regulations that govern both public and private organization research into the effects of medicines. They stressed that trust and open-mindedness toward each other are important for a good collaboration.

Another safeguard mentioned by some respondents was related to transparency. They argued that in a large network and with a developing ecosystem, it is important to be able to track every step and decision made regarding techniques and methods. One respondent explained how several decisions are made in the process of data analyses, which can influence the quality and value of the results (quotation 9). A few respondents also mentioned that to safeguard the quality of data analyses, especially in the developmental phase of the ecosystem, decisions about technical aspects such as programming and writing scripts for analyses need to be transparent for all DAPs. In this way, DAPs can perform their own quality checks, if desired, and provide valuable feedback.

Theme 3: Challenges for a Knowledge-Generating Ecosystem

When asked about their perspective on the development of a knowledge-generating ecosystem, respondents talked about the challenges they have experienced thus far and which, according to them, are relevant when building the ecosystem.

Data (Is Not Information)

Some respondents explained that there were challenges in harmonizing the databases and executing studies because of the heterogeneity of the data across all databases. Some respondents also mentioned that it may be challenging to generate reliable information based on such heterogenic data, databases, and IT systems. Most importantly, data are not (yet) information or knowledge. To overcome this challenge, respondents discussed 3 types of solutions. First, to be able to interpret data and develop valuable information, many respondents emphasized the need to involve experts who know the data and the real-life health care context of the persons whose personal data are being processed and data points represented in the different data sets (quotation 10). Second, respondents mentioned the need for security and quality assessments to ensure that analytic scripts fit the data and are run correctly at every organization. Third, a few respondents preferred to work in small teams so that they could exchange experiences with scripts, data analyses, and research questions. According to them, working in small teams creates a better overview of the possibilities and limitations of data.

Governance

Some respondents experienced challenges owing to governance procedures. On the one hand, it was mentioned that these procedures are challenging because countries have different data privacy rules, which sometimes complicate the ability to perform observational studies (quotation 11). On the other hand, it was mentioned that these procedures are challenging because their own company or organization restricts certain (research) activities. Some respondents argued that in academia, people exert extreme caution regarding governance, which creates an additional barrier to collecting, sharing, and analyzing data. One respondent assumed that the involvement of academic institutions in the consortium implied that matters such as data handling, privacy and confidentiality, and trust were adequately addressed. However, according to the respondent, this also led to an increase in bureaucratic steps, making collaboration more intricate and challenging (quotation 12). Furthermore, respondents agreed that having fragmented governance procedures led to slow processes and unfulfilled opportunities. According to these respondents, a clear overview of what can be done with the data could be of great help.

Concerning governance, some respondents discussed the need for trust between all collaborators, especially regarding the aim of the ecosystem and methods used within the ecosystem. It was also mentioned that people need to trust the decisions made by people taking a more leading role in the ecosystem and that trust between the public and private participants is necessary to ensure that robust knowledge is going to be generated transparently within the ecosystem. Finally, many respondents emphasized the need for a good sustainability model for the ConcePTION LHS (quotation 13).

Discussion

Principal Findings

The results of our analysis indicate that respondents felt responsible to participate in an LHS for pregnant and lactating people. Although respondents emphasized the professional opportunities that come with participating in a large public-private partnership, many respondents collaborated because they wanted to help develop an ecosystem that can transform real-world data into new knowledge on medication safety and efficacy.

Moral Responsibility

From our interviews, it seems that people mainly reflect upon their views and responsibilities from the perspective of their professional role as a data analyst or pharmacoepidemiologist. As a result, most answers were linked to the more technical side of realizing a system in which real-world data can be used, together with a sense of moral responsibility toward the quality of their data, databases, and data analyses (under theme 1 and as mentioned in quotation 5). On the one hand, technological responses are not surprising because of the expertise of our respondents. On the other hand, our respondents work at the core of data processing and analysis, which means that their role is also to handle the data ethically. Some respondents mentioned that they assume that compliance with rules and regulations is being taken care of by other departments of their organization or other people within the LHS, and therefore, they did not worry so much about the ethical handling of data. However, compliance with rules and regulations is a narrow understanding of handling data ethically because it often solely refers to protecting the privacy and confidentiality of persons whose personal data are being processed—an aspect extensively discussed in the interviews and sometimes perceived as a complicating factor for research. Although many respondents viewed contributing to ConcePTION as an opportunity to generate new information for pregnant and lactating people, there appears to be a lack of widespread moral responsibility toward handling data from the perspective of pregnant and lactating people. Some respondents also considered pregnant and lactating people themselves to be disconnected from the work they are responsible for. However, during the member check, some respondents expressed that they did not feel accurately represented in the portrayal of their views on this topic. For them, it was important to recognize that they feel responsible for contributing to the ConcePTION project [25].

Trust and Transparency

Interestingly, trust and transparency were discussed as important aspects of the relationship between the participating organizations. Respondents explained that trust and open-mindedness are important conditions for working toward a common data model and getting everyone to share the same vision for the LHS. In the literature on public-private partnerships, big data research, and data-intensive research in health care, trust is also often mentioned as a crucial principle for effective collaboration [10,26,27]. During the interviews, there was hesitancy among respondents about the prospects of public-private collaboration. Some respondents mentioned that they believe they are officially constrained by their institution to closely collaborate with the pharmaceutical industry or cannot share any data (pseudonymized or not) with the pharmaceutical industry. This constraint challenges the effectiveness of the collaboration and, as a result, might complicate the development of a sustainable LHS as a public-private partnership. Interestingly, the ConcePTION project currently operates as a consortium under a consortium agreement, making reference to the European Network of Centers for Pharmacoepidemiology and Pharmacovigilance code of conduct (2010) [28]. The European Network of Centers for Pharmacoepidemiology and Pharmacovigilance code of conduct aims to maximize transparency and promote scientific independence. Furthermore, a consortium agreement typically addresses the issues of a conflict of interest by making agreements on ownership and intellectual property, obligations and rights of the participating parties, and third-party agreements. It seems that although many of the concerns of our respondents are addressed in the consortium agreement, they are not aware of these arrangements or they still experience dilemmas regarding the collaboration and their own interests, which can lead to a continued lack of trust between the public and private industries. It might be worthwhile to close this gap between the consortium agreements and the experiences of collaborators by ensuring that everyone understands the consortium structure. In the literature on large research consortia, it has been argued that transparency is important for realizing an appropriate governance framework for these types of complex collaborations. Here, transparency refers to the accessibility and visibility of the governance structures. For example, within a consortium, good governance requires that those internal or external to the project know what governance structures and procedures are in place, what mechanisms for legitimate decision-making have been adopted, and where the authority and responsibility for different types of actions are located in the consortium [17]. Our interviews underline the importance of transparency in the context of governance of an LHS with public and private organizations. One solution is the installation of a separate independent body, especially when the contractual agreement of the consortium has ended. Some scholars have suggested a Data Access Committee that can help protect persons whose personal data are being processed from foreseeable harm, stimulate social value, and mandate clear lines of accountability, terms of reference, and membership [29].

Public Trust

The above-described perceptions of trust are of course important; however, both the literature and our previous interview study with women during preconception, pregnancy, and nursing show that public trust is also of crucial importance for the development of an LHS [20]. In the literature, it is emphasized that it is important to meet the public expectations for transparency when developing an LHS, which in turn will strengthen or maintain trust in not only the LHS but also the institutions working within the LHS [26]. People anticipate that their voluntary contribution of data will be used to enhance the care for others and they expect that their good faith will not be taken advantage of. Therefore, much depends on the extent to which uses of personal data are seen as serving the public interest and conducted by those with a public interest orientation. It is of great importance that in an LHS, public interest is considered to realize transparency, increase responsibility, and earn the trust of the public. Interestingly, some of our respondents seem to expect that others in their organization are taking care of these principles that are important for public trust or are, again, not fully aware of the governance and arrangements within the organization or the collaboration.

Future of an LHS for Pregnant and Lactating People

Many respondents viewed the ability to conduct scientific research within a broader context as a crucial opportunity. Engaging with a diverse range of organizations can not only enhance the quality of data analyses but also improve the integrity of individual databases. Although research is essential in a knowledge-generating ecosystem, the implementation of research within the health care system is equally important. Respondents affiliated with academic institutions emphasized the significance of publishing new findings in scientific journals, as this is a key aspect of their professional responsibilities. In an LHS, it is imperative to move beyond the conventional practice of publishing primarily in scientific journals and instead prioritize the ethical integration of learning within the delivery of care [30]. This approach would allow for the continuous improvement of care through the application of new insights, while also ensuring the proper management of data. Pharmaceutical companies have already applied this method to a certain extent by generating evidence and translating findings onto product labels and educational materials for health care providers. Perhaps, the dissemination of new insights is an area in which these parties should work together and learn from each other. As LHSs mature, it is crucial that all stakeholders recognize and embrace the system’s necessity and value, extending beyond the project phase to include patients, physicians, scientists, institutional boards, pharmaceutical companies, governments, and other relevant parties.

Limitations

Our study had several limitations. First, we have tried to purposefully include both public and private industry partners; however, we have received more responses from people working in public organizations. Thus, we were not able to include people working in the eastern part of Europe, which challenges the generalizability of our findings, as Eastern European organizations might reflect a different culture and attitude toward an LHS. Second, although we wanted to avoid socially desirable responses, the topic of moral responsibility regarding data handling was not always organically discussed during the interviews. To address this topic, the interviewer directly asked some respondents about their sense of responsibility for specific aspects of their work. Openly discussing the topic could have influenced the initial position of the respondent. We would also like to emphasize that we spoke to individuals who represent their organization in the context of the consortium; however, they do not represent the views of their organizations. Therefore, their views were subjective and might differ from those of other people working in the same organization. It would be interesting to understand the views of DAPs outside the context of pregnancy. As mentioned in the *Introduction* section, in many areas of health care, LHSs are seen as a promising way to learn from real-world data. To establish a successful LHS, more research is needed on the perspectives of the stakeholders involved.

Conclusions

To conclude, people working for DAPs have different reasons for contributing to a project such as IMI ConcePTION, which aims to build an LHS for pregnant and lactating people. The most common motivation was opportunity. The opportunities included creating knowledge on medication safety during pregnancy, examining medication safety in the European context, collaborating with and learning from other experts, stimulating scientific research, presenting their database, and securing financial support. Although many respondents expressed a responsibility to enable real-world data analyses, their focus was primarily on their work and contribution to the project rather than safeguarding ethical data handling from the perspective of pregnant and lactating people. The results of our interviews underline the importance of a transparent governance structure that addresses decision-making processes, authority, responsibility, and accountability. Trust is crucial for the success and sustainability of a public-private LHS, relying on the relationship between DAPs and public trust. For an LHS, it is essential that all relevant stakeholders recognize and embrace the need for and added value of the system itself.

Acknowledgments

The ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now) project received funding from the Innovative Medicines Initiative 2 Joint Undertaking under grant 821520. This Joint Undertaking receives support from the European Union’s Horizon 2020 research and innovation program and European Federation of Pharmaceutical Industries and Associations (EFPIA). The study leading to these results was conducted as part of the ConcePTION consortium. This paper reflects the personal views of the respondents and authors and not necessarily the Innovative Medicines Initiative ConcePTION. The authors are grateful to all respondents for their contribution to this study. The authors would like to thank their contact persons for the support and recruitment of respondents for this interview study.

Data Availability

The data sets generated and analyzed during this study are not publicly available because individual privacy could be compromised. In addition, no permission was obtained from the participants for public availability. The data set is available from the corresponding author (MJH) upon reasonable request.

Authors' Contributions

MJH, RvdG, MC, and MCJMS were responsible for the concept and design of the study. MJH was responsible for recruiting participants. MJH was responsible for data collection, initial drafting of the manuscript, and conducting the thematic analysis, to which RvdG, MCJMS, and JJMvD provided substantial input along the way. RvdG, MCJMS, MC, and JJMvD revised the manuscript critically. All authors approved the final version of the manuscript.

Conflicts of Interest

MCJMS is leading a department that conducts regulatory-required research for COVID-19 vaccine manufacturers based on the European Network of Centers for Pharmacoepidemiology and Pharmacovigilance code of conduct and is the project coordinator of Innovative Medicines Initiative ConcePTION (Continuum of Evidence from Pregnancy Exposures, Reproductive Toxicology and Breastfeeding to Improve Outcomes Now).

Abstract

Background: Recently, digital media, including internet websites and smartphone apps, have become popular resources for parents in searching for child health care information. Higher health literacy among parents in obtaining adequate health care information and making proper decisions may lead to improved child health outcomes and a reduction in the burden on health care professionals. However, few studies have examined the association between the provision of child health care information apps and parents' health literacy.

Objective: This study aims to evaluate whether parents' use of an app that provides child health care information is associated with their health care knowledge, their health literacy, and emergency room visits for their children.

Methods: Participants were recruited during checkups for their 1.5-year-old children at health centers within Saku City in 2022. Parents who agreed to participate were included in this study; individuals were excluded if they were not the mother or father of the child or did not have a smartphone. Participants were asked if they had used the Oshiete-Doctor app, which was distributed by Saku City free of charge to improve the home nursing skills of parents and guardians. Sociodemographic data of parents and children, data on health care knowledge about children, data on the frequency of emergency room visits in the past 6 months, and health literacy scores (HLSs) of parents (measured with the HLS-EU-Q47 [European Health Literacy Survey Questionnaire]) were collected from participants in this cross-sectional survey. Univariable and multivariable analyses were conducted to examine the associations of app use with health care knowledge, health literacy, and emergency room visits.

Results: In total, 251 respondents completed the survey (response rate: 251/267, 94%). Although the proportion of health care workers was significantly higher among app users than among non–app users (*P*=.005), no other participant attributes were significantly associated with the use of the app. The proportions of participants with higher health care knowledge and participants with higher total HLSs were significantly higher among app users than among non–app users (*P*=.001 and *P*=.003, respectively). After adjusting for potentially confounding covariates, these proportions were still significantly higher among app users than among non–app users (*P*=.02 and *P*=.007, respectively). Emergency room visits were significantly more frequent among app users than among non–app users (*P*=.007) in the univariable analysis, but the association was not significant (*P*=.07) after adjusting for sociodemographic variables.

Conclusions: This study showed a significant association between parents' use of a child health care information app and higher child health care knowledge and health literacy. The use of the app may lead to more appropriate health decisions and behaviors in children's health care. Future studies are needed to evaluate the association between app use and emergency room visits.

KEYWORDS

health literacy; European Health Literacy Survey Questionnaire; HLS-EU-Q47; child; preschool; parent education; health care knowledge; apps; digital media; emergency room visit; mobile phone

Introduction

Despite the increased health concerns during the COVID-19 pandemic, parents were discouraged from visiting medical facilities to avoid infection [1], and opportunities for classes and social gatherings to provide health care information to their children were limited. Ishikawa et al [2] reported a decline in health literacy among people during the COVID-19 pandemic.

Health literacy is the ability to access, understand, evaluate, and apply health care information, and it is related to health behaviors and outcomes [3]. Greater parental health literacy in obtaining adequate health care information and making proper decisions may lead to appropriate health care service use, which, in turn, may result in improved child health outcomes while alleviating health care professional burdens.

In recent years, mobile health (mHealth) has emerged as an effective approach to improving health literacy. Digital media, including internet websites and smartphone apps, have become popular resources for parents in searching for health care information [4]. A cross-sectional study conducted in Switzerland reported that >90% of parents with children younger than 2 years use digital media to obtain health care information regarding their children, and their main reason for doing so is having 24-hour access to such information [5]. mHealth apps are wellness programs that are available on smartphones and other mobile devices. In 2017, more than 325,000 mHealth apps became available worldwide [6]. Parents have high expectations for mHealth apps. According to a focus group study in Australia, child-rearing mothers place a high value on using web-based sources and apps to receive information and support [7].

There is great potential for using mHealth apps to obtain information, and an increasing number of initiatives use apps to provide health education [8]. A systematic review showed that IT-based interventions can result in positive health literacy outcomes [9]. For example, providing information via an app, in addition to the traditional method of providing printed booklets during pregnancy, reduces the risk of postpartum depression [10]. Further, a study in China reported that an app-based intervention that included injury prevention significantly improved the safety behaviors of parents of preschool children [11].

The inappropriate use of pediatric emergency departments is a growing concern worldwide [12,13]. In Japan, many municipalities provide free medical care for children. Consequently, many visits to pediatric emergency rooms are nonurgent. Previous studies suggested that lower parental health literacy, in addition to sociodemographic factors, is associated with increased nonurgent emergency room visits [14,15]. One of the possible benefits of improving health literacy through apps is the potential to reduce the inappropriate use of pediatric emergency departments. However, few studies have examined the association between the provision of child health care information apps and parents' health literacy.

Since 2016, we have been conducting a project in which a health care information app for parents—Oshiete-Doctor (which translates to *Doctor, tell me*)—is being used to improve parents' nursing skills at home. This app is free and uses numerous friendly illustrations to make information accessible to parents with low health literacy. The app is supervised by pediatricians and provides information on emergency room visits and knowledge on home care for childhood diseases. The app is expected to help parents make appropriate decisions regarding their children's health care.

This study aimed to evaluate the associations between parents' use of the health care information app and their health literacy, their health care knowledge, and pediatric emergency room visits for their children. We hypothesized that parents using the app would be more likely to have correct knowledge about their children's health care, have higher health literacy, and use the pediatric emergency room less frequently when compared to parents who do not use the app.

Methods

Ethical Considerations

This study was approved by the Institutional Review Board of Teikyo University (approval number: 22-011-2). Participants' selection of the item "Agree to participate" in the introductory statement of the questionnaire was considered as consent to participate in this study. The statement introduced this study and described that participation was voluntary, consent could be withdrawn at any time, data would be anonymized, and participants would be offered a ¥500 (US $3.30) Amazon gift voucher as compensation.

Study Participants and Data Collection

Parents of 1.5-year-old children who participated in the medical checkups provided at 3 health centers in Saku City, Nagano Prefecture, between May 11 and October 5, 2022, were recruited. The principal investigator (MS, a pediatrician) explained the study to each participant, and those who agreed to participate were included in this study.

Individuals were excluded if they were not the mother or father of the child or if they did not have a smartphone. The city staff collected the questionnaires.

Description of the App

The Oshiete-Doctor app, which was developed in 2016, is funded by Saku City and is provided free of charge to improve the home nursing skills of parents and guardians. It provides information on the following five topics: guidelines regarding hospital visits for children who are sick, explanations for child illnesses, information on vaccinations, information on childcare support groups, and disaster countermeasures for children. In Saku City, information regarding the app is distributed to all citizens when they register for birth certificates at the city office. The app is used throughout Japan and has been downloaded nearly 400,000 times.

Measures

Health Literacy Score

The Japanese version of the HLS-EU-Q47 (European Health Literacy Survey Questionnaire) [16] was modified to measure parental health literacy (ie, parents' health literacy scores [HLSs]). The original HLS-EU-Q47 was developed to measure health literacy in the general population based on a conceptual framework reflecting 4 information-processing dimensions (accessing, understanding, appraising, and applying) within 3 health domains (health care, disease prevention, and health promotion) [17], and it has been validated in a Japanese population [15]. The difficulty level of each item was rated on a 4-point Likert scale (1=very difficult; 2=difficult; 3=easy; 4=very easy), with a higher score indicating higher health literacy. In this study, we used 16 questions in the health care domain (items 1-16) by replacing "you" with "your child" to measure parental health literacy related to child health (eg "On a scale from very easy to very difficult, how easy would you say it is to find information about symptoms of illnesses that concern *your child*?"). In the health care domain, health literacy refers to the ability to access information on medical or clinical issues; understand, interpret, and evaluate medical information; make informed decisions on medical issues; and comply with medical advice [17]. We considered the questions in the health care domain to be appropriate for evaluating the competencies that users can improve by referring to the app. First, the app provides information on symptoms of children's illnesses (question 1), treatments (question 2), and emergency procedures (question 3) to help parents access accurate information. Second, this app includes detailed instructions on emergency procedures for children, hospital visits (question 7), and medications (question 6 and question 8) to promote accurate understanding of the information. Third, by providing accurate information that is verified by a physician, the app helps parents improve their competency for evaluating medical information (question 9 and question 12). Fourth, the app introduces recommendations for visiting a doctor and managing children who are sick (question 13), as well as for emergency medical calls (question 15). As a result, the capacity to make decisions and apply medical behaviors can be improved. We included the set of questions used in this survey in Multimedia Appendix 1. The total scores for the health care domain and the subscale scores for each dimension (ie, accessing, understanding, appraising, and applying) within the health care domain were calculated. Following a previous study [18], scores of participants who answered fewer than 80% of the questions were excluded from the analysis. The index score was standardized to unified metrics, ranging from 0 to 50, by using the following formula: (mean − 1) × (50/3). The Cronbach α for the total scale was 0.886. In the analysis, participants were divided into 2 groups based on their median scores. Although binarization may result in information loss, we believed that the benefits of binarization are significant, in that it facilitates data interpretation and reduces model complexity.

Health Care Knowledge

Health care knowledge was assessed by using the following three statements on important and common pediatric emergencies, for which the app provides information: (1) "if your child develops a fever at night, you should take him/her to the hospital immediately, even if he/she is healthy and hydrated"; (2) "when a child is drowning, you should notice because he/she will be making noises"; and (3) "when a child vomits due to gastroenteritis, disinfection with alcohol is effective." Responses to these statements were rated on a 4-point Likert scale (1=agree; 2=somewhat agree; 3=somewhat disagree; 4=disagree), with higher scores indicating better health care knowledge. The total scores for the three statements were calculated as the health care knowledge scores. In the analysis, health care knowledge scores were divided into high or low scores based on the median.

Emergency Room Visits

Respondents were asked about the number of emergency room visits that their children had within the past 6 months.

Use of the Oshiete-Doctor App

The use of the Oshiete-Doctor app was assessed based on their answers to the following question: "Do you use apps for childhood illnesses or well-being?" The respondents were asked to select 1 or more of the following four options: (1) "Oshiete-Doctor app"; (2) "Q-SUKE, the app developed by the Fire and Disaster Management Agency"; (3) "other apps"; and (4) "did not use an app." Based on their responses, respondents were classified as either Oshiete-Doctor app users or Oshiete-Doctor app nonusers.

Sociodemographic Data

We included sex, age, education status, self-rated economic status, current health care worker status, gestational weeks, birth weight, birth order, and past medical history of the children in our analysis. Education status was divided into 3 categories (high school graduate or lower, vocational school and 2-year college, and university graduate or higher) and then classified as "university graduate" or "non–university graduate." With regard to self-rated economic status, participants reported their subjective economic status as "very good," "good," "fair," "poor," or "very poor." Self-rated economic status was then classified as "very good - good," "fair," or "poor - very poor." With regard to current health care worker status, participants who answered that they were health care workers were categorized as "yes," whereas participants who answered that they were not health care workers were categorized as "no." Gestation weeks were classified as either "<37 weeks" or "≥37 weeks." Birth weights were classified as either "<2500 g" or "≥2500 g." Birth order was divided into 4 categories (first, second, third, and fourth or more) and then classified as either "first child" or "second child or more." With regard to the past medical history of the children, participants who answered that their children had any past medical history were categorized as "yes," whereas participants who answered that their children did not have any past medical history were categorized as "no."

Data Analysis and Statistics

Continuous variables were described as summary statistics (mean and SD or median and quartiles), while categorical variables were expressed as frequencies and percentages. The participants were divided into 2 groups based on their use of the Oshiete-Doctor app, and sociodemographic characteristics were compared by using the chi-square test or 2-tailed *t* test.

We also conducted univariable analyses (chi-square test or *t* test) and multivariable analyses (multiple logistic regression analyses) to examine the association between participant demographics and HLSs, as well as the association between emergency room visits and health care knowledge scores.

In the multivariable analysis, we included attributes of parents (sex, age, education, self-rated economic status, and health care professional status) and children (sex, birth order, and past medical history) as variables.

We included these variables because previous studies have shown that they may influence the association between pediatric emergency visits and parental health literacy [19-21]. A *P* value of <.05 was considered statistically significant. Stata 17 (StataCorp LLC) was used to analyze the data.

Results

Respondents' Characteristics

A flowchart of the survey is shown in Figure 1. A total of 251 respondents completed the survey (collection rate: 267/300, 89%; response rate: 251/267, 94%). Of them, 109 (43.4%) used the app. As shown in Table 1, 90.8% (228/251) of the respondents were female, 37.1% (93/251) had a university degree or higher, and 46.2% (116/251) of their children were firstborn. Overall, 20.3% (51/251) of the respondents were health care workers, and this proportion was significantly higher among app users than among non–app users (*P*=.005). No other participant or child attributes were significantly associated with app use.

Figure 1. Study participant flow diagram.

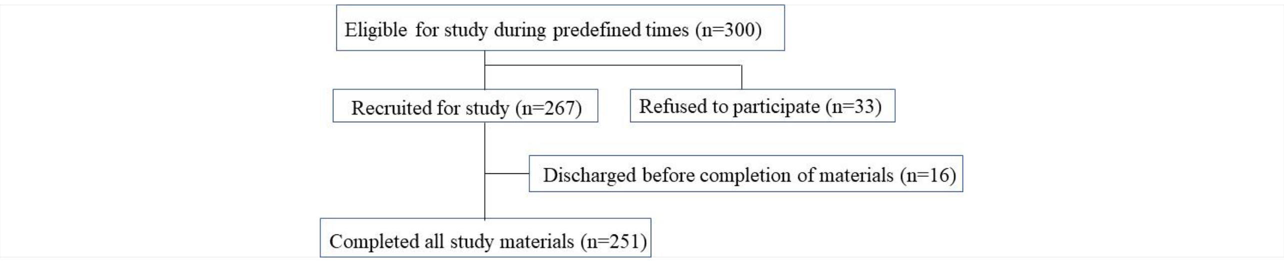

Table . Characteristics of app users and app nonusers.

Characteristics		App users (n=109)	App nonusers (n=142)	All participants (N=251)	*P* value[a]
Sex, n (%)					.08

[a] *P* values were generated using a *t* test or chi-square test.

[b] The "Self-rated economic status" indicates the current financial status of the participants on a 3-point scale ("good"=3; "normal"=2; "poor"=1).The

data were treated as a categorical variable.

[c] Significant at the *P*<.05 level.

Association Between App Use and the Health Care Knowledge Score

Health care knowledge scores were examined in terms of app use (Table 2).

Table . Differences in the proportions of parents with higher health care knowledge scores by app use.

	Univariable analysis			Multivariable analysis	
	App users, n/N (%)	App nonusers, n/N (%)	OR[a] (95% CI; *P* value)	Parents included in analysis, n	aOR[b] (95% CI; *P* value)[c]
High health care knowledge score	80/109 (73.4)	74/142 (52.1)	2.5 (1.5-4.3; .001[d])	218	2.1 (1.1-4.0; .02[d])
High score for knowledge about night fever	99/108 (91.7)	127/141 (90.1)	1.2 (0.5-2.9; .67)	217	0.7 (0.3-2.1; .56)
High score for knowledge about drowning	100/108 (92.6)	133/141 (94.3)	0.8 (0.3-2.1; .58)	197	0.5 (0.1-1.6; .25)
High score for knowledge about alcohol disinfection	80/109 (73.4)	77/141 (54.6)	2.3 (1.3-3.9; .003[d])	217	2.4 (1.3-4.4; .007[d])

[a] OR: odds ratio.

[b] aOR: adjusted odds ratio.

[c] Attributes of caregivers (sex, age, education, economic status, and health care worker status) and children (sex, birth order, and past medical history) are adjusted in the logistic regression analysis.

[d] Significant at the *P*<.05 level.

In the univariable analysis, the proportion of parents with higher health care knowledge scores was significantly higher among app users than among non–app users (*P*=.001), and the proportion of parents with higher scores regarding alcohol disinfection during gastroenteritis was significantly higher among app users than among non–app users (*P*=.02).

After adjusting for parent and child characteristics in the multivariable analysis, these differences remained statistically significant (*P*=.003 and *P*=.007, respectively).

Association Between App Use and Health Literacy

The mean HLS of the participants was 24.2 (SD 7.3). The differences in the proportions of parents with higher health literacy, as measured with health care-related subscales of the HLS-EU-Q47, by app use, are shown in Table 3.

In the univariable analysis, the proportion of parents with higher total HLSs was significantly higher among app users than among app nonusers (*P*=.03), and the proportion of parents with higher HLSs for the evaluation subscale was significantly higher among app users than among app nonusers (*P*=.03).

After adjusting for parent and child characteristics in the multivariable analysis, the difference in the proportion of parents with higher total HLSs between app users and app nonusers remained statistically significant (*P*=.008).

Table . Differences in the proportions of parents with higher health literacy, as measured with health care–related subscales of the HLS-EU-Q47[a], by app use.

	Univariable analysis			Multivariable analysis	
	App users, n/N (%)	App nonusers, n/N (%)	OR[b] (95% CI; *P* value)	Parents included in analysis, n	aOR[c] (95% CI; *P* value)[d]
High total score	53/102 (52)	50/132 (37.9)	1.8 (1.1-3.0; .03[e])	206	2.2 (1.2-4.0; .008[e])
High access score	55/105 (52.4)	66/133 (49.6)	1.1 (0.7-1.9; .67)	209	1.1 (0.6-2.0; .76)
High understanding score	68/108 (63)	78/141 (55.3)	1.4 (0.8-2.3; .23)	216	1.3 (0.7-2.4; .34)
High evaluation score	53/108 (49.1)	49/140 (35)	1.8 (1.1-3.0; .03[e])	215	1.8 (0.99-3.2; .056)
High application score	48/107 (44.8)	50/135 (37)	1.4 (0.8-2.3; .22)	211	1.8 (0.96-3.2; .07)

[a] HLS-EU-Q47: European Health Literacy Survey.

[b] OR: odds ratio.

[c] aOR: adjusted odds ratio.

[d] Attributes of caregivers (sex, age, education, economic status, and health care worker status) and children (sex, birth order, and past medical history) are adjusted in the logistic regression analysis.

[e] Significant at the *P*<.05 level.

Association Between App Use and Emergency Room Visits

In the univariable analysis of the association between a history of emergency room visits in the past 6 months and app use, emergency room visits were significantly more frequent among app users (26/102, 25.5%) than among non–app users (15/130, 11.5%; odds ratio [OR] 2.6, 95% CI 1.3-5.3; *P*=.007). This association was not significant in the multivariable analysis (parents included in analysis: n=216; adjusted OR 1.9, 95% CI 0.94-4.0; *P*=.07), in which the total HLS (a binary variable) was added to the adjusted variables (model 1).

Discussion

Principal Results

This is the first study to examine the associations between the use of an app for parents that was developed in Japan and child-rearing parents' health care knowledge, their health literacy, and emergency room visits for their children. The mean HLS of the participants was 24.2 (SD 7.3), which is similar to that in previous studies [16,22]. Recently, the internet has become an indispensable tool for gathering information, and mobile apps have played a significant role. Similarly, a greater number of maternal and child health interventions using mHealth technology have been observed in the field of maternal and child health [23], and mobile apps are used to support maternal and child health care interventions [24].

Our app provides knowledge about health care for children. A significant association was found between app use and accurate health care knowledge. Fadda et al [25] reported that their smartphone app intervention for parents increased parents' knowledge of measles-mumps-rubella vaccination and parents' psychological empowerment toward vaccinating their children. They demonstrated the effectiveness of interventions that use mobile devices to provide information. These findings are consistent with those of our study. However, in our study, there were no statistically significant differences between app users and app nonusers with high scores for the statement about visiting the emergency room at night if their child had a fever (*P*=.56) and the statement regarding their response to their child drowning (*P*=.25). This may be because these two statements were easy for most participants to answer correctly (correct answers for the statement about night fever: 226/249, 90.8%; correct answers for the statement about drowning: 233/249, 93.6%).

This study found a significant association between app use and parental health literacy. The measure of health literacy used in this study was designed to assess the subjective manageability of health-related tasks, focusing on both individuals and the underlying circumstances in which health-related tasks are performed [26]. The use of the Oshiete-Doctor app may lower the barriers to accessing, understanding, appraising, and applying health care information and thus result in the greater manageability of child health care.

Contrary to our expectations, we found a positive association between the use of the app and emergency room visits in the past 6 months. However, a systematic review reported an association between low parental health literacy and increased emergency room visit rates [27]. One possible reason for the contradictory result from the systematic review is that our study did not evaluate the appropriateness of emergency room visits. Although we hypothesized that the use of the app would reduce unnecessary emergency room visits, a higher emergency room visit rate may reflect more careful attention to the child and appropriate decisions based on the app. Another possibility is that the parents may have downloaded the app after experiencing an emergency room visit. In the region where this study was conducted, the app is widely known among health care professionals, who may have recommended the app to parents who visited the emergency room. Future studies are needed to evaluate the association between app use and emergency room visits.

Limitations

There are several limitations to this study. First, the HLS-EU-Q47 has a limitation in its self-reporting formula. Therefore, the survey results may reflect the subjective manipulation of the participants and may not always correspond to the objective findings. However, it has been used for comparative studies in other countries, and there is also a Japanese version [16]; therefore, its reliability and validity have already been established, which is why it was chosen in our study. Second, this study was observational and could not rule out the influence of confounding environmental factors (except for the use of other apps) that could have contributed to the increase in parents' health literacy. In addition, as this was a cross-sectional study, there is a possibility of causal reversal. Third, a high proportion of medical personnel was observed in this study (51/251, 20.3%). Nagano Prefecture, which includes Saku City, has more medical personnel per 100,000 people when compared to the national average. For example, the number of public health nurses per 100,000 people is 82.6, which is nearly double the national average (44.1 per 100,000 people) and makes Nagano Prefecture the region with the most public health nurses in the country [28]. Therefore, it may be difficult to apply our results to parents of 1.5-year-old children from other regions. However, this study exhibits small participant bias because it was conducted with participants of a municipal infant health examination. In Japan, health checkups are available for all infants, and the follow-up rate is very high. In addition, the collection rate was very high because of the full cooperation of the city. Therefore, the results are expected to accurately reflect the reality of parents raising infants and children in this region.

Conclusions

This study showed a significant association between parents' use of a child health care information app and higher health literacy and health care knowledge. The use of the app may help parents increase their knowledge and ability to manage their children's health by lowering barriers to accessing, understanding, evaluating, and applying health information. Future studies are needed to evaluate the impact of app use on health behaviors, including emergency room visits.

Acknowledgments

The authors express their sincere gratitude to the participating health care centers and all the individuals involved in this study. The authors would also like to thank Editage for English language editing. This study was supported by JSPS (Japan Society for the Promotion of Science) KAKENHI (grant number: 20H03919).

Data Availability

Data are available from the co-corresponding authors (MS and HI) on reasonable request.

Authors' Contributions

MS and HI equally contributed to the manuscript as the co-corresponding authors. MS and HI conceptualized and designed the study. MS collected, analyzed, and interpreted the data and drafted the initial manuscript. AS and HI supervised data collection and contributed to the analysis and interpretation of the data. All authors critically reviewed and revised the manuscript, approved the final manuscript as submitted, and agreed to be accountable for all aspects of this study.

Conflicts of Interest

None declared.

Abstract

Background: A concussion is a common adolescent injury that can result in a constellation of symptoms, negatively affecting academic performance, neurobiological development, and quality of life. Mobile health (mHealth) technologies, such as apps for patients to report symptoms or wearables to measure physiological metrics like heart rate, have been shown to be promising in health maintenance. However, there is limited evidence about mHealth engagement in adolescents with a concussion during their recovery course.

Objective: This study aims to determine the response rate and response rate patterns in concussed adolescents reporting their daily symptoms through mHealth technology. It will also examine the effect of time-, demographic-, and injury-related characteristics on response rate patterns.

Methods: Participants aged between 11-18 years (median days since injury at enrollment: 11 days) were recruited from the concussion program of a tertiary care academic medical center and a suburban school’s athletic teams. They were asked to report their daily symptoms using a mobile app. Participants were prompted to complete the Post-Concussion Symptom Inventory (PCSI) 3 times (ie, morning, afternoon, and evening) per day for 4 weeks following enrollment. The primary outcome was the response rate pattern over time (by day since initial app use and the day since injury). Time-, demographic-, and injury-related differences in reporting behaviors were compared using Mann Whitney *U* tests.

Results: A total of 56 participants were enrolled (mean age 15.3, SD 1.9 years; n=32, 57% female). The median response rate across all days of app use in the evening was 37.0% (IQR 27.2%-46.4%), which was significantly higher than the morning (21.2%, IQR 15.6%-30.5%) or afternoon (26.4%, IQR 21.1%-31.5%; *P*<.001). The median daily response was significantly different by sex (female: 53.8%, IQR 46.2%-64.2% vs male: 42.0%, IQR 28.6%-51.1%; *P*=.003), days since injury to app use (participants starting to use the app >7 days since injury: 54.1%, IQR 47.4%-62.2% vs starting to use the app ≤7 days since injury: 38.0%, IQR 26.0%-53.3%; *P*=.002), and concussion history (participants with a history of at least one prior concussion: 57.4%, IQR 44.5%-70.5% vs participants without concussion history: 42.3%, IQR 36.8%-53.5%; *P*=.03). There were no significant differences by age. Differences by injury mechanism (sports- and recreation-related injury: 39.6%, IQR 36.1%-50.4% vs non–sports- or recreation-related injury: 30.6%, IQR 20.0%-42.9%; *P*=.04) and initial symptom burden (PCSI scores greater than the median score of 47: 40.9%, IQR 35.2%-53.8% vs PCSI scores less than or equal to the median score: 31.9%, IQR 24.6%-40.6%; *P*=.04) were evident in the evening response rates; however, daily rates were not statistically different.

Conclusions: Evening may be the optimal time to prompt for daily concussion symptom assessment among concussed adolescents compared with morning or afternoon. Multiple demographic- and injury-related characteristics were associated with higher daily response rates, including for female participants, those with more than 1 week from injury to beginning mHealth monitoring, and those with a history of at least one previous concussion. Future studies may consider incentive strategies or adaptive digital concussion assessments to increase response rates in populations with low engagement.

Introduction

Concussion is a significant public health problem that affects approximately 20% of adolescents in the United States each year [1,2]. The prevalence of lifetime concussions has been estimated to be between 6.5% and 18.3% among adolescents aged 13-17 years [3], with approximately 13.7% experiencing persistent symptoms for at least 3 months [4]. Given the critical developmental changes that occur during this period, persistent symptom burden and delayed recovery from concussion may negatively affect adolescents' neurobiological and cognitive development [5].

Adolescents with a concussion can present with a variable symptom burden and recovery trajectories. Prior studies have shown that sex, age, nonadherence to medical care, injury mechanism, and previous history of concussion have been associated with prolonged recovery times [6-9]. For example, patients less likely to adhere to follow-up recommendations had a higher risk of prolonged recovery than those who demonstrated consistent medical adherence [9]. Given the variability in symptom burden and recovery, concussion evaluation, treatment, and follow-up recommendations must be individualized for each adolescent [10]. For instance, based on an individual's symptom constellation, treatments could be tailored into multiple lines such as cognition, vision, and behavioral therapies [10-12]. Individualized treatment relies on the real-time monitoring of symptoms in natural environments [13].

The adoption of ecological momentary assessments using mobile health (mHealth) has increased for monitoring disease prognosis and rehabilitation [14,15], and can be used in concussion symptom monitoring. mHealth apps have been developed for patients with a concussion to report their real-time symptoms and activities multiple times per day to collect more granular information on symptom trajectory than is provided during periodic clinic visits [16,17].

Previous studies have used mHealth technology to facilitate follow-up for patients with traumatic brain injury, providing an opportunity for patients to report important details on the variability of symptoms and other sequelae [14,18]. Patients can provide real-time symptoms instead of relying on memory at the next in-person visit, which can be influenced by recall bias [19]. Documenting symptom presence and intensity in the moment can improve the reliability of self-report data and augment care individualization. While these studies show promise for these mHealth technologies, understanding the parameters that influence a patient's engagement with the technology is critical to optimizing future implementation. Adolescents represent a unique patient population in this regard, as they are both high users of mobile technology while at the same time generally less engaged health care consumers [20]. In a systematic review, Wen et al [15] summarized nearly 20 studies that used mHealth technology to engage youth from a variety of clinical settings, reporting that patients on average responded to 77% of the prompts. These studies examined a wide range of patient behaviors across several diseases. Specific to concussion, several studies examined mHealth technologies to track symptoms or activity after injury. Reporting behaviors (eg, response rate) ranged from 50% to 90% due to differing assessments, tracking frequencies, and duration of follow-up [15-17,21,22]. Furthermore, these studies tend to reduce response rates to a single number (eg, the percentage of days in which participants completed responses divided by the number of prompts received [15,23]), with limited exploration of variability in response patterns within a day, across recovery duration, or by certain patient or injury characteristics. Understanding trends and factors influencing adolescent reporting behaviors is important to assist both clinicians and researchers in designing mHealth strategies to investigate concussion recovery trajectories and provide individualized management strategies.

The objectives of this study were to determine the response rate pattern over time to prompts for reporting daily symptoms in concussed adolescents through mHealth technology; identify the time of day when response rates were the highest; and examine the effect of time-, demographic-, and injury-related characteristics on response rate patterns.

Methods

Ethical Considerations

This study was approved by the Children's Hospital of Philadelphia institutional review board (17-013875 and 18-014862). Participants or their parents or legal guardians provided verbal assent or written informed consent. Of note, while participants received a financial incentive to participate in the overall study, they did not receive additional compensation to respond to the mHealth prompts. Data were deidentified.

Study Design and Participants

This study was a prospective observational cohort study approved by our institution's review board. Participants with a concussion aged 11-18 years were recruited between September 28, 2018, and June 8, 2021, from the concussion clinic of our tertiary care academic medical center and a suburban school's athletic teams as part of a larger prospective observational study [24]. The diagnosis of concussion was made by a trained sports medicine pediatrician following the most recent international consensus statement on concussion [25]. All participants had an initial in-person clinical assessment, either as part of a clinic visit or in the school's athletic training room, within 28 days of injury. Enrollment in the mHealth study could occur at this initial visit or a subsequent visit. Participants were excluded from enrollment in the larger study if they were still recovering from a previous concussion (or within 30 days of clearance from a previous concussion). Participants were excluded from this analysis if there were missing demographic or injury variables. Injury mechanism and concussion history were not recorded for 1 participant, who was thus excluded from specific subgroup analyses.

Upon enrollment, participants were instructed to download the mHealth tool onto their smartphones via an SMS text message invitation. This tool allowed the participants to report their symptoms 3 times daily for 28 days following enrollment. The details of the mHealth tool are described below.

For analyses, participant age, sex, date of injury, injury mechanism, and concussion history were abstracted from the electronic medical record.

mHealth Tool

Recovering Concussion Update on the Progression of Symptoms (ReCoUPS) is a mobile app protocol developed by the study team for patients to report real-time symptoms and activities following concussion. The ReCoUPS app “pings” (prompting with a chime or vibration) participants 3 times per day: morning (9 AM to 1 PM), afternoon (4-7 PM), and evening (8 PM). Participants reported symptoms using the Post-Concussion Symptom Inventory (PCSI) [26]. The adolescent PCSI (used for participants aged ≥13 years) includes 21 concussion symptoms rated using a 7-point Likert scale from 0 (none) to 6 (severe), with total symptom scores ranging from 0 to 21 and total symptom severity scores ranging from 0 to 126. The child PCSI (used for younger children aged <13 years) is a 17-item symptom checklist with symptoms rated on a 3-point scale from 0 (none) to 2 (a lot), with total symptom scores ranging from 0 to 17 and total symptom severity scores ranging from 0 to 34. The PCSI has been demonstrated to be a valid and reliable symptom assessment in the pediatric setting [26].

Data Analysis

The response rate was computed through 2 time-based approaches: (1) response rate by days since first app use and (2) response rate by days since injury. The two response rates examine response trends over time, examining the median response across days following injury. These 2 time-based response rates differ from one another as patients enrolled in the app during regular clinical visits that occurred at varying times since injury.

Specifically, response rate by days since first app use and response rate by days since injury were calculated as the number of completed prompts on a given day divided by the number of prompts received on that day across all participants for each day since first app use and each day since injury, respectively. Response rate was examined both by session time (morning, afternoon, and evening prompts; equation 1 in Multimedia Appendix 1) and daily (responding at least once per day, equation 2 in Multimedia Appendix 1). Thus, response rate by day represents the percentage of participants who completed prompts each session time (or at least once daily) on each day (ie, single value per day and time series for response rate trend).

Additionally, subgroup response rates were computed. Subgroups included demographics (sex and age), injury features (injury mechanism, concussion history, initial symptom burden on enrollment), and time between the date of injury and date of first app use (ie, days from injury to app use). The age range was categorized as younger teens (ie, ages 11-14 y) and older teens (ages 15-18 y). Days from injury to app use was categorized into two groups: ≤7 days and >7 days. Initial symptom burden was categorized into two groups based on the median initial PCSI score of the overall sample: ≤47.0 points and >47.0 points. Since there were only complete initial PCSI scores for children aged 13-18 years, this scale was relevant for all participants with valid data.

Descriptive statistics were used to summarize demographic and injury characteristics. For continuous variables, means with SDs were computed for normally distributed data, and medians with IQRs were computed for skewed data. For categorical variables, frequencies were computed. For each type of response rate, the Friedman test was used to examine the differences in response rate based on session time (ie, morning, afternoon, and evening). Post hoc analyses were performed via pairwise Mann Whitney *U* test with Bonferroni *P* value adjustment. Differences in response rate by days since first app use were tested across demographic-related (ie, sex and age), injury-related (ie, injury mechanism, concussion history, and initial symptom burden on enrollment), and days from injury to app use subgroups through Mann Whitney *U* tests. Comparisons of response rate by days since injury based on sex, age, injury mechanism, concussion history, and initial symptom burden were performed using Mann Whitney *U* test. Differences in the initial symptom burden at the clinical visit by all subgroups were also tested via Mann Whitney *U* test. All statistical analyses were performed using R version 4.2.2 (R Foundation for Statistical Computing). The significance level was set at .05.

Results

Sample Composition

The final sample included 24 (43%) male participants and 32 (57%) female participants with an average age of 15.3 (SD 1.9) years. The flowchart of participant inclusion is shown in Figure 1. Table 1 summarizes the demographic and injury characteristics of the study cohort. The final injury-related subgroups included 34 (61%) participants with sports- and recreation-related injuries and 21 (38%) with non–sports- and recreation-related injuries. There were 30 (54%) participants with a history of at least one prior concussion and 25 (45%) without concussion history. No significant differences in the initial symptom burden at clinic visits by demographic- and injury-related groups were observed.

Figure 1. Flowchart of participant selection in this study.

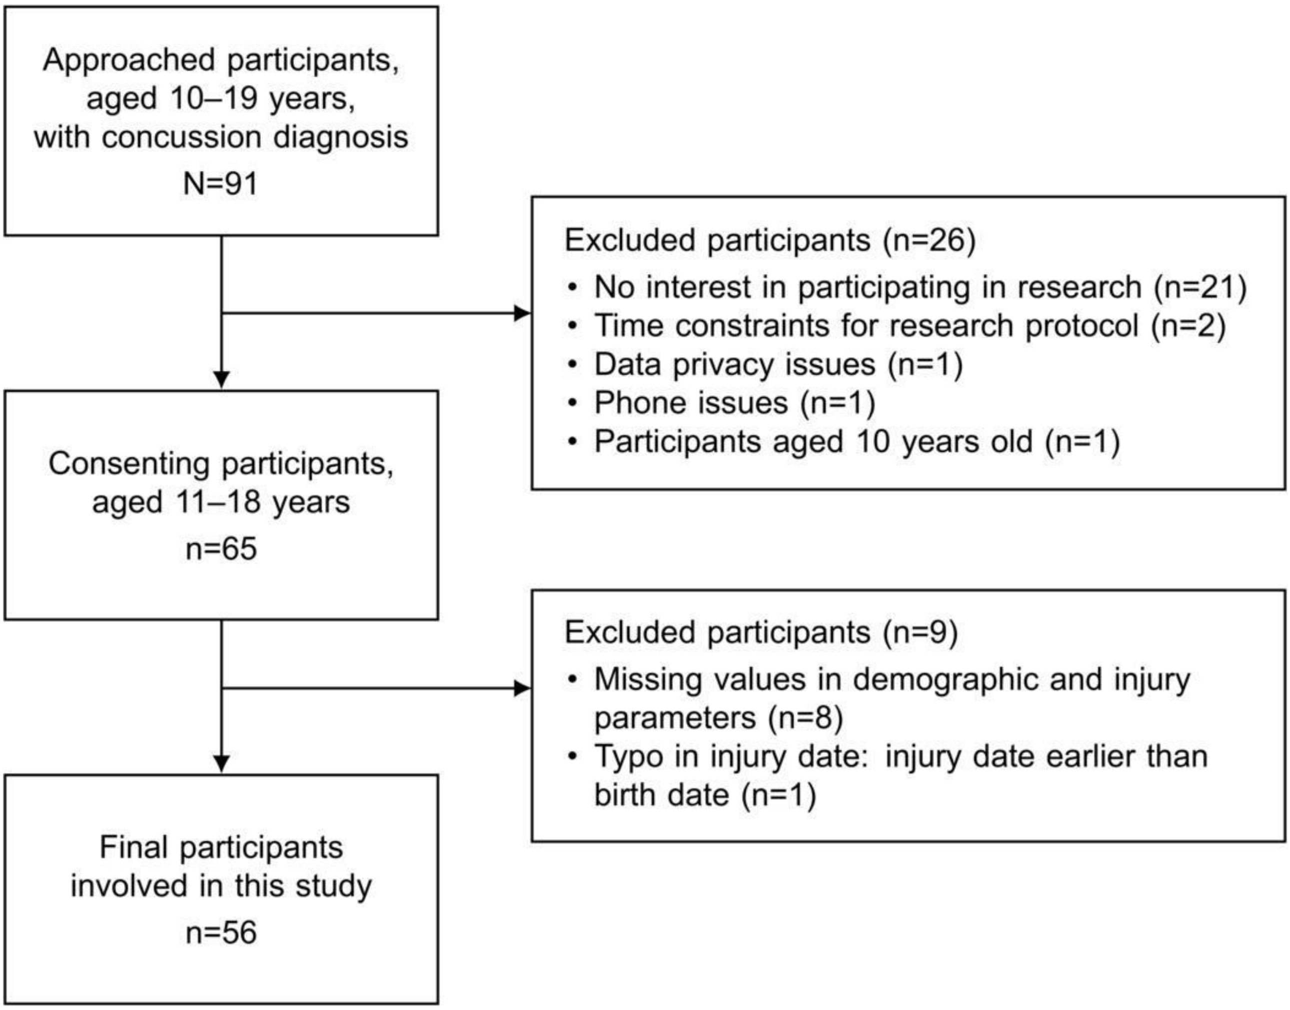

Table . Demographic and injury characteristics of participants (N=56).

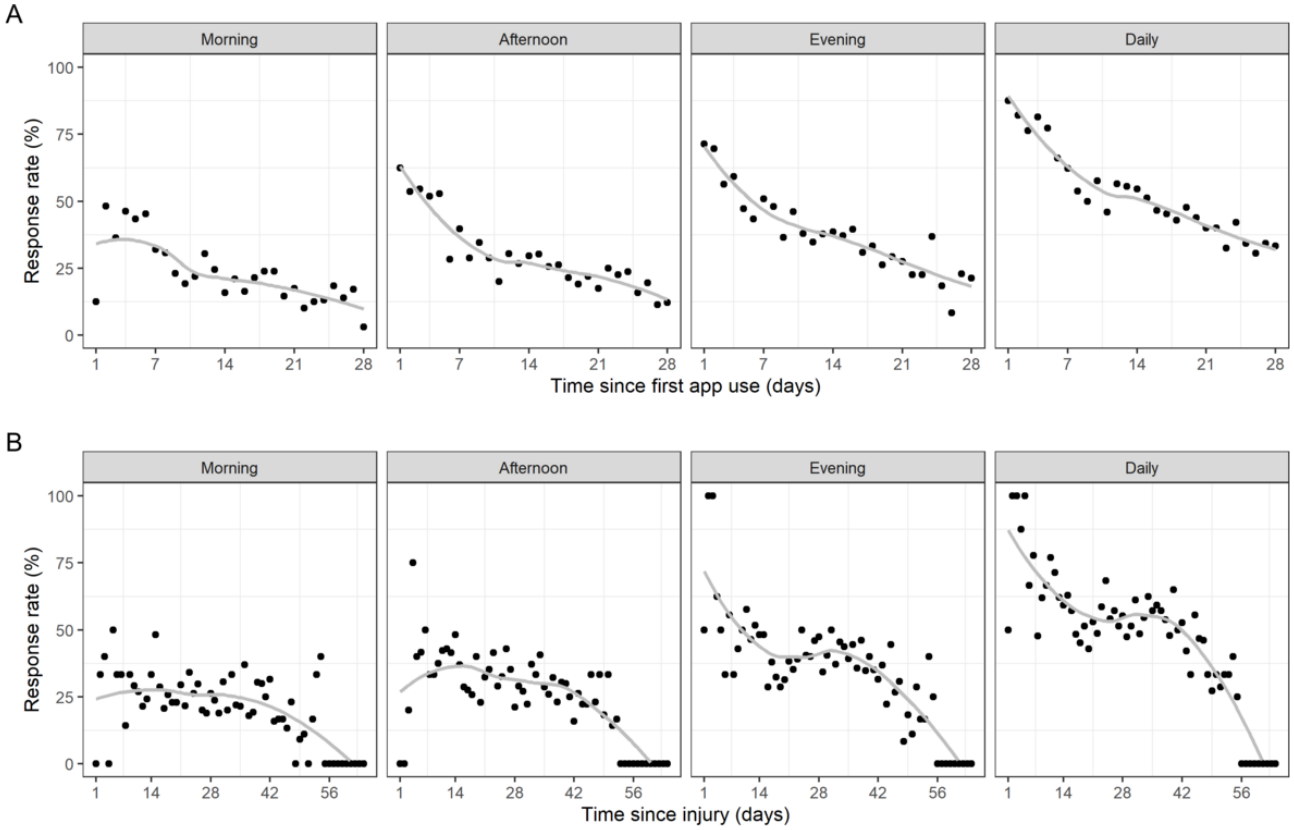
		Value
Sex, n (%)		
	Female	32 (57)
	Male	24 (43)
Race/ethnicity, n (%)		
	Non-Hispanic White	40 (71)
	Non-Hispanic Black	2 (4)
	Hispanic	4 (7)
	Other	10 (18)
Mechanism of injury, n (%)		
	Sports- and recreation-related injury	34 (61)
	Non–sports- and recreation-related injury	21 (37)
	Not reported	1 (2)
Previous history of concussion, n (%)		
	Yes	30 (53)
	No	25 (45)
	Not reported	1 (2)
Age at injury (years), median (IQR)		15.0 (14.0-17.0)
Post-Concussion Symptom Inventory total score at initial clinic visit, median (IQR)		47.0 (27-68)
Days since injury at enrollment, median (IQR)		11.0 (6-21)

Overall Response Rate Pattern

The response pattern varied substantially over time. On average, response rates by days since first app use started high (49/56, 88% of participants responded at least once on the first day of using the app) and decreased by approximately 50% over the duration of the study, with the steepest declines within the first 10 days (Figure 2, top). When considering variations by session time, the evening response rate was generally higher than the morning and afternoon response rates. The daily response rate by days since injury also started high, declined to approximately 50% (18/34) at day 21, plateaued until day 35, and then decreased sharply until the completion of the study period (Figure 2, bottom). The plateau reflects the varying times post injury that participants enrolled in the study (Figure S1 in Multimedia Appendix 1). For example, 23% (15/56) of the participants started using the app between days 21 and 28 post injury.

Figure 2. Response rate pattern by morning, afternoon, and evening, and daily by (A) days since first app use and (B) days since injury. Each black dot indicates the response rate that day, defined as the number of participants who completed prompts divided by the number of participants who received notifications for that day. The solid gray lines represent smoothed trend lines through local regression. A daily response was defined as a participant completing a response at least once per day (morning, afternoon, or evening).



Response Rates by Days Since First App Use

Figure 3 and Table 2 show comparisons of response rate patterns by days since first app use for time-, demographic-, and injury-related groups. Overall, the evening response (median 37.0%, IQR 27.2%-46.4%) was significantly higher than the morning response (median 21.2%, IQR 15.6%-30.5%; *P*<.001). For demographic-related comparisons, many of the differences were driven by differences in the evening response rates. For female patients with concussion, evening (median 44.4%, IQR 33.0%-52.6% vs median 25.0%, IQR 14.3%-34.1%; *P*<.001) and daily response rates (median 53.8%, IQR 46.2%-64.2% vs median 42.0%, IQR 28.6%-51.1%; *P*=.003) were significantly higher than those in male patients with concussion. There were no significant differences by age. For injury-related comparisons, afternoon (median 30.4%, IQR 24.7%-39.0% vs median 24.3%, IQR 14.0%-30.9%; *P*=.04) and evening response rates (median 39.6%, IQR 36.1%-50.4% vs 30.6%, IQR 20.0%-42.9%; *P*=.04) in the sports- and recreation-related injury group were significantly higher than those in the non–sports- and recreation-related injury group; however, daily rates were not statistically different. Participants with a history of at least one prior concussion had significantly higher responses rates at every session time than those without injury history (eg, median daily response rate: 57.4%, IQR 44.5%-70.5% vs 42.3%, IQR 36.8%-53.5%; *P*=.03). Participants who started to use the app after 7 days post injury demonstrated significantly higher morning (median 23.8%, IQR 17.2%-34.6% vs median 14.3%, IQR 8.9%-23.9%; *P*=.006), evening (median 42.1%, IQR 31.0%-53.0% vs median 22.6%, IQR 16.4%-38.2%; *P*=.002), and daily responses rates (median 54.1%, IQR 47.4%-62.2% vs median 38.0%, IQR 26.0%-53.3%; *P*=.002) than those who started to use the app sooner. Participants whose initial symptom burden was larger than the median PCSI score showed higher evening response rates than those whose burden was smaller than or equal to the median PCSI score (median 40.9%, IQR 35.2%-53.8% vs median 31.9%, IQR 24.6%-40.6%; *P*=.04); however, daily rates were not statistically different.

Figure 3. Comparisons of daily response rate by days since first app use by (A) sex, (B) age group, (C) days from injury to app use, (D) concussion history, (E) initial symptom burden, and (F) injury mechanism. The solid lines represent smoothed trend lines through local regression. Daily response was defined as a participant completing a response at least once per day (morning, afternoon, or evening). Response rate was defined as the number of participants who completed prompts divided by the number of participants who received notifications for that day. PCSI: Post-Concussion Symptom Inventory.

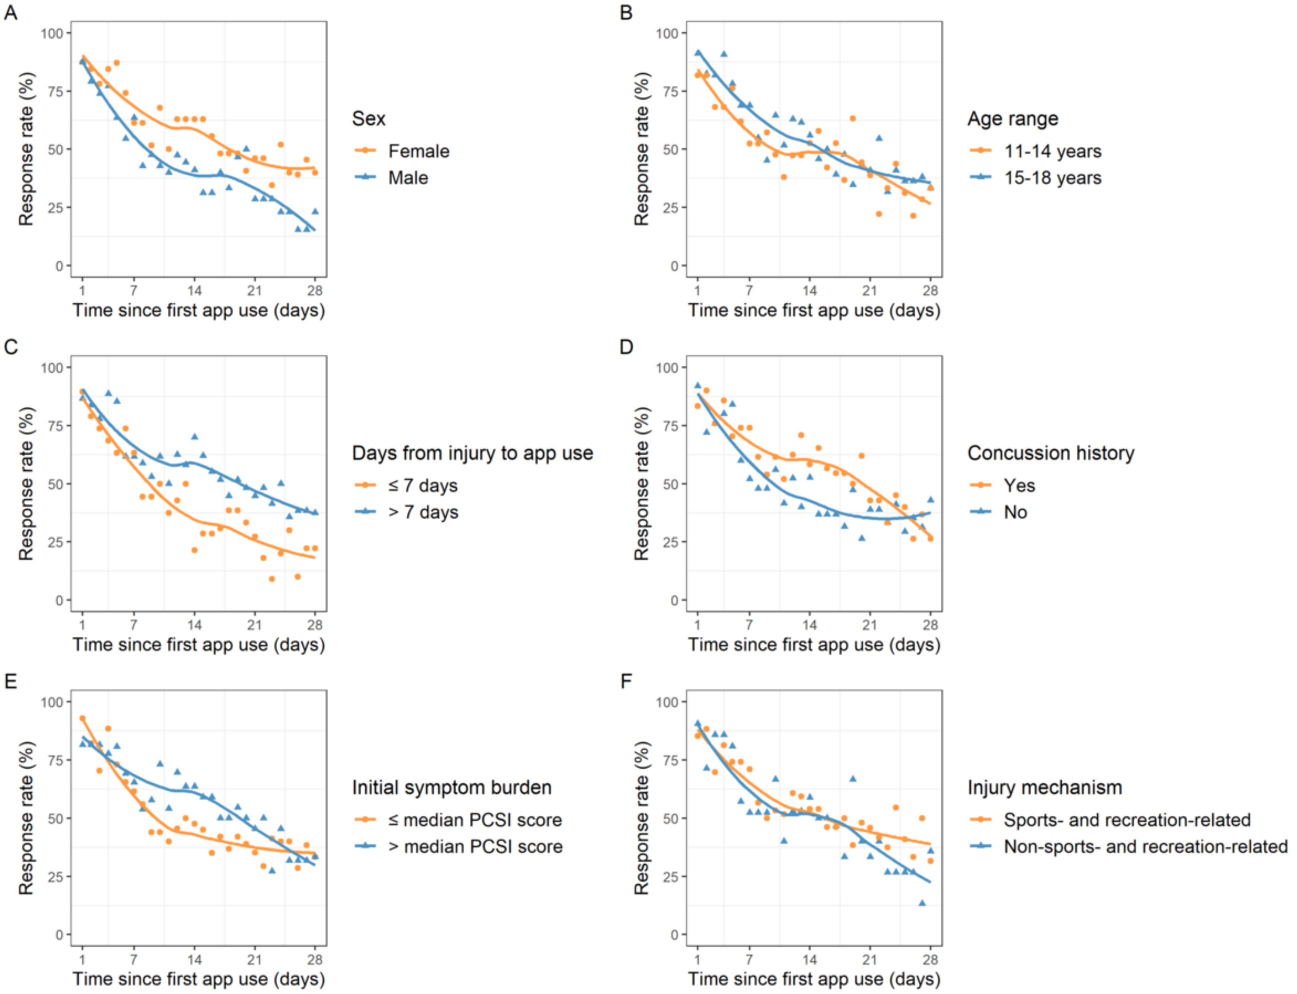


Table . Response rate by days since first app use overall and by time-, demographic-, and injury-related features. The value in the table represents the median response rate across the reporting days and is complementary to the time trends in Figure 3.

Variables	Morning (%)		Afternoon (%)		Evening (%)		Daily (%)	
	Median IQR	*P* value	Median IQR	*P* value	Median IQR	*P* value	Median IQR	*P* value

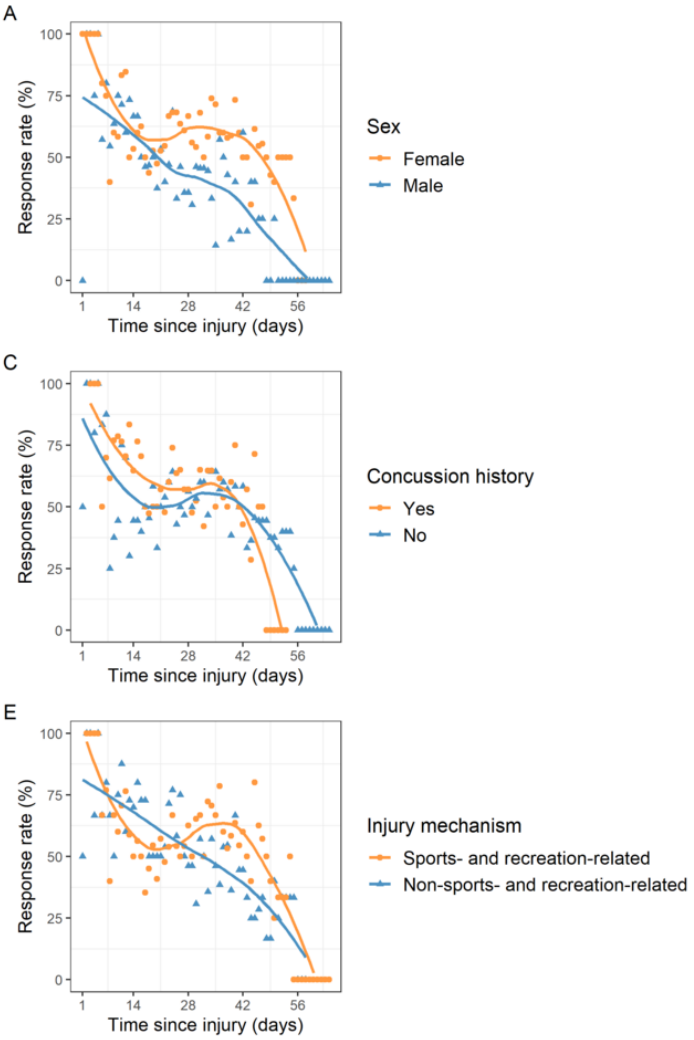
Response Rates by Days Since Injury

Figure 4 and Table S1 in Multimedia Appendix 1 show comparisons of response rate patterns by days since injury for demographic- and injury-related groups. Plateau periods were observed approximately 3-6 weeks post injury. Some of the subgroup patterns for days since injury followed those reported for days since app use. Evening response rates (median 37.0%, IQR 26.3%-46.0%) were significantly higher than morning (median 21.7%, IQR 12.8%-30.1%; *P*<.001) or afternoon response rates (median 28.1%, IQR 16.4%-35.1%; *P*=.003). Session and daily response rates in female patients with concussion were significantly higher than those in male patients with concussion (eg, median daily response rate 58.1%, IQR 50.0%-67.7% vs median 40.0%, IQR 0.0%-55.2%; *P*<.001). Participants with a history of at least one prior concussion had significantly higher session and daily response rates than those without a history of concussion (eg, median daily response rate 57.1%, IQR 50.0%-70.3% vs 45.5%, IQR 37.2%-58.3%; *P*=.003). Effects of injury mechanism and initial symptom burden were no longer significant when considering days since injury (*P*=.07-.88), and age group began to show an effect, with older teens demonstrating a slightly higher daily response rate than younger teens (median 54.4%, IQR 43.0%-66.7% vs median 50.0%, IQR 35.6%-57.1%; *P*=.03).

Figure 4. Comparisons of daily response rate by days since injury by (A) sex, (B) age group, (C) concussion history, (D) initial symptom burden, and (E) injury mechanism. The solid lines represent smoothed trend lines through local regression. Daily response was defined as a participant completing a response at least once per day (morning, afternoon, or evening). Response rate was defined as the number of participants who completed prompts divided by the number of participants who received notifications for that day. PCSI: Post-Concussion Symptom Inventory.



Discussion

The purpose of this study was to investigate the self-reporting of symptom behaviors via an mHealth app (ReCoUPS) among adolescents with a concussion. Generally, response rate patterns varied between and within participants and days. Approximately half of the study sample responded at least once per day, with the evening representing the session time with the highest engagement across the enrollment period. Multiple demographic- and injury-related characteristics were associated with higher daily response rates, including female participants, longer time from injury to initiating mHealth monitoring, and history of a previous concussion. While not significant when considering daily response rates, there were session time differences in response rate by initial symptom burden and injury caused by sports and recreation activities. Responses by age did not show significant differences.

As expected, response rates started high, with nearly 90% of patients responding at least once on the first day of app use, then declined over time. Participants were not given reminders aside from the scheduled “pings” to complete a symptom evaluation. A prior study using a similar version of this app explored different incentive strategies and demonstrated how features like incentives that are more engaging and motivating for youth can increase response rates [27]. The decreasing engagement may reflect concussion recovery, as symptom presence and severity decreased over time in the studies using mHealth technology to monitor patients with a concussion [17,21,28,29]. Regarding response patterns across the three daily time points used in this study, evening (ie, prompts were sent at 8 PM and remained open until midnight) had the highest response rate and may be the optimal time to prompt adolescents in assessing their concussion symptoms. As evening hours may be less busy from school and extracurricular commitments, adolescents may prefer spending time in other activities using electronic devices (eg, smartphones and tablets), increasing the chance to respond to mHealth prompts.

Our findings reiterate the importance of sex differences in concussion. Female adolescents showed significantly higher response rates than male adolescents over recovery duration—for both time since injury and time since first app use. Factors attributing to response differences may be related to the manifestation of sex-based differences in symptoms that stem from differences in anatomy, biological underpinnings, and pubertal stage [6,30,31]. Behavioral expression and socially constructed roles associated with gender may also explain the higher rates in female adolescents [32]. For example, female adolescents have been shown to be more willing to report symptoms after concussion [33] and with greater frequency [6]. Particularly in digital use, female adolescents were found to have stronger motives for interpersonal communication and self-expression than male adolescents [34,35], which may explain why higher response rates were observed in female adolescents while using the mHealth app in this study.

Clear reporting differences existed between adolescents with and without concussion history. Adolescents with a concussion history had nearly twice the morning and afternoon response rates than those with no concussion history. For trends over time, similar patterns were observed. Studies have shown that adolescents with a history of a previous concussion continue to endorse more physical, cognitive, and fatigue symptom domains [36,37], and have longer recovery [8,38] than those without a concussion history. Persistent symptom presence and severity in adolescents with previous concussions may drive them to monitor their symptom patterns more carefully and frequently than those without a concussion history. Additionally, adolescents with a concussion history may have established trustworthy relationships with clinical providers during previous health care visits and, thus, may be more likely to follow assigned mHealth instructions such as reporting daily symptoms.

Adolescents with sports- and recreation-related injury demonstrated slightly higher response rates than those with non–sports- and recreation-related injury, particularly for the afternoon and evening session times. The desire to return to play may primarily motivate adolescents with a concussion to adhere to the instructions from health care providers with the hope of shortening recovery time [39,40]. Especially for adolescent athletes, there is a concern that absence from games or practice can let teammates down or even lead to their replacement on the team [41,42]. Individual desire to maintain team and peer acceptance in sports, and social support may drive adolescents who are injured via sports-related mechanisms to actively engage in mHealth solutions.

The differences in response rate between higher-than-median symptom burden versus lower-than-median symptom burden were inconsistent. For example, evening and daily response rates in participants with higher symptom burden were greater; however, morning response rates showed the opposite trend. High symptom burden may affect self-reporting behaviors both positively and negatively [28]. Adolescents with a concussion and higher symptom burden may demonstrate a stronger motive to engage with medical care compared to those with a lower symptom burden, facilitating mHealth app use to report daily symptoms. Alternatively, electronic devices (eg, computers, mobile phones, and tablets) may induce concussion-related symptoms such as headache and increased sensitivity to light [43,44], which could prevent adolescents with a concussion from adhering to digital health services or interventions. Our finding warrants further study to investigate symptom burden–related barriers that prevent self-reporting to mHealth services.

Reporting behavior was also affected by the time between injury and initial engagement with the app. Our finding showed that adolescents whose first use of the mHealth app was more than 7 days post injury demonstrated greater response rates than those whose first use was within 7 days of injury. Our finding may imply that the adolescents whose symptoms are sustained or even increased after 7 days post injury may have stronger motives in engaging in processes to support their recovery. Early presentation for medical care has been found to lower the risk of prolonged recovery [7,38,45]; therefore, those who present later and thus engage with the app later may be motivated to find ways to relieve symptom burden and may view regular engagement with the app as one means to do so. Encouraging reporting in the early period may be needed to help adolescents and families understand their symptom trajectory as well as how their health care provider can use that information to determine the next steps.

Older adolescents (ages 15-18 y) demonstrated slightly greater daily response rates than younger adolescents (ages 11-14 y), although most differences were not significant. Although it has been suggested that younger adolescents may be more likely to self-report concussions due to less negative perceptions of reporting injuries [46,47], ecological momentary assessment research has suggested that young children may find self-report methods more challenging to engage in [48]. Additionally, a larger foundation of concussion knowledge may guide older adolescents to report symptoms more regularly; previous research has suggested an association between age and concussion knowledge [46,49,50]. The younger participants may be less informed about concussion knowledge and therefore less likely to report.

There were several limitations in this study. First, the sample size in this study was small, though similar to or greater than other mHealth studies on patients with concussion. These data provide guidance for considerations for the implementation of mHealth in future studies of youths with a concussion with larger sample sizes. Second, our study enrolled adolescents aged 11-18 years, but participants were predominantly older adolescents (ages 15-18 years). Thus, the results should not be extrapolated to the younger pediatric population. Third, participants were predominantly White. This limitation warrants further study to investigate the application of mHealth technology in diverse communities, which may help clinicians and researchers understand the barriers to digital health equity, especially for non-Hispanic Black communities [9]. Fourth, because concussion cases were from a specialty care referral program, reporting behaviors may be biased toward adolescents who seek specialist care, which may include a population with more prolonged recovery. Lastly, our response rates were lower than some existing literature [23,29,48]; however, this was likely due to the lack of incentive strategies, lack of reminder prompts, and longer tracking duration compared to those studies. Dynamic incentivization showed higher response rates (IQR 47.6%-82.5%) in youths with concussion from the emergency department setting when tracking their daily symptoms compared with flat incentivization (IQR 20.6%-68.3%) [27].

In summary, adolescents with concussion demonstrated the ability to regularly report concussion symptoms via an mHealth tool in their natural living environment without financial compensation. To optimize future mHealth tool use from both the research and clinical perspectives, and for adolescents with concussion, evening may be the best prompt time. Response rates among adolescents varied by certain demographic- and injury-related characteristics. Multiple groups were more likely to engage in reporting daily symptoms: female patients, those who had a longer time from injury to app use, and those with a history of prior concussions. Using mHealth apps to document symptom presence and intensity daily can improve the reliability of self-reported data on symptom history at regular clinic visit intervals by eliminating the reliance on memory. Accurate and reliable measurement of postconcussion symptoms on a more granular basis than is captured during clinical visits could further improve clinical decision-making for personalized treatment. This is particularly important for a concussion, which is a dynamic traumatic brain injury in which symptom burden can increase or decrease rapidly. To promote adolescents' adherence to mHealth use, especially for those groups who had low engagement in the monitoring app studied herein, future studies may improve mHealth app features like adding reminder prompts and using incentive strategies or adaptive digital concussion assessments to increase response rates.

Acknowledgments

This work was supported by the National Institutes of Neurological Disorders and Stroke of the National Institutes of Health (R01NS097549: multiple principal investigators: Margulies, KBA, and CLM; and 1K23NS128275-01: principal investigator: DJC). Abstract

Background: Milk and egg allergies significantly impact the quality of life, particularly in children. In this regard, food oral immunotherapy (OIT) has emerged as an effective treatment option; however, the occurrence of frequent adverse reactions poses a challenge, necessitating close monitoring during treatment.

Objective: This study aims to evaluate the ability of a new mobile/web app called OITcontrol to monitor milk and egg OIT.

Methods: Patients undergoing milk or egg OIT were recruited and divided into 2 groups: the active group used the OITcontrol app in conjunction with standard written monitoring methods, whereas the control group relied solely on written diaries. Investigators documented hospital doses, hospital reactions, and administered treatments on the website. Patients recorded their daily allergen home-dose intake, home reactions, and administered treatments using the app. The following variables were compared between both groups: number and severity of hospital and reported home reactions, patient's adhesion to the OITcontrol app or written diary or both in terms of daily home-dose intake and home reactions recording, and treatment and dose adjustment compliance at home in case of reaction.

Results: Sixteen patients were assigned to be monitored using the OITcontrol app along with additional written methods (active group), while 14 patients relied solely on a written paper diary (control group). A similar distribution was observed in terms of sex, age, basal characteristics, allergen treated in OIT, premedication, and sensitization profile. Active patients reported a comparable number of hospital and home reactions compared with the control group. In terms of recording system usage, 13/16 (81%) active patients used the OITcontrol app, while 10/14 (71%) control patients relied on the written diary. Among active patients, 6/16 (38%) used both methods, and 1 active patient used only written methods. However, control patients recorded home reactions more frequently than active patients (*P*=.009). Among active patients, the app was the preferred method for recording reactions (59/86, 69%), compared with the written diary (15/86, 17%) or both methods (12/86, 14%; *P*<.001). Treatment compliance in home-recorded reactions was similar between both groups (*P*=.15). However, treatment indications after an adverse reaction were more frequently followed (*P*=.04) in reactions recorded solely in the app (36/59, 61%) than in the written diary (29/71, 41%) or both systems (4/12, 33%). Moreover, compliance with dose adjustments after a moderate-severe reaction in home-recorded reactions was higher in the active group than in the control group (*P*<.001). Home reactions recorded only in the app (16/19, 84%) were more likely to follow dose adjustments (*P*<.001) than those recorded in the written diary (3/20, 15%) or using both methods (2/3, 67%).

Conclusions: The OITcontrol app appears to be a valuable tool for monitoring OIT treatment in children with food allergies. It proves to be a suitable method for recording daily home dose intakes and reactions, and it seems to enhance adherence to treatment indications following an adverse reaction as well as compliance with dose adjustments in home reactions. However, additional studies are necessary to comprehensively grasp the benefits and limitations of using the OITcontrol app in the management of OIT.

adverse reactions; egg allergy; food oral immunotherapy; mHealth; milk allergy; monitoring

Introduction

Food allergies are increasingly prevalent worldwide, particularly within the European population [1]. Children, in particular, often experience allergies to common foods such as eggs and milk, which can lead to severe reactions [2]. Notably, these allergies constitute a significant factor in causing anaphylaxis during early childhood [3]. Research indicates that approximately 50% of children with allergies naturally outgrow their milk and egg allergies. However, a substantial number of patients do not experience spontaneous resolution of these allergies [4,5]. The prevailing method for treating food allergies involves the complete avoidance of the allergen. However, with milk and egg allergies, which are found in numerous everyday foods, steering clear of the allergen is challenging. Consequently, over 20% of children and adolescents who experience anaphylaxis are already aware of the allergen, necessitating avoidance [3]. Indeed, food allergies in children significantly impact the quality of life for parents and caregivers, particularly in terms of the self-management of the condition [6].

Oral immunotherapy (OIT) for food, involving the oral administration of allergens to induce tolerance, has proven to be an effective treatment for persistent food allergies in children, despite the occurrence of frequent adverse reactions [7-9]. In typical OIT protocols, incremental doses of the allergenic food are administered in a hospital setting, and once tolerated, these doses are continued daily at home. This daily allergen consumption continues until the target food dose is reached, marking the completion of the buildup phase [10]. Subsequently, the established target dose is maintained at home to sustain the acquired tolerance, marking the beginning of the maintenance phase. Although most reactions typically occur during the hospital-based buildup phase, it is noteworthy that reactions can also manifest during the maintenance phase, after home dose intake [11,12]. Patients undergo education on avoiding potential cofactors and managing potential reactions at home [13]. Furthermore, it is crucial to adjust the prescribed allergen dose in the event of a reaction [14] or if patients are experiencing an intercurrent disease [10]. This information, along with specific treatment guidelines for addressing reactions at home, is typically conveyed verbally and in writing to caregivers and patients undergoing OIT treatment. Indeed, the management of OIT necessitates vigilant oversight both from the medical staff during hospital-based doses and from patients and their families during home-based doses.

Certain studies have reported an enhancement in the quality of life for patients treated with OIT at the culmination of the buildup phase [15-19]. However, contrasting findings exist, with some studies demonstrating no discernible differences [20] and others even describing a decline in the quality of life for certain patients following OIT treatment [21]. It has been suggested that the absence of improvement in quality of life after OIT could be linked to the numerous hospital visits required during the up-dosing phase [22] and the frequent occurrence of adverse reactions [23].

To assist patients in managing home doses and provide targeted information in conjunction with OIT treatment, a web platform designed for health staff and a hybrid mobile app for patients, named OITcontrol (University of Navarra, Pamplona, Spain), have been developed. OITcontrol enables medical staff to record doses and reactions in the hospital, and caregivers/patients can use it to log information regarding doses and reactions while at home. OITcontrol serves as a reminder for the timing and administration instructions for daily home doses. Additionally, it provides guidance on specific treatments following a reaction and offers evidence-based dose adjustment instructions through dedicated algorithms [24-26].

The objective of this study was to assess the effectiveness of the OITcontrol app in monitoring patients undergoing food OIT treatment, with a focus on (1) evaluating its capability to document adverse reactions occurring at home, and (2) examining patient adherence to specific recommendations regarding home adverse reactions, including prescribed treatment and adjustments for the next day's dose.

Methods

Study Population

This study was conducted in Spain, specifically at the Hospital Universitario Donostia in Donostia-San Sebastián and Hospital Ramón y Cajal in Madrid. The participants were patients aged either 2 years and older for those diagnosed with milk allergy or between 5 and 18 years old for those diagnosed with egg allergy. The diagnosis was established through immunoglobulin E (IgE)–derived clinical history and positive skin prick tests, IgE sensitization to the allergenic food, or both. These patients were invited to undergo OIT treatment in accordance with the

Spanish OIT guidelines [10], with the study period spanning from April 2019 to April 2021. Parents of patients or their legally authorized representatives, and in the case of a mature minor, the children themselves, were provided with comprehensive information regarding the risks and benefits associated with the OIT treatment. Those patients who opted for OIT and reported the use of smartphones were extended an invitation to participate in the study. The participants were monitored until they completed the OIT buildup phase or until the predetermined conclusion of the study in April 2021.

Ethics Approval

Before participation, written informed consent was acquired from all involved patients, adhering to the prevailing ethical-legal regulations, as outlined in the Helsinki Declaration. The study protocol received approval from the ethics committees of all participating hospitals (2018.199 University of Navarra; PI2017053, Euskadi; Hospital Universitario Ramón y Cajal).

Allergy Diagnosis

For patients undergoing milk or egg OIT, a skin prick test was conducted using commercial extracts of milk, alpha-lactalbumin, beta-lactoglobulin, and casein for milk allergy, whereas white and yolk egg, ovomucoid, and ovalbumin were used for evaluating egg allergy. Measurements of wheal and flare sizes were taken 15 minutes after the test, and wheals with a diameter equal to or greater than 3 mm were deemed positive [27]. The determination of specific IgE levels for the entire extract (milk or white and yolk egg) and its components (alpha-lactalbumin, beta-lactoglobulin, and casein for milk or ovomucoid and ovalbumin for egg) was conducted using fluorescence enzyme immunoassay with ImmunoCAP (Thermo Fisher). Specific IgE values equal to or exceeding 0.35 kUA/L were classified as positive.

Food OIT Treatment Protocols

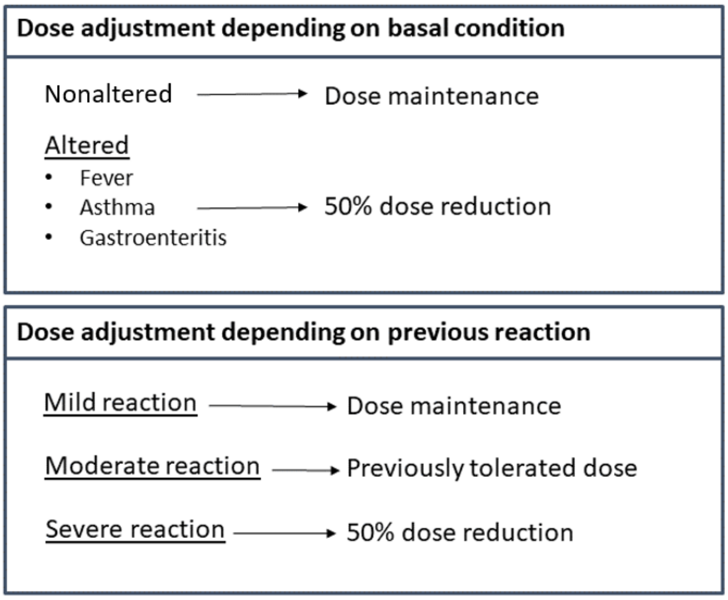
Patients underwent treatment with initially grouped dosing schedules at the hospital, in accordance with the Spanish OIT guidelines [14]. Subsequently, weekly increments in hospital doses were administered. The allergen dose that was tolerated at the hospital was then maintained daily at home between hospital visits. For milk OIT, ultra-high temperature milk was used until, whenever feasible, the final dose of 200 ml milk was reached. For egg OIT, the process involved the use of lyophilized egg white powder (ovo-des; Cantabria Labs Nutrición Médica), pasteurized egg white, or boiled whole egg until the target of 4000 mg of egg white powder, 30 ml of pasteurized liquid egg white, or 1 boiled whole egg was achieved, respectively, where possible [14].

Intervention

Before commencing OIT, patients were consecutively recruited, ensuring a balanced distribution between the control group (PaperPRO group) and the active group (OITcontrol group). The medical staff provided oral and written general recommendations to all patients and caregivers (referred to as patients hereafter). All patients were given detailed explanations and written instructions regarding various aspects, including how to administer the allergen dose, a list of cofactors to avoid, guidelines for treating different types of home reactions, and instructions for dose adjustment following a moderate/severe reaction or in the presence of altered basal conditions (axillary fever of ≥38°C, asthma, or gastroenteritis; Figure 1) [8-10]. Patients underwent training to manage home reactions, which included the use of specific medication tailored to each type of reaction (Table S1 Multimedia Appendix 1) [24]. Furthermore, within the category of severe reactions, written recommendations for patients outlined 2 additional severe reactions: anaphylaxis, which was considered when 2 or more symptoms distinct from oral allergy syndrome (OAS) were reported, and anaphylaxis with bronchospasm, when bronchospasm was one of the symptoms accompanying anaphylaxis. For these scenarios, prescriptions of epinephrine and a combination of epinephrine and bronchodilator (salbutamol) were provided, respectively. The term "anaphylaxis" is used in the "Results" section to describe an anaphylactic reaction, irrespective of the presence of bronchospasm. The severity of reactions was categorized based on Sampson's severity classification into mild, moderate, and severe reactions [28].

Patients were instructed to maintain a daily record of the allergen dose taken and any reactions experienced, noting the type of reaction and the administered treatment, in a paper-based diary as part of patient-reported outcomes (PaperPRO). Furthermore, individuals in the active group were provided training on the utilization of the OITcontrol app on their smartphones to document home doses and reactions. These patients were also encouraged to concurrently use the written diary (OITcontrol group).

Figure 1. Patient's specific information described in the written diary or implemented in the OITcontrol app.



OITcontrol App

OITcontrol is a mobile app designed for patients, available on Google Play (Google LLC) or Apple Store (Apple Inc.) [29], and a website for health staff [30], accessible through 3 distinct user interfaces: (1) The doctor's interface for prescribing allergen and rescue treatment, accessible as a website platform recommended for use on a computer; (2) the interface for nurses or health personnel responsible for administering food/medication doses, accessible as a website platform intended for use on a tablet; and (3) the patient interface, available as a mobile app, accessible exclusively through the log-in credentials provided by the doctor (Figure 2).

Within OITcontrol, when a doctor prescribes an OIT treatment for a patient, the app allows for the prescription of allergen dose increases, scheduled step rises following the OIT protocol, and outlines home/hospital treatment procedures in the event of a reaction (doctor's credentials are necessary for access). Once the treatment commences, the app provides daily reminders for the patient's dose, indicates the observation time, and incorporates an algorithm outlining actions and treatments to be used in the case of a home reaction, contingent on the type of reaction [24] (Table S1 Multimedia Appendix 1). Each symptom is associated with a specific indication in the app. In addition, the app computes 2 additional severe reactions: anaphylaxis, identified when 2 or more symptoms distinct from OAS are reported, and anaphylaxis with bronchospasm, recognized when anaphylaxis occurs alongside symptoms of bronchospasm, mirroring the written recommendations. The app provides general recommendations on how to take the daily dose, including guidance on avoiding cofactors, taking the dose at a consistent time, and the need for observation and rest after dose intake. These recommendations align with those provided in writing to every patient.

The platform/app is designed to retain the last tolerated allergen dose on a daily basis. It does not automatically prescribe increases in allergen dose. However, it is programmed to automatically decrease the dose in 2 specific situations:

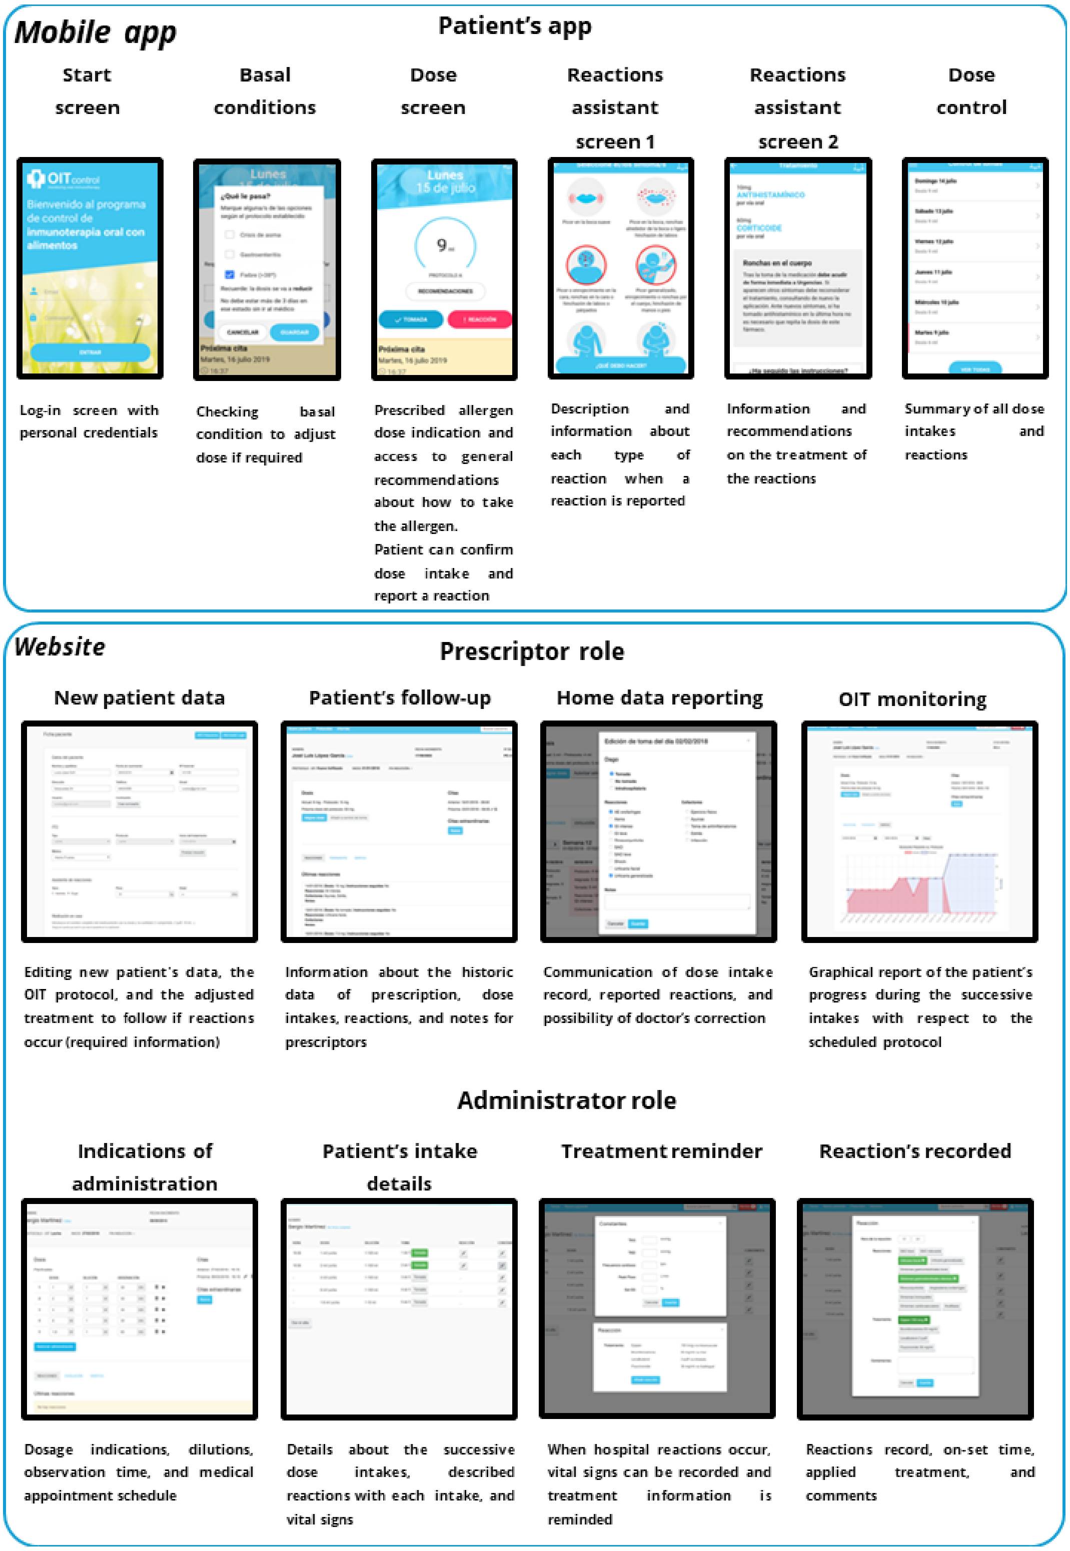
- When the basal condition is linked to a reaction, such as in the presence of gastroenteritis, fever, or an asthma attack, the app automatically decreases the dose to half of the scheduled amount [8,10].
- In the event of a moderate/severe reaction, the app adjusts the dose for the next day [8,26] (Figure 1).

OITcontrol facilitates guiding the patient through home treatment and enables medical staff to closely monitor the patient, even when they are at home.

For the health staff, OITcontrol serves several functions:

- It accumulates the complete OIT history of the patient, including protocol modifications, allergen doses linked to reactions, and cofactors involved in reactions. This information is provided by the patient at home and by the health staff during hospital visits. These data are accessible in real-time, constituting an electronic data capture system.
- It serves as an electronic prescription tool for drugs and allergen doses, allowing doctors to prescribe electronically.
- It sends real-time notifications about the patient's reactions. In the case of a severe reaction, a second notification is dispatched via email.
- It facilitates the management of hospital dose administrations, covering both the multiple-dose initial phase and the unique-dose weekly increase. It generates a summary of the hospital visit, which can be integrated into any digital history system. The app allows for the export of structured text containing patient-specific data for seamless integration.
- It conducts an anonymous analysis of clinical data from hospital patients, considering factors such as the type of reactions, age, sex, and assigned protocol.

Figure 2. Visual description of the functions and usability of the OITcontrol app for patients and website for medical staff.



Log-in screen with personal credentials

Checking basal condition to adjust dose if required

Prescribed allergen dose indication and access to general recommendations about how to take the allergen. Patient can confirm dose intake and report a reaction

Description and information about each type of reaction when a reaction is reported

Information and recommendations on the treatment of the reactions

Summary of all dose intakes and reactions

Editing new patient's data, the OIT protocol, and the adjusted treatment to follow if reactions occur (required information)

Information about the historic data of prescription, dose intakes, reactions, and notes for prescriptors

Communication of dose intake record, reported reactions, and possibility of doctor's correction

Graphical report of the patient's progress during the successive intakes with respect to the scheduled protocol

Dosage indications, dilutions, observation time, and medical appointment schedule

Details about the successive dose intakes, described reactions with each intake, and vital signs

When hospital reactions occur, vital signs can be recorded and treatment information is reminded

Reactions record, on-set time, applied treatment, and comments

Data Collection

The OIT buildup phase was organized into weekly hospital visits with interhospital home doses. Investigators documented hospital doses, the type of reactions that occurred during hospital visits, and the administered treatment. At home, all patients were encouraged to record daily outcomes in a written diary, including the amount of the daily allergen dose taken, instances of reactions, the type of symptoms experienced, and the treatment administered. Moreover, active patients were encouraged to use the OITcontrol app to document comparable information. The use of the OITcontrol app or a written diary was deemed effective when at least five consecutive home doses had been registered or when 1 reaction had been recorded during the follow-up. The medical staff documented the information in the digital clinical history regarding home dose intakes and home reactions reported verbally by the patients during weekly hospital visits.

Users' Satisfaction Questionnaire

An anonymous electronic satisfaction questionnaire regarding the use of the OITcontrol app was distributed to the initial 10 patients in the OITcontrol group. Additionally, 11 previous patients were included in the survey to verify the correct performance and use of the app before initiating the validation study. These participants were recruited from both the Hospital Universitario Donostia in Donostia-San Sebastián and Hospital Ramón y Cajal in Madrid. The same questionnaire was administered after the first and fourth week of app use. The questionnaire included a few demographic questions and inquired about the general impression of the app, the assessment of texts and screens, and the evaluation of terminology. The respondents provided ratings on a scale ranging from 1 (poor) to 5 (good) or from 1 (poor) to 9 (good) for the 22 items included in the questionnaire.

Statistical Analysis

The distribution of variables was assessed for normality using the Shapiro-Wilk test. Normally distributed quantitative values were presented as mean and SD, while nonnormally distributed quantitative values were described as medians and IQRs (Q1-Q3). Qualitative values were reported as frequencies (percentages). Proportions were compared using the chi-square test or Fisher exact test when the expected frequencies were below 5. Quantitative variables were analyzed using the Student *t* test or Mann-Whitney *U* test based on normality. The clinical statistical analysis was conducted using Stata IC 12.0 (StataCorp LLC). Differences with a *P* value <.05 were considered statistically significant.

Results

Baseline Characteristics of the Sample

Thirty participants were enrolled in the study, with 16 patients monitored using both written methods and the OITcontrol app (ie, the OITcontrol group) and 14 patients monitored solely through a written paper diary (ie, the PaperPRO group). A comparable distribution was observed concerning sex, age, basal characteristics (bronchial asthma/previous anaphylaxis with OIT food), the allergen used in OIT, premedication, and sensitization profile (Table 1).

No significant differences (*P*=.07) were observed in terms of follow-up time between PaperPRO patients (median 146.5 days, Q1-Q3 98-213 days) and OITcontrol patients (median 196.5 days, Q1-Q3 147.5-336.5 days). However, it is worth noting that 5/14 (36%) PaperPRO patients and 13/16 (81%) OITcontrol patients (*P*=.01) underwent OIT treatment during the COVID-19 pandemic. In fact, a similar number of hospital dose increases were observed between PaperPRO patients (mean 9.9, SD 6.4) and OITcontrol patients (mean 14, SD 9.5; *P*=.18). Likewise, the number of home OIT days was comparable between the PaperPRO group (median 128, Q1-Q3 89-192) and the OITcontrol group (median 167.5, Q1-Q3 135-287.5; *P*=.11).

Table 1. Baseline characteristics of the sample.

Characteristics	PaperPRO group (n=14)	OITcontrol group (n=16)	*P* value
Female, n (%)	5 (36)	10 (63)	.14
Age (years), mean (SD)	6.9 (1.9)	7.6 (3.7)	.75
Asthma, n (%)	5 (36)	7 (44)	.65
Previous anaphylaxis with OIT[a] allergen, n (%)	7 (50)	13 (81)	.08
OIT with egg, n (%)	8 (57)	8 (50)	.70
OIT with milk, n (%)	6 (43)	8 (50)	.70
Antihistaminic premedication, n (%)	0 (0)	4 (25)	.07
Omalizumab premedication, n (%)	1 (7)	1 (6)	.92
Total immunoglobulin E value (kU/L), median (Q1-Q3[b])	494.5 (120-858)	258 (87-931)	.57
In egg OIT patients			
OIT with egg, n (%)	8 (57)	8 (50)	.70

Casein	7.5 (3-9)	3.7 (1-12)	.56

[a] OIT: oral immunotherapy.

[b] Q1-Q3: first quartile-third quartile.

OIT Adverse Reactions

PaperPRO patients experienced 5 hospital reactions, while OITcontrol patients experienced 19 hospital reactions. Table 2 summarizes hospital reactions. In the PaperPRO group, the 5 hospital reactions were experienced by 5 different patients (1 reaction per patient), whereas in the active group, the 19 reactions were experienced by only 3 patients (the first patient had 1 reaction, the second had 3 reactions, and the third had 15 reactions). No differences were observed regarding the number of hospital reactions per patient, the number of hospital reactions per hospital dose given, the type of reactions, or the severity of the reactions between both groups of patients.

Concerning home reactions, PaperPRO patients reported 56 home reactions, while OITcontrol patients reported 97 home reactions (*P*=.70). Table 3 summarizes home reactions. More than one-half of all patients included in the study (19/30, 63%)

experienced a home reaction. Globally, only moderate home reactions were more frequently reported by PaperPRO patients than OITcontrol patients (*P*=.047). However, no differences were observed regarding the specific type of reaction between both groups of patients.

Table 2. Hospital reactions.

Reactions	PaperPRO group (n=14)	OITcontrol group (n=16)	*P* value
Hospital reactions, n	5	19	.45
Hospital reaction/hospital visit, median (Q1-Q3[a])	0 (0-0.1)	0 (0-0)	.18
Patients with hospital reactions, n (%)	5 (36)	3 (19)	.29

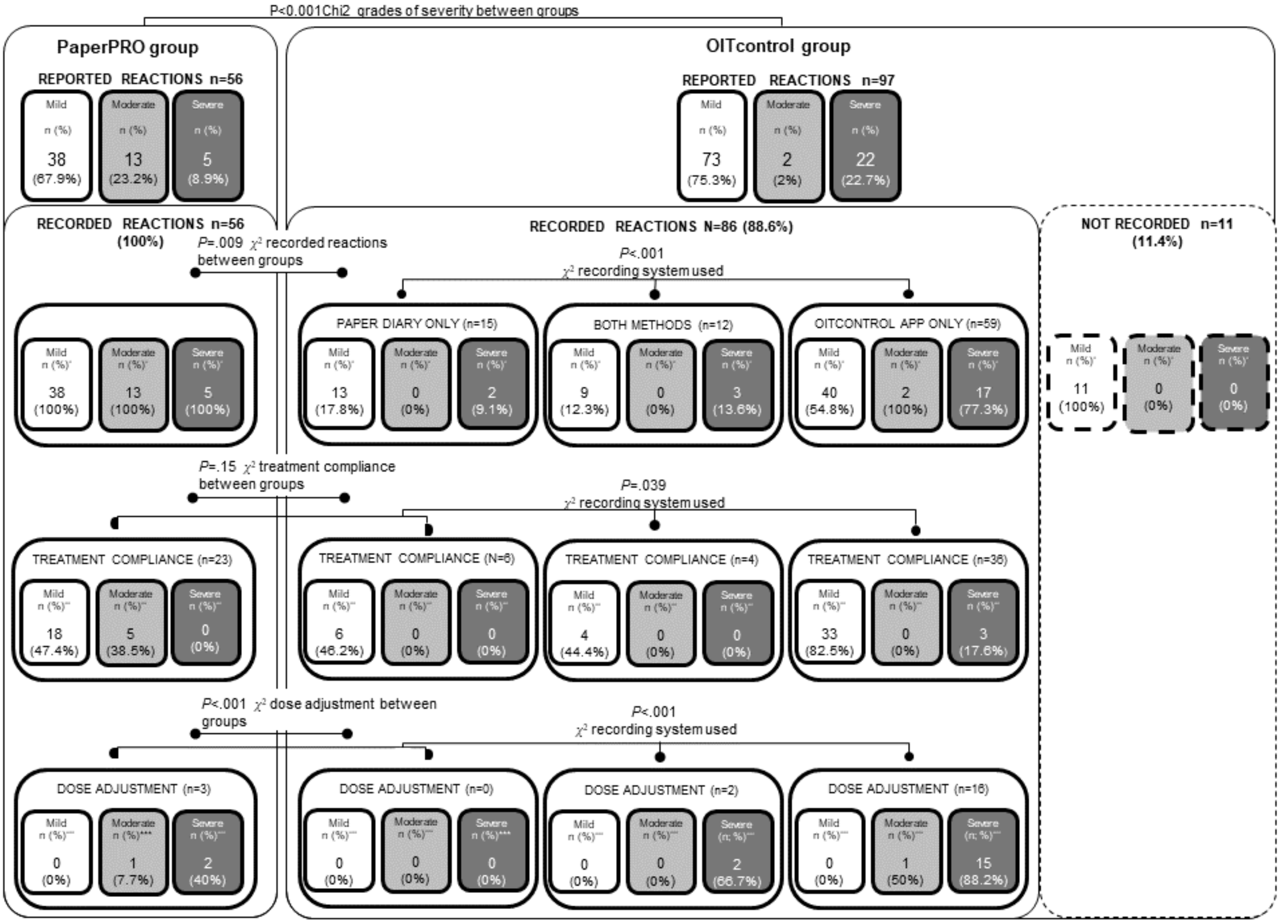
Home Data Recording

In the OITcontrol group, 81% (13/16) of patients used the OITcontrol app, while in the PaperPRO group, 71% (10/14) used the written diary (*P*=.53). As mentioned previously, patients in the OITcontrol group were advised to record daily taken allergen doses and home reactions using both methods: the written paper and the app. Following these recommendations, 38% (6/16) of OITcontrol patients used both methods. One active patient used only the written diary without using the OITcontrol app. Interestingly, none of the patients collected all daily dose intakes, regardless of the monitoring method used.

When analyzing reported reactions, every home reaction experienced in the PaperPRO group was recorded in the written diary (56/56, 100%), while 89% (86/97 reactions) of the home reactions experienced in the OITcontrol group were recorded (*P*=.009). Active patients preferred using only the app (59/86, 69%) rather than the written diary (15/86, 17%) or both methods (12/86, 14%) to record home reactions (*P*<.001). These data are summarized in Figure 3. Every reaction recorded by the OITcontrol group in both recording methods, written diary and OITcontrol app, was documented using the same description regarding allergen dose, type of symptoms, and administered treatment.

Figure 3. Summary of reported and recorded home reactions in both study groups, including the number of reactions documented, the treatment compliance and the dose adjustment performed after a moderate or severe reaction in recorded reactions through written diary, OITcontrol® app, or a combination of both monitoring systems. * Percentage of recorded reactions among reported reactions for each severity grade in each group. ** Percentage of reactions that followed indicated treatment among recorded reactions for each severity grade in each group. *** Percentage of reactions that follow dose adjustment after a moderate-severe reaction among recorded reactions for each severity grade in each group.



App Assistance Evaluation

Treatment compliance in home-recorded reactions was analyzed between both groups and the monitoring method used. The indicated treatment was followed in 23 of the 56 (41%) recorded reactions in the PaperPRO group and in 46 of the 86 (53%) home-recorded reactions in the OITcontrol group (*P*=.15). Analyzing the monitoring system used, treatment was observed to be followed more frequently (*P*=.04) in reactions recorded only in the app (36/59, 61%) than in the written diary (29/71, 41%) or both systems (4/12, 33%; Figure 3). In general, treatment compliance was observed more frequently (*P*<.001) in mild reactions (61/100, 61%) than in moderate (5/15, 33%) and severe reactions (3/27, 11%). However, it is worth noting that in recorded mild reactions, treatment compliance was quite high, possibly because no treatment was indicated for the frequently reported mild OAS (every recorded mild OAS was correctly managed in both groups: 12 in the PaperPRO group and 31 in the OITcontrol group). In fact, mild reactions excluding mild OAS (18/57, 32%), moderate (5/15, 33%), and severe reactions (3/27, 11%) followed treatment prescription correctly in similar rates (*P*=.11). Interestingly, in most of the reactions where prescribed treatment was not followed, the common attitude among patients was not to apply any treatment, which was consistent across both groups. Detailed data are provided in Tables 4-6.

Dose adjustments after a moderate-severe reaction in home-recorded reactions were analyzed between both groups and the monitoring method used. Among the 18 doses that should have been adjusted after a moderate-severe reaction in the PaperPRO group, only 3 (17%) were adjusted. By contrast, among the 24 recorded doses requiring adjustment after a moderate-severe reaction in the OITcontrol group, 18 (75%) were correctly adjusted (*P*<.001). In general, dose adjustment was more frequently performed (*P*<.001) in those reactions recorded only in the app (16/19, 84%) than in those recorded in the written diary (3/20, 15%) or in both methods (2/3, 67%). The severity of reactions was associated with better compliance, as adjustments were made after severe reactions (19/27, 70%) more frequently (*P*<.001) than after moderate reactions (2/15, 13%). Data are summarized in Figure 3.

Table 4. Comparison of the adequacy of the treatment applied in recorded reactions of written diary users from both groups of patients.[a]

Written diary (indicated treatment)	Treatment applied

[b] AH: antihistamine.

[c] CST: corticosteroid.

[d] EPI: epinephrine.

[e] BD: bronchodilator.

[f] Italicized values indicate the number of patients that followed the prescribed treatment correctly.

Users’ Satisfaction Questionnaire

A total of 15 users answered the questionnaire in the first week, and 11 responded in the fourth week. Among the 15 users answering in the first week of app use, 7/15 (47%) were females, with most aged between 35 and 44 years (8/15, 53%); 5/15 (33%) were between 45 and 54 years and 2/15 (13%) were between 25 and 34 years; 9/15 (60%) of them reported very frequent use of a smartphone (1=no use to 5=very frequent use: 3/15, 20%, rated the use 4/5; 2/15, 13%, rated the use 3/5; and 1/15, 7%, rated the use 2/5). In general, the app received positive ratings, being considered easy to use in most functions and screens, with suitable text. However, there were suggestions that error messages could be clearer. The questionnaire results are summarized in Tables 7-9.

Table 7. Results of the usability questionnaire after 1 week and 4 weeks of use of the OITcontrol app: general opinions.

Questions and rating	Results at 1 week of use	Results at 4 weeks of use
OITcontrol app is		
1=terrible to 5=wonderful, mean (SD)	3.9 (0.7)	4.3 (0.6)
1=frustrating to 5=easy, mean (SD)	4.1 (0.7)	4.3 (0.6)
1=boring to 5=exciting, mean (SD)	3.6 (0.8)	3.8 (0.9)
1=difficult to 5=easy, median (Q1-Q3[a])	5 (4-5)	5 (4-5)
1=too slow to 5=too fast, mean (SD)	3.3 (1)	3.2 (0.9)
1=unreliable to 5=highly reliable, median (Q1-Q3)	3.9 (3.9-4.4)	3.9 (2.8-4.4)
1=noisy to 5=noiseless, mean (SD)	4.4 (0.6)	4.7 (0.5)

[a] Q1-Q3: first quartile-third quartile.

Table 8. Results of the usability questionnaire after 1 week and 4 weeks of use of the OITcontrol app: opinion about how easy/difficult is to use different functions.

Questions	Rating	Results at 1 week of use	Results at 4 weeks of use
Know I should take the dose	1=difficult to 5=easy, median (Q1-Q3[a])	5 (5-5)	5 (5-5)
Know how to take the dose	1=difficult to 5=easy, median (Q1-Q3)	5 (4-5)	5 (4-5)
Know indications after reaction	1=difficult to 5=easy, mean (SD)	4.6 (0.5)	4.6 (0.5)
Record the dose intake and its additional information	1=difficult to 5=easy, mean (SD)	4.6 (0.5)	4.8 (0.4)
Receive the alarm at the dose intake time	1=difficult to 5=easy, mean (SD)	3.9 (1)	4 (1.2)
Consult past dose intake record	1=difficult to 5=easy, median (Q1-Q3)	5 (4-5)	5 (4-5)
Consult the next hospital visit	1=difficult to 5=easy, median (Q1-Q3)	5 (4-5)	5 (4-5)
To correct mistakes	1=difficult to 5=easy, mean (SD)	3.5 (0.9)	3.5 (1.2)

[a]Q1-Q3: first quartile-third quartile.

Table 9. Results of the usability questionnaire after 1 week and 4 weeks of use of the OITcontrol app: opinions about text and screens.

Questions	Rating	Results at 1 week of use	Results at 4 weeks of use
The texts on the screen are...difficult or easy to read?	1=difficult to 9=easy, median (Q1-Q3[a])	8 (7-9)	8 (7-9)
Is the information highlighted helpful?	1=absolutely not to 9=of course yes, median (Q1-Q3)	8 (7-9)	8 (7-9)
Is the transition from one screen/information to another confusing or clear?	1=confuse to 9=clear, median (Q1-Q3)	8 (7-8)	7 (6-8)
Does the use of terms...encourage or discourage its use?	1=discourage to 9=encourage, mean (SD)	5.9 (2.3)	5.8 (2.5)
Does the use of terms encourage or discourage learning?	1=discourage to 9=encourage, mean (SD)	6.2 (2.5)	6.3 (2.1)
Error messages...are they confusing or clear?	1=confuse to 9=clear, mean (SD)	6.6 (1.7)	5.5 (2.5)
The messages that appear on the screen...Are they difficult or simple?	1=difficult to 9=simple, mean (SD)	7.9 (1.1)	8.2 (0.9)

[a]Q1-Q3: first quartile-third quartile.

Discussion

Principal Findings

This study demonstrates that OITcontrol, a patient advisor app incorporating medical algorithms, goes beyond serving as an electronic report and is an effective method for monitoring home OIT. Moreover, our findings suggest that OITcontrol emerges as an appealing method for overseeing OIT treatments, as it has been predominantly used by the active group. Additionally, instructions provided by the app have been adhered to more consistently than the written indications regarding treatment and dose adjustments following a reaction.

eHealth technology has seen widespread adoption in recent years, particularly in the context of respiratory allergy [31-33]. Conversely, the application of eHealth technology in food allergy has primarily focused on the development of mobile apps designed to complement patient care. These apps often provide features such as allergen-free product searches, meal planners, or tools for locating allergy-adapted restaurants [34,35]. OITcontrol aligns with the objectives of eHealth apps, serving not only the beneficial purposes for patients with allergies but also catering to the needs of clinicians and researchers [36]. It exemplifies the use of health informatics by automating physician orders [37].

Previous reports have indicated that as few as 20% of patients are genuinely compliant with paper-based diaries [38]. In our sample, reporting compliance was remarkably high. PaperPRO patients exhibited perfect adherence in recording home reactions, surpassing the OITcontrol group. In the OITcontrol group, patients displayed a preference for recording home reactions within the app. This observation may be due to the control group's potentially better performance when using only 1 monitoring system, as opposed to the active group using 2 systems. Alternatively, it could be indicative of underreporting of home reactions by the control group, possibly trivializing or forgetting to report reactions when using standard methods compared with having an additional monitoring intervention.

Indeed, a previous electronic web-based reporting system implemented for OIT, which focused on dose and home reactions reporting, demonstrated higher adherence than that observed in our sample. However, the rate of reported home reactions was quite similar to our data [39]. Nevertheless, Nachshon et al [39] highlighted some limitations of this monitoring web-based system, including challenges related to the patient's description of reactions. In this regard, OITcontrol provides a tabulated selection of reactions rather than an open-ended description box. It appears that these predefined reactions are effectively described, as treatment compliance and dose adjustment after a reaction were more successful, particularly for those reactions recorded in the app.

Home reactions documented in the OITcontrol app were more consistently treated correctly compared with those recorded in the written diary, despite the fact that treatment compliance was notably low, particularly among patients experiencing moderate and severe reactions. It is worth noting that epinephrine is underused in cases of anaphylaxis, even among well-informed and trained parents familiar with the use and indications of autoinjectors. This could be attributed to reasons such as the unavailability of the autoinjector, difficulty in recognizing anaphylaxis, and concerns about potential adverse effects [40-45]. In our limited sample, patients who required self-injectable epinephrine rarely used it, irrespective of whether they followed written or electronic recommendations. However, the correct treatment in mild reactions was more frequently adhered to. Further, a larger sample of patients is needed to assess whether the OITcontrol app could enhance treatment compliance for home reactions and contribute to adjusting home doses after moderate-severe reactions. Our data, albeit based on a limited number of reactions, suggest that OITcontrol app recommendations regarding dose adjustment were followed more consistently than written recommendations.

Conclusions

In conclusion, the OITcontrol app appears to enhance treatment and dose adjustment compliance in home reactions, although further studies are needed to confirm the efficacy of the app in this regard. As a monitoring system, the OITcontrol app is deemed a suitable method in OIT treatment for recording daily dose intakes and home reactions during the buildup phase.

Acknowledgments

The authors extend their gratitude to Maite Lacunza for technical support, Paola Quan for her assistance with figure design, and Jorge Nuñez Córdoba for providing statistical advice. Funding for the development of the OITcontrol app and its clinical validation was generously provided by the Navarra Government (Economic development grants: 2016/PI041 and 2017/PI065) and the Sociedad Española de Alergología e Inmunología Clínica (SEAIC) in 2018. Additionally, this work received support from the Redes de Investigación Con Objetivos en Salud (RICORS)-Red De Enfermedades Inflamatorias (REI)—RD21/0002/0028, Instituto de Salud Carlos III, Madrid, Spain, and the Fundación Tecnología y Salud de Instituto de Investigación Sanitaria de Navarra (IdisNA).

Abstract

Background: Industry 4.0 (I4.0) technologies have improved operations in health care facilities by optimizing processes, leading to efficient systems and tools to assist health care personnel and patients.

Objective: This study investigates the current implementation and impact of I4.0 technologies within maternal health care, explicitly focusing on transforming care processes, treatment methods, and automated pregnancy monitoring. Additionally, it conducts a thematic landscape mapping, offering a nuanced understanding of this emerging field. Building on this analysis, a future research agenda is proposed, highlighting critical areas for future investigations.

Methods: A bibliometric analysis of publications retrieved from the Scopus database was conducted to examine how the research into I4.0 technologies in maternal health care evolved from 1985 to 2022. A search strategy was used to screen the eligible publications using the abstract and full-text reading. The most productive and influential journals; authors', institutions', and countries' influence on maternal health care; and current trends and thematic evolution were computed using the *Bibliometrix* R package (R Core Team).

Results: A total of 1003 unique papers in English were retrieved using the search string, and 136 papers were retained after the inclusion and exclusion criteria were implemented, covering 37 years from 1985 to 2022. The annual growth rate of publications was 9.53%, with 88.9% (n=121) of the publications observed in 2016-2022. In the thematic analysis, 4 clusters were identified—artificial neural networks, data mining, machine learning, and the Internet of Things. Artificial intelligence, deep learning, risk prediction, digital health, telemedicine, wearable devices, mobile health care, and cloud computing remained the dominant research themes in 2016-2022.

Conclusions: This bibliometric analysis reviews the state of the art in the evolution and structure of I4.0 technologies in maternal health care and how they may be used to optimize the operational processes. A conceptual framework with 4 performance factors—risk prediction, hospital care, health record management, and self-care—is suggested for process improvement. a research agenda is also proposed for governance, adoption, infrastructure, privacy, and security.

(JMIR Pediatr Parent 2024;7:e47848) doi:10.2196/47848

KEYWORDS

Industry 4.0; Fourth Industrial Revolution; bibliometrics; maternal health care; antenatal care; postnatal care; lean operations; maternal; pregnancy monitoring; pregnancy; maternal care; monitoring; thematic analysis; data mining; machine learning; IoT; Internet of Things; artificial intelligence; deep learning; digital health; wearable; mobile phone

Introduction

The Fourth Industrial Revolution, often referred to as Industry 4.0 (I4.0), has revolutionized all sectors with smart technology [1]. For example, Dolgui and Ivanov [2] posit that I4.0 technologies improve efficiency in manufacturing with minimal use of resources. The increased adoption of I4.0 technologies drives the cyber-physical transformation of manufacturing, logistics, and supply chain in business. There has been a heightened interest in adopting and adapting I4.0 technologies in health care delivery [3]. Li and Carayon [4] point out that using I4.0 tools has transformed the provision of digital health services, such as electronic health records, wearable devices, and storage, among other tools, and has led to improved health outcomes and quality of care. Implementing I4.0 in health care has led to a new term being coined, "Health 4.0," which is a deployment of health care driven by the success of I4.0 [5]. Maternal health care is one aspect that can benefit from increased efficiencies and quality of care. According to Ahsan et al [6], several health professionals are using new technologies to monitor and improve the quality of patient care they provide remotely. For example, the condition of the mother and the fetus can be monitored using nonintrusive remote monitoring tools [7,8]. The literature on I4.0 is expanding exponentially, with each successive evolution characterized by an increase in the development and innovation of new tools to facilitate how patients and service providers interact. Sustainable Development Goal (SDG) 3.1 [9] aims to ensure access to health care facilities and reduce the global maternal mortality ratio to less than 70 per 100,000 live births. The challenge faced by society and organizations is determining how best they can take advantage of I4.0 technology to ensure the success of SDG 3.1.

While previous research has explored the general potential of I4.0 technologies for health care, specific applications in maternal health care remain underexplored. Luo et al [10] offer valuable insights through a bibliometric analysis but lack a deeper exploration of real-world impacts on practices, policies, and patient outcomes. Similarly, Guo et al [11] highlight the growth of artificial intelligence (AI) research in health care but fail to delve into specific applications with the most significant potential for improvement. Existing reviews on I4.0 technologies [5,6,12] offer broad overviews of applications and management but lack specific use cases and their long-term societal and health care system impacts. This study addresses this gap by investigating the challenges and successes of implementing I4.0 technologies in various maternal health care settings. A conceptual framework for implementing I4.0 technologies in maternal health care is proposed. Further, we highlight insights and directions by mapping the thematic landscape of I4.0 in maternal health care. A research agenda is also developed for future research direction. A total of 136 papers were analyzed bibliometrically. The objectives were to (1) determine the most productive and influential journals in I4.0 research in maternal health; (2) determine authors', institutions', and countries' influence on I4.0 research in maternal health; (3) investigate the current trends and thematic evolution of I4.0 research in maternal health; and (4) develop a conceptual framework for guiding the implementation of I4.0 technologies in maternal health.

In addition, to gain further insight into the use of I4.0 technologies in health care, three research questions were explored: (1) What are the most critical applications of I4.0 in maternal health care? (2) To what extent is I4.0 technology used in maternal health care? and (3) What are the open research issues and areas for future research?

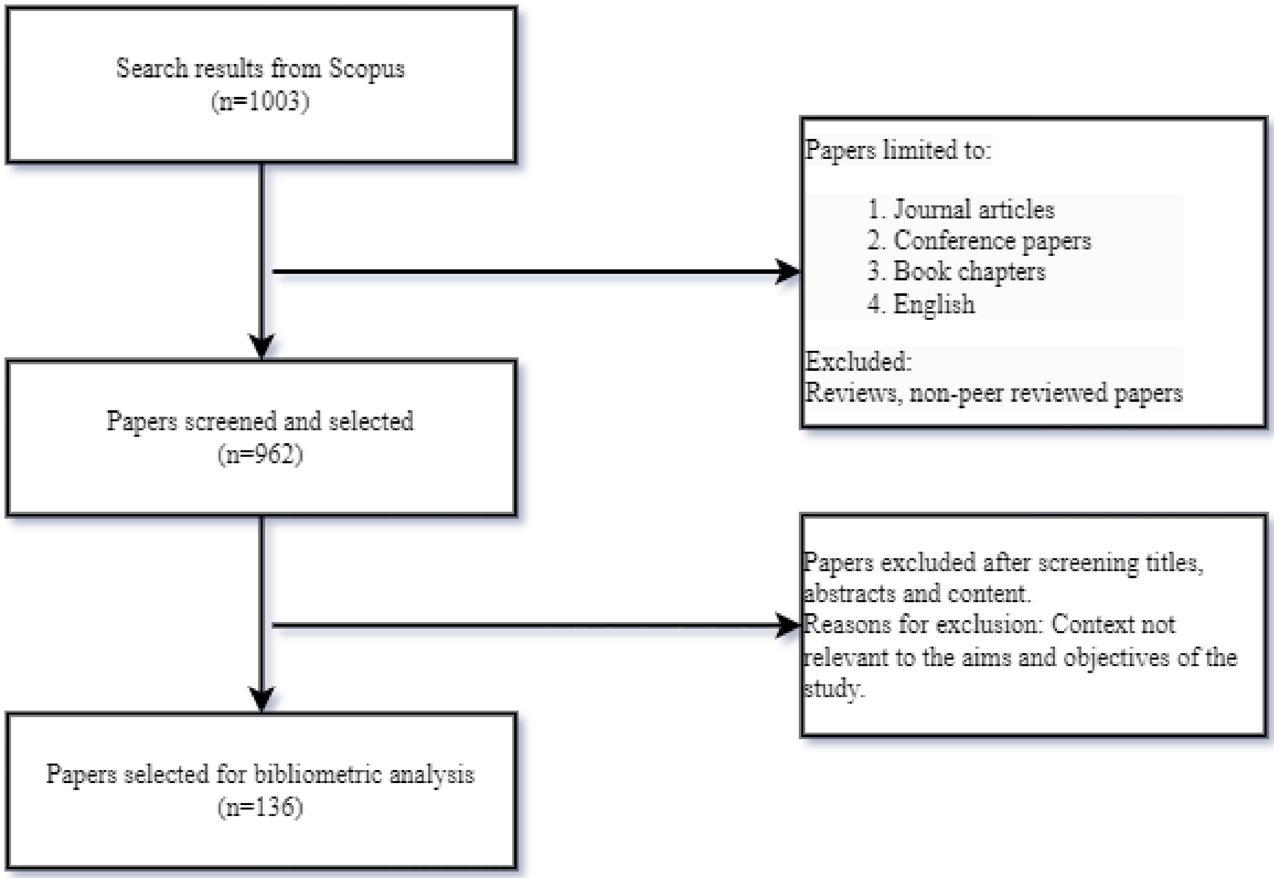
Methods

Search and Screening Strategy

The first step was to search for relevant research. The search was conducted on the Scopus electronic database because it indexes peer-reviewed research used by multidisciplinary researchers. Only articles in English (journals, conference papers, and book chapters) were reviewed to focus the study. According to Paul et al [12], I4.0 applications, the Internet of Things (IoT), big data analytics (BDA), cloud computing, blockchain, and AI have had a significant impact on Health 4.0. A search string was thus formulated to focus only on these I4.0 technologies (applications). The primary focus was also limited to maternal health care. The following search string was thus formulated: *(("IoT" OR "Internet of Things") OR (Big Data Analytics) OR ("Cloud Computing" OR "Cloud") OR ("Blockchain" OR "Block chain") OR ("Artificial Intelligence" OR "AI")) AND (maternal)).*

A total of 1003 unique papers in English were retrieved using the search string, and 136 papers were retained after implementation of the inclusion and exclusion criteria, covering 37 years from 1985 to 2022. Our search strategy encompassed all published scholarly literature on the application of IoT, AI, BDA, cloud computing, and blockchain technologies in the domain of maternal health care. We included journal articles, conference proceedings, and relevant book chapters. To ensure the quality and focus of the analysis, we restricted our selection to (1) papers published in the English language and (2) those directly addressing I4.0 technologies and maternal health care. We excluded from the analysis editorials, news articles, discussion comments, and review papers; articles that discuss maternal health care but does not mention I4.0 technologies; and articles that highlight I4.0 technologies but merely mention maternal health care. Figure 1 illustrates the retrieval strategy.

Figure 1. Flowchart summarizing the retrieval strategies.



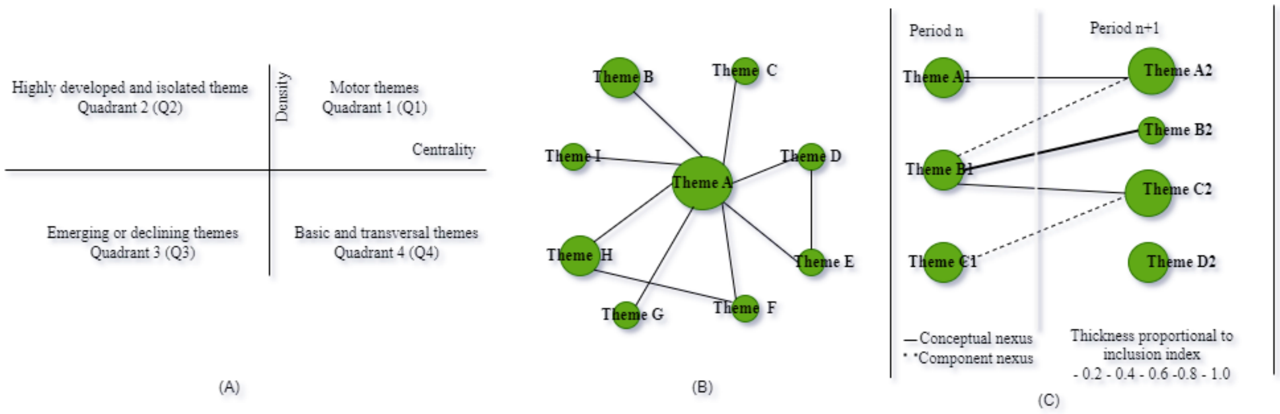
A total of 623 authors contributed to the literature between 1985 and 2022. The papers were mainly cowritten, with an average of 5.22 authors per paper. All the papers were multiauthored, save for 1 paper. The earliest publication was by Hernandez et al [13] , entitled “Expert system for prediction of foetal condition during labour,” presented at the *IEEE-Engineering in Medicine and Biology Society Annual Conference* in 1985. The latest published paper by Jaba Deva Krupa et al [14], entitled “An IoMT enabled deep learning framework for automatic detection of foetal QRS: A solution to remote prenatal care,” was published in the *Journal of King Saud University - Computer and Information Sciences*.

Method of Analysis

Bibliometric techniques were used to analyze the development of I4.0 technologies in maternal health care. Bibliometrics research has been used extensively to map the development of research, including lean supply chain management [15], traceability and lifecycle relationship [16], health technology research [10], supply chain management [17], AI in health care [11], and the theory of constraints [18]. According to Cobo et al [19] and Noyons et al [20], bibliometric analysis has 2 main objectives: research mapping analysis and academic performance analysis. Science mapping as a bibliometric technique helps monitor the structure and evolution of research by reviewing relationships among authors, disciplines, and areas of study [21]. Performance analysis quantitatively and qualitatively measures an entire field of research to determine the most effective and productive research. Further, Cobo et al [19] state that while most research focuses on measuring the scientific performance of a group of actors (countries, universities, departments, and researchers), there is a need to measure the performance of given research conceptually by interrogating specific themes or whole thematic areas.

The *Bibliometrix* R package [22] was used to compute the descriptive statistics and bibliometric analysis, including the articles’ analysis, based on the year of publication, citations, authors, affiliation, keywords, coauthorship, and thematic evolution. The conceptual science mapping was conducted following the 4-step methodology proposed by Cobo et al [19]. The first step is to detect research themes. For each period, keywords are extracted from the identified papers to build a network based on a keyword co-occurrence. The nodes represent the keywords, while an edge connects 2 nodes if they coappear in a set of papers [15]. Similar items constitute a cluster and are calculated based on the frequency of keyword co-occurrences. The second step is to visualize identified themes and thematic networks. A graphic representation of the detected themes is presented in a strategic diagram (Figure 2) and a thematic network [23]. Two dimensions are used to characterize each theme—centrality and density. Centrality measures the degree of interaction of the network with other networks, while density is the internal strength of the network [24]. According to Cobo et al [19], the themes can be classified into four quadrants: (1) motor themes (quadrant 1): they exhibit strong centrality and high density; themes in this quadrant are considered well-developed and suitable for structuring a research field; (2) niche themes (quadrant 2): these are highly developed and isolated themes considered of marginal importance to the research field; (3) emerging or declining themes (quadrant 3): these themes exhibit low density and centrality; thus, they may be considered emerging or disappearing; and (4) basic themes (quadrant 4): these represent relevant but not well-developed themes. The third step is to analyze the evolution of detected themes. The research themes are analyzed using an evolution map. The last step is to carry out the performance analysis. The production and scientific impact is measured quantitatively and qualitatively.

Figure 2. (A) Strategic diagram, (B) thematic network, and (C) thematic evolution [23].



Results

Overview

This section describes the evolution of I4.0 in maternal health care in terms of publications, citations, and impact by analyzing the following bibliometric indicators—published articles, most productive and influential journals, most productive and influential authors, and most productive and influential institutions and countries. The bibliometric performance analysis is structured into 2 parts—the production and impact of papers and the impact of authors, journals, countries, and research areas.

Publications and Citations

Figure 3 shows the distribution of publications per year and the number of publications (NP) has increased in recent years. Three periods can be observed in the development of publications—1985-2005, 2006-2015, and 2016-2022. The initial period spans 20 years, with only 1 publication in 1985 indicating that I4.0 technologies still needed to be fully adopted in maternal health care. The second period saw 14 publications. However, it can be noted that there was a fluctuation in terms of publications. There was an exponential growth in publications in the last period, with 121 articles published (121/136, 88.9% of all publications in 1985-2022). The annual growth rate of publications for this period is 15.84% compared to the overall growth rate, which stands at 9.53%, implying an increasing NP.

Figure 3. Distribution of publications (1985-2022).

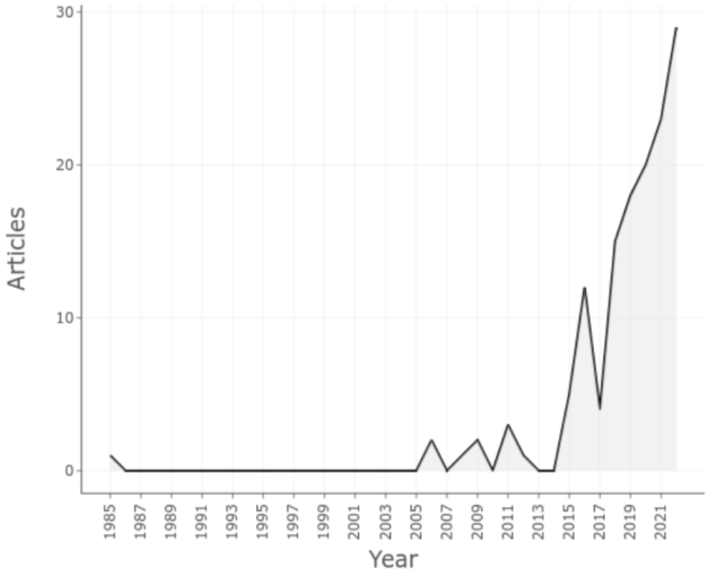


Figure 4 shows the average citations per year. The trends mirror the publications per year with no citations before 2005. However, from 2006 to 2015, there were fluctuations in citations, with the highest average (1.59, SD 0.40) for the period recorded in 2009. In the last period, there was a gradual increase in the number of citations from a low of 0.5 to a high of 4.5 per year. The increase in research may be traced back to 2011 when the term “Industry 4.0” was first coined [10]. Given their identified advantages, there was a deliberate effort to increase and adopt I4.0 technologies [25]. The slow and sporadic adoption within health care can be attributed to several factors; extensive capital investments were required to implement these technologies and train the workforce, thus averting job disruption risks [26]. Studies also underscore limitations like a lack of adequate infrastructure, a shortage of digital skills among the workforce, the risk of security breaches, the potential disruption of existing jobs, and challenges in ensuring consistent data quality as significant barriers to I4.0 integration [27,28].

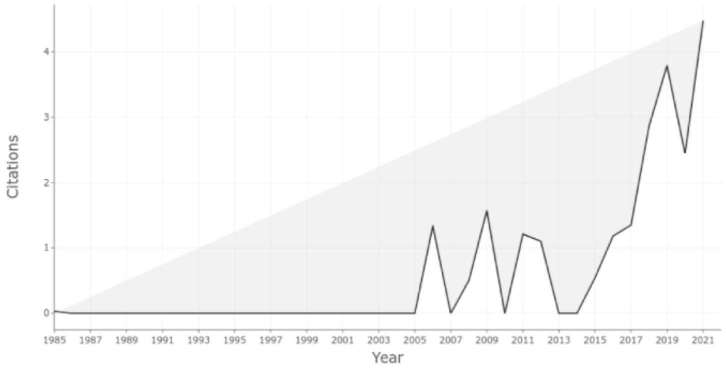
Figure 4. Citations by year (1985-2022).



Most Productive Authors and Authors Impact

Table 1 shows the most productive authors during the 1985-2022 period. It gives the NP of the first 10 productive researchers. Moreira and Rodrigues have produced the highest NP with 8 each. They are followed by 4 other researchers with 5 publications each. These results indicate that the research on implementing I4.0 technology is widespread, with no one dominant researcher in the field. Table 1 also shows the most relevant authors and their local impact. It quantifies the contribution of an individual author to a published set of articles. The publication start year indicates the first year the author was published.

Table 1. Top 10 most relevant authors and author’s local impact.

Authors	NP[a]	h_index	g_index	m_index	TC[b]	PY_start[c]
Moreira	8	6	8	0.857	122	2016
Rodrigues	8	6	8	0.857	122	2016
Axelin	5	4	5	1.000	85	2019
Azimi	5	4	5	1.000	85	2019
Liljeberg	5	4	5	1.000	85	2019
Rahmani	5	4	5	1.000	85	2019
Saleem	4	4	4	0.571	86	2016
Abelha	3	2	2	0.250	7	2015
Kumar	3	3	3	0.600	67	2018
Machado	3	2	2	0.250	7	2015

[a] NP: number of publications.

[b] TC: total number of citations.

[c] PY_start: the year of first publication of articles.

Top 10 Most Local Cited Authors

Local cited authors measure how many times the authors have cited an author included in this corpus. Accordingly, this can be interpreted as a measure of the impact of authors conducting research on I4.0 in maternal health care. Moreira and Rodrigues, authors with more scientific production and the highest impact, are cited more (4 times) by other authors in the corpus. It should be noted that the low number of citations may be attributed to the fact that the core technologies behind I4.0 in maternal health care are still in development and are yet to gain wider traction and acceptance [3,12].

Most Local Cited Sources, Most Relevant Sources, Source Local Impact, and Source Dynamics

The local citations are taken from the reference lists and measure the number of times other papers in the corpus cite a paper. The paper has to appear in at least 1 of the reference lists of the other papers in the collection. In our collection, we have 2244 cited sources. *Fertility and Sterility* stands out with 63 articles, followed by *American Journal of Obstetrics & Gynecology* with

50 articles, *Reproductive Medicine and Biology* with 33 articles, *PLOS ONE* with 32, *Human Reproduction* with 31 articles, and with *BMC Pregnancy and Childbirth* at number 5 with 25 articles.

The most relevant source is the *Lecture Notes in Computer Science* (including subseries *Lecture Notes in Artificial Intelligence* and *Lecture Notes in Bioinformatics*), with 4 publications and a total citation count of 10. The *Journal of Maternal-Fetal & Neonatal Medicine* has the most citations with a total of 44 citations. However, with 3 publications, it is the third most relevant source.

Most Relevant Affiliations

The most relevant affiliation is the University of Turku in Finland with 11 articles, followed by Brazilian universities, namely, the University of Fortaleza (second with 7 articles), the National Institute of Telecommunications (fifth with 5 articles), and the Instituto Federal De Educação (eighth with 4 articles). The University of California and the University of California, Irvine in the United States are tied for third, with 6 articles each. The rest of the institutions are from Asia, accounting for 4 of the top 10 relevant affiliations—Shenzhen Technology University (sixth with 5 articles) and Anna University, Jinan University, and King Saud University, with 4 articles each.

Country Scientific Production and Most Cited Countries

The United States is positioned in the first place with a frequency of 80; followed by India with a frequency of 50; and China, Brazil, and Portugal making up the top 5 with a frequency of 34, 30, and 17, respectively. The top 10 most prolific countries are thus located in the United States, Asia, and Europe. However, it can be noted that some research focusing on I4.0 technologies in health care emanates from Africa. Most of this research is concentrated in East Africa—Kenya (n=5), Tanzania (n=2), and Uganda (n=2)—with a frequency of 9 combined. Nigeria is the most prolific country in Africa, with a frequency of 8. South Africa has a frequency of 2.

The most cited countries represent the origin of scientific production referenced by the authors from the collection. Most of the articles reference articles with their origin—Finland (77 citations); Canada (67 citations); the United States (61 citations); and China and Portugal, with 60 citations each.

Most Global and Local Cited Papers

Table 2 shows the 10 most relevant studies sorted by total citations. A globally cited paper is an article in the collection that has been cited by other papers indexed by a particular database, which in this study was Scopus. The total number of citations represents the total citations received by a selected article "all over the world." The most frequently cited work was "Missing data resilient decision-making for health care IoT through personalisation: A case study on maternal health" [29]. The objective was to develop a personalized missing data resilient system in an IoT monitoring system, as data acquisition is generally interrupted in long-term monitoring systems. The paper has 55 citations and averages 13.75 per year.

Table 2. Top 10 most globally cited papers.

Paper	TC[a]	TC/y[b]
Azimi et al [30]	55	13.75
Catley et al [31]	41	2.41
Moreira et al [29]	36	9.00
Akbulut et al [32]	36	7.20
Rigla et al [33]	35	7.00
Sayers et al [34]	31	2.21
Kumar et al [35]	22	11.0
Moreira et al [36]	22	4.40
Miyagi et al [37]	21	5.25
Tejera et al [38]	21	1.75

[a] TC: total number of citations.

[b] TC/y: total number of citations per year.

The leading papers on I4.0 in maternal health care are presented in Table 3. Only the first 10 top publications are presented based on the local citations. All the papers were published within the last 5 years (2017-2021). The most cited paper is by Azimi et al [30], which is also the most globally cited publication.

Table 3. Top 10 most influential papers on I4.0 in maternal health care.

Authors	Title	Summary of research	Source	LC[a]	GC[b]
Azimi et al [30]	Missing data resilient decision-making for health care IoT through personalisation: a case study on maternal health	This research proposed an approach that considers variability and context information to minimize bias when inputting missing data values.	FGCS[c]	3	55
Miyagi et al [39]	Feasibility of deep learning for predicting live birth from a blastocyst image in patients classified by age	An AI[d] classifier using deep learning with convolutional neural networks (CNN) was developed. The model used images of blastocysts categorized by maternal age to predict the likelihood of achieving a live birth. The authors argue that the model provides an efficient, quick, and economical diagnosis means and permits remote examination.	RMB[e]	2	21
Lopez et al [40]	Wearable technology model to control and monitor hypertension during pregnancy	A technological model was proposed to monitor the care of pregnant women through alerts provided by a group of health parameters. The model combines a group of the patients' parameters, such as blood pressure, heart rate, and physical technology with a wearable device.	CISTI[f]	2	15
Yarlapati et al [41]	Early prediction of LBW cases via minimum error rate classifier: a statistical machine learning approach	The authors reformulated a forecasting problem as a classification problem between low birth weight (LBW) and not low birth weight (NOT-LBW). They implemented a model using health indicators of pregnant women for early detection of potential LBW.	ICSC[g]	2	8
Moreira et al [42]	Smart mobile system for pregnancy care using body sensors	Presents a mobile monitoring solution to indicate high-risk pregnant women enduring hypertension. The mobile system alerts health care staff if there is a change in hypertension condition during pregnancy.	ICST[h]	2	20
Ueno et al [43]	Pregnancy prediction performance of an annotation-free embryo scoring system on the basis of deep learning after single vitrified-warmed blastocyst transfer: a single-center large cohort retrospective study	The authors discussed an embryo assessment model, iDAScore, developed using deep learning. The model performed better than an annotation-dependent ranking tool or traditional embryo assessment tools.	FAS[i]	1	7
Li et al [44]	The impact of healthcare monitoring technologies for better pregnancy	The authors performed an experimental analysis based on a sample of 315 pregnant women. The study highlighted a high recognition and acceptance of wearing wearable Internet of Things (IoT) devices during pregnancy by pregnant women.	ICET[j]	1	2
Huang et al [45]	Using deep learning in a monocentric study to characterise maternal immune environment for predicting pregnancy outcomes in the recurrent reproductive failure patients	The researchers applied artificial intelligence to analyze patients' medical information with recurrent reproduction failure (RRF). A machine learning model to predict the pregnancy outcomes for patients with RRF at any gestational period, namely, biochemical pregnancy, clinical pregnancy, ongoing pregnancy, and live birth was developed	FII[k]	1	5
Sarhaddi et al [46]	Long-term IoT-based maternal monitoring: System design and evaluation	An IoT-based system to monitor maternal health during pregnancy and postpartum was developed. Further, an artificial intelligence method for analyzing the data was integrated. The researchers implemented a proof-of-concept monitoring system for an actual human participant study.	SSS[l]	1	5
Mhajna et al [47]	Wireless, remote solution for home fetal and maternal heart rate monitoring	The researchers developed a solution to fuse information gathered from a wireless abdominal belt that is self-applied to obtain fetal heart rate (FHR) and maternal heart rate (MHR).	AJOG[m]	1	17

Thematic Evolution of the Field

The first period from 1985 to 2005 and the second period from 2006 to 2015 were combined since the first period had only 1 paper published. The evolution of I4.0 development in maternal health care was thus analyzed across 2 periods, from 1985 to 2015 and from 2016 to 2022. Figures 5 and 6 represent the strategic maps of the main themes and trends for each period based on the authors' 250 most frequently used words. Table 4 lists the keywords per cluster (I4.0 technologies) by their frequency.

Figure 5. Thematic map for the period 1985-2015.

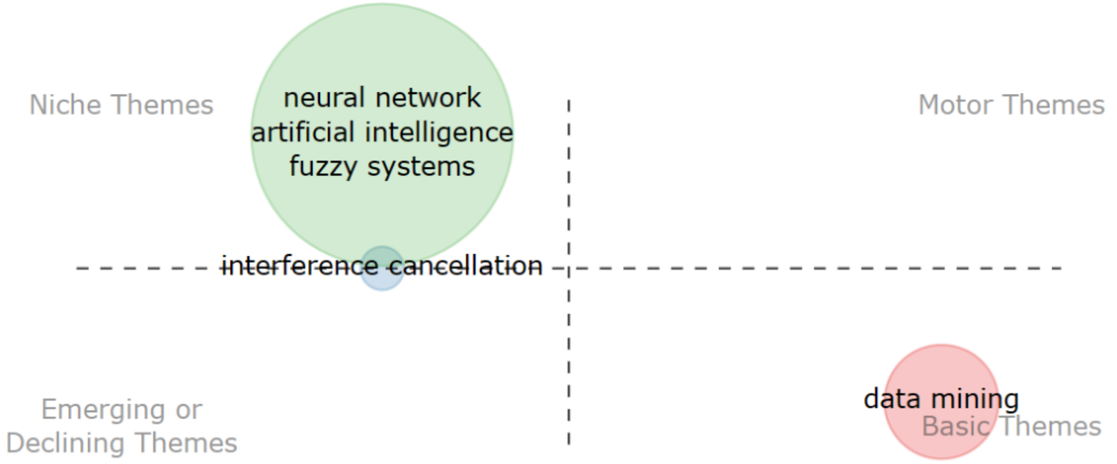

Figure 6. Thematic map for the period 2016-2022. ECG: electrocardiogram.

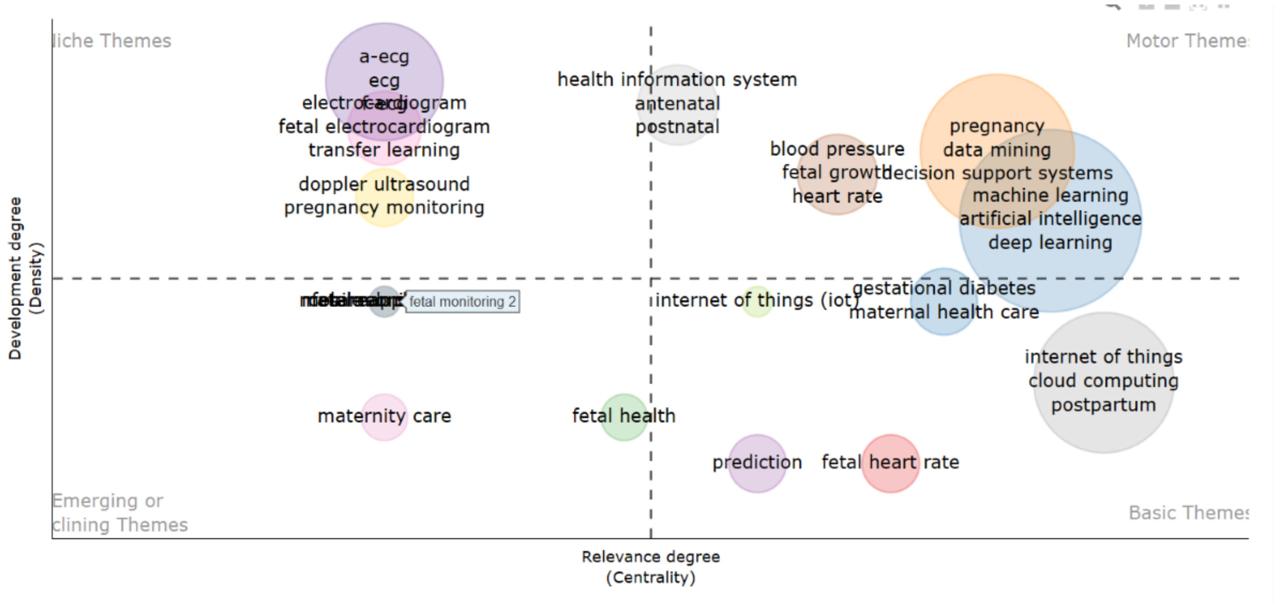

Table 4. Cluster keywords and period.

Period and cluster	Keywords
1985-2015	
Neural network	"Neural networks," "artificial intelligence," and "fuzzy systems"
Data mining	"Data mining"
2016-2022	
Machine learning	"Artificial intelligence," "deep learning," "neural networks," "risk prediction," "telemedicine," and "digital health"
Internet of Things	"IoT," "wearable devices," "m-healthcare," and "cloud computing"

The most highly developed theme was neural networks, including AI and fuzzy systems. Artificial neural networks were mostly used as classifiers. Normal, hypertensive, and preeclamptic pregnancies using maternal heart rate variability indexes were explored [38]. Another predominant use case was the prediction of high-risk preterm births using neural networks [31]. AI and fuzzy systems were used to analyze extracted fetal electrocardiogram data [48,49].

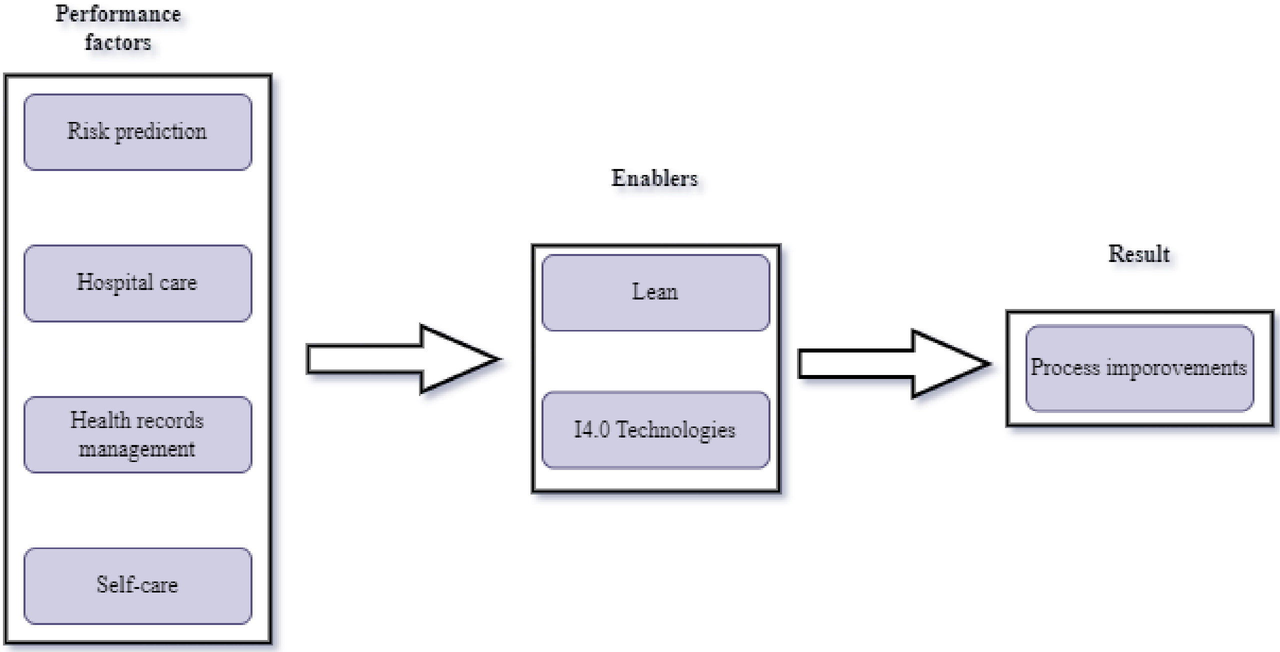
Figures 5 and 6 show that there has been a shift in themes focusing on I4.0 from niche themes that are considered of marginal importance in the research field to themes with high density and centrality. From 2016 to 2022, new themes such as deep learning, IoT, and cloud computing were developed. Prior to the 2016-2022 period, several factors hindered the widespread adoption of cloud computing in health care. These included concerns among users regarding data security and privacy, a perceived loss of control over data governance, and a lack of trust in the compliance practices of cloud service providers [50,51]. In 2016-2022, cloud computing was widely accepted despite security concerns and regulations were adopted to address these concerns [52]. Moreira et al [42] and Lopez et al [40] developed an IoT-based system to monitor hypertension in pregnant women, with alerts sent in the event of a change in hypertension. Sarhaddi et al [46] combined the IoT and AI to monitor maternal health during pregnancy and postpartum. Vitals of pregnant women were collected using sensors and further analyzed for anomalies using AI. Mhajna et al [47] developed a self-applied wireless abdominal belt to obtain fetal heart rate and maternal heart rate. Conoscenti et al [53] postulated that connected devices spread sensitive personal patient data and thus privacy can only be guaranteed by the system's technical design. They proposed a peer-to-peer system, particularly blockchain, to architect privacy-preserving in IoT systems. Fernandez-Carames and Fraga-Lamas [54] used blockchain to ensure, among others, seamless authentication, data privacy security, and robustness against attacks. However, it must be noted that from the identified I4.0 technologies that have impacted health care, as suggested by Paul et al [12], blockchain in maternal health care has not gained widespread adoption in health care; this may be due to technical challenges, regulatory uncertainties, and the lack of interoperability between different blockchain platforms [3].

Discussion

Conceptual Framework

The World Health Organization recommends that all pregnant women have at least 4 antenatal care (ANC) assessments carried out in the following cycles: 8-12 weeks, 24-36 weeks, 32 weeks, and 36-38 weeks [55]. According to Busumani et al [56], timely ANC booking helps to identify and monitor expecting mothers who might be at risk. Recordkeeping is essential when it comes to monitoring patients' health. For example, good ANC is crucial as it aims to prevent or detect complications during pregnancy. Pregnant women are encouraged to share information with their health care providers during pregnancy. Sibanda et al [3] posit that 1 area that stands to benefit from adopting manufacturing practices is maternal health care. With many processes in maternal health care, it stands to benefit by adopting Lean practices. According to Ilangakoon et al [57] , Lean practices are tools and techniques used in manufacturing to improve processes. The authors further suggest that Lean tools and techniques, when used in health care (Lean health care), simplify health care processes by adding value and eliminating processes that lead to waste. This section suggests a conceptual framework adapted from Ilangakoon et al [58] and a research agenda. Figure 7 shows the conceptual framework that combines I4.0 technologies and Lean practices in health care as developed from the reviewed literature.

Figure 7. Conceptual framework. I4.0: Industry 4.0.



Four factors contributing to the operational performance in maternal health care were identified from the reviewed literature and they are risk prediction, hospital care, health records management, and self-care. These factors must be optimized to streamline services and focus on value-adding services. Therefore, from the literature and the work by Ilangakoon et al [58] , I4.0 technologies and Lean practices were identified as enablers. When performance is optimized, it results in improved patient care, timely disease diagnosis, ease of access to patient records by all stakeholders, patient involvement in their care, and innovative product development.

As noted in Table 5, to enhance operational performance in maternal health care, 4 critical factors from the literature were identified: risk prediction, hospital care, health records management, and self-care. Directly optimizing these factors influences the delivery of value-adding services such as timely treatment, risk analysis, self-monitoring, and reduced hospital wait times. We propose that I4.0 technologies and Lean practices can enable this optimization. For example, AI-powered risk prediction tools facilitate timely disease diagnosis, while secure and accessible electronic health records promote patient involvement in their care. We anticipate enhanced patient outcomes, seamless information sharing among collaborators, and improved treatment plans by effectively using these enablers. Our results highlight the prominence of I4.0 technologies, AI, cloud computing, BDA, and IoT in improving maternal care. As expected, blockchain technology, being relatively new, is less widely adopted within the health care sector at present.

Table 5. Performance improvement of maternal processes with I4.0 technologies.

Performance factor	Process improvement	Sources
Risk prediction	Timely treatment and risk analysis may prevent more extended hospitalizations, detailed examinations, and waiting for diagnostics. With AI[a] and BDA[b], longer diagnostic processes and corrective treatment plans can be managed more effectively. Doctors can predict risk and find mitigatory measures.	[35,39,41,59]
Hospital care	The waiting time of the patient to receive medical service or preparation when being admitted to the hospital in an emergency is an issue that needs consideration. In the event of a complicated pregnancy, vital parameters of the patient can be sent ahead before admission into a hospital so that precautionary arrangements may be made and waiting time saved. Using the IoT[c] and the cloud to store sensor data allows vital parameters to be collected and sent before admission.	[14,60,61]
Health records management	During ANC[d] and postnatal care, different stakeholders play a role in managing a pregnant woman, depending on the state of the pregnancy. In a hierarchical health care system, if a lower-level facility cannot assist, they may refer the pregnant woman to a higher-level facility. However, in some cases, the woman can visit any secondary health care facility by self-referral. Thus, records must be kept for ease of sharing between health facilities and to remove the burden of carrying out tests that would have been done at another facility. This also reduces the time to treatment.	[5,6]
Self-care	Unlike other care processes, ANC is preventive and may be carried out at home or a health care facility accessible to the mother. Frequent consultations are encouraged. However, it can be noted that these consultations might clog the hospital systems and, in some developing countries, care facilities may be further from where the expectant mother is. Systems using the IoT, cloud computing, BDA, and AI have been developed to allow for home-based care. Sensors monitor the woman at home and provide data to caregivers remotely. In the event of an anomaly, alerts are sent. The expectant mother can also self-monitor through smart wearable devices or smartphones.	[7-9]

[a] AI: artificial intelligence.

[b] BDA: big data analytics.

[c] IoT: Internet of Things.

[d] ANC: antenatal care.

Conclusions

Discussion

This paper reviewed the state of the art in the evolution and structure of I4.0 technologies in maternal health care and how they may be used to optimize the operational processes. The study examined the state of research over the period of 1985-2022. We critically evaluated 37 years of I4.0 technologies in maternal health care to identify the main research themes in the field, identify opportunities, and set a research agenda. The study period was divided into 3 periods—1985-2005, 2006-2015, and 2016-2022. For analysis purposes, the first 2 periods were combined. A total of 136 publications during the entire period were identified and reviewed. There was a notable increase in the last period accounting for 121 publications. The research in this period reflects the innovative use of I4.0 technologies. The tools developed help doctors lessen the burden of constantly monitoring patients by providing automated recommendations to patients sent through wearable devices or smartphones. Technologies such as the IoT and cloud computing allow for easy data collection, data sharing among medical practitioners, and remote care of expectant mothers, while AI and BDA allow medical practitioners to gain more insights into patient data.

A noteworthy increase in the amount of research literature can be observed in bibliometric performance. Moreira and Rodrigues are the most prolific authors who have been key in developing I4.0 in maternal health care. Regarding scientific mapping, a conceptual framework was developed from the identified clusters with 4 performance factors suggested—risk prevention, hospital care, health records management, and self-care. Furthermore, how I4.0 technologies can be used to improve operational processes was discussed.

Contributions to Theory, Implications for Practice, and Research Agenda

The main contributions of this study were identifying research themes and their evolution, a conceptual framework informed by the literature, and performance factors to optimize operations in maternal health care processes.

Regarding implications for practice, our research has suggested a conceptual framework with 4 performance factors—risk prediction, hospital care, health records management, and self-care, which serve as pillars to optimize operations in maternal health care. This could be useful for health care facilities that want to optimize their operations, those overwhelmed by patients, or those in resource-limited countries with a huge turnover of health care professionals. Moreover, innovative ideas may be adapted to suit their environments from the identified use cases of I4.0 technologies in maternal health care. Further stakeholders such as policy makers, technologists, and health care professionals need to consider the areas that have a potential impact on technological advancement and they are explained in the next section.

Telemedicine and Remote Medicine

The IoT significantly expands the potential for remote monitoring and self-care in maternal health, reducing the frequency of hospital visits. Stakeholders must explore how wearables and remote monitoring devices enhance prenatal and postnatal care access, particularly within underserved communities. Key considerations include improving affordability, addressing the digital divide, and providing appropriate patient training to ensure equitable access to these technological advancements.

AI, Data Sharing, and Analytics

AI promises to improve predictive modeling to identify high-risk pregnancies at an earlier stage, enabling earlier interventions. Additionally, AI can contribute to developing personalized treatment plans for individual patients. However, addressing the potential for bias within data sets used for these applications is crucial to ensure equitable outcomes for all patients. Secure data-sharing platforms driven by technologies such as blockchain have the potential to facilitate the exchange of maternal health data across institutions while maintaining patient privacy. Big data analysis derived from these data can then inform public health interventions aimed at reducing disparities in maternal health care access and outcomes.

I4.0 Technologies and Collaboration

In pursuing effective maternal care practices, effective collaboration models are crucial for developing and implementing technology-driven maternal care solutions. Key considerations should be the best practices in building effective partnerships among all stakeholders, namely policy makers, technologists, and health care professionals.

Regulatory Frameworks and Ethics

Interdisciplinary teams should prioritize addressing ethical concerns related to privacy, consent, and equity when deploying new technologies, especially AI use in health care [62]. Considerations should be made on how teams can work together to address the ethical issues regarding privacy, patient consent, and equitable deployment of I4.0 technologies. Furthermore, with a lack of regulatory frameworks for deploying these technologies, stakeholders should proactively address the regulatory complexities.

Regarding theoretical contributions, our bibliometric review helped identify the leading journals for literature and publication, the universities and institutions leading in research, and the most prolific and leading researchers in the field for possible collaboration. The review outlined the research field’s evolution and development and suggested a research agenda. In terms of the latter, a researcher may be able to discover new research avenues in the following sections.

Governance Considerations for Implementing I4.0 Technologies in Health Care

Much research focused on the use of AI in maternal health care. However, most of the reviewed literature was conceptual in the form of frameworks, models, and prototypes with no implementations on production systems. This can be attributed to ethical issues in adopting AI in mainstream systems. There is thus scope for further research to identify the challenges and obstacles limiting the implementation of prototypes in an actual medical setting and the development of ethical frameworks. IoT-based systems collect data from various devices (“things”) remotely from expectant mothers to be used in health care facilities to monitor them and, in some cases, made available to research institutions. The issue now is who the owners of the data are. How should that data be used? The ownership of health data is a sensitive issue that warrants further scrutiny.

Developing Adoption Frameworks or Models

It can be noted that most of the research to solve challenges in maternal health care is coming from outside Africa, yet the continent has a high maternal mortality rate. However, the developed solutions can be adapted to the African context. Health care processes are many and varied and most are not standardized, which brings challenges in adapting the developed solution to another context. Another issue is the interoperability challenges between disparate systems. There is scope for further research on developing frameworks and models to guide the interoperability of disparate systems. Furthermore, research is needed on how the I4.0 technologies can be applied in maternal health care to optimize processes and integrate them into existing systems.

Infrastructure, Privacy, and Security Mechanisms

IoT applications collect data through the use of many sensors, and in most cases, they are used in conjunction with technologies such as cloud computing to store data. Data are analyzed for insights using BDA tools. Adequate infrastructure is required for flexible performance and management of large volumes of data, which is an issue that is critical in the proper performance of IoT applications. Unauthorized access to sensor data in transit or stored on the cloud threatens patient data integrity and this problem needs to be resolved. Blockchain and more specifically, nonfungible tokens have been used to secure and guarantee data ownership. This open research area needs to be explored within the context of maternal health care.

Limitations

Our study has limitations that deserve acknowledgment. While we are confident that Scopus, a multidisciplinary database publishing peer-reviewed research, provided a valuable foundation for our analysis, future studies could benefit from including additional databases like Web of Science to potentially capture a broader range of relevant publications. Additionally, the scope of explored I4.0 technologies could be broadened. This study focused on 5 key technologies, but future research could investigate the potential applications of 3D printing, augmented reality, virtual reality, digital twins, and cyber-physical systems in improving maternal health care. Finally, while “maternal health” was a broad keyword for this initial investigation, a more refined set of keywords might be necessary in future studies to ensure a comprehensive capture of specific research within the broader field.

Abstract

Background: Child and Family Health Nursing (CFHN) services provide universal care to families during the first 2000 days (conception: 5 years) to support optimal health and developmental outcomes of children in New South Wales, Australia. The use of technology represents a promising means to encourage family engagement with CFHN services and enable universal access to evidenced-based age and stage information. Currently, there is little evidence exploring the acceptability of various models of technology-based support provided during the first 2000 days, as well as the maternal characteristics that may influence this.

Objective: This study aims to describe (1) the acceptability of technology-based models of CFHN support to families in the first 6 months, and (2) the association between the acceptability of technology-based support and maternal characteristics.

Methods: A cross-sectional survey was undertaken between September and November 2021 with women who were 6-8 months post partum within the Hunter New England Local Health District of New South Wales, Australia. Survey questions collected information on maternal demographics and pregnancy characteristics, perceived stress, access to CFHN services, as well as preferences and acceptability of technology-based support. Descriptive statistics were used to describe the characteristics of the sample, the proportion of women accessing CFHN services, maternal acceptability of technology-based support from CFHN services, and the appropriateness of timing of support. Multivariable logistic regression models were conducted to assess the association between maternal characteristics and the acceptability of technology-based CFHN support.

Results: A total of 365 women participated in the study, most were 25 to 34 years old (n=242, 68%), had completed tertiary level education or higher (n=250, 71%), and were employed or on maternity leave (n=280, 78%). Almost all (n=305, 89%) women reported accessing CFHN services in the first 6 months following their child's birth. The majority of women (n=282-315, 82%-92%) "strongly agreed or agreed" that receiving information from CFHN via technology would be acceptable, and most (n=308) women "strongly agreed or agreed" with being provided information on a variety of relevant health topics. Acceptability of receiving information via websites was significantly associated with maternal employment status (*P*=.01). The acceptability of receiving support via telephone and email was significantly associated with maternal education level (adjusted odds ratio 2.64, 95% CI 1.07-6.51; *P*=.03 and adjusted odds ratio 2.90, 95% CI 1.20-7.00; *P*=.02, respectively). Maternal age was also associated with the acceptability of email support (*P*=.04).

Conclusions: Technology-based CFHN support is generally acceptable to mothers. Maternal characteristics, including employment status, education level, and age, were found to modify the acceptability of specific technology modalities. The findings of this research should be considered when designing technology-based solutions to providing universal age and stage child health and developmental support for families during the first 2000 days.

Introduction

The first 2000 days of a child's life (conception: 5 years) is a critical time for physical, cognitive, social, and emotional development [1]. Routine health care services or interventions provided in early life have been shown to be protective of poor health outcomes and improve early life experiences, such as learning outcomes, mental well-being, and relationships, as well as healthy growth and development [2,3]. Future health outcomes for children are influenced by these early life experiences and exposures, and subsequently the cumulative effects of positive or negative later life experiences [3].

Given the first 2000 days are a critical period of child health and development, the World Health Organization and governments internationally have released policy frameworks and guidelines that outline strategies and objectives to support the health and development of children during the first 2000 days [4,5]. One example is the First 2000 Days implementation strategy, a government framework that has been released in New South Wales (NSW), Australia [1,6]. A key objective within this framework is that NSW Health provides universal access to child and family health care via Child and Family Health Nursing (CFHN) services. CFHN services support the health and development of children from birth to 5 years across the state through a family centered approach. Services routinely offered by CFHN services include universal health home visits in the first month of a child's life, postnatal care, immunizations, child health, and developmental checks (through the Personal Health Record or "Blue Book"), feeding support and maternal psychosocial assessments and screening [1]. Despite the availability of this comprehensive service, only half of the 100,000 families of children born each year within NSW continue to access CFHN services within the first year [7], limiting the capacity of CFHN services to provide ongoing and universal health care to families consistent with best practice guidelines.

The delivery of health care services via technology represents a promising way to increase family engagement with CFHN services and provide universal access to evidence-based information consistent with recommendations. In Australia, the COVID-19 pandemic resulted in the widespread adoption of digital technologies to deliver health care services [8-10] including care routinely offered by CFHN services. For example, CFHN services at a local and state level currently use technology, such as telehealth, email, and social media, to support the delivery of care to women and families across NSW [11,12]. While emerging evidence supports the effectiveness and acceptability of nurse-delivered telehealth consultations [11,12], to our knowledge, there is little evidence of the acceptability of other models of technology-based support provided to families during the first 2000 days.

While characteristics, such as age, education, computer literacy, ethnicity, employment, socioeconomic position, and gender, have been associated with the uptake and acceptability of digital health interventions more broadly [13,14], there is limited evidence that comprehensively examines associations between maternal characteristics and the acceptability of technology-based CFHN services, which may be important for designing services that are tailored to individual needs [15]. Given the current evidence gaps, this study aimed to describe (1) the acceptability of technology-based models of CFHN support to families in the first 6 months, by differing health topics, as well as preferences for timing of information receipt; and (2) the association between the acceptability of technology-based support by maternal characteristics hypothesized to influence adoption of technology-based interventions.

Methods

Ethical Considerations

This study is reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [16]. Ethical approval to undertake the study was obtained from the Hunter New England (HNE) Human Research Ethics Committee (16/11/16/4.07), Aboriginal Health and Medical Research Council (1236/16), and the University of Newcastle Human Research Ethics Committee (H-2017-0032). This research was conducted in compliance with informed consent guidelines and adhered to national law and regulations regarding the protection of personal information, privacy, and human rights.

Study Design and Setting

A cross-sectional survey conducted via computer-assisted telephone interview (CATI) was undertaken between September and November 2021 with women who were 6-8 months post partum within the HNE Local Health District of NSW, Australia. The HNE area is a socioeconomically and geographically diverse region covering approximately 130,000 square kilometers, encompassing major metropolitan, regional, and remote locations [17]. In 2020, there were 10,377 births in the HNE region, accounting for 11.2% of births in NSW [18].

Context

In NSW, CFHN services provide public health care to women and their families in the child's first 5 years of life. Health professionals that attend to these services include child and family health nurses, registered midwives, doctors, allied health workers, Aboriginal health workers, and practitioners [19]. Across NSW, there are approximately 417 CFHN services, and approximately 16.3% of CFHN services are located in the HNE Local Health District [19]. The provision of CFHN services may include but not be limited to health home visits, breastfeeding or infant feeding education and support, maternal and child routine screening (ie, maternal psychosocial screening and child vision and hearing screening), child health checks, immunizations, contraception, mental health, and parenting education [20].

Sample and Recruitment

Women who were 26-37 weeks (6-8 months) post partum, had received antenatal care from public maternity services in the HNE region (responsible for the provision of antenatal care to approximately 70% of women across the district) [17,18] and had previously participated in an antenatal survey while pregnant and agreed to be contacted for future surveys were eligible to participate in the study [21,22]. As per eligibility criteria for the initial antenatal survey, women were ineligible if they were younger than 18 years of age, had an unfortunate pregnancy-related outcome, including stillbirth or death of child, or were not proficient in English preventing them from undertaking the survey unaided.

Recruitment Procedure

All women in the sampling frame (N=713) were invited to participate in the CATI via a mailed written information statement. The written information statement included an outline of the purpose of the survey and a toll-free number to opt-out or decline survey participation. Electronic medical record data (ie, child's date of birth and live birth) and previous antenatal survey data (ie, consent to be contacted again) were used to generate a weekly sample of eligible women over an 8-week period. A weekly sample of 100 women were approached to participate in the study for the first 6 weeks, with 68 and 47 women approached in the final 2 weeks of recruitment, respectively. Participants were approached in descending order of their child's date of birth (ie, parents of older babies were approached first).

Recruitment Procedure for Non-Aboriginal Women

One week after information statements were mailed, non-Aboriginal women were contacted via telephone and invited by a female interviewer to participate in the survey through a CATI. Women received up to 10 phone attempts over a two-week period to invite study participation. As per formal ethics approval, verbal consent to participate in the study was sought from women during the CATI. Women who declined to participate during the CATI were offered the opportunity to complete the web-based survey. Women who opted to complete the web-based survey were sent an individual survey link to their mobile number or email address. Prior to accessing the web-based survey, women were reminded, on the survey's display screen, that participation was voluntary and that it was possible to decline the survey at any point. Women's consent into the study and survey completion status (both via the CATI and web-based) were saved into a central survey database held by the research team.

Recruitment Procedure for Aboriginal and Torres Strait Islander Women

As per advice received through local cultural consultation processes, women of Aboriginal or Torres Strait Islander origin and/or women who attended or were enrolled to attend an Aboriginal Maternal and Infant Health Service as identified via medical record data were sent an SMS text message after the mail out of the information statement. The SMS text message offered women one of three options as follows: (1) to complete the survey via CATI; (2) to complete the web-based survey; or (3) to decline participation. As per the procedures described above, women who opted to complete the web-based survey were sent an individual survey link to their mobile number which was active for 2 weeks. Women who opted to complete the survey via telephone or did not reply to the SMS text message within 5 days were contacted via telephone and invited to participate in the study by a female interviewer. Women who declined participation via SMS text message were recorded in the central survey database. All women who opted to complete either the telephone or web-based survey were given the opportunity to identify as Aboriginal or Torres Strait Islander or both (regardless of their previous medical record or antenatal survey data). As per ethics and local consultation processes, women who identified as Aboriginal and/or Torres Strait Islander during the CATI were offered the choice of undertaking the survey with a female Aboriginal interviewer.

Data Collection Procedures

Both the CATI and web-based surveys were developed in REDCap (Research Electronic Data Capture; Vanderbilt University) electronic data capture tools [23]. Survey consent and responses were also stored in REDCap which acted as the central survey database. All survey items were developed and based on local, state, and national health surveys with postpartum women [24,25] and surveys conducted in similar health settings (ie, antenatal services) to assess self-reported acceptability and care by the health service [22]. The surveys were reviewed by child and family health nurses, dietitians, Aboriginal health care workers, and end users (mothers and Aboriginal and Torres Strait Islander women) and pilot-tested prior to use.

Outcome Measures

Women were asked the following questions in this survey: Aboriginal and/or Torres Strait Islander origin; country of birth; residing postcode, current employment status (full-time, part-time, casual, paid or unpaid maternity leave, unemployed, home duties, student, retired, full-time carer, unable to work due to health problems); timing of their return to work after birth (in months); the child's date of birth. The survey items were adapted from previous surveys with postpartum women [25] and the Australian Infant Feeding Study [24]. Maternal education status, first or subsequent pregnancy status, and maternal age were not collected in this survey as they were previously collected via the initial antenatal survey with women or medical record data [22]. Participants were asked about their perceived stress via the "perceived stress scale" [26]. The tool is a validated 10-item scale that asks participants to rate their feelings and thoughts in the last month on a 5-point Likert scale from 0 (never) to 4 (very often). For example, the first item asks "In the last month, how often have you been upset because of something that happened unexpectedly?"

Participants were asked about whether they had accessed CFHN services in the first six months since the birth of their baby (yes or no) and the location of the visit (home or clinic).

Preferences and Acceptability of Technology-Based Support for Child and Family Health Services

Questions around the acceptability of perceived models of care were developed using a 5-point Likert scale (strongly agree to disagree) and were informed using previous surveys with women attending antenatal services [22]. To assess the perceived acceptability for various technology-based CFHN service provision models, mothers were asked: "Can you tell me if you strongly agree, agree, neither agree or disagree, disagree or strongly disagree with receiving information from the health service to support the health of you and your baby for each of these models of technology?" Where five digital delivery models (accessible within current NSW health care systems) were listed (1) SMS text message, (2) website, (3) telehealth services, (4) phone, (5) email, and women were prompted to indicate their acceptability for each option listed. To assess preferences for health-related topics, mothers were asked "Please tell me whether you believe it would be okay to receive support and advice on these topics via technology-based services. You can respond with strongly agree, agree, neither agree or disagree, disagree or strongly disagree." A list of 11 health-related topics (informed by key Blue Book topics aligned with focus areas of CFHN service provision) were given as options for this question including (1) breastfeeding or bottle feeding, (2) growth checks and immunization reminders, (3) introduction to solids (including timing, portion and type of foods), (4) fussy eating, (5) sleep and settling, (6) age and stage developmental milestones, (7) healthy growth, (8) healthy eating, (9) mental health, (10) social support, (11) parent groups or networks, and women were able to select all response options that applied. Preferences for the timing of the receipt of technology-based support were assessed by asking: "In addition to usual care, if the health service was to provide families with information and support via technology about feeding your baby, when would be the ideal time to receive this information." Women were instructed to select all response options that applied, including (1) 1st trimester, (2) 2nd trimester, (3) 3rd trimester, (4) 0-6 months after birth, and (5) 7-12 months after birth.

Characteristics Associated With Perceived Acceptability of Technology-Based CFHN Models of Care

We explored if there were any differences in acceptability by technology-based models of CFHN support by characteristics hypothesized to influence acceptability and use of digital health interventions [13] such as maternal age, maternal education, socioeconomic area, geographical remoteness, current employment status, first pregnancy, Aboriginal or Torres Strait Islander origin, perceived stress, and CFHN service access (in first 6 months post birth).

Data Analysis

All data were analyzed using the statistical software package SAS (version 9.3; SAS Institute). Descriptive statistics were used to describe the (1) characteristics of the sample, (2) the proportion of women accessing child and family health services in the first 6 months, (3) acceptability of receipt of technology-based support from child and family health services, and (4) appropriate timing of information receipt. Data regarding the characteristics of the sample are presented categorically. Maternal age and timing of return to work after birth were trichotomized where maternal age was categorized as "18-24 years," "25-34 years," and "≥35 years" and women's timing of return to work after birth was categorized as "0-3 months," "4-6 months," and ">6 months." Condensed response categories were created for (1) Aboriginal or Torres Strait Islander Origin ("Aboriginal and/or Torres Strait Islander" or "Neither Aboriginal or Torres Strait Islander" and "don't know"), (2) maternal education ("high school or less" or "tertiary education or more"), and women's current employment status including "employed" (full-time, part-time, or casual); "maternity leave" (paid or unpaid) or "unemployed" (home duties, unemployed, retirees, or full-time carers). Women's residential postcode was used to determine socioeconomic areas using the 2016 socioeconomic indexes for areas [27], which were dichotomized at the median into areas of "most disadvantage" or "least disadvantage." Women's residential postcode was also used to determine geographical remoteness ("major cities" or "regional or remote") using the Access/Remoteness Index of Australia [28]. Women's perceived stress was determined using the 10-item perceived stress scale [26] where scores were assigned ranging from 0 to 4 for each respective question. The score for each question was then summed to provide a total score of 40. "Low stress" was defined as a score ranging from 0 to 13, "moderate stress" was defined as a score ranging from 14 to 26, and "high stress" was defined as a score of 27 to 40. Child age at the time of survey completion is presented continuously (mean, SD). Women's reported acceptability of CFHN via varying models of technology was dichotomized into "acceptable" (agreed or strongly agreed) and "not acceptable" (strongly disagree, disagree, or neutral).

Logistic regression models were created to assess associations between maternal characteristics [(1) Aboriginal and/or Torres Strait Islander status, (2) age, (3) education, (4) socioeconomic status, (5) geographical remoteness, (6) employment status, (7) first pregnancy, (8) perceived stress, and (9) use of CFHN services] and a measure of the acceptability (agree or strongly agree) of technology. Separate logistic regression models were undertaken for each of the five technology models [(1) website, (2) telehealth, (3) telephone, (4) SMS text message, and (5) email], exploring 45 crude logistic regression models in total. Both crude (unadjusted) and models adjusted for all 9 participant characteristics are presented.

In the instance where regression models were unable to produce an odds ratio (OR; if 100% of the group were in one comparison arm), a Haldane-Anscombe correction [29] was applied, whereby the data was weighted in order to add 0.5 to each cell frequency. Statistical significance was set at *P*<.05.

Results

Characteristics of Sample

A total of 356 (50% response rate) women participated in the study. While most of the characteristics between the consenting and nonconsenting sample were similar, self-reported Aboriginal and/or Torres Strait Islander status was significantly (*P*=.03) higher within the nonconsenting sample (n=36, 11.6%) compared with the consenting sample (n=23, 6.6%). The majority (n=315, 88%) of consenting study participants were born in Australia with 57% (n=202) of participants residing in major cities and 43% (n=154) of participants in regional or remote locations. Aboriginal and/or Torres Strait Islander women represented 7% (n=23) of the sample. Most of the women were between the ages of 25 and 34 years old (n=242, 68%), had completed tertiary level education or higher (n=250, 71%), and were on maternity leave (n=140, 39%). Of those that were currently employed (n=140), just over half (n=79, 56%) returned to work between 4 and 6 months after birth. The majority of women (n=205, 58%) had perceived stress scores rated as “low” at the time of the survey. The full characteristics of the sample are presented in Table 1.

Table 1. Characteristics of women who participated in the survey.

Characteristics	Value (N=356)
Aboriginal and/or Torres Strait Islander[a], n (%)	
Yes	23 (7)
No or don’t know	325 (93)

High stress	18 (5)

[a] There were missing data for this survey item and the denominator does not total 356 (ie, the women did not respond to the item or skipped the question).

[b] Defined by residential postcode using the 2016 Socioeconomic Indexes for Areas.

[c] Defined by residential postcode using the Access/Remoteness Index of Australia.

A total of 89% (n=305) of women reported accessing CFHN services in the first 6 months following their child's birth, with 86% (n=262) of visits occurring in the home and 58% (n=177) of women having visited a clinic.

Preferences and Acceptability of Technology-Based Support From Child and Family Health Services

As shown in Table 2, the majority of women "strongly agreed or agreed" that receiving information from the health service via technology would be acceptable (range: 82%-92%; Cronbach α=0.66), with "website" being rated as the most accepted (n=315, 92%). Most women "strongly agreed or agreed" with being provided with information on all health topics via technology (range: 90%-98%). The most accepted topics were "growth checks and immunization reminders" (n=335, 98%), "healthy eating" (n=333, 97%), and "introduction to solids" (n=331, 97%). Women reported a preference to receive information about feeding their baby in the 3rd trimester of pregnancy (n=173, 50%) or 0-6 months after birth (n=201, 59%).

Table 2. Women who agree or strongly agree to receipt of CFHN[a] support via technology-based services during the first 6 months (in addition to usual CFHN care), and timing preferences for provision of support.

Variable	Value (N=343), n (%)

7-12 months after birth	33 (10)

[a] CFHN: Child and Family Health Nursing.

[b] "Acceptability" was defined as "agree" or "strongly agree" with receipt of technology-based information.

[c] Women were instructed to select all that apply.

Associations With Perceived Acceptability of Technology-Based CFHN Models of Care

While the acceptability of technology-based CFHN services was high for participants overall, some associations were found between maternal characteristics and the acceptability of support provided by technology-based CFHN services (Tables 3-5 and Tables S1 and S2 in Multimedia Appendix 1). Website acceptability was significantly associated with employment (*P*=.01), where women had higher odds of reporting website acceptability if they were employed (adjusted OR 3.30, 95% CI 1.22-8.91) or on maternity leave (adjusted OR 5.06, 95% CI 1.61-15.91) compared to women who were unemployed. For telephone acceptability, women who had received a "high school education or less” had higher odds of agreeing or strongly agreeing that support provided by telephone would be acceptable compared to women who had received “tertiary education or higher” (adjusted OR 2.64, 95% CI 1.07-6.51; *P*=.03). Additionally, women who reported it was their first pregnancy had lower odds of telephone acceptability compared to those that had a previously reported pregnancy (adjusted OR 0.37, 95% CI 0.18-0.76; *P*=.007). For email acceptability, women who had received “high school education or less” had higher odds of reporting email support as acceptable compared to those who had a “tertiary education or higher” (adjusted OR 2.90, 95% CI 1.20-7.00; *P*=.02). Similarly, women who had accessed a CFHN service in the first 6 months since birth had a higher odds (adjusted OR 2.44, 95% CI 1.07-5.53; *P*=.03) of reporting email support as acceptable compared with those that had not accessed a CFHN service. Women’s age was also associated with email acceptability (*P*=.04), where women aged 25-34 years reported higher acceptability of email support (n=206, 87%) compared to women aged 18-24 years (n=32, 76%) and those 35 years and older (n=49, 75%). There were no significant differences between maternal characteristics and telehealth or SMS text messaging acceptability.

Discussion

Principal Findings

This study describes the acceptability of technology-based models of CFHN support to families in the first 6 months postpartum and identifies maternal characteristics that may influence the acceptability or adoption of such technology-based models. Our findings indicate most mothers (90%-98%) would find receiving information on key health topics via technology-based platforms acceptable. While there was high acceptability across a range of maternal characteristics, employment status, education level, and age were significantly associated with maternal acceptability of receiving various types of digital support and should be considered when developing technology-based models of CFHN support or care.

The technology platform that the highest proportion of mothers found acceptable for receiving health information was websites (n=315, 92%), followed by telehealth (n=306, 89%), telephone (n=295, 86%), email (n=287, 84%) and SMS text messaging (n=282, 82%). Given that mothers universally (ie, >80%) reported these technology-based platforms as acceptable, these findings suggest that various models of technology-based support would be suitable for providing families with child health and parenting support. This finding is largely consistent with the wider published literature, indicating that pregnant women and new mothers believe that the use of digital platforms, such as websites or SMS text messages, is a preferable and appealing method for receiving health information due to the convenience of the delivery models [30,31].

Almost all mothers surveyed in this study indicated that they would like to receive information related to growth checks and immunizations (n=335, 98%), healthy eating (n=333, 97%), and the introduction of solids (n=331, 97%). However, at least 90% of mothers indicated an interest in another eight topics including breastfeeding or bottle feeding, sleep and settling, and healthy growth, highlighting that new mothers are interested in accessing information across a broad spectrum of health topics related to their babies. Approximately 50% of mothers indicated a preference for receiving health information during the 3rd trimester and 59% of mothers in the first 6 months after birth. This finding is consistent with previous qualitative research that found mothers were most open to receiving parenting information closer to or after the baby was born, but not while in the hospital [30]. The 3rd trimester and first 6 months after birth when the mother is home with her newborn represents a highly receptive period for providing mothers with supportive, relevant, and reliable child health and parenting information.

Early motherhood represents a period in which women are interested in accessing a wide range of parenting information. Increasingly, the use of digital media sources represents an opportunity for women to access information that is of relevance to them, and at times that is convenient. Specifically, qualitative data has indicated that mothers tend to favor digital media during early motherhood, as they valued that the information was: (1) immediate (ie, quick Google search), (2) regular (ie, regular release of information without their intervention), (3) detailed, (4) entertaining (ie, relatable content or means of alleviating boredom), (5) customized, (6) practical (ie, how to), (7) professional, (8) reassuring, and (9) unbiased (ie, noncommercial) [32]. However, the most acceptable and equitable digital or technology mode for supporting mothers to assess child health and parenting information during this time remains unclear.

To the authors’ knowledge, very few studies have previously examined the association between the acceptability of various technology-based models of CFHN care with maternal characteristics [33,34]. Our findings indicated that websites had higher odds of being acceptable if the mother was employed or on maternity leave. An Australian study conducted in 2010 by Wen et al [35] found that lower-income households and less educated mothers tended to have lower rates of internet access for accessing health information. These findings suggest a possible inequity of websites for providing child health and parenting information, however, the spread of smartphones and internet access over the past decade has likely reduced this potential inequity [35]. In addition, we found higher odds of telephone and email support being acceptable if the mother had received a “high school education or less” compared with women who received a “tertiary education or higher.” Email was also more acceptable if the mother had accessed the CFHNs in the first 6 months following the birth, and if the mother was 25-34 years old. Maternal characteristics were not significantly associated with the acceptability of telehealth or SMS text messaging modalities, suggesting that CFHN support offered through these platforms may be more equitably accessed by mothers, however, further research exploring this topic is timely.

Limitations

Limitations of this research include the cross-sectional nature of the study and possible selection bias (influenced by a 50% response rate), which may limit the generalizability of these findings. Additionally, the sampling of mothers may have been slightly skewed to include mothers who are more engaged with CFHN services, as 89% (n=305) of mothers in the sample accessed CFHNs in the first 6 months following birth, which is higher than HNE-wide CFHN service attendance (<70%). However, the survey question used to capture this data did not ask if mothers attended all scheduled CFHN service visits in the first 6 months, therefore participant engagement with CFHN services may appear artificially high, as other characteristics of the sample are similar to that of the broader HNE region [36], with approximately 62% of mothers aged between 25 and 34 years and 91.5% from English speaking backgrounds [37]. Although previous research has demonstrated high acceptability and feasibility for delivering health advice to women using mobile apps [38], this research did not explore the acceptability of mobile apps given the well-known technological issues often experienced with the development and upkeep of mobile apps [39]. Rather, this research focused only on technology-based platforms that are already readily available within the health service. As such gaps remain in our understanding of mother acceptability for a range of possible technology platforms for delivering CFHN care, outside of those assessed in this study. Additionally, some of the regression analyses conducted for this study produced wide confidence intervals, suggesting a level of uncertainty in some of the associations and should be considered when interpreting the findings.

Conclusions

The findings of this study indicate that mothers are interested in using technology to access information related to a variety of child health and development topics, specifically within the first 6 months post partum. Technology-based models of providing this support to mothers, alongside CFHN services were found to be highly acceptable among new mothers, however, maternal characteristics, including employment status, education level, and age, were found to significantly modify maternal acceptability of technologies including websites, telephone, and email. Despite mothers indicating an appetite for receiving age and stage-relevant health and development information via technology-based approaches, future research is warranted to ensure technology-based models of CFHN care are accessed equitably by mothers.

Abstract

Background: Sexual health indicators for adolescents and young adults (AYAs) aged between 13 and 25 years are particularly poor on Reunion Island. Access to accurate information as well as sexual health and contraceptive services are vital to maintaining sexual well-being. Teleconsultations offer a promising approach to addressing the sexual health and contraceptive needs of AYAs who are more susceptible to engaging in unprotected sexual intercourse. However, the literature on digital sexual health services for this demographic group is limited.

Objective: This study aims to describe the feasibility of a pilot sexual health and contraceptive teleconsultation web service used by AYAs on Reunion Island.

Methods: A descriptive, retrospective study was conducted at the Reunion Island University Hospital Center using a convenient sample. Eligible participants were informed about the program through various communication channels, including seminars for health care professionals, radio broadcasts, posters, flyers, press articles, videos, and social media posts. AYAs accessed a web-based platform named SEXTUOZE from December 15, 2021, to September 30, 2022, that offered sexual health information and teleconsultations. Data collected included participant and teleconsultation characteristics, patient satisfaction, and the quality of completeness of medical records.

Results: A total of 22 teleconsultations were scheduled and 7 were completed, all via synchronous video communication (duration: median 35 min). Overall, 4731 sessions were generated on the SEXTUOZE website. Reasons cited for accessing the web services were to seek sexual health advice (8/22, 36%), receive an initial birth control prescription (12/22, 55%), and inquire about condom prescriptions (2/22, 9%).

Conclusions: While teleconsultation use for sexual health was initially low, it rose toward the end of the study period. Considering all elements of the implementation theory, future research should design interventions that not only are more operative and tailored but also ensure their adoption and sustainability in various health contexts.

Introduction

Adolescent pregnancy, defined as pregnancy in adolescents and young adults (AYAs) younger than 20 years, is a global public health concern occurring in high-, middle-, and low-income countries [1]. According to the World Health Organization, complications in pregnancy are the leading cause of death for girls aged 15 to 19 years [2]. These pregnancies are influenced by various interconnected factors, including sociocultural norms, lack of sexual education, poor economic conditions, and relationship dynamics, as well as limited access to reproductive health services. Lack of access to and use of contraceptive methods has been considered a key factor [1]. Social and family pressures, as well as media influences, also play a significant role [3].

On Reunion Island, a French overseas department situated in the Indian Ocean, unwanted pregnancies are a significant concern [4]. In 2022, according to the French National Institute of Statistics and Economic Studies (INSEE), 4.3% of births involved mothers younger than 20 years, a rate almost 3 times higher than that of mainland France (1.7%) [5]. The abortion rate was 13%, double that of mainland France [6]. Abortion rates were also high among young people aged 20 to 24 years, with 26.9% in metropolitan France and the overseas territories [6]. Moreover, data from the regional health observatory in 2019 reported that only half of sexually active AYAs aged 15 to 17 years used contraception during their first sexual encounter [7].

For young women aged 15 to 25 years who had already had their first sexual intercourse, a survey reported that 56% used a contraceptive method other than condoms and that a lack of knowledge and negative perceptions of contraception, along with the family taboo surrounding sexuality, contributed to it [7]. Some AYAs were aware of various contraceptive methods; however, their fragmented understanding of how to obtain them prevented the effective prevention of unwanted pregnancies [8]. de Pirey et al [9] presented that nearly a quarter of Reunionese minors who had an abortion or gave birth in 2009 never used any contraceptive method and that 42% did not use any contraceptive method in the month their pregnancy began. This study also reported that these minors had difficulties in accessing contraception, citing financial or confidentiality issues [9].

Sexual health resources available to AYAs on Reunion Island are substantial; however, they may be hindered by the mountainous geography and the isolated nature of many villages [10]. Patient access to sexual health services, particularly for AYAs who have scheduling constraints such as attending school or who do not drive, may be significantly impacted. This phenomenon may also be aggravated by the heterogeneous distribution of health care services on the island [10]. There are 3 free drop-in sexual health centers (known as the Centres Gratuits d'Information, de Dépistage et de Diagnostic [CeGIDD]) and 10 family planning and education facilities (Centres de Planification et d'Éducation Familiale [CPEF]) located on the island, which offer free birth control consultations and sexually transmitted illness (STI) screenings for AYAs. Contraception is free of charge and can be provided without informing the parents of minors [10]. Moreover, digital coverage extends to 80% of the territory, and in 2017, a total of 78% of the population older than 15 years were reported to have internet access at home [11].

Telemedicine activities, such as teleconsultations, are a promising approach to improving access to health care services [12]. Telemedicine is the use of telecommunications technology to provide medical care, consultations, and health education remotely. It can include services such as web-based doctor visits, remote monitoring of patients, digital transmission of medical data, and the provision of health information via electronic communication. The aim of telemedicine is to enhance the accessibility and quality of health care, particularly for individuals in remote or underserved areas, by overcoming the physical distance between patients and health care providers [12].

In gynecologic care, telemedicine may provide an innovative solution for improving access to sexual health services [13-15]. Globally, teleconsultations allow access to contraceptive care [16], birth control advice [17], medication-induced abortions [18], and the management of STIs [19]. However, access to sexual health care and contraceptive methods faces several contemporary challenges, particularly concerning teleconsultation services for AYAs. Literature has reported the frequency of internet connection failures, lower acceptability of such services, confidentiality, and data security concerns among a younger audience while confronted by the lack of data on the number and satisfaction of teleconsultations carried out [20]. Patients consulting gynecologists via digital health services in Australia reported satisfaction with their experience, finding it useful, time-saving, and cost-efficient [21]. In another study, although face-to-face care was preferred, digital health services for AYA contraceptive needs were perceived as both acceptable and accessible by most patients [19]. A study on young adults examined how AYAs used contraceptive methods over time, based on telemedicine consultations with health care professionals [22]. The implementation of teleconsultations for sexual and reproductive health in isolated regions, such as Reunion Island, presents a unique opportunity to overcome geographical and sociocultural barriers. Few studies have explored the impact of such solutions in insular contexts, providing valuable insights into the adaptation and implementation of these services in similar regions around the world. The objective of this study was to evaluate the feasibility of a sexual health teleconsultation website focused on providing detailed information and issuing contraceptive prescriptions for AYAs on Reunion Island.

Methods

Study Design

A retrospective single-center analysis of a sexual health pilot program implemented at the University Hospital of Reunion Island was conducted from December 15, 2021, to September 30, 2022. In June 2020, the pilot program consisted of two phases: (1) designing a website and teleconsultation platform (SEXTUOZE) within a Symphony Framework environment, and (2) evaluating the feasibility of the teleconsultations. A 24-month budget was allocated to complete the project; 14 months were required for the website development due to administrative, technological, and institutional issues, leaving only 10 months for testing with AYAs. The platform was developed by a team comprised of midwives, nurses, doctors, and the primary investigator, in collaboration with the development team. Due to time constraints, AYAs were not invited to participate in the setup process. Multimedia Appendix 1 details how SEXTUOZE worked. The implementation of the teleconsultation platform responded to a governmental request as part of the sexual health strategy in France [23]. The study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines.

Publicity

Information about the pilot study and SEXTUOZE was disseminated through seminars for 150 health care professionals, radio broadcasts, posters, flyers, news articles, videos, and social media posts. Two hundred students attended the presentations at their schools. Content was shared on 2 social media networks (Facebook and Instagram) under the hashtag #Sextuoze. Participating nurses and midwives managed the sites after specific training. Weekly publications and daily stories were posted throughout the 10-month study period, following specific hospital guidelines. The various media campaigns provided information about the digital health services, their mission, and how they worked to encourage AYAs to use sexual health and contraceptive web-platform services.

Sampling and Recruitment

We used convenience sampling, including all AYAs aged 15 to 25 years residing on Reunion Island, who accessed the SEXTUOZE teleconsultation platform during the study period. Potential participants were informed about the program through various communication channels, including seminars for health care professionals, radio broadcasts, posters, flyers, press articles, videos, and social media posts (Facebook and Instagram).

Study Intervention

The teleconsultations concerned information and education about sexuality (including prevention of STIs, the morning-after pill, birth control, and prevention of sexist behavior and sexual violence) as well as birth control (including first-time prescriptions for young females and condoms). The 3-month follow-up after birth control initiation (as per French Health Authority guidelines) was also offered. AYAs had the opportunity to participate in teleconsultations with midwives using a computer or smartphone. Teleconsultations were available 6 days a week from Monday to Friday (6 AM to 7 PM) and on Saturday from 6 AM to noon. A total of 1000 consultation slots were offered during the study period. Once an account was created, AYAs had direct access to the appointment scheduling system and could register for the time slot that suited them. Appointments up to 2 hours before a teleconsultation were possible. A teleconsultation was free of charge and adhered to privacy and confidentiality laws. Patients received a link via email both 1 day prior and again a few minutes before their appointment. Teleconsultations could be carried out with the patient alone or in the company of a primary caregiver. At the end of each teleconsultation, participants were invited to answer a Likert-scale satisfaction question: “On a scale of 1 to 5, how would you rate your overall satisfaction with this teleconsultation? (1: very dissatisfied; 2: dissatisfied; 3: neutral; 4: satisfied; 5: very satisfied).” After 24 hours, participants received an online satisfaction evaluation form as well.

Study Variables

The study variables examined included scheduled teleconsultation appointments, the total number of completed teleconsultations, the mean duration of teleconsultations, website traffic, patient satisfaction, and the quality and completeness of the medical files.

Data Collection

An Excel (Microsoft Corporation) file was created for data to store account creation and appointment scheduling information. Patient characteristics, including age, sex, socio-professional data, contraceptive prescription, medical history, and satisfaction, were extracted from their electronic medical records.

Statistical Analysis

Descriptive statistics were expressed in numbers and percentages, including the median. Statistical analyses were performed using SAS (version 9.4; SAS Institute Inc).

Ethical Considerations

In accordance with French regulations, we received informed consent from each patient (by telephone) before accessing their medical files. This process ensured that participants understood the study’s objectives, the nature of the data collected, and their rights to confidentiality. This study was approved by the Research Ethics Committee of the University Hospital of Bordeaux, France (reference number: CER-BDX 2023 - 74) and was registered with the National Institute of Health Database (#F20220518181737).

Results

Website Traffic

Overall, 4731 sessions were recorded on the platform, including visits, whether to consult information on sexual health and contraception or to explore the teleconsultation services offered (Figure 1). Out of these sessions, 69 unique users created an account on the platform to access the teleconsultation services, among which 22 scheduled a teleconsultation appointment. The mean number of monthly sessions was 473 sessions per month, with the highest at 789 sessions at the start of the study and the lowest at 287 sessions in June 2022 (Figure 2). These variations may have been related to both the general and targeted messaging of communication campaigns. Presentations in schools, combined with the distribution of posters and flyers, were the most effective means of promotion, as indicated by the increase in website traffic. Radio broadcasts did not seem to positively influence website traffic (Figure 3).

Figure 1. Study flowchart.

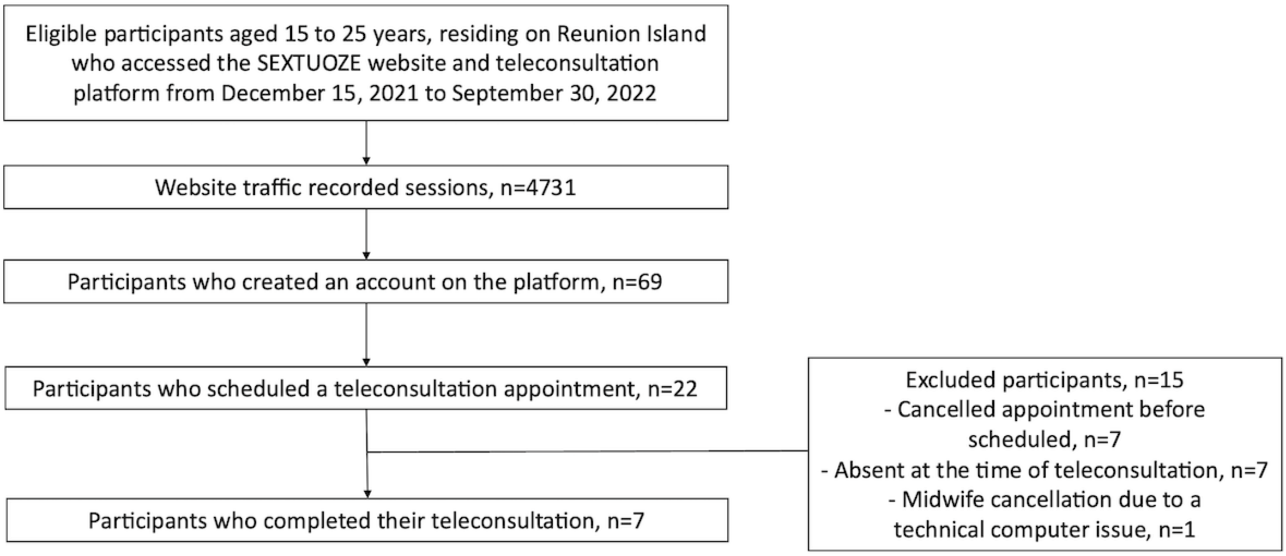

Figure 2. Monthly website traffic data from December 2021 to September 2022 on Reunion Island.

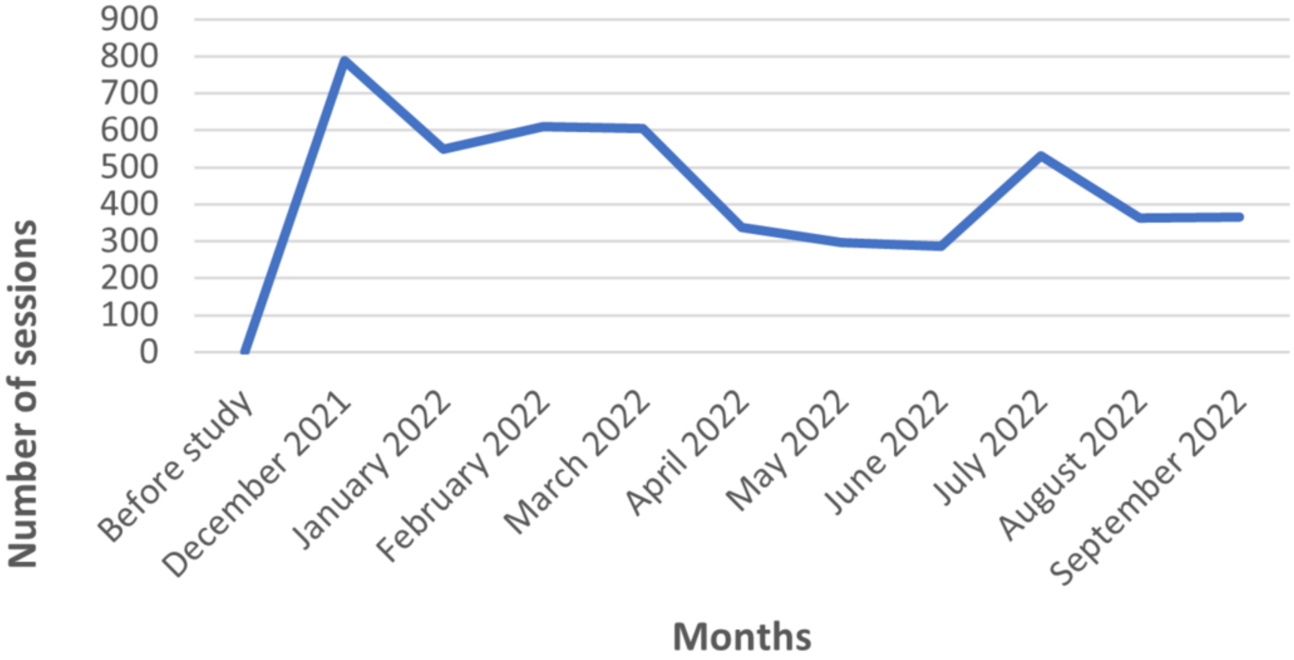

Figure 3. Impact of communication campaign on website traffic. The campaign was to promote the use of a teleconsultation platform for sexual health services to adolescents and young adults residing on Reunion Island.

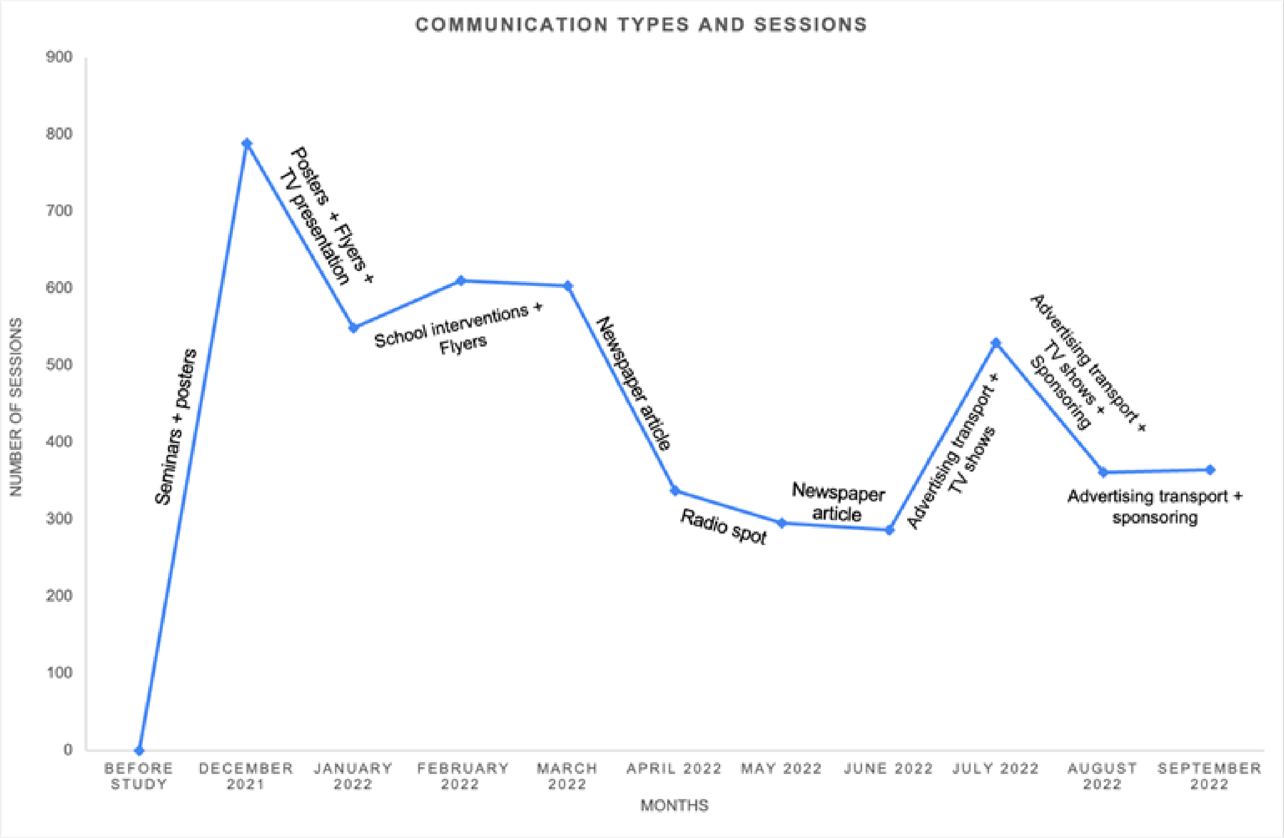

Sexual Health and Contraceptive Teleconsultations

A total of 22 AYAs scheduled a teleconsultation appointment. Of these, 7 (32%) AYAs completed their consultation, 7 (32%) AYAs canceled before the scheduled date, 7 (32%) AYAs were absent at the time of teleconsultation, and in one case, a midwife canceled due to a technical computer issue. Among the scheduled consultations, 55% (n=12) were for an initial birth control prescription, while 36% (n=8) were for sexual health advice. Consultations related to inquiring about condom prescriptions represented 9% (n=2) of cases. No birth control follow-up consultation was scheduled. Completed teleconsultations were conducted via videoconferencing and lasted for a median duration of 35 minutes. Among the 7 patients who completed teleconsultation, the median age was 18 years, and all were females who resided in the northern and southern regions of Reunion Island. Various birth control methods were prescribed, including pills, implants, patches, and intrauterine devices (Table 1).

Table . Patient and teleconsultation use characteristics.

Variables		Value
Age (years; N=7), median (IQR)		18.0 (15.0-24.0)
Sex (female), n (%)		7 (100)
Education level		
	Secondary (high school)	—[a]
	Tertiary (university)	—
Region of residence		
	Northern region of Reunion Island	—
	Southern region of Reunion Island	—
Living with primary caregiver/parent		—
Teleconsultation duration, median (IQR)		35.0 (25.0-60.0)
Reason for teleconsultation		
	Sexual health counseling	—
	First contraception prescription	—
Contraception prescribed		—
Type of prescribed contraception		
	Intrauterine device	—
	Implant	—
	Pill	—
Experience of teleconsultation, n (%)		
	Very satisfactory	5 (71)
	Satisfactory	2 (29)

[a] —: Confidential.

Patient Satisfaction

Participants revealed high levels of self-perceived satisfaction with the use of teleconsultation for contraceptive care. Most AYAs expressed positive feedback, with 5 out of 7 reporting that they were very satisfied and 2 out of 7 indicating they were satisfied with their teleconsultation experience. It should be noted that the satisfaction forms sent online were not returned by any of the teleconsultants.

Quality and Completeness of Medical Files

The survey on the use of teleconsultation for contraceptive care among AYAs demonstrated complete compliance with the required information submission. All necessary data for the teleconsultations were successfully provided by the participants, ensuring that the process was thorough and efficient.

Discussion

Principal Findings

To our knowledge, this is the first study to assess the feasibility of a sexual health and contraceptive teleconsultation platform on Reunion Island. Establishing this platform necessitated the collaboration of a multidisciplinary team to navigate administrative, technological, and institutional challenges. While the number of completed teleconsultations was low, website traffic results indicated a notable interest in digital health care. The low use of teleconsultations for obtaining contraception was also observed in an American study by Yarger et al [22], wherein only 6% of 1630 young adults declared teleconsultation use. A lack of collaboration between researchers and stakeholders, particularly AYAs, to gather information on their needs and determine the optimal approach to implement and communicate interventions may explain the low use of teleconsultations observed in our study. Active participation of stakeholders, including children, parents, and health care providers, at all stages of developing a health intervention is essential to increase the effective use of health care interventions [24,25]. Co-design, as defined by Sanders and Stappers [26], involves collective creativity throughout the design process and can potentially lead to the development of more engaging, satisfying, and useful interventions for potential end users. Moreover, cocreation, practiced at the early front end of the design development process, can have positive, long-term effects. Involving AYAs in the co-design of the platform, according to cocreation principles, may have improved outcomes. Despite efforts to promote the program and sexual health and contraceptive websites to both health professionals and the general public, very few AYAs were informed about the program, which was crucial to reaching them.

Social media networks such as Instagram and Facebook social media networks were used to inform the target group about SEXTUOZE during the study period because these platforms are widespread among AYAs and are considered to be important tools in promoting sexual health [27,28]. On the other hand, when combined with other distribution channels, they did not result in providing significant awareness among AYAs. This finding aligns with existing literature, such as a study by Lim et al [29], which indicated that many young adults in Australia were not comfortable accessing health information through social media channels. In hindsight, our communication strategy may not have been sufficiently captivating or motivating to achieve the expected results. Employing a community manager may have been more effective in developing a successful strategy.

Considering that sexual behavior is a sensitive matter that can lead to social stigma, it is well established that confidentiality is a key element in optimally functioning sexual and reproductive health care services [30]. Confidentiality protection encourages AYAs to autonomously seek care and share sensitive information necessary for providing appropriate care [31]. Studies have shown that many AYAs are unaware of the specific privacy safeguards concerning the transmission of sexual health care information in place [32,33]. However, the understanding of confidentiality may vary according to age, with young adolescents being less aware of their right to confidentiality [33]. It is essential to make it clear to young adults that their privacy will be ensured, even when it is through digital communication. This is especially relevant given that most countries are moving toward integrated health care models with electronically accessed information that connects existing health care provider structures, regional clinical result databases, and the sharing of patient records [34]. For example, a study conducted in the United States found that 88% of adolescents were more inclined to seek sexual health services if they were assured of their privacy and confidentiality [35]. This underscores the significance of transparent communication regarding privacy policies and the implementation of robust data protection measures. Such measures are crucial for fostering trust and encouraging AYAs to use these services without fear of exposure or judgment.

Analyzing the causes behind why participants dropped off at different stages (such as canceling the scheduled appointment and not showing up) allowed us to identify specific friction points. For example, technical issues and a lack of familiarity with teleconsultations were 2 such reasons in this study. On Reunion Island, among those aged 15 to 44 years, 9 out of 10 have high-speed internet at their residence. However, those residing in the highlands of the island are less well equipped, with only 70% having internet access at home and 58% having high-speed internet [11]. By addressing these obstacles, we can propose targeted solutions to improve service adoption in the future. This analytical approach, which focused on optimizing user processes, can be applied to other contexts and teleconsultation use services, providing valuable insights to enhance the efficiency and acceptability of digital health solutions.

Limitations

Our study had several limitations. First, the small sample size limited the generalizability of our findings. The low number of completed teleconsultations may not have represented the broader population of AYAs on Reunion Island. Second, self-selection bias may have influenced the results, since those who chose to participate might have differed from those who did not in terms of motivation and access to digital resources. Third, the short duration of the evaluation period may not have been sufficient to capture the full potential and challenges of implementing the teleconsultation service. Changes in behavior take time and are a complex and iterative process that individuals who are aware of best health practices do not always succeed in adjusting [36]. Last, the lack of returned satisfaction forms restricted our understanding of patient experiences and satisfaction. Future research should aim to include larger and more diverse samples to enhance the generalizability of findings. Longitudinal studies would be beneficial to assess the long-term impact and sustainability of teleconsultation-based sexual health services. Additionally, strategies to improve awareness and engagement, such as involving community managers and leveraging popular social media platforms such as TikTok, should be explored. Ensuring digital literacy and addressing barriers to internet access are crucial for equitable implementation. For example, implementing community-based digital literacy programs could help bridge the digital divide. Moreover, maintaining robust confidentiality and privacy measures will be essential to building trust and encouraging the use of teleconsultation services among AYAs. Policy makers should consider supporting teleconsultation initiatives through funding and regulatory frameworks to ensure their sustainability and effectiveness.

Our study also may have highlighted several key lessons that can be used for future initiatives. First, stakeholder engagement is critical for the success of teleconsultation services. Involving AYAs in the design process could have enhanced the usability and acceptance of the platform. Second, effective time management is crucial to ensure timely development and evaluation. Our pilot program had a budget allocated for 24 months to develop and evaluate the platform. However, due to unforeseen administrative and public procurement obstacles, the development phase took longer than initially planned (14 mo) instead of the projected 6 months. Consequently, we were left with only 10 months to conduct the evaluation. Therefore, delays in development can significantly reduce the time available for evaluation and optimization. Third, a well-thought-out awareness and engagement campaign is essential for encouraging the target population to use the services. Robust data confidentiality and protection measures are also necessary to build trust and encourage use among AYAs.

Conclusion

Our study demonstrates the feasibility and challenges of implementing a teleconsultation platform for sexual health in an isolated region. SEXTUOZE was functional and authorized prescriptions for contraception and sexual health advice and information; however, the demand for teleconsultations was low, and no follow-up or request for emergency contraception was made. By identifying friction points and proposing improvements, we provide valuable insights that can be applied to other similar contexts. This innovative approach, both conceptually and empirically, can contribute to the international body of literature and may underscore the importance of future research to develop more effective, tailored, and sustainable interventions.

Acknowledgments

The authors would like to thank the president of the Reunion Region, Manuella Pothin (research director); Clemence Allombert (midwife); Sarah Ramond (midwife); Julie Royer (midwife); Adrien Maigne (midwife); Mélanie Begorre (project manager); Maeva Ma-Tsi-Leong (data manager); Victorine Lenclume (biostatistician); Stanislas Brochier (Ascomédia); Christophe Hamond (Over-The-Moon); Dominique Talandier (computer scientist); Moira Nativel (secretary); Cécile Carpaye (secretary-purchasing division); Claudine Somon-Payet (health manager); school nurses and all other health professionals; Valérie Berger (nurse manager); and Dr Antoine Bertolotti for their support in this work. We also offer our gratitude to Acacia Tools for their proofreading and reviewing services. This work has been cofinanced by the European Union, the French Prefecture, and the University Hospital Center of Reunion Island.

Data Availability

Data supporting the results or analyses presented in this manuscript can be found in the medical records.

Authors' Contributions

DR and NB developed the research project concept and design. DR obtained funding and managed the research project with all professionals. DR, NB, and EC analyzed data. DR, NB, EC, and CM wrote the manuscript. All authors approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Adolescent voices are frequently excluded from sexual and reproductive health (SRH) research. Despite progressive policies and access to SRH care, adolescents in New York City who live in neighborhoods with high poverty and those who identify as Black or Hispanic experience poor SRH outcomes, including high rates of unplanned pregnancies and sexually transmitted infections.

Objective: This qualitative study aims to guide Black and Hispanic adolescent mothers in identifying problem areas in SRH care and cocreate health service recommendations with input from health care stakeholders to address those problems and improve SRH experiences.

Methods: Through ethnographic interview methods, adolescent mothers in New York City shared their experiences from before pregnancy through parenting and identified problem areas in adolescent SRH services and education. Data were analyzed inductively and using situational analysis. Adolescent participants attended 2 cocreation workshops. In the first workshop, they confirmed interview findings, set priorities, and created rough prototypes. Following the first workshop, health care providers were interviewed to inform refinement of the rough prototypes. Adolescents further developed prototypes in the second cocreation workshop and named the resulting toolkit.

Results: A total of 16 adolescent mothers participated in 47 interviews, and 10 (63%) participants attended at least 1 cocreation workshop. They highlighted deficiencies in sexual health education and emphasized the roles of health care providers and parents, rather than schools, in improving it. Adolescent participants designed recommendations for adolescents and health care providers to support quality conversations between adolescents, parents, and health care providers and created a preappointment checklist to help young patients initiate conversations with health care providers. Young participants stressed that sex education should address topics beyond sexually transmitted infections and pregnancy, such as emotional health and relationships. They created guidelines for health care providers outlining communication strategies to provide respectful, unbiased care and contraceptive counseling that encourages adolescent autonomy. Participants shared specific suggestions for how to support young parents respectfully. Health care stakeholders recommended adding information on confidential care; supporting lesbian, gay, bisexual, transgender, and queer youth; and focusing on improving communication between health care providers and patients rather than creating educational materials. In the second workshop, adolescent participants revised the prototypes based on feedback from health care stakeholders and named the toolkit of recommendations First Steps.

Conclusions: This study highlighted the important roles that parents and health care workers play in adolescent sexual health education. Cocreated toolkits offer a practical approach for health care providers to engage adolescents and their parents in meaningful, adolescent-centered conversations that can promote health, safety, and well-being.

Introduction

Background

Much of the research on adolescent sexual and reproductive health (SRH) is deficit-focused, aiming to change individual behaviors. This deficit model, which focuses on challenges, rather than strengths, can perpetuate beliefs that certain groups, particularly young people of color and those living in marginalized communities, need to be rescued or saved by members of the oppressing community [1,2]. Such practices minimize the lived experiences and expertise of youth and can perpetuate cycles of poor health outcomes [1], by failing to acknowledge the root causes of health inequities, such as racism, segregation, and inequitable health policies [1,2].

Adolescent participation in SRH research is vital, given the rising rates of sexually transmitted infections (STIs) [3] and the significant racial, ethnic, geographic, and socioeconomic disparities among pregnant and parenting adolescents [4]. However, few research studies include adolescents in roles that harness their wisdom about their SRH needs and experiences. There is a need for strengths-based research approaches that engage adolescents as experts to not only improve SRH outcomes but also to address the root causes of the sustained and widening inequities.

Adolescent SRH outcomes in New York City (NYC) expose stark health inequities. Youth living in NYC neighborhoods experiencing high poverty and those who identify as Black or Hispanic experience the highest rates of pregnancy, childbirth, and STIs [5,6]. In NYC, non-Hispanic Black adolescents report pregnancies at rates 4 times higher than non-Hispanic White adolescents and 7 times higher than Asian adolescents [6]. Similar disparities are present in birth data, with Hispanic or Latinx adolescents giving birth at a rate 4 times higher than Asian adolescents and 3 times greater than non-Hispanic White adolescents.

Adolescent childbirth and parenting are associated with poor social, educational, and health outcomes for young parents and their children. Pregnant adolescents are at high risk of complications such as pre-eclampsia and labor and delivery concerns, including hemorrhage requiring blood transfusion [7]. Infants born to adolescent parents are more likely to have low Apgar scores and require assisted ventilation and intensive care [7]. Parenting adolescents have lower chances of graduating from high school and report high periods of joblessness [8,9].

Adolescents are generally at high risk of STIs, and social determinants of health including poverty and discrimination increase this risk for marginalized adolescents [10,11]. In NYC, Black adolescents and those living in neighborhoods with high poverty experience chlamydia and gonorrhea infections at the highest rates [5]. STIs are often undetected due to low rates of testing and many sexual partners experiencing asymptomatic infections [10]. Data on STI testing prevalence among adolescents in NYC is limited; however, nationally, just 20.4% of sexually active adolescents reported being tested in the last 12 months [11].

STIs are associated with adverse outcomes, including cancer, pelvic inflammatory disease, and infertility, and many STIs require lifelong treatment [12]. Female adolescents are at a higher risk for certain infections such as chlamydia related to normal biological changes associated with development [13]. Pregnant and parenting adolescents are at higher risks of STIs [13], as they are less likely to consistently use STI prevention behaviors, such as condom use [14,15].

Adolescent SRH research in the United States has focused on increasing knowledge about sexual health [16,17], increasing contraceptive use [18-21], and developing decision support tools to guide contraceptive method choice [22-24]. Many studies have found modest or no effects on sexual health outcomes. As the adolescent pregnancy rate decreases, disparities persist, and those experiencing pregnancy are more likely to develop an STI, indicating a significant gap in SRH education and health care.

Few studies have investigated adolescent family planning experiences or behaviors beyond encouraging the consistent and correct use of a contraceptive method, and even fewer have investigated this phenomenon in parenting adolescents who are at an increased risk for repeat pregnancies and STIs [25,26]. This approach to mitigating adolescent pregnancy is situated in a research approach where health care providers and researchers design models of care to address predetermined problems based on their expertise [27] and measure success using outcomes such as contraceptive uptake or STI rate. Research approaches that de-emphasize factors beyond these clinical outcomes, such as satisfaction with care, are of particular concern for adolescents who will experience age-appropriate life course changes that can affect their SRH decisions and preferences over time.

The studies that have investigated adolescent SRH with a more flexible and creative approach found that adolescent SRH decisions are dynamic and influenced by numerous factors and relationships, beyond the evidence-based effectiveness focus of providers [28-30]. For instance, one randomized controlled trial found that individually tailored motivational interviewing that allowed for flexible conversations about concerns beyond contraception, between participants and nurse interventionists, significantly reduced the rate of repeat adolescent pregnancy

[31]. Adolescents are capable of describing their distinct health care needs, but they often receive care in health service settings designed for adults or preadolescent children [32]. Their voices are often not included in health services design due to barriers to their participation in research [33].

Aims

There is a need to expand on the studies that support adolescent-centered health services and to use research approaches that are inclusive, collaborative, strengths-based, and creative to facilitate adolescent participation in the design of their SRH care. To meet this need and address the wide and sustained SRH inequities, this study aimed to (1) use ethnographic and design research to guide adolescent mothers to identify problem areas in SRH care and (2) cocreate recommendations to improve SRH education and services with both health care stakeholders and adolescent parents to improve SRH experiences. Adolescent mothers are an ideal population to participate in cocreation to improve SRH for the broader adolescent population based on their experiences with the SRH care and education systems at key time points before, during, and after an adolescent pregnancy.

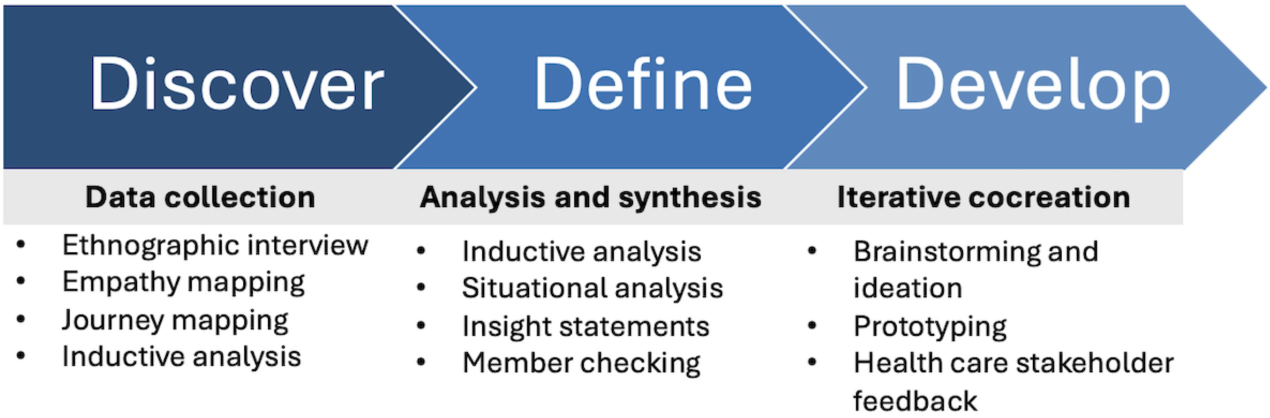
Methods

Overview

This study presents findings from a qualitative human-centered design (HCD) study with a sample of adolescent mothers living in NYC. HCD is a research methodology in health care that considers the expertise of stakeholders, and more specifically beneficiaries of health services, essential to the problem-solving and solution-generating processes [34]. HCD uses iterative processes where researchers are deeply immersed in a specific context and take a facilitator's role to support all stakeholders, whose expertise is recognized as central, in defining and reframing problems as well as creating and refining solutions [35-37]. HCD is an appropriate method to investigate persistent problems and disparities that are not improved by existing interventions [27]. It is a promising approach to addressing health disparities where the needs of vulnerable and marginalized populations may not be met by traditional research approaches [38].

HCD follows a phased process where researchers and stakeholders first investigate and define problems before they prototype and evaluate solutions. The Double Diamond, more recently called the Framework for Innovation, is a visual representation of the iterative processes used in HCD. Problem-solving and innovation in the Double Diamond framework are divided into 4 phases: discover, define, develop, and deliver [39]. In the discover phase, researchers and designers use ethnographic methods to develop a deep understanding of the experiences and contexts of service users. In the define phase, a problem is defined and redefined based on data from the discover phase and input from stakeholder groups. In the develop phase, prototypes are created to address the problems identified in the define phase and feedback is elicited to improve the prototypes. In the deliver phase, the final product is put into practice and evaluated for its impact on outcomes. This paper reports on this project's discover, define, and develop phases. Figure 1 displays a process diagram that shows the methods of data collection, analysis, and cocreation in each of the 3 phases.

Figure 1. Process diagram.



Positionality

The first author (LG) conducted all study procedures as part of a doctoral dissertation. She is a cisgender White woman who is bilingual (Spanish and English), bicultural by heritage (Hispanic Costa Rican and White Italian heritage), and works as a maternal–child home visiting nurse. Coauthors served as mentors with expertise in health services research (AS), adolescent sexual health (YL), and HCD research (ALF).

Theoretical Framework

HCD elevates the voices of stakeholders if carried out in its ideal, participatory form where studies acknowledge the context, culture, and political nature of complex problems. Fayard and Fathallah [40] suggested that researchers need to apply a critical stance to recognize the expertise of stakeholders, consistently reflect on positionality and the researcher's influence on the study, and maintain a commitment to a political viewpoint that reflects the goals and needs of the participants and their communities.

To adopt this critical stance, we used intersectional feminist theory to guide data collection, analysis, and researcher reflexivity. Intersectional feminism considers the intensified effects of overlapping racism, classism, and other forms of oppression on marginalized women [41-43]. This framework encouraged continual consideration of the power matrix that adolescent parents in NYC face, including the health and socioeconomic disparities sustained by racism, poverty, and societal judgment.

Participants and Recruitment

We recruited adolescent participants from a home visiting program for first-time parents, from a childcare program located in NYC public schools, and through snowball sampling. Participants were eligible if they were aged <20 years, lived in NYC, had English or Spanish proficiency, and had ever experienced a live birth. We recruited health care stakeholders for the develop phase by contacting members of an adolescent health special interest group of a professional organization focused on SRH and a nursing health services research collaborative. Health care stakeholders were eligible if they were licensed registered nurses (RNs), physicians, nurse practitioners, or physician assistants. We expanded inclusion criteria to include students in a degree-granting program for these health care roles to include the views and opinions of trainees with recent experiences in health education. We continued recruitment efforts until meaning saturation was achieved per Hennink et al [44], where authors developed an understanding of the various dimensions of single codes and an overall understanding of the data in both Spanish and English.

Ethical Considerations

LG translated consent forms and all study materials into Spanish, and a native speaker confirmed translations. All study procedures and materials in English and Spanish were approved by the New York University institutional review board (FY2023-7308). New York State Public Health law considers parents aged <18 years to be adults and allows them to make health decisions for themselves and their children without parental consent. Consistent with this law, all participants, regardless of age, provided written informed consent. The consent form included specific language about the mandated reporting of suspected child abuse and neglect and the procedures to do so. In addition, participants were made aware that the research team could provide them with resources for physical health; mental health; and educational, parenting, and other needs.

All participants were aware that their participation was voluntary and could be revoked at any point during the study, and declining would not affect their relationship with their referral source. Participants received US $30 cash or gift card incentive for completing each interview, up to 3 total. Before cocreation sessions, participants were reminded of the group-based nature of the workshops and that they did not need to share their names or other identifying information with the group and could keep their cameras off. Adolescent participants received a US $50 cash or gift card incentive for cocreation workshop, up to 2 workshops.

Discover Phase

Overview

The discover phase used multiple qualitative data collection tools to support immersion into the adolescent context and to build rapport and trust with participants. LG conducted all data collection following a 3-section semistructured interview guide, composed of ethnographic interview questions (section 1), card sorting (sections 1 and 2), empathy mapping (section 3), and journey mapping (section 3). Participants could elect to complete data collection in up to 3 research encounters to offer flexibility for scheduling. All participants chose the location of interviews, including an online option on Zoom (Zoom Video Communication, Inc). Participants completed a demographic survey and reported contraceptive history.

Ethnographic Interview

Ethnographic interviews are appropriate data collection techniques during the discover phase of HCD studies as they are exploratory and conversational and build trust with participants [45]. We used both descriptive and structural ethnographic interview questions to encourage participants to use their own language and describe how they organized their thinking about sex education, family planning, and sexual activity. The interview guide included specific questions about birth control and contraceptive counseling at time points from before their pregnancies through parenting.

Card Sorting

Design researchers use card sorting to build rapport through interactive activities that can ease participant discomfort in discussing sensitive topics such as sex [46,47]. Card sorting helps researchers understand and visualize how and why participants organize or categorize knowledge related to a phenomenon. In card sorting, we asked participants to group people in their lives who either should or should not speak to adolescents about sexual health and to rank the trustworthiness of sexual health information sources.

Mapping

Design researchers use empathy mapping [48] to uncover a person’s unspoken beliefs by dividing a page into 4 sections: do, say, think, and feel. Participants completed 4 total maps, 2 from their perspectives as adolescents and 2 regarding how they believe adults would fill out maps about adolescents. In total, 2 maps focused on adolescents generally and 2 focused on parenting adolescents. They completed each map by answering the questions, (1) “What do adolescents/parenting adolescents do/say/think/feel about sex and family planning? and (2) “What do adults do/say/think/feel about adolescent/parenting adolescent sex and family planning?”

Journey mapping [48] displays the steps people take and the emotions accompanying those actions when engaging with a service. Participants reflected on experiences receiving sex and family planning counseling before, during, and after pregnancy and described positive or negative moments along the journey. Templates and examples of completed card sorts, empathy maps, and journey maps are available upon request.

Data Analysis

Data analysis co-occurred with data collection. Data were analyzed inductively, first through open coding and later using focused coding to categorize findings [49]. Situational analysis derived from grounded theory [50] identified influential people, objects, and organizations that affect adolescent sexual decision-making. Findings specific to situational analysis are published in a separate manuscript [51]. Findings were synthesized into insight statements or short statements that capture the important motivations, tensions, and perspectives that encompass an HCD problem [52]. Interviews were audio recorded on a password-protected recorder, anonymized, and professionally transcribed. Audio recordings were deleted after transcription was completed and transcripts were confirmed for accuracy. Transcripts were read multiple times for immersion into the data and were analyzed using Atlas TI (ATLAS.ti Scientific Software Development GmbH). Spanish language transcripts were coded in Spanish. Analyses were confirmed through team-based discussions and through member checking, where participants offered feedback or confirmed the researcher's findings. Reflexivity and reflection on positionality were achieved through memoing and by discussing with research mentors (AS, YL, and ALF), with the first author paying specific attention to emotional and physical responses during interviews and analyses.

Define Phase

Overview

In the define phase of an HCD study, a problem is defined and redefined based on data from the discover phase and inputs from stakeholder groups. We invited participants with English proficiency who completed at least 1 interview segment to attend the first group cocreation workshop conducted on Zoom to maximize young participants' ability to attend. Spanish-speaking workshops will be conducted in a future study, given limited resources and a smaller sample.

Workshop 1: Define

LG started the first workshop by providing a positionality slide and facilitating a group discussion on rules for participation, including agreeing to maintaining confidentiality, respecting others' comments, and being open to learning new things. The first half of workshop 1 focused on supporting adolescent participants to define the key problems in SRH care and prioritize which problems to address through cocreation.

As the first step to defining the problems, LG presented insight statements. Participants had opportunities to share feedback on insight statements and suggest changes to statements if they disagreed. Together, adolescents and LG transformed insight statements into design opportunities or short statements that summarized the challenges and encouraged participants to think broadly about solutions.

Develop Phase

In the develop phase, researchers and stakeholders create and refine solutions to design opportunities. The research team selected a toolkit to design multiple solutions that could be tailored to a specific context.

Workshop 1: Develop

Using a virtual whiteboard and guided by the design opportunities, the group individually and then collectively brainstormed a list of important content areas a messaging toolkit for health care providers and adolescents should address. LG encouraged participants to think about general sexual health and education and address specific contraceptive counseling needs as identified in insight statements. A second whiteboard was created considering how participants imagined the toolkit recommendations could be used. After brainstorming a range of ideas, LG presented 2 personas and accompanying scenarios for the development of rough toolkit prototypes. We created personas or fictional characters that represented different service users' needs, experiences, pain points, and goals. LG refined rough prototypes after the first workshop based on the group's goals and feedback during workshop discussions.

Health Care Professionals' Feedback

LG conducted interviews using a semistructured interview guide to elicit feedback on prototypes developed with adolescents participating in workshop 1 with health care professionals, including RNs, pediatricians, and obstetrician-gynecologists. In addition to these interviews, LG led a group discussion in a graduate-level nursing SRH course. LG provided a summary of the findings from the discover and define phases and introduced different versions of the prototypes from the first workshop. The interview guide asked health care professionals to share feedback on the content of the prototype; the strengths, weaknesses, and usefulness of the prototype in their practice; and how they imagined the toolkit could be disseminated and used in the future. Consistent with the develop phase, versions of the toolkit were created and refined according to providers' feedback to be shared with adolescent stakeholders in a subsequent workshop.

Workshop 2

In workshop 2, LG summarized health care stakeholders' feedback on the toolkit for the adolescent participants. Discussions focused on reviewing feedback on the proposed length, toolkit content, and the primary audience. During the group discussion, LG and participants continued to iterate on and refine the prototypes. The final 15 minutes of the workshop were spent naming the toolkit, brainstorming ways to use the toolkit, and discussing future directions for the project.

Results

Overview

A total of 16 adolescent participants signed written informed consent. Demographics are presented in Table 1.

Table 1. Interview and cocreation workshop participant characteristics (N=16).

Participant characteristics	Participants, n (%)
Age (y)	
14	1 (6)
15	1 (6)
16	1 (6)
17	5 (31)
18	5 (31)
19	3 (19)
Race or ethnicity	
Black	3 (19)
Both Black and Hispanic	4 (25)
Hispanic	9 (56)
Interview language	
English	12 (75)
Spanish	4 (25)
Highest education completed	
<9th grade	2 (12)
9th grade	4 (25)
10th grade	3 (19)
11th grade	5 (31)
High school diploma	1 (6)
High school equivalency	1 (6)
Birthplace	
United States	12 (75)
Dominican Republic	2 (12)
Ecuador	2 (12)
Years living in the United States for foreign-born individuals	
1	1 (6)
2-5	2 (12)
>5	1 (6)
Neighborhood income below the federal poverty level (%)	
<20	1 (6)
20-24.9	8 (50)
25-29.9	6 (38)
>30	1 (6)
Insurance	
Medicaid	13 (81)
Private insurance	2 (12)
Uninsured	1 (6)
Contraceptive history	
Condoms	12 (75)
Withdrawal	10 (63)
Natural family planning or fertility awareness	9 (56)

Participant characteristics	Participants, n (%)
Oral contraceptive pill	6 (38)
Implant	6 (38)
Injection	4 (25)
Patch	3 (19)
Ring	0 (0)
Intrauterine device	0 (0)
Emergency contraception	3 (19)

All participants identified as cisgender women or girls with a median age of 17.5 (IQR 17-18) years. Most participants were interviewed in English (12/16, 75%), insured by Medicaid (13/16, 81%), and had not received a high-school diploma (14/16, 88%). Participants identified as Black (3/16, 19%), both Black and Hispanic (4/16, 25%), or Hispanic (9/16, 56%). Contraceptive histories varied, with most participants having used condoms (12/16, 75%). The implant (6/16, 38%) and oral contraceptive (6/16, 38%) were the most common hormonal methods. In total, 10 (63%) of the 16 participants attended at least 1 cocreation workshop, with 9 (56%) attending each workshop and 8 (50%) attending both workshops.

Discover Phase

Overview

Participants completed 47 (98%) of 48 interview segments, with 11 (69%) of the 16 participants having at least 1 in-person interview that was conducted at their homes, schools, or a community organization. The remaining interviews took place on Zoom where mapping exercises were completed using Google Slides. The interview segment duration ranged from 22 to 63 minutes. We saw no differences in interview quality by length, language, age of participant, or virtual versus in-person setting.

Sex Education Needs

Participants described lacking quality sex education at school, in their homes, and with health care providers. Despite living in a large city with progressive reproductive health policies around contraception and abortion, most participants received no sex education in their school or received a single class period as part of a health class that addressed other topics such as nutrition and substance use. At the same time, many shared that school is not the best place for young people to learn about sex due to the group setting and concerns that school staff do not have the training and resources necessary to provide up-to-date information.

In card sorting, all participants agreed that parents or other trusted adults in a young person's life such as an older cousin or aunt should be speaking to adolescents about sexual health. However, in their experiences, participants said that most adults overreacted or were judgmental and uncomfortable in these conversations. Participants saw parental disapproval of sexual activity as a universal experience for all young people. In the interviews, they reflected on their experiences and wished that their parents had understood normative adolescent development, which could have created a safe environment for conversations about sexual activity and safety. On the other hand, some participants grew up in families where adolescent sex or pregnancy was seen as acceptable or inevitable, which changed the way sexual health was discussed in their homes.

In addition to parents, all participants believed that health care professionals should be educating young people about sex because of their education and training in the health care space. Some believed that health care workers could bridge the SRH communication gap between parents and their children. Many shared that pediatricians did not assess for sexual activity or did so briefly only to move on from the topic if a young patient said they were not sexually active. Instead, participants shared that they began to learn about sexual health in more detail after they discovered their pregnancy and that at this time point, they found health care providers to be judgmental and paternalistic, especially around birth control. Almost all participants experienced coercive contraceptive counseling, with providers pressuring them to long-acting reversible contraception (LARC) and providing biased counseling that did not address the side effects. Providers with the LARC-first mentality dismissed participants' desires to use other less effective methods, discouraged LARC removal, and diminished participants' trust.

Contraceptive Use

Many participants shared that they did not want to use contraception, even when actively avoiding pregnancy. Discussions about side effects took place in interviews with every participant. Many had personally experienced negative side effects, including mood changes, weight gain, and undesired vaginal bleeding or menstrual changes. Some participants described feeling uncomfortable with the idea of LARC methods being placed inside their bodies and disliking needles as reasons to decline the injection. While most participants had used condoms at least once, many described them as difficult to use consistently because of issues with partners, skin irritation, and not having or using them in the moment of sexual activity.

Define Phase Workshop 1

During the first cocreation workshop, LG shared findings from interviews with participants in the form of insight statements and asked them for feedback and validation. Insight statements and quotes from interviews that represent each statement are provided as a Multimedia Appendix 1.

Insight statements focused on desiring adults, especially parents, to understand and accept normative adolescent sexual activity, recognizing insufficient sex education in school, and requesting that parents and health care professionals take on roles to educate adolescents about sex. Three specific insight statements guided cocreation activities, as follows: (1) young people do not have a way to learn about sex and contraception that includes their parents (or an adult they trust) and health care providers (who have the knowledge and training), (2) young people who do not want to become pregnant do not use birth control; and (3) health care providers put pressure on young people, especially young parents, to use birth control, and it affects how they counsel their patients. They do not accept “no” as an answer the first time. Using “how might we” questions, LG transformed insight statements into design opportunities to guide cocreation.

Develop Phase

Workshop 1: Develop (Brainstorming Toolkit Content)

In workshop 1, the group discussed the goal of creating recommendations to help adolescents, parents, and health care providers have high-quality conversations about sexual health and contraception. The first cocreation activity asked participants to consider what SRH content should be included in the recommendations. Using sticky notes on a web-based whiteboard (Figure 2), participants brainstormed the topics they felt were important to include in sex education that would be used by adolescents, health care professionals, parents, and trusted caregivers. After initial brainstorming, the group categorized and grouped sticky notes into 3 content areas: contraceptive-specific content, general sex education, and other.

Figure 2. Workshop 1 content brainstorming categorized. Formatting and spelling in the figure represent the tool as it was created during the session. STD: sexually transmitted disease.

What education should be included about sex?		What education should be included about birth control?		What other topics should be included?		How should our suggestions be available to people? How could they be used by doctors/nurses, parents, and young people?	
STDs	Protection	Different types	List all the options	How to talk to someone you're having sex with about condoms	Emotional attachment - changes to relationship after sex	School - guidance counselor	Clinic- talking to a doctor
Sex is a choice, consent	Condoms	Side effects	Birth control failure	Confidentiality		School with a teacher	Pamphlet or flyer in waiting room
baby	Planning for or preventing a pregnancy	someone that tells you that is okay to take care of yourself / use protection	The cost if you don't have insurance	How to talk to your parents or people you trust about sex			
It's okay to wait	be careful with who you have sex	Hearing from people with the real experience	Plan B				

To address general sexual health issues, participants wanted content that addressed STIs, condoms, planning for or preventing pregnancy, choosing an intimate partner, and consent. Participants shared important topics specific to contraception, including a list of all the birth control options available and recognition of the birth control failure rate. Participants asked for the content to address emergency contraception specifically. Along with a complete list of all contraceptive options, participants wanted honest descriptions of side effects and desired testimonies of real people’s positive and negative experiences using a specific method. Workshop participants discussed the importance of having an adult who will not judge a young patient who wants to use contraception.

In addition to general sexual health and contraception content, participants asked for specific information related to emotional health, especially around how the relationship with a partner can change after having sex. They suggested 2 content areas about communication, including tips for how to talk to a partner about condom use and ways to talk to parents or other trusted adults about sex.

Workshop 1: Personas and Prototyping

LG created 2 personas (Multimedia Appendix 2) based on interview data to reflect participants’ challenges and experiences. One persona was a sexually inexperienced cisgender girl aged 14 years, Alyssia, who was in a new relationship and considering sexual activity with a new partner aged 15 years. She had a close relationship with her mother, but when they talked about sex, her mother used generic messages such as “If you do that, be safe.” She had 2 goals, first to learn about sex from her pediatrician whom she trusts and second to open a communication channel with her mother to be able to talk about these topics without her mother becoming angry or uncomfortable. At a recent routine pediatric screening, her pediatrician did not mention sexual health and she was too shy to ask for sex education.

Workshop participants brainstormed recommendations and advice to share with Alyssia and her pediatrician to help Alyssia meet her goals. Participants believed that it was the pediatrician’s job to conduct a sexual health assessment and to present sexual health as a normal conversation point. They also stressed that even if a pediatrician was using the "right words" that support normative sexual activity to introduce sexual health, young patients would need to feel that the checkup was in a safe and judgment-free environment. Participants introduced the idea of a preappointment checklist as a way for Alyssia to alert the pediatrician about sensitive topics that she wanted to discuss. They felt that this would be a way to ensure the pediatrician made time for sexual health discussions or could connect Alyssia with someone else at the clinic to continue the conversation if they ran out of time. They suggested that the checklist should include physical sexual health topics such as STIs and birth control, along with relationship and emotional health content. Participants brainstormed ways for Alyssia to have a productive appointment with her pediatrician. First, they stressed the importance of Alyssia's pediatrician being responsible for starting the conversation about sex. Second, they shared that private conversations and an understanding of confidential care with the option to include a parent or trusted adult are the best ways for a young person to feel comfortable.

The second persona was Vanessa, a cisgender girl aged 17 years. She was a sexually active patient presenting to the gynecologist to start birth control. She expressed a desire to use the oral contraceptive pill, but the gynecologist disagreed and focused counseling on the intrauterine device and the implant. Vanessa wanted to learn more about the pill and avoid pregnancy. Workshop discussions about Vanessa's case focused on designing recommendations for health care providers to improve contraceptive counseling experiences.

First, participants discussed what guidelines the gynecologist could follow to improve this encounter. They shared that health care providers need to be accepting of a patient's requests while also doing their job using questions such as, "What makes you interested in the pill?" They suggested that health care providers need to begin contraceptive counseling sessions with broad and open-ended questions such as "What birth control methods did you have in mind?" rather than assuming that a young patient wants a long-acting method. They emphasized the importance of Vanessa feeling safe during the appointment and feeling comfortable speaking about her SRH needs.

The group responded to a final set of questions about how health care providers should speak to and support young parents. In terms of contraceptive counseling, participants wanted to be treated the same as adult pregnant or parenting patients and given respect and autonomy. Many shared that they wanted health care providers to care about them as a person and a parent, rather than a young person at risk of a subsequent poor outcome. Others shared that the assumption that a young mother is sexually active and desires birth control or will not be able to abstain from sexual activity is harmful and leads to a loss of trust in the health care provider.

Following this workshop, LG organized prototyped recommendations into separate "recommendations toolkits" for adolescents and health care workers. LG created an electronic mock-up of rough prototyped toolkits using the Canva software (Canva Pty Ltd).

Health Care Stakeholder Feedback

Prototype feedback interviews ranged from 20 to 40 minutes with 10 health care professionals, including RNs (n=6, 60%), pediatricians (n=3, 30%), and obstetricians-gynecologists (n=1, 10%). Nurses in a graduate-level SRH class in NYC (8/10 students, 80%) also provided feedback. While most (7/10, 70%) RN and obstetric stakeholders had practice experience in the NYC area, pediatric providers represented more geographic diversity, with experiences from New England, the southeastern United States, and the West Coast represented. When reviewing the prototypes, they believed that the content requested by the adolescent participants was appropriate and could help health care providers understand adolescents' needs. Health care stakeholders were unsurprised that young parents felt judged and had negative experiences with SRH providers. To address these negative experiences, they suggested that the toolkit could focus on improving adolescent-health care provider communication, rather than duplicating preexisting educational resources. However, health care provider participants shared 1 concern about adding to the cognitive burden placed on primary care providers to serve as sex educators, given their limited time and resources.

They recommended adding information on the ability to provide confidential SRH care to minors and information on inclusive and respectful care of sexual and gender-diverse youth, including normalizing the use of pronouns. Pediatricians suggested adding practical tips for health care stakeholders to conduct routine sexual health appointments with adolescents, such as adding conversation starters or reviewing the steps of a sexual health assessment. They believed that the previsit checklist could be helpful, both for young patients and health care providers to prioritize sensitive topics and to consider including or excluding parents or supportive adults based on a young patient's request. LG iterated on the prototype versions after interviews to present to participants in workshop 2 for additional revisions.

Workshop 2

In the second workshop, adolescent participants discussed health care stakeholders' suggestions to improve communication between health care workers and adolescents, rather than recreating educational materials. Participants agreed, and cocreation workshop 2 focused on refining the toolkit made for health care providers.

First, LG shared health care stakeholders' questions about how to help young patients feel safe to have sexual health discussions with them. Participants shared that the most important aspect of a conversation was that it was nonjudgmental and that health care providers addressed them with respect by giving them time and attention, not following checklists, or being focused on the computer. Participants shared that hearing personal stories from a health care provider about their own life or the experiences of their patients or friends can help a person to feel comfortable and humanize SRH education and counseling. Participants shared that many young patients do not know that they can receive SRH care confidentially and that this may affect their trust in a health care provider.

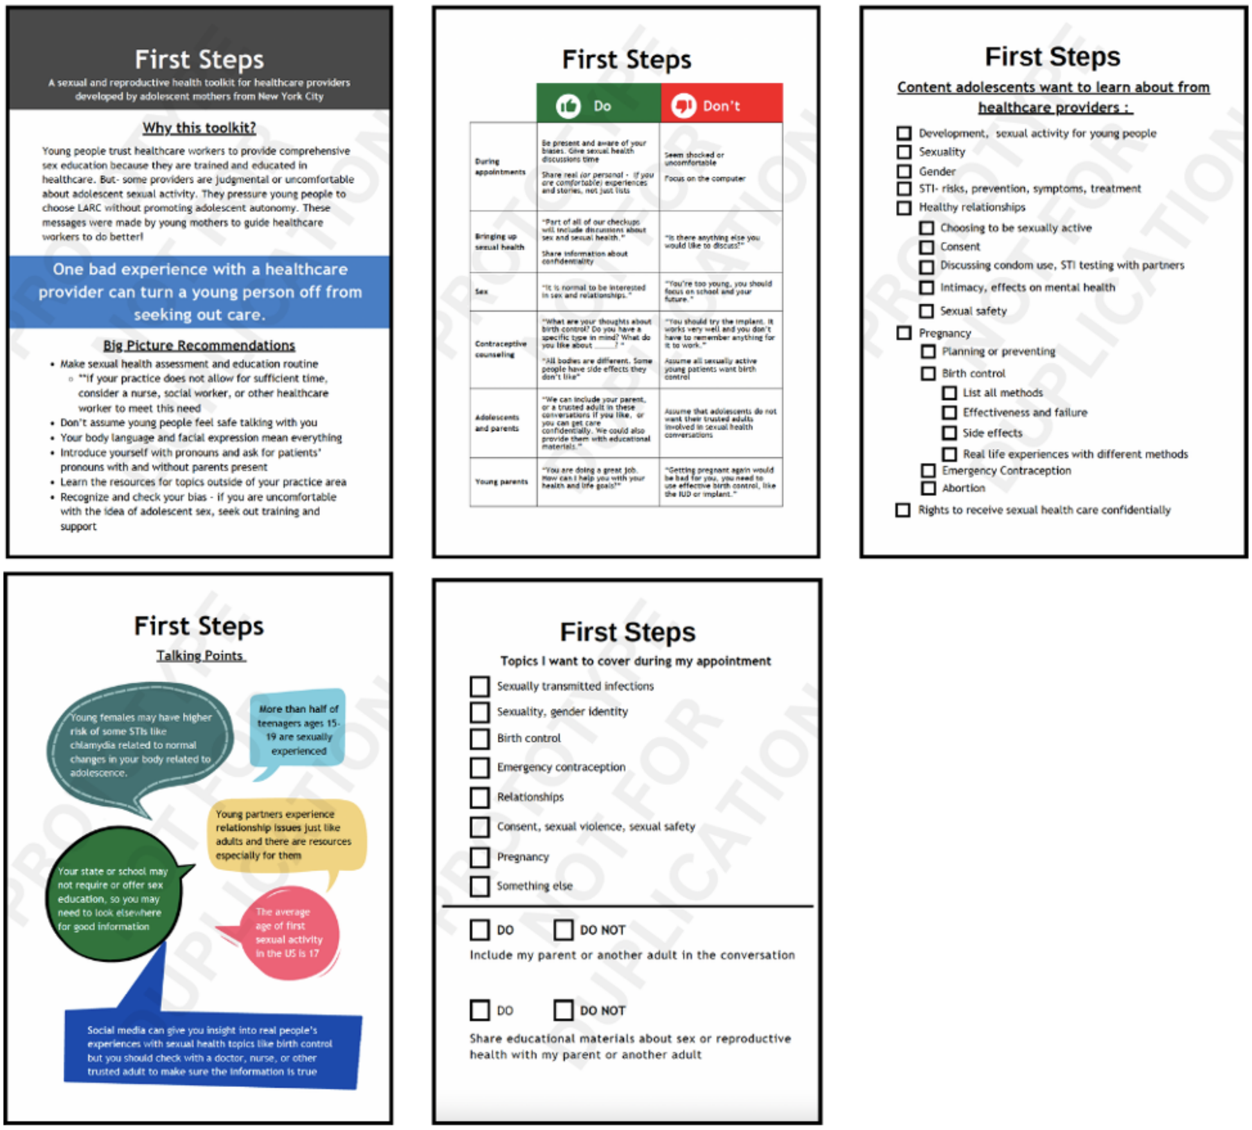
Participants discussed the proposed preappointment checklist and felt that it could encourage autonomy by motivating adolescents to set appointment goals and priorities. They also responded positively to the checklist having talking points related to specific SRH topics. The group reviewed the list of topics on the checklist, and participants opted to add consent and sexual violence aspects, which were not included in the sex education they had received at school or home. Finally, the group brainstormed a list of appointment “dos and don’ts” to provide concrete recommendations to guide health care providers to find the words needed to conduct sexual health assessments.

At the end of the workshop, participants took time to name the toolkit. The group agreed on First Steps as they felt that the guidelines that they had created were building blocks for health care providers to improve their SRH care to adolescents. Following the workshop, LG continued to refine the toolkit using the Canva design software and reviewed the toolkit with coauthors while considering plans for future refinement, dissemination, and implementation.

Final Toolkit

The final toolkit is a 5-page document (Figure 3), with each page functioning as a stand-alone sheet that could inform care. The first page introduces the creation of the toolkit with adolescent mothers and their motivation to participate in the project based on their prior experiences with poor care. This first page offers big-picture recommendations for health care providers working with adolescent patients, including making sexual health assessment routine, recognizing biases, and considering body language and facial expression as components of a safe space.

Figure 3. Toolkit final prototype.



First Steps

A sexual and reproductive health toolkit for healthcare providers developed by adolescent mothers from New York City

Why this toolkit?

Young people trust healthcare workers to provide comprehensive sex education because they are trained and educated in healthcare. But- some providers are judgmental or uncomfortable about adolescent sexual activity. They pressure young people to choose LARC without promoting adolescent autonomy. These messages were made by young mothers to guide healthcare workers to do better!

One bad experience with a healthcare provider can turn a young person off from seeking out care.

Big Picture Recommendations

- Make sexual health assessment and education routine
  - **If your practice does not allow for sufficient time, consider a nurse, social worker, or other healthcare worker to meet this need
- Don't assume young people feel safe talking with you
- Your body language and facial expression mean everything
- Introduce yourself with pronouns and ask for patients' pronouns with and without parents present
- Learn the resources for topics outside of your practice area
- Recognize and check your bias - if you are uncomfortable with the idea of adolescent sex, seek out training and support

First Steps

	Do	Don't
During appointments	Be present and aware of your biases. Give sexual health discussions time Share real *(or personal - if you are comfortable)* experiences and stories, not just lists	Seem shocked or uncomfortable Focus on the computer
Bringing up sexual health	“Part of all of our checkups will include discussions about sex and sexual health.” Share information about confidentiality	“Is there anything else you would like to discuss?”
Sex	“It is normal to be interested in sex and relationships.”	“You’re too young, you should focus on school and your future.”
Contraceptive counseling	“What are your thoughts about birth control? Do you have a specific type in mind? What do you like about ______? ” “All bodies are different. Some people have side effects they don’t like”	“You should try the implant. It works very well and you don’t have to remember anything for it to work.” Assume all sexually active young patients want birth control
Adolescents and parents	“We can include your parent, or a trusted adult in these conversations if you like, or you can get care confidentially. We could also provide them with educational materials.”	Assume that adolescents do not want their trusted adults involved in sexual health conversations
Young parents	“You are doing a great job. How can I help you with your health and life goals?”	“Getting pregnant again would be bad for you, you need to use effective birth control, like the IUD or implant.”

First Steps

Content adolescents want to learn about from healthcare providers :

☐ Development, sexual activity for young people
☐ Sexuality
☐ Gender
☐ STI- risks, prevention, symptoms, treatment
☐ Healthy relationships
  ☐ Choosing to be sexually active
  ☐ Consent
  ☐ Discussing condom use, STI testing with partners
  ☐ Intimacy, effects on mental health
  ☐ Sexual safety
☐ Pregnancy
  ☐ Planning or preventing
  ☐ Birth control
    ☐ List all methods
    ☐ Effectiveness and failure
    ☐ Side effects
    ☐ Real life experiences with different methods
  ☐ Emergency Contraception
  ☐ Abortion
☐ Rights to receive sexual health care confidentially

First Steps

Talking Points

Young females may have higher risk of some STIs like chlamydia related to normal changes in your body related to adolescence.

More than half of teenagers ages 15-19 are sexually experienced

Young partners experience relationship issues just like adults and there are resources especially for them

Your state or school may not require or offer sex education, so you may need to look elsewhere for good information

The average age of first sexual activity in the US is 17

Social media can give you insight into real people's experiences with sexual health topics like birth control but you should check with a doctor, nurse, or other trusted adult to make sure the information is true

First Steps

Topics I want to cover during my appointment

☐ Sexually transmitted infections
☐ Sexuality, gender identity
☐ Birth control
☐ Emergency contraception
☐ Relationships
☐ Consent, sexual violence, sexual safety
☐ Pregnancy
☐ Something else

☐ DO ☐ DO NOT
Include my parent or another adult in the conversation

☐ DO ☐ DO NOT
Share educational materials about sex or reproductive health with my parent or another adult

The second page displays a table with the “dos and don’ts” for various categories, including introducing sex, contraceptive counseling, and working with young parents. Dos include offering both confidential private care and the inclusion of parents or trusted adults at appointments, sharing real people’s experiences, including their own experiences, and providing contraceptive counseling that supports adolescent autonomy. Don’ts address coercive contraceptive counseling approaches, shaming young patients for being sexually active, and assuming that all adolescent participants would like their SRH care to be kept private from their parents.

The third page offers talking points that can help normalize sexual health behavior and offer educational information about various factors that affect adolescents' decisions and behaviors. The fourth page presents a list of SRH topics that adolescent participants wanted health care workers to be able to provide education or resources about. The preappointment checklist is the toolkit's final page. The checklist includes a list of topics adolescents can use to alert health care providers of the SRH content they want to learn about and includes options to request the involvement of a parent or trusted adult either during an appointment or through educational materials.

Discussion

Principal Findings

This study used HCD and cocreation techniques with adolescent mothers and health care stakeholders to design a toolkit to help health care providers deliver high-quality, adolescent-centered SRH care. Using HCD supported us in acknowledging the importance of adolescents' agency and recognizing their expertise as necessary components to develop health services that are meaningful and useful. Using HCD not only guided adolescent participants to identify the SRH problems they have seen and experienced but also generate solutions that are relevant to their experiences and needs [53]. While still subject to bias and power dynamics, HCD and other participatory approaches can address common concerns in research where interventions designed by experts in a field can lead to the development of culturally unsafe interventions that are ineffective or even harmful [54].

Comparison With Prior Work

Our findings are consistent with previous literature, and through the HCD approach, these findings supported the cocreation of the First Steps toolkit. Participants described insufficient SRH education, and many believed that they did not have the knowledge they needed when they were contemplating engaging in sexual activity or discovered that they were pregnant. Similar to our participants, the SRH education that adolescents received depends on the norms and values in their homes and schools, with some favoring comprehensive sex education and others endorsing abstinence-only education or avoiding the topic [55-58].

In cocreation workshops, adolescents brainstormed ways to fill the gaps left by insufficient sex education. While participants described parents as responsible for communicating with their children about SRH, they acknowledged that some parents may not have the comfort or knowledge to do so. Instead, they identified health care workers as responsible adults with the knowledge and training to educate them, and potentially their parents, on SRH. At the same time, participants shared that their experiences with health care workers were judgmental or coercive, putting pressure on them to use a specific birth control method and focusing on risk rather than their overall health or well-being. These findings are consistent with literature examining adolescent experiences with health care providers where young patients have experienced or feared the health care provider's judgment about their sexual health behaviors [59] or counseling that was biased due to their age [60]. Researchers have begun to recognize contraceptive coercion at the hands of health care providers, realizing that counseling methods such as tiered-effectiveness counseling are at odds with reproductive justice tenets [61]. First Steps not only confirmed these findings but also offered suggestions and actionable practice changes to address longstanding reproductive health concerns and amplified the importance of reproductive autonomy.

Toolkit recommendations focused on content areas that adolescents believed should be included in SRH education, guidance to health care workers on how to discuss sex with young patients, and a previsit checklist that could help adolescent patients alert health care staff that there are specific SRH topics they would like to discuss at a checkup. Many of these concepts are not new to the SRH literature, including respecting adolescent patients as capable of making autonomous decisions [62,63] and the importance of trust and nonjudgmental care [63,64]. However, the First Steps toolkit provides tangible recommendations for health care providers to improve health service delivery created by adolescents in their language and based on their needs and expertise. Beyond modules or training, the toolkit offers an actionable change to practice that can be implemented in diverse contexts. The toolkit can be paired with the few existing education-focused interventions that support the engagement of both parents and health care providers, such as Families Talking Together, a sex education program for Black and Latino youth aged 10 to 14 years [65].

First Steps addresses adolescent–health care provider communication, filling a gap in research where studies typically focus on increasing SRH knowledge, exploring experiences, or testing interventions designed by health care providers and researchers as the experts. First Steps, on the other hand, is innovative having been created through the phases of HCD with both adolescents and health care stakeholders, focusing on improving SRH service experiences and adolescent communication with trusted adults. The toolkit enables health care providers and researchers to use existing education resources while strengthening their relationships with adolescents and the trusted adults in their lives.

Strengths and Limitations

This study engaged an underresearched population, adolescent mothers, to share their experiences and participate in redesigning SRH service delivery through cocreation. The use of HCD methods allowed for considerable time in the field and immersion into the adolescent context, while the workshops brought participants together to share their experiences and expertise. This study's most significant strengths are cocreation and the design of a tangible deliverable that uses adolescent mothers' words to recommend actionable SRH practice and education changes. Adolescent mothers are frequently overlooked in research; however, our findings, participant retention, and the toolkit deliverable collectively exemplify their wisdom and commitment to the health and well-being of their communities.

Varied data collection techniques, member checking, and additional confirmation of insight statements during group sessions strengthened the credibility of the findings. LG is an experienced home visitor with >10 years of experience working with young parents and their infants and toddlers. However, she was the sole researcher conducting interviews and facilitating cocreation workshops, which may have led to biases in analyses and interpretations. This bias was mitigated as much as possible through group-based discussions, reflection through memoing, and discussion of LG's positionality with participants.

The adolescent participants are reflective of the adolescent parenting population in NYC in terms of race, age, and ethnicity; however, their experiences and recommendations to improve practice may not meet the needs of nonparenting adolescents, those from rural communities, or those with different heritage backgrounds, potentially limiting the transferability of the findings. The geographic diversity of health care stakeholders and the participatory HCD approach may have helped to mitigate the effect of this limitation. Similarly, all participants identified as cisgender women or girls, and their SRH experiences and proposed care solutions may not meet the needs of sexual and gender-diverse adolescents. Owing to resource constraints, LG did not recruit enough Spanish-speaking participants to conduct separate cocreation workshops with those participants; however, their perspectives from interviews were included in cocreation discussions and generally matched the perspectives of English-speaking participants.

Implications

Methods such as HCD can guide researchers to conduct studies that support adolescents in identifying problems and creating solutions. Elevating the voices and expertise of adolescent mothers addresses a gap in research, where adolescents who are already parents are under-studied in favor of prevention programs focused on nulliparous adolescents. This study provides methodological guidance to conduct a multilingual HCD study that includes virtual and in-person interviews and a cocreation component with adolescents. Future research can support adolescents, including those who are already parents, to design sexual health education and assessments that are adolescent-centered and foster a sense of safety. Replication of the earliest phases of the project will ensure that toolkit recommendations meet the needs of diverse populations, including adolescents from rural communities, immigrants from regions and countries not represented in this study, and sexual and gender-diverse adolescents.

Health care providers can use the toolkit and introduce the preappointment checklist to their patients to normalize sexual health discussions, support parent involvement if desired, and situate themselves as sexual health educators. Additional research to further refine the prototype and consider how to best evaluate the toolkit in practice is needed and planned for future study. Health care providers working in geographically diverse settings, particularly those in states that restricted access to SRH services and education, will have unique and important insights that can inform the creation of multiple versions of the toolkit for use in diverse health services contexts, including school-based health centers.

There are opportunities for continuing education and interdisciplinary collaboration in pediatric care settings. Such practices support specialization in the various SRH topics that adolescents described as important to their overall SRH knowledge besides STIs and pregnancy, including relationship and emotional health. Adolescent health care sites can consider adding mental health providers, RNs, or other health care workers to deliver holistic SRH care and education without adding additional practice burdens on primary care providers.

Conclusions

Despite decades of commitment from researchers, policy makers, and health care providers seeking to increase adolescent SRH knowledge and improve access to services, poor outcomes still persist and health disparities continue to widen. There is a need to address adolescent SRH concerns from the perspectives of adolescents themselves and to value and recognize their lived experiences as essential to the development of health services. This HCD study exemplifies adolescents' wisdom, creativity, and abilities to be the designers of their own SRH care. The study supports adolescent participation in the redesign of health services and education in the United States and offers health care stakeholders the opportunity to reflect on the care they provide, with actionable and constructive practice changes that can improve SRH education, service experiences, and ultimately, outcomes.

Acknowledgments

Funding for this study comes from the Society of Family Planning Emerging Scholars in Family Planning (grant SFP17-ES4).

Authors' Contributions

LG participated in the conceptualization, design, and implementation of the study, including analysis, manuscript preparation, and revision, as a part of a doctoral dissertation. LG secured the study funding. Coauthors YL, ALF, and AS participated in the design and implementation of the study, supervision, and contributed to reviewing and editing the manuscript. All authors approved the final manuscript.

Conflicts of Interest

Abstract

Background: Screening for risk behaviors is a routine and essential component of adolescent preventive health visits. Early identification of risks can inform targeted counseling and care. If stored in discrete fields in the electronic health record (EHR), adolescent screening data can also be used to understand risk behaviors across a clinic or health system or to support quality improvement projects.

Objective: Goals of this pilot study were to adapt and implement an existing paper adolescent risk behavior screening tool for use as an electronic data capture tool (the eTeenQ), to evaluate acceptance of the eTeenQ, and to describe the prevalence of the selected risk behaviors reported through the eTeenQ.

Methods: The multidisciplinary project team applied an iterative process to develop the 29-item eTeenQ. Two unique data entry forms were created with attention to (1) user interface and user experience, (2) the need to maintain patient privacy, and (3) the potential to transmit and store data for future use in clinical care and research. Three primary care clinics within a large health system piloted the eTeenQ from August 17, 2020, to August 27, 2021. During preventive health visits for adolescents aged 12 to 18 years, the eTeenQ was completed on tablets and responses were converted to a provider display for teens and providers to review together. Responses to the eTeenQ were stored in a REDCap (Research Electronic Data Capture; Vanderbilt University) database, and for patients who agreed, responses were transferred to an EHR flowsheet. Responses to selected eTeenQ questions are reported for those consenting to research. At the conclusion of the pilot, the study team conducted semistructured interviews with providers and staff regarding their experience using the eTeenQ.

Results: Among 2816 adolescents with well visits, 2098 (74.5%) completed the eTeenQ. Of these, 1811 (86.3%) agreed to store responses in the EHR. Of 1632 adolescents (77.8% of those completing the eTeenQ) who consented for research and remained eligible, 1472 (90.2%) reported having an adult they can really talk to and 1510 (92.5%) reported feeling safe in their community, yet 401 (24.6%) reported someone they lived with had a gun and 172 (10.5%) reported having had a stressful or scary event that still bothered them. In addition, 157 (9.6%) adolescents reported they were or wondered if they were gay, lesbian, bisexual, pansexual, asexual, or other, and 43 (2.6%) reported they were or wondered if they were transgender or gender diverse. Of 11 staff and 7 providers completing interviews, all felt that the eTeenQ improved confidentiality and willingness among adolescents to answer sensitive questions. All 7 providers preferred the eTeenQ over the paper screening tool.

Conclusions: Electronic capture of adolescent risk behaviors is feasible in a busy clinic setting and well accepted among staff and clinicians. Most adolescents agreed for their responses to risk behavior screening to be stored in the EHR.

Introduction

Adolescence is a period of rapid and complex transitions. Biological maturity often precedes psychosocial maturity and the choices made during this period can have both immediate and long-term health consequences. While many adolescent risk behaviors are transient or experimental, habits and unhealthy coping strategies with origins in adolescence may persist into adulthood [1,2]. In addition, limit-testing behaviors explored during adolescence can increase risk for injury and can contribute to long-term morbidity and mortality [3].

Routine risk behavior screening of adolescents is an important part of providing comprehensive and equitable care to this age group and it is a recommended best practice by the American Academy of Pediatrics [4,5]. Early recognition and response to high-risk adolescent behaviors can help to maintain youth on a healthy trajectory. Standardized questionnaires assessing adolescent risk behaviors have been found to help shift the focus of primary care visits from data gathering to discussion and counseling around sensitive topics. Furthermore, use of standardized questionnaires can improve organization and efficiency during the visit [6].

Many primary care practices rely on paper adolescent screening tools. However, these tools are often not completed by patients and results of the paper screening are inconsistently recorded in the electronic health record (EHR), making it difficult to monitor individual or population-level risk behaviors over time [7]. Electronic data capture for adolescent risk behavior screening has several potential advantages over paper screening and is generally preferred by adolescents [8-10], including those engaging in high-risk behaviors [9,11].

Nevertheless, barriers to adoption of electronic risk behavior screening tools remain, including clinical and institutional inertia and concerns regarding confidentiality of patient-reported risk behaviors collected on electronic tablets or similar devices [12]. In addition, risk behavior screening in primary care through paper or electronic methods may prolong visits and crowd out time for addressing other acute health issues.

In this pilot project, we adapted a paper-based adolescent risk behavior screening tool, the Adolescent and Young Adult Teen Questionnaire [13], which was developed by the Minnesota Department of Health and is currently in use in our health system as a paper screening tool at all primary care clinics, for use as an electronic data capture tool, the eTeenQ. We then pilot-tested the eTeenQ at 3 primary care clinics within our large, integrated, Midwestern health system, with goals of evaluating patient and clinician acceptance of the eTeenQ and describing the prevalence of selected adolescent risk behaviors as reported through the eTeenQ.

Methods

Adaptation of the Paper Risk Screening Tool for Electronic Data Capture as the eTeenQ

The multidisciplinary project team, which included 2 primary care physicians, 1 project manager, and 2 members of the HealthPartners Institute software engineering team, applied an iterative process over a 4-month period to adapt a paper risk behavior screening tool, the Adolescent and Young Adult Teen Questionnaire, for use as an electronic data capture form to be completed at the point of care on an electronic tablet. Two unique data entry forms were created with attention to (1) user interface and user experience (UI/UX), (2) the need to maintain patient privacy, and (3) the potential to transmit and store data for future use in clinical care and research. Additional considerations that affected the overall design of the eTeenQ included the need for the system to be stable, process responses quickly, and require limited ongoing maintenance. The overall architecture of the eTeenQ is shown in Multimedia Appendix 1.

The first electronic, web-based form created allowed clinic staff at check-in to enter the patient medical record number (MRN) and then to confirm the patient identity (Multimedia Appendix 2). The GetPatientDemographics application programming interface (API) from Epic Systems was used to identify the correct patient. The second electronic, web-based form created enabled adolescent patients to complete the 29-item fixed-response questions on safety, physical activity, diet and body image, school, self-harm, gender identity, sexual identity, and sexual activity that comprise the Adolescent and Young Adult Teen Questionnaire (Multimedia Appendix 3). The second form contained additional questions for adolescents to consent for their survey responses to be used for research and stored in the EHR, as described below. The eTeenQ forms were developed in REDCap (Research Electronic Data Capture; Vanderbilt University). REDCap is a secure web application used for building and managing online databases and surveys [14].

At the point of care, responses to the eTeenQ are converted to a provider display and adolescents and their primary care providers review responses together on the tablet during the visit. As shown in Multimedia Appendix 4, the provider display highlights eTeenQ “positive screens” or responses requiring attention during the visit. In real time, eTeenQ responses are stored in a REDCap secure external database [14]. For patients who consented to have their data stored in the EHR, after completing the eTeenQ and pressing Submit, a copy of their eTeenQ responses was automatically saved. The SetSmartDataValues API from Epic Systems was used to securely transfer the data from REDCap to custom discrete data elements created in the EHR for the project.

Additional security was integrated to the build of the tool to prevent the use of the tool outside the health system’s intranet. Software use and data transfer were closely monitored throughout the project, and the tablet firmware was maintained.

Setting and Population for Pilot Implementation

HealthPartners Care Group includes a multispecialty group practice of more than 1800 physicians, 8 hospitals, 55 primary care clinics, 22 urgent care locations, 24 dental clinics, and numerous specialty practices in Minnesota and western Wisconsin. The care group uses a common EHR (Epic; Epic Systems Corporation). Adolescents aged 12 to 18 years receive primary care within the care group from physicians trained in pediatrics, family medicine, or internal medicine, as well as from advanced practice providers, including nurse practitioners and physician assistants.

In June 2018, all 55 primary clinics within HealthPartners Care Group implemented comprehensive screening for well-being and risk behaviors among adolescents aged 12 to 18 years during well visits. At the time of check-in, patients and their parents were each handed a letter that described policies related to confidential care for adolescents and notified them that the adolescent would be completing a paper questionnaire for teens (based on the Adolescent and Young Adult Teen Questionnaire [13] developed by the Minnesota Department of Health). The letter provided at check-in also advised the adolescents and their parents that during the visit the parent would be asked to leave the room so the provider could review responses to the paper questionnaire in private with the adolescent. After the visit, the paper questionnaire was shredded, and it was at the discretion of the clinician to document any patient responses or discussion related to the risk behaviors identified in the EHR.

This pilot implementation of the eTeenQ took place at 3 clinics within the HealthPartners Care Group. Clinic A, located in a small town in Minnesota, had 27 pediatricians participate during the period from January 18, 2021, to August 27, 2021; clinic B, located in a metropolitan area of St Paul, Minnesota, had 5 pediatricians participate during the period from January 18, 2021, to August 27, 2021; clinic C, located in a Minneapolis suburb, had 3 pediatricians and 8 family medicine clinicians participate during the period from August 17, 2020, to August 27, 2021.

All patients aged 12 to 18 years and presenting for a preventive health or well visit with a participating primary care provider at a pilot site during the study period were eligible to participate. Eligible visits were identified through current procedural terminology (CPT) codes for these preventive health visits: 99384, 99394, 99385, and 99395; they were also identified through the *International Classification of Diseases, 10th Revision–Clinical Modification (ICD-10-CM)* codes Z00.121, Z00.129, Z00.00, and Z00.01.

Training and Support

All staff and providers at the 3 pilot sites attended lunchtime in-person or virtual training(s) regarding the pilot test and implementation of the eTeenQ. At each clinic, an operational staff member and a provider were designated as site champions and points of contact for the research team. Throughout the pilot study, research staff regularly connected by phone, email, or in person with the clinic site champions to obtain informal feedback about the intervention, including identification and triage of any challenges with workflow, technology, or confidentiality.

Pilot Clinic Workflow for the eTeenQ

Successful implementation of the eTeenQ required careful attention to clinic workflow. Electronic tablets were preloaded with a link to the eTeenQ data capture form. As shown in Multimedia Appendix 2, at the time of registration staff opened this link and entered the patient's MRN. After a verification process to confirm that the MRN corresponded to the correct adolescent patient, the tablet was handed to the patient along with instructions to complete the eTeenQ on their own, without input from parents or other guardians (Multimedia Appendix 2). After completing the eTeenQ, patients completed 2 additional questions regarding permission to import the eTeenQ data into the EHR and permission for responses to the eTeenQ to be accessed for research. Patients were instructed to hand the electronic tablet to the rooming staff so it could be reviewed by the clinician in advance and discussed during the confidential portion of the visit.

Prior to entering the patient room, the clinician reviewed the data on the tablet. Any survey responses that would generally require attention during the visit were highlighted on the provider display in order to facilitate efficiency (Multimedia Appendix 3).

Evaluating Use of the eTeenQ and Responses

Use of the eTeenQ was assessed by comparing the total number of adolescent preventive health visits at the 3 participating sites during the pilot period to the number of completed eTeenQ surveys stored in the REDCap database. For those consenting for their data to be used in research, eTeenQ responses were linked to administrative data (eg, age, sex, race/ethnicity, and insurance type) as recorded in the EHR. Selected responses were compared by age group (12-14 years vs 15-18 years) with the chi-square test with a 2-sided $P<.05$ as the threshold for significance. All analyses were conducted in SAS (version 9.4; SAS Institute).

Obtaining Feedback From Providers and Clinic Staff at Pilot Sites

At the conclusion of the pilot, the study primary investigator (SN) conducted brief in-person or virtual semistructured interviews with participating clinic providers and staff to understand their experiences using the eTeenQ. Questions for clinic staff included the following: "How did this pilot go?" "How did it work to hand out the tablets at the front desk to adolescents to complete the eTeenQ before the visit?" "Can you tell me about any difficulties with the technology or workflow?" "What ideas do you have about improvements we should make to the workflow or technology before spreading across primary care?" and "Do you have any additional feedback regarding this pilot?"

Questions for providers included the following: "How did this pilot go?" "Can you tell me about any difficulties with the technology or workflow?" "How did it work to review the Teen Questionnaire on a tablet?" "As compared to prior to the pilot, how did use of the eTeenQ impact visit efficiency?" "As compared to prior to the pilot, how did use of the eTeenQ impact quality of care?" "As compared to prior to the pilot, how did use of the eTeenQ impact adolescent clinician communication?" "As compared to prior to the pilot, how did use of the eTeenQ impact parent-clinician communication?" "As compared to prior to the pilot, how did use of the eTeenQ impact adolescent confidentiality?" "Did you make changes to clinical care or documentation as a result of the data reviewed on the tablet during the visit?" "Were you able to find the results of the eTeenQ in Epic, after the visit?" "How satisfied are you with electronic capture of eTeenQ data on a tablet?” (3-point scale for responses) and “Do you have a preference for how adolescent risk behavior screening should be administered at your clinic in the future?”

The study primary investigator took notes during the semistructured interviews. These notes were reviewed by the full study team to identify common themes regarding perceptions, preferences, and actual use of the eTeenQ.

Ethical Considerations

This study was reviewed and approved by the HealthPartners Institutional Review Board (A19-123). Implementation of the eTeenQ at pilot sites was approved with a waiver of informed consent. Adolescent consent for eTeenQ survey responses to be used for research and to be stored in the EHR was obtained as described below.

Adolescents consented for their eTeenQ responses to be used for research by reading the following prompt and then answering the consent question on the tablet:

> *We are asking all teens who complete the Teen Questionnaire on a tablet for permission to group their answers together in a large database. This data will be used to better understand the health of teens in our clinics and to improve care for teens in the future. We will not include your name or other information about you in the database. This study is voluntary. That means you can tell us that you do not want us to use your answers to the questionnaire for research. This will not affect your care today or in the future. We expect up to 1000 adolescents to participate in this study.*
>
> *Do you give permission to use your answers to this questionnaire for research?*

Adolescents consented for their eTeenQ responses to be stored in their EHR by reading the following prompt and then answering the consent question on the tablet*:*

> *The information in this questionnaire is confidential. It will be used by the doctors and nurses taking care of you to provide the best care possible. In the occasion that your parent or guardian requests a copy of your entire medical record, it is possible they may see the answers you provided on this form. If you report that you intend to harm yourself or to harm others, we are required to intervene on your behalf.*
>
> *Do you give permission to save this information in your medical record so that it can be used to help take care of you at future medical appointments?*

Results

Evaluating Use of the eTeenQ

During the pilot period, among 2816 eligible adolescents with well visits, 2098 (74.5%) completed the eTeenQ. Of the 2098 adolescents who completed the eTeenQ, 1653 (78.8%) consented to have their data used for research and 1811 (86.3%) agreed to have their data stored in the EHR. After excluding 21 responses due to incorrect MRN linkage to the EHR or because the patient had an a priori research opt-out recorded in their EHR, the final analytic sample included 1632 adolescents; 818 (50.1%) were female and the mean age was 14.5 (SD 1.8) years. (Figure 1, Table 1)

Figure 1. Flowsheet of study eligibility and consent for data to be used in research. EHR: electronic health record; MRN: medical record number.

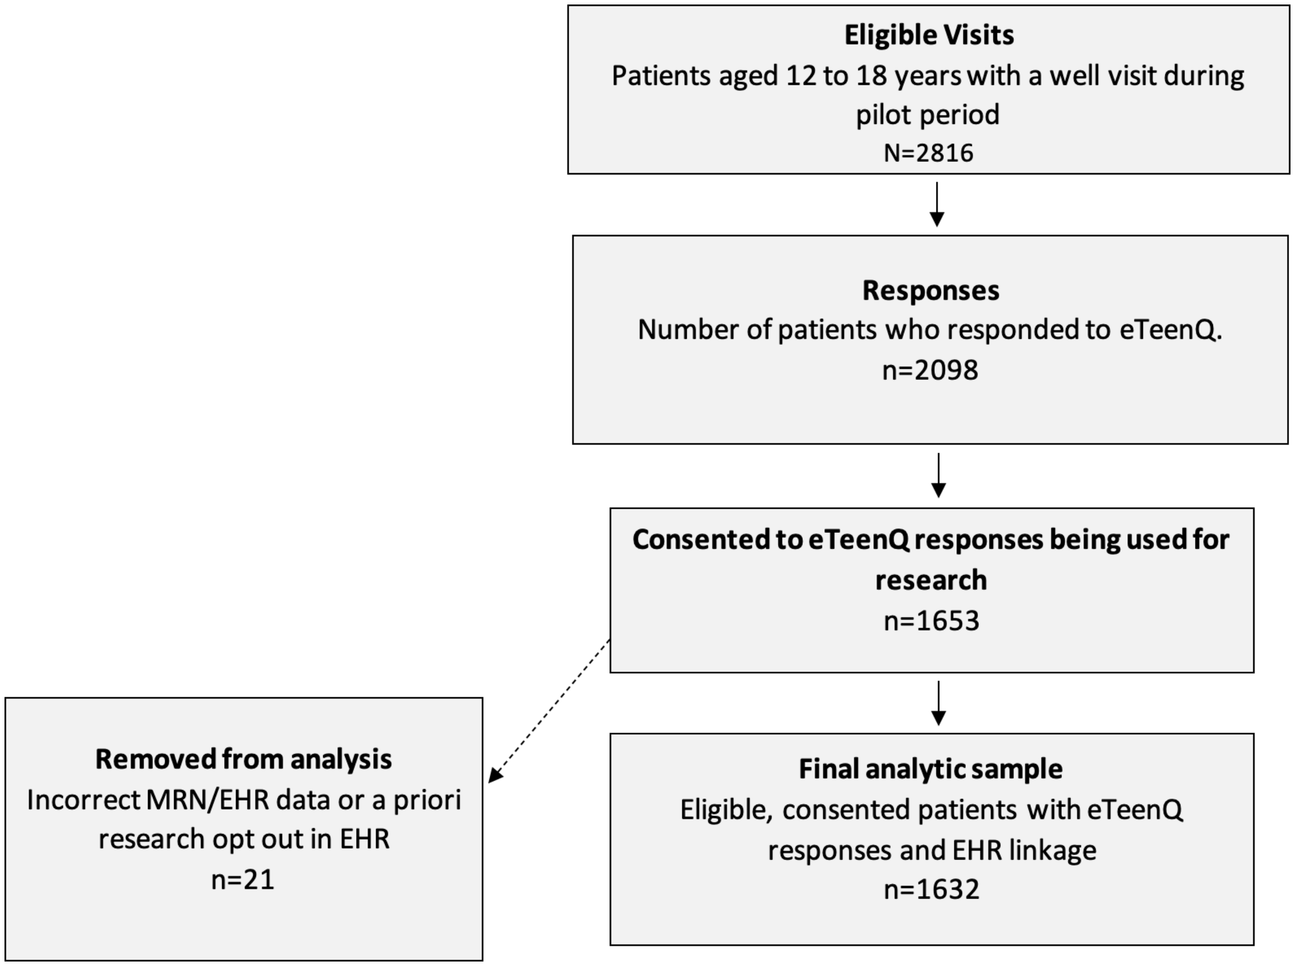

Table . Characteristics of sample (n=1632).

Characteristics		Values
Site, n (%)		
	Clinic A	997 (61.1)
	Clinic B	231 (14.2)
	Clinic C	404 (24.8)
Age (years), mean (SD)		14.5 (1.8)
Sex, n (%)		
	Female	818 (50.1)
	Male	814 (49.9)
Race/ethnicity, n (%)		
	White	1224 (75)
	Black/African American	139 (8.5)
	Asian	72 (4.4)
	Native Hawaiian or Pacific Islander	60 (3.7)
	American Indian or Alaska Native	4 (0.3)
	Other (or multiple)	74 (4.5)
	Unknown	59 (3.6)
	Hispanic	70 (4.3)
Insurance type, n (%)		
	Commercial	1284 (78.7)
	Public	340 (20.8)
	Missing	8 (0.5)

Overall data quality was good. Of 1632 respondents in the analytic sample, 1562 (95.7%) responded to all 29 questions in the eTeenQ. The most common question skipped was “How often do you use marijuana?” but this was only left incomplete for 10 (0.6%) respondents.

Across all 1632 teen respondents, 1472 (90.2%) reported having an adult they can really talk to and 1510 (92.5%) reported feeling safe in their community, yet 401 (24.6%) reported someone they lived with had a gun and 172 (10.5%) reported having had a stressful or scary event that still bothered them. In addition, 263 (16.1%) reported missing 7 or more days of school and 196 (12%) reported their grades were worse than they used to be. In addition, 157 (9.6%) responded they were or wondered if they were gay, lesbian, bisexual, pansexual, asexual, or other, and 43 (2.6%) reported they were or wondered if they were transgender or gender diverse. Risk behaviors were more common among older adolescents (aged 15-18 years; n=774) as compared to younger adolescents (aged 12-14 years; n=858). For example, 137 (17.7%) of older adolescents reported ever having had any kind of sex (with anyone of any gender) as compared to 9 (1%) of younger adolescents ($P<.001$). Similarly, 133 (17.2%) of older adolescents reported ever having used alcohol and 94 (12.1%) reported ever having used marijuana, as compared to 25 (2.9%) and 11 (1.3%), respectively, reporting use among younger adolescents ($P<.001$ for comparisons by age group).

Feedback From Providers and Clinic Staff at Pilot Sites

Across the 3 pilot clinics, 18 providers and clinic staff provided feedback through semistructured interviews. All felt that their adolescent patients liked using the tablets for completing the eTeenQ. They believed that patients were more honest with their responses using the tablet and noted more “positive screens” than when screening for adolescent risk behaviors on paper. They felt the tablets enhanced privacy and they particularly liked the provider display on the tablet that highlighted the “positive screens” or topics to address during the visit.

Challenges with the eTeenQ reported during interviews included isolated interruptions of Wi-Fi connectivity and confusion about which tablet belonged to which adolescent when 2 or more siblings with well visits were in the same examination room. In addition, adolescents occasionally clicked past the provider display screen, and the provider was then unable to review the eTeenQ responses on the tablet. Despite these occasional minor difficulties, primary care providers felt that the eTeenQ improved the quality of care they were able to provide and enhanced adolescent confidentiality. When asked their screening preference going forward, paper vs electronic, all respondents chose electronic.

Discussion

Principal Results

In this pilot study conducted in 3 busy community-based clinics within a large health system, we demonstrated that a paper adolescent risk screening tool can be converted for use as an electronic form; that adolescents were generally adherent to completing electronic risk screening on tablets at the time of preventive health visits, with a majority agreeing to have their responses stored in the EHR; and that implementation of the eTeenQ was feasible and well accepted by providers. Furthermore, the conversion of adolescent questionnaire responses to an intuitive provider display may have improved identification of risk behaviors requiring attention or further discussion during the visit. Storage of eTeenQ responses in a discrete field in the EHR can allow clinicians or researchers to evaluate adolescent risk behaviors across a clinic or geographic region, and ultimately can be used to design and implement targeted quality improvement projects.

Limitations

Several limitations to this pilot study should be noted. First, the participating clinics were not randomly selected. These clinics were motivated sites and had site champions who were engaged partners throughout the pilot. The successful adaptation and implementation of the eTeenQ at our pilot sites may not be generalizable to other clinics or health systems. A second limitation was that while adolescents complete several questionnaires at their preventive health visits, due to limitations in scope and budget, in our pilot only the eTeenQ was completed electronically. Thus, teens were filling out forms both electronically and on paper, which was cumbersome for staff and patients. Third, as a pilot project, we were not able to optimize all aspects of UI/UX, and the transfer of the data from REDCap to the EHR required a manual trigger following patient consent. If widely implemented, we would encourage additional modifications to the display and updates to the architecture to allow eTeenQ responses to flow seamlessly, in real time, into the EHR, and the incorporation of all adolescent screening tools for completion through electronic data capture. Further enhancements should also support completion of risk behavior screening in the days prior to preventive health visits. Fourth, as a small pilot study, our assessment of provider and staff acceptance of the eTeenQ was based on brief semistructured interviews and did not include formal qualitative analyses.

Comparisons With Prior Work

Findings from this pilot study were consistent with prior research, which has demonstrated that adolescents appear to more accurately report and be more willing to disclose sensitive information when questioned electronically vs on paper or in person [15,16]. In a pilot study conducted in 2015 in an academic adolescent clinic in Seattle, teens aged 13 to 18 years reported they preferred an electronic screen to a paper version. Prior studies have also noted that adolescents also perceive their visits as more confidential, feel they are listened to more carefully, and report they are more satisfied with their visit when computerized screening is used, as compared to other approaches to adolescent risk behavior screening [17]. Our study adds to the literature, as we conducted this work outside of an academic setting in 3 community-based clinics.

A potential benefit of electronic data capture is that forms can be easily modified and can include additional skip patterns or branching logic to support additional targeted data collection. For example, for those responding "yes" or "sometimes" to the eTeenQ single screening question regarding gender identity, "Are you or do you wonder if you are transgender or gender diverse?" in future iterations additional questions could then display allowing the patient to specify their gender identity [18].

We are not aware of prior research on adolescent preferences for storing sensitive information in the EHR. Prior to conducting this pilot, health system leaders had assumed that adolescent patients would not want their responses to adolescent risk screening stored in the EHR, as there would be a potential risk for disclosure to parents or others accessing their medical records. As such, we were surprised to find that 86% of adolescents consented to store their eTeenQ responses in the EHR. Recording of eTeenQ responses in discrete fields in the EHR is critical for follow-up of risk behaviors at future visits. If not documented, important health information revealed through risk behavior screening may be lost and not available at a patient's next medical encounter. In addition, adolescents may assume that communication between care teams occurs in the EHR and may not reveal vital sensitive information during a subsequent visit.

Conclusions

The use of electronic data capture for adolescent risk screening in primary care is feasible for collecting sensitive information in busy, community-based primary care settings. Most adolescents were agreeable to having their data stored in the EHR, and staff and primary care providers preferred electronic to paper screening. Providers felt that electronic screening enhanced confidentiality and that the eTeenQ improved the quality of care overall.

Acknowledgments

This research was supported by the HealthPartners Institute internal grants program. HealthPartners Institute is a 501c(3) nonprofit organization dedicated to conducting high-quality, public-domain health research, often in collaboration with other academic and research organizations throughout the world. The funder was not involved in the study design; conduct of the study; collection, management, analysis, or interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication. We would like to thank the participating clinicians and staff at the following pilot sites: Park Nicollet Clinic Bloomington, HealthPartners Clinic Stillwater, and HealthPartners Clinic St Paul.

Abstract

Background: The substantial increase in smartphone ownership has led to a rise in mobile health (mHealth) app use. Developing tailored features through mHealth apps creates a pathway to address the health care needs of pediatric patients with cancer and their families who have complex care needs. However, few apps are designed specifically to integrate with pediatric cancer care.

Objective: This study reports a systematic search and analysis of mHealth apps available on the Apple App (iOS) and Google Play (Android) stores designed for pediatric cancer through a list of features that serve (1) patients, (2) caregivers, or (3) both audiences.

Methods: Following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, we reviewed apps for pediatric patients with cancer and caregivers available as of January 30, 2024. We searched the Apple App and Google Play stores with a list of keyword combinations focusing on pediatric cancer care. The inclusion criteria were (1) specifically apps targeted toward pediatric patients with cancer, their families, or both; (2) available in either app store; and (3) available in English. Apps were assessed using the Mobile Application Rating Scale (MARS). The MARS is a quality assessment for mHealth apps, including components of engagement, functionality, aesthetics, and informational quality (5-point Likert scale items—1: low and 5: high quality).

Results: In total, 22 apps were identified and 17 of those apps were available on both platforms. The most popular features (n=12) were resource sharing, symptom tracking, reminders, care team connections, journaling, community support, medication tracking, data visualizations, and appointment tracking. Features and interfaces were designed for caregivers (n=9) more frequently than the patients (n=7) while a subset of apps created options for both users (n=6). A total of 16 apps received positive reviews (mean 4.4, SD 0.59; Min=3.1, Max=5.0). A small subset (n=3) achieved over 5000 downloads; however, the majority (n=15) had fewer than 500. More than half (n=12) of the apps were not available in English. Apps requested access to a range of device functionalities to operate (mean 2.72, SD 3.13; Min=0, Max=10). Out of 22, a total of 17 apps were publicly accessible. The mean MARS scores for the apps ranged from 1.71 (SD 0.75) to 4.33 (SD 0.82). Overall, apps scored high on functionality (mean 3.72, SD 0.54) but low on engagement (mean 3.02, SD 0.93).

Conclusions: Our review highlights the promising yet underdeveloped potential of mHealth apps in pediatric oncology care, underscoring the need for more inclusive, comprehensive, and integrative digital health solutions. Future developments should actively involve key stakeholders from the pediatric oncology community, including patients, families, and health care professionals, to ensure the apps meet specific needs while addressing linguistic and cultural barriers.

Introduction

Approximately 400,000 children are diagnosed with cancer each year internationally, and the incidence continues to rise annually [1]. Fortunately, treatment advances have also resulted in significant improvements in survival rates [2,3]. Despite these significant advances, pediatric cancer remains a leading cause of death among children [4]. The management of pediatric cancer is complex and requires multidisciplinary care that involves ongoing monitoring, management of physical or psychological symptoms, and social support for families. This includes community resources, symptom management, rehabilitation, and access to educational content for patients and their families. Digital interventions, such as mobile health (mHealth) apps, have the potential to meet these needs in real time while eliminating barriers like the distance from a medical center, lifestyle demands (eg, work and school), and mental health stigma [5].

mHealth apps are software apps designed to run on mobile devices, such as smartphones and tablets [6]. The significant increase in mobile or smartphone ownership has simultaneously led to a rise in the use of mHealth apps. Furthermore, the global proliferation of mobile devices among the younger demographic underscores the feasibility of mHealth apps for pediatric patients with cancer. Recent statistics indicate that technological access is substantial among the adolescent cohort [7]. Approximately 95% of adolescents possess or at least have access to smartphones and 90% have access to a desktop or laptop computer in the United States. Notably, almost half (46%) of this demographic reported to be online almost constantly [7]. mHealth apps offer a range of health-related services and resources, such as tracking symptoms, providing medication reminders, and connecting patients with health care professionals [5,8]. The use of mHealth apps in the context of pediatric cancer is an emerging field that holds great potential for improving the management and outcomes of this disease [5,9]. mHealth can provide valuable support for families dealing with pediatric cancer, including access to emergency contact information, educational resources, and social support networks [10]. Some apps also provide pediatric cancer families with tools to improve psychosocial well-being and health outcomes [11]. Additionally, these apps can help health care professionals to monitor and track patient progress more efficiently while providing more personalized care [12].

Despite the increasing number of mHealth apps developed for patients with cancer, there is a lack of literature on pediatric cancer regarding the mHealth apps available on the market. To our knowledge, a limited literature has focused on mHealth apps for caregivers of pediatric patients with cancer [5,9]. One of the early investigations highlighted cancer apps for adolescent and young adult patients with cancer with their functionalities for symptom tracking, pain management, monitoring, and medication management [13]. Looking at the broader literature, the studies mostly reported findings on a specific mHealth app, which might be focusing on electronic medical diaries for mood, symptom and treatment tracking [14], care after cancer treatment [15], pre-rehabilitation support [16], and posttreatment medical adherence [17]. In addition, newer mHealth technologies have leveraged wearable technologies for tracking physical activity [18,19], social media behaviors [19,20], web-text messaging for weight management [21], and gamification of monitoring symptoms to address cancer-associated pain through self-guidance [22,23].

mHealth apps for pediatric patients require further investigation to explore the potential benefits collectively. Therefore, a broader perspective (beyond the apps available in the current literature) is required to understand the current state of the mHealth apps. In line with that, the evaluation of those apps further contributes to the current state of the app market in pediatric oncology care. The aim of this systematic search is (1) to investigate currently available mHealth apps designed specifically for pediatric oncology in mobile app repositories (Google Play store and Apple App store); (2) to analyze the features and cost of services provided; and (3) to conduct a descriptive analysis to inform developers, designers, and clinician scientists. Our study aims to evaluate pediatric cancer–specific mHealth apps that ultimately improve psychosocial and health outcomes in vulnerable populations.

Methods

Overview

We performed an observational, cross-sectional, descriptive study of all smartphone apps associated with pediatric cancer available on the iOS (Apple App store) and Android (Google Play store) platforms. We only evaluated apps available in these 2 online stores.

Ethical Considerations

Institutional review board approval was not obtained as this is not human subjects research per our institutional policy and does not require institutional review board approval.

Mobile App Search

The methodology used was based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) system (see Checklist 1 for the PRISMA checklist) [24]. The search was conducted on January 2024 by a researcher (DIJ), accessing app stores via mobile devices (Apple iPhone SE and Google Pixel 4a). The review used a series of keyword combinations (n=116) through the Apple App store and Google Play store. The search terms included “pediatric,” “kid,” “teen,” “youth,” “adolescent,” “child,” “infant,” “little,” “minor,” “onco-,” “teenager,” “young,” “blood,” “bone,” “leukemia,” “lymphoma,” “oncology,” “tumor,” and “cancer.”

Inclusion Criteria

The coauthors (MSSF, MAS, ES, and DIJ) reviewed apps for eligibility. For inclusion in the review, apps met the criteria, which are (1) specifically related to supporting pediatric patients with cancer or families; (2) available in the Apple App store or Google Play store (Android) as of January 30, 2024; and (3) available in English (not exclusively). Free apps (no cost), apps for a fee and free trial apps (freemium), and subscription service apps were included. Apps that functioned as multi-institutional patient portals were excluded for being too broad to be considered a service for pediatric oncology care. A total of 196 apps were identified in both app stores. At the screening round, 159 apps were excluded due to not meeting our inclusion criteria based on store descriptions. Then, the eligible apps (n=37) were assessed for full inclusion (downloading and reviewing the apps). At this stage, we excluded 15 additional apps as they were identified as not being specific to the target population (n=7), not having an English interface (n=1), or were no longer available in either app store by the time the researchers initiated the analysis (n=7).

Data Collection and Analysis

Data were collected on the variables of descriptions, app rating (out of 5), number of reviews, total cost of services, intended user demographic, file size, supported languages, app privacy and data access requests, latest updates, and the app features from the app stores. App features were determined by reading the app description, reviewing snapshot images provided in the store, downloading the apps from each store on one of the mobile devices (Apple iPhone SE or Google Pixel 4a), and reviewing the original publisher's website post or press release. Each app was categorized by the level of access required before using the app (no account required, log in via account, closed sign-ups, and shutdown). A secure set of credentials was used for "login via account" apps. Data were recorded on a Microsoft Excel sheet for analysis (see Multimedia Appendix 1).

App Quality Assessment

We used the Mobile Application Rating Scale (MARS), which is a 23-question assessment of mHealth interventions, to measure apps in 5 domains including engagement, functionality, aesthetics, and information (see Textbox 1) [25]. We used information from the store page and in-app information to evaluate the population of eligible apps. We included 17 apps for MARS evaluation. Apps unavailable for download or that had special access requirements (not publicly available; n=5) were not evaluated. To measure credibility (the legitimacy of the app publisher) and evidence (scientific reports on the test or trial of the app) subcategories in the MARS, apps were cross-verified with external sources from the store page and in-app info, such as the developer's company page or ClinicalTrials.gov (as suggested by MARS guidelines). A total of 2 researchers evaluated the apps using the MARS instrument and resolved any disagreements via discussion and consensus. Finally, we reported the descriptive results. All included apps were available in the Apple App store but not in the Google Play store (n=5). For those available in both stores, we observed no difference in the user interface; therefore, apps were downloaded and tested on an iPhone SE for the quality assessment. Please see Multimedia Appendix 2 for the MARS scoring for each app.

Textbox 1. Mobile Application Rating Scale (MARS) domains.

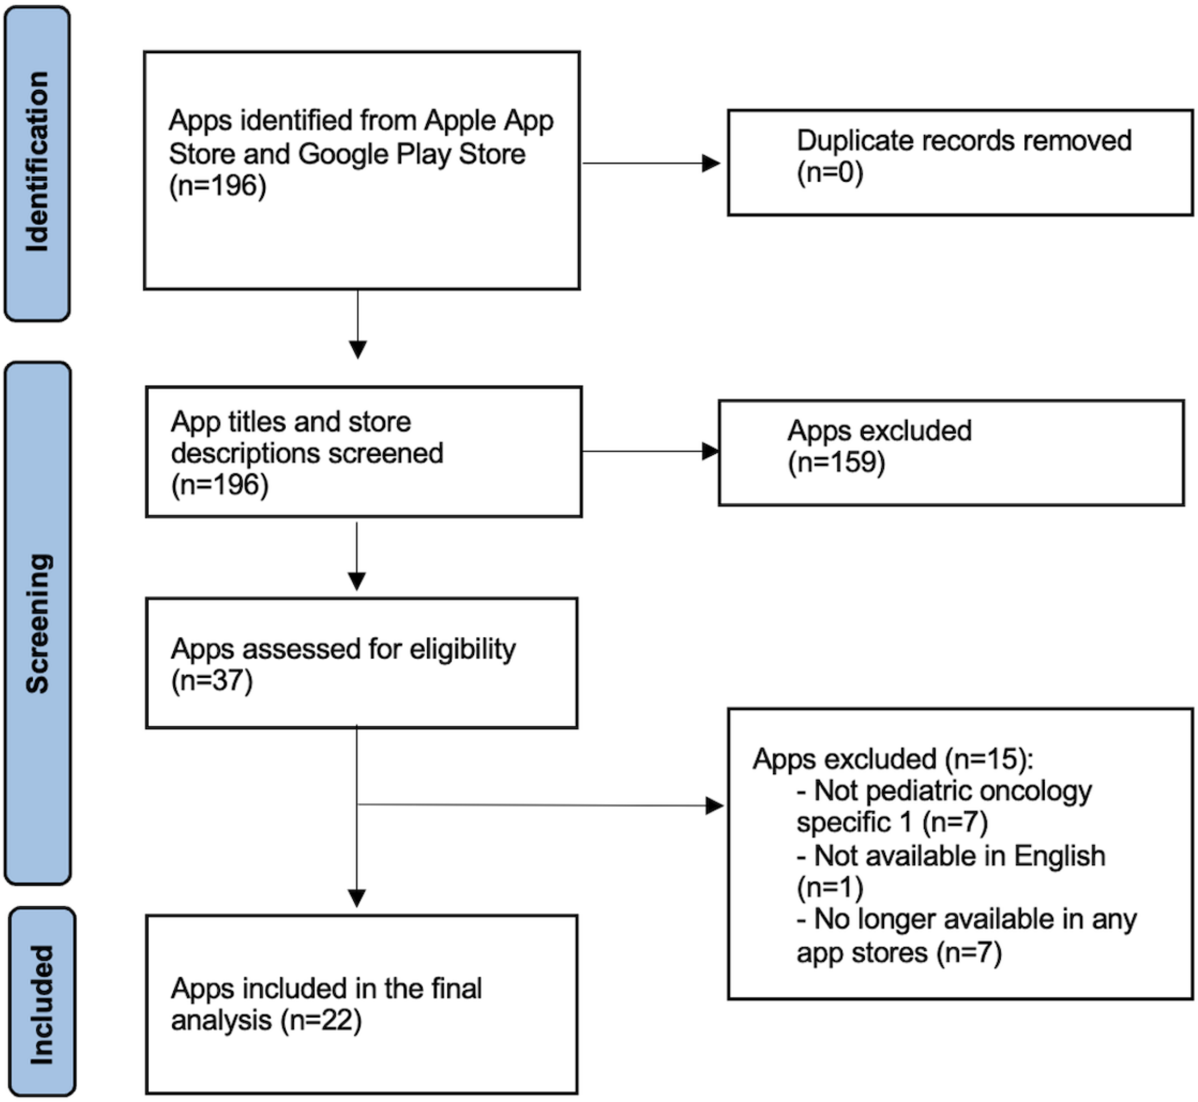
- Engagement: This domain measures how appealing, flexible, and well-targeted an apps for the target audience. This may include techniques for entertainment (ie, gamification), app features (ie, sound, content, notifications), and applicability between caregiver and pediatric patient age groups.
- Functionality: This measures basic app functions, ease of use, navigational difficulty, and gestural components. This may include how quickly buttons and menus react to user inputs. Additionally, this measures how logically consistent device-specific interactions are, such as taps, swipes.
- Aesthetics: This assesses the layout, graphical design, and visual appeal of the app. This may include quality of graphics or size of the visuals.
- Information: This domain evaluates the quality, quantity, and credibility of information within the app. This includes understanding the source of the content such as the developer and sponsor from their linked store page as well as scientific literature.

Results

Overview

In total, 22 apps were included in this review of pediatric cancer apps within the digital marketplace. Figure 1 illustrates the PRISMA flow diagram of the review. Most apps were available in both the Google Play (Android) and Apple App stores and shared the same features for both Android and iOS users (see Multimedia Appendix 1). Therefore, our report is based on consolidated data (Google Play or Android and Apple App store) for each app. More specifically out of 22 apps, 17 of them were available on both marketplaces. The remaining 5 apps were exclusively present on the Apple App store either because the Google Play store (Android) version was taken down or was never created. No apps were exclusively available on the Google Play store.

Figure 1. PRISMA flow diagram. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



App Features

We grouped and summarized the features of the apps by frequency (see Table 1). The resource and information feature was the most frequent property (n=17, 77%). This feature allows users to access guidebooks and video course material related to pediatric cancer. Following that, the symptom tracking feature (n=12, 55%) allowed users to log journal entries or short reports on their immediate symptoms. Reminders (n=10, 45%) let users customize push notifications for important treatment-related events. Connections to care teams, journaling, and community support (n=9, 41%) provided speed-dial options for oncological health care, a logging feature for clinical guidance, and a social component to connect with other pediatric patients with cancer or caregivers directly. Medication tracking and data visualization or graphs (n=8, 36%) saved or described dosage instructions and created pictures to describe variables over time such as medication adherence. The ability to share data, appointment tracking, and health activity data (n=6, 27%) presents a repository for users to save important documents to send pictures to a health care team; schedule upcoming medical appointments on the app calendar; and record basic aerobics, mindfulness activities, and nutritional habits. Integration with other health apps (n=2, 9%) allowed the platform to access other downloaded health and fitness data tracking apps in the patient or caregiver’s phone, such as Apple Health or the Fitbit App (Google).

Most apps (n=16) were free to use and publicly available. “Tracker, Reminder - CareClinic” had additional in-app purchases (up to US $60 total) that expanded on the existing features of the software.

Table . Apps and feature distribution.

App names	App features

[a] Only available in Apple App store.

App Quality Assessment

For each app, we calculated the mean and SD values of MARS scores under 4 categories (Table 2). In addition, we report "objective score," which represents the mean value of 4 categories. Functionality (mean 3.66, SD 1.05) scored the highest among the 17 apps following aesthetics (mean 3.51, SD 1.02), information (mean 3.49, SD 0.80), and engagement (mean 3.02, SD 1.05). See Multimedia Appendix 2 for detailed scoring in each category.

Table . App evaluations with the Mobile Application Rating Scale[a].

App names	Engagement, mean (SD)	Functionality, mean (SD)	Aesthetics, mean (SD)	Information, mean (SD)	Objective score, mean (SD)
COG KidsCare	3.80 (0.98)	4.50 (0.50)	4.33 (0.47)	4.67 (0.75)	4.33(0.82)
My Cancer Tracker	3.00 (1.10)	4.25 (0.43)	4.00 (0.82)	3.17 (0.69)	3.50 (0.96)
CancerAid	2.60 (1.36)	4.25 (0.83)	3.67 (0.94)	4.17 (1.07)	3.67 (1.29)
Net Cancer Health Storylines	4.00 (1.10)	4.50(0.87)	4.00 (0.00)	4.20 (0.75)	4.18 (0.86)
Pain Squad	4.00 (0.63)	4.75 (0.43)	4.00 (0.82)	4.14 (0.99)	4.21 (0.83)
HomeTown Cancer Predisposition	1.60 (0.80)	4.00 (0.71)	3.00 (0.82)	4.00 (1.22)	3.06 (1.39)
Heroes Circle	1.80 (0.75)	1.50 (0.50)	2.33 (0.47)	2.25 (0.43)	1.94 (0.66)
The Breath Brake App	1.80 (0.75)	1.75 (0.83)	1.67 (0.47)	1.60 (0.80)	1.71 (0.75)
Kid’s Guide to Cancer	2.80 (1.33)	3.75 (1.30)	5.00 (0.00)	4.00 (0.89)	3.76 (1.31)
BELONG Beating Cancer Together	4.40 (0.80)	5.00 (0.00)	4.33 (0.94)	3.40 (1.02)	4.24 (1.00)
Tracker, Reminder – CareClinic	4.60 (0.49)	2.50 (0.50)	4.67 (0.47)	3.00 (1.41)	3.65 (1.28)
Outcomes4ME Cancer Care	3.00 (0.89)	4.75 (0.43)	4.00 (0.82)	4.33 (1.11)	4.00 (1.11)
I’ll explain it to you	1.80 (0.98)	4.75 (0.43)	2.33 (0.47)	4.00 (1.26)	3.24 (1.52)
FORTEe Get Strong	3.20 (1.17)	2.25 (0.43)	2.67 (0.47)	2.67 (0.75)	2.72 (0.87)
Our Journey with Cancer	1.40 (0.80)	3.00 (0.00)	2.00 (0.00)	3.40 (0.49)	2.47 (0.98)
LLS Coloring for Kids	4.60 (0.49)	4.25 (0.43)	3.67 (0.94)	3.67 (0.75)	4.06 (0.78)
OncoPower	3.00 (1.41)	3.50 (0.50)	3.00 (0.82)	2.80 (1.60)	3.06 (1.26)
Average score	3.02	3.72	3.45	3.50	3.40

[a] Objective score reflects average of 1 through 4 for each app.

Audience Categories

Apps were split into 3 groups based on their intended audience. In the first group, apps that focused on a pediatric population, between the ages of 0 and 17 years (n=7), used activities designed to interest the younger demographic to convey valuable information or make certain features more accessible from a medical literacy perspective. In the second group, apps that focused on caregivers, 18 years and older (n=9), were more likely to create direct connections to health care and generate data visualizations to translate numbers into meaningful interpretations. In the last group, the rest of the apps targeted both pediatric patients and caregivers (n=6). These apps proposed separate user accounts to differentiate parent and child, as well as the targeted features.

User Ratings and Reviews

The majority of apps (n=18) had user ratings publicly available for review and analysis. A total of 4 apps did not receive any user reviews or ratings (Hometown Cancer Predisposition, Kid’s Cancer Guide, AYABytes, and FORTEe Get Strong). These apps had between 1 and 100 posted reviews per app, whereas there were apps that received a high number of user ratings, such as “Tracker, Reminder - CareClinic” (n=3100) and “BELONG Beating Cancer Together” (n=5770). A total of 16 apps received high ratings (mean 4.4, SD 0.59; Min=3.1, Max=5.0).

Downloads and Storage

CancerAid, Cancer.Net Mobile, BELONG Beating Cancer Together, and My Cancer Tracker were downloaded by more than 5000 users. The rest of the apps were downloaded by fewer than 500 users. Apps required between 1.7 and 235.3 MB of storage for saving health-related information and app functionality (mean 67.03 MB, SD 58.38 MB).

Language Availability

To be included, apps were required to have an English option. The majority of the apps provided English exclusively (n=12). However, 10 apps provided multilanguage options including Spanish (n=4), French (n=4), Arabic (n=2), German (n=2), Chinese (n=2), Hebrew (n=1), Dutch (n=1), Italian (n=2), Hindi (n=1), Romanian (n=1), and Portuguese (n=1).

Data and Health Information Privacy

Apps typically request access to key hardware or software features built into the device to exercise the full length of capabilities designed into the mHealth app. These requests appear as pop-up notifications that require input before continuing to use the app (mean 2.72, SD 3.13; Min=0, Max=10). The types of requests across both app stores included approved access to the calendar, files, camera, microphone, location, user ID, device ID, Wi-Fi networks, contacts, and phone status. Based on our observation, none of the apps mentioned any type of encryption on the app store or in-app. Similarly, none of the apps provided 2-step verification options or similar security measures after account creation.

Discussion

Principal Findings

The principal findings of our systematic search and analysis study reveal a noticeable scarcity of pediatric oncology-specific mHealth apps in the digital marketplace, highlighting a critical gap in resources aimed at supporting pediatric patients with cancer and their families. Despite the growing prevalence of mHealth solutions in the broader health care landscape [26], our analysis underscores the underrepresentation of pediatric patients with cancer in this technological advancement [27]. Similarly, Jupp et al's [28] earlier review identified only 1 out of 28 qualifying oncology apps that specifically served pediatric patients.

The existing apps predominantly focus on educational resources, symptom tracking, and medication reminders. We observed that the adoption of these apps may rely on how well an app can both target specific diagnoses and remain applicable to the wider oncology audience. Therefore, high functionality may have come at the cost of aesthetics and engagement quality of the apps and lacking concise and quality information. While these features align with general needs within chronic illness management, they often lack the specificity and depth required for the complex care trajectories typical in pediatric oncology. This includes focusing on cancers more common in children than adults, implementing risk-based medical follow-ups, a systematic plan for lifelong surveillance, managing symptoms, addressing developmental delays or educational disruption, and mitigating long-term effects of treatment [29,30].

Quality Assessment

Of the objective domains, functionality scored the highest while engagement scored lowest on average. The prioritization of equipping patients and their caregivers with accessible tools is a strong theme among newer mHealth apps, especially in pediatric oncology. These health management apps can create the structure needed for caregivers and patients to monitor progress, which leads to better accountability and overall better patient outcomes [31]. However, the design of these apps often does not incorporate tactics to maintain attention or consistent usage, such as gamification, in the long term. This in combination with the lower information scores creates an obstacle to sustained adoption. An app may be highly functional and aesthetically professional but lacks specific flexibility and informative quality for caregivers, patients, or both.

Lower scores for engagement are consistent with other studies in the literature that used MARS for oncology app interventions [32]. Additionally, the developers' tendency to focus on implementation rather than building evidence-based features highlights a trend of understudied interventions on the market today [33]. Many of the apps included in this study either were minimally tested in a usability trial or were not rigorously tested at all. New users of these apps may find oncology mHealth apps helpful for minor tracking purposes like notifications but might find them problematic with evolving treatment plans, expanding diagnostic information, and available support groups in the area.

Target Population

Of the few apps currently available for pediatric cancer, apps were designed to target children and adolescent patients, caregivers, or both user populations. Apps designed for adolescents and young adults (AYA) with cancer are of interest since nearly two-thirds of AYAs within the United States report using an app for health behaviors, including medication reminders [34]. Several studies have reported the informational needs of AYAs in a cancer care app by highlighting features such as free-text diaries. The overarching goal of a cancer care app is expected to help monitor the impact of the disease and treatment in their day-to-day life and emotions [14]. Additionally, there is a need for personalized data to be adapted to a patient's specific condition, considering factors such as the type, history, and severity of cancer [27], as well as age-appropriate content that addresses topics like diagnosis, treatment options, sustaining social ties, and strategies to manage the illness [35]. These abilities help AYAs to be more independent with self-care, thus easing the transition to adulthood and long-term survivorship [36]. Additionally, more recent pediatric oncology literature has called out the gap in the child's voice, particularly in symptom assessment [37-39]. mHealth apps designed specifically for children could provide that opportunity to improve reporting standards.

Value of Apps in Patient Care

In our study, the majority of the apps focused on educational (information) resources for different user audiences. This aligns with Vaffis et al's [30] finding as mHealth apps focus on cancer as an important component of patient disease management. Moreover, this is an expected finding as pediatric cancer treatment requires complex treatment regimens, daily medications, intensive side effects, and symptom burden [40]. In addition, medication tracking, symptom tracking, and notifications for reminders are other major features. This matched with the need and also the major challenge to the oncological treatment plans, which is managing medication nonadherence or noncompliance. Missed treatments during home care are major causes of increased adverse outcomes including infection, relapse, and death in this vulnerable population [41]. Therefore, the apps have been aiming to address this vital issue via those critical features, aligning with earlier apps [13]. In addition, the literature presents evidence to support the efficacy of digital interventions in improving medication adherence, psychosocial well-being, and health outcomes in children and adolescents with chronic health conditions [5]. This indicates that mHealth apps aim to improve adherence, self-management and alleviating symptom burden could be essential to improving the use of the apps, and health outcomes.

Inclusivity

Furthermore, our findings highlight a significant language barrier, with more than half of the reviewed apps available exclusively in English. The accessibility of these digital interventions in alternative languages is a step toward closing the gap in care [42,43]. However, this has been an improvement as a review in 2017 cited that only 20% of all medication apps were offered alternative languages [36]. In addition, the digital divide between socioeconomic and ethnic groups reduces the availability of such resources to underserved populations including limited English proficiency patients and families [44,45]. New approaches via mobile apps should be considered, as these platforms can help with medical literacy and build self-care routines among patients and families [46,47]. In addition, developers and decision makers should consider device compatibility and dependency on cellular connectivity to reduce problems due to inconsistent service, limited storage, data plan requirements, or budget-friendly smartphones that are outside of the regularly maintained cycle of software updates [14,20,36]. Such an approach may support scalable, accessible, and affordable use.

Privacy and Security

Finally, data security and privacy are important as patients and families are storing and sharing personally identifiable information and confidential health information via apps. Health care institutions create guidelines for handling sensitive data; however, the privacy and security of personal health apps remain the responsibility of end users. Unfortunately, the Health Insurance Portability and Accountability Act (HIPAA) does not regulate third party apps or their services [48]. Other regulations such as the Children’s Online Privacy Protection Act (COPPA) have been a major piece of legislation for protecting child information from third-party organizations, yet it has limited protections with regard to health care information [49-51]. To ensure adequate protection, app stores hosting mHealth tools should have additional protocols to require justification for the necessity of accessing requested phone sensors and other sensitive health informatics (eg, camera, location, and microphone) [48].

Limitations

This review provided an overview of pediatric cancer-specific apps limited to the currently available apps in the Google Play and Apple App Store. We included these 2 common app stores because they are available in 2 major smartphone operating systems (iOS and Android) and are accessible by the majority of end users [52]. We have not included other stores, such as the Galaxy Store or Amazon Appstore, due to their limited user base and specific requirements for service (ie, the Amazon Appstore requires additional app installations) which may not be applicable for a broader audience of pediatric patients with cancer and caregivers. We focused on the US market for available apps as both app stores are regionally locked due to our physical location. In addition, we focused on apps available in the English language with additional language options. That limited our access to other apps that do not include English language as an option, or alternative apps for different regions or languages. We were not able to use content or sentiment analysis with all user comments because not all apps had a sufficient volume of comments to be analyzed. In addition, we have not received feedback from developers, patients, and clinicians about the apps during the study. This may have limited the study’s objectivity by not including their insights about the apps. Finally, the apps have a life cycle and are subject to change depending on developer updates and business or are not accessible and have restricted access. Some apps could be also removed from these stores for any reason, which may reduce the ability to evaluate these apps continuously and replicate this review with the same set of apps.

Future Works

Further research is suggested to investigate how developers create mHealth interventions through theory-based frameworks and collaborations (ie, co-design). Based on the MARS, we recommend future interventions to balance focus between extensive customizability and reliable intractability.

Additionally, future development efforts must prioritize the involvement of pediatric oncology stakeholders, including patients, families, and health care professionals, to ensure that the apps are not only technically sound but also deeply aligned with the specific needs, reducing linguistic and cultural barriers. We suggest a focus on evidence-based implementations and rigorous testing approaches for intervention, validation, adoption, and effectiveness. Going beyond, future research may expand how these apps are created from the developer’s perspective and ways to enable cross-disciplinary collaborations including patient and clinician stakeholders as well. Other avenues of research may also incorporate recent innovations in virtual reality, extended reality, and artificial intelligence to create more effective mobile and web apps.

Conclusions

Our study examined the landscape of mHealth apps for pediatric cancer. While mHealth apps hold promise for enhancing care and support for pediatric cancer treatment, our findings underscore the need for more inclusive, comprehensive, and integrated digital health solutions. The complexity of pediatric cancer is a multifaceted challenge, and mHealth apps can bridge the gaps to become a fundamental source of support for patients and caregivers from diagnosis to survivorship.

Abstract

Background: Children with cancer or cancer-like disease risk treatment-related isolation, which can negatively impact their peer relationships and social competencies and exacerbate their loneliness. During the COVID-19 pandemic, increased online socialization became the new normal imposed by national isolation guidelines. To adhere to the treatment-related isolation guidelines, children with cancer were offered online classmate "ambassador" visits during hospitalization.

Objective: This study aimed to identify facilitators and barriers to online classmate "ambassador" visits during children with cancer's hospitalization through a qualitative descriptive process evaluation using the Consolidated Framework for Implementation Research.

Methods: From January to April 2022, we conducted 39 individual semistructured interviews with hospitalized children (n=16), their classmates (n=16), teachers from their schools (n=3), and study nurses (n=4) from involved hospitals. Most interviews (n=37, 95%) were conducted online using Microsoft Teams or Google Meet, while 2 (5%) interviews were conducted in person at the participants' residences. This approach allowed us to gain a broad understanding of the facilitators and barriers to online ambassador visits.

Results: We identified four themes: (1) working together, (2) ensuring participation, (3) staying connected, and (4) together online. The themes are described in terms of facilitators and barriers to online ambassador visits with 3 Consolidated Framework for Implementation Research domains: innovation, individuals, and the implementation process.

Conclusions: Addressing the social needs of hospitalized children through online visits with their classmates may be relevant when one-on-one meetings are problematic. The online visits are highly dependent on collaboration between study nurses and teachers and assessing the needs of the hospitalized children. While a high degree of adult engagement and a stable internet connection are pivotal, these online visits can promote much-needed social interaction between children across physical settings.

Introduction

In Denmark, 200 children aged between 0-18 years are diagnosed with cancer annually [1]. The positive advancement in treatment for childhood cancer has positively impacted the overall 5-year survival rates, which now exceeds an 80% chance for survival [2]. Although survival is expected for most children diagnosed with cancer, the treatment is often intense, involving chemotherapy, surgery, irradiation, and long periods of hospitalization [2,3]. As a result of the tough treatment, most children with cancer face long-term effects, which continue to plague them into their survivorship [3]. Childhood cancer survivors report long-term effects such as fatigue, impaired physical function, and poor cognitive function [4,5]. Furthermore, children with cancer and childhood cancer survivors also face social difficulties due to absenteeism from school, as well as leisure and social activities during treatment [6,7]. Consequently, their absence disrupts peer relationships, decreases social competencies, and increases feelings of loneliness [7,8]. Thus, treatment-related long-term effects combined with social isolation during treatment can hurt childhood cancer survivors' long-term well-being [3,8].

When returning to school after treatment, childhood cancer survivors often experience uncertainty and fear of losing their social relationships with classmates or peers [9,10]. It is, therefore, essential that children with cancer stay connected with school during hospitalization to maintain a sense of normalcy, develop social skills, and ensure successful re-entry after treatment [11-13]. A 2016 systematic review shows that school re-entry programs and peer education of classmates about cancer can further promote positive attitudes toward the child with cancer [14]. This positive classmate attitude was associated with greater motivation for interacting with the child with cancer and including them in social situations [14]. In 2013, a multimodal intervention called RESPECT (Rehabilitation Including Social and Physical Activity and Education in Children and Teenagers With Cancer) was designed to target and ameliorate children with cancer's physical, social, and academic functioning during hospitalization. The intervention included education of classmates about children with cancer and cancer treatment, visits by classmate "ambassadors" to the hospital, and establishing a link between the hospital and the child's school peer group through in-hospital supervised activity [15,16]. Previous research from the RESPECT study has shown that social interaction by hospitalized children with cancer can promote a sense of connectedness with their classmates while, in turn, motivating the classmates to support them [17-19].

Recently, technologies, including video conferencing and telepresence robots, have become viable options for socialization and schooling [20,21]. These technologies have been shown to positively impact homebound or hospitalized children's perceived social presence, academic behavior, and sense of normalcy [22-24]. As the COVID-19 pandemic shut down schools worldwide and the accompanying restrictions to physically isolate became inevitable, the need for technologies to support academic and social performance came to the forefront [25,26].

In response to the COVID-19 pandemic, hospitals and schools in Denmark prohibited in-person visits from March 2020 to April 2022, and the RESPECT study was forced to shift from in-person to online ambassador visits. We speculate that online visits may not be a better stand-alone option for school re-entry but could be seen as a supportive component. In some countries or settings, the online option may be more accessible than in-person visits, for example, a hospitalized child in isolation. However, it is still important to know the degree to which school re-entry programs and online ambassador visits complement each other and how online visits contribute. In this study, we aimed to identify facilitators and barriers to online ambassador visits for hospitalized children with cancer through a qualitative descriptive process evaluation using the Consolidated Framework for Implementation Research (CFIR). By identifying facilitators and barriers to online visits, this qualitative process evaluation intended to inform other health care professionals or professionals working closely with hospitalized children on what to be aware of when offering online visits to hospitalized children. Hopefully, our findings will inspire others to provide a social connection between hospitalized children and their peers.

Methods

Design

A qualitative descriptive process evaluation of online classmate "ambassador" visits was conducted with semistructured interviews after implementation. We used qualitative descriptive research to uncover the participants' experiences through their descriptions of the online ambassador visits. Qualitative descriptive research design has been predominantly used within health care research to provide direct descriptions of phenomena where the experiences are described from the participants' viewpoint [27]. In this study, qualitative descriptive research offers the opportunity to gather direct, rich descriptions of the online visits from the involved participants: hospitalized children, their ambassadors, their teachers, and the study nurses [27]. The knowledge gained from our participants' descriptions can be used to design future online psychosocial interventions for hospitalized children. The CFIR was used to interpret the participants' descriptions of facilitators and barriers to online visits [28]. As the meta-theoretical basis for the CFIR includes several implementation aspects, the CFIR provides a helpful framework for illuminating facilitators and barriers across 38 constructs within the five domains: (1) innovation, (2) outer setting, (3) inner setting, (4) individuals, and (5) implementation process [28]. The innovation domain refers to the proposed changes implemented and includes aspects of the intervention such as the innovation source and strength, evidence quality, relative advantage, adaptability, trialability, complexity, design, and cost [28]. The inner setting refers to the environment where the intervention is implemented, for example, hospital, school, city, etc. The inner setting domain includes team culture, compatibility, leadership engagement, and the implementation climate [28]. The outer setting domain refers to the context in which the intervention's inner setting exists and includes patient needs and resources, the level at which the implementing organization is connected with other organizations, peer pressure, and external policies and incentives [28]. The individuals domain refers to personal beliefs, knowledge, self-efficacy, and attributes that affect the intervention's implementation [28]. The implementation domain refers to activities and strategies used to implement the intervention, including planning, executing, reflecting, evaluating, and key intervention stakeholders, for example, opinion leaders, engagement, and project champions [28].

The RESPECT Study

The initial RESPECT study was a controlled intervention study implemented at the University Hospital of Copenhagen from 2012 to 2019. An in-depth description of the RESPECT intervention study, including inclusion and exclusion criteria for participation, is described elsewhere [15,29]. Based on qualitative results from the RESPECT study [17,19], it was decided to implement this study nationwide, offering (1) educational sessions for classmates on cancer and treatment and (2) facilitation of classmate "ambassador" visits during hospitalization as an integral part of the RESPECT implementation study (Textbox 1).

Textbox 1. Overview of the RESPECT (Rehabilitation Including Social and Physical Activity and Education in Children and Teenagers With Cancer) intervention study and the RESPECT implementation study.

The RESPECT intervention study. **Started in 2012. Ended in 2019.**

- Purpose: explore if involving healthy classmates at the hospital from the time of diagnosis and throughout treatment will improve the physical, educational, and social function of children with cancer, including facilitating their re-entry to everyday life after treatment.
- One intervention group from the pediatric oncology ward at the University Hospital of Copenhagen (Rigshospitalet).
- Three control groups from the pediatric oncology wards at Aarhus University Hospital, Aalborg University Hospital, and Odense University Hospital.

The RESPECT intervention study consists of:

- Educational sessions for classmates and teachers on childhood cancer, treatment, side effects, physical activity, and the RESPECT study in the school classroom by the study nurses.
- Supervised in-hospital physical activity. This component begins when the child with cancer or cancer-like disease is included in the RESPECT study.
- After the educational session, 2 classmates are elected as ambassadors in collaboration with the classmates, their parents, their teachers, and the study nurses.
- Classmate “Ambassador” visits during hospitalization. Ambassador visits are offered every 14th in-hospital stay day.

June 2019

- The national implementation of the RESPECT study began. The RESPECT intervention study changes to the RESPECT implementation study.

The RESPECT implementation study. Started in 2019. Ongoing.

- Purpose: to improve the social and educational well-being of children with cancer or cancer-like diseases during hospitalization, including facilitating their transition to everyday life after treatment.
- Offered at 4 Danish pediatric oncology wards: University Hospital of Copenhagen (Rigshospitalet), Aarhus University Hospital, Aalborg University Hospital, and Odense University Hospital.

The RESPECT implementation study consists of:

- Educational sessions for classmates and teachers on childhood cancer, treatment, side effects, physical activity, and the RESPECT study in the school classroom by the study nurses.
- After the educational session, 2 classmates are elected as ambassadors in collaboration with the classmates, their parents, their teachers, and the study nurses.
- Classmate “ambassador” visits during hospitalization. Online ambassador visits are offered every 14th in-hospital stay day.

March 2020

- COVID-19 pandemic hits Denmark, causing national lockdowns, including lockdowns at all 4 pediatric oncology wards and schools. No in-person ambassador visits are allowed. The RESPECT implementation study adapts to an online app format using Microsoft Teams (Microsoft) or Google Meet (Google).
- Online educational sessions for classmates and teachers on childhood cancer, treatment, side effects, and the RESPECT study by study nurses.
- Two classmates are chosen as ambassadors online in collaboration with the classmates, their parents, their teachers, and the study nurses.
- Online classmate “ambassador” visits during hospitalization. Online ambassador visits are offered every 14th in-hospital stay day.

Participation in the RESPECT Implementation Study

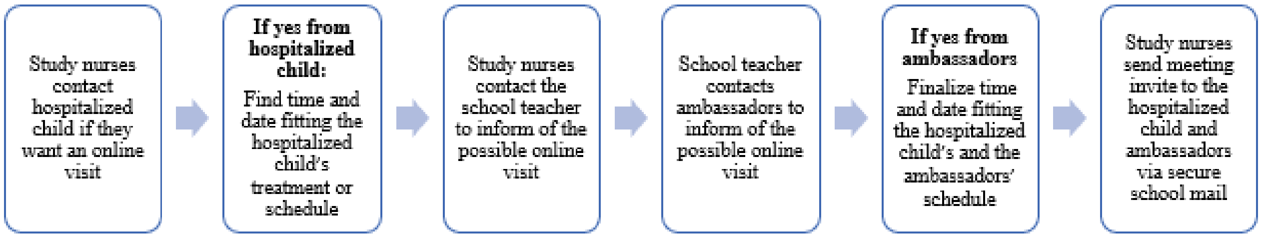
Study nurses invited hospitalized children to participate in the RESPECT implementation study if they were (1) school-aged (6-18 years old); (2) diagnosed with cancer or cancer-like diseases, for example, immune deficiency or severe aplastic anemia; (3) treated with chemotherapy, radiation, surgery, or hematopoietic stem cell transplantation; and (4) receiving cancer treatment at a pediatric oncology ward in Denmark. Classmates were introduced to an “ambassador” function during the educational session in the classroom and could apply for the role, which involved visiting the hospitalized child throughout the treatment trajectory or until the classmate no longer wished to hold the function.

The classmates were also informed of the practicality of the ambassador visits, such as being transported to and from the hospital, that the time duration of the ambassador visits was always on a school day between 9 AM and 3 PM, and what to expect as an ambassador visiting the hospital, for example, seeing children who are sick. If needed, ambassadors were replaced with new ones. Further, 2 ambassadors per hospitalized child were identified in collaboration with the classroom teacher, the hospitalized child, the hospitalized child’s parents, the ambassadors’ parents, and this study’s nurses. All ambassadors were screened by this study's nurses. The inclusion criteria for becoming an ambassador were (1) being a classmate to the hospitalized child and (2) possessing educational, emotional, and social competencies to support the hospitalized child. Children with cancer or cancer-like diseases and their classmates were excluded if they were (1) unable to speak Danish or (2) had severe mental disability.

The RESPECT Implementation Study During the COVID-19 Pandemic

To ensure that children with cancer stayed socially connected with their school classmates during the COVID-19 pandemic, the RESPECT implementation study adapted their in-person educational sessions and ambassador visits to a digital format using Microsoft Teams (Microsoft) or Google Meet (Google). Manuals or guidelines on how to organize or facilitate these online educational sessions or online ambassador visits were not developed before the initiation of the online visits. Guidelines were eventually developed simultaneously with conducting the online ambassador visits and based on experiences gained during the intervention. They were updated nationally during weekly meetings between this study's nurses and the principal investigator of the RESPECT study. The online visits were led by study nurses associated with the RESPECT implementation study. The online visits were offered via secure mail accounts and were scheduled by this study's nurses. These visits took place between 9 AM and 3 PM, with a frequency of 1 visit every 14th in-hospital day (Figure 1).

Figure 1. Preparation process for online ambassador visits.



The online ambassador visits took place during regular school hours. The teachers were responsible for assisting the ambassadors with setting up their equipment, for example, logging in to Microsoft Teams or Google Meet but they were not required to be present during the online visits. The hospitalized children decided if they wanted their parents or this study's nurse to be present during an online visit. In most cases, the parents did not participate but were present in the hospital room. The online visits did not have a fixed timeframe but ranged from 10 to 90 minutes, depending on the hospitalized children's well-being on the day and the motivation of hospitalized children and their ambassadors to continue the session. Equipment such as computers, telephones, or tablets facilitated the online visits. The hospitalized children and the ambassadors often used computers provided by the school but a mobile device with an internet connection and secure mail account to access Microsoft Teams or Google Meet was acceptable.

Participants and Recruitment

We recruited participants from the RESPECT implementation study for this study. All children with cancer or cancer-like diseases (hospitalized children), ambassadors, RESPECT study nurses, and teachers with experience in online ambassador visits were eligible to join this study. We used a convenience sample strategy to include the participants in this study. We strived to include participants representative from all of Denmark to provide nuanced descriptions of online visits. We included hospitalized children with cancer from 3 out of 4 hospitals that have a pediatric oncology ward. The criteria for inclusion of the hospitals were that the RESPECT implementation study must have been implemented and offered online visits during the COVID-19 pandemic.

The implementation of the RESPECT implementation study was scheduled for the fourth hospital but was postponed due to the COVID-19 pandemic. As a result, the fourth hospital did not meet our inclusion criteria. From the RESPECT implementation study, 123 hospitalized children were identified as eligible to participate in this study. Out of these, this study's nurses invited 34 hospitalized children to participate in this study. If the hospitalized child consented to participate, their ambassadors were also contacted regarding participation. Study nurses from the RESPECT study and schoolteachers were invited to participate if they had facilitated at least one online visit during the COVID-19 pandemic. Author NNB, a female PhD student without prior knowledge of the participants, contacted the invited participants by telephone regarding participation in this study. Of these 34 hospitalized children, 16 agreed to participate, as well as 16 of their ambassadors, 4 RESPECT study nurses, and 3 schoolteachers (Figure 2).

In total, 26 participants were from Zealand (University Hospital of Copenhagen), and 13 participants were from Jutland (University Hospital of Aarhus and University Hospital of Aalborg) in Denmark. The 16 hospitalized children (8 boys and 8 girls) were treated for leukemia (n=9), immune deficiency (n=3), extracranial solid tumors (n=2), tumors located in the central nervous system (n=1), or severe aplastic anemia (n=1). The hospitalized children and their ambassadors were aged between 7-16 (mean 10.5, SD 2.8) years. The hospitalized children participated in 4.5 (SD 3.5) online visits with a range of 1-12 online visits. Participant characteristics are presented in Table 1 below.

Figure 2. Recruitment process.

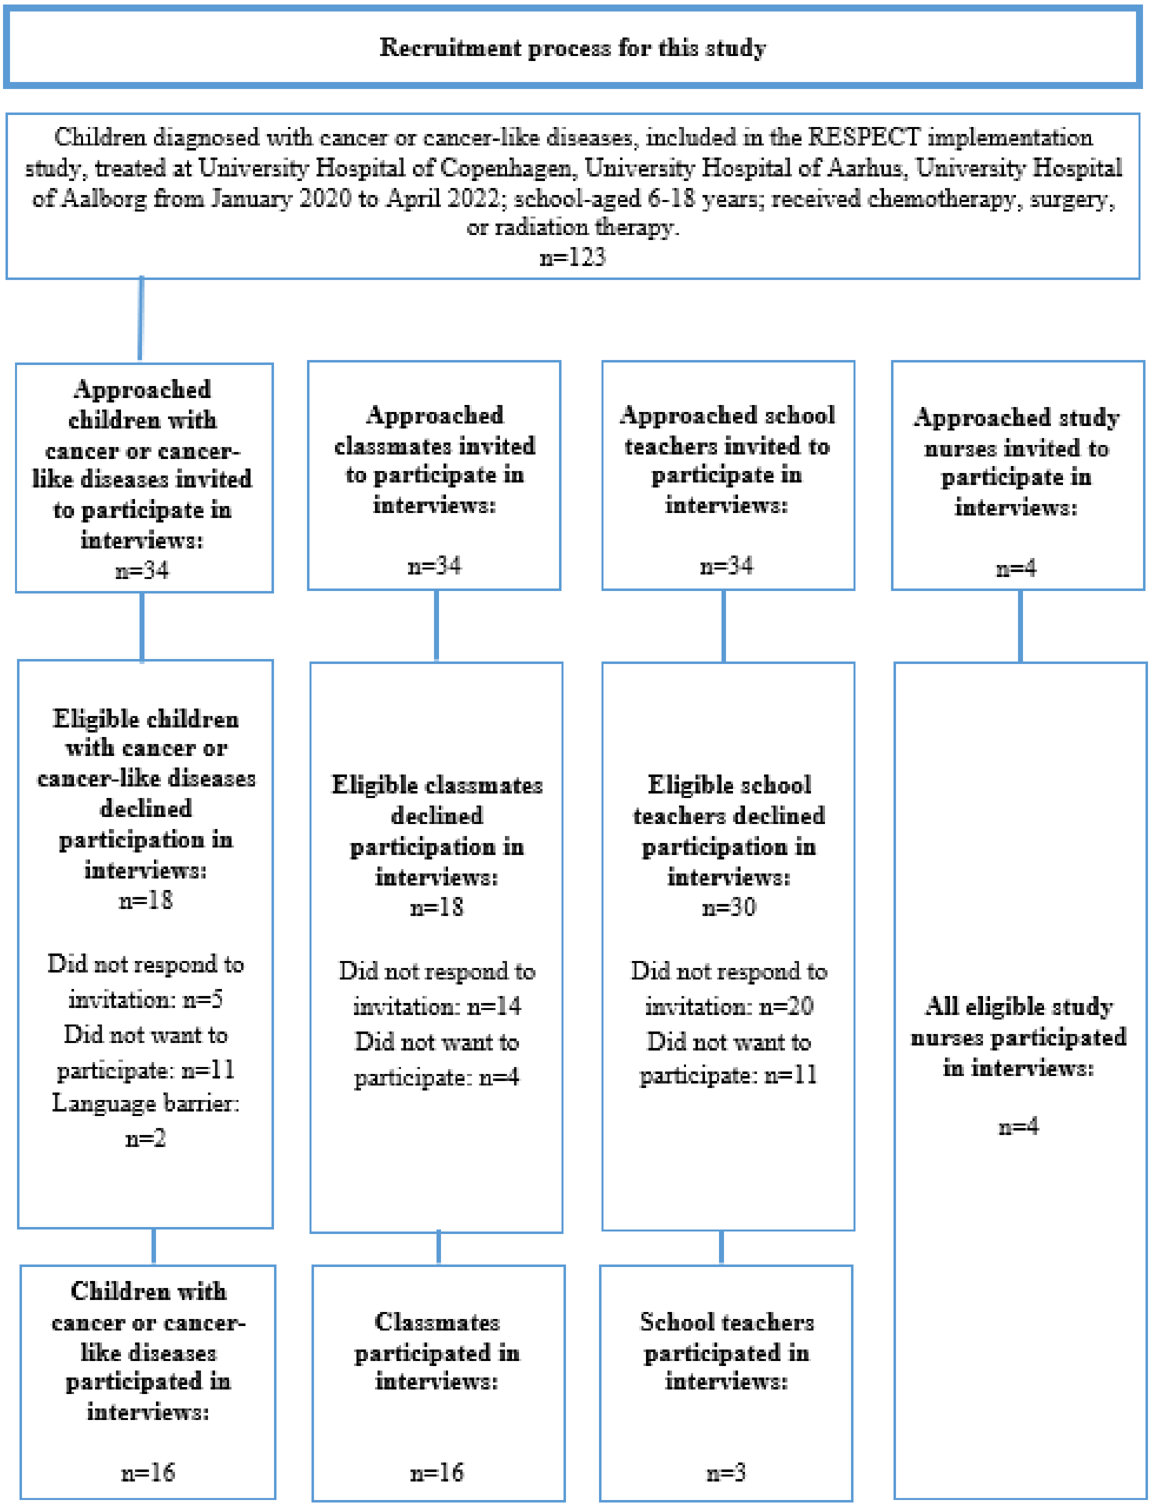


Table 1. Participant demographics. Note that ambassadors and schoolteachers are presented by region, not by hospital site, as they are not linked to the hospital.

Participant demographics	Children with cancer (n=16)	Ambassadors (n=16)	Study nurses (n=4)	Teachers (n=3)
Sex, n (%)				
Male	8 (50)	6 (38)	—[a]	1 (33)
Female	8 (50)	10 (62)	4 (100)	2 (67)
Type of cancer or cancer-like diseases, n (%)				
Leukemia	9 (56)	—	—	—
Tumors located in the central nervous system	1 (6)	—	—	—
Extracranial solid tumors	2 (12)	—	—	—

Ethical Considerations

The RESPECT implementation study is a part of the original RESPECT study (file H-20077439). The Danish Data Protection Agency (file P-2021-208) approved the RESPECT study. Participants provided written and informed verbal consent, and parents gave consent on behalf of their children under 15 years of age. All participants were informed of their right to withdraw from this study at any time. Participants were pseudonymized for privacy considerations.

Data Collection

In total, 4 semistructured interview guides were developed targeting the hospitalized children, ambassadors, teachers, and this study's nurses (Multimedia Appendix 1). These guides were designed to elicit participants' descriptions of online ambassador visits (including facilitators and barriers) and used open-ended questions to encourage reflection on their experiences [27]. The semistructured interviews were held from January to April 2022. Interviews were conducted by the first author (NNB), who introduced herself and this study's aim before starting each interview. NNB has experience in performing qualitative interviews as well as in interviewing children across age groups. Some of the younger children (n=4) preferred being interviewed with their parents present for emotional support. No parent contributed to the interviews. Most interviews (37/39, 95%) were conducted using Microsoft Teams or Google Meet, while 1 hospitalized child and 1 ambassador preferred being interviewed at home. All interviews were audio recorded and varied in duration from 8 to 55 (mean 15.6, SD 10.7) minutes.

Data Analysis

Interviews were transcribed verbatim by a student assistant using a transcription guide to ensure consistency. A Danish and English medical writer ensured that all descriptions were captured and interpreted correctly in English. A deductive analysis inspired by Braun and Clarke's [30] approach to Thematic Analysis was used. The data were organized and coded using NVivo coding software. Due to our qualitative descriptive research design, we aimed to stay as close as possible to the participants' descriptions of their experiences with online visits during the analysis process. CFIR was applied in the analysis as an interpretation tool to gain an in-depth understanding of facilitators and barriers to implementing online ambassador visits in a hospital setting. The analysis used the following steps: (1) the transcripts were read repeatedly until author NNB gained an in-depth understanding of the participants' descriptions of the online classmate visits; (2) author NNB coded the participants' descriptions into the CFIR domains; (3) authors NNB, MW, and HBL assigned the CFIR domains into overarching themes; (4) the themes were discussed and reviewed within the author group to ensure that the participant descriptions were rightfully captured within the CFIR domains and themes; and (5) themes were finalized after thorough discussion and agreement. All authors agreed on the final themes, and disagreements were discussed and resolved within the author group.

Results

Overview

We identified the following four themes from the participants' descriptions of the online ambassador visits: (1) working together, (2) ensuring participation, (3) staying connected, and (4) together online. The themes included facilitators and barriers to online ambassador visits within 3 CFIR domains: innovation, individuals, and the implementation process.

Working Together

Collaboration between the hospital and the school was an essential element when planning and facilitating online ambassador visits and included sharing information about the well-being and frame of mind of the children and technical support. Collaboration between the hospital and schools exemplifies the CFIR construct of "teaming" within the implementation process. This study's nurses experienced collaboration with teachers as demanding when the teachers were not keen to secure online visits. These experiences were often linked to technical problems faced by the teachers or to their limited time.

> *Having the resources can be challenging for the teachers. They often say no thanks to the online visits because they do not have the resources. The teachers want to participate, but the practicality [of it] can be problem[atic]* [Study nurse]

Time constraints and technical issues led some teachers to disregard online visits. They were also seen as barriers that negatively impacted collaboration. The hospitalized children and their ambassadors never mentioned collaboration between the hospital and the school. Rather, the hospitalized children explained that they had a close relationship with this study's nurses, which increased their willingness to participate in online visits. Collaboration between the hospitalized children and this study's nurses was seen as a facilitator for ensuring participation in the online visits and also fit into the CFIR construct of "teaming" within the implementation process.

> *Most times, it is me who gets to decide what activities we do, but the nurse is the one who knows about my overall plan with school and my treatment during the day. I think it is nice [that] the nurse helps me because sometimes I don't know what I want to talk about.* [Hospitalized child aged 12 years]

This study's nurses elaborated that they depended on the hospitalized children's collaboration to ensure that online visits occurred as intended, for example, ensuring social interaction. Collaboration between this study's nurses and the hospitalized children exemplifies the CFIR construct of "planning" within the implementation process. When planning online visits, this study's nurses identified their roles and responsibilities and defined the goals for success in collaboration with the hospitalized children.

Ensuring Participation

Online ambassador visits required some level of adaptability to ensure the participation of the hospitalized children and their ambassadors. The teachers explained that schools used different online apps, such as Microsoft Teams and Google Meet, designed for emergency teaching during the COVID-19 pandemic. This study's nurses adapted the setting of the online visits to fit each school's preferred apps.

The CFIR construct "adaptability" within the innovation domain refers to how the intervention can be modified and tailored to fit into the inner settings [31]. In this study, the inner settings are the hospitals and schools where online visits are implemented. Using the schools' preferred apps, this study's nurses ensured that the teachers did not have to learn new technologies and had easy access to online visits. Thus, adapting to the setting was seen as a facilitator for online visits. This study's nurses explained that they also adapted the content of online visits to ensure participation by the hospitalized children and their ambassadors.

> *…an unfocused, younger [or] sick child not feeling up to it or experiencing mood swings… that's when communication breaks down and [when] online visits become boring … that's when I terminate the [online ambassador] visit.* [Study nurse]

Adaptability of the content of online visits also included changing the duration of the visit to accommodate the hospitalized child's preferences and daily well-being. Adapting the content was described as a facilitator for the online visits. This study's nurses' decision regarding the duration of online visits was based on a "quality over quantity" value assessment. The children expressed that the timeframe for online visits was acceptable and that having a shorter timeframe did not impact their feelings of social connectedness.

This study's nurses explained that they often participated actively during online visits if the hospitalized child desired their participation. The older children preferred to be alone with their ambassadors, whereas the younger children preferred the study's nurses to take part in games or conversations.

> *I liked the privacy with my ambassadors during the [online] visits. I said to the nurse I wanted to be alone with my ambassadors so she started [Microsoft] Teams for me and then left. She [the nurse] came back when it was time to finish the visit.* [Hospitalized adolescent aged 14 years]

By assessing the needs of the intervention recipients, that is, the hospitalized children, this study's nurses ensured that online visits met their needs, which CFIR underscores as important when implementing an intervention [31]. The younger hospitalized children experienced that this study's nurses' participation, including offering games or conversation topics, helped them feel socially connected to their ambassadors. This resulted in the hospitalized children being more interested in repeating the experience; hence, the participating role of this study's nurse was seen as a facilitator of online visits.

> *…During the online visit, the two ambassadors started to play because they were physically together. I think they forgot [about] the hospitalized child. I tried to redirect their attention back to their ambassador visit, but I had to devise a game to keep them focused.* [Study nurse]

This study's nurses described the younger children as having problems sitting still or staying focused for long periods of time. If a study nurse was unsuccessful in redirecting the children's attention back to the visit, the visit would be terminated to ensure that any future online visits were perceived as positive experiences.

Staying Connected

The hospitalized children explained that they were happy to see their ambassadors during online visits, as they often felt isolated from their school and social activities. The ambassadors also felt isolated from their school class due to the COVID-19 pandemic lockdown. As such, online visits provided an opportunity for both groups to sustain social interactions.

> *I got an insight into what was happening at school; how everyone was doing, and stuff like that. Knowing all of that helped me [during my hospitalization].* [Hospitalized child aged 16 years]

The hospitalized children described receiving information from their ambassadors, for example, about new classmates, new teachers, or the latest gossip, provided them with a sense of social connectedness.

Likewise, some ambassadors expressed how they experienced a sense of social connectedness with the hospitalized child, as the visits provided the ambassador with news about the hospitalized child's life in the hospital. Understanding how the hospitalized children and their ambassadors experience connectedness during hospitalization is an example of the CFIR construct of "reflecting and evaluating" within the implementation process (ie, how successful the intervention is based on both qualitative and quantitative data) [31]. The ambassadors took great pride in their role and described it as being "information providers," as such, the link between the hospital and the school, and as "supportive peers." The most common task of the ambassadors was to share news from school.

> *She [the child with cancer] was happy that I told her [about what was going on in school]. She cheered up because I told her funny things like [the fact that] we got a new student in our class. She thought that was interesting.* [Ambassador aged 11 years]

This quote exemplifies how the ambassadors are happy to provide a sense of connectedness and social interaction as they perceive the hospitalized children's feedback on sharing information from the school as positive. According to the CFIR construct "innovation delivers" within the implementation process domain, locating and understanding priorities from the innovation delivers is vital when implementing an intervention [31]. As innovation deliverers, the ambassadors' motivation to participate in online visits stemmed from their desire to support the hospitalized child. The ambassadors also enjoyed receiving information about the everyday activities of the hospitalized children, reinforcing their feelings of social connectedness with the hospitalized children. However, the hospitalized children preferred receiving news and information from their ambassadors. Some of the teachers explained that choosing the right ambassadors to participate in online visits could enhance the social interaction experience.

> *Participating in online visits and socially interacting with each other can be difficult if they [the hospitalized child and their ambassadors] do not know each other. I think having [that] friendship before participating is important.* [Teacher 2]

If the hospitalized children and their ambassadors did not have preexisting relationships and had nothing in common to talk about, then social interaction would require more intervention by this study's nurse. As such, ambassador selection can be seen as an important facilitator of social connectedness during hospitalization.

Together Online

According to the construct "assessing context" within the implementation process, facilitators and barriers to implementing or delivering the intervention must be identified and assessed [31]. The hospitalized children and their ambassadors found the online ambassador visits favorable as they provided the opportunity to connect socially during hospitalization and the pandemic lockdown. However, both groups expressed that online visits could not replace in-person social interactions, including touching, playing physically together, or watching a movie together.

> *Being on Microsoft Teams is okay but not what I like. When you're together in person, you can do a lot of things like run around.* [Hospitalized child aged 9 years]

Despite having no experience with in-person ambassador visits, the children still expressed that they preferred in-person visits to online ones and that online visits were more favorable than no visits at all. This study's nurses described the online setting as a potential barrier to the children's social interaction, as communicating face-to-face online was intense for most of the children, resulting in the children being shy and not knowing what to talk about. Likewise, the ambassadors expressed that being limited to talking was boring as they would have preferred to do physical activities together with the hospitalized child.

> *I would have liked to visit her [the hospitalized child] in the hospital. It was a bit boring online because all we did was talk. If we had been together in the*

> *hospital, we could walk around or sit together* [Ambassador aged 11 years]

Some of the hospitalized children mentioned that their treatment-related physical changes made them conscious of their appearance during the online visits, and the setting amplified their consciousness about their altered appearance. Consequently, the hospitalized children participated in online visits without using the camera. Their ambassadors stated that they did not feel as socially connected without being able to see the hospitalized child on the screen. The hospitalized children explained that being together with their ambassadors was more important to them than their altered appearance, so much so that, in some cases, they felt relaxed enough to participate online using the camera. The teachers also described the online setting as a potential barrier for ambassadors to understand the hospitalized children's circumstances, including the severity of their disease or its treatment.

> *I think online visits can be difficult for the ambassadors because the setting is [similar to] watching a movie. Understanding the hospitalized child's treatment through a movie [lens] can be difficult.* [Teacher]

Another potential barrier often seen in the setting of online visits is having a poor internet connection. This study's nurses and teachers described how the hospital and school internet connections could fluctuate in terms of quality and negatively impact the integrity of the visits.

> *Sometimes, we canceled the online ambassador visits because of poor internet [connection]. That was a bit annoying because I had looked forward to seeing him [the hospitalized child]* [Ambassador aged 13 years]

Having a poor internet connection caused some ambassadors to feel discouraged that they could not keep their promise of social connectedness to the hospitalized children. Consequently, the hospitalized children and their ambassadors were not eager to participate in online visits when the internet was not fully functional.

Discussion

Overview

This qualitative process evaluation study aimed to identify facilitators and barriers to online ambassador visits during the hospitalization of children with cancer. Using qualitative descriptive research and CFIR, we gained an understanding of the online visit, including possibilities and difficulties faced by the hospitalized children, their ambassadors, schoolteachers, and study nurses. We found that the dominant facilitator was located within the construct of "teaming" in the implementation process domain, as the online visits required a high level of collaboration and adult facilitation. The main barrier was found within the "assessing context" construct in the implementation process domain, as the internet connection was considered a major barrier for online visits. Finally, further consideration should be given to the fact that, to date, online visits cannot provide the same level of social connectedness between children as physical visits.

In this study, close collaboration between this study's nurses and the teachers and close collaboration between this study's nurses and hospitalized children were seen as pivotal facilitators of online visits. However, strategies regarding implementation and collaboration are needed to specify the involvement of the various players associated with the intervention. CFIR suggests careful consideration of the individual's capability (interpersonal competence, knowledge, and skills to fulfill their role) and their motivation for fulfilling their role when implementing an intervention [31]. Based on our findings, we suggest that assessing the individuals' capability can potentially strengthen collaboration, as we found that identifying and outlining the roles of the individuals delivering the intervention and collaboration between this study's nurses and the hospitalized children formed the basis for successful integration of the online visits and led to strengthening feelings of social connectedness. Other studies suggest involving stakeholders, for example, health care professionals, teachers, and children, is vital to successful implementation [32-34]. However, based on our findings, strategies or guidelines on how to ensure collaboration when involving different stakeholders such as study nurses, teachers, hospitalized children, and ambassadors should be considered as we found that the collaboration between this study's nurses and teachers was not without challenges.

Another finding was that the hospitalized children had individual needs and preferences for the content of the online visits and the study's nurses' participation. Likewise, previous research suggests that pediatric interventions are not one-size-fits-all, and to ensure participation and involvement, there must be an element of individualization, that is, accommodating an individual's needs and preferences [35-37]. Our findings suggest that, depending on age, children interacted differently. Young-aged children were especially impacted, which was considered a potential barrier to online visits. Younger children needed more facilitation, and as such, this required more time commitment from this study's nurses. Interestingly, a study from 2013 reported similar findings, which included that time commitments were a barrier to their nurse-led videoconferencing intervention [38]. Considering that our study finding is similar to the study from 10 years ago, further research on how to accommodate time commitment issues should be actively pursued. We argue that setting achievable goals for each online visit should be required and that these goals should be discussed with all participating children. Regardless, research on actively involving intervention recipients in designing and adapting interventions for children is needed. When offering pediatric interventions, the adaptability of the intervention also requires consideration. In our study, both the setting and the content of the online visits were adaptable. This ensured participation and supported a feeling of being socially connected during the COVID-19 pandemic.

This study shows that online visits can lead to social connectedness between hospitalized children and their ambassadors. A central finding is that receiving new information during the visits supported the hospitalized children's feelings of social connectedness. Similarly, Pennant et al [39] found that hospitalized children and young adults benefited from social support during treatment, as social support was associated with feelings of “not being alone” and better coping strategies [40]. Our findings suggest that knowledge about each other and the children’s pre-existing relationships facilitated social interaction. Therefore, exploring the children’s motivation for participating in online visits could enhance feelings of social connectedness, limit the need for adult supervision, and thus reduce time consumption by this study’s nurses.

Lastly, it is important to note that this study’s nurses and teachers considered the online setting a barrier to social interaction. In contrast, the children proclaimed that the online setting presented an opportunity to interact socially and gave them a sense of connectedness. These findings align with previous research showing that videoconferencing technologies can strengthen friendships and relationships with peers and provide a sense of social presence for children with chronic diseases [24,38]. Although the online setting provided an opportunity to interact socially, our findings showed that the children preferred in-person visits to online visits as the online visits were perceived as boring in some situations. However, the online visits were better than no visits at all. Therefore, we suggest online visits may be a good option for hospitalized children in the absence of an in-person option but that in-person visits remain preferable. Furthermore, our findings show that a good internet connection is indispensable when offering online visits as a poor internet connection can impact the children’s motivation to participate and ultimately lead to negative views about social interaction online. Likewise, Weibel et al [24] found that poor internet connection and audio capabilities limited the children’s use of telepresence robots. Johannessen et al [41] also argued that having a poor internet connection is problematic for online dialogue. This is supported by previous research showing that poor internet quality is the primary source of technological difficulties when using online formats [42-44]. Although these studies report that poor internet connection is problematic for online social interaction or web-based interventions, none of the studies provide any solutions.

Limitations

Most (9/16, 56%) of the hospitalized children involved in this study were diagnosed with leukemia, and the remaining 7 (44%) children were diagnosed with other cancers or cancer-like diseases. Thus, further work is needed to explore whether this study’s findings are transferable to children with other diagnoses. Furthermore, only 3 (9%) of the 34 eligible teachers wanted to participate in this study, which limited variety in the description of online ambassador visits.

A central limitation of this study was that CFIR was not formally applied when developing the interview guides but only during data analysis. Consequently, we did not address constructs from the outer setting and inner setting domains. Hence, some key elements require further consideration. The online ambassador visits were part of an existing study offering in-person ambassador visits during hospitalization. This study has been ongoing since 2013, with several guidelines for in-person ambassador visits. Furthermore, this study’s nurses connected to this study were familiar with organizing and facilitating in-person ambassador visits, which may have impacted their readiness for change when the COVID-19 pandemic resulted in physical isolation across Denmark. Another example is how schools in Denmark changed from an in-person classroom teaching format to an online context during the COVID-19 pandemic. This impacted how the participants adapted to the online ambassador visits [45]. The schools’ readiness for change may also have impacted how the participants adapted to the online ambassador visits. Previous results from the RESPECT study show that children with cancer and their classmates are motivated to participate in in-person classmate visits [17,18,29]. Thus, we believe that the combination of an already existing organizational structure derived from our experiences with in-person ambassador visits and our knowledge of the classmates’ motivation to participate in in-person ambassador visits has enhanced this study’s nurses’ flexibility to adapt from the in-person to the online context. Therefore, we are unsure if implementing online ambassador visits in other settings may differ from ours.

Future Perspective

Emerging research highlights the importance of staying socially connected with peers and classmates during cancer treatment [37,39,46] and that there is a need for interventions that specifically target the relationship between children with cancer and their classmates [11,47,48]. Our study findings suggest that online visits with classmates or ambassadors can meet the hospitalized child’s need for social connectedness, albeit in-person visits are preferable for some children. Accordingly, online ambassador visits may prove valuable when in-person visits are not an option due to long distances and hospital isolation. However, the same finding also warns of the need to be aware of the children’s ages and individual preferences. Thus, it is advisable to assess and address the needs of the participating children, including the differences in needs across ages and individual preferences. While poor internet connection can negatively impact online social interaction, knowledge about how to accommodate internet consistency is limited. Future web-based interventions should consider establishing an appropriate internet connection to ensure participation. Based on our findings, we suggest that health care professionals offering online visits to hospitalized children align their expectations with those of the participating children regarding the purpose and context of the visits. This study’s findings may be transferable to other pediatric settings as knowledge about online visits and their facilitation during hospitalization can be applied across disease groups and cultures. However, research is needed to understand how to implement online visits in other contexts.

Conclusions

Hospitalized children and their ambassadors benefited from participating in the online ambassador visits as these visits contributed to enhanced social connectedness. This study’s findings showed that online social interaction between hospitalized children and their ambassadors is possible but requires being attentive to the individual needs of the hospitalized children and continuous collaboration between the hospital and school regarding organizing and facilitating. The online visits were pivotally reliant on sound internet connections. Including classmates during treatment should not be underestimated when addressing the social needs of hospitalized children. Future online psychosocial interventions can advantageously consider the collaboration between involved participations, sensitivity regarding individual preferences, and creating a stable internet connection when offering online visits during hospitalization.

Acknowledgments

Gratitude is extended to the study nurses associated with the RESPECT (Rehabilitation Including Social and Physical Activity and Education in Children and Teenagers With Cancer) study, who were instrumental in helping the hospitalized children during the COVID-19 pandemic. This study's nurses continue tirelessly to provide social and emotional support to hospitalized children and their families participating in the RESPECT study. We are also grateful to the hospitalized children, their classmates, and teachers for participating in this study and sharing their experiences with online ambassador visits during the COVID-19 pandemic. This work is part of the Childhood Oncology Network Targeting Research, Organization & Life Expectancy (CONTROL) and the Danish Childhood Cancer Foundation (2019-5934).

Authors' Contributions

HBL designed and implemented the RESPECT (Rehabilitation Including Social and Physical Activity and Education in Children and Teenagers With Cancer) intervention study. HBL and VS implemented the RESPECT implementation study. NNB created this study's design, recruited participants, conducted data collection and analysis, and prepared this paper. HBL and MW contributed to the analysis as well. CEW, PEB, MO, KBN, VS, and MKF all contributed to the preparation of this paper. All authors revised this paper critically to ensure intellectual content and approved the final version of this paper.

Conflicts of Interest

None declared.

Abstract

Background: Young people and families endure protracted waits for specialist mental health support in the United Kingdom. Staff shortages and limited resources have led many organizations to develop digital platforms to improve access to support. myHealthE is a digital platform used by families referred to Child and Adolescent Mental Health Services in South London. It was initially designed to improve the collection of routine outcome measures and subsequently the "virtual waiting room" module was added, which includes information about child and adolescent mental health as well as signposting to supportive services. However, little is known about the acceptability or use of digital resources, such as myHealthE, or about sociodemographic inequalities affecting access to these resources.

Objective: This study aimed to assess the usability and acceptability of myHealthE as well as investigating whether any digital divides existed among its userbase in terms of sociodemographic characteristics.

Methods: A survey was sent to all myHealthE users (N=7337) in May 2023. Caregivers were asked about their usage of myHealthE, their levels of comfort with technology and the internet. They completed the System Usability Scale and gave open-ended feedback on their experiences of using myHealthE.

Results: A total of 680 caregivers responded, of whom 45% (n=306) were from a Black, Asian, or a minority ethnic background. Most (n=666, 98%) used a mobile phone to access myHealthE, and many had not accessed the platform's full functionality, including the new "virtual waiting room" module. Household income was a significant predictor of caregivers' levels of comfort using technology; caregivers were 13% more likely to be comfortable using technology with each increasing income bracket (adjusted odds ratio 1.13, 95% CI 1.00 - 1.29). Themes generated from caregivers' feedback highlight strengths of digital innovation as well as ideas for improvement, such as making digital platforms more personalized and tailored toward an individual's needs.

Conclusions: Technology can bring many benefits to health care; however, sole reliance on technology may result in many individuals being excluded. To enhance engagement, clinical services must ensure that digital platforms are mobile friendly, personalized, that users are alerted and directed to their full functionality, and that efforts are made to bridge digital divides. Enhancing dissemination practices and improving accessibility to informative resources on the internet is critical to provide fair access to all using Child and Adolescent Mental Health Services.

Introduction

Overview

In the United Kingdom, Child and Adolescent Mental Health Services (CAMHS) offer support for mental health difficulties among individuals under the age of 18 years. In April 2023, around 700,000 children and young people in England accessed mental health services [1]. Young people who are referred to CAMHS have to wait over 12 weeks before receiving treatment [2]. This can be a risky period for young people, with some experiencing deterioration in their mental health while awaiting treatment [3]. It can also lead to fragmented service delivery, since caregivers often contact other children's mental health agencies while waiting [4]. In addition, the longer a young person spends waiting, the more likely they are to miss their first appointment [5], and the less likely they are to engage in treatment [6], and these missed appointments further increase wait times [7].

As well as reducing waiting times, it is crucial to think about what CAMHS can provide to young people and their parents or carers while they are waiting for assessment or treatment. There is an increasing amount of attention on the potential for digital innovation in mental health services, which can entail delivering therapy and accessing resources via the internet. CAMHS settings are also increasingly considering how digital innovation can support caregivers' involvement [8]. However, it is essential to consider digital exclusion when discussing and designing digital innovations. Digital exclusion can occur when individuals are not able to access digital services; for example, they may not own a smartphone or computer [9], or lack interest in using technology [9]. More vulnerable groups are also more likely to be affected by digital exclusion, such as those who are older, unemployed, and more socially isolated [10].

Digital innovation can include internet-based portals that inform and engage service users [11]. The myHealthE platform was launched in 2021, as a digital solution to assist collection of caregiver-completed routine outcome measures for young people accessing CAMHS in South London [12]. In England, the National Health Service Outcomes Framework policy [13] recommend the use of routine outcome measures to assess the impact of their interventions in CAMHS [14]. myHealthE facilitates the collection of routine outcome measures from the point of referral, providing clinicians, caregivers and parents a useful way of assessing young people's current mental health symptoms as well as tracking progress over time [12]. Since myHealthE's staggered implementation in 2021, over 10,000 caregivers whose young people were referred to South London and Maudsley National Health Service Foundation Trust (SLaM) CAMHS have registered with the myHealthE platform.

In 2022, an extensive public user engagement campaign led by the South London Listens program highlighted the urgent need to provide a better pathway to access information for caregivers and young people while waiting for a CAMHS assessment. A recommendation from the campaign to create a "virtual waiting room" was taken forward by SLaM. After rapid consultation with senior managers, clinicians, and caregivers, a "minimal viable product" online module was developed. This new "virtual waiting room" module hosted new resources and signposting information selected by local CAMHS clinicians, which included, for example, a welcome video explaining the service, psychoeducation videos about low mood and anxiety, as well as external links to UK mental health charities like Mind. This new module was successfully integrated into the myHealthE platform in January 2023 [15]. Enrolled caregivers were then contacted twice (2 weeks apart) in January and February 2023, via personalized email messages to make them aware of the recent updates. Before this update, caregivers reported in a previous small-scale evaluation that myHealthE was generally easy-to-use [12]. No larger scale investigation of its accessibility has since been conducted.

The aim of this study was, first, to conduct a large-scale baseline assessment of the usability and acceptability of the myHealthE platform as well as of its new "virtual waiting room" module. This study also aimed to investigate whether differences in sociodemographic characteristics reveal any digital divides among the caregivers who use myHealthE.

Research Questions

1. How often, using which devices, and for what purposes are caregivers accessing the myHealthE platform?
2. Are sociodemographic characteristics (ie, age, ethnicity, marital status, and household income) associated with a digital divide, namely, (1) levels of comfort with the internet and technology and (2) perceived usability of the myHealthE platform?
3. How has the myHealthE platform and the inclusion of a virtual waiting room module been received by caregivers?

Methods

Ethical Considerations

This project was given approval by SLaM CAMHS Audit and Service Evaluation Committee on April 13, 2023 (Project #236). The project involved a voluntary survey sent to current the current userbase of myHealthE. Participation was anonymous since caregivers did not provide their names on completion and there was no way to link data in order to identify participants. No compensation was provided.

Participants and Procedures

On May 5, 2023, a text message was sent to all caregivers registered with the myHealthE site containing a link to the online voluntary survey hosted on Qualtrics. The survey was kept open for 6 weeks. There were a total of 29 questions on the survey, displayed on 6 pages. The participants were able to go back and change their answers. The participants saw a bar at the top of the screen indicating their progress through the survey. No incentives for completion were offered. IP addresses were checked to ensure there were no identical addresses.

Measures

Sociodemographic Characteristics

The participants were asked their age range, gender, ethnicity, marital status, and household income.

Access of and Attitudes Toward myHealthE

To answer Research Question 1, participants were asked what kinds of digital devices they own and they were asked a single choice question on how frequently they access the myHealthE site, and a multiple choice question on what their reasons were for doing so. They were asked when they first signed up to myHealthE to determine whether they had seen myHealthE before its "virtual waiting room" update in January 2023. For the participants that had signed up to myHealthE before 2023, they were asked if they noticed a change, and then whether they felt the update had improved the myHealthE platform. All participants were asked how helpful and how easy they found it to access the myHealthE resources. The participants were also asked 2 open-ended questions: (1) “Can you give any recent examples of a positive experience of using myHealthE?” and (2) “Do you have any ideas on ways it can be improved?”

The participants were then asked two questions rated on 5-point Likert scales from “very comfortable” to “very uncomfortable”: (1) How comfortable do you feel using technology? and (2) How comfortable are you with accessing the internet? The data for levels of comfort with (1) the internet and (2) technology were polarized rather than normally distributed, and therefore a binary variable was created by grouping the participants who answered “very comfortable” and “slightly comfortable” into one variable and the ones who answered “very uncomfortable” and “slightly uncomfortable” into one variable. Those who answered “neither uncomfortable nor comfortable” were excluded from the analysis.

The System Usability Scale (SUS) was used to measure participants’ views on the usability of the myHealthE platform [16]. It contains 10 items rated on a Likert scale from “Strongly disagree” to “Strongly agree.” It has been shown to have good reliability and face validity [17]. A total of 5 items are phrased in agreement (eg, “I thought the system was easy to use”) and five are phrased in disagreement (eg, “I thought there was too much inconsistency in this system”). The word “system” was replaced with “myHealthE” for this study. Half of the items were reverse-coded so that a higher response indicated a more positive view of the usability of the myHealthE platform. The responses to the items from the SUS questionnaire were converted numerically so the responses to each item ranged from 0 to 4. Then scores were summed and multiplied by 2.5 so that total scores ranged from 0 to 100.

Analysis

Quantitative Data

We conducted statistical analyses to investigate the association between sociodemographic characteristics, levels of comfort with the internet and technology, and perceived usability of myHealthE (Research Question 2).

To examine these digital divides, we conducted a multiple linear regression, with SUS scores as the outcome variable and sociodemographic characteristics of age, gender, ethnicity, marital status, and household income as predictor variables. Gender, ethnicity, and marital status were treated as categorical variables, while age and household income were treated as ordinal variables. Those who were widowed were removed from the marital status variable due to small cell counts (n=3). Similarly, multiple logistic regression models were conducted with levels of comfort with (1) the internet and (2) technology as outcome variables, and the same sociodemographic characteristics as predictor variables. Threshold for statistical significance was set at .05. Complete case analysis was used.

Qualitative Data

The qualitative feedback was analyzed using reflexive thematic analysis [18] to answer Research Question 3. Feedback to both open-ended questions was merged and read through twice and then coded to capture the smallest meaningful unit of information. Then codes were grouped conceptually to create initial themes. These initial themes were compared to the original data and redefined and redeveloped until a final set of themes and subthemes were generated and discussed within the research team. This set of themes and subthemes captured how the authors interpreted participants’ feedback to the two questions, with a focus on both participants’ experience with the myHealthE platform as well as digitalization in general.

Results

The survey was sent out to 7337 users of myHealthE, and a total of 680 individuals responded, giving a 9.27% response rate.

Demographics

There was a total of 680 participants, of whom 552 (81.2%) completed the survey and 128 (18.8%) provided partial data. The majority of respondents were female, and most were aged in their 30s or 40s. The participants were ethnically diverse: White British was the majority ethnic group (341/644, 53%) followed by Black British or Black African or Caribbean (126/644, 19.6%). The most common marital status was single (274/630, 43.5%; Table 1).

Table . Sociodemographic characteristics.

Characteristics[a]		Participants, n (%)
Gender (n=675)		
	Women	644 (95.4)
	Men	31 (4.6)
Age (years) (n=664)		
	25 and younger	17 (2.6)
	26 - 30	34 (5.1)
	31 - 35	107 (16.1)
	36 - 40	125 (18.8)
	41 - 45	168 (25.3)
	46 - 50	119 (17.9)
	51 - 55	70 (10.5)
	56 - 60	24 (3.6)
Ethnicity (n=644)		
	White British	341 (53)
	Black British or Black African or Caribbean	126 (19.6)
	Any other White background	77 (12)
	Mixed or multiple ethnic groups	56 (8.7)
	Asian or Asian British	27 (4.1)
	Other ethnic group	17 (2.6)
Marital status (n=630)		
	Single	274 (43.5)
	Married or civil partnership	254 (40.3)
	Divorced or dissolved civil partnership	59 (9.4)
	Separated	40 (6.3)
	Widowed	3 (0.5)
Household income (n=519) [b]		
	Below £10,000	128 (24.7)
	£10,001-£20,000	124 (23.9)
	£20,001-£30,000	81 (15.6)
	£30,001-£40,000	48 (9.2)
	£40,001-£50,000	31 (6)
	£50,001-£60,000	31 (6)
	Above £60,000	76 (14.6)

[a] Data were missing for gender (5/680, 0.7%), age (16/680, 2.4%), ethnicity (36/680, 5.3%), marital status (50/680, 7.4%), and household income (161/680, 23.7%).

[b] Conversion rate: British £1=US $1.26732.

myHealthE Access and Usage

The participants were asked what type of internet-enabled devices they owned (Table 2). Over 98% (647/659) owned a smartphone, and 53.4% (352/659) exclusively owned a phone. One percent (8/640) stated they did not own any internet-enabled device. Table 2 describes the frequency of access and reasons for using myHealthE. The majority of participants used myHealthE less than once a month, and a third used myHealthE once a month. Most (528/640, 82.5%) only used myHealthE for one purpose, with the main reason cited as completing outcome measures (575/640, 89.8%).

Table . myHealthE access and usage.

myHealthE access and usage		Responses, n (%)
Type of device (n=659) [a]		
	iPhone	396 (60.1)
	Android phone	274 (41.6)
	Laptop	239 (36.3)
	iPad or tablet	168 (25.5)
	PC	65 (9.9)
	I don’t own any devices	8 (1.2)
Number of devices owned (n=651)		
	1	353 (54.2)
	2	148 (22.7)
	3	112 (17.2)
	4	33 (5.1)
	5	5 (0.8)
Frequency of myHealthE usage (n=640)		
	Less than once a month	367 (57.3)
	Once a month	230 (35.9)
	Once a week	37 (5.8)
	Multiple times a week	6 (0.9)
Number of reasons for using myHealthE (n=640)		
	1	528 (82.5)
	2	70 (10.9)
	3	28 (4.4)
	4	14 (2.2)
Reasons for using myHealthE (n=640)		
	Completing questionnaires	575 (89.8)
	Looking at information about CAMHS	109 (17)
	Looking at resources on myHealthE	54 (8.4)
	Looking at other organizations	40 (6.3)
	Other reason	41 (6.4)

[a] Participants could select multiple options in response to type of device and reasons for using myHealthE. Data were missing for type of device (21/680, 3.1%), number of devices (29/680, 4.3%), frequency of myHealthE usage (40/680, 5.9%), and reasons for using myHealthE (40/680, 5.9%).

The myHealthE “Virtual Waiting Room” Module

Very few of the 585 participants who had been registered with the myHealthE site before the update had noticed the “virtual waiting room” update (62/537, 11.5%), and many were not sure whether myHealthE had improved following the update (Table 3). Excluding the “not sure” response option, more participants thought that the update had improved myHealthE than made it worse. Everyone was asked whether they found the new resources helpful and whether they found the resources on the “virtual waiting room” module easy to access. Slightly more participants stated they found the resources more helpful than unhelpful. However, many participants subsequently indicated that had been unaware of the new “virtual waiting room” module resources.

Table . myHealthE “virtual waiting room” update.

Questions on myHealth update[a]		Responses, n (%)
Which year did you first use myHealthE? (n=637)		
	2021	115 (18.1)
	2022	205 (32.2)
	2023	95 (14.9)
	I don’t know	222 (34.9)
Did you notice the update to the myHealthE site? (n=537)		
	Yes	62 (11.5)
	Not sure	253 (47.1)
	No	222 (41.3)
Do you feel the new update improved the myHealthE site? (n=277)		
	Much improved	37 (13.4)
	Somewhat improved	51 (18.4)
	Neither improved nor worsened	37 (13.4)
	Somewhat made worse	2 (0.7)
	Made much worse	2 (0.7)
	Not sure	148 (53.4)
Do you find the resources on myHealthE helpful? (n=601)		
	Very helpful	22 (3.7)
	Somewhat helpful	165 (27.5)
	Neither helpful nor unhelpful	275 (45.8)
	Somewhat unhelpful	35 (5.8)
	Very unhelpful	104 (17.3)
Do you find the resources on myHealthE easy to access? (n=601)		
	Very easy	90 (15)
	Slightly easy	64 (10.6)
	Neither easy nor difficult	142 (23.6)
	Slightly difficult	13 (2.2)
	Very difficult	6 (1)
	I did not know about these resources	286 (47.6)

[a] All participants (n=680) were presented with the question "Which year did you first use myHealthE?" Only those who answered “2021,” “2022“ or “I don't know” were presented with the question "Did you notice the update to the myHealthE site?" (n=585). Only those who answered “yes“ or “not sure” were presented with the question "Do you feel the new update improved the myHealthE site?" (n=315). Data were missing for ”Which year did you first use myHealthE?” (43/680, 6.3%), ”Did you notice the update to the myHealthE site?” (48/585, 8.2%), ”Do you feel the new update improved the myHealthE site?” (38/315, 12.1%), ”Do you find the resources on myHealthE helpful?” (79/680, 11.6%), and ”Do you find the resources on myHealthE easy to access?” (79/680, 11.6%).

Digital Divides

Levels of Comfort With Technology and the Internet

The participants were asked how comfortable they were with technology and with the internet in general. The majority of participants were slightly (130/659, 19.7%) or very comfortable (261/659, 39.6%) using technology and slightly (88/659, 13.4%) or very comfortable (337/659, 51.1%) using the internet, but around a quarter of participants were slightly (64/659, 9.7%) or very uncomfortable (132/659, 20%) using technology and slightly (39/659, 5.9%) or very uncomfortable (127/659, 19.3%) using the internet.

System Usability Scale

For 128 participants, at least one of their responses to the SUS was missing, so they were removed from analyses of SUS. The mean overall SUS score was 62.4 (SD 15.0) with the median score as 60 (IQR 50-72.5), meaning most participants found myHealthE neither easy nor difficult to use, with a slight skew toward participants finding it easy.

Examining the Association Between Sociodemographic Factors and Digital Divides

A multiple regression was run with SUS score as the outcome variable and age, gender, ethnicity, marital status, and household income as predictor variables. None of these sociodemographic characteristics were found to be statistically significantly associated with SUS score except those whose marital status was “separated” when compared with those who were “married.” (Table 4). However, a similar difference was not found for those who were “single” or “divorced.”’

Multiple logistic regressions were run with internet comfort and technology comfort as the outcome variables (uncomfortable vs comfortable) and age, gender, ethnicity, marital status, and household income as predictor variables (Table 5). Household income was a statistically significant predictor of how comfortable participants were with the internet and technology, with higher income being associated with higher levels of comfort. When compared with married participants, single and divorced participants were less likely to be comfortable with using technology; however, there was not a significant difference when modeling internet comfort.

Table . Multiple linear regression analysis between each sociodemographic characteristic (predictor) and System Usability Scale score (outcome), n=461.

Covariate and response category	Estimate (SE)	*P* value
Age	−0.74 (0.54)	.17
Gender		
Female	Ref[a]	Ref
Male	−6.76 (4.05)	.10
Ethnicity		
White British	Ref	Ref
Black British or Black African or Caribbean	−1.88 (2.07)	.36
Any other White background	1.67 (2.59)	.52
Mixed or multiple ethnic groups	2.51 (2.59)	.33
Asian or Asian British	−0.99 (4.01)	.81
Other ethnic group	−1.79 (4.66)	.70
Marital status		
Married	Ref	Ref
Single	−0.48 (1.93)	.80
Divorced	−1.52 (2.91)	.60
Separated	−6.52 (3.07)	.03
Household income	0.36 0.42)	.39

[a] Ref: reference.

Table . Multiple logistic regression analysis between sociodemographic characteristics (predictors) with (1) level of comfort with the internet (outcome; "uncomfortable" is the reference category), n=442 and (2) level of comfort with technology (outcome; "uncomfortable" is the reference category), n=444.

Covariate and response category	Levels of comfort with the internet			Levels of comfort with technology		
	Adjusted odds ratio (95% CI)	Standard error	*P* value	Adjusted odds ratio (95% CI)	Standard error	*P* value
Age	1.04 (0.89 - 1.21)	0.078	.63	1.05 (0.91 - 1.22)	0.075	.52
Gender						
Female	Ref[a]	Ref	Ref	Ref	Ref	Ref

[a] Ref: reference.

Understanding Attitudes Toward myHealthE

There were 142 responses to the question asking about positive experiences and 138 responded to the questions on ideas for improvement. The thematic analysis generated 3 themes and 8 subthemes (Table 6).

Table . Themes and subthemes.

Themes and subthemes	Illustrative quotations
Digitalization results in less personalization	
Digitalization reduces human contact	“A human should talk to me.” “I don’t know if anybody reads the information collected.”
The content isn’t personalized towards me and my child	“Make it personal. You have my details.” “Some questions are about my child’s behavior at school but he doesn’t attend school.”
Barriers to participation in a digital world	“Every time I check for updates to our case I have to reset my password.” “There should [be] good communication through the post!!!”
A platform with opportunities	
Room for improvement; introduce more functionality	“Add a medical record scroll down menu containing child’s all reports.” “…a way to communicate or leave a message that can’t be included in a questionnaire.”
Give us more information and support	“Update on local group meetings.” “Tools to assist parents or webinars for accessing tools and services”.
Lack of awareness; missed opportunities	“I wasn’t aware of these new resources mentioned in the questions above. So I recommend promoting those more.”
Digitalization brings insight and usability	
Data collation gives information and hope to caregivers	“Completing the questionnaires and seeing the results over time helps me understand my son’s progression.” “It always prompts me and updates me of progress, so I know I haven’t been lost in the system.”
MyHealthE has good usability	“Easy to fill questionnaire.” “Useful links to access support.”

Digitalization Results in Less Personalization

This theme captured how among all the benefits of digitalization, caregivers also were left with a lack of personal connection around their child’s journey with health services. This theme contained 3 subthemes.

Digitalization Reduces Human Contact

Respondents highlighted how they wanted themselves or their child to have contact with a real person. Caregivers felt that it was their right to be able to speak to someone about their child’s welfare: “A human should talk to me,” and some noted that the format of myHealthE made them feel “disconnected from [their children’s] care.” Caregivers wanted more to come from their completion of questionnaires like having “someone who contacts parents or carers after every test to discuss the results.” Caregivers seemingly struggled to see the direct benefit to their child from their completion of questionnaires, and feared that the information they were providing was not being used: “I don’t know if anybody reads the information collected.” Some caregivers were left with a negative emotional impact on themselves: “I don’t know why I bother filling it in as even though I see how in the red and in desperate need of help my son is, he does not get any help.”

The Content Isn’t Personalized Toward Me and My Child

Caregivers seemed to find that myHealthE felt generic and not tailored toward their or their child’s needs. Suggestions of personalization included using caregiver’s and children’s names and other details: “Make it personal. You have my details.” Caregivers felt they could not fully capture the difficulties that their child and their family had been experiencing in just one questionnaire: “Box ticking does not give a full picture of what is happening.” There was also a sense that some questionnaires were not appropriate in terms of age, disability, and school attendance: “my son is a teenager (16) and for me answering questions about sharing toys in school or playing with kids has no sense for me”; “Some questions are about my child’s behavior at school but he doesn’t attend school.”

Barriers to Participation in a Digital World

Respondents highlighted their difficulties with accessing the platform: “can never log in… so unsubscribed”; “can’t access the site”; “every time I check for updates to our case I have to reset my password” and with completing the questionnaires: “The forms weren’t fillable on my tech.” Caregivers also struggled to use some of the functionality on the platform: “unable to input my child’s new school.” One respondent also highlighted how digital information is not their preferred method of communication: “there should [be] good communication through the post!!!”

A Platform With Opportunities

This theme depicted how caregivers identified numerous ways in which myHealthE could be improved and it also seemed that the survey itself had highlighted potential benefits of the platform of which respondents were not previously aware. This theme contained 3 subthemes.

Room for Improvement; Introduce More Functionality

Respondents noted that the site had reduced functionality on mobile phones, and one respondent suggested an app: "I struggled to remember where to logon. I [wish] there was an app?" One caregiver also noted it would be valuable to be able to "share to print on android phone." Users also highlighted the benefits of integration of information from other platforms with myHealthE: "Booking a GP appointment through the app"; "add a medical record scroll down menu containing child's all reports."

Some respondents had ideas for how the information from routine outcome measures could be better used: "It would be nice if the information collected [could be] used towards building up reports for the assessment team to have a better understanding to that child." Caregivers asked for more information about the questionnaires: "state where and who the information from the questionnaires go to." Respondents also felt that they needed: "a way to communicate or leave a message that can't be included in a questionnaire."

Give Us More Information and Support

Caregivers wanted more "information on help is available"; one suggestion being information about what is available locally: "update on local group meetings." Caregivers seemingly wanted to know how they could help their child: "tools to assist parents or webinars for accessing tools and services."

Lack of Awareness; Missed Opportunities

For some respondents, the survey had alerted them to the existence of resources on the myHealthE site: "I wasn't aware of these new resources mentioned in the questions above. So I recommend promoting those more." A suggestion was made to "send parents/carers a link or text about it or even create a flyer."

Digitalization Brings Insight and Usability

This theme captured how users of myHealthE also noted its benefits. It contained 2 subthemes.

Data Collation Gives Information and Hope to Caregivers

Once caregivers on myHealthE complete a questionnaire, they can see their data summarized, as well as seeing any changes from their previous questionnaire. Respondents noted that they like the visualization: "it's interesting to see the questionnaire results overtime in a graph." Caregivers noted that they enjoyed how their child's scores had change: "at the end you see improvement or difficulties. It really picks up on how our home life is at the moment" and that viewing these data also helped them make insight into their child: "completing the questionnaires and seeing the results over time helps me understand my son's progression." The questionnaires also seemed to give caregivers hope: "It always prompts me and updates me of progress, so I know I haven't been lost in the system."

myHealthE Has Good Usability

There were also a number of strengths of the myHealthE platform that were noted by caregivers. Some respondents found it easy to use: "easy to fill questionnaire"; "logging in and answering questionnaires was easy." Caregivers also highlighted its helpfulness: "it helped me to get more info about how to get help for my child." Numerous examples of the myHealthE platform were also highlighted as positive: "very helpful and useful information; "useful links to access support"; "simple explanation of resources."

Discussion

Principal Findings

This study surveyed 680 caregivers of young people waiting for treatment in CAMHS to determine the acceptability and use of myHealthE, as well as investigating any digital divides. It found that the majority of caregivers were accessing myHealthE exclusively using a phone, and most accessed the platform less than once a month. Caregivers were not accessing the full functionality of the myHealthE platform, including its new "virtual waiting room" module. Caregivers gave recommendations on how myHealthE could be improved, including ensuring the site is personalized. This study also showed that household income is a significant predictor of digital divides.

How Often, Which Devices, and for What Purposes Are Caregivers Using myHealthE?

The majority of caregivers indicated that they were only using their phones to access the digital world. Therefore, platforms like myHealthE must ensure they have been designed with mobile use in mind to maximize their accessibility. Any current and future development of digital resources for CAMHS populations must focus on testing new platforms via this medium.

The participants did not use myHealthE particularly frequently, with the majority using it less than once a month. This is not surprising, however, since up until the "virtual waiting room" module was launched, the only use for the system was to complete outcome measures which caregivers were alerted to once every three months. Caregivers were alerted to the new "virtual waiting room" update by text message; however, this survey has demonstrated this was not sufficient, since many were not aware of the full functionality of the platform. This study has, therefore, highlighted the need for developers of digital platforms to establish users' baseline awareness of a platform's features. It gives motivation for continual improvement and an increase in dissemination of features on platforms like myHealthE to promote awareness of and engagement with digital resources.

Does a Digital Divide Exist Between the Caregivers Who Access myHealthE?

We did not find strong evidence for associations between sociodemographic characteristics and System Usability Scale scores. However, we found household income to be a predictor of comfort with the internet and technology, with higher income predicting greater levels of comfort. Household income is an indicator of social deprivation and vulnerability, a known source of digital divide [10]. It is important to note that we still found this to be a factor, even within a sample of individuals whose level of comfort with the internet and technology was sufficiently high to own a device and complete an online survey. There was also some evidence that individuals who were single or divorced were less comfortable with technology compared to married individuals.

It is important to note that this study investigated digital divides using an online survey, meaning it is possible that other sociodemographic characteristics would have been found to predict usability and comfort if a nondigital survey was used. For example, despite ethnicity not being found to be a significant predictor of responses to the SUS or levels of comfort with the internet or technology, it is a known factor in literature concerned with digital divides, and must continue to be addressed in the development of digital platforms [19]. In addition, other variables not measured by this study, such as education level, have been found to influence digital divides [20]. Future studies should continue to investigate digital divides using study designs with a range of data collection methods, and should consider investigating the interaction between sociodemographic variables such as household income and ethnicity.

How Has myHealthE and Its New "Virtual Waiting Room" Module Been Received by Caregivers?

Respondents' views on digitalization were polarized. Its pitfalls were made clear and there was a general sense of depersonalization. Caregivers felt that the platform was generic and not tailored toward their family. Positive aspects included the visualization of change in their child's score on outcome measures. Suggestions from caregivers included using their names and their young people's names in notifications. Customizability has also been named as a recommendation by participants in other studies of digital platforms [21]. Digital platforms in mental health settings could also improve their user experience by tailoring questionnaires and content to suit certain mental health presentations, neurodiversity, and different age ranges of children.

The System Usability Scale measured participants' views on the usability of myHealthE. The average score was 62.4, which represents "high marginal" acceptability [22] and is lower than the previous evaluation of myHealthE using SUS, which found that a sample of 8 participants rated it at 78 [12]. However, this study had a much larger sample size, and it is likely therefore to be more representative of the true response of the myHealthE userbase. It is essential that digital platforms use measures like the SUS to evaluate their usability in a standardized manner; however, this is not currently common practice [23].

Caregivers were asked whether they thought myHealthE had been improved by the "virtual waiting room" update in January 2023, which expanded the platform from exclusively collecting routine outcome measures, to also including information about CAMHS, mental health resources, and information on other organizations. Only 11.5% (62/537) of respondents indicated they had noticed the update to the site. This demonstrates that the two alerts sent to caregivers were not sufficient to notify them of this update. Therefore, despite efforts being made to build and populate the new "virtual waiting room' module, insufficient effort had been made to promote awareness of and engagement in these resources. Therefore, digital platforms should consider a variety of methods to notify their userbase of updates, such as using both text and email as well as suggesting users visit new webpages when they are on the site.

Strengths and Limitations

This study is the first evaluation of the myHealthE platform in its current form using both quantitative and qualitative analyses, and has resulted in specific recommendations for the improvement of all digital platforms used by CAMHS populations.

A major limitation of this study is that, by using an online survey, our ability to measure digital divides was limited, and likely affected by sampling and response bias. The appraisal of comfort with the internet and technology are particularly likely to be overestimated, since by the study's design, participants were all able to respond to an online survey using an internet-enabled device. In addition, fewer than 10% of myHealthE's total userbase responded to the survey, indicating that our results are likely representative of those who are more motivated to complete online surveys. Another limitation was the lack of male respondents. This limitation stems from the underlying electronic health record system in SLaM, which permits only one contact detail for a primary caregiver to be listed, and female caregivers are often preferentially recorded in these fields. Therefore, findings relating to gender should be interpreted with caution.

Conclusions

This study provides a baseline assessment of the acceptability and usability of the myHealthE platform. It provides useful guidance for all health care providers for children and young people on developing online resources for caregivers and young people waiting to access mental health services. It also considered barriers to accessing these platforms. We found that although there was, in general, good acceptability and usability of myHealthE, there were still numerous recommendations made by users and opportunities for improvements. For example, this study highlighted the importance of ensuring digital platforms are mobile friendly. It also highlighted potential gaps between development and dissemination of new information to service users; it is not simply enough to create new materials, we must ensure that service users are fully informed. Finally, it is essential that platforms like myHealthE are not solely designed for individuals with high digital literacy, but also consider how individuals might be being excluded through digitalization. Bridging digital divides, particularly those observed among different sociodemographic groups, such as different income levels, is crucial.

Acknowledgments

We thank members of the Child and Adolescent Mental Health Services Digital Lab for their expertise on myHealthE platform and help with the interpretation of the findings. We also thank the caregivers' patient and public involvement groups at CAMHS and South London Citizens for their feedback on the myHealthE platform and the Maudsley Charity for funding the platform's recent developments. The research activities received no other external funding. AW received support from Administrative Data Research UK, an Economic and Social Research Council investment (part of UK Research and Innovation) (grant ES/W002531/1). JD is supported by National Institute for Health and Care Research (NIHR) Clinician Science Fellowship award (CS‐2018‐18‐ST2‐014) and received additional funding from the Medical Research Council (MR/Y030788/1; MR/W002493/1). JP, CG, AM work within the CAMHS Digital Lab, which is partly funded by the NIHR Maudsley Biomedical Research Centre (grant NIHR203318). This study represents independent research funded by the NIHR Maudsley Biomedical Research Centre at South London and Maudsley National Health Service Foundation Trust and King’s College London. Abstract

Background: Little is known about the role of exposure to e-cigarette–related digital content, behavioral and mental health factors, and social environment on the change in adolescent e-cigarette use during COVID-19 shelter-in-place orders and remote schooling.

Objective: The aim of the study was to examine changes in adolescent e-cigarette use during shelter-in-place and remote schooling in association with exposure to e-cigarette–related digital content and other correlates: stronger e-cigarette dependence, feeling lonely, inability to socialize, e-cigarette use to cope with shelter-in-place, and the number of family members aware of participants' e-cigarette use.

Methods: A cross-sectional survey conducted between August 2020 and March 2021 included 85 California adolescents (mean age 16.7, SD 1.2 years; 39/85, 46% identified as female and 37/85, 44% as Hispanic) who reported e-cigarette use in the past 30 days. Multivariable penalized logistic regressions determined associations adjusted for age, race and ethnicity, and mother's education. The outcome of increased e-cigarette use was defined as more frequent use of e-cigarettes of the same or stronger nicotine or tetrahydrocannabinol concentration.

Results: Almost all respondents (83/85, 98%) reported using social media more since shelter-in-place, and 74% (63/85) reported seeing e-cigarette digital content. More than half (46/85, 54%) reported increased e-cigarette use during shelter-in-place. Most individuals who increased use were exposed to e-cigarette digital content (38/46, 83%) compared to those who did not increase e-cigarette use (25/39, 64%), but the association was nonsignificant after adjusting for demographics (adjusted odds ratio [AOR] 2.34, 95% CI 0.71 - 8.46). Respondents who felt lonely (AOR 3.33, 95% CI 1.27 - 9.42), used e-cigarettes to cope with shelter-in-place (AOR 4.06, 95% CI 1.39 - 13.41), or had ≥2 family members aware of participants' e-cigarette use (AOR 6.42, 95% CI 1.29 - 39.49) were more likely to report increased e-cigarette use.

Conclusions: Almost all participants reported using social media more during shelter-in-place, with many respondents reporting increased e-cigarette use, and significant associations with loneliness and use to cope with shelter-in-place. Future interventions should consider leveraging digital platforms for e-cigarette use prevention and cessation and address the mental health consequences of the COVID-19 pandemic.

KEYWORDS

adolescents; social media use; e-cigarette use; mental health; COVID-19 shelter-in-place orders; remote schooling; smoking; vape; e-cigarette implications; COVID-19; anxiety; depression

Introduction

Background

In 2021, 3.3% of middle and 14.1% of high school students in the United States reported e-cigarette use in the past 30 days [1]. Feelings of anxiety, depression, or stress (43.4%) and the use of e-cigarettes by friends (28.3%) are commonly cited reasons for adolescent e-cigarette use [2]. Harmful effects on the developing brain and lungs [3] and a higher risk of addiction to nicotine and other drugs [4,5] are some of the adverse health outcomes associated with youth e-cigarette use [6,7]. In addition to nicotine e-cigarettes, the 2021 Monitoring the Future national survey [8] revealed past 30-day use of tetrahydrocannabinol (THC) cannabis e-cigarettes among 4.7% of 8th graders, 12.4% of 10th graders, and 18.3% of 12th graders; and studies in adolescents have shown concurrent use or couse of both nicotine and cannabis [9-12]. Such use of nicotine and THC vaporizers is worrisome due to the hazardous health effects of not only nicotine [13-15] but also THC use [16-18] and potentially elevated health risks associated with couse of both products [19,20].

e-Cigarette use among US adolescents remains a concern [1,21] despite declines in prevalence from 2020 to 2021 [22,23]. The decrease in adolescent use might be related, among other factors [24-26], to the increased public awareness about COVID-19 [23,27,28] and the impact of shelter-in-place orders in the early stage of the pandemic [28,29] (hereafter referred to as “shelter-in-place”). At the same time, both quantitative [28] and qualitative [30] studies reported *increased* youth e-cigarette use due to boredom, stress, or as a distraction during shelter-in-place [23].

A meteoric rise of social media use and prolonged screen time accompanied the COVID-19 pandemic [31]. Frequency of social media use is positively correlated with exposure to e-cigarette–related digital content that, in its turn, is associated with positive attitudes toward e-cigarette use [32]. Observational [33-39] and experimental [40,41] studies have shown that social media use and exposure to social media content (eg, advertisements or posts) are associated with increased willingness and intention to use e-cigarettes [40], increased curiosity [41] and odds of experimental [41,42] and subsequent [38] e-cigarette use among e-cigarette naïve adolescents, greater perceived norms [40] and benefits of e-cigarettes [42], lower perceived danger [39,40], and more positive attitudes toward e-cigarettes among youths and adolescents [40]. Increased prevalence of adolescent cannabis use has also been associated with exposure to social media cannabis marketing [43].

Goal of This Study

The need to reduce exposure to e-cigarette–related digital content on social media to prevent tobacco initiation has been raised [44,45], but little is known about the effect of exposure to e-cigarette–related digital content on the change in e-cigarette use among adolescents using tobacco.

To our knowledge, this cross-sectional study is the first to assess the association between exposure to e-cigarette–related digital content on social media and increased e-cigarette use during the unique time frame of shelter-in-place and remote schooling among California adolescents currently using e-cigarettes. Prior research has shown that e-cigarette use is associated with secondhand smoke exposure among family and friends and a pro–e-cigarette social environment [46-48] as well as with mental health and psychological distress [49-52]. Thus, we also aimed to determine potential correlates of increased e-cigarette use during shelter-in-place, including the level of e-cigarette dependence, feeling lonely, inability to socialize during shelter-in-place, e-cigarette use to cope with shelter-in-place, and awareness of family members of participants’ e-cigarette use.

Methods

Study Design and Recruitment

This was a cross-sectional study with a convenience sample of adolescents (N=85) who provided their responses to a web-based survey between August 2020 and March 2021. The eligibility criteria included being a middle or high school student in California before California started shelter-in-place on March 19, 2020 [53] and who reported current (past 30-day) use of any e-cigarette products containing nicotine (eg, disposable or pod-based) or THC (eg, marijuana vaporizers and “weed pens”).

SIS International Research recruited adolescent participants by reaching out to their research panels and by posting the study screener on the web. To qualify for the study, adolescents had to be ages 13 - 18 years, attending middle or high school in California, and using e-cigarettes at the start of the COVID-19 pandemic. SIS verified adolescents’ age and demographics by reviewing supporting documentation. The research team pilot-tested the survey questionnaires, which were administered anonymously on the Qualtrics platform (Qualtrics, Provo, UT) and designed to take approximately 20 minutes to complete.

Ethical Considerations

The study was approved by the University of California, San Francisco Institutional Review Board (20 - 31136). In the first few months of the study, adolescents provided assent, and a parent or legal guardian provided informed consent, but subsequently, adolescents were later allowed to consent for themselves, consistent with California law, which allows adolescents to consent to medical treatment for substance abuse. Participants received a US $20 gift card incentive. Each participant was assigned a unique survey identification number, and SIS kept their identities confidential. To validate entries of deidentified data, the research team manually checked each completed survey based on geolocation, duration of survey completion, quality of responses to open questions, as well as demographic data (age, gender, and race). Among 126 entries received, 97 were valid responses. We then eliminated 12 duplicate observations for 9 participants, retaining only the response with a longer survey duration time. The final analytic sample included 85 participants with valid responses, who completed the survey between August 12, 2020, and March 4, 2021, during remote schooling; shelter-in-place orders in California were lifted effective June 15, 2021 [54].

Measures: Outcome and Exposure of Interest

The survey items assessing changes in the frequency of use and concentration of e-cigarettes had the potential to directly demonstrate the impact of shelter-in-place by asking: “Overall, have you changed HOW MUCH you vape since the Shelter-in-Place rules?” and “Overall, has the STRENGTH of your vape changed since the Shelter-in-Place rules?” Given the significant correlation between the 2 variables (77.7% of overall agreement in responses, Cramer $V \chi^2_1$=0.59; P<.001), we used an aggregate outcome: increased e-cigarette use during shelter-in-place. This was a binary variable (yes or no) defined as a self-reported increase in the frequency of e-cigarette use *and* an increase or no change in the nicotine or THC concentration in the e-cigarettes used (Table S1 in Multimedia Appendix 1). Thus, selecting the response “taking more frequent hits or by using more days a month” and also reporting increased strength or no change in the concentration of e-cigarettes were classified as having increased e-cigarette use. Inconsistent changes in the frequency and concentration of e-cigarettes (eg, weaker concentration but more frequent use and vice versa, n=8) were not counted as an increase [55].

Exposure to e-cigarette digital content on social media was coded as a binary variable (yes or no) defined as affirmative responses to the following question: “At any point during Shelter-in-Place have you viewed vape advertisements or vaping digital content on any social media sites?” Both “not sure” and “no” responses were coded as “no exposure.”

Correlates and Covariates

e-Cigarette Use

The survey included images and provided examples of e-cigarette brands in questions about lifetime and past 30-day use of disposable (eg, Puff Bar), pod- or cartridge-based (eg, JUUL), or other types of nicotine e-cigarettes (eg, mod-based e-cigarettes, e-hookahs, and e-cigars) and THC vaporizer products (eg, Evolab).

We assessed e-cigarette dependence using the 4-item e-cigarette dependence scale (EDS) [56], with a possible range from 0 to 16 (Cronbach α=0.87) [57]. The survey also included questions about tobacco use among those who lived with the respondents (eg, a family member or a friend), which we further dichotomized for logistic modeling: any family member or friend versus nobody, the number of people who lived with the respondents (in categories: alone, 1 - 2, 3, and ≥4), how many family members and who (eg, a parent and a sibling) were aware that respondents used e-cigarettes (in categories: 0, 1, and ≥2), as well as reasons why respondents reported increased or decreased e-cigarette use during shelter-in-place (eg, being bored, lonely, and stressed).

Social Media Use

Participants reported whether they used social media more since shelter-in-place (yes or no) and what types of apps or websites respondents used in the past 30 days; we then derived the number of web-based platforms or apps used by respondents. Social media intensity was measured with 6 survey items (Cronbach α=0.83) adapted from the Facebook Addiction Scale by Andreassen et al [58] rating agreement with statements about social media use on a 5-point Likert scale from 1=never to 5=always; we used the average score similar to past research (Table S2 in Multimedia Appendix 1) [59].

COVID-19 and Coping With Shelter-in-Place Orders

Respondents reported whether they had been tested positive for COVID-19 and the methods used to cope with shelter-in-place (eg, using e-cigarettes and social media). We measured anxiety over COVID-19 using agreement with 6 statements on a Likert scale: 1=strongly disagree to 5=strongly agree and calculated the average score of the 6 items (Cronbach α=0.77; Table S2 in Multimedia Appendix 1).

Psychological Distress

We used the Kessler 6 Scale to measure shelter-in-place–related psychological distress over the past 30-day recall period (scores ranged from 0 to 24) [60,61]. We summed the score values and classified those with score ≥13 as severe psychological distress during shelter-in-place [60]. Respondents also reported other possible concerns they felt during shelter-in-place and how often they felt lonely (dichotomized to all or most of the time vs less often or never).

Sociodemographic Characteristics

The participants provided data about their age (in years); school grade as of fall 2020: high school (grades 9 - 12) or middle school (grades 6 - 8); self-identified sex; race and ethnicity that were combined to create a four-level covariate representing those who were (1) non-Hispanic African American or Black, (2) non-Hispanic White, (3) non-Hispanic other race, and (4) Hispanic, of any race; as well as mother’s highest level of educational attainment as a proxy for socioeconomic status [27]—a four-level variable: (1) General Education Development test or high school degree or lower, (2) some college, (3) some graduate or professional degree, and (4) unknown.

Statistical Analysis

All analyses were conducted using SAS software (version 9.4; SAS Institute). Two-sided P values ≤.05 were deemed statistically significant. Descriptive statistics included frequencies and proportions for categorical variables, means and SDs or medians and the IQRs (25th and 75th percentiles) for normally and nonnormally distributed continuous variables, respectively. As suggested to be a superior method to handle small sample and sparse data [62], we conducted bivariate and multivariable penalized logistic regressions with profile-likelihood CIs for nonlinear models [63] to assess unadjusted and adjusted odds ratios (AORs and odds ratio) with 95% CIs. In penalized logistic regression modeling, the likelihood is “penalized” by half of the logarithm of the determinant of the information matrix [62].

We assessed adjusted associations of increased e-cigarette use during shelter-in-place with exposure to e-cigarette content on social media and with other predictors of interest that were significant on α=.10 in unadjusted models. We adjusted all multivariable models for potential confounding factors, similar to prior research: age, race and ethnicity, and mother’s educational attainment [27,28,64]. Complete case analysis (n=84) was used in all models because of the small amount of missing data (n=1, 1%). We found no substantial collinearity in the models. Because of the exploratory nature of our study, we report all results that reached statistical significance [65]. We also present supplement models with results significant at $P \le .007$ (ie, .05/7) using Bonferroni correction (Tables S4-S10 in Multimedia Appendix 1).

Sensitivity Analyses

First, we reran all penalized multivariable logistic regression models while excluding 3 respondents who had reported 0 days and times of e-cigarette use in the past 30 days in the final survey. These data contradicted their prior responses about current e-cigarette use in the screening questionnaire (ie, which violates the eligibility criteria).

Second, we carried out traditional multivariable logistic regression models with normal-based Wald CIs to compare results with the primary analysis that used penalized regression modeling with profile-based CIs. For the third and fourth sensitivity analyses, we carried out multivariable logistic regression models (penalized and traditional for comparison) to assess correlates of 2 separate outcome variables: increased frequency of e-cigarette use and increased concentration of e-cigarettes used.

Results

Respondent Characteristics

Most participants were high school students (80/85, 94%), many identified as male (45/85, 53%) and Hispanic (37 of 85, 44%), and the mean age was 16.7 (SD 1.2) years (Table 1). One (1%) respondent was 19 years of age but was still in high school and, thus, was included in the analysis. Many reported that their mothers had at least some college education (37/85, 44%) and had received or were obtaining a graduate or professional degree (18/85, 21%).

Table . Respondent characteristics (N=85).

Characteristic or behavior	Values[a]
Demographic characteristics	
Age (n=84) (years), mean (SD)	16.7 (1.2)
School grade, n (%)

e-Cigarette Use

All respondents reported past 30-day use of nicotine e-cigarette products, and 68 of 85 (80%) reported past 30-day use of THC vaporizers; 75 of 85 (88%) had ever used THC vapor products. The average and median EDS scores were 8.3 (SD 4.4) and 9 (IQR 4 - 11), respectively. Three-quarters of the respondents (64/85, 75%) reported household e-cigarette use among people with whom they lived. Many (51/85, 60%) increased the frequency of e-cigarette use, and the main reasons among 48 (of 51) respondents who reported were (1) being bored (n=32, 67%), (2) stressed (n=27, 56%), (3) lonely (n=21, 44%), and (4) having other people around who used e-cigarettes (n=12, 25%; Table S3 in Multimedia Appendix 1). Many (38/85, 45%) said that e-cigarettes they used were of stronger concentration, and 46 of 85 (54%) reported increased frequency of e-cigarette use of the same or stronger concentration during shelter-in-place (Table S1 in Multimedia Appendix 1).

Social Media Use

Almost all participants said that they used social media more since shelter-in-place (83/85, 98%), and the intensity of social media use was moderately high (median 3.5 of 5, IQR 2.7 - 3.8). Many reported seeing e-cigarette advertisements or other digital content on social media during shelter-in-place (63/85, 74%). Of 85 respondents, 74 (87%) named a total of 11 social media platforms or apps they had been using in the past 30 days (median 4, IQR 3 - 6; range 1 - 8). Almost all of those 74 reported past-month use of at least 2 social media platforms (n=73, 99%), and 48 (65%) said they used at least 4 platforms. The top 5 web-based platforms listed by the 74 respondents were Instagram (n=58, 78%), YouTube (n=51, 69%), Snapchat (n=50, 68%), TikTok (n=45, 61%), and Twitter (n=44, 59%).

COVID-19 and Coping With Shelter-in-Place Orders

The level of anxiety over COVID-19 was moderately high among the respondents (median 3.8 of 5, IQR 3.3 - 4.2). Participants (N=85) reported 14 ways how they coped with shelter-in-place; the top 5 were examined in subsequent regression analyses: being on social media (n=76, 89%), using e-cigarettes (n=56, 66%), playing videogames (n=48, 56%), watching television (n=46, 54%), and streaming videos (n=29, 34%).

Psychological and Emotional Distress

Many participants reported feeling lonely (35/85, 41%), and the average level of psychological distress was 12 (SD 5.1), with 46% (39/84) reporting severe psychological distress.

Participants (N=85) also endorsed the following concerns: not being sure when life would go back to normal (n=49, 58%), being "stuck at home" with their family all the time (n=49, 58%), being frustrated that their routine or plan has been disrupted (n=45, 53%), being unable to meet up or hang out with the people they wanted to (n=42, 49%), and being worried about the COVID-19 (n=33, 39%).

Correlates of Increased e-Cigarette Use

The association between increased e-cigarette use during shelter-in-place and exposure to e-cigarette–related digital content on social media was borderline significant (odds ratio 2.58, 95% CI 0.98 - 7.13; *P*=.06) in the unadjusted analysis (Table 2) and nonsignificant (AOR 2.34, 95% CI 0.71 - 8.46; *P*=.19) after controlling for demographics (Figure 1 and Table S4 in Multimedia Appendix 1). Among the other 6 predictors assessed in the adjusted modeling (Figure 1 and Table S4 in Multimedia Appendix 1), 3 were positively associated with increased e-cigarette use: having ≥2 family members (vs no one) who were aware about participants' e-cigarette use (AOR 6.42, 95% CI 1.29 - 39.49; *P*=.04), using e-cigarettes to cope with shelter-in-place (AOR 4.06, 95% CI 1.39 - 13.41; *P*=.02), and feeling lonely (AOR 3.33, 95% CI 1.27 - 9.42; *P*=.02). Older participants were more likely to report increased e-cigarette use based on all models (Table S4 in Multimedia Appendix 1).

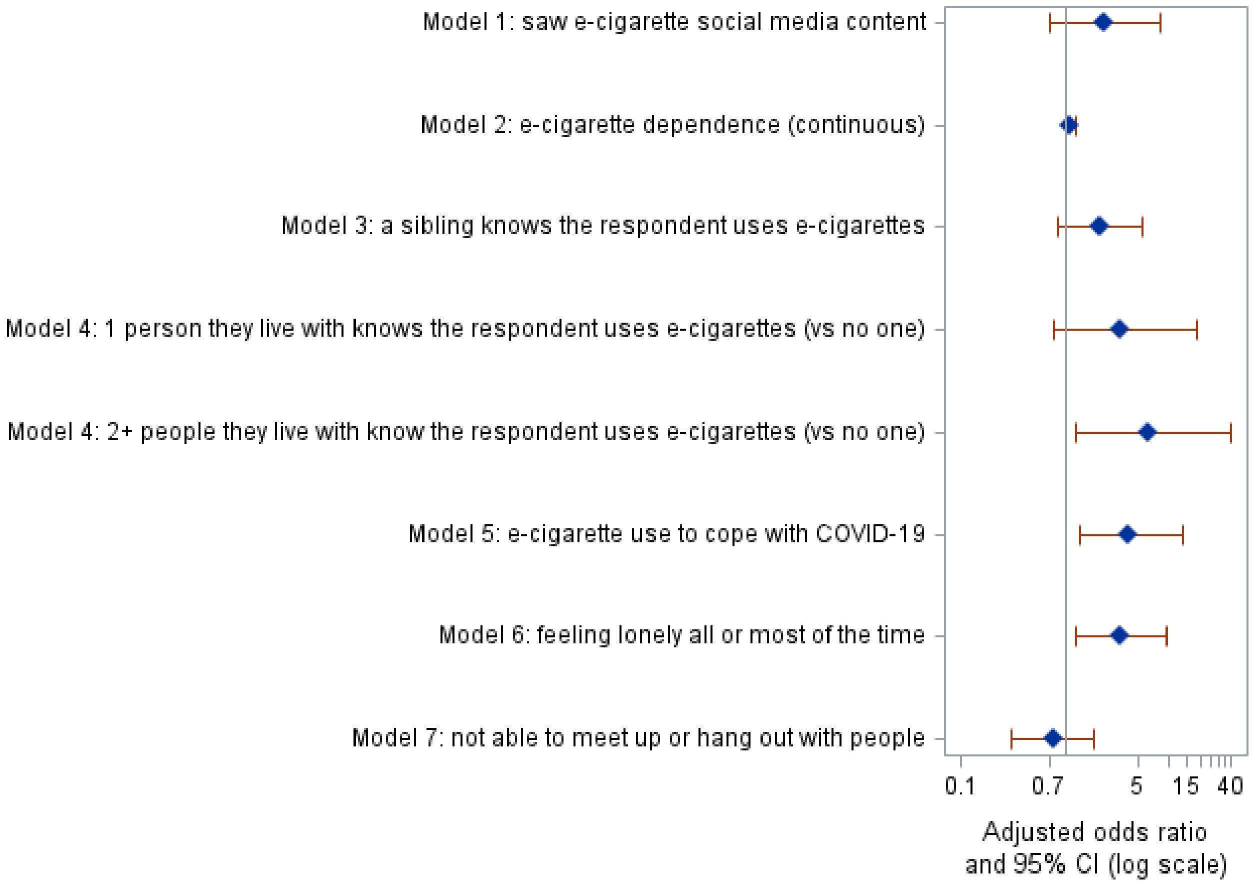
[e] GED: General Education Development test.

[f] THC: tetrahydrocannabinol.

[g] Includes the following: Among Us, Discord, Teams, and Zoom.

[h] One participant was excluded due to missing values and an unpredictable sum of scores.

Figure 1. Forest plot based on results of 7 adjusted penalized logistic regressions with self-reported increased adolescent e-cigarette use during shelter-in-place as the outcome (n=84). Results shown are adjusted odds ratios and their 95% confidence intervals (CIs) for the main predictors of interest in each of the 7 models assessed. All models were adjusted for age, race and ethnicity, and mother's highest level of educational attainment.



Sensitivity Analyses

Results of the first sensitivity analysis (Table S5 in Multimedia Appendix 1), while excluding 3 observations with inconsistent data on past 30-day e-cigarette use (n=81), confirmed our primary findings. Results from the second sensitivity analysis to compare traditional versus penalized logistic regression models showed similar findings in terms of the directionality and the significance of the associations assessed. The only exception was a statistically significant association in the traditional logistic regression for increased use and e-cigarette use dependence (AOR 1.13, 95% CI 1.01 - 1.28; *P*=.04; Table S6 in Multimedia Appendix 1), whereas this result had borderline significance in the primary analysis (AOR 1.12, 95% CI 1.00 - 1.25; *P*=.06; Table S4 in Multimedia Appendix 1).

The third sensitivity analysis of correlates of increased frequency of use revealed consistent results with the primary findings for increased e-cigarette use (Tables S7 and S8 in Multimedia Appendix 1). The fourth sensitivity analysis of correlates of increased concentration of e-cigarettes used also showed similar results, except for no or borderline significant associations with increased age in both penalized and traditional logistic regressions, and consistently positive associations with increased e-cigarette use dependence and lower odds for increased concentration among those who were limited in social interaction during shelter-in-place (Tables S9 and S10 in Multimedia Appendix 1).

Discussion

Principal Findings

This cross-sectional study of 85 California adolescents using e-cigarettes revealed many increased social media use during shelter-in-place (83/85, 98%), often as a way of coping with shelter-in-place (76/85, 89%). We found that a larger proportion of respondents who reported increased e-cigarette use (vs those who did not) also viewed e-cigarette–related social media digital content during shelter-in-place (38/46, 82% vs 25/39, 64%), but differences were not statistically significant likely due to the small sample size. Comparable to prior research [66,67], the average EDS score in our sample was 8.3 (SD 4.4). Consistent with national [8,21,25] and California surveys [68], and in accordance with previous studies [46,49,50,69], older adolescents, those who used e-cigarettes to cope with shelter-in-place, and those who had ≥2 family members being aware of participants' e-cigarette use were more likely to report changes of increased e-cigarette use during shelter-in-place. A novel finding of our study was that loneliness was associated with increased e-cigarette use, in contrast with prior studies that found no significant differences [70] or associations with decreased e-cigarette use [71] among young people during the COVID-19 pandemic. We found only one prepandemic study suggesting a higher risk of e-cigarette use initiation among tobacco-naïve adolescents with high internalizing problems, including loneliness [49].

Comparison With Prior Work

Our hypothesis that the exposure to e-cigarette–related digital content would impact adolescent e-cigarette use during shelter-in-place was based on previous studies, which were mainly focused on tobacco-naïve youths [36,38], compared tobacco users to nonusers [33,72], or were conducted before the COVID-19 pandemic. In contrast, our survey was done during the unique time and settings of shelter-in-place orders and remote schooling, and the sample was restricted to adolescents who were currently using e-cigarettes. However, we lacked data on the type of advertisement or digital content that the respondents had seen on social media. Being exposed to both pro- and anti–e-cigarette use digital content [73] could have shifted the results toward the null. These findings warrant future research with a larger sample to better understand whether different types of exposure to e-cigarette content on social media may have different impacts on current consumers of e-cigarettes or on tobacco-naïve youths, including after the COVID-19 pandemic.

The risk of adolescent e-cigarette use can vary by the type and frequency of web-based venues used [36]. Camenga et al [38] found that Facebook advertisements increased cigarette use in the cohort of e-cigarette–naïve youths. Exposure to cannabis advertisements on Facebook, Instagram, and Twitter was also associated with increased past-year cannabis use among adolescents [43]. Unlike past research before the COVID-19 pandemic, we did not see any differences in the odds of increased e-cigarette use associated with the use of specific social media platforms during shelter-in-place. This could likely be explained by increased overall social media use among adolescents during shelter-in-place and a high proportion of respondents who used multiple existing social media platforms (up to 8 web-based platforms or apps) in our study. Further, our survey rather asked about the use of web-based platforms in general and not about exposure to e-cigarette–related content viewed on specific social media sites.

By providing trustworthy and relevant content [74], social media can become an effective channel for the implementation and promotion of intervention measures to prevent both cannabis and nicotine e-cigarette use and couse among adolescents. Although data to support the effectiveness of web-based e-cigarette cessation interventions among adolescents are lacking [75,76], past research has shown feasibility [77,78] and successes [79] of web-based interventions for smoking prevention among adolescents and young adults and viability of recruitment of young adults through social media in e-cigarette use cessation [80]. However, given the increased social media use among young people in recent years and especially during the COVID-19 pandemic, improved regulations are needed to make social media use safer for adolescents [81]. In addition to the protection of personal data, such regulations should also be designed to prevent abilities of advertisers to use social media algorithms and marketing strategies for manipulating adolescent users into viewing e-cigarette advertisement or other pro–e-cigarette content [82].

Secondhand smoke exposure among family or friends and a pro–e-cigarette social environment can increase the risk for e-cigarette use initiation [46] and susceptibility to both cigarette [48,69] and e-cigarette use [47,48]. Despite not being statistically associated with increased e-cigarette use during shelter-in-place, 64 of 85 (75%) of our respondents reported household e-cigarette use among their coresidents; and those who increased e-cigarette use were significantly more likely to report 2 or more family members who were aware of participants' e-cigarette use. These findings raise questions regarding potential approval or indifference and lack of concern toward adolescent e-cigarette use among family members and their nearest social environment. Future research is recommended to assess attitudes and perceived harms among relatives or coresidents of adolescents and its impact on e-cigarette use.

Mental health problems and psychological distress may increase the risk for e-cigarette use initiation [49,50] and current use [12,51,52]. The elevated risk of adolescent e-cigarette use has been associated with internalizing (eg, feeling lonely and depressed) and externalizing (eg, conduct disorder) problems [49,51] and perceived stress [51]. The prevalence of mental health conditions among adolescents during the lockdown and social isolation period of the COVID-19 pandemic accelerated the youth mental health crisis [83,84], resulting in increased rates of anxiety and depressive symptoms [52,85] and suspected suicidal attempts [86]. A survey of Utah youths showed an increase in psychological distress indicators before versus after the COVID-19 pandemic period from an average level of 7.8 to 8.8 and revealed a positive association between psychological distress and e-cigarette use [52]. Compared to the Utah study, the average level of psychological distress among our respondents was higher (mean 12, SD 5.1), suggesting that many adolescents were experiencing at least moderate mental distress [87]; over 45% screened for severe psychological distress (39/84, 46.4%). Unlike the Utah survey that included both tobacco users and nonusers [52], our study restricted to e-cigarette users found that no differences of reporting increased e-cigarette use during shelter-in-place by the level of psychological distress [49,50].

Another novel aspect of the study is the measurement of cannabis vaporizer use during shelter-in-place. Earlier studies among US youths have found that 30.6% of those who had ever used e-cigarettes reported THC and nicotine couse [88]. In our survey, 88% (75/85) reported ever-use and 80% (68/85) reported past 30-day use of THC vaporizers in addition to nicotine e-cigarettes, highlighting a high prevalence of couse among those who had used nicotine e-cigarettes in the past month. Our study included adolescents residing in California, which was the first state to legalize medical cannabis in 1996 and adult recreational cannabis sales since 2018 [89], although some authors claim no effect of such regulations on adolescent use [90]. Concerns regarding mental health and the increased risk of psychological distress during shelter-in-place among adolescents using both substances underscore the need for further studies of tobacco and cannabis couse among adolescents with mental health symptoms [12,52].

Limitations

First, this survey had a descriptive, cross-sectional study design; causal inferences may not be derived. However, several key features of the survey design, including eligibility criteria, the time frame, and the language used in the questionnaire, have the potential to directly demonstrate the impact of shelter-in-place on the associations assessed. Second, the potential for generalizability of the study results outside California may be limited, as this was a sample of California adolescents only. However, the sample matches the demographic characteristics of California, with 44% (37/85) of our respondents identified as Hispanic, which aligns with prior California surveys in 2018 [68] and 2020 [91] that reported 47% and 52% participants of Hispanic ethnicity, respectively. Third, due to the small sample size, statistical power to detect significant differences was limited. Fourth, these were self-reported data, collected through web-based questionnaires during the COVID-19 lockdown and remote schooling, when adolescents could have been more closely monitored by their parents or guardians. Fifth, the survey did not ask about whether the respondents were aware of e-cigarette, or vaping product, use-associated lung injury. The increased public awareness regarding the harmful health effects of e-cigarettes associated with the 2019 e-cigarette, or vaping product, use-associated lung injury outbreak [92] might have contributed to the 2020 - 2021 decrease in the youth e-cigarette use [26].

Conclusions

Participants exposed to e-cigarette digital content had twice the odds of reporting increased e-cigarette use during shelter-in-place, but the results were not statistically significant in the adjusted analysis. Given almost all participants reported using social media more during shelter-in-place and associations of increased e-cigarette use with loneliness and coping with shelter-in-place, future e-cigarette use interventions should consider leveraging of digital platforms while addressing the mental health consequences of the COVID-19 pandemic.

Acknowledgments

The authors thank all participants for providing their responses. The authors thank Alina Belohlavek for programming the surveys and Dr Nadra Lisha for providing statistical advice regarding the analysis of a small sample. Support for BH-F and VP was provided by the US Food and Drug Administration's Tobacco Center of Regulatory Science (grant U54HL147127). The authors have not used a generative artificial intelligence tool during the preparation of this work. The study was supported by the Tobacco-Related Disease Research Program of California (R00RG3131). The funding sources had no role in the design and conduct of the study, data analysis and interpretation, preparation, review, or approval of the manuscript.

Data Availability

The datasets generated during this study are available from the principal investigator (VG) on reasonable request.

Authors' Contributions

VP and VG shaped the research question with guidance and support from PML. VP conducted data analysis, provided and interpreted the results, and drafted the manuscript. PML and BH-F provided resources for the development of questionnaires. VG developed the study design and questionnaires, supervised data collection and the findings, administered the project, and led funding acquisition. All authors revised and approved the final version of the manuscript.

Conflicts of Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper. BH-F is a paid expert scientist in some litigation against the e-cigarette industry and an unpaid scientific advisor and expert regarding some tobacco-related policies. No other authors have any conflicts to disclose.

Abstract

Background: Transition from pediatric to adult health care varies and is resource intensive. Patient-centered health information technology (HIT) interventions are increasingly being developed in partnership with patients.

Objective: This study aims to develop an internet-based mobile app intervention for patients with brain-based disabilities to improve transition in care readiness.

Methods: The app was designed for patients aged 15 to 17 years with brain-based disabilities having the ability to use a mobile app. A multidisciplinary team, an industry partner, and a patient and family advisory council was assembled. We hypothesized that existing tools could be migrated into the app to address education, empowerment, and navigation. We used cognitive learning theory to support chapters targeting transition in care skill sets. We used the agile iterative methodology to engage stakeholders.

Results: We developed a novel MyREADY Transition HIT platform. An electronic mentor supported cognitive learning with messaging, quizzes, rewards, and videos. We used gaming to guide navigation through a fictitious health care city. Adapting existing tools was achieved by the patient and family advisory council requesting personalization. Our iterative design required time-consuming back-end technology management. Developing the platform took 24 months instead of our grant-approved 12 months, impacting the onset of the planned trial within the allotted budget.

Conclusions: A novel patient-centered HIT platform to improve health care transition was successfully developed in partnership with patients and industry. Careful resource management was needed to achieve timely delivery of the end product, flagging the cautious planning required to deliver HIT tools in time for the much-needed trials informing their clinical application.

Introduction

Background

A growing number of adolescents with pediatric-onset health conditions have survived to adulthood owing to advances in medical care [1,2]. The Society of Adolescent Medicine defines *health care transition* as "a purposeful, planned process that addresses the medical, psychosocial and educational/vocational needs of adolescents and young adults with chronic physical and medical conditions as they move from child-centered to adult-oriented health care systems" [3-6]. Despite published guidelines, the resource-intensive process of transition in care at the point of care varies widely between institutions and health care systems [2,3,7,8].

Transition in care is largely policy-driven rather than patient-centered [9,10]. Variably between jurisdictions, transition in care is usually mandated to occur when a patient is aged between 18 and 21 years, irrespective of transition readiness [11-13]. However, among youth with chronic conditions, age correlates poorly with transition readiness [14]. Similar to other chronic conditions, brain-based disabilities (BBDs) such as autism, cerebral palsy, epilepsy, fetal alcohol spectrum disorder, and spina bifida require transition in care interventions to improve their outcomes [8]. Youth with BBD report barriers to transition in care, including inadequate support, information, and preparation, resulting in difficulty in navigating adult care systems [3,8,15,16].

Although there are various definitions of patient-centered care, core concepts uniformly highlight the central role that patients and families should play in health care delivery. The Institute of Medicine defines patient-centered care as "care that is respectful and responsive to individual patient preferences, needs and values, and ensuring that patient values guide all clinical decisions" [17]. Systematically, elements include respect for patient preferences, psychosocial support, information, education, and access. Patient-facing mobile apps offer a promising approach to supporting health care transition by educating, engaging, and empowering youth and their families to manage their own health in collaboration with their health care providers [18].

Objective

The Readiness in Youth for Transition Out of Pediatric Care (READYorNot) BBD trial will test a health information technology (HIT) intervention in a randomized controlled trial (RCT) that aims to improve transition readiness in youth with BBD [19]. In this study, we describe the development of the mobile app that serves as the intervention in the READYorNot BBD trial [19]. The app was created to deliver educational content through an internet-based gamified interface, designed to engage and empower youth with BBD to navigate health care transition. Adolescents with chronic diseases have been shown to benefit from strategies that promote independence with health care management [12]. In line with these findings, our goal was to develop an internet-based patient-facing and patient-centered mobile app for youth with BBD to improve transition readiness. We report the design approach of partnering with patients and industry to develop a novel patient-centered HIT platform to improve health care transition. We targeted 3 cognitive pillars of transition in care: education, empowerment, and health care system navigation. In this paper, we illustrate (1) methodological principles relative to technology design, (2) a stakeholder engagement process that incorporates principles of patient-centered care, and (3) content development and strategies to reinforce learning. The subsequent RCT [19] will test the effect of the mobile technology developed by our team on transition readiness as a primary end point.

Methods

We developed the MyREADY Transition BBD app as a stage of the READYorNot BBD trial (RCT; ClinicalTrials.gov NCT03852550) [19].

Patient Population

This project was conducted within the Child Health Initiatives Limiting Disability–Brain Research Improving Growth and Health Trajectories (CHILD-BRIGHT) pan-Canadian network. The CHILD-BRIGHT projects focus on optimizing the health and well-being of infants, children, and youth with brain-based developmental disabilities [20]. Eligibility for enrollment in the READYorNot BBDs RCT [19] included patients who are aged between 15 and 17 years; have a diagnosis of autism spectrum disorder, cerebral palsy, epilepsy, fetal alcohol spectrum disorder, or spina bifida; have cognitive ability to provide informed consent; have the ability to read and understand English or French; have access to the internet and a smartphone, iPad, tablet, or desktop computer; and have a TRANSITION-Q score of >40 to benchmark the minimum threshold for transition readiness based on our earlier work [21]. In our app development, we decided on a target population of BBDs, including conditions that originate before an individual reaches the age of 18 years; that continue or can be expected to continue indefinitely; and that constitute a substantial impairment in three or more areas of major life activity including (1) self-care, (2) receptive and expressive language, (3) learning, (4) mobility,

(5) self-direction, (6) capacity for independent living, and (7) economic self-sufficiency. In addition, we considered the most prevalent BBDs among adolescents who were followed in the Canadian recruitment sites who would participate in our subsequent trial designed to test the efficacy of the mobile app. For the trial, we developed a detailed diagnostic reference document for recruitment; for example, adolescents with spina bifida occulta without any neurological loss and spina bifida of any type that has not resulted in hydrocephalus and developmental disability were excluded. The rationale for targeting individuals aged 15 to 17 years stems from several key considerations. This age group represents a cohort that is typically approaching the transition from pediatric to adult health care services, making them particularly relevant for the intervention's focus on transition support. By targeting adolescents who are nearing the transition period, we can ensure that they have ample opportunity to engage with the intervention and benefit from the support provided by the app. By selecting adolescents who are close to transition but still within a developmental stage conducive to learning and adaptation, we aim to maximize the effectiveness and impact of the intervention on their transition readiness and outcomes.

Methodological Principles Relative to Technology Design and Development

We assembled a multidisciplinary team of technology developers (HIT platform design); transition psychologists (content development); and stakeholders (patients, family members, and clinicians). The HIT team (AM, RR, and AV-DL) included technology experts, patient-centered care experts, health services researchers, and industry partners. We partnered with 360Medlink, a software company with experience in the development of multimedia solutions in the health care industry [22]. The transition psychology and informational content team (AHK, KA, CBF, BG, AV-DL, AM, and JWG) included clinical psychologists and transition experts in BBD who led the development of the educational content. The stakeholder engagement team (JWG, RR, SS, BG, AM, and AV-DL) included experts in developmental pediatrics and neurology and patient engagement to lead the stakeholder engagement activities and reports. Detailed information on the expertise and demographics of the teams is shown in Table 1.

To maintain continuous responsivity to feedback from stakeholders, we adhered to principles of Agile software development [23,24]. This programming approach enables dynamic collaboration with users as illustrated in Figure 1. The 3 teams communicated weekly to make iterative adjustments to the app based on feedback. We tested proposed solutions in subsequent consultations and repeated this process until a final solution was reached. An example of a storyboard reiteration is shown in Figure 2.

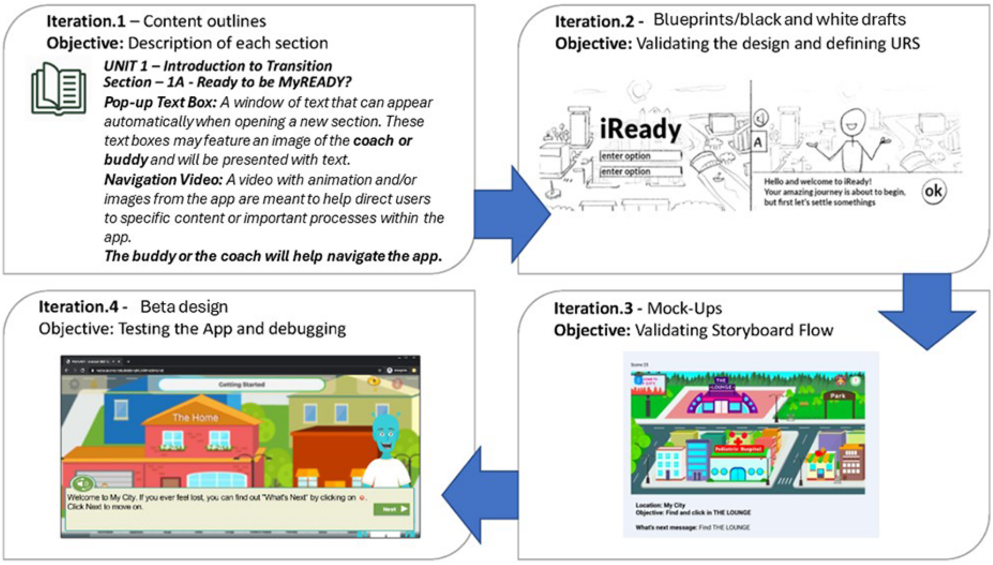
Figure 1. Description of agile iterative methodology. The figure provides a visual illustration of the agile iterative methodology applied to the life cycle of concept, app, and content development. URS: user requirement specification.

Figure 2. Interface development showing progress from descriptions to wireframes to final version. The figure illustrates the interface developmental process. All the design elements (buildings, rooms, objects, mentor, and accessories); logo; and the content (mentor messages, videos, and challenges) followed this developmental 4-step process. URS: user requirement specification.

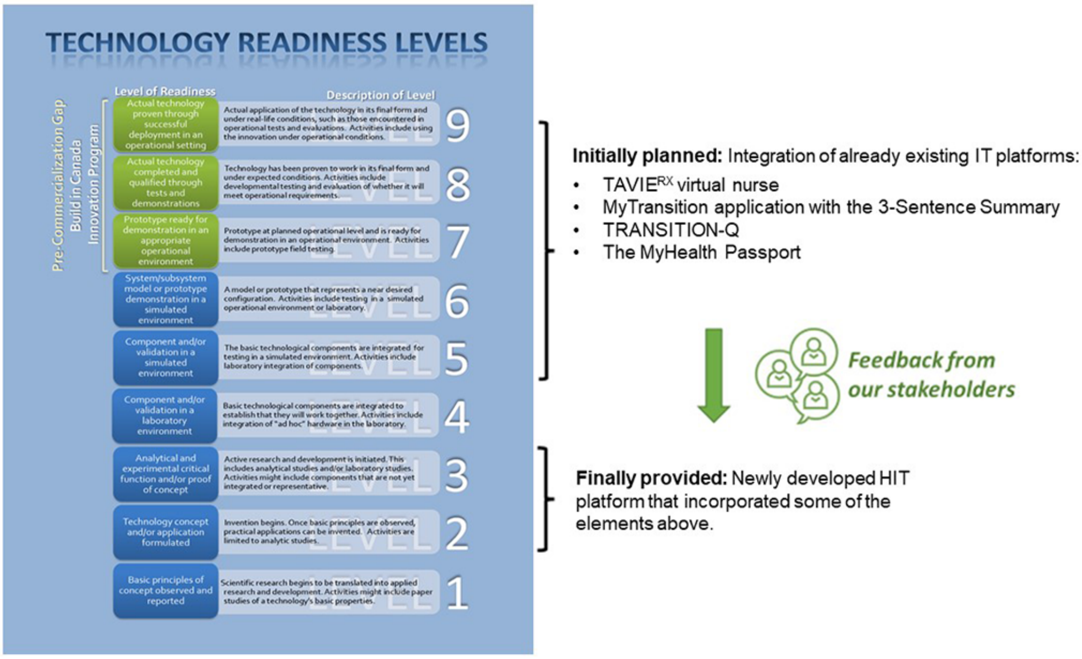


UNIT 1 – Introduction to Transition
Section – 1A - Ready to be MyREADY?
Pop-up Text Box: *A window of text that can appear automatically when opening a new section. These text boxes may feature an image of the* ***coach or buddy*** *and will be presented with text.*
Navigation Video: *A video with animation and/or images from the app are meant to help direct users to specific content or important processes within the app.*
The buddy or the coach will help navigate the app.

Stakeholder Engagement Process

App development was a collaborative process involving a series of research and stakeholder engagement activities. We used a participatory approach that incorporated stakeholder engagement and created an app that was patient centered and aimed for the highest probability of effectively meeting the needs of the BBD population. Our approach to eliciting feedback and making decisions was grounded in the principles of collaboration, transparency, and pragmatism to ensure that stakeholder input was carefully considered and incorporated wherever feasible [25]. We hypothesized that elements of existing patient-facing HIT tools could be leveraged to create a novel population-specific app. We reviewed patient-facing apps that could be adapted to meet our needs, including the TAVIE virtual nurse platform designed to improve patients' health knowledge and self-efficacy through guided need-specific content [26]. We evaluated existing BBD transition tools, including the MyTransition app [27], which includes resources to support health care transition including a 3-sentence summary to teach adolescents a concise method of summarizing their medical condition [28]; TRANSITION-Q, a validated scale for measuring skills needed to manage one’s own health care [21]; and the MyHealth Passport, a web-based tool developed by the Good2Go Transition Program [29] of the Hospital for Sick Children in Toronto [30]. We hypothesized that we could incorporate existing tools for the app development based on a technology readiness level between 5 and 6 of 9 levels, a method used to assess the maturity of technology relative to acquisition readiness [31] (Figure 3). We planned a 12-month pre-RCT development phase aiming to achieve a technology readiness level of 8, meaning that the app technology has been proven to work in its final form and under expected conditions and is now ready to be deployed and tested in real-life situations [31].

Figure 3. Description of technology readiness levels. The figure defines technology readiness levels used to predict the process from innovation concept to commercialization. HIT: health information technology. The left panel of the figure (Technology Readiness Levels) is a copy of the version available at https://buyandsell.gc.ca/initiatives-and-programs/build-in-canada-innovation-program-bcip/program-specifics/technology-readiness-levels.



Level of Readiness	Description of Level	
Actual technology proven through successful deployment in an operational setting	Actual application of the technology in its final form and under real-life conditions, such as those encountered in operational tests and evaluations. Activities include using the innovation under operational conditions.	9
Actual technology completed and qualified through tests and demonstrations	Technology has been proven to work in its final form and under expected conditions. Activities include developmental testing and evaluation of whether it will meet operational requirements.	8
Prototype ready for demonstration in an appropriate operational environment	Prototype at planned operational level and is ready for demonstration in an operational environment. Activities include prototype field testing.	7
System/subsystem model or prototype demonstration in a simulated environment	A model or prototype that represents a near desired configuration. Activities include testing in a simulated operational environment or laboratory.	6
Component and/or validation in a simulated environment	The basic technological components are integrated for testing in a simulated environment. Activities include laboratory integration of components.	5
Component and/or validation in a laboratory environment	Basic technological components are integrated to establish that they will work together. Activities include integration of "ad hoc" hardware in the laboratory.	4
Analytical and experimental critical function and/or proof of concept	Active research and development is initiated. This includes analytical studies and/or laboratory studies. Activities might include components that are not yet integrated or representative.	3
Technology concept and/or application formulated	Invention begins. Once basic principles are observed, practical applications can be invented. Activities are limited to analytic studies.	2
Basic principles of concept observed and reported	Scientific research begins to be translated into applied research and development. Activities might include paper studies of a technology's basic properties.	1

Initially planned: Integration of already existing IT platforms:

- TAVIE^{RX} virtual nurse
- MyTransition application with the 3-Sentence Summary
- TRANSITION-Q
- The MyHealth Passport

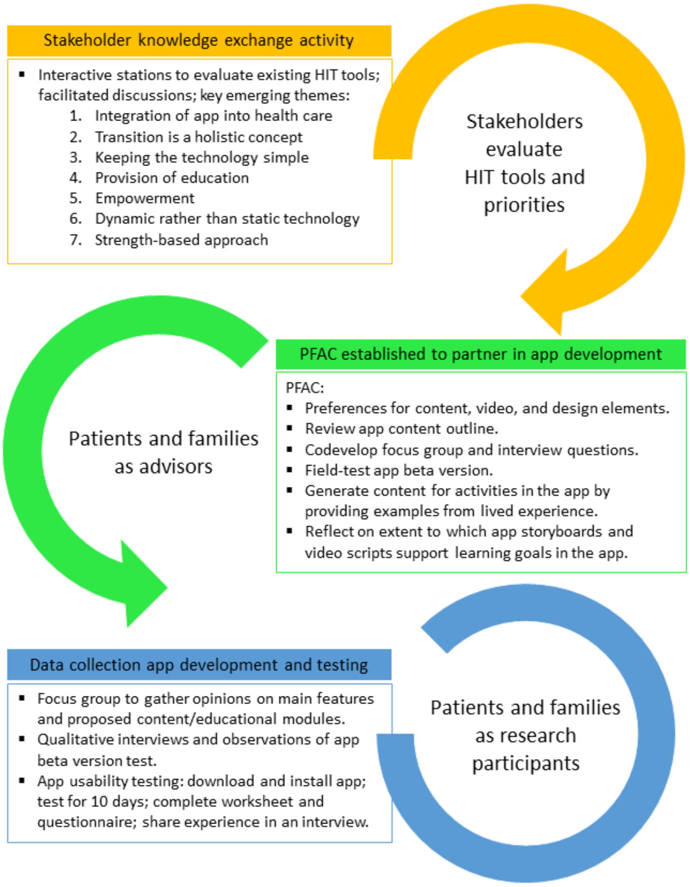
Feedback from our stakeholders

Finally provided: Newly developed HIT platform that incorporated some of the elements above.

We adopted a patient-oriented research methodology, engaging key stakeholders (youths with disabilities, families, and clinicians) and integrating their input throughout the design and development process. We hosted a stakeholder knowledge exchange activity to interact with existing HIT tools and discuss priorities before beginning app development. We formed a patient and family advisory council (PFAC) comprising a group of stakeholder partners including 1 adolescent in transition, 3 young adults at posttransition stage, and 5 parents who partnered with us on key discussions and decision-making. Among the adolescents and young adults, 2 were male and 2 were female. These youth and parent partners had a collective lived experience of cerebral palsy, autism spectrum disorder, stroke with hemiplegia, mental health conditions, prematurity with chronic health conditions, rare disorders, and complex medical needs. We hosted regular meetings with the PFAC to garner input about the concept and discuss the contents of the app. We conducted a focus group to help inform and finalize the proof-of-concept beta version of the app. We observed and interviewed adolescents and young adults and parents during an app beta version test. Adolescents, young adults, parents, and clinicians later participated in app usability testing by downloading and installing the app, testing it for 10 days, completing a worksheet and questionnaire, and sharing their experience during a qualitative interview to field-test the acceptability of the tool principally at the patient and family level and point of care to adjust and optimize the intervention tool before the subsequent clinical trial phase.

The user requirement specification list was created collaboratively by the HIT team described in Table 1. This collaborative effort drew upon extensive experience in similar health care and pharmaceutical projects, as well as adherence to best practices in app development within the health care sector. The list captured the functional and nonfunctional requirements of the app, thereby guiding its development and ensuring its alignment with stakeholder needs and regulatory standards (details in Multimedia Appendix 1). To finalize the inclusion of the user requirements, after consultation with the PFAC, 4 members from each of the psychology content development team and the stakeholder engagement team were asked to adjudicate the final inclusion or exclusion of the technical specification. The list was shared among all the stakeholders to define the minimum viable product for the app [32,33]. The process of stakeholder engagement is illustrated in Figure 4 and described in Multimedia Appendix 2.

Figure 4. Illustration of the stakeholder engagement process and activities. HIT: health information technology; PFAC: patient and family advisory council.



Stakeholder knowledge exchange activity

- Interactive stations to evaluate existing HIT tools; facilitated discussions; key emerging themes:
  1. Integration of app into health care
  2. Transition is a holistic concept
  3. Keeping the technology simple
  4. Provision of education
  5. Empowerment
  6. Dynamic rather than static technology
  7. Strength-based approach

PFAC established to partner in app development

PFAC:
- Preferences for content, video, and design elements.
- Review app content outline.
- Codevelop focus group and interview questions.
- Field-test app beta version.
- Generate content for activities in the app by providing examples from lived experience.
- Reflect on extent to which app storyboards and video scripts support learning goals in the app.

Data collection app development and testing

- Focus group to gather opinions on main features and proposed content/educational modules.
- Qualitative interviews and observations of app beta version test.
- App usability testing: download and install app; test for 10 days; complete worksheet and questionnaire; share experience in an interview.

Content Development

The transition psychology and informational content team designed preliminary content tailored to the specific needs of the BBD population. In alignment with what we learned from our research and stakeholder engagement activities, the goals were education and self-management through guided activities [15,34]. We tailored the content directly to youth while remaining mindful of the needs and expectations of other stakeholders including parents or guardians and health care providers [16].

Grounded in the principle of cognitive learning theory [35], we framed the learner as an active participant engaging with information from internal and external sources. Information was presented via a gamified interface in which a user navigates through a learning environment with the support of a guide and visits various areas of the learning environment to move through the content at a self-directed pace; this fosters motivation and intervention adherence while moving through educational sessions and achieving specific learning objectives.

The content and format of the chapters were developed systematically based on the core values and principles that emerged from stakeholder consultations and subjected to the user requirement specification list and minimum viable product criteria. Principles of social learning theory emphasized environmental and cognitive factors as well as the importance of modeling positive behavior, informed the development of a visual depiction of a city that the user learns to navigate, and included a mentor to guide users through the content. We incorporated quizzes, mentor dialogue, educational videos, as well as challenges and activities during each session. We created opportunities for self-evaluation, including a visual progress bar, a sliding scale for self-assessment of transition readiness, and checkpoints. We included a toolbox of transition resources for users, enabling access to key information about their health condition and treatment plan, thereby facilitating patient-provider communication. We cocreated multimedia content working with Spectrum Productions [36], a nonprofit social enterprise employing individuals on the autism spectrum, to film conceptual and testimonial videos with patient-actors.

Ethical Considerations

Hamilton Integrated Research Ethics Board (HiREB 2952) approval was obtained. For components of the study where patients and families were engaged as research participants (focus group, formative usability test, and summative usability test), adolescent participants provided assent and parents or caregivers provided consent for the participation of their child and themselves. We adhered to local, national, regional, and international laws and regulations regarding protection of personal information, privacy, and human rights.

Results

Technology Readiness Level and Elements

The app was developed from June 2017 to June 2019, and the English language version was launched in iOS and Android versions in the App Store and Google Play, respectively, on June 19, 2019. This was 12 months longer than (ie, twice as long as) the anticipated time in the funded grant application. Although the resources used in our preliminary design served as a starting point for development, feedback from our stakeholders motivated the creation of a completely newly developed HIT platform, reducing the technology readiness level from 5 to 6 at the onset of our study to a level of 2 to 3 as characterized in Figure 3.

The READYorNot BBD intervention includes 3 elements: the MyREADY Transition BBD mobile app, a content library containing the transition curriculum, and a back-end platform that manages the data and features of the user interface. To minimize time requirements and costs, the app was developed in Unity, a cross-platform tool, that works primarily with iOS and Android devices as well as with internet browsers. The final app comprises 985 storyboards or scenes; 88 testimonial and 46 conceptual videos; and 47 reward-driven challenges in English and in French.

Content management capabilities include indexing, search and retrieval (search boxes on the forms and reports of the indexed data by attributes such as publication dates, keywords, or population); content hierarchy with unlimited depth and size and an integrated file manager for video with multiple language support; format management (ensuring that content and videos fit the format and structure required for download); revision control (enabling content version management, including duplication and edition after initial publication); and publishing (which pushes the content in a digestible and preformatted way via the app user interface).

On the back-end platform, the app is run by a content management system that administers the users' information, journey completion (progression and adherence), and perceived value data. The content management system was designed using open-source resources, including the MySQL relational database, allowing for greater flexibility and customization as well as more timely development and scalability, while minimizing the costs associated with using branded solutions [37]. The content management system automatically pushes notifications to users based on predefined content deployment rules as well as user activity and enables administrators to access a dashboard containing user analytics reports. The content management system supports several administrative features in an easy-to-use interface, including onboarding, offboarding, secure authentication of users' access, monitoring users' data and activity, and push notifications to enhance users' adherence.

The dashboard (initially supported by Sisense data analytics software [Sisense] and currently by Microsoft Power-BI [Microsoft Corp]) contains user demographics, device type, operating system, user progression, and perceived value as well as options for data exportation. The dashboard incorporates preconfigured graphs and reports that can be filtered by key performance indicators.

The app requires an internet connection during the initial download and setup and for certain features (eg, video playback and voiceover). To ensure that users maintain access to the content, we designed the app to function offline if necessary. To do so, we optimized the balance between maximizing offline availability of key features and minimizing the download size.

Customization and Personalization of the App Based on Stakeholder Engagement

Key emerging themes from the stakeholder engagement process described in Figure 4 included the importance of viewing transition as a holistic concept, the need to keep the technology simple, and the central role of education. To increase the patient-centered focus of the app, in response to the PFAC, we incorporated features that were customized to the population with BBDs as well as options to personalize the experience of using of the app based on preferences and needs. True to the process of engagement, we also incorporated features to maximize adherence. The key features that were enhanced through customization or personalization are summarized in Multimedia Appendix 3. Features that can be both customized and personalized include privacy settings and notification, mentor appearance, text-to-speech and volume control, choice of language, color contrast and animation, and tailored resources.

Content Output

The content is deployed in five educational chapters: (1) Introduction to Transition; (2) Knowledge is Power; (3) Communication is Key; (4) Time to Take Charge; and (5) The Other Side (ie, adult care). Up to 19 sequential educational sessions are distributed along the chapters as illustrated in Figure 5. The subdivision of the educational curriculum into multiple sessions ensures that the content delivery is optimized to the attention span of youth with BBD. Each session contains between 40 and 55 scenes and includes an average of 7 videos covering conceptual material and testimonials from adolescents with BBD. The learning environment is presented in the context of a "Journey in the City," an internet-based environment that reinforces learning through gamification.

The transition curriculum is delivered through a gamified user experience in which the content of each session is provided through a combination of activities including challenges, games, and quizzes. These activities are designed to maintain the user's interest by introducing problem-solving elements and allowing users to collect rewards upon completion. The sessions have a recursive structure, and their predictable nature allows the user to easily navigate through the content. Each session begins at the same location and guides the user to a new location to access the main content and activity of that session as illustrated in Figure 6. The sessions conclude by guiding the user back to the start location while providing a summary of the key concepts learned and an opportunity to collect a reward.

Throughout their journey, the user is accompanied by a mentor that guides them through the learning environment, progressively introducing each educational activity, delivering informational messages, reminders, and motivational reinforcements. The user can build a relationship with the mentor, which simulates contact with a peer who has been through the transition process and facilitates learning by modeling positive behavior [3,38]. Users can customize the mentor's appearance as they accumulate rewards by completing activities.

Figure 5. Content scheme and session environment. Content scheme and session environment as user advances through the “Journey in the City,” an internet-based environment that reinforces learning through gamification. In the app, the user navigates through a simulated city (“My City”) by engaging with a series of internet-based buildings, each containing a thematic educational session. The user’s navigation is based in "the lounge," which acts as the starting point for each session.

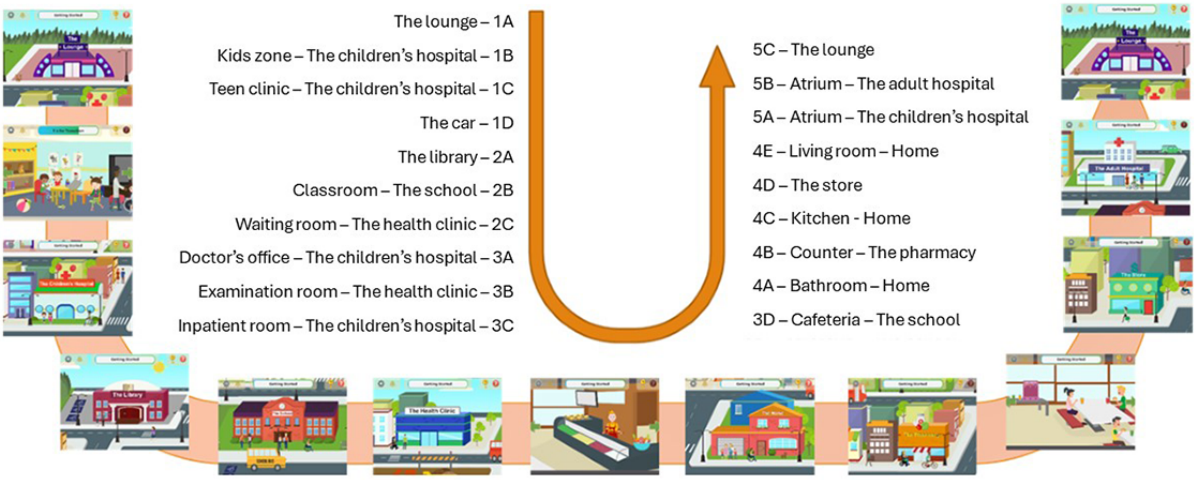


Figure 6. Workflow and recursive structure of educational sessions. The sessions have a recursive structure, and their predicable nature is intended to facilitate navigation through the content. Each session begins at the same location and guides the user to a new location to access the main content and activity of that session. The sessions conclude by guiding the user back to the start location while providing a summary of the key concepts learned and an opportunity to collect a reward.

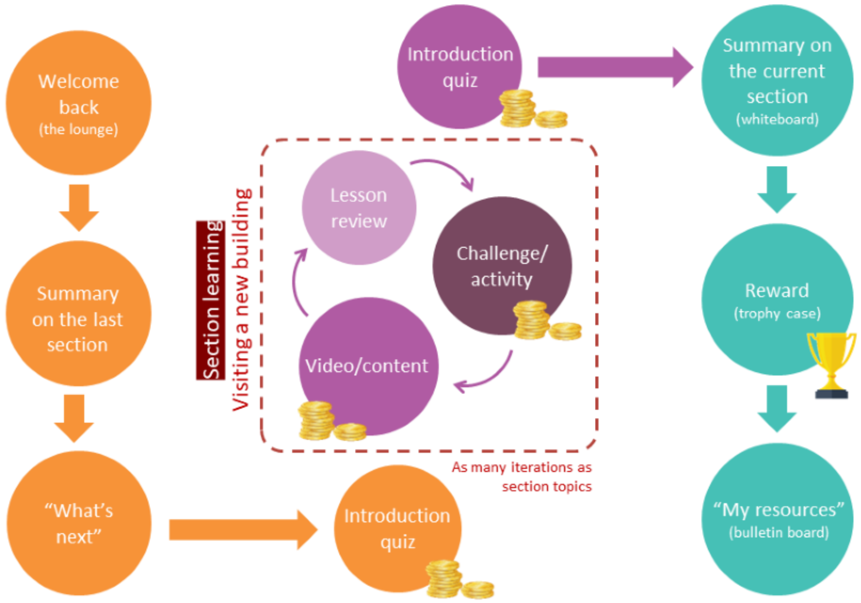

Discussion

Principal Findings

In this study, we describe our experience developing a novel digital platform (MyREADY Transition BBD app) that delivers educational content through an internet-based gamified interface designed to engage and empower adolescents with BBD to navigate health care transition. To our knowledge, this is the first HIT intervention intended to improve transition readiness for youth with BBD. We hypothesized that existing tools could be migrated into the app to address education, empowerment, and navigation. Stakeholder feedback led us to create a custom-designed platform. Furthermore, although the development of the transition curriculum incorporated principles of cognitive and social learning theory, we found that the educational content needed to be delivered in a way that captivated the users. This led us to adopt gaming features and internet-based multimedia expression of contents to harness learning styles of youth with BBD. Finally, perhaps the most challenging but also rewarding aspect of our iterative design process was the rigorous incorporation of stakeholder engagement, requiring a back-end technology management platform that was cumbersome and required labor-intensive hands-on support. Our experience provides insight for other app developers, health care providers, and researchers about the process and efforts needed to develop apps for youth with special needs.

Youth with lifelong health conditions exhibit substantial variability in transition readiness [11-13]. Since policy-driven transfer of care is variable, we sought to develop an intervention that improves transition readiness. There is an increasing need to support the process of health care transition in a way that is adaptive to the demands of the adult health care system [4]. As an increasing number of HIT platforms designed to meet care gaps for specific populations are being developed in partnership with patients and industry, adjustment of time, budget, and expectations need to be carefully managed to achieve timely delivery of high-quality end products. The gaming elements, multimedia features, and journey-like processes throughout the app were designed to foster engagement and adherence to the educational curriculum [39]. Throughout the content development, stakeholders highlighted the need to deliver the transition curriculum using a strategy that is adapted to the learning requirements of youth with BBD [12]. This required a creative approach that merges the principles of cognitive and social learning theory with contemporary gamification strategies [40] and evidence on health intervention technology preferences among youth [12,41,42]. We incorporated several gaming elements into the app, including an internet-based environment, objective-based learning modules, challenges, and rewards [39]. In tandem with this, the mentor simulates peer-supported social learning, which has been identified as an important facilitator for learning among youth with BBD [3,38]. Gamification has the potential to reinforce learning and increase engagement with the transition curriculum [43-45].

Patient-centered, patient-facing mobile apps offer a promising approach to supporting health care transition by educating, engaging, and empowering youth and their families to manage their own health in collaboration with their health care providers [18]. Our project aligns with translational research design methods where the philosophy for using patient-centered design is to understand the needs of the people at the center of the research. Designing research in this way, based on an understanding of the needs and knowledge of user-centered design principles, aims to reduce the gap between research and its application. Our efforts to understand the users at the center of the project are evident both in our research approach and in our iterative methods to develop the app based on stakeholder feedback. Gelinas et al [46] provided recommendations from a Delphi panel regarding the oversight of patient-centered outcomes research, including the recommendation to use a formal taxonomy of patient involvement in research to disambiguate and distinguish between 3 broad roles patients may take, namely, study personnel, advisor, and research participant. In our project, we engaged patient and family stakeholders as advisory members in some instances and as research participants in other instances. We used these complementary approaches to garner input during the app development and usability testing process and to embed patients and families as formal advisors in key discussions and decision-making. We applied this user-centered, participatory approach by design to create a patient-centered app with a high probability of effectively meeting the needs of the population with BBDs. Many of the content and design decisions were made in collaboration with the READYorNot PFAC. The PFAC for this project was diverse and included both caregivers and youth in various stages of transition, some of whom transitioned to adult care during their time on the project. Having input from those currently living the transition experience allowed the app to be shaped in real time by youth's changing perspectives. While these partnerships were invaluable to the success of our app development, it is understandably difficult to recruit and retain youth to be involved in research; it requires time and flexibility in order to build a working relationship that may not be feasible in some circumstances. Researchers who are finding it challenging to engage youth may choose a consultation service such as the Child and Youth Advisory Council through Alberta Health Services or the National Youth Advisory Panel within the CHILD-BRIGHT network. Use of consultation services can be complementary to the other partnership activities, as there is often a need to use a suite of engagement tools when engaging youth with busy schedules.

We used an iterative technology methodology to incorporate stakeholders' feedback. It was difficult to adapt existing tools due to our commitment to personalization and customization of app features guided by our PFAC. Our iterative design required time-consuming back-end technology management. Developing the platform took 24 months instead of our grant-approved 12 months, impacting the planned trial onset within the allotted budget. An increasing number of HIT tools are being developed to meet care gaps [42,47,48]. Many of these tools are designed for patients with specific health conditions but may not be tailored to the needs and characteristics of specific populations, which can negatively impact adherence [49]. We aimed to design a patient-centered HIT intervention for youth with BBD, a population with a range of specific health conditions as well as specific usability needs, which posed unique design challenges [50,51]. Although numerous public funding agencies are calling for patient partners in research design and implementation, guidelines that estimate the impact of this engagement on achieving study deliverables are scant. Moreover, industry partners, pivotal to the success of product development, are to date, ill-equipped to handle the excess labor required to achieve this. Thus, despite the potential benefits of stakeholder engagement, the implementation of these partnerships remains challenging for HIT tool development, as it involves additional logistical considerations, significantly more time and funding, and careful management of stakeholders' expectations and responsibilities. As such, the co-design process requires a shift away from traditional health research processes and timelines.

In our study, we define *education* as the provision of information and resources aimed at enhancing participants' understanding of various aspects related to their health care and transition process. This includes imparting knowledge about their medical condition and health care rights and responsibilities, as well as empowering them with skills to effectively advocate for their needs within the health care system. Empowerment refers to the process of equipping individuals with the confidence, skills, and self-efficacy to actively participate in decisions regarding their health and health care. This involves fostering a sense of autonomy, self-advocacy, and self-management, empowering participants to take ownership of their health and well-being. Health system navigation encompasses the ability to navigate and access health care services effectively in Canada, including understanding how the health care system operates, accessing appropriate services and resources, and overcoming the barriers to care. These domains were selected based on their significance in facilitating successful transitions to adult health care and improving health outcomes among adolescents with chronic conditions.

Limitations

We achieved our goal although the time required to create the app exceeded the time that we planned initially. We chose to design a mobile app to be used by youth rather than parents or clinicians. While the latter are also important stakeholders in supporting health care transitions, youth are at the forefront of this process and stand to benefit the most from this type of intervention. With respect to the design process, several features that were suggested during the stakeholder consultations were omitted from the app due to budget, feasibility, and time constraints, leading to challenges with balancing the needs and expectations of stakeholders against the complexity of the resulting platform. A related challenge was to manage the contrasting timelines of the overarching research project and the software development. Finally, the effectiveness of this app in improving transition outcomes is yet to be evaluated. We did not systematically measure stakeholder engagement and satisfaction with our design approach of partnering with patients and industry to develop the app. However, we have published a commentary on navigating meaningful engagement and lessons learned from partnering with youth and families [52].

We recognize it is a limitation that the app is accessible only to people with a smart device or a computer with a navigator and internet access. While we have designed an offline mode, an internet connection is still required for initial download of the app, and a continuous internet connection is essential for accessing videos and text-to-speech features and synchronization with the content management system. Once we have completed the RCT and determined which components of the intervention have the highest probability of improving transition readiness, we will incorporate those in the future iterations of the intervention and explore how to maximize the accessibility of the app. Moreover, future iterations of the platform may incorporate measures to mitigate disparities in access to technology and internet services and digital literacy, thus aligning with broader goals of promoting health equity. Despite the limitation, mobile apps are a complementary approach to reducing care gaps, addressing health inequities by improving access to resources and support that may not be available in the clinical environment.

The importance of experimental implementation cannot be overstated. Although implementation science has made great advances in the use of digital technologies to advance knowledge translation and improve self-management and adherence, rigorous clinical trials need to measure their impact on well-specified outcomes. The process of engagement of patients as partners in research needs to be well characterized and accounted for in research planning. The MyREADY Transition BBD app will be implemented and tested in the READYorNot BBD trial, an ongoing cluster RCT, which began recruitment in June 2020 in 4 regions across Canada [19]. The objective of this trial is to assess the impact of this innovative tool on transition readiness among youth with BBD. The trial is designed to include 264 adolescents aged 15 to 17 years with BBD who meet minimum health and technology literacy criteria in order to potentially benefit from this intervention. We will collect and analyze data pertaining to the usability and patient experience of the app as well as how the app operates to further optimize the intervention. We hope that this intervention will be used by youth with BBD and be endorsed by health care providers and experts in Canada and elsewhere.

Conclusions and Future Directions

The MyREADY Transition BBD mobile app delivers educational content through an internet-based gamified interface, which was designed to engage and empower youth with BBD to navigate health care transition. The impact of this app on transition readiness and outcomes is being measured with an ongoing trial, the results of which will guide future development of apps for youth with special needs and steps toward dissemination. This intervention has the potential to improve transition outcomes during health care transition from pediatric to adult health care systems. Our process has the potential to inform other researchers tackling the growing need for HIT tools to support patients and families transitioning through the health care system. Technology platforms developed in partnership with patients and industry can be patient centered, but careful resource management is needed to achieve timely delivery of end products for the much-needed trials that will inform their application in clinical practice.

Acknowledgments

The authors would like to acknowledge the important contributions of the patients and families who partnered as advisors on our patient and family advisory council: Dana Arafeh, young adult and patient partner in Ontario, Canada; Musa Arafeh, young adult and patient partner in Ontario, Canada; Kyle Chambers, young adult and patient partner in Ontario, Canada; Claire Dawe-McCord, young adult and patient partner in Ontario, Canada; Michael Frost, young adult and patient partner in Alberta, Canada; Julia Hanes, young adult and patient partner in Ontario, Canada; Jessica Havens, young adult and patient partner in Alberta, Canada; JoAnne Mosel, parent and family partner in Quebec, Canada; Kinga Pozniak, parent and family partner in Ontario, Canada; Connie Putterman, parent and family partner in Ontario, Canada; Roger Stoddard (in memory), parent and family partner in New Brunswick, Canada; Nathan Tasker, young adult and patient partner in Ontario, Canada; and Donna Thomson, parent and family partner in Ontario, Canada. The authors would also like to thank the wider group of family, clinician, and technology stakeholders who participated during app development.

The authors gratefully acknowledge funding from the Child Health Initiatives Limiting Disability–Brain Research Improving Growth and Health Trajectories network, funded under the Canadian Institutes of Health Research (CIHR-SCA-145104) Strategy for Patient-Oriented Research initiative, and with funding partner support from Montreal Children's Hospital Foundation, Faculty of Health Sciences of McMaster University, New Brunswick Health Research Foundation, McMaster Children's Hospital Foundation, and Hamilton Health Sciences.

AM and JWG and received research grants from the Canadian Institutes of Health Research Strategy for Patient-Oriented Research. AM holds grants from the Heart and Stroke Foundation of Canada and the Fonds de recherche du Québec–Santé, where she is a senior clinical research scholar. JWG held the Scotiabank Chair in Child Health Research (2013-2021).

Abstract

Background: Regular physical activity and exercise are fundamental components of a healthy lifestyle for youth living with type 1 diabetes (T1D). Yet, few youth living with T1D achieve the daily minimum recommended levels of physical activity. For all youth, regardless of their disease status, minutes of physical activity compete with other daily activities, including digital gaming. There is an emerging area of research exploring whether digital games could be displacing other physical activities and exercise among youth, though, to date, no studies have examined this question in the context of youth living with T1D.

Objective: We examined characteristics of digital gaming versus nondigital gaming (other exercise) sessions and whether youth with T1D who play digital games (gamers) engaged in less other exercise than youth who do not (nongamers), using data from the Type 1 Diabetes Exercise Initiative Pediatric study.

Methods: During a 10-day observation period, youth self-reported exercise sessions, digital gaming sessions, and insulin use. We also collected data from activity wearables, continuous glucose monitors, and insulin pumps (if available).

Results: The sample included 251 youths with T1D (age: mean 14, SD 2 y; self-reported glycated hemoglobin A_{1c} level: mean 7.1%, SD 1.3%), of whom 105 (41.8%) were female. Youth logged 123 digital gaming sessions and 3658 other exercise (nondigital gaming) sessions during the 10-day observation period. Digital gaming sessions lasted longer, and youth had less changes in glucose and lower mean heart rates during these sessions than during other exercise sessions. Youth described a greater percentage of digital gaming sessions as low intensity (82/123, 66.7%) when compared to other exercise sessions (1104/3658, 30.2%). We had 31 youths with T1D who reported at least 1 digital gaming session (gamers) and 220 youths who reported no digital gaming (nongamers). Notably, gamers engaged in a mean of 86 (SD 43) minutes of other exercise per day, which was similar to the minutes of other exercise per day reported by nongamers (mean 80, SD 47 min).

Conclusions: Digital gaming sessions were longer in duration, and youth had less changes in glucose and lower mean heart rates during these sessions when compared to other exercise sessions. Nevertheless, gamers reported similar levels of other exercise per day as nongamers, suggesting that digital gaming may not fully displace other exercise among youth with T1D.

Introduction

Type 1 diabetes (T1D) is a common chronic medical condition among children [1]. It is characterized by a loss of endogenous insulin production in the pancreas and an inability to self-regulate blood glucose levels. The daily treatment for T1D includes vigilant glucose monitoring, carbohydrate counting, and intensive insulin delivery, with the goal of trying to achieve near-normal glucose levels [2]. Additionally, it is important for youth living with T1D to participate in regular physical activity and exercise as part of achieving a healthy lifestyle [3]. Current clinical recommendations guide youth living with T1D to achieve at least 60 minutes of moderate- to vigorous-intensity physical activity daily [4], which are the same recommended duration, intensity level, and frequency of physical activity as those recommended for youth without T1D [5,6]. However, results of a recent meta-analysis showed that many youth living with T1D do not meet the minimum recommended levels of physical activity and may even be less physically active than peers without T1D [7].

For all youth, regardless of disease status, minutes of physical activity compete with other daily activities, including school, extracurricular activities, sleep, meals, and socializing [8]. Playing digital games is another popular leisure activity for many youth [9]. Digital games represent any game that is played by using an electronic device. In 2021, it was estimated that the typical US teenager spent almost 2 hours per day playing digital games [10]. Although there is an emerging body of research examining whether playing “serious digital games” could be an effective method of preventing disease in youth [11-14], studies have also explored whether digital games could be displacing other physical activities and exercise among youth [15], thereby potentially contributing to poorer health outcomes [10]. To date, the association between digital games and daily physical activity minutes among youth with T1D has received no attention.

The Type 1 Diabetes Exercise Initiative Pediatric (T1DEXIP) study is a real-world observational study of physical activity and glycemic levels in youth living with T1D from across the United States [16]. The study collected youth-specific (eg, age, insulin regimen, and hypoglycemia fear) and event-specific (eg, type, duration, and intensity of activity) data that were hypothesized to influence the acute glycemic response to physical activity in youth living with T1D. In this study, we used data from the T1DEXIP study to (1) examine characteristics of youth-identified digital gaming sessions versus nondigital gaming exercise sessions (other exercise) and (2) test whether youth with T1D who played digital games regularly (at least 30 min/day; ie, gamers) engaged in less other exercise than youth who did not play digital games (ie, nongamers). Moreover, related to our second aim, we examined whether gamers identified more barriers to physical activity and fear of hypoglycemia than nongamers. We sought to be the first to examine these important factors for youth living with T1D to inform the pediatric diabetes literature and guide in-clinic exercise consultations among youth living with T1D.

Methods

Ethical Considerations

The Jaeb Center for Health Research Institutional Review Board approved all study-related materials prior to participant recruitment. We obtained parent informed consent and participant assent electronically before screening and data collection. Data collection lasted from October 6, 2021, to December 17, 2022. We identified youth’s data by using a study-specific identification number. We compensated youth up to US $100 for their participation.

Procedures

We recruited participants from pediatric diabetes centers across the United States and through diabetes community conferences, workshops, and web-based platforms. Eligible youth were aged 12 to 17 years, had a T1D diagnosis, were on an intensive insulin regimen (open-loop insulin pump, hybrid closed-loop pump, or multiple daily injections), and spoke English. Youth and parents completed web-based surveys. For 10 days, youth logged any exercise session that lasted >10 minutes, any digital gaming activities, 3 days of food intake, and insulin dosing (multiple daily injections only) in a study-specific version of the Bant Diabetes smartphone app (University Health Network and the Hospital for Sick Children). To objectively measure blood glucose levels, insulin use, and physical activity, we collected continuous glucose monitor (CGM), insulin pump (if available), and wrist-worn activity tracker (Garmin vívosmart 4; Garmin International Inc) data from youth.

Measures

Youth completed a study-specific demographic and medical history survey to report their age, race, ethnicity, sex, contact information, and diabetes history (including duration of T1D, insulin delivery method, previous occurrences of severe hypoglycemia or diabetic ketoacidosis, and most recent glycated hemoglobin A_{1c} [HbA_{1c}] level). To measure youth’s perceptions of barriers to physical activity, they completed the Barriers to Physical Activity in Type 1 Diabetes (BAPAD1) scale [17]. The BAPAD1 scale is a 12-item survey that was validated for use in youth living with T1D. BAPAD1 scale items include general barriers to physical activity (ie, bad weather and school schedule), as well as potential diabetes-specific barriers (ie, risk of hypoglycemia or hyperglycemia). Youth responded to items by using a 7-point Likert scale (1: extremely unlikely; 7: extremely likely), with higher scores indicating the perception of more barriers to physical activity. To measure youth’s fear of hypoglycemia, they completed the Hypoglycemia Fear Survey-Child version (HFS-C) [18,19]. This 25-item survey, which was validated for youth with T1D, measures hypoglycemia fear based on the youth’s level of worry about hypoglycemia and use of hypoglycemia avoidance behaviors. The HFS-C uses a 5-point Likert scale (0: never; 4: almost always). Higher scores on the HFS-C reflect greater levels of hypoglycemia fear. To measure parents’ fear of their child experiencing hypoglycemia, parents completed the Hypoglycemia Fear Survey-Parent version (HFS-P) [19,20]. This is also a 25-item survey, which was designed to measure fear based on the parent’s level of worry about hypoglycemia and use of avoidance behaviors. The HFS-P uses the same response scale as the HFS-C. Higher scores on the HFS-P also reflect greater levels of parent-reported hypoglycemia fear.

Statistical Analysis

Analyses compared exercise characteristics during digital gaming sessions and other exercise sessions, changes in glucose during digital gaming sessions and other exercise sessions, and mean heart rates during digital gaming sessions and other exercise sessions. An additional analysis compared digital gaming sessions to walks and low-intensity exercise sessions. The calculation of changes in glucose during a digital gaming session and an other exercise session required a CGM reading at the start and end of the session, and mean heart rate calculation required at least 15 minutes of heart rate readings. Analyses also evaluated participant characteristics, exercise characteristics, average changes in glucose during other exercise sessions, and mean heart rates during other exercise sessions for gamers versus nongamers. We completed the analyses by using SAS software, version 9.4 (SAS Institute Inc).

Results

Sample Characteristics

Our sample included 251 youths with T1D. Overall, youth were aged a mean of 14 (SD 2) years; they reported a mean HbA_{1c} level of 7.1% (SD 1.3%), a mean diabetes duration of 5.3 (SD 2.9) years, and a mean physical activity level of 2.7 (SD 0.6) on the Physical Activity Questionnaire [21]; and 105 (41.8%) youths were female. Youth logged 123 digital gaming sessions and 3658 other exercise (nondigital gaming) sessions over the 10-day period (Table 1). Types of other exercise sessions that youth reported included walking, basketball, gym class, playing with friends, cycling, running and jogging, swimming, baseball and softball, soccer, and volleyball.

Table . Comparison of digital gaming and other exercise sessions.

		Digital gaming exercise sessions	Other exercise sessions
Number of exercise sessions		123	3658
Exercise duration (min), median (IQR)		60 (35-115)	40 (20-75)
Glucose at start of exercise (mg/dL), mean (SD)		154 (61)	163 (66)
Change in glucose (mg/dL), mean (SD)		–3 (54)	–15 (58)
Heart rate during exercise (beats/min), mean (SD)		99 (18)	109 (16)
Exercise time of day, n (%)			
	Night (12 AM to <6 AM)	0 (0)	21 (0.6)
	Morning (6 AM to <12 PM)	15 (12.2)	914 (25)
	Afternoon (12 PM to <6 PM)	53 (43.1)	1984 (54.2)
	Evening (6 PM to <12 AM)	55 (44.7)	739 (20.2)
Exercise intensity, n (%)			
	Low	82 (66.7)	1104 (30.2)
	Medium	39 (31.7)	2150 (58.8)
	High	2 (1.6)	404 (11)

Characteristics of Gaming Versus Other Exercise Sessions

The median duration of digital gaming and other exercise sessions was 60 (IQR 35-115) minutes and 40 (IQR 20-75) minutes, respectively. Prior to digital gaming, youth's mean glucose level was 154 (SD 61) mg/dL, and prior to other exercise sessions, youth's mean glucose level was 163 (SD 66) mg/dL. Youth's mean glucose change was –3 (SD 54) mg/dL during digital gaming and –15 (SD 58) mg/dL during other exercise sessions. When compared to other exercise sessions, during digital gaming, the percentage of glucose time in range (70-180 mg/dL) was higher, and youth experienced slightly less hyperglycemia and hypoglycemia (Figure 1). Youth's mean heart rate was 99 (SD 18) beats per minute (BPM) during digital gaming and 109 (SD 16) BPM during other exercise sessions. Youth's mean heart rate during sedentary periods that occurred at the same time as digital gaming but on different days was 90 (SD 12) BPM. Youth described a greater percentage of digital gaming sessions as low intensity (82/123, 66.7%) when compared to other exercise sessions (1104/3658, 30.2%); however, youth described digital gaming as similar in intensity to walking (Table 2). Additionally, when compared to walking and low-intensity exercise, youth had less changes in glucose and lower mean heart rates during digital gaming, digital gaming sessions had longer durations, and digital gaming was more likely to take place during the evening.

Figure 1. Glucose metrics for digital gaming and other exercise sessions. The percentages on the right of each bar indicate the average percentage of time spent in each glucose category. The numbers to the left of each bar specify glucose levels in mg/dL.

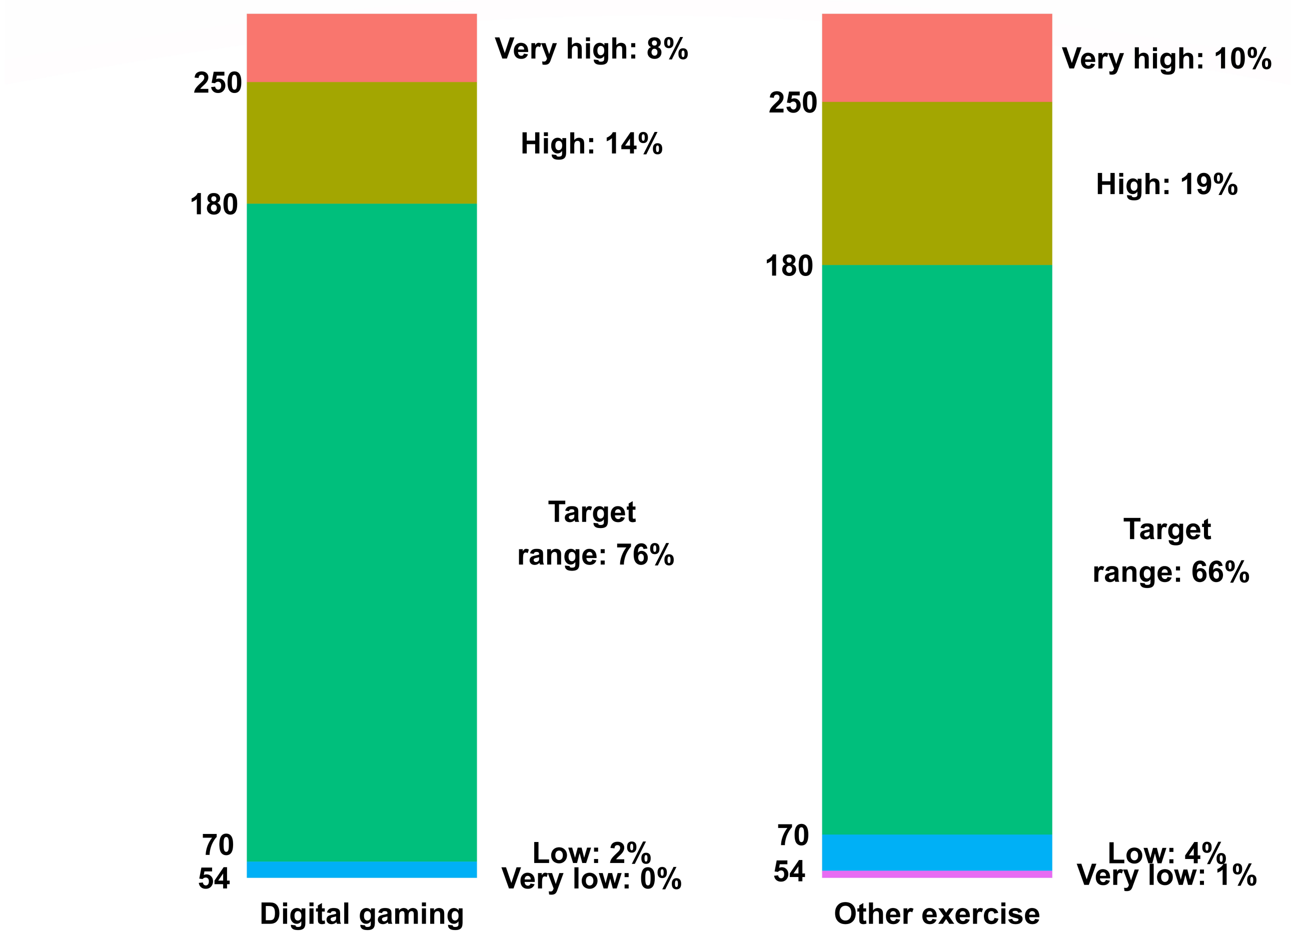

Table . Digital gaming versus walking versus low-intensity exercise.

		Digital gaming exercise sessions	Walking	Low-intensity exercise
Number of exercise sessions		123	975	503
Exercise duration (min), median (IQR)		60 (35-115)	30 (15-45)	40 (25-60)
Glucose at start of exercise (mg/dL), mean (SD)		154 (61)	168 (68)	162 (66)
Change in glucose (mg/dL), mean (SD)		–3 (54)	–16 (53)	–16 (54)
Heart rate during exercise (beats/min), mean (SD)		99 (18)	107 (15)	106 (15)
Exercise time of day, n (%)				
	Night (12 AM to <6 AM)	0 (0)	0 (0)	2 (0.4)
	Morning (6 AM to <12 PM)	15 (12.2)	266 (27.3)	121 (24.1)
	Afternoon (12 PM to <6 PM)	53 (43.1)	527 (54.1)	258 (51.3)
	Evening (6 PM to <12 AM)	55 (44.7)	182 (18.7)	122 (24.3)
Exercise intensity, n (%)				
	Low	82 (66.7)	601 (61.6)	503 (100)
	Medium	39 (31.7)	367 (37.6)	0 (0)
	High	2 (1.6)	7 (0.7)	0 (0)

Comparing Gamers to Nongamers

Our sample included 31 gamers and 220 nongamers who were similar in age, insulin regimen, HFS-C total score, HFS-P total score, and BAPAD1 scale score (Table 3). In contrast, we observed a greater percentage of male youths (26/31, 83.9%) in our gamer sample versus our nongamer sample (120/220, 54.5%). Gamers recorded 86 (SD 43) minutes of other exercise per day, whereas 80 (SD 47) minutes were reported by nongamers (Table 4). A follow-up correlation confirmed that there was no association between minutes of digital gaming and minutes of other exercise per day among gamers. The average glucose level at the start of other exercise sessions was 167 (SD 73) mg/dL for gamers versus 163 (SD 66) mg/dL for nongamers, and the mean glucose change during other exercise sessions was –17 (SD 60) mg/dL versus –15 (SD 58) mg/dL, respectively. Exercise characteristics and mean heart rates during other exercise sessions were similar for gamers and nongamers.

Table . Participant characteristics for gamers and nongamers.

		Gamers (n=31)	Nongamers (n=220)
Age (y), mean (SD)		14 (2)	14 (2)
Sex, n (%)			
	Female	5 (16.1)	100 (45.5)
	Male	26 (83.9)	120 (54.5)
BMI percentiles (%), mean (SD)		69 (27)	61 (27)
Insulin modality, n (%)			
	Multiple daily injections	4 (12.9)	34 (15.5)

	High	29 (6.2)	375 (11.8)

Discussion

In this study's cohort of physically active youth with T1D, digital gaming sessions lasted longer and were more likely to be described as low intensity, relative to activities such as walking, playing sports, and other physically active social activities that youth engaged in on a regular basis. We also found differences in mean heart rates, changes in glucose, and glucose metrics during digital gaming versus during other exercise sessions. The slightly higher percentage of glucose time in range (70-180 mg/dL) during digital gaming versus other exercise sessions could have been due to the lower starting glucose levels and the little change in glucose during digital gaming. Although the mean heart rate during digital gaming was lower than that during other exercise sessions, it was higher than that during sedentary periods that occurred at the same time as digital gaming but on different days, which is consistent with existing data [22]. Also consistent with existing evidence are youth's perceptions of digital gaming intensity. In an accelerometry study, researchers characterized digital gaming as similar in intensity to walking or light jogging [23]. However, our study of free-living exercise among youth with T1D offers new results; we reported differences in changes in glucose during exercise and differences in mean heart rates when comparing digital gaming sessions, walking, and low-intensity exercise. We believe that these novel results can help to inform in-clinic exercise consultations among youth with T1D, as youth, parents, and health care professionals may otherwise be unaware of how these activities, particularly digital gaming, may impact glucose levels and heart rates in youth [24,25].

Youth with T1D who reported digital gaming also participated in other exercise. Moreover, comparing daily minutes of other exercise between our gamers and nongamers revealed no differences. This result is consistent with a Dutch study of youth without T1D, which found that the time youth spent playing digital games did not replace the time spent in other physical activities [15]. When comparing gamers to nongamers, there were no differences in hypoglycemia fear or perceived barriers to physical activity. In general, adolescents with T1D report few barriers to physical activity [26], and only hypoglycemia avoidance behaviors [27] appear to be associated with their physical activity.

As an important limitation, this analysis of T1DEXIP study data was likely underpowered to detect differences. Gamers accounted for only 12.4% (31/251) of our sample, which was lower than expected, and this could be an indication of underreporting. Relatedly, because the T1DEXIP study recruited a physically active sample of youth with T1D, it is possible that daily minutes of other exercise may not generalize to typical youth living with T1D. Therefore, we need future research to confirm our study results in a large sample of youth with T1D who report more diverse levels of daily physical activity. It would also be valuable to recruit a large sample of youth with T1D based on their digital gaming habits to determine if minutes of other exercise sessions differ for youth with T1D who self-identify as novice gamers and those who self-identify as avid gamers. We acknowledge the limitation of a possible Hawthorne effect. Youth who participated in the T1DEXIP study were aware that we were interested in examining the associations between their daily physical activity and glycemic levels; therefore, it is possible that they may have altered their gaming and exercise frequencies during the 10-day observation window. Strengths of this study include its real-world observational design and the large number of exercise sessions captured within a large sample of youth with T1D. We also believe that our methods are strong because we used validated surveys and, when available, objective and noninvasive data sources (eg, CGMs, Garmin wearables, and insulin pumps) [28].

In conclusion, for a physically active sample of youth with T1D, our results identified some differences in the duration and intensity of digital gaming versus other exercise sessions, as well as some differences in the mean heart rates and glucose changes during digital gaming versus other physical activity sessions, and suggested that playing digital games may not displace daily minutes spent engaged in other exercise for youth with T1D who are regular gamers. In light of the similarity in daily minutes spent engaged in other exercise between youth with T1D who identify as gamers and those who identify as nongamers, it is possible that interventions for promoting physical activity among youth with T1D should focus on reducing the impact of other barriers to physical activity (eg, hypoglycemia risk and sedentary screen time) rather than target digital gaming.

Acknowledgments

The Type 1 Diabetes Exercise Initiative Pediatric (T1DEXIP) study was supported by the Leona M. and Harry B. Helmsley Charitable Trust. Dexcom provided continuous glucose monitors at a discounted rate.

Data Availability

The data sets generated by the Type 1 Diabetes Exercise Initiative Pediatric (T1DEXIP) study are available on the Vivli platform [29].

Authors' Contributions

SRP wrote the first draft and reviewed and edited the manuscript. SB conducted statistical analyses and wrote and edited the manuscript. RLG, PC, MAC, JLS, and MCR contributed to discussions and reviewed and edited the manuscript.

Conflicts of Interest

SRP reports receiving grants from the Leona M. and Harry B. Helmsley Charitable Trust, the National Institutes of Health (NIH), and the Jaeb Center for Health Research, as well as an honorarium from the American Diabetes Association outside the submitted work. RLG, SB, and PC report no conflicts of interest. MAC is the chief medical officer of Glooko, Inc, and has received research support from Dexcom and Abbott Diabetes Care. Children’s Mercy Kansas City has received grants or contracts for MAC from the NIH, the Leona M. and Harry B. Helmsley Charitable Trust, JDRF, the Emily Rosebud Foundation, Eli Lilly, the Jaeb Center for Health Research, Tolerion, and Garmin. JLS serves, or has served, on advisory panels for Bigfoot Biomedical, Cecelia Health, Insulet Corporation, Medtronic Diabetes, StartUp Health Diabetes Moonshot, and Vertex. JLS has served as a consultant to Abbott Diabetes, Bigfoot Biomedical, Insulet, Medtronic Diabetes, and Zealand Pharma. Yale School of Medicine has received research support for JLS from Abbott Diabetes, the Jaeb Center for Health Research, JDRF, Insulet, Medtronic, the NIH, and Provention Bio. MCR serves on the following advisory panels: Zealand Pharma A/S, Zucara Therapeutics, and Indigo Diabetes. MCR acts as a consultant for the Jaeb Center for Health Research and has given lectures sponsored by Dexcom, Inc; Novo Nordisk; and Sanofi. He is also a shareholder, or holds stocks in, Supersapiens and Zucara Therapeutics.

Abstract

Background: Digital interventions are increasingly popular for the provision of nonpharmacological pain interventions, but few exist for adolescents with menstrual pain. User-centered design involves incorporating users across phases of digital health intervention design, development, and implementation and leads to improved user engagement and outcomes. A needs assessment is the first step of this approach.

Objective: The goal of this study was to conduct a needs assessment to understand menstrual pain management needs and preferences and mindfulness experiences, preferences, and knowledge of adolescents with menstrual pain to inform the future development of an app for managing menstrual pain.

Methods: We used an explanatory sequential mixed method design that included a survey followed by focus groups. Adolescents aged 13-17 years completed a survey (n=111) and participated in focus groups (n=16). Data were analyzed using descriptive statistics and thematic content analysis and synthesized to provide specific recommendations based on adolescent responses.

Results: Adolescents (n=111) who completed the survey reported a moderate understanding of mindfulness and menstrual pain. Over three-quarters (n=87, 78%) of participants practiced some form of mindfulness and 87% (n=97) of survey participants used nonpharmacological pain management strategies. Teens had a moderate perception that mindfulness could help their menstrual pain (mean 4.51/10, SD 2.45, with higher scores suggesting more interest). Themes were generated related to mindfulness experiences, menstrual pain knowledge and experiences, and app functionality. These themes underscored adolescents’ need for continued support and flexible access to mindfulness activities; their awareness of multiple influences to pain, with potential for further education in this area; and the need for menstrual pain–specific content, along with content relevant to typical day-to-day experiences of adolescents.

Conclusions: Adolescents with menstrual pain have an interest in using a mindfulness app for pain but have unique needs that need to be addressed to ensure app engagement and relevance for this population. Concrete recommendations for future app development are provided.

Introduction

Dysmenorrhea, or menstrual pain, is experienced by over 90% of adolescents who menstruate and has been associated with mental health symptoms, nonsuicidal self-injury, and decreased quality of life [1-3]. For a quarter of these youth, the severity of their pain prevents them from engaging in daily activities and contributes to school absenteeism [4]. Increasingly, it is recognized that persistent, unmanaged dysmenorrhea may lead to the development of chronic pain [5,6]. Despite the impacts of dysmenorrhea on adolescent well-being, there are few accessible, evidence-based treatment options available for adolescents. Prevailing interventions are primarily pharmacological, which is not always a good fit given potential side effects and barriers to accessing care [7,8]. There is a need for accessible and effective interventions for adolescents with dysmenorrhea.

Digital health interventions, such as app-based interventions, are increasing in popularity, particularly given their ability to reduce barriers to accessing health-related services [9,10]. Recent estimates show that 95% to 98% of youth and young adults in Canada and the United States have a smartphone [11,12]; the ubiquity of smartphone access suggests that an app-based intervention maybe a viable option for adolescents with menstrual pain in Western populations. Although there is a plethora of apps related to menstruation [13,14], only a fraction of these apps contains pain-related content, and the accuracy and quality of this content are low [15,16]. Importantly, few of the available menstrual pain apps are designed specifically for adolescents [16] who may have different menstrual knowledge [3], menstrual cycle characteristics [17], and app use preferences than adults. Consequently, adolescents may benefit from an app designed specifically for their age group [10,18,19].

User-centered design is a digital intervention design approach that involves collaboration with end users (eg, patients and parents) throughout all stages of app development and implementation. User-centered design in the development of health-based apps has been shown to increase satisfaction, mitigate barriers to engagement, and improve user adoption [20-23]. In the user-centered design, the end user is included in the development process through the use of focus groups and surveys, participatory design sessions, and usability testing [24]. This multistep approach begins with a user needs assessment [21,25], which is integral in identifying and prioritizing the needs of the end user, in this instance, adolescents with menstrual pain.

To our knowledge, there are no apps developed with and for adolescents that incorporate both user-centered design and evidence-based content for the management of dysmenorrhea. Evidence-based nonpharmacological therapies such as cognitive behavioral therapy and mindfulness-based interventions have been applied as treatments for chronic and specific pain-related disorders [26,27]. As a first step in filling the gap in access to nonpharmacological interventions, this study focused on adolescents’ perception of mindfulness as a potential intervention for dysmenorrhea.

Mindfulness-based interventions are rooted in theories of mindfulness and focus on changing one’s relationship with pain and suffering [28]. Research suggests that mindfulness-based interventions may be beneficial in adolescent populations for a range of concerns [29-31] and have demonstrated potential in reducing pain and improving pain acceptance and ability to cope in youth with chronic pain [32]. The aspects of mindfulness in combination with other therapeutic approaches have also been successfully integrated into face-to-face treatments for adults with dysmenorrhea [33]. In this investigation, we focused on determining adolescents’ interest in mindfulness over other interventions for several reasons. First, past research suggests that many youth report positive experiences with mindfulness programs and the impact of mindfulness skills on their day-to-day lives [34-36]. Mindfulness-based interventions also have the potential to lend themselves better to younger teens over approaches that may require adaptation based on cognitive skills [31,37-39]. Additionally, mindfulness strategies (eg, meditations) may be more easily applied by youth in an app-based platform without therapist guidance than other interventions [40,41], which is important given the high prevalence of dysmenorrhea yet limited availability of nonpharmacological treatment options [17,42].

This study reports the first step in the user-centered development of a self-management, mindfulness-based app for teens with dysmenorrhea, that is, a needs assessment. Although digital modalities for the delivery of mindfulness-based interventions, such as smartphone apps, may be a promising means through which pain interventions may be offered, understanding whether teens are interested in mindfulness-based strategies for their pain and what type of content would be valuable to them in an app is essential. The goals of this needs assessment were to identify (1) mindfulness knowledge, experiences, and preferences; (2) menstrual pain management knowledge, experiences, and preferences; and (3) app use experiences and preferences among Canadian adolescents who experience dysmenorrhea. Using a 2-phased approach that relied on both administering a survey (phase 1) and conducting focus groups (phase 2), adolescent views were gained to inform future app development. The findings of this investigation will be used to engage in subsequent steps of the user-centered design process, including usability testing and pilot testing of the resulting app.

Methods

Research Design Overview

An explanatory sequential mixed methods design was selected for this investigation [43]. In this approach, quantitative data are collected first and are followed by the collection of qualitative data to gain a deeper understanding of quantitative findings. In phase 1 of our investigation, descriptive quantitative data and narrative responses were collected via a web-based survey. These findings of this survey are reported in accordance with the CHERRIES checklist (Checklist for Reporting Results of Internet E-Surveys) [44] (Multimedia Appendix 1). Subsequently, phase 2 involved focus groups to gain further insight into the experiences of adolescents described in phase 1. Qualitative findings from the focus group responses are reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [45] (Multimedia Appendix 2).

Participants

A convenience sample of participants aged 13 to 17 years was recruited between January and July 2022 to participate in a web-based survey (phase 1) and a focus group (phase 2). To be eligible, adolescents were required to have had their first period, experience pain with their period, and live in Canada. Adolescents who were aged 13 to 15 years were required to have consent from a parent or legal guardian to participate in the survey (note that for simplicity, we refer to “parent” to reflect all guardians who provided consent from hereon). All participants (ie, 13-17 years of age) were required to have parental consent to participate in the focus group.

Ethical Considerations

This study was approved by the University of Saskatchewan Research Ethics Board (BEH 3013). Survey responses from participants aged 16-17 were anonymous. Participants aged 13-15 were known to the research team, but did not report identifying information in the survey and rather entered a participant ID to ensure that survey responses were from participants who had appropriate parental consent. Due to the nature of the focus groups, anonymity was not possible, but the importance of maintaining other participants' confidentiality was discussed prior to beginning each focus group. Survey participants were entered into a draw for 1 of 5 CAD $50 (approximately US $36.89) Amazon gift cards. Focus group participants received the choice of a CAD $50 honorarium or a CAD $50 Amazon gift card (approximately US $36.89) for their participation.

Measures

Needs Assessment Questionnaire

The 27-item needs assessment questionnaire was developed to gather information about adolescents’ (1) phone use patterns and preferences (5 items); (2) mindfulness knowledge and experiences (6 items); (3) pain knowledge and impact of menstruation on daily functioning (5 items); (4) use of existing menstrual and mindfulness apps (1 item); and (5) perceived barriers and facilitators of, interests in, and recommendations for a mindfulness app for adolescents with menstrual pain (6 items). Additionally, the questionnaire queried demographic information (4 items), including age, sex assigned at birth, gender identity, and ethnic or racial background. Question formats throughout the survey included yes or no questions (eg, “have you ever practiced mindfulness or meditated?”), multiple-choice responses (eg, “when do you experience the most pain or physical discomfort with your period [select all that apply]?”), 11-point numeric rating scales (eg, “what would you rate your level of understanding of what mindfulness is?”; 0=no understanding and 10=complete understanding), and open-ended questions (eg, “what would motivate you or help you to use the app to use mindfulness when you are experiencing period pain?”). The measure was developed by the first author (MMG) and reviewed by all coauthors and study research assistants.

Focus Group Interview Guide

A 10-question semistructured interview guide was developed by our multidisciplinary team and comprised questions that built upon the information gathered in the needs assessment survey. Participants were asked about their experiences with pain, including their understanding of contributors to their pain, their experiences with mindfulness, their experience with menstrual apps, their interest in using a mindfulness app for period pain, their perception of challenges and motivators for using health apps, and any suggestions to inform future app development.

Procedure

Phase 1: Web-Based Survey

Adolescents were the primary participants of this study; however, to increase enrollment, the parents of adolescents were also targeted throughout the recruitment and involved in the enrollment phase to provide consent for their adolescent to participate where needed. Participants were recruited using Facebook and Instagram advertisements posted on the research team’s Facebook and Instagram accounts targeting adolescents and parents of adolescents.

Participants aged 16 and 17 years accessed the survey via a link provided in recruitment materials. Prior to gaining access to the survey, participants were required to review the consent form outlining the rationale for the study, the duration of the survey, data storage and security, confidentiality measures, and their right to withdraw. After reviewing the consent form, participants provided their informed consent by proceeding to the next page of the survey. For participants aged 13-15 years, the interested adolescent or their parent completed a web-based form to indicate the adolescent’s interest in the study. A research assistant contacted the parents of each adolescent to confirm the adolescent’s eligibility and obtain parental consent. Adolescent assent was also obtained. Following receipt of consent and assent, the research assistant sent the adolescent a link to the web-based questionnaire.

The survey duration was approximately 10-20 minutes, and the survey was conducted via SurveyMonkey. All survey questions were voluntary and presented across 6 pages with backtracking enabled. Question randomization was not used, and no questions were conditionally displayed. The survey was distributed via 2 survey links: an open survey for adolescents 16-17 years, where IP addresses were used to identify unique survey respondents and prevent multiple, same-person responses, and a closed survey for adolescents 13-15 years, where the link was provided directly to participants by the researchers. Participants had the option of providing their email to be contacted regarding the focus group, entered into the draw for the gift card, or both.

Phase 2: Web-Based Focus Groups

Participants were recruited using Facebook and Instagram advertisements targeting adolescents and parents of adolescents posted on the research team's Facebook account. Additionally, phase-1 adolescents interested in participating in a focus group were able to indicate their interest at the end of the survey. Interested participants were contacted by a research assistant to schedule a consent and assent call via Zoom (Zoom Technologies Inc) with the adolescent and their parents. During the call, the research assistant reviewed the purposes of the study using a shared PowerPoint (Microsoft Corp) presentation. If the family remained interested in participating, the research assistant reviewed the consent and assent information with the family, enrolled the adolescent, and gathered demographic information.

Participants were enrolled in 1 of 3 groups based on their availability. Focus groups were conducted digitally via Zoom and were audio and video recorded to allow for later review. Each group had 4 to 7 participants and lasted up to 90 minutes. All researchers (ie, MMG, ARB, and a research assistant) involved in the focus groups were Canadian female individuals. Focus groups were led by 1 member of the research team and a second team member took field notes. Following the completion of the focus groups, audio from the groups were transcribed verbatim to allow for analysis.

Analytic Plan

Overview

Demographic information from the survey and the focus group were analyzed using descriptive statistics. Across both phases of the sequential explanatory design, we used SPSS (IBM Corp) to calculate quantitative results, and Microsoft Excel was used for the organization of narrative data. Survey responses and focus group responses were analyzed separately, and results were grouped based on findings that addressed each of the study objectives (ie, mindfulness knowledge and experience, dysmenorrhea knowledge and experiences, and app use preferences). Narrative responses from open-ended survey questions and phase-2 focus groups were examined using an experiential realist framework. In an experiential framework, the analyses aim to explore participants' understanding, while a realist framework aims to capture (rather than construct) the reality of participants within the data set [46]. This framework was chosen, given the study goal of understanding adolescents' experiences as a means of proposing concrete recommendations for app development.

Analysis of Survey Responses

Closed-ended survey questions from the needs assessment survey were analyzed using descriptive statistics. Open-ended questions of the needs assessment survey questions were examined question by question. Codes were formulated from responses with no limit placed on how many codes could be developed. Developed codes were then examined for similarities and grouped into themes. Theme frequency was reported to understand how important ideas were to adolescents compared to other ideas [47].

Analysis of Focus Group Responses

Reflexive thematic analysis [46] was used for analysis of the focus group data. Following verbatim transcription of the focus group recordings, an inductive (ie, data-driven) approach to examining the data was taken, with a focus on the semantic level of meaning of responses. Codes were formulated within each question of the focus group interview by 1 member of the research team (MMG), again with no limit placed on the number of codes, and similar codes were grouped to formulate themes. Reflexive thematic analysis involves critically considering the researchers' personal and professional experiences and biases that may impact data interpretation. The research team is interested in improving digital interventions, with backgrounds in nursing and psychology.

Synthesis of Qualitative and Quantitative Findings

To bring a comprehensive understanding of the ideas from each phase and research objective (ie, mindfulness, menstrual pain, and app preferences), the qualitative and quantitative findings were synthesized. The themes generated from focus groups were combined with survey findings related to mindfulness and dysmenorrhea knowledge and experiences and app use preferences to identify resulting needs for adolescents. Specific recommendations for future app development were then generated based on the combined results.

Results

Demographic Information

A total of 143 participants completed some portion of the survey and 108 (76%) completed the final page. Participants who had completed less than 80% of survey questions (n=32, 22%) were considered to have withdrawn and were removed, resulting in a final sample of 111 participants. Demographic characteristics of participants in both phases are summarized in Table 1.

Table 1. Demographic characteristics of survey participants (n=111) and focus group participants (n=16).

Characteristics	Survey participants	Focus group participants
Age (years)

[a] N/A: not applicable.

[b] Participants could provide a response in more than 1 category.

Phone and App Use

Among survey participants (n=111), 87% (n=95) had an Apple device and 14% (n=15) had an Android device. Most participants did not have unlimited data (n=70, 63%) or were unsure (n=9, 8%). Most used apps included social networking apps (n=107, 96%), utility apps (n=82, 74%), entertainment apps (n=81, 73%), productivity apps (n=69, 62%), and gaming apps (n=63, 57%).

Mindfulness Knowledge and Experiences

Survey Results

Nearly all survey participants (106/111, 95%) reported having heard of mindfulness. Participants reported a moderate understanding of mindfulness (mean 6.63, SD 2.32 out of 10; 0=no understanding and 10=complete understanding) and how to use mindfulness (mean 5.70, SD 2.59 out of 10; 0=no understanding; 10=complete understanding). Over three-quarters (87/111, 78%) of respondents reported having practiced mindfulness. The most common types of mindfulness activities used by 84 participants who reported any type of activity were meditation (n=57, 68%), yoga (n=53, 63%), breathing (n=32, 38%), music (n=17, 20%), movement (eg, walking; n=10, 12%), and art-based activities (eg, coloring; n=5, 6%). Among survey participants, 53 (48%) reported using meditation apps. YouTube (n=17, 32%), Spotify or other podcast apps (n=10, 19%), Headspace (n=8, 15%), and calm (n=7, 13%) were the most used meditation apps or websites.

Focus Group Results

Overview

Focus group participants were asked to discuss their experiences with mindfulness. Participants' experiences largely occurred in school settings, through their parents, or in mindfulness-based extracurricular, such as yoga classes. Three themes were generated based on participants' described experiences.

Theme 1: Discouraging School Experiences

Exposure to mindfulness at school was common and participants with this experience described challenges with learning mindfulness in this setting. Responses were categorized into 2 subthemes. The first subtheme related to *discontinued support.* Several participants reported that mindfulness was practiced throughout elementary and middle school but that in high school support from teachers in learning and practicing mindfulness stopped, making it difficult to maintain their mindfulness practice. This pattern of reduced support as students age was captured by a participant who described:

> *Before [in elementary school] it'd be every day we'd have something to do with [mindfulness]. Now [in high school] you kind of fend for yourself. You don't get too much support anymore.* [Participant 22, 13 years old]

A second subtheme related to the school setting being an *unconducive environment* for mindfulness was generated. Participants described difficulty practicing mindfulness at school because of distractions in the classroom. They also described feeling self-conscious due to having their peers around or being distracted by noise, which interfered with their perception of how helpful the practice was:

> *When we did it at school...there was a lot of people talking...and it makes it really hard to concentrate. So, I don't think it helps in large groups of people who don't want to take it seriously.* [Participant 42, 17 years old]

Theme 2: Personalization Needed

Participants described a need for mindfulness activities to be interesting or personalized to the individual. The generality of mindfulness was identified as a barrier to its use:

> *I do agree that mindfulness is important and applies to everyone and what can help anyone in many ways. But it doesn't necessarily seem all that inviting when it's super general.* [Participant 61, 16 years old]

Many participants identified yoga as a way through which they practiced mindfulness. Participants noted that not all youth found sitting and meditating to be the most beneficial approach. These ideas were captured by a participant who stated:

> *Some people, especially as teenagers with emotions and energy and whatnot, might find it hard to relax. I know a lot of people who just can't relax or [they] find it really hard to sit still and not talk, but I think mindfulness was a part of finding your way to do that. And if your way is movement or if your way is sitting there with your head down –mindfulness is finding a way that works for you in a way that you find beneficial.* [Participant 124, 14 years old]

Theme 3: Real-Time Use of Mindfulness Is Tricky

Integrating mindfulness into everyday life or sustaining a mindfulness practice was a challenge for youth. The challenges identified by youth included difficulty using mindfulness when it would be most needed, difficulty using strategies when busy, or the tendency to stop using mindfulness when there is no motivation to continue. A participant described the following experience trying to implement mindfulness on their own:

> *I think it did help in terms of lowering my heartrate and making me feel more calm and in the present. But I feel like sometimes when I try to incorporate it into my daily life it just never turns out right, because if I'm stressed, I can't think of a way to calm myself down. It just doesn't work for me that well.* [Participant 1, 16 years old]

The following quotation from a participant captured the challenges with sustaining the practice:

> *...because of COVID I had to stop going [to a yoga class] and now I'm so busy with schoolwork. So now [it's] just pushed aside and [after COVID-19] mindfulness isn't something I do once a week or something like that.* [Participant 21, 14 years old]

Dysmenorrhea Knowledge and Experiences

Survey Results

On average, adolescents who completed the survey rated their knowledge of contributors to period pain and symptoms as moderate (mean 5.39, SD 2.30 out of 10; 0=no knowledge and 10=extremely knowledgeable). They also reported moderate levels of knowledge related to how to manage their menstrual pain (mean 5.78, SD 2.46 out of 10; 0=no knowledge and 10=extremely knowledgeable). Most survey participants (97/111, 87%) reported using nonpharmacological pain management strategies to manage menstrual symptoms, including hot water bottles or heating pads (83/111, 75%), rest or sleep (81/111, 73%), baths or showers (73/111, 66%), exercise (28/111, 25%), relaxation exercises (21/111, 19%), and mindfulness or meditation (16/111, 14%).

Focus Group Results

Overview

Focus group participants were asked to discuss their understanding of factors that contribute to their pain, which resulted in 2 themes.

Theme 1: Wavering Degree of Control Over Menstrual Pain

Participants described their ability to control pain as a variable across their menstrual cycle and impacted by environmental and individual factors. This theme led to 3 subthemes related to the participants' experiences. The first subtheme related to how *context matters*. Participants described that the degree to which they felt comfortable in a situation affected their pain level. Being familiar and comfortable with those around them and being in low stress and calm situations were helpful in managing pain. Similarly, when participants felt in control of the situation, pain was easier to tolerate. This subtheme was captured by the following:

> *If you're somewhere comfortable where you know you have the resources...you feel a lot more comfortable when you get pain. When you're out in public or you have something to do that you need to do you're like a lot more uncomfortable, and it can even be worse because you're not like listening to your body.* [Participant 124, 14 years old]

The second subtheme related to *moments of helplessness* due to menstrual pain. Participants recognized that although pain was generally not constant, there were times in their lives when they felt a loss of control due to pain. This was reflected by 1 participant who stated:

> *I literally woke my parents up at night screaming because my cramps were so bad and I felt bad for screaming. But they hurt that much and that was to the point that one night my mom was like, ok, that's it, you're going on birth control. And I mean, it helps*

> *a bit. But, at the same time, I still get cramps and I'm nauseous, which makes me think maybe I should try a different birth control because in gym, if I go and do something, I get cramps just by doing stuff. And it's really annoying because when I have to go sit off to the side.* [Participant 143, 17 years old]

The final subtheme was *pain management is challenging.* Within this subtheme, there were varying perspectives related to how medication and self-care could be helpful. Several participants acknowledged being aware of activities they could do to help with pain but struggled to be motivated to engage in them. This challenge was well reflected by a participant who stated:

> *...doing exercise helps, but when I'm in pain, to actually start doing it is really, really hard. So, most of the time I just don't end up doing it because I don't feel like getting up and actually starting. But if I were to start, it would probably be better.* [Participant 127, 13 years old]

Within this subtheme, several participants also described medications as either being the only strategy that helped or the only treatment option available to them:

> *I have really bad period pain to the point where I had to get an [intrauterine device], because that was the only thing that would stop it, and then I still had to get prescribed naproxen. So, I know...people say, that exercising helps with period pain, but for me, I find it makes it worse. I cannot really keep doing anything. And, well, nothing will make it really better. Meds would but that's about it.* [Participant 118, 16 years old]

Theme 2: Mind-Pain Interaction

Participants identified a relationship between what went on in their minds and their menstrual pain. Several components of the "mind" influences were discussed by participants. For instance, they described being aware that engaging in another activity could help distract from the pain but that thinking about pain most often led to more pain:

> *I know for me when I have any type of pain, if I'm busy doing something all day or out with friends I don't really notice it as much. And then I come home and I'm lying in bed and it usually hurts more when I'm thinking about it. Then [the pain] usually just doesn't go away until I'm busy again or get myself watching a show or something, and then I just kind of forget about it.* [Participant 42, 17 years old]

Participants also believed that their mood, stress, or the anticipation of pain could increase pain. These ideas were captured in the following quote:

> *My mood definitely affects how it feels. When you're at school and you're getting stressed about something or you're doing physical activity at school or even if it's hanging out with...people who make you feel a certain way, whether that be stressed, annoyed, that sort of thing – it definitely aggravates how you feel. And then it aggravates how you're feeling in regards to your period, your pain.* [Participant 31, 15 years old]

Perceptions of Current and Potential App Use

Survey Results

Nearly two-thirds (70/111, 63%) of survey participants reported using a website or app to track their period, with Flo (34/111, 31%) and Clue (21/111, 19%) being the most common. Participants had a moderate perception that mindfulness could help cope with menstrual periods (mean 4.51, SD 2.45 out of 10; 0=not at all helpful and 10=extremely helpful). Approximately one-third (36/107, 34%) of participants provided a rating of 3 or lower out of 10 that mindfulness could be helpful, 43% (46/107) provided a rating from 4 out of 10 to 6 out of 10, and nearly a quarter (25/107, 23%) of participants provided a rating of 7 out of 10 or higher (Multimedia Appendix 3). Participants (n=111) indicated that if they were to use mindfulness during their period, they would likely use it 1-2 times (n=59, 53%) or 2-4 times (n=42, 38%). From a list of preferred app features provided to participants, adolescents were most interested in period tracking features, receiving feedback after logging pain and symptoms, and seeing insights into their mindfulness use (Table 2).

Table 2. Survey participants' endorsement of each proposed app feature.

App feature[a]	Values (n=110), n (%)
Charts that track your pain from period to period	99 (89)
Receiving feedback after logging your menstrual pain (eg, recommendations to help manage pain)	98 (88)
Seeing how you are doing over time with practicing mindfulness (eg, tracking chart and number of minutes practiced)	75 (68)
Notifications reminding you to track your period	75 (68)
Charts that track other aspects of your period from period to period	67 (60)
Receiving positive feedback after logging your mindfulness practice (eg, way to go! and congratulations!)	66 (60)
Notifications reminding you to practice mindfulness	47 (42)
Sharing how you have been doing on the app with family and friends	10 (9)
Other	13 (12)

[a] Participants could provide a response in more than 1 category.

Survey participants were asked to indicate what would motivate and deter them from using an app for mindfulness when experiencing period pain. The themes from survey participant responses and the frequency of these responses are summarized in Table 3. Reminders to use the app, the app being effective in reducing their pain or increasing knowledge about periods, and the app being engaging were identified as essential motivators. Common barriers included the app not being free, being difficult to use, or having ads.

Table 3. Barriers and facilitators to app use among survey participants.

Barriers and facilitators	Values (n=111), n (%)
Themes related to facilitators to use[a]	
Reminders	32 (30)
Effective	16 (15)
Engaging or rewards	14 (13)
Encouraging or inspiring messaging	11 (10)
Design or aesthetic	8 (8)
Research evidence	8 (8)
Charts or tracking	6 (6)
Feedback	5 (5)
Other	6 (6)
Themes related to barriers to use[a]	
Not free	22 (22)
Difficult to use (eg, complicated, glitches, or lags)	21 (21)
Ads	19 (19)
Too many notifications	15 (15)
Visually unappealing or poor design	14 (14)
Not helpful	9 (9)

[a] Participants' responses were categorized into more than 1 theme, when applicable.

Focus Group Results

Overview

Focus group participants were asked to consider how or when they could see themselves using a mindfulness app to help with their period pain. Two themes were generated.

Theme 1: Manage Painful Parts of Period

Adolescents were most willing to consider using an app during the painful parts of their period. Several indicated they might not be motivated to use the app during parts of their cycle when they did not experience pain.

> *I would probably use it the first three days when I start [my period], because that's when the pain is the*

> *worst. But then after that it’s just fine. So, then I'm good.* [Participant 81, 14 years old]

Participants also noted that an app that helped with the management of severe pain would be beneficial if it provided tools that could be used when not feeling able to move due to pain. This was reflected by the following response:

> *I just think when I see things like “go out and take a hike, breathe some nature,” I'm not feeling very obligated to do that when I'm in my sweatpants and my hair's a mess. I don't really want to do that. But, you know, little things that I can do from the comfort of my bathroom floor would totally help me out in that second and third day during my cycle.* [Participant 119, 17 years old]

Theme 2: Navigate Emotions During Menstrual Cycle

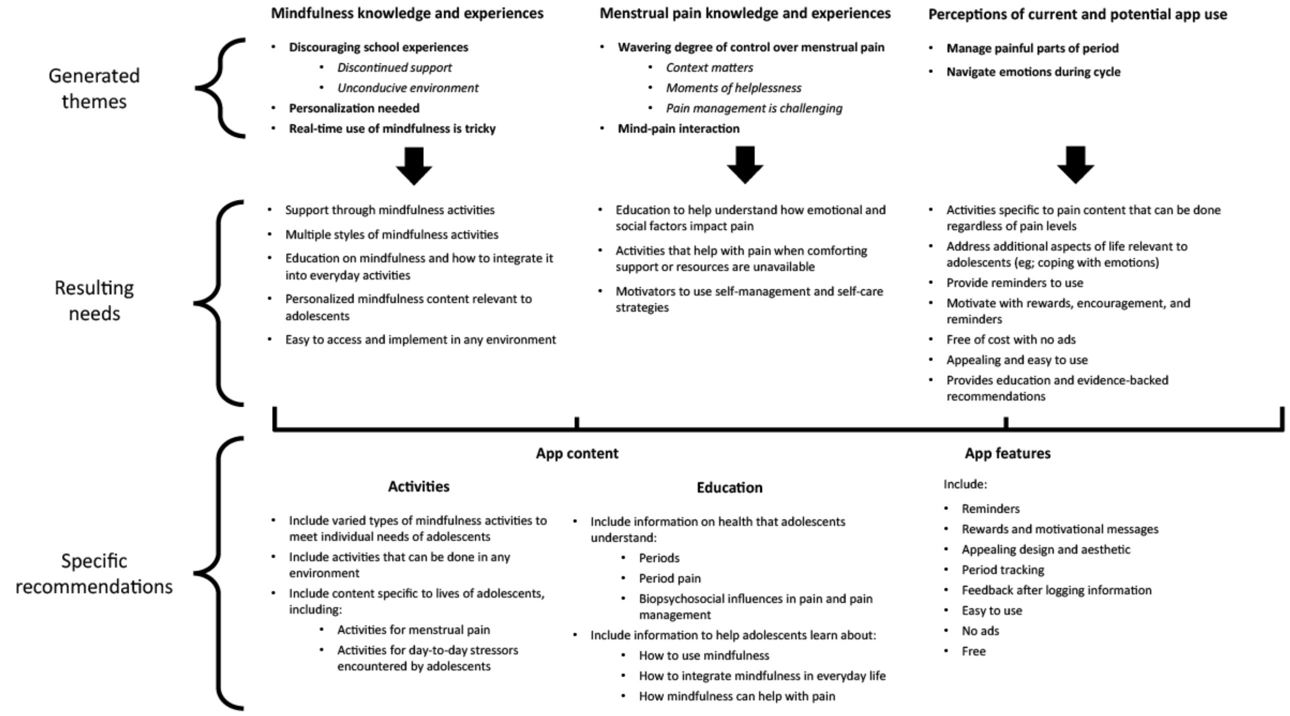
Participants frequently mentioned that emotions that occurred around the time of their period could lead to challenges in their lives. Participants discussed that having tools to manage these emotions would be useful and that they would be motivated to use an app that addressed aspects of their lives beyond pain. For instance, 1 adolescent stated:

> *If it was paired with things I can do to manage those extreme emotions, that would be so incredibly helpful. That would really help me out because paired on top of teenage hormones, mental illness, and then that period pain and that irritability, things get wild. So, it would really be helpful if I had something like that in place.* [Participant 119, 17 years old]

Synthesis of Results: A Summary Model

The findings from the data synthesis process are summarized in Figure 1. The 7 themes and 5 subthemes generated throughout the focus group analysis were merged with survey findings to result in 5 needs related to mindfulness, 3 needs related to menstrual pain, and 7 needs related to app use in menstruation (Figure 1). This process of connecting findings across phases allowed for the development of specific recommendations for future app development. Recommendations were divided into content recommendations and design or app feature recommendations.

Figure 1. Summary model of survey and focus group findings. Generated themes and survey responses were transformed into resulting needs. From the needs, specific recommendations are made for content and features of a future app.



Regarding content recommendations, adolescents wanted information specific to dysmenorrhea, along with activities and information relevant to the experiences and emotions of adolescent life. To counteract inconsistent school support, the app should provide easy access to ongoing support and be usable in any environment. Education content needs to improve understanding of periods, pain, and emotions; evidence-based information is important to youth. Education content needs to outline how mindfulness can help with pain and day-to-day experiences. Recommendations related to features include continuous access, being visually appealing and easy to use, having motivators or rewards built in, having reminders, and that the app be ad-free and of no cost.

Discussion

We examined the specific needs and experiences of adolescents to inform the future development of a mindfulness-based, self-management app for dysmenorrhea. Overall, there was general agreement that mindfulness could be helpful for dysmenorrhea. In line with findings from other researchers [48], many adolescents engaged in some form of nonpharmacological pain management. However, participants reported experiencing pain management challenges and feelings of helplessness around pain, and this was the case even among some participants who used pharmacological options. This is not surprising given that prescribed medications are estimated to only work for a quarter of individuals who use them [8]. Only a small percentage of this survey sample used meditation or mindfulness to manage their menstrual symptoms. Despite low use of mindfulness specifically for menstrual pain, most youth surveyed had used apps or websites to access mindfulness activities, suggesting interest in these approaches for developing mindfulness skills.

Over half of the survey participants had experience with mindfulness, with exposure in school being common, albeit suboptimal. This is consistent with research showing that school-based mindfulness programs may not be effective [49]. Focus group participants provided insight into the reasons for this, including the environment being distracting and the inconsistent support that occurs in school settings. These findings suggest that future app-based interventions need to provide easy and continuous access to guided mindfulness activities. This could be achieved through ongoing access to the app and supportive information in the app, or by the inclusion of some form of app-based mindfulness coaching (eg, access to professional or peer support).

The need for a personalized experience was evident across themes. In school settings, focus group participants were dissatisfied with the generality of mindfulness programs and desired activities tailored to their personal preferences. Difficulty being still and staying engaged with meditations are common for youth [50], and many survey and focus group participants identified active forms of mindfulness, such as yoga, as beneficial. Adolescents also desired a variety of mindfulness activities based on their pain level; mindfulness activities that could be performed lying down when experiencing incapacitating pain were requested by some participants, which contrasted with other youth who preferred movement-based mindfulness activities for when the pain was tolerable. Overall, these diverse needs illustrate that app-based interventions must offer the ability to select from a variety of activities based on personal preference and pain level.

The need for personalization in relation to app content was also identified. Focus group participants voiced the desire for an app that addresses the unique needs of youth, including navigating difficult emotions that may occur throughout adolescence. In line with well-established research across pain conditions [51], adolescents noted increased pain when experiencing strong emotions, as well as pain being exacerbated by social or situational factors. Focus group participants' desire for the inclusion of mindfulness activities that address mental, social, and physical aspects of their day-to-day lives is an important finding of this investigation.

Participant responses also pointed to a need for educational content relevant to early menstruators. Survey participants indicated that evidence-based information explaining how mindfulness may improve pain would motivate them to use the app. Although a general understanding of dysmenorrhea was reported by participants, previous research has found that most youth desire more information about menstrual health [3]. Education programs offered to young women to improve knowledge of dysmenorrhea are effective and increase knowledge and the likelihood of seeking professional help [52].

Across our findings, the importance of a biopsychosocial focus to any future app is evident from the participants' indication that an app needs to address various aspects of their lives and participants' understanding that their pain is affected by more than just their physical experiences. Biopsychosocial considerations are often overlooked in the context of dysmenorrhea [53]; yet, psychoeducation about the biopsychosocial nature of pain is an integral piece to pain management programs [51]. Such educational information may help adolescents engage with psychological approaches and understand how they may apply in the context of period-related pain. Psychoeducation on mindfulness and how it might affect pain would also be relevant in addition to mindfulness activities.

Overall, our findings reflect the relevance of conducting a needs assessment as adolescents provided insightful information into the needs of a future app, which may have been overlooked. In line with a user-centered design, future phases of app development should engage youth to evaluate app content and design to improve the engagement of youth in the app. Nevertheless, this study is not without its limitations. Our sample size is small as the purpose was to understand users' needs rather than to gain an understanding of the prevalence of experiences. Participants were predominantly White and identified as a woman or girl. Adolescents who participated may have had more interest in or knowledge of the topic of menstrual pain than those who did not. As the research was conducted in Canada, menstruation was likely being considered through a Western lens. The generalizability of our findings across diverse populations, including cultural and gender identities, as well as countries with lower access to mobile phones, is limited. Other evidence-based interventions, such as cognitive-behavioral therapy, were not considered in this investigation and may provide valuable alternatives to mindfulness-based approaches.

Dysmenorrhea is common in adolescence, and many adolescents are not receiving adequate treatment for their dysmenorrhea, which is problematic given the established consequences of unmanaged pain. Digital interventions that offer nonpharmacological support for dysmenorrhea may be beneficial. Our findings provide an important framework for future app development. Specific content and app feature recommendations were identified and derived directly from adolescents' preferences and needs. Incorporation of these user recommendations in subsequent app design phases may lead to improved engagement and efficacy of digital intervention, ultimately leading to improvements in the experiences of youth with dysmenorrhea.

Abstract

Background: Social media has become a popular method to recruit participants, particularly for studies with hard-to-reach populations. These studies still face challenges in data quality and, for longitudinal studies, sample retention. However, in addition to aiding in recruitment, social media platforms can help researchers with participant verification and tracking procedures during the study. There is limited previous research describing how longitudinal studies can use social media to screen and retain participants.

Objective: This paper describes strategies implemented to screen and retain a nationwide sample of sexual minority youth who were recruited through social media platforms for a longitudinal study testing a drug abuse prevention program.

Methods: Our screening strategies for participants included collecting necessary demographic information (name, phone, email, and social media accounts), verifying this information using publicly available web-based records, and sending confirmation emails to ensure working email addresses and correct dates of birth. Retention strategies included communications designed to develop positive participant relationships, incentives for survey completion, regular updating of participant contact information, targeting hard-to-reach participants, and using social media as an alternative means of contacting participants.

Results: During enrollment, although the only demographic data required were a phone number and an email address, 87.58% (1065/1216) of participants provided their Instagram as an alternative means of contact. This form of alternative communication remains the most preferred with 87.40% (1047/1198) of participants continuing to provide an Instagram username as of January 2023, about 3 years after recruitment began. In comparison, other alternative means of contact (eg, Facebook and alternative email) were provided by only 6.43% (77/1198) to 56.18% (673/1198) of participants. Direct messaging on Instagram was used to successfully confirm participant identity, remind participants to take annual follow-up surveys, and update lost participant contact information. Screening and retention strategies used in the study have helped achieve 96.30% (1171/1216) to 96.79% (1177/1216) sample retention across 3 waves of data collection.

Conclusions: Though social media can be a helpful tool to recruit participants, attrition and participant authenticity difficulties may be associated with this method. Screening and retention strategies can be implemented to improve retention. Internet searches are effective for screening youth to ensure they meet eligibility requirements. Additionally, social media—Instagram in this study—can help to track and locate participants who do not respond to traditional contact methods.

Introduction

With the rise in social media popularity, web-based recruitment methods for clinical trials have become increasingly popular. Social media allows researchers greater access to nationwide samples [1]; adolescents [2-6]; and hard-to-reach populations [7,8], such as sexual minority individuals [9-13] and people who use substances [14-16]. However, some research has associated web-based recruitment with lower retention rates than in-person recruitment methods [17,18]; researchers have theorized that web-based recruitment lacks the connection and commitment from participants that come from in-person recruitment [18]. Further, there is a greater opportunity in longitudinal studies to lose participants over time due to changes in contact information or the desire to no longer participate in the study [19]. Thus, longitudinal studies that recruit through social media are at high risk for participant attrition.

Despite these challenges, researchers have identified methods to increase retention rates of samples recruited on the web, including frequent communication between surveys [20], financial incentives [21], and building positive rapport with participants [21,22]. Previous research has been able to maintain high retention rates after recruiting participants on social media. One study recruited youth aged between 12 and 25 years using advertisements on social media, Google, Craigslist, and a web-based neighborhood forum; they found retention rates of 78.11% at the 3-month follow-up and 72.18% at the 6-month follow-up [23]. Another study recruited using a similar method of advertising on social media, a collaborating website, and a newsletter and found a retention rate of 88.4% at the 2-week follow-up [24]. Our previous research has used social media (eg, Facebook advertisements) to recruit youth for 2 longitudinal web-based drug abuse prevention programs that maintained retention rates of 97% at the 1-year follow-up [25] and 84.75% at 3-month follow-up [13].

Much of what researchers know about using social media recruitment strategies comes from reports using Facebook. Several studies and systematic reviews have confirmed that advertising on Facebook is more cost-effective and time-efficient than in-person recruitment [7,8,14,15,26,27]. Facebook has also been a valuable tool for locating and communicating with participants in longitudinal studies [28,29]. However, trends in social media have shifted in recent years, especially among younger demographics. In 2015, 71% of teenagers reported using Facebook, while only 52% reported using Instagram [30]. This was notably different in 2022 when 32% of teens reported using Facebook, while 62% reported using Instagram [31]. Instagram has already been used as a successful tool in recruiting sexual and gender minority adolescents and young adults [32-38]. Thus, in 2020, we used Facebook and Instagram to recruit for Free2b, a nationwide 5-year web-based drug abuse intervention program for sexual minority youth (ClinicalTrials.gov NCT03954535).

Though recruiting on social media is cost-effective, timely, and grants access to large and diverse samples, it does not guarantee the authenticity of participants that in-person recruitment allows [39,40]. Social media recruitment requires a thorough screening process to confirm and ensure the legitimacy and eligibility of potential participants. However, thorough screening processes may lead to a more committed sample that can withstand attrition typically seen in longitudinal studies recruited on the web. Throughout the Free2b study, we also used Facebook and Instagram to verify youth's identities, maintain contact with participants, and locate hard-to-reach participants. To date, little has been published on the use of social media to screen and retain participants in a longitudinal study. This paper describes how thorough screening processes using internet searches and social media, Instagram in particular for sexual minority youth samples, along with a range of retention strategies, help maintain retention in longitudinal clinical trials for youth recruited through social media.

Methods

Social Media–Based Recruitment

We used Facebook ads and Instagram promoted posts to recruit participants for a longitudinal trial of a drug abuse prevention program called Free2b. By clicking an ad or post, youth were taken to the study recruitment website. This website contained a brief consent video about study procedures, duration, compensation, and eligibility criteria (English speaking; aged 15 years or 16 years; US resident; access to the internet through computer or tablet; and identifying as lesbian, gay, bisexual, queer, or questioning [LGBQ]). At the conclusion of the video, youth who were still interested in participating could connect to a web-based informed assent quiz. The quiz assessed youth's knowledge of study aims, procedures, risks, protections, and compensation. Youth who passed the quiz were then allowed to consent to study participation.

Consented youth were asked to provide demographic information: first name, last name, sexual orientation, date of birth, primary and alternative email, primary and alternative phone number, social media handles (Instagram, Facebook, Twitter, and alternative social media), zip code, and alternate contact information (optional). Youth were expressly told that the alternate contact would only be used if their other forms of contact no longer worked. IP addresses were automatically collected upon form submission.

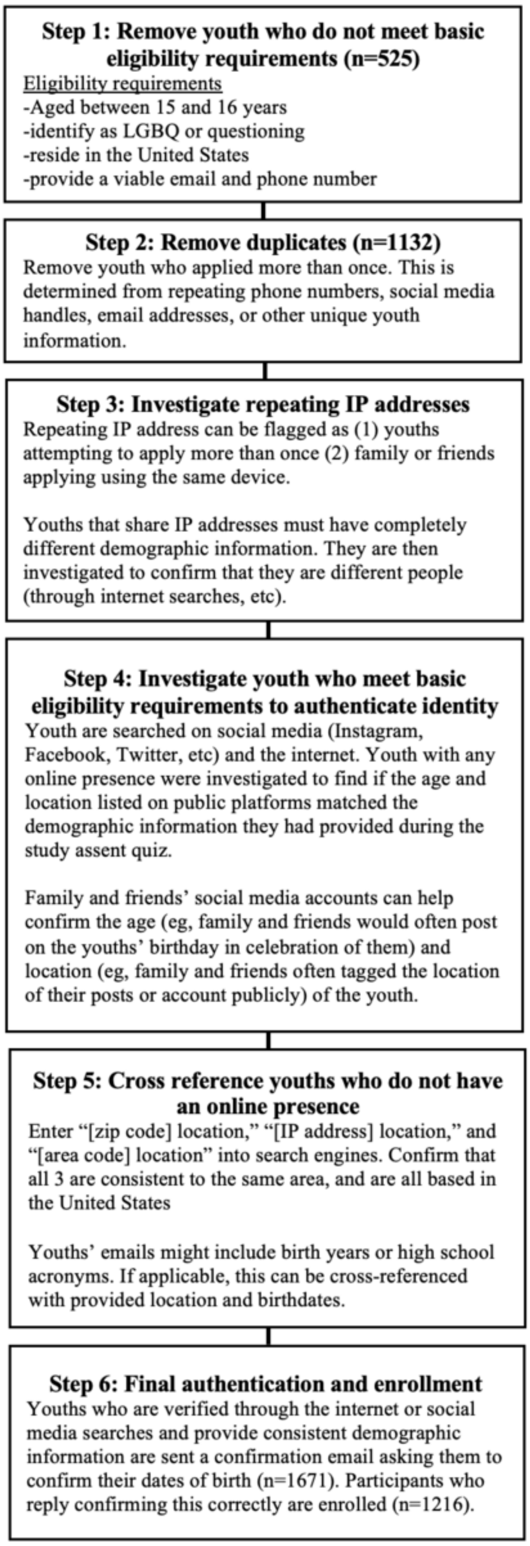
Eligibility Screening and Enrollment

The process to screen consented youth was systemized for research assistants (RAs). RAs were trained to use the steps outlined in Figure 1 to help ensure the authenticity of consenting youth. First, we removed youth who did not meet eligibility requirements: aged between 15 and 16 years, identify as LGBQ or questioning, reside in the United States, and have a phone number and email address. We then removed duplicate names, phone numbers, email addresses, and IP addresses.

To the extent possible, the demographic data from youth who had consented were cross-referenced with information from web-based searches and the social media handles the youth provided. Google searches of names with zip codes often confirmed their existence, location, and age. For example, high school athletes may have profiles showing their names and grades in school. Social media accounts could confirm age and location. Instagram and Twitter bios frequently contained age, high school, and city. Posts and tagged posts were also useful when they referenced birthday celebrations. Confirming sexual orientation was not a required element of screening as many adolescents have not publicly disclosed their sexual orientation and because sexual orientation often changes during adolescence [41]. However, when a lesbian, gay, bisexual, trans, queer, or questioning [LGBTQ] symbol or post was present on youth's social media, it was noted as a point of authenticity; the lack of such content did not exclude youth from the study. For youth with private or limited social media accounts or no web-based presence, we used other methods to help confirm their identities. For instance, an IP address, cell phone area code, and zip code that correlated helped verify a youth's authenticity; sometimes an email address included a birth year that matched their provided age or included a name that matched their provided first and last name.

Once youth cleared the aforementioned steps, we sent them an email asking them to reply back confirming the contact information they provided after consenting and we asked them to provide us with their birthdate. Only youth who replied to this email and who accurately confirmed the birthdate they provided during consent were enrolled in the study and randomly assigned to a study condition.

Figure 1. Flowchart of screening strategies implemented during the recruitment phase. LGBQ: lesbian, gay, bisexual, queer, or questioning.



Step 1: Remove youth who do not meet basic eligibility requirements (n=525)

Eligibility requirements
-Aged between 15 and 16 years
-identify as LGBQ or questioning
-reside in the United States
-provide a viable email and phone number

Step 2: Remove duplicates (n=1132)

Remove youth who applied more than once. This is determined from repeating phone numbers, social media handles, email addresses, or other unique youth information.

Step 3: Investigate repeating IP addresses

Repeating IP address can be flagged as (1) youths attempting to apply more than once (2) family or friends applying using the same device.

Youths that share IP addresses must have completely different demographic information. They are then investigated to confirm that they are different people (through internet searches, etc).

Step 4: Investigate youth who meet basic eligibility requirements to authenticate identity

Youth are searched on social media (Instagram, Facebook, Twitter, etc) and the internet. Youth with any online presence were investigated to find if the age and location listed on public platforms matched the demographic information they had provided during the study assent quiz.

Family and friends' social media accounts can help confirm the age (eg, family and friends would often post on the youths' birthday in celebration of them) and location (eg, family and friends often tagged the location of their posts or account publicly) of the youth.

Step 5: Cross reference youths who do not have an online presence

Enter "[zip code] location," "[IP address] location," and "[area code] location" into search engines. Confirm that all 3 are consistent to the same area, and are all based in the United States

Youths' emails might include birth years or high school acronyms. If applicable, this can be cross-referenced with provided location and birthdates.

Step 6: Final authentication and enrollment

Youths who are verified through the internet or social media searches and provide consistent demographic information are sent a confirmation email asking them to confirm their dates of birth (n=1671). Participants who reply confirming this correctly are enrolled (n=1216).

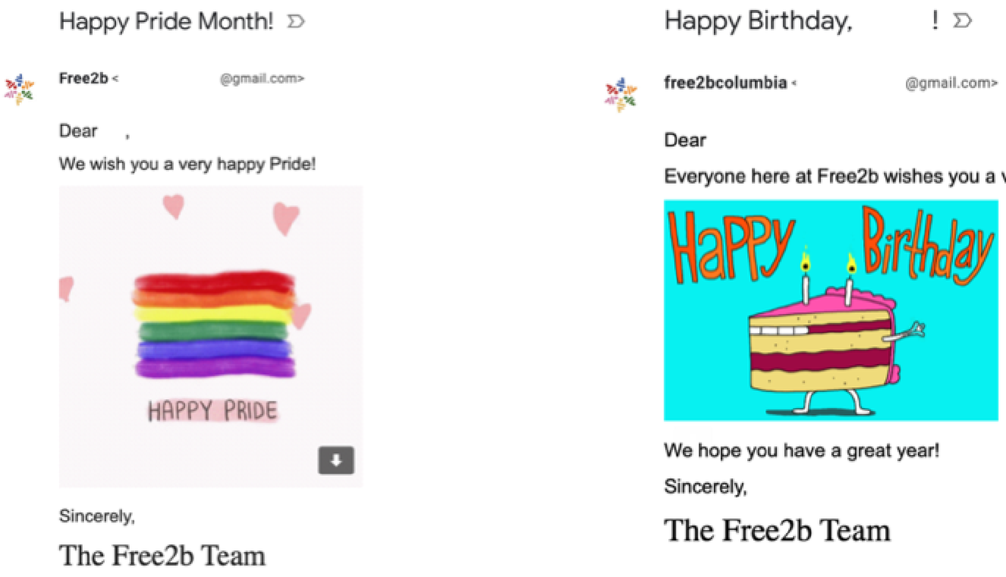
Building Positive Relationships With Participants

Building rapport with participants is important in longitudinal studies to help maintain retention [42,43]. RAs were trained to use a friendly and appreciative communication style to communicate with participants through phone calls, text messages, emails, and direct messages (DMs) on social media. The language used in messages and calls was positive, supportive, understanding, and appreciative of participants' time. For example, RAs frequently started messages with language that acknowledged participants' busy schedules (eg, "I know it's the beginning of the school year and things are probably pretty hectic right now.") to convey an understanding that the study surveys were unlikely to be their priority.

Given our understanding that participants were busy, we maintained the philosophy that no participant is "lost" unless we have no working contact information. However, even when a participant met the standards to be considered "lost," they were not removed from the study. This allowed us to recover participants who may have chosen to skip a survey one year, but then chose to take the next year's survey.

We also built positive relationships by honoring when participants requested needing more time to complete a survey (eg, during finals week). Annual holiday and birthday texts and emails (Figure 2) helped maintain contact but also served to build rapport. Email correspondence encouraged participants to contact us with questions or concerns and included the study phone number and the principal investigator's phone number and email to facilitate this contact.

Figure 2. Examples of holiday and birthday messages sent to participants throughout the study.



Happy Pride Month!

Free2b < @gmail.com>

Dear ,

We wish you a very happy Pride!

Sincerely,

The Free2b Team

Happy Birthday, !

free2bcolumbia < @gmail.com>

Dear

Everyone here at Free2b wishes you a very happy birthday!

We hope you have a great year!

Sincerely,

The Free2b Team

Communication Strategies

Given the importance of sample retention to longitudinal research, timely communication with participants is essential. Project email and social media accounts were checked regularly; RAs were expected to respond immediately to participants' texts, phone calls, emails, or DMs on social media. Each interaction was logged in a shared database to record contact history. This record helped determine the best methods of contact for a participant. Before making contact, RAs read through a participant's contact log for previous successful contacts (eg, a participant might respond to texts more often than calls). RAs were also instructed to vary their contact methods, switching between text, email, voicemail, or social media. These methods increased the chances of participants seeing our communication attempts. We also made an effort to send messages with different wording or images (eg, for holiday cards each year) to participants, rather than repeatedly sending the same template message. This helped our communication come across as individually tailored, rather than as an automated message to all participants.

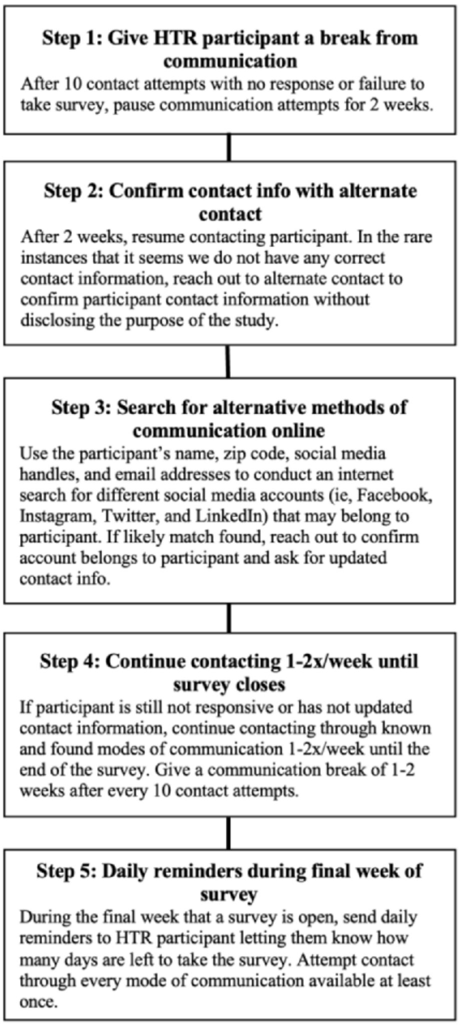
Finally, RAs were instructed to maintain frequent communication and reminders without overwhelming participants. As described earlier, they often started texts and phone calls with understanding language. Additionally, most reminders to take surveys included a link so participants would not have to go through their inbox to find the original survey reminder. When talking to participants on the phone, RAs always offered to send a follow-up text or email with the survey link. Finally, if a participant had not taken a survey after numerous reminders, or they mentioned that they are busy with other activities, we offered to pause communications and asked them when they would like us to check back.

Update Contact Info Surveys

To minimize the likelihood of losing participants between annual surveys due to changes in their contact information, we attempted to update participant contact information quarterly. We provided participants with their phone number or phone numbers; email address or email addresses; social media account handles; zip code; and if they have provided one, their alternate contact's phone number in a brief web-based form. If all of their contact information was up to date, they simply clicked "correct," or they could update their information if necessary. Youth could also continue to provide no alternate contact, add an alternate contact, remove the alternate contact they had provided, or change the one they provided.

Inevitably, some participants are lost over time due to frequent changes in contact information, competing priorities for time, or loss of interest in continuing in the study [44]. If we reached out to a participant more than 10 times with no response, they were considered "hard-to-reach." RAs were trained on standard protocols for contacting hard-to-reach participants (Figure 3). Once a participant became "hard-to-reach," we took a break from contacting them for several weeks. We then conducted an internet search and used social media to try to reconnect. In the rare instance that a cell phone and email was no longer working, and we were confident we were no longer reaching the participant, we discreetly reached out to their alternate contact without disclosing the purpose of the study. Youth who were considered "hard-to-reach" were always asked if they would like to be removed from the study or take a break from participation so that we did not bother them unnecessarily or needlessly spend time trying to collect survey data. Though some youth who did not respond to our survey reminders may no longer have wished to participate, we did not make this decision for them.

Figure 3. Flowchart of steps taken to contact hard-to-reach (HTR) participants and remind them to complete annual surveys.



Step 1: Give HTR participant a break from communication
After 10 contact attempts with no response or failure to take survey, pause communication attempts for 2 weeks.

Step 2: Confirm contact info with alternate contact
After 2 weeks, resume contacting participant. In the rare instances that it seems we do not have any correct contact information, reach out to alternate contact to confirm participant contact information without disclosing the purpose of the study.

Step 3: Search for alternative methods of communication online
Use the participant's name, zip code, social media handles, and email addresses to conduct an internet search for different social media accounts (ie, Facebook, Instagram, Twitter, and LinkedIn) that may belong to participant. If likely match found, reach out to confirm account belongs to participant and ask for updated contact info.

Step 4: Continue contacting 1-2x/week until survey closes
If participant is still not responsive or has not updated contact information, continue contacting through known and found modes of communication 1-2x/week until the end of the survey. Give a communication break of 1-2 weeks after every 10 contact attempts.

Step 5: Daily reminders during final week of survey
During the final week that a survey is open, send daily reminders to HTR participant letting them know how many days are left to take the survey. Attempt contact through every mode of communication available at least once.

Ethical Considerations

Study procedures were approved by the Columbia University Institutional Review Board (IRB-AAAR5072). A waiver of parental permission was granted to reduce risks; such waivers may also increase participation from adolescents who are not out to their parents [45]. Because our sample could be considered a vulnerable population, a detailed data and safety and monitoring plan was also established, and a Data and Safety Monitoring Board met no less than once a year. A primary charge for the Data and Safety Monitoring Board in year 1 was to review Institutional Review Board–approved recruitment and informed consent procedures.

After completing the aforementioned consent processes, participants received US $30, US $35, US $40, US $45, and US $50 for each of the 5 waves of data collection (pretest; posttest; and 1-, 2-, and 3-year follow-up, respectively). Participants were able to choose from several e-gift card options. As soon as a survey was completed, participants were notified that they would receive their e-gift card within 36 hours. Sending e-gift cards in a timely manner showed our appreciation and helped maintain positive relationships with participants. We also reminded participants to redeem their gift cards when they were close to expiring.

Results

Rates of Provided Participant Contact Information

All participants were required to provide a primary email and phone number in order to be enrolled in the study, but 11.76% (143/1216) also provided an alternative phone number and 51.23% (623/1216) provided an alternative email. At the time of recruitment, 87.58% (1065/1216) of enrolled Free2b participants provided an Instagram account as part of their contact information, as compared to 19.98% (243/1216) providing an alternate contact (eg, family or friends), 15.13% (184/1216) providing a Facebook account, and 29.03% (353/1216) providing an alternative social media account (eg, Twitter, Tumblr, or TikTok). Only 10.61% (129/1216) provided no form of alternate contact or social media accounts (Table 1). The percentage of participants with an Instagram account has remained relatively stable in the approximately 3 years since recruitment. Throughout the study, Instagram has remained the most commonly provided alternative method of contact. As of

January 2023, a total of 87.40% (1047/1198) of Free2b participants have provided Instagram handles, while only 22.37% (268/1198) of participants have provided an alternate contact with a cell phone number, 19.37% (232/1198) have provided a Facebook account, 30.47% (365/1198) have provided an alternative social media account, 6.43% (77/1198) have provided an alternative phone number, and 56.18% (673/1198) have provided an alternative email.

Table 1. Number of participants who provided each type of alternative contact information at enrollment and 3 years after recruitment.

Type of contact information	At enrollment (2020; n=1216), n (%)	Currently (January 2023; n=1198), n (%)
Alternate contact	243 (19.98)	268 (22.37)
Alternative email	623 (51.23)	673 (56.18)
Alternative number	143 (11.76)	77 (6.43)
Facebook	184 (15.13)	232 (19.37)
Instagram	1065 (87.58)	1047 (87.40)
No alternate contact number or social media	129 (10.61)	117 (9.77)
Other social media	353 (29.03)	365 (30.47)

Direct Messaging and Locating Hard-to-Reach Participants Through Social Media

If participants have not taken their surveys after multiple automated reminders, they are added to a "call list" to receive personalized communication from RAs. First, RAs attempt to contact them through traditional contact methods (phone calls, text messages, and emails); if this is not effective, they begin adding social media contacts (eg, direct messaging on Instagram) in addition to traditional methods. Of the 17 participants on the call list for Survey 1 who completed the survey, 100% received only traditional contacts, and 0% received a combination of traditional and social media contacts. Of the 102 participants on the call list for Survey 2 who completed the survey, 71.6% (73/102) received only traditional contacts and 28.4% (29/102) received a combination of traditional and social media contacts. Of the 100 participants on the call list for Survey 3 who completed the survey, 77% (77/100) received only traditional contacts and 23% (23/100) received a combination of traditional and social media contacts. Finally, of the 121 participants on the call list during Survey 4 who completed the survey, 81.8% (99/121) received only traditional contacts and 18.2% (22/121) received a combination of traditional and social media contacts (Table 2).

Table 2. The percentage of participants who were on the call list and then took the survey after traditional contact (phone and email) versus a combination of traditional and social media (eg, Instagram direct messages) contacts.

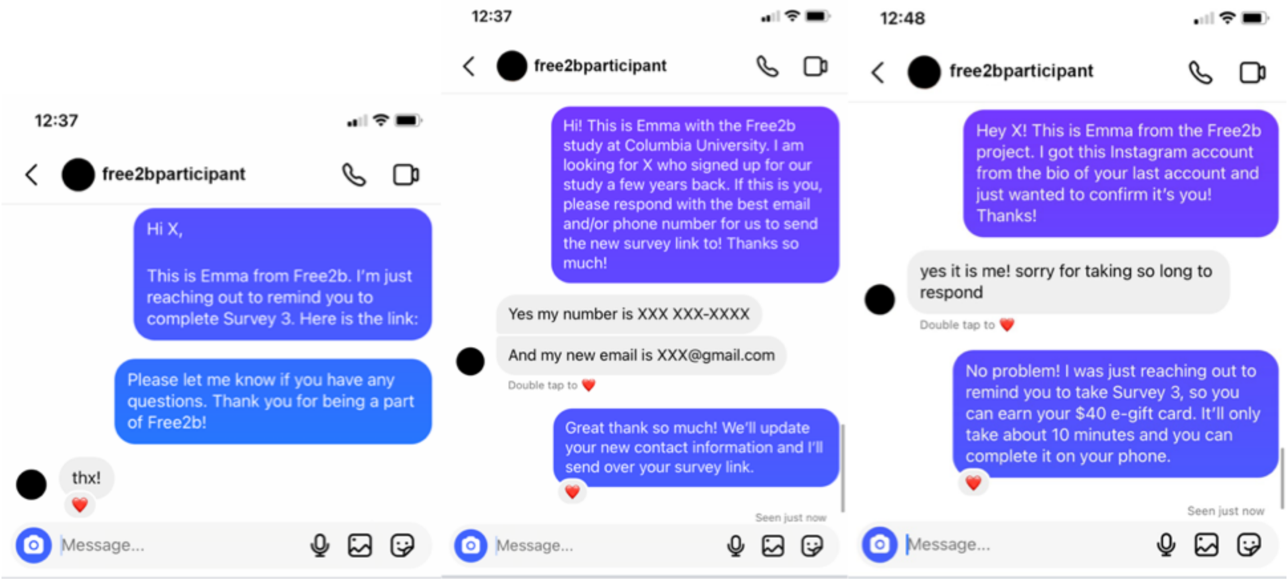
Survey number	Combination of traditional and social media contacts, n (%)	Traditional contacts (phone and email), n (%)
Survey 1 (n=17)	0 (0)	17 (100)
Survey 2 (n=102)	29 (28.4)	73 (71.6)
Survey 3 (n=100)	23 (23)	77 (77)
Survey 4 (n=121)	22 (18.2)	99 (81.8)

Social Media Versus Traditional Contact Methods for Survey Reminders

Both Instagram and Facebook offer a direct messaging feature. However, unlike our attempts to communicate with participants through Facebook DMs, communication through Instagram DMs was frequently successful. As seen in the left screenshot in Figure 4, an anonymized recreation of an interaction with a study participant, Instagram DMs resulted in direct replies or liked messages. Instagram also notified us when the participants read our DMs by displaying "seen" under read messages. Moreover, success of Instagram survey reminders was evidenced by the completion of surveys soon after DM reminders: of the participants who received social media contacts, 41% (12/29) completed Survey 2, 39% (9/23) completed Survey 3, and 27% (6/22) completed Survey 4 within 48 hours of being sent a reminder through DM. In particular, Instagram proved to be a useful method for contacting hard-to-reach participants, who otherwise did not respond to calls, texts, and emails to take follow-up surveys. Attempts to contact participants on Facebook did not yield similar results.

Instagram was also a helpful tool for finding lost participants for whom we had no working contact information. When a participant was "lost," we used Google to search for the participant's new social media accounts. Both Facebook and Instagram were used to DM lost participants, but only Instagram resulted in successful participant discoveries (middle and right screenshots in Figure 4). Despite the success that these examples indicate, there were still instances where our Instagram DMs were ignored, never seen, or we were simply unable to send messages to participant accounts.

Figure 4. Examples of interactions with participants through direct messages on Instagram that have been recreated and anonymized.



Hi X,

This is Emma from Free2b. I'm just reaching out to remind you to complete Survey 3. Here is the link:

Please let me know if you have any questions. Thank you for being a part of Free2b!

thx!

Hi! This is Emma with the Free2b study at Columbia University. I am looking for X who signed up for our study a few years back. If this is you, please respond with the best email and/or phone number for us to send the new survey link to! Thanks so much!

Yes my number is XXX XXX-XXXX

And my new email is XXX@gmail.com

Great thank so much! We'll update your new contact information and I'll send over your survey link.

Hey X! This is Emma from the Free2b project. I got this Instagram account from the bio of your last account and just wanted to confirm it's you! Thanks!

yes it is me! sorry for taking so long to respond

No problem! I was just reaching out to remind you to take Survey 3, so you can earn your $40 e-gift card. It'll only take about 10 minutes and you can complete it on your phone.

Retention Strategies

Our incentives increased in value as the study continued and ranged from US $30-US $50. These incentives are almost always claimed by the participants: 99.59% (1208/1213) claimed their Survey 1 gift card, 99.41% (1170/1177) claimed their Survey 2 gift card, and 99.32% (1168/1176) claimed their Survey 3 gift card. Of the few participants who did not claim their gift cards, only 1 or 2 participants per survey explicitly stated that they did not want their gift card.

Our success in developing and maintaining positive relationships with participants has been demonstrated by the messages we occasionally receive from participants expressing their appreciation for the project:

Example 1:

> *Hi Free2b folks, I just wanted to send a message that the project has seen me through a lot of change (both with time and otherwise)...Thank you for providing this space.*

Example 2:

> *I appreciate you . I am glad to be apart [sic] of this after so many years (it's very exciting).*

Example 3:

> *Thank you! I'm not sure if this is a no-reply kind of thing, but in the case that it's not, I want to show my gratitude! Thank you for the opportunity to be in this study, it really means a lot to me. I am very excited to see the impact this will have! And the money has helped me so much, I was able to pay for my first binder with it! I am eternally grateful.*

Example 4:

> *Good morning to whoever is reading this!!! Hi I'm ______ and I'm a part of the Free2b program and I want to say thank you! Your website has really allowed me to open up with those around me, as a bisexual and proud young female.*

Such messages from participants frequently express gratitude, that the study is helpful for them, interest in the outcome of the research, or that the project has had a positive impact on how they feel about their sexual orientation.

Finally, 3 Update Contact Info Surveys were sent in between each study survey. Participants were not incentivized to complete these surveys, but still, 87.14% (1057/1213) of participants completed at least 1 Update Contact Info Survey between Survey 2 and 3 and 84.17% (1021/1213) completed at least 1 between Survey 3 and Survey 4.

Retention Rates

Our Instagram and Facebook recruitment and screening techniques allowed us to verify and enroll 1216 participants in the Free2b study. Retention at the first survey after enrollment was 99.75% (1213/1216). The second survey, taken about 4 months later, was completed by 96.79% (1177/1216) of participants. We were able to maintain similarly high retention at 96.71% (1176/1216) in the 1-year follow-up survey (Survey 3) and 96.30% (1171/1216) in our 2-year follow-up (Survey 4). Of the participants who did not take Survey 2, a total of 28% (10/36) were recovered in Survey 3. Of the participants who took Survey 2 but not Survey 3, a total of 9% (1/11) were recovered in Survey 4. Additionally, of the participants who did not take Surveys 2 or 3, a total of 17% (5/30) were recovered in Survey 4. Overall, since the end of the recruitment period, we have only lost 6 participants (<1%), as defined by a participant not completing any follow-up surveys to date and having zero working contact information. Despite the difficulty in reaching these participants, they are still invited to participate in each survey, and we contact them each year.

The 3 participants who did not take Survey 1 were exited from the study, and 15 participants asked to exit the study after the first survey. After Survey 2, one additional participant asked to be exited, bringing our total exited participants to 19.

Discussion

Principal Findings

Due to the increased popularity of social media and other messaging platforms, researchers have more opportunities to identify and communicate with participants in longitudinal clinical trials. This paper reports on the use of social media to aid participant screening and retention in a longitudinal study for sexual minority youth. Our findings suggest that a sample recruited through social media platforms can achieve minimal attrition with certain screening and retention strategies. Our results confirm the effectiveness of commonly published retention strategies [42,43,46] and offer new methods, such as using social media to maintain contact with participants. Study findings further suggest that Instagram is an effective method for communicating with and finding potentially lost participants over Facebook for sexual minority youth. This points to the importance of researchers following social media trends to meet their potential or enrolled participants where they are.

Overall, the various retention and screening strategies used in this study have shown promising results, with retention rates ranging from 96.30% (1171/1216) to 96.79% (1177/1216) in follow-up surveys. Our retention rates are somewhat higher than other studies with sexual minority youth. In a study of sexual minority youth whose sample included minors, retention rates at each study wave ranged from 82% to 90% [47]. Another study of sexual minority youth aged between 18 and 19 years found retention rates ranging from 85.9% to 89.5% [48].

Sexual minority youth are a hard-to-reach population, making it difficult to recruit using in-person methods [49]. However, social media has presented an accessible way to reach this demographic [1,2,5,6]. We used Instagram and Facebook to recruit a large nationwide sample of sexual minority youth. But studies that use web-based recruitment can be vulnerable to poor data quality as eligibility is harder to verify compared to in-person methods [40]. A common strategy in web-based recruitment is the use of eligibility screening questions to remove ineligible applicants [39,50]. However, screening questions do not guarantee authentic answers. Moreover, when studies such as ours compensate participants, duplicate or fraudulent enrollees are common [51]. Therefore, the benefits of web-based recruitment can be offset by risks to sample validity and data integrity. There is limited literature outlining the extent of these threats and how to mitigate them [40].

By cross-referencing demographic data provided by the participant with publicly available information and confirming participant birthdates through email, we improved the overall quality of this study data. If we had not validated their email by asking for their birthday confirmation, we may have enrolled people in the study who provided inactive email addresses and who were not 15-16 years old. Without collecting sufficient contact information at the study's onset—primary and alternative phone numbers, primary and alternative emails, social media handles, and an optional alternate contact—sample retention would likely have been lower.

As seen in Table 1, Instagram was consistently the most common alternative contact method youth provided. This is unsurprising given the popularity of Instagram among our age demographic [31]. This may also be due to our recruitment methods through Instagram. Many participants had already interacted with us on Instagram—through DMs, comments, and likes—and thus may have been more comfortable sharing their handle. We have continued to use Instagram to reach participants throughout the duration of the study given its continued popularity among the sample. During survey data collection, reminders through Instagram DM were successful, as seen through the participants who took the survey within 48 hours of receiving a reminder DM. Instagram DMs were also useful to help update participant contact information. Understanding the most popular form of social media among a recruited demographic may help researchers to remain in contact with hard-to-reach participants.

The retention strategies used in this study include those traditionally used in longitudinal clinical trials as well as new methods that reflect the current shifts in social media trends. Traditional methods include survey incentives, building positive relationships with participants, and regularly updating participant contact information [42,43,52]. The incentives for each survey were popular as evidenced by the high number of gift card acceptances after each survey. Training RAs to have consistent communication standards and demonstrate respect for participants' time helped us build rapport. Evidence of our success at building these positive relationships includes when they frequently thanked us for their birthday or holiday messages or upon receipt of their gift card.

Worth noting are the examples of participant messages outlined in our results. Sometimes participants were unsure if they were emailing a "real person" (eg, "not sure if this is a no-reply kind of thing"). This concern likely resulted from the use of templates for mass emails related to surveys or gift cards. Though we personalized these emails with first names, the concerns voiced by some participants is an important reminder that adolescents are savvy and able to detect when correspondence is mass generated versus individually written. Researchers may benefit from ensuring they have a mix of automated and individualized messages, as we did, to maintain positive relationships.

Throughout the study we reached out to participants to update their contact information through a brief survey. This task required minimal effort on behalf of the participant. The ease of use of the survey likely contributed to the high rates of completion. In turn, the correct contact information minimized attrition. These surveys may have also helped us to maintain positive relationships with our participants as we were able to note changes in names, pronouns, and gender identities, thereby minimizing the chance to use a deadname or misgender a participant, which can be detrimental when maintaining rapport with sexual minority youth [53].

Tracking lost participants and finding alternative methods to contact hard-to-reach participants are both crucial to prevent attrition. Throughout the study, we used Instagram to reach out to hard-to-reach participants as an alternative contact method when calls, texts, and emails were ineffective. Social media contacts were successful as seen when participants took their survey within 48 hours of receiving a DM reminder from us. This success is likely attributable to participants' frequent use of the app; those who were active on the platform may have been more likely to see our DMs over calls, texts or emails which can be deemed spam.

When tracking lost participants, we implemented multiple strategies. Researchers have commonly used multiple forms of web-based methods to track participants: search engines (eg, Google) and fee-based directories (eg, White Pages) are 2 common examples [54]. Though search engines are useful to locate participants, they often do not provide new methods of contact. Therefore, we used social media to locate and DM potentially lost participants. Social media platforms, primarily Facebook, have also been used by researchers to search for participants. Despite the reported success shown on tracking through Facebook [28,54,55], we have primarily used Instagram over Facebook due to its higher popularity among our sample (Table 1).

Unless requested to be exited, no participant was considered lost from the study. We used social media to "recover" participants whom we lost contact with due to changes in their contact information. After finding a profile on Instagram that matched their demographic information, we reached out to participants regarding their participation in the study (middle screenshot in Figure 4). In some instances, we were also able to use old accounts to update contact information. After attempting to reach some participants through Instagram, we found that their accounts were no longer active, but they had added a link to their new account in their bio through which we were able to reach them (right screenshot in Figure 4). Overall, Instagram has been useful as an alternative contact method for survey reminders, to track down lost participants, and to build positive relationships with participants.

Limitations

A limitation of using Instagram to screen and maintain contact with participants is that Instagram frequently changes its policies, including how DMs can be sent. In March 2021, Instagram announced it would be banning adults from direct messaging teenagers under the age of 18 years who do not follow the adult's account [56]. This may affect retention efforts when using Instagram as a contact method in a sample of youth. It is unclear how this policy will change in the future. Moreover, people can easily change their profile handle names, preventing us from finding previously provided accounts. An additional limitation of using social media as a method to recover participants is that these methods are more effective with participants who have uncommon names, as it was very difficult to find participants on social media if there were hundreds or thousands of users with the same name. Finally, efforts to communicate or contact participants through social media were likely less effective for participants who were not out or did not want to be publicly associated with our Instagram account.

Conclusion

This paper demonstrates effective screening and retention methods to conduct a longitudinal clinical trial for sexual minority youth. Social media, particularly Instagram, was found to be useful both in the screening process and in maintaining contact with participants throughout the study. Through the use of similar thoughtful screening and retention strategies, others may be able to replicate our high retention rates. Future research is needed to determine the efficacy of individual strategies, as well as to test these strategies in different populations and on new social media platforms as they gain popularity.

Abstract

Background: Ocular following responses (OFRs)—small-amplitude, short-latency reflexive eye movements—have been used to study visual motion processing, with potential diagnostic applications. However, they are difficult to record with commercial, video-based eye trackers, especially in children.

Objective: We aimed to design and develop a noninvasive eye tracker specialized for measuring OFRs, trading off lower temporal resolution and a smaller range for higher spatial resolution.

Methods: We developed a high-resolution eye-tracking system based on a high-resolution camera operating in the near-infrared spectral range, coupled with infrared illuminators and a dedicated postprocessing pipeline, optimized to measure OFRs in children. To assess its performance, we: (1) evaluated our algorithm for compensating small head movements in both artificial and real-world settings, (2) compared OFRs measured simultaneously by our system and a reference scleral search coil eye-tracking system, and (3) tested the system's ability to measure OFRs in a clinical setting with children.

Results: The simultaneous measurement by our system and a reference system showed that our system achieved an in vivo resolution of approximately 0.06°, which is sufficient for recording OFRs. Head motion compensation was successfully tested, showing a displacement error of less than 5 µm. Finally, robust OFRs were detected in 16 children during recording sessions lasting less than 5 minutes.

Conclusions: Our high-resolution, noninvasive eye-tracking system successfully detected OFRs with minimal need for subject cooperation. The system effectively addresses the limits of other OFR measurement methods and offers a versatile solution suitable for clinical applications, particularly in children, where eye tracking is more challenging. The system could potentially be suitable for diagnostic applications, particularly in pediatric populations where early detection of visual disorders like stereodeficiencies is critical.

Introduction

Eye movements have long been used to gain insights into the operation of brain structures involved in motor and cognitive processes. Furthermore, they provide opportunities to diagnose nervous system pathologies through their oculomotor signatures [1], including parkinsonian syndromes [2,3], amyotrophic lateral sclerosis [4], Huntington disease [5], Alzheimer disease [6], and minimal hepatic encephalopathy [7].

In our daily lives, we unconsciously engage in various types of eye movements. The involuntary eye movements that are responsible for maintaining the stability of images on the retina include the vestibulo-ocular reflex, smooth pursuit, and optokinetic nystagmus. Abrupt onset of visual motion induces reflexive eye movements with ultra-short latencies, known as ocular following responses (OFRs). These responses constitute the initial component of the optokinetic nystagmus response, supporting the translational vestibulo-ocular reflex in gaze stabilization [8]. Despite their small magnitude, typically compensating for only 4% - 10% of retinal slip, OFRs have proven valuable for investigating the processes underlying visual motion processing in humans and nonhuman primates [9-20]. Furthermore, by using scleral search coils [11] to record eye movements in stereoblind adults, their potential for diagnosing stereoanomalies has been recently revealed [21].

Stereoblindness, the inability to use the disparity between the retinal images from the 2 eyes to sense depth, is an often irreversible central nervous system disorder, with a prevalence of around 7% [22]. It is usually associated with, and often a result of, strabismus (misalignment of the 2 eyes) or anisometropia (a large difference in the refractive power between the 2 eyes). If not treated early, it often leads to amblyopia, a central (and thus not correctable with lenses) visual acuity deficit in 1 eye.

Early diagnosis during the critical childhood period of visual development is crucial to prevent the development of amblyopia, with early intervention (ideally, during the first 12 - 36 months of life) leading to improved outcomes [23-25]. Several clinical tests are currently available to assess binocular depth perception, such as the Titmus, TNO, and Lang tests, but they require patient cooperation, and so are poorly suited to assess stereodeficiencies in infants and young children [26], which remains a challenge.

Measuring OFRs requires minimal subject cooperation. As they are mediated by disparity-sensitive cortical neurons, sensitive to interocular correlations [27], they are affected by stereoblindness [27]. Accordingly, they have the potential to be used to detect stereo deficits in an objective manner, particularly in patient populations not well suited to current methods (such as children, especially preverbal ones, and nonverbal individuals of any age). Despite their potential, due to their small amplitude (usually less than half a degree), OFRs are rarely recorded. Typically, they have been measured using costly eye-tracking equipment, such as scleral search coils and dual-Purkinje eye trackers, which is almost never available in clinical practice. Recently, noninvasive, general-purpose, commercial, video-based eye-tracking systems have also been used to record OFRs, but these require averaging responses over many, often 100 [28-30] or more (up to 400 [30]), repeated presentations of the same stimulus, collected over multiple sessions, a process unsuitable for clinical practice and in pediatric populations.

This need for averaging is due to the limited spatial resolution of commercial eye trackers, which in turn is a consequence of their need to provide high temporal resolution and operate over a large range of eye positions. However, this is the wrong trade-off for the low speed and small size of OFRs, and a video system operating with a different trade-off might achieve the spatial accuracy needed to reliably record OFRs. The aim of our study is to conceptualize, design, and implement a high-resolution eye tracking system, with compensation for small head movements, suitable for noninvasive measurement of OFRs in children. This system is intended to address the challenges associated with traditional eye tracking methods, maximizing subject comfort and minimizing recording duration and required subject cooperation, making it suitable for application in pediatric clinical contexts.

Methods

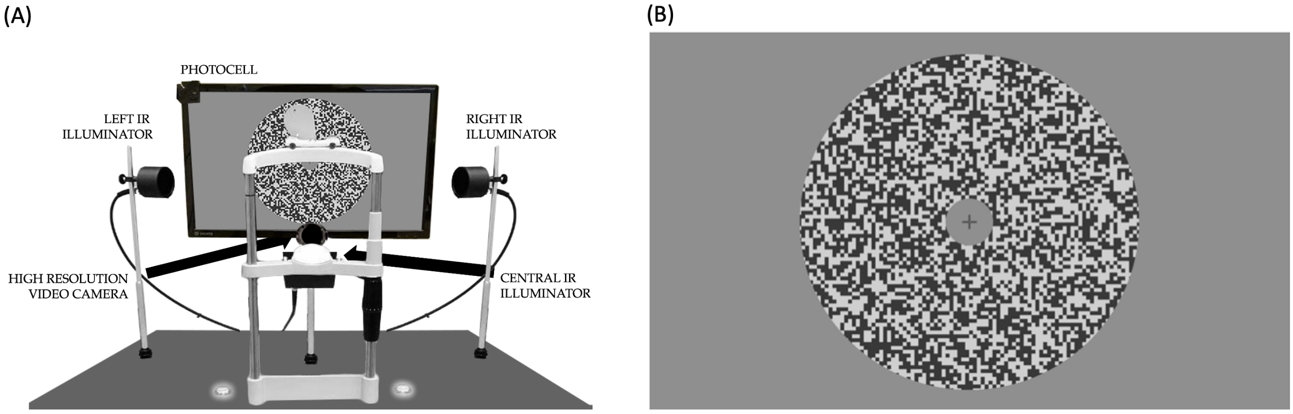
Ethical Considerations

Each participant's parent or legal guardian provided written informed consent prior to their child's involvement in the study. They were informed that the test would not directly benefit their child, that participation was entirely voluntary and unrelated to any clinical care the child was receiving at the eye clinic that day, and that their decision to decline participation would not impact their child's clinical care at the hospital, either currently or in the future. The equipment used in the study was demonstrated to the parent, and a few sample trials were conducted to illustrate the visual stimulation and what was expected of the child. Additionally, the parent was present throughout the testing session. No compensation was provided to participants in this study. To ensure privacy, all data were anonymized prior to analysis to prevent any potential identification of participants. The study (RC 31/24) was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Scientific Board of the Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) "Burlo Garofolo."

Requirements

OFRs are reflexive movements, with consistent temporal dynamics and a latency (for high-contrast stimuli) of 70 - 80 milliseconds in humans [28,31]. In a typical experiment, 4 or more different conditions, each corresponding to a different motion stimulus, are presented in succession. Each presentation represents a trial, and each condition is presented once in a block of trials. Multiple such blocks are recorded (possibly over multiple sessions) so that the average response to each condition can then be computed. Typically, a trial lasts between 1.5 and 2 seconds, with a fixation period of approximately 1 second, during which the first frame of the stimulus and a fixation cross are shown on the screen (Figure 1B). This is followed by a short (usually 200-millisecond) period of stimulus motion (during which the fixation cross is not visible), followed by a short period during which a blank screen is presented. Subjects are usually encouraged to limit eye blinking to this blank period.

Figure 1. (**A**) Our custom-designed eye-tracking apparatus. (**B**) Sample random-dot stimulus used to induce ocular following responses in experiments. IR: infrared.



In some cases, the latency is itself a focus of the study; therefore, high temporal resolution is necessary. However, in most cases, the measure of interest is the magnitude of the response (ie, the displacement of the eyes) in the so-called open-loop period [10]. This is the period during which the eye movement itself does not alter the projection of the visual input on the retina, and it goes from the movement latency to twice the latency (after this time, the retinal velocity of the stimulus would become equal to the difference between the actual velocity of the stimulus and the velocity of the eye 1 movement latency earlier). The onset latency varies somewhat from subject to subject and as a function of the contrast and size of the stimulus [10,13,15], but for high-contrast large stimuli, it varies between 70 and 80 milliseconds. Under such conditions, quantifying the OFR as the eye displacement between 80 milliseconds and 160 milliseconds after stimulus onset is appropriate for most subjects.

The most basic system for measuring OFRs must then determine, with the highest resolution possible, the displacement of 1 eye during the open-loop period. The stability of eye fixation during the period that precedes the onset of the OFRs should also be verified, discarding trials in which the subject moved their eyes around stimulus onset (such motion would alter the motion of the stimulus on the retina during the open-loop period). The acquisition of just 3 frames (motion onset, 80 milliseconds later, and 80 milliseconds after that) should suffice for measuring at least OFRs to the simplest stimuli [32]. As we are interested in the motion of the eye in the head, it is important to accurately estimate and subtract off movements of the head over the same time period. More complex visual stimulations, in which the dynamics or the latency of OFRs might be informative, would require higher temporal resolutions. In those cases, the high temporal resolution of an eye coil system (1 millisecond) would certainly be helpful, but it is hard to envision situations in which acquiring more than 10 frames over a 200-millisecond period would be strictly required to answer a scientific or clinical question. Once the images are acquired by the camera, there would then be between 1 and 2 seconds, depending on the exact trial duration, during which the images could be downloaded to disk for offline analysis.

Given the typical size of OFRs, with a maximum displacement during the open-loop period ranging across subjects between 0.05° and 0.5°, a resolution of less than 0.05° would be highly desirable. To put this in perspective, peak-to-peak noise levels with a scleral search coil system, the most sensitive system for recording eye movements, are typically less than 0.03° [33]. In contrast, commercial eye trackers often have difficulties in reliably detecting eye displacements smaller than 0.5° [34,35]. With an average eye diameter of 22 - 24 mm, 0.05° corresponds to a pupil displacement of approximately 10 µm. Head movements of such small amplitudes must therefore also be reliably detected.

We designed and built a video-oculography system, utilizing a combination of off-the-shelf components and custom-designed elements, to fulfill these specifications.

Video Acquisition System

The image acquisition system we designed consists of a high-resolution camera, infrared (IR) illuminators, a photocell to be mounted to the monitor, and an Arduino controller to monitor the output of the photocell and trigger a frame acquisition from the camera. The camera we selected is a monochromatic FLIR Grasshopper 3 GS3-U3-51S5M-C [36]. It contains a Sony IMX250 ⅔” complementary metal-oxide-semiconductor sensor, with a resolution of 2448 × 2048 pixels (approximately 5 megapixels), square pixels with a side of 3.45 µm, and a maximum acquisition rate (at full frame size) of 75 Hz. We paired it with a Computar M5028-MPW2 C-Mount ⅔” 50 mm, f/2.8 lens [37]. Since we are interested in recording in the near-IR spectral range, we blocked the visible spectrum by placing in front of the lens a Hoya R72 IR filter with a cutoff wavelength of 720 nm [38]. To ensure proper lighting, we used 3 IR LED illuminators (1 on each side of the subject and 1 in front of and below the subject). We assembled them using multiple (2 for the front, 12 for the sides) 800-nm LEDs held in custom-designed 3D-printed enclosures. A common problem with commercial eye trackers is that the sustained illumination required by high temporal resolution often results in eye dryness and subject discomfort. To allow for bright IR illumination of the eye during image acquisition while minimizing the amount of IR power delivered to the eye, our illuminators are pulsed for only 2 milliseconds at a time, synchronized with the acquisition of a frame by the camera (the camera exposure duration was set to 1 millisecond to minimize motion blur). When recording 3 frames/trial, in an experiment with 4 stimulus conditions (the bare minimum for OFR experiments), 30 repeated presentations of each condition, and a 2-second trial duration, this results in a 4-minute recording experiment during which the illuminators are lit for only 720 milliseconds. Additional illumination occurs in the setup period required to properly focus the lens on the subject's eye. With an experienced operator, this process typically lasts less than 30 seconds; during this process, frames are acquired at 10 Hz (and the illuminators are lit 2 milliseconds every 100 miliseconds), resulting in an additional 600 milliseconds of IR illumination.

To control the timing of the camera shutter and the illuminators, we designed and programmed an Arduino-based controller and connected a photocell placed in front of the top left corner of the monitor to an Arduino analog-to-digital input. Our stimuli are then designed so that the luminance of the area of the screen under the photocell increases on the frame on which the fixation point is turned off and the experimental stimulus starts drifting. The Arduino-controlled circuit detects this change and sends a 2-millisecond transistor-transistor logic (TTL) pulse to the analog circuit that powers the IR illuminators and the camera shutter. The illuminators are turned on essentially instantly, whereas the camera, which is configured to trigger on the rising edge of the TTL pulse, begins the acquisition of a frame approximately 0.3 milliseconds later. Shutter aperture is set to last 1 millisecond, irrespective of the duration of the TTL pulse. The acquisition of successive frames (with associated illumination pulses) is then triggered automatically by the Arduino controller at the desired delays (with submillisecond resolution). The controller we designed allows for the manual selection (using a rotating knob) of 1 of 9 programs, each associated with different numbers and timings of acquisition frames (relative to the first one, which is always triggered by the photocell). The timing of these sequences can be easily customized by modifying the Arduino code. As mentioned previously, the camera we selected has a pixel size of 3.45 µm, and the minimum focusing distance of the lens we selected is approximately 50 cm (appropriate also for the distance between the subject and the monitor, allowing us to place the camera under the monitor). A camera pixel will therefore cover a square with a side of approximately 40 µm on the subject's eye. Given our desired 10 µm resolution (as detailed previously), our image analysis pipeline will need to detect displacements of one-fourth of a pixel or better. Since even very small translations or vibrations of the head would introduce artifacts of the same order of magnitude as the movements we are attempting to measure, these need to be compensated for.

Head Movement Compensation

The problem of head stabilization is common to all video-based systems (whereas scleral search coil systems are insensitive to small head translations). Gross head stabilization is usually provided by using a chin and forehead rest, often augmented with a headband. This is sufficient for situations in which only a coarse localization of the eye is required, but it is not sufficient when accurate determination of eye position is required.

One solution to the problem is to tightly stabilize the head, which is usually accomplished either through a bite bar (in which the subject's teeth are trapped in a dental mold fixed to the recording apparatus) or through a tight-fitting helmet that is then mechanically or magnetically held firmly in place. However, both of these solutions are impractical, uncomfortable for the subject, and ill-suited to pediatric clinical environments.

A noninvasive solution to this problem, used by most commercial video eye trackers, is to track the reflex on the cornea caused by an IR LED (the corneal reflex or first Purkinje image) [39,40]. When the eye rotates in the head, this reflex does not (to a first-order approximation) move in the image plane (whereas the pupil's center does). In contrast, when the head translates, the reflex translates with it (and so does the pupil's center). To estimate from video images the motion of the eye when the head is not perfectly stabilized, one can then subtract the displacement of the corneal reflex (an estimate of head-in-space motion) from the displacement of the pupil center (an estimate of eye-in-head + head-in-space motion). The resolution of the final measure is limited by the resolution with which the displacement of the corneal reflex can be tracked; in our case, this will also have to be in the order of one-fourth of a pixel or better. We attempted to use this approach but found it unsatisfactory for two reasons: (1) properly placing the illuminators to get an appropriate corneal reflex can be cumbersome and time-consuming, and (2) we could not reliably achieve the desired resolution given the small area covered by the corneal reflex [35].

To more accurately track small movements of the head, we placed an IR-absorbing black circle on a small sticker (which we call a "head marker") just under the bridge of the nose of the subject. We chose this location because it is close to the pupil we image (allowing them to both fit in the same photo frame) and because this area of the face is minimally sensitive to changes in facial expression. Just like the corneal reflex, tracking the head marker allows us to track the motion of the head and infer the movement of the eye in the head, but in a way that is less sensitive to the placement of the illuminators; in addition, due to the size of the marker, it provides high spatial resolution. The only downside is that it requires careful focusing of the camera, as both the pupil and the head marker need to be in focus for optimal resolution.

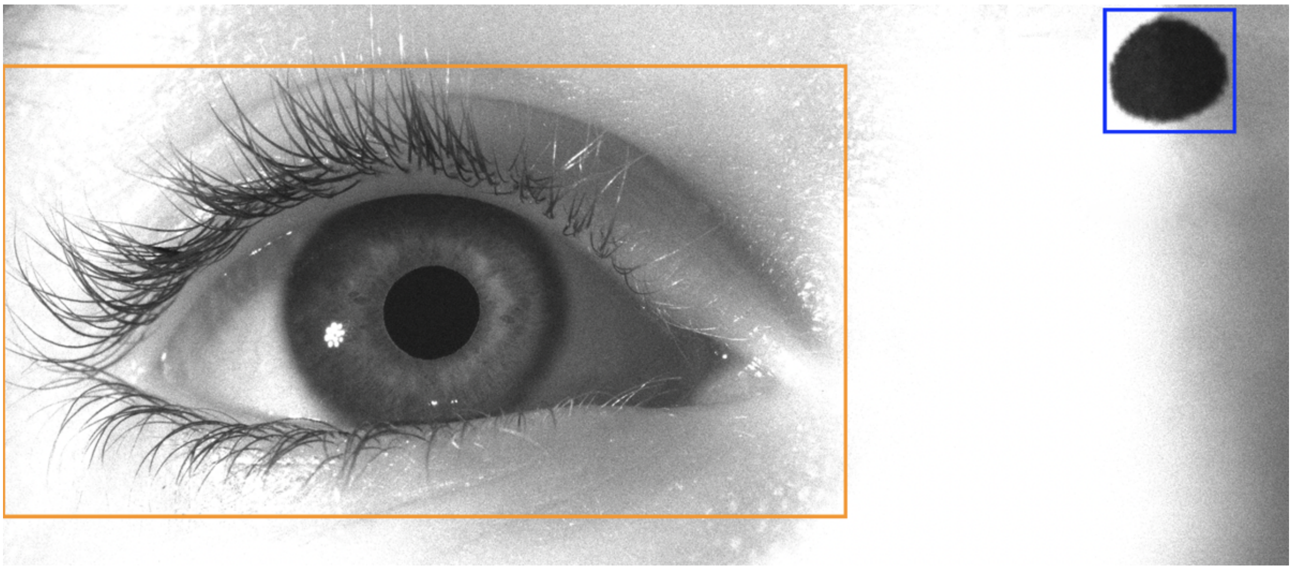
Image Analysis

Region of Interest Detection

During the experiment, all the image frames acquired (3 per trial at a minimum) were stored on disk. All the image processing aimed at extracting the magnitude of OFRs took place offline, after the experiment was over. The first step, as in any image analysis pipeline, was that of identifying regions within the image in which the features of interest are located. Traditionally, the detection of such regions of interest (ROIs) has been handled by feature-based detection algorithms, usually augmented by heuristic rules tailored to the specific problem at hand. For example, the eye region is often isolated using a 3-stage face and eye detection algorithm based on Haar cascade classifiers [41,42]. Alternatively, the high luminance associated with the corneal reflex can be used to locate the eye, specifically targeting the pupil [43]. More recently, the increase in available computational power and the development of deep-learning neural networks have revolutionized image processing, leading to faster and more robust solutions. For object detection tasks, You Only Look Once (YOLO) networks have proven to be very efficient and accurate [44,45]. Furthermore, YOLO networks can detect multiple objects in a single pass through a neural network, making them exceptionally fast [46,47].

For the first stage of our image processing pipeline, we used the YOLO V8 model to identify the image regions that contain the recorded eye and the head marker (Figure 2). A second YOLO network was then used to identify the pupil area within the eye region detected by the first network. We opted against extracting the pupil and the head marker regions directly because they share similar features. Both models were trained using a custom dataset consisting of 1380 images from 84 subjects. For the first model, we created a dataset in which we used classical computer vision algorithms to annotate the ROIs in each image, followed by manual validation. For the second model, we used traditional algorithms to annotate the pupil region within the eye ROIs extracted in the previous step, again followed by manual validation. These datasets were carefully designed to cover a wide range of eye dimensions, shapes, and (to a smaller extent) head tilts, ensuring that the models exhibited robust performance across diverse subject populations. As no deep-learning solution is infallible, we set a threshold on the confidence score generated by the models for the identification of ROIs to discard images in which the regions could not be identified (eg, when a subject blinked and the pupil was not visible or only partially visible). This ensures the accuracy of the subsequent image processing steps.

Figure 2. Sample image captured by our eye-tracking system (eye and marker regions of interest identified by the You Only Look Once model are marked with orange and blue rectangles, respectively). The corneal reflections of our infrared illuminators can also be seen to the left of and below the pupil. As the ocular following responses are conjugate, recording a single eye is sufficient [21].



Head Marker Displacement

As noted above, our goal is to measure the rotation of the eyes within the head over a small time interval (typically 80 milliseconds). To do this, we need to also estimate by how much the head translated in the same period. We do this by measuring the displacement of the head marker across 2 image frames, taken at the beginning and end of the period of interest. Notably, we are not interested in identifying the absolute location of the head marker in each image, only its displacement across images; however, this must be done with subpixel resolution (ideally less than 0.2 pixels).

The solution we have adopted takes the head marker ROIs identified in the 2 images, shrinks them down to a tight rectangle around the marker, then verifies that the rectangles in the 2 images are the same size. This is almost always the case; the exceptions are cases in which there were large movements of the head, and those trials would be discarded anyway. The distance in the image plane of the 2 rectangles gives us the head translation in whole pixels. To find the subpixel fraction of the displacement, we then performed a 2D cross-correlation between the area within the rectangle in one image and the 9 regions with the same area that are within 1 pixel of the rectangle in the other image. This yields a 3 × 3 matrix of cross-correlation values, which we subjected to Fisher r-to-Z transformation, then bilinearly interpolated to find the subpixel location of the peak. We also used a quadratic interpolation but saw no significant improvement in accuracy. The pixel and subpixel displacements were then added to provide our estimate of head displacement.

Pupil Displacement

The solution we adopted for the head marker cannot be used for the pupil because the pupil's size (and to some extent its shape) changes continuously, even within 80 milliseconds [48,49]. Accordingly, we used an algorithm that extracts the pupil's center in each image. First, we took the pupil region identified by the YOLO network and shrank it down to a tight rectangle around the pupil. Next, we used a series of filters (ellipses of various sizes and aspect ratios) to locate the pupil center with pixel-level resolution. As the previous step already provided a fairly accurate bounding box for the pupil, only a few filters were needed. If no filter resulted in a good enough match (a very rare occurrence), the trial was discarded. We then fit an anti-aliased annulus to the pupil, restricting our search space to ± 1 pixel around the pixel size identified with the first step. The limiting factor of the accuracy in vivo is the shape of the pupil (which is not always perfectly elliptical). More importantly, its location is not rigidly tied to the direction of the visual axis, introducing a hard limit on the spatial resolution of any pupil-based eye position determination [50-52], making estimates of accuracy based on an artificial eye, found on commercial system specifications, hard to translate in practice. The displacement of the eye (in the plane of the image) was then computed by simply subtracting the coordinates of the center of the ellipses fitted to the pupil in the 2 images. Finally, the displacement of the eye in the head was estimated by subtracting from this pupil displacement the displacement of the head marker computed previously.

Results

Overview

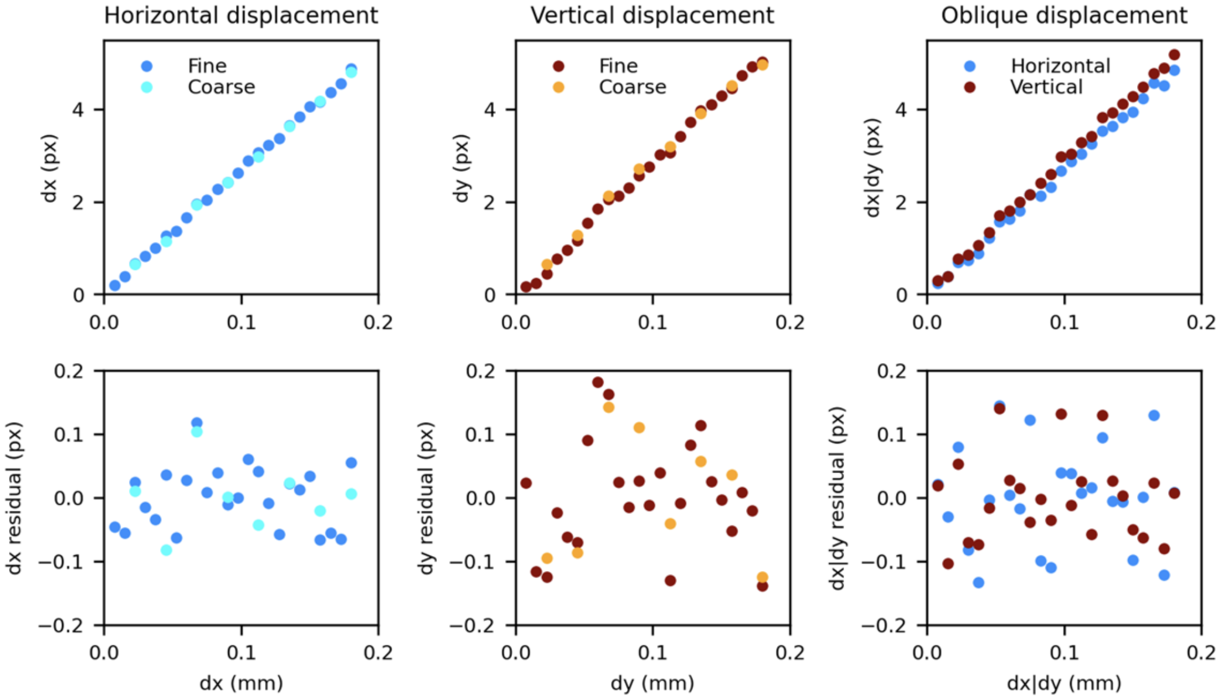
To assess our system's performance, we: (1) evaluated the resolution of our head marker displacement algorithm in artificial and real-use settings, (2) compared the OFRs measured simultaneously with our system and with a scleral search coil in an experienced adult subject, and (3) evaluated the ability of the system to measure OFRs in a clinical setting. As mentioned previously, we consider calibration results obtained with an artificial eye, common in the literature, to be of limited value in practice, and did not pursue that approach.

Artificial Marker Calibration

We mounted a head marker on a plastic block attached to a manual X-Y micro manipulator rigidly mounted to the end of a table. On the same table, we rigidly mounted our camera approximately 50 cm from the head marker. We then displaced the marker in small increments (by a total distance of up to 180 µm) either horizontally, vertically, or diagonally, and manually triggered the camera to acquire images of the marker at various displacements. Horizontal and vertical series were repeated with either a fine (7.5 µm) or coarse (22.5 µm) increment; only the fine increment was used for the oblique displacements. The displacement of the marker between each of the images and the initial reference image was then extracted with the algorithm described.

In Figure 3, we plotted the estimated (in pixels) and actual (in mm) displacement of the marker for all experiments, as well as the residuals obtained by regressing out from the estimated displacements a linear prediction based on the data.

Figure 3. Artificial marker calibration results. Top row: estimated displacement (y-axis, in pixels) and actual displacement (x-axis, in mm) of the marker across all experiments. Bottom row: residuals after linear regression. Px: pixels.



The slope of the regression matches what we expected from the geometry of the setup, with a slight difference in slope between horizontal and vertical displacements, likely due to an imperfect alignment of the camera. The standard deviation of the residuals varied between 0.05 pixels in the horizontal direction and 0.08 pixels in the vertical direction (corresponding to 2 - 3 µm of displacement). This is better than our desired 10 µm accuracy, although the conditions of this test (ideal lighting, minimal vibrations, accurate focus) are not those of everyday practice.

Reliability Estimation of Head-Tracking Method in an Adult Population

To estimate the reliability of our head-tracking method under actual recording conditions, we recruited 7 subjects (6 males, 1 female, aged 21 - 51 years). All subjects had healthy vision (normal or with slight myopia), did not wear eyeglasses or contact lenses during the experiment, and had no difficulties seeing or fixating their gaze on the fixation target. Note that the goal of this experiment was to evaluate our ability to detect small head movements; therefore, small uncorrected optical deficits were inconsequential. We presented to our subjects moving stimuli known from previous studies to induce strong OFRs: a patch of high-contrast random dots (Figure 1B) that drifted either up or down at 50°/s within a 28° diameter circular aperture. During each trial, we captured 4 frames at specific time points: t0=0 milliseconds, t1=80 milliseconds, t2=100 milliseconds, and t3=180 milliseconds. Given that our system extracts the displacement of the head marker's position across pairs of frames, if it were perfectly accurate, the sum of the displacements between frames t0 and t1 and between frames t1 and t3 should exactly match the sum of the displacements between frames t0 and t2 and between frames t2 and t3 (in both cases representing the displacement between frames t0 and t3). Differences between these 2 sums represent a measurement error.

We found that, across subjects, the mean (SD) of the head displacement measurement error (computed as described previously) was 0.09 pixels in the horizontal direction and 0.11 pixels in the vertical direction (corresponding to <5 µm of displacement). As expected, this is worse than in the artificial setting described before, but still better than our requirements.

Comparative Evaluation of the Designed System and Scleral Coils for Measuring OFRs

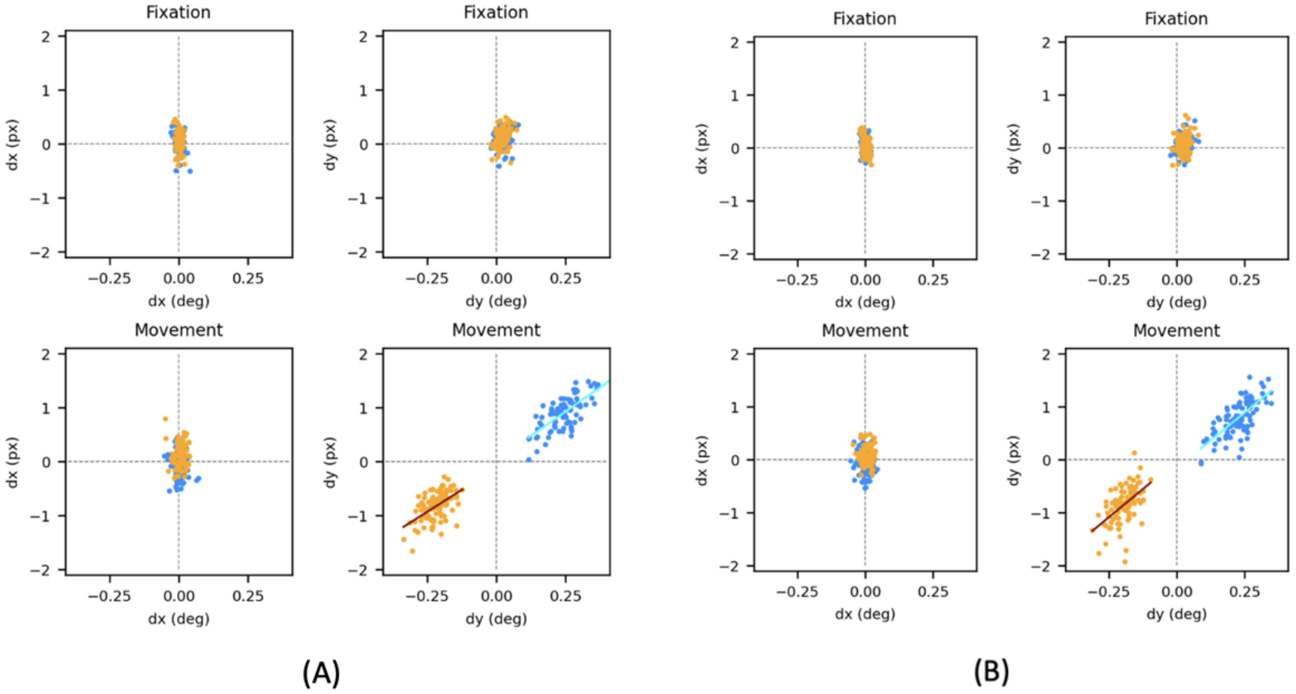
To evaluate the overall ability of our system to measure OFRs, we then fitted a subject with a scleral search coil and performed an experiment in which we presented a high-contrast random dot stimulus that drifted either up or down at 50°/s within a 28° diameter circular aperture. The subject (male, 51 years old) was highly experienced, having participated in hundreds of OFR recording sessions with scleral eye coils, and was used to the discomfort associated with wearing coils and to suppressing saccades and blinks. We recorded the induced OFRs using both the search coil and our video-based recording system. This was repeated twice; in the first session, we placed the camera on the side of the monitor (ie, a little farther from the subject), while in the second session, we placed it under the monitor (ie, closer to the subject; this was the location of choice for all our subsequent uses of the system).

In Figures 4A and B, we plotted the results of these experiments, showing separately horizontal and vertical deviations measured with the 2 systems (coils on the abscissa in degrees, eye tracker on the ordinate in pixels) during the fixation and movement windows. Using a highly practiced subject with steady fixation has the advantage of evaluating the system under close to ideal conditions. We separately analyzed responses to upward (blue) and downward (orange) drifting stimuli. Converting the pixel displacements extracted by our software into equivalent degrees of visual angle, we found consistent results across the 2 sessions. During the fixation epoch, the variability (SD) of the coil signal ranged between 0.01° and 0.02°, whereas that of the eye-tracking system ranged between 0.03° and 0.05°. During the movement period, along the horizontal direction, the variability of the coil signal was 0.02°, while that of the eye tracker ranged from 0.04° to 0.06°.

During the movement period, the scatter in the vertical direction was considerably larger (SD between 0.04° and 0.06° for the coil, and 0.08° for the eye tracker), but part of that scatter was due to variability in the underlying movement that is being measured (ie, the OFRs).

If we assume that all the shared variability is due to the underlying signal and that the noise of the 2 eye-tracking systems is uncorrelated, we can then assign all the covariance to the OFRs and use the correlation coefficient between the 2 measures to infer the actual variability of each measurement system. This yields a vanishingly small estimate of noise for the coil system and an estimate of the noise introduced by the eye tracker of between 0.06° and 0.07°. Since the coil system cannot have infinite resolution, this indicates that there is some shared variability (possibly due to head movements that were not perfectly compensated for), so these values represent an upper limit estimate of the noise introduced by our video recording system. Its resolution is very close to our desired goal, and it is likely at the limit of what can be obtained with a pupil-tracking system. However, note how much farther away the distributions of values measured for upward versus downward movements along the x-axis are compared to the y-axis, resulting in a d' measure that is almost twice as large with coils. This highlights the superiority of the coil system in ways that accuracy numbers do not convey.

Figure 4. Simultaneous ocular following response recordings with search coils and our eye tracker in a single adult subject. (A) Setup with the camera on the right of the monitor (1 pixel corresponds to approximately 0.29°). (B) Setup with camera under the monitor (1 pixel corresponds to approximately 0.24°). Each dot represents a different trial, color-coded based on the stimulus direction of motion (orange=downward, blue=upward); we plotted the eye-in-head displacement based on coil measurements (in degrees) on the x-axis, while the displacement based on our eye tracker measurements (in pixels) was plotted on the y-axis. Horizontal and vertical eye displacements in the head were plotted separately for the fixation (0 - 80 milliseconds, top row) and movement (80 - 160 milliseconds, bottom row) epochs. The rationale for selecting these epochs is outlined in the Methods section (Requirements). Deg: degrees; px: pixels.



Evaluation of System Performance in a Clinical Pediatric Population

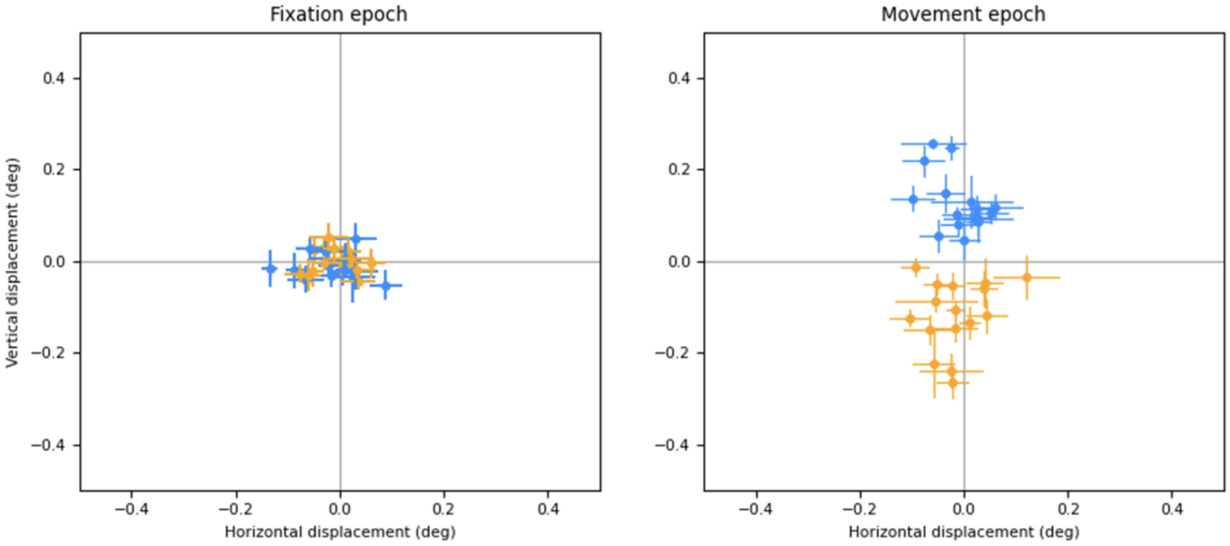
As the steady fixation and cooperation typical of a highly experienced subject cannot be expected in a clinical setting, it is also important to evaluate the ability of the system to detect OFRs in a varied clinical population. As one of the goals behind the development of this recording system is to be able to record OFRs in children, we measured OFRs in a cohort of 16 cooperating children (7 males, 9 females, aged 5 - 12 years) at the Ophthalmology Department at the Institute for Maternal and Child Health-IRCCS “Burlo Garofolo” (Trieste, Italy). All children underwent a complete ophthalmological and orthoptic examination, with indication of the best corrected visual acuity, the cycloplegic refraction, and the presence of any horizontal and/or vertical manifest strabismus angle with prisms. The inclusion criteria for normal subjects were at least best corrected visual acuity of 20/20 without correction, a cycloplegic refraction between 0.50 and 2.00 diopters, without astigmatism, without anisometropia, and absence of any type of strabismus.

We separately analyzed responses to upward (blue) and downward (orange) drifting stimuli. The displacements of the eye (eye-in-head) during the fixation epoch (frames t1=80 milliseconds versus t0=0 milliseconds) and the movement epoch (frames t2=160 milliseconds versus t1=80 milliseconds) were then computed by subtracting the head marker displacements (head-in-space) from the pupil displacements (eye-in-space). The rationale for selecting these epochs is outlined in the Methods section (Requirements). These measures were all computed in pixels and were then converted to degrees of visual angle based on the geometry of our recording systems, assuming an eye diameter of 22 mm (average for children in this age group) and resulting in a conversion factor of 0.168°/pixel.

In Figure 5, scatter plots of the average eye displacements for all 16 subjects during the fixation (left) and movement (right) epochs are shown. In the fixation period, there was no significant displacement (unpaired 2-tailed *t* test, $P>.05$) in any of the subjects. In the movement epoch, all subjects showed significant differences (unpaired 2-tailed *t* test, $P<.05$) between vertical displacements induced by vertically drifting stimuli (upward versus downward).

This demonstrates that, with this system, it is possible to measure OFRs in children in a clinical environment, with minimally instructed subjects, during a single, brief recording session lasting less than 3 minutes.

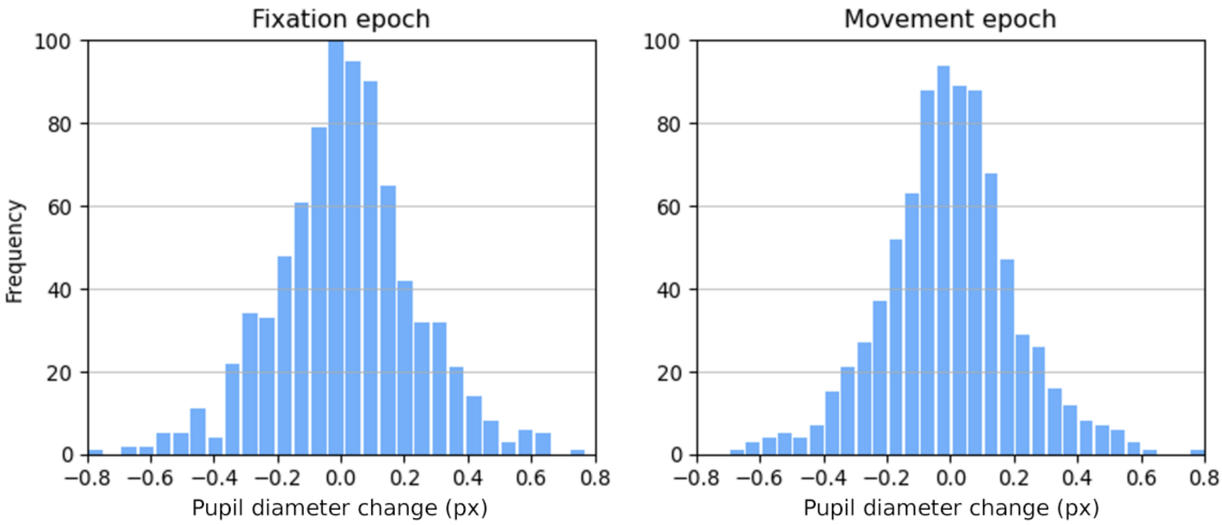
Figure 5. Eye-tracker ocular following response recordings for 16 children in response to stimuli drifting upward (blue) or downward (orange). Average (and ±1 SEM bars) eye displacements recorded in 16 subjects are plotted separately for the fixation (left panel) and movement (right panel) windows. Deg: degrees.



Pupil Diameter Changes as a Possible Cause of Error in the Measurement

The data from the previous experiment allowed us to quantify the variation in pupil size that can be expected in OFR experiments. In Figure 6, we report the distribution of pupil diameter changes (expressed in camera pixels) that we observed in the 16 pediatric subjects during the fixation (mean 0.01, SD 0.22) and movement epochs (mean 0.00, SD 0.21). Since the SD of the pupil diameter change is equal to our desired accuracy, changes in pupil diameter cannot simply be assumed to be negligible and ignored.

Figure 6. Distribution of pupil diameter changes (expressed in camera pixels) during the fixation (left panel) and movement (right panel) epochs, pooled across 16 subjects.



Discussion

Eye movements can provide a window through which we can gain insight into brain function and dysfunction [53-55]. This has long been recognized; over the years, several methods for recording eye movements have been developed, leading to numerous scientific and clinical discoveries. Unfortunately, because of the challenges in recording them, the potential diagnostic value of OFRs has only been recognized recently.

Here, we described a system that, thanks to a spatial resolution that approaches that of a magnetic search coil system, allows for the recording of OFRs noninvasively in a pediatric clinical setting. The system could potentially be useful for the identification of stereodeficiencies in young children and nonverbal adults. Due to the sensitivity of OFRs to motion and disparity signals, more widespread recordings in clinical populations will likely lead to additional clinical applications of the proposed solution.

Traditional eye movement recordings methods such as scleral search coils and dual-Purkinje eye trackers offer high precision but are expensive and complex to use. In addition, the former is invasive, while the latter requires strict head stabilization, both undesirable in pediatric populations. Commercial, video-based eye-tracking systems are now in widespread use, despite their often-high cost. However, they lack the desired spatial accuracy [35], thus requiring extensive averaging over long recording sessions, making them impractical for routine clinical use. Our system addresses these problems.

Further improvements in spatial resolution are possible but would not be easy to achieve. As the pupil changes shape and size constantly (Figure 6) and wobbles in the eye as it moves [48-52], significantly higher resolutions based on pupil tracking are probably unachievable. Tracking the motion of the iris would be a natural next step, but partial occlusion from the eyelids introduces hurdles, especially for vertical movements. In any case, increases in the spatial resolution of eye tracking would have to be matched by improved spatial resolution in the detection of head movements, an equally daunting task.

The proposed system, thanks to its demonstrated ability to noninvasively record OFRs in short recording sessions, offers a versatile solution suitable for clinical applications, particularly in a pediatric population, where eye tracking is more challenging. The system could potentially be suitable for diagnostic applications, particularly in pediatric populations, where early detection of visual disorders like stereodeficiencies is critical.

Acknowledgments

The authors would like to thank orthoptists Giorgia Sferlazza, Rita Silvia Giganti, and Francesca Malannino for their support during data acquisition. This work was supported by the Italian Ministry of Health through the contribution given to the Institute for Maternal and Child Health IRCCS "Burlo Garofolo," Trieste, Italy. Abstract

Background: Concussion, or mild traumatic brain injury, is a growing public health concern, affecting approximately 1.2% of the population annually. Among children aged 1 - 17 years, concussion had the highest weighted prevalence compared to other injury types, highlighting the importance of addressing this issue among the youth population.

Objective: This study aimed to assess adherence to Return to Activity (RTA) protocols among youth with concussion and to determine if better adherence affected time to recovery and the rate of reinjury.

Methods: Children and youth (N=139) aged 5 - 18 years with concussion were recruited. Self-reported symptoms and protocol stage of recovery were monitored every 48 hours until symptom resolution was achieved. Daily accelerometry was assessed with the ActiGraph. Data were collected to evaluate adherence to the RTA protocol based on physical activity cutoff points corresponding to RTA stages. Participants were evaluated using a battery of physical, cognitive, and behavioral measures at recruitment, upon symptom resolution, and 3 months post symptom resolution.

Results: For RTA stage 1, a total of 13% of participants were adherent based on accelerometry, whereas 11% and 34% of participants were adherent for stage 2 and 3, respectively. The median time to symptom resolution was 13 days for participants who were subjectively reported adherent to the RTA protocol and 20 days for those who were subjectively reported as nonadherent (*P*=.03). No significant agreement was found between self-report of adherence and objective actigraphy adherence to the RTA protocol as well as to other clinical outcomes, such as depression, quality of life, and balance. The rate of reinjury among the entire cohort was 2% (n=3).

Conclusions: Overall, adherence to staged protocols post concussion was minimal when assessed with accelerometers, but adherence was higher by self-report. More physical activity restrictions, as specified in the RTA protocol, resulted in lower adherence. Although objective adherence was low, reinjury rate was lower than expected, suggesting a protective effect of being monitored and increased youth awareness of protocols. The results of this study support the move to less restrictive protocols and earlier resumption of daily activities that have since been implemented in more recent protocols.

KEYWORDS

pediatric concussion; guidelines; adherence; return to school; return to sport; actigraphy

Introduction

Concussion, or mild traumatic brain injury, is a public health epidemic with an annual incidence of approximately 1.2% of the population [1]. According to the 2019 Canadian Health Survey on Children and Youth, head injuries or concussions had the highest weighted prevalence at 4.4% among children aged 1 to 17 years in Ontario, compared to other injury types [2].

In 2015, our research team developed evidence-based Return to Activity (RTA) and Return to School (RTS) protocols for children and youth with concussion [3,4]. These protocols (now updated) [5], and similar protocols based on the Sports Concussion Consensus statements [6,7], are the main management strategy for concussion recovery. It is important to determine whether youth adhere to these protocols before they can be evaluated in randomized control trials. At present, the most common method to assess adherence to the RTA/RTS protocols in youth is through self-report [6,8]. Literature suggests, however, that self-reported adherence estimates in youth are impacted by time since injury, age, mechanism of injury, receptivity to recommendations, and gender differences in activity [9-11]. To assess adherence, device-based measures of physical activity should be used, as they are reliable and minimize the bias associated with self-report [12-18]. As such, the primary aim of this study was to evaluate adherence to the RTA protocol using accelerometry and compare accelerometry-based adherence to self-report. The secondary objective was to evaluate postconcussion symptoms, recovery times, and rate of repeat head injury as well as to determine an association between adherence to RTA protocols and outcomes related to symptoms, repeat head injury, cognition, balance, quality of life, and depression. It was hypothesized that youth who were more adherent would have a lower incidence of repeat injury; shorter times to RTA; and better outcomes in quality of life, mental health, and cognition. Henceforth, youth will be used to refer to participants aged 5 - 18 years in this study.

Methods

Ethical Considerations

This study was approved by the Hamilton Integrated Research Ethics Board (REB #14 - 376). Informed assent/consent was obtained from participants and parents.

Study Design

Participants were recruited from the local Hospital Emergency Department, community referrals from their primary physician, and rehabilitation or sports medicine clinics. Eligibility criteria included the following: a physician-diagnosed concussion within the past 12 months, being 5 - 18 years of age, active symptomatology, and English-speaking ability. Youth were deemed ineligible if they had a confirmed brain injury requiring resuscitation, admission to the pediatric critical care unit, or surgical intervention, and if they refused to wear the ActiGraph. This prospective longitudinal cohort study had 3 measurement time points: recruitment/first visit; symptom resolution; and final visit, which occurred 3 months post symptom resolution or 6 months post enrollment if symptoms did not resolve within the study time frame. This investigation consisted of various outcomes, including electroencephalogram, [19,20] magnetic resonance imaging (MRI) [21], cognition [22,23], and sleep [24], which were published previously. Data on self-reported adherence, and adherence to RTS protocols specifically, were published by DeMatteo et al [8].

Assessment of RTA and RTS Protocol Stages and Symptoms

The CanChild protocols [3,4] consist of 6 stages of RTA and 5 stages of RTS, made with reference to the Zurich guidelines [25]. Youth were advised that no high intensity physical activity or contact sports was permitted while they were symptomatic. They were also informed that “rest” does not equate to social isolation or sensory deprivation. Once recruited, youth received the ActiGraph and the 2015 CanChild protocols [3,4] immediately. Participants completed surveys every 48 hours using REDCap (Research Electronic Data Capture; version 14.5.10, 2024; Vanderbilt University)—a browser-based data management application [26]. The surveys included the Post-Concussion Symptom Scale (PCSS) [27], RTA/RTS stages, and an assessment of cognitive activity [3]. The PCSS [27] is common across concussion evaluations [7] and consists of a 22-symptom checklist scored on a 0 - 6 Likert scale. This was adapted for younger children using a dichotomous yes/no scale [28]. The cognitive scale assessed cognitive activity on a scale of 1 - 5 and was adapted from Brown et al [29]. The second in-person visit occurred at symptom resolution. The label of symptomatic or nonsymptomatic was based on the return of participants’ self-identified current reporting of symptoms to their preinjury symptom status.

Measurement of Adherence to Protocols

To assess physical activity in the RTA protocols, youths were outfitted with an ActiGraph Gt3X waist-worn monitor accelerometer (ActiGraph LLc). The ActiGraph accelerometer provides a high-resolution measure of the duration, intensity, and frequency of movement and is validated for use in youth [12-17]. Participants were provided standardized instructions on how to wear the accelerometer and to record times of nonwear in a log diary. Accelerometry data were downloaded into 30-second epochs and visually inspected by trained personnel to ensure wear times matched those reported by participants. The data were cleaned to remove any nonwear periods or spurious data using ActiLife (version 6.13.4; ActiGraph LLc). The 30-second epoch was selected for analyses, as shorter epochs are more accurate to measure exercise intensity during intermittent physical activity [30]. Only valid days, defined as at least 6 hours and no more than 19 hours of wear time, were included in the analysis. Activity count data were then scored for analysis of adherence. To do this, daily time spent being sedentary or engaging in light physical activity (LPA), moderate activity, vigorous physial activity, and moderate-to-vigorous physical activity (MVPA) were calculated using the Evenson et al [14] cut points. Youth were considered adherent if there was 80% adherence to the physical activity requirements for the corresponding stage of the RTA protocol. Only participants who had complete actigraphy data were included in analyses (n=84). For stage 1, unlimited LPA was permitted, MVPA was limited to ≤2.5% of wear time and no consecutive bouts of ≥5 minutes at any intensity were recommended. In stage 2, baseline activity observed in stage 1 was permitted, as well as an extra 30 minutes of LPA, but no consecutive bouts ≥5 minutes of MVPA were recommended. In stage 3, baseline activity observed in stage 2 was permitted, as well as an extra 60 minutes of MVPA and upto two 15-minute bouts of MVPA. Only adherence to RTA stages 1 - 3 were assessed with accelerometry because these stages had quantifiable activity amounts defined in the RTA protocol [4], and RTS did not have objective adherence data.

Subjective reported adherence to the RTA/RTS protocols was based on the following criterion: if participants received a label of "yes" to the questions asked by the research personnel: "Has the child been following the RTA/RTS guidelines correctly?" based on a self-reported progression through the RTA/RTS stages being associated with a decreasing self-report PCSS score. [8] Participants were categorized separately for RTA and RTS. Participants labeled as "Did not adhere" to both RTS and RTA, as well as participants labeled as "Adhered" to one but not both RTA and RTS protocols, were deemed "Did not adhere."

Standardized Neurocognitive, Depression, Quality of Life, Coordination, and Balance Tests

Participants completed the short form of the Children's Depression Inventory (CDI) [31]; the KIDSCREEN-52 [32]; Immediate Post-Concussion and Cognitive Test (ImPACT) [33]; and subsets of balance, bilateral coordination, running speed, agility, and strength from the Bruininks-Oseretsky Test of Motor Proficiency Second Edition (BOT-2) [34] at each in-person visit.

Statistical Analyses

Demographic and injury data are presented as mean (SD), recruitment details are reported in percentages, and the PCSS score is reported as median, which better reflects the data due to a few outliers. Adherence for each participant was calculated for stages 1 - 3 of RTA as described above. Adherence was determined a priori to be considered the primary predictor of outcomes, but as the adherence rate was very low, alternative analyses were performed (as explained in the *Results* section). The ActiGraph calculated adherence for RTA was then compared to the self-reported rating of adherence for RTA, and agreement was assessed using Cohen κ.

The rate of repeat head injury was calculated as a percentage of total injuries. A Mann-Whitney *U* Test was performed to assess time to RTA stage 3 and 6 and time to symptom resolution for those who adhered or did not adhere [15,35]. Only participants who reported continued symptoms up until 3 months post symptom resolution, self-reported adherence to RTA/RTS, and reported the final stage of RTA/RTS were analyzed. Participants who responded "no" to the question "On more than one occasion, have you had any symptoms of concussion in the last two weeks?" were given a PCSS score of 0. Significance was set at *P*=.05. Scores for the BOT-2, CDI, ImPACT, and KIDSCREEN-52 were reported as mean (SD) and median. All the data were tested for normality using the Shapiro-Wilk test. Time to symptom resolution, time to stages, and PCSS scores were not normally distributed. Data were analyzed using SAS (version 9.4; SAS Institute) and SPSS (version 23.0; IBM Corp), with significance set at *P*<.05.

Results

Overview

Of the 139 participants who consented to the study, 107 (76.9%) participants completed follow-up assessments, 12 (8.6%) participants were lost to follow-up, and 20 (14.3%) participants withdrew from the study. Of the 20 participants who withdrew, 7 (35%) participants did so immediately after consent, 12 (60%) participants withdrew after the first in-person visit, and 1 (5%) participant withdrew before the final visit.

The cohort included 64 (46%) boys and 75 (54%) girls with a median age of 13.4 years. A total of 103 (74.1%) participants sustained their concussion via a sports-related injury, with most injuries obtained during recreational play (n=29, 28%) and ice hockey (n=26, 25%). This was the first concussion for 58.3% (n=81) of participants (Table 1). The median time from injury to the first visit was 7.8 days (mean 34.8 days, minimum 2.9 hours, and maximum 320.9 days). The mean time from injury to symptom resolution visit was 95.4 (SD 43.4) days for first in-person visits and 162.6 (SD 75.7) days for final visits.

Of the participants who remained in active enrollment (n=114), 16 (14%) participants did not achieve symptom resolution in the 6-month follow-up period (Table 1). Median time to symptom resolution was 16 days (Q1-Q3: 8-28; mean time 27, SD 33 days).

The rate of participants having another concussion during the follow-up period was 2% (n=3).

Table . Participant demographics, symptom resolution, and rate of reinjury (N=139).

Demographics	Values

ActiGraph Adherence Evaluation

Based on the participant analysis, 13% (4/30) of participants adhered to stage 1; 11% (8/74) adhered to stage 2; and 34% (17/50) adhered to stage 3 (Table 2). Of note, only 1 participant from this cohort (N=139) adhered to all 3 stages.

Table . Days of participant adherence per stage to the Return to Activity (RTA) protocols based on actigraphy (N=139).

Participant ActiGraph adherence data (N=139)	Stage 1	Stage 2	Stage 3
Wear time criteria met, n (%)	30 (21.6)	74 (53.2)	50 (36.0)
Adhered	4 (13.3)	8 (10.8)	17 (34)
Did not adhere	26 (86.7)	66 (89.2)	33 (66.0)
Wear time criteria not met or PCSS[a] and stage data not available, n (%)	109 (78.4)	65 (46.8)	89 (64.0)

[a]PCSS: Post-Concussion Symptom Scale.

ActiGraph data with sufficient wear time and the corresponding PCSS score and RTA stage were considered complete and then analyzed in 30-second epochs for 80% adherence to stages 1, 2, and 3. Participants were labeled as “Adhered” to each stage if they had at least 1 day in adherence to ActiGraph cut points for stage 1, 2, or 3. Participants were given a final label of “Did not adhere” if they did not meet the cut points corresponding to stage 1, 2, or 3.

Subjective Reported Adherence

Of the 105 participants with self-reported data, 59 (56.1%) participants adhered to the RTA protocol [11], 56 (53.3%) adhered to the RTS protocol, and 50.4% (n=53) were adherent to both protocols (Table 3).

Table . Subjective adherence reported for the Return to School (RTS) and Return to Activity (RTA) protocols (n=105).

Adherence	RTS	RTA	RTS and RTA
Adhered, n (%)	56 (53.3)	59 (56.1)	53 (50.4)
Did not adhere, n (%)	49 (46.6)	46 (43.8)	52 (49.5)

Objective ActiGraph Versus Subjective Self-Report

Cohen κ was performed to determine if there was agreement between actigraphy and self-reported adherence to the RTA protocol. There was no statistically significant agreement between the two measures (κ=0.49, 95% CI 0.32 - 0.66; *P*=.57; Table 4). Among the 84 participants with both ActiGraph and self-reported data, there was 48% (n=40) agreement between the two. A total of 36 (43%) participants self-reported adherence to the RTA protocol but failed to meet the ActiGraph adherence cut points.

Table . Agreement of adherence between ActiGraph versus subjective report (n=84). There was no statistically significant agreement between the two measures (κ=0.49, 95% CI 0.32 - 0.66; *P*=.57).

Subjective report	Actigraphy		
	Adhered, n (%)	Did not adhere, n (%)	Total, n (%)
Adhered	16 (19)	36 (43)	52 (62)
Did not adhere	8 (9)	24 (29)	32 (38)
Total	24 (29)	60 (71)	84 (100)

Time to Symptom Resolution and RTA/RTS Completion

Those with subjective reported adherence to the RTA protocol had a significantly shorter time in days (median=13) to symptom resolution than those who did not subjectively adhere (median=20; *U*=724.50; *P*=.03; Table 5).

The difference in time to symptom resolution was assessed, using a Mann-Whitney *U* test, for participants who self-reported adherence and nonadherence to RTA and RTS protocols (n=90). Time to symptom resolution was calculated as the time from initial injury to symptom resolution. Only participants who had a date of symptom resolution verified by research personnel were included in the analyses.

There was no statistically significant difference in time from injury to RTA stage 3 (*P*=.61) or stage 6 (*P*=.24) for participants who self-reported adherence or nonadherence (Tables 6 and 7).

Table . Time to symptom resolution and Post-Concussion Symptom Scale (PCSS) score for youth with concussion based on subjective adherence or nonadherence to Return to Activity (RTA) and Return to School (RTS) protocols (n=90).

PCSS Score at Symptom Resolution

The difference in the average number of symptoms as reported on the PCSS or postconcussion system inventory at stage 5 of RTS and stage 6 of RTA was assessed, using a Mann-Whitney *U* test, for participants who self-reported adherence and nonadherence to RTS/RTA protocols (n=86). There was no statistically significant difference in the PCSS score at stage 5 or stage 6 of RTS (*P*=.78) and RTA (*P*=.29), respectively, for participants who adhered or did not adhere to the protocols (Table 5).

Adherence and Nonadherence: Depression, Quality of Life, Neurocognitive, and Balance Tests

The KIDSCREEN-52 physical and psychological well-being subsections scores improved from the first to final visit across most participants. The scores were considered "high," demonstrating that participants felt they were physically fit and healthy and viewed life positively [29]. Participants' CDI total T-score decreased for symptoms of depression from the first to the final visit (*P*=.33), where scores were in the average/low range (<60). Across all 3 visits, most participants scored in the "average" category. From the first to the final visit, the ImPACT subsection scores increased, suggesting an improvement in cognitive performance (*P*=.13).

There was no significant difference in the BOT-2, CDI, and KIDSCREEN-52 total or subsection scores between those who reported they subjectively adhered or those who did not adhere to the RTA and RTS protocols. There was a significant difference in the ImPACT Impulse Control Composite Score at the final visit for those who adhered to the RTA protocol (mean score 7.3, SD 5.1) versus those who did not adhere (mean 11.9, SD 11.7; *P*=.04).

Discussion

This prospective cohort study examined adherence to the RTA protocol, the rate of reinjury and time to symptom resolution among youths with concussion. It is one of the few investigations that has assessed physical activity in youth with concussion using accelerometry [36]. Our findings indicate that youth have lower adherence to RTA stages, as measured by accelerometry, when physical activity is more restricted, with adherence improving as more activity is allowed. Actigraphy analysis showed that 13% of participants were adherent to the RTA stage 1; 11% were adherent to stage 2; and 34% were adherent to stage 3. Huber et al [37] examined collegiate and high school football players post concussion using the Fitbit Charge HR. The authors found that athletes with concussion had a great deal of variability in activity levels the first few days post injury, suggesting differences in how the athletes interpreted "rest." Although in Huber et al [37] the activity monitors were worn for only 2 weeks, their findings are similar to ours in that there is lower adherence in the early stages. In our study, the generally low adherence rate was not conducive to any statistical prediction analyses or modeling, as the study had set an a priori standard of 80% compliance to qualify as "adherent" to predict whether these adherent youth would have better outcomes. This required examining the data in other ways, resulting in compelling findings. First, we observed that the PCSS score decreased as youth progressed through the RTS/RTA protocols [8] and remain low at the final stage of RTS/RTA, despite low adherence according to activity monitoring. We also observed a rate of reinjury of merely 2%, which is lower than the rates presented in the literature [38,39]. In addition, the same referral-based sample of patients at the McMaster Acquired Brain Injury Concussion Clinic in the 2013 - 2014 period (before the RTA/RTS protocols were first introduced) documented a reinjury rate of 37% among the 464 youths followed clinically. Notably, 36 (43%) participants self-reported adherence to the RTA protocol but failed to meet the actigraphy cut points. This suggests that they believed they were following the activity recommendations outlined in the protocols. It is speculated that they had modified their typical activities to some degree, which then felt like adherence to them. Presumably, their activity choices were guided by symptom relief and moderated by the conservative approach used in the CanChild protocols [3,4]. It also suggests that our arbitrary choice of 80% for a label of adherence was unrealistic, too high, and maybe even unnecessary. It was observed that participants who self-reported adherence to the RTA protocols achieved symptom resolution in a median of 13 days, and those who self-reported nonadherence achieved symptom resolution in 20 days. These data suggest that the mere presence of the protocols may alter behaviors, facilitating symptom resolution and reducing rates of reinjury as noted above.

The lack of adherence meant the youth were doing more than what the protocols recommended, which may seem contradictory to the low reinjury rate and symptom recovery patterns. However, existing evidence has shown that some cognitive and physical exertion early in recovery leads to shorter recovery times and syptom improvement [31,32,38-42]. In addition, Grool et al [43] examined 2413 youths with concussion and observed that physical activity within 7 days of acute injury was associated with reduced risk of persistent postconcussion symptoms [43]. Therefore, the nonadhering youth in our study were, in fact, getting some physical and cognitive activity early on. Yet the fact that they were not fully participating in activity may have contributed to the positive outcomes. The patterns demonstrated by the youth in this study provide valuable information for clinicians. They help define what activities and treatments are tolerable and acceptable for youth post concussion, meaning these are the levels of activity and treatment that youth can manage without exacerbating symptoms or causing further harm. Additionally, the study may indicate what is helpful, meaning the interventions or practices that contribute to positive outcomes and aid in the recovery process.

In light of these findings [8], along with data from our systematic review [44], the RTA/RTS protocols have been updated [5]. Some major revisions include a shortened rest period in stage 1 and the recommendation that youth progress through the stages before they are symptom free [5]. With these latest revisions, adherence of youth to the 2019 RTA/RTS protocols is expected to be greatly improved, although this requires further investigation.

This study is not without limitations. First, data on race and socioeconomic status were not collected. Second, adherence to RTA stages 1 - 3, but not stages 4 - 6, were assessed because only these stages had quantifiable physical activity cut points. Therefore, we were unable to objectively assess adherence to the later stages of the RTA protocol. Third, we accepted youth with concussion experiencing both acute and prolonged symptoms due to the nature of the research question. As such, the variability in time to symptom resolution and stage may be due to the prolonged symptoms of some participants. Finally, although we were able to retain the majority of participants, some were lost to follow-up or never achieved symptom resolution within the study period.

Overall, adherence to staged protocols post concussion was minimal according to the accelerometric data, but it was higher by self-report. More physical activity restrictions as specified in the RTA protocol, resulted in lower adherence. Although adherence was low, reinjury rate was lower than expected, suggesting a protective effect of being monitored and increased youth awareness of protocols. The results of this study support the move to less restrictive protocols and earlier resumption of daily activities that have since been implemented in more recent protocols.

Acknowledgments

The authors would like to thank the participating families in this study for their effort and commitment, and all the Back to Play team members for their hard work and support throughout all stages of this project. We would also like to thank Canadian Institute of Health Research (CIHR) for funding this study as well as the local Children’s Hospital Emergency Department staff and physicians for the recruitment support.

Conflicts of Interest

None declared.

Abstract

Background: Length measurement in young children younger than 18 months is important for monitoring growth and development. Accurate length measurement requires proper equipment, standardized methods, and trained personnel. In addition, length measurement requires young children's cooperation, making it particularly challenging during infancy and toddlerhood.

Objective: This study aimed to develop a length artificial intelligence (LAI) algorithm to aid users in determining recumbent length conveniently from smartphone images and explore its performance and suitability for personal and clinical use.

Methods: This proof-of-concept study in healthy children (aged 0-18 months) was performed at KK Women's and Children's Hospital, Singapore, from November 2021 to March 2022. Smartphone images were taken by parents and investigators. Standardized length-board measurements were taken by trained investigators. Performance was evaluated by comparing the tool's image-based length estimations with length-board measurements (bias [mean error, mean difference between measured and predicted length]; absolute error [magnitude of error]). Prediction performance was evaluated on an individual-image basis and participant-averaged basis. User experience was collected through questionnaires.

Results: A total of 215 participants (median age 4.4, IQR 1.9-9.7 months) were included. The tool produced a length prediction for 99.4% (2211/2224) of photos analyzed. The mean absolute error was 2.47 cm for individual image predictions and 1.77 cm for participant-averaged predictions. Investigators and parents reported no difficulties in capturing the required photos for most participants (182/215, 84.7% participants and 144/200, 72% participants, respectively).

Conclusions: The LAI algorithm is an accessible and novel way of estimating children's length from smartphone images without the need for specialized equipment or trained personnel. The LAI algorithm's current performance and ease of use suggest its potential for use by parents or caregivers with an accuracy approaching what is typically achieved in general clinics or community health settings. The results show that the algorithm is acceptable for use in a personal setting, serving as a proof of concept for use in clinical settings.

Introduction

Regular and accurate measurement of anthropometric parameters in young children is important for monitoring growth and development, and for facilitating timely interventions to ensure appropriate growth [1,2]. Body length measurements are required for two key World Health Organization (WHO) growth standards: (1) length for age and (2) weight for length [3]. Accurate length measurement requires specialized equipment (a properly calibrated length board), skilled personnel, and a cooperative child [4-7]. Studies have reported inaccuracy and variability of length measurements, even in clinical settings [5,6,8,9]. In practice, achieving the "gold-standard" level of accuracy with the standard method is very challenging for untrained or inexperienced personnel. Although parents and caregivers want to track their children's growth closely, many find measuring their child's length at home technically challenging. Thus, there is an unmet need to develop a tool that is easy to use and addresses the key obstacles in taking accurate length measurements. This can potentially be upscaled and deployed in both personal or home and clinical environments.

Mobile devices are increasingly used for fast and efficient collection of real-world data, especially through smartphone images. Advances in artificial intelligence and computer vision technology, particularly deep learning, have enabled complex image recognition and prediction tasks to be performed on such image data [10-14]. These include challenging tasks such as predicting the physical size of a 3D object from one or more 2D images, which could translate to clinical use in determining a person's anthropometric measurements. Most of the existing image-based approaches focus on predicting the standing height of adults [15,16], although a couple of approaches for predicting the recumbent length of young children have been proposed [17,18]. Unlike manual measurements, these automated image-based approaches do not rely on standardized positioning of the child's body but must overcome certain challenges to produce accurate predictions. The relevant body parts must be automatically identified within the image by locating key landmarks such as the head and limb joints. The length prediction method must also account for body parts having variable orientation and distance from the camera, which affects their apparent lengths in the image. Image artifacts, such as blurring due to the child's movement, must also be detected and accounted for. One group proposed a stereoscopic vision system that uses 2 cameras to photograph the child simultaneously from different angles and estimates the child's body length based on the 2 images using the parallax principle [17]. Another group proposed a method involving the detection of customized round markers placed on the child's body before image capture. The markers allow both the detection of body landmarks in the image and the estimation of their 3D position relative to the camera; these are used to predict overall body length [18]. However, neither approach fully overcomes all current challenges with child length measurement since they still require specialized equipment or additional manual setup.

We developed a length artificial intelligence (LAI) algorithm to automatically predict children's length from smartphone images. To our knowledge, the LAI algorithm is the first approach that does not require specialized equipment or precise placement of body segment markers for length prediction. This innovative approach could make it much more practical and convenient for parents or caregivers to take regular length measurements for their children. In this proof-of-concept study, we examined the LAI algorithm's performance for automated length prediction and compared its performance with international standards such as those from the WHO [19-21] and measurements taken in general or community health clinic settings [8,22]. These comparisons allowed us to assess the feasibility of using the LAI algorithm in scenarios where specialized equipment and skilled personnel are unavailable. In addition, we explored users' experience and expectations for a digital measurement tool that could be used in home or clinic environments.

Methods

Study Design and Participants

An exploratory, observational, cross-sectional pilot study was conducted between November 2021 and March 2022 at KK Women's and Children's Hospital, Singapore. The study was prospectively registered at ClinicalTrials.gov (NCT05079776).

Eligible participants were children aged between 0 and 18 months whose parents (1) had a smartphone or tablet with access to the internet, (2) were able to complete the study questionnaires, and (3) took and uploaded images onto an online form. Children who were unable to undergo length measurement by the standardized technique recommended by the WHO [23] (eg, children with structural abnormalities of the lower limbs or orthopedic conditions such as club foot and hip dysplasia) were excluded from the study.

The study duration was a maximum of 2 days. On day 1 (clinic setting), investigators measured the participant's body length using the standardized WHO length measurement technique [23]. They then used a smartphone to take 6 top-view photos of the participant in a supine position. Each photo included a standard-size reference card. On day 1 or 2 (home setting), parents took and uploaded 6 smartphone photos of the participant in a supine position with the reference card. Investigators and parents were given a list of image quality requirements and guidelines for capturing good-quality images. Parents and investigators completed their respective user experience questionnaires after the image upload process.

Ethical Considerations

KK Women’s and Children’s Hospital’s independent ethics committee approved the study before its initiation (approval no.: 2021/2540). The study was conducted in accordance with good clinical practice, the Declaration of Helsinki, and the local laws and regulations of Singapore. Written informed consent was obtained from the parent(s) of each participant before any study-related activities were undertaken. The participants’ parent(s) received vouchers (equivalent to 30 Singapore dollars, or US $22.32) as a token of appreciation for participating in the study. Participant data were pseudonymized for analysis.

Study Assessments

Standardized Length Measurements

The body length of the participant was measured twice by investigators to the nearest 0.1 cm using the standardized WHO technique [23]. As the participants were younger than 2 years old, measurements were taken supine by 2 investigators using an infant length board. The average of the 2 measurements was recorded as the participant’s body length and used as input to the LAI algorithm. If the 2 measurements differed by more than 0.5 cm, a third measurement was taken and the average of the three measurements was used.

User Experience Questionnaires

Customized questionnaires were used to capture user feedback from investigators and parents on their experience with taking suitable photos according to the study requirements and on other items relating to using a digital measurement tool, including expected accuracy and desirable features.

LAI Algorithm Overview

The LAI algorithm uses state-of-the-art imaging and machine learning techniques to estimate a participant’s length from a single image, such as a smartphone photo. The current algorithm was designed to predict the length of children up to 18 months. The input to the algorithm is a digital image of the participant in a supine position and a reference object (standard size card, 85.6 mm by 54.0 mm). The first step involves extracting image features for both the participant and the reference card (Figure 1). Landmark extraction models are used to detect landmarks on the participant’s face and body (shoulders, hips, knees, ankles, heels, etc) within the image. These estimate the length of individual body segments in pixels. The card detection and card segmentation models are used to locate the reference card in the image and compare its pixel dimensions against its known physical dimensions to generate a pixel per metric value. The feature extraction step thus generates a set of quantitative features used in the length prediction step (Figure 1). A model incorporating these features predicts the total body length in millimeters. The algorithm returns a predicted length value as output only if the key feature extraction steps (body and card features) are successful.

Figure 1. LAI algorithm overview. From an input image of a child in a supine position and a standard reference object, anthropomorphic landmarks of the body and face are extracted, along with the detection and segmentation of the reference object (a standard size card, 85.6 mm by 54.0 mm). These are used by the LAI algorithm to predict the length of the child. LAI: length artificial intelligence.

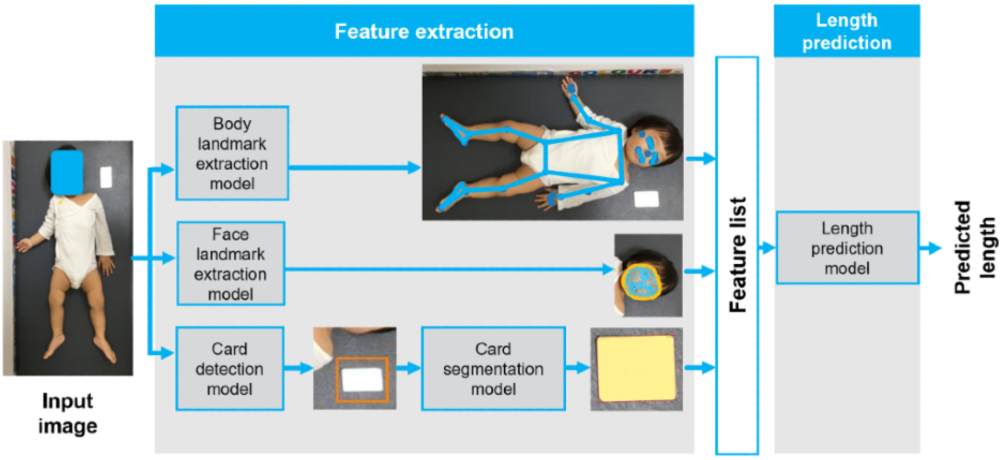

Image Datasets

The investigator and parent datasets consisted of all images taken by the investigators and the parents, respectively.

Image Requirements

To maximize the number of images usable for length prediction, photo-taking guidelines were given to investigators and parents. This included no clothing on the head or feet (eg, cap, socks, etc); no loose or baggy clothing to ensure that the body contour was visible; high contrast between the background, participant, and reference card; participant and reference card placed on the same flat and stable surface; participant positioned not more than 10 cm from the reference card; taking the image at an angle of 90 degrees from the surface on which the participant and card were placed; and participant’s legs not bent with the entire body visible to the camera. Images that fail to meet these requirements, such as those shown in Figure 2A-F, may fail to generate length predictions.

Following further testing and optimization, automated flags (warnings) were incorporated into the LAI (Figure 3). This allows the tool to detect uploaded images that do not meet the specified requirements and warn users that length prediction may be unsuccessful. In total, 4 different types of warnings were implemented.

Figure 2. Challenges with image-based length prediction. Images that pose challenges for length prediction by the LAI algorithm include those where (A) the camera is not positioned perpendicularly (90-degree angle) above the participant during image capture, (B) the participant and reference card are not placed on a flat horizontal surface, (C) there is blurring or glare, (D) there are baggy clothes on participant affecting the visibility of body contour, (E) there is low contrast of the participant with background, and (F) the face or body is not fully visible. LAI: length artificial intelligence.

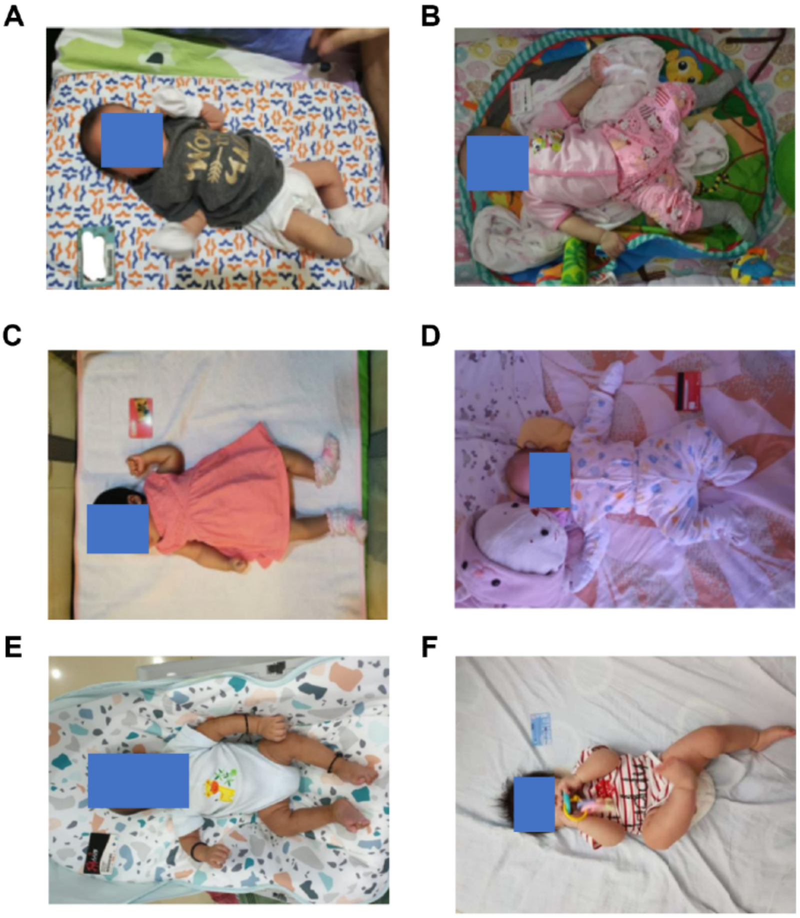

Figure 3. Schematic diagram of image flow. A total of 2490 images were collected in this study and 2224 images were analyzed. A total of 266 images were not analyzed due to protocol deviations (resubmission of images, submission of images outside the stipulated visit window, or images that did not meet the requirements). Of 2224 images analyzed, 2211 images produced a length prediction. The algorithm did not produce a prediction for 13 images due to unsuccessful pose segmentation (m=7) or unsuccessful card segmentation (m=6). High-quality images refer to images that did not generate any warnings. m (%): number and percentage of images in the specified category.

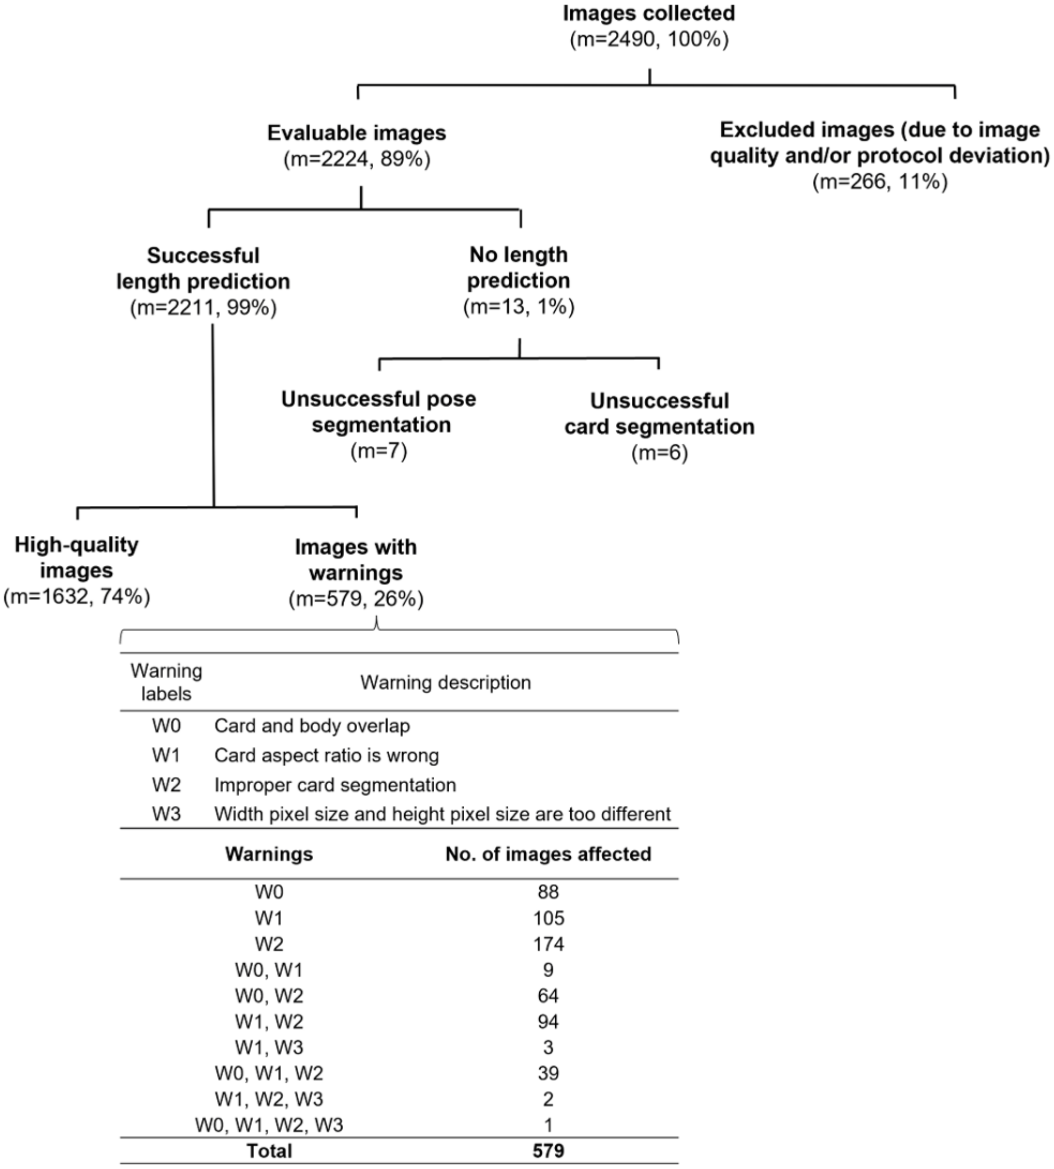

Warning labels	Warning description
W0	Card and body overlap
W1	Card aspect ratio is wrong
W2	Improper card segmentation
W3	Width pixel size and height pixel size are too different

Warnings	No. of images affected
W0	88
W1	105
W2	174
W0, W1	9
W0, W2	64
W1, W2	94
W1, W3	3
W0, W1, W2	39
W1, W2, W3	2
W0, W1, W2, W3	1
Total	**579**

Model Training and Performance Metrics

The LAI model was trained on the set of images collected by investigators (investigator dataset) and the investigator-generated length measurements. As described above, a set of features was generated, along with warnings. Only images that did not produce warnings were used to train the model. A 5-fold cross-validation was performed. Cross-validation is a statistical resampling method commonly used in applied machine learning to evaluate model performance with limited datasets [24,25]. The dataset was divided into 5 folds (subsets of data used for model training and testing) using 3 criteria: each participant's images should appear in only 1-fold; similar numbers of participants and images per fold; and similar distribution of measured body lengths across folds. In addition, details are provided in the *Cross-Validation Procedure* section in Multimedia Appendix 1. A bagged model was used for prediction. Hyperparameter optimization (HPO) incorporated a random feature selection step and was implemented using a state-of-the-art HPO framework [26]. The training was performed using a 2-step process. In the first step, a model was trained on all images from the investigators in the current training fold. A subset of these images within the 90th percentile of the training error was then selected, and the model was retrained on these images to ensure that outliers did not affect the training. Finally, all test images (from the investigators and parents) without warnings within the current fold were used to predict and calculate validation errors. The average validation error from all folds was used to drive the HPO framework to find the best model.

Performance metrics were calculated on a per-image and per-participant basis. For a given image i, the body length (p_i) predicted by the trained model was compared with the corresponding participant's WHO-standardized length measurement (m_i) to derive the following performance metrics: error (E_i, cm: difference between measured and predicted length $E_i = [m_i - p_i]$); absolute error (AE_i, cm: absolute value of the error $AE_i = E_i$); and absolute percentage error (APE_i, %: AE as a percentage of the length measurement,). Bias (average of *E*, cm;), mean AE (MAE; average of AE, cm), mean APE (average of APE, %), percentages at each AE cutoff (≤1 cm, ≤2 cm, ≤5 cm, and ≤10 cm), and percentages at each APE cutoff (≤2%, ≤5%, ≤10%, and ≤20%) were also calculated. Missing values due to errors, where the model did not return a predicted length value, were counted and reported separately. For participants with successful length predictions based on at least 9 images, the predictions for each image were averaged to generate a single predicted length for that participant.

The performance of the LAI model was evaluated using 5-fold cross-validation performed on the combined investigator + parent datasets and investigator-generated length measurements. To assess the LAI algorithm's performance relative to measurements in general clinic settings [8,22], the appropriate performance metrics were compared with published values for the technical error of measurement (TEM), an index commonly used in anthropometry to assess the accuracy and reliability of measurements [19-21].

Statistical Analysis

Due to the exploratory nature of this study, there was no formal sample size calculation. It was estimated that a complete dataset from 200 participants (standardized length measurements, images taken by investigators, images taken by parents, and completed questionnaires from investigators and parents) would allow model performance to be adequately assessed. Assuming a 20% dropout rate, 250 participants were planned for enrolment.

Descriptive statistics were used to summarize participant characteristics and user experience questionnaire responses. Continuous variables were summarized using mean, median, and minimum and maximum values. Discrete variables were summarized using percentages and frequencies by category, including missing values. No statistical testing of formal hypotheses was conducted.

Results

Characteristics of Participants and Image Data

In total, 215 participants were enrolled in the study, of whom 50.7% (n=109) were female. The mean age was 6.1 (SD 5; range: 0.0-17.7) months and the median age was 4.4 months. All participants completed the clinic-based data collection procedures, and 200 participants completed both clinic-based and home-based data collection procedures to provide a complete dataset of length measurements, images, and questionnaires.

A total of 2490 images were taken and uploaded (1290 images by 8 investigators at the clinic and 1200 images by 200 parents at home; Figure 3). Of these, 89.3% (2224/2490) of images were analyzed, and 10.7% (266/2490) were excluded due to image quality or protocol deviations.

Length Prediction Performance of the LAI Algorithm

The LAI produced a length prediction for 2211 (99.4%) out of 2224 images (Figure 3). In total, 0.6% (13/2224) of images did not produce a prediction due to either unsuccessful pose segmentation (7 images) or unsuccessful card segmentation (6 images). For the set of 1632 high-quality images (those that did not generate any warnings; Figure 3), the bias (mean error) for individual image predictions was minimal (0.03 cm; Table S1 in Multimedia Appendix 1). Most of the length predictions for these individual images (1557/1632, 95.4%) were within 10% of the measured length (Figure 4 and Table S1 in Multimedia Appendix 1). We found that length prediction was improved by averaging over multiple images for a participant. For 88 participants who had predictions for ≥9 images, the majority of these averaged length predictions (71/88, 81%) were within 5% of the measured length (Figure 4 and Table S1 in Multimedia Appendix 1).

The overall distributions of errors for individual image predictions and participant-averaged predictions are illustrated in Figure 5 [8,19,20,22]. Published interobserver TEM ranges for length measurements from the WHO Multicenter Growth Reference Study (0.48 cm [19], 0.70 cm [20]) and general clinics or community health settings (1.41 cm [22], 1.25-1.59 cm [8]) are indicated on the figure for comparison. The MAE for individual image predictions was 2.47 cm, and the MAE for participant-averaged predictions was 1.77 cm, which approaches the TEM range reported in general clinics or community health settings [8,22].

A quarter of the images with successful length predictions (579/2211, 26.2%) generated at least 1 warning (Figure 3). For this study dataset, the most common warning was improper card segmentation. The numbers of images affected by each type of warning are shown in Figure 3. Figure 6 illustrates the percentages of images available for length prediction under scenarios where different warning types are ignored, and the corresponding MAE values. The length prediction workflow can be adjusted to use more or less stringent settings, which affects the number of images retained for prediction and prediction error. Retaining fewer but higher quality images (fewer warnings) for prediction resulted in smaller MAE values (2.47 cm on images without any warnings); conversely, ignoring more warning types allowed more images to be used, but led to an increased MAE (3.39 cm using all images regardless of warnings). Similarly, the MAE for participant-averaged predictions decreased from 2.48 cm (n=155) to 1.77 cm (n=88) when only high-quality images without warnings were used for prediction (Table S1 in Multimedia Appendix 1).

Figure 4. Scatter plot depicting length predictions made by the model versus gold-standard length measurements made by the investigators. For length predictions on individual images, the majority fell within 10% of the participant's measured length. For averaged length predictions (per participant, for participants who had predictions from ≥9 images), the majority fell within 5% of the measured length. Blue circles represent predictions from all individual images. Red squares represent averaged predictions for children who had predictions from at least 10 images. The thick black line indicates the ideal prediction (ie, length prediction equal to the measured length). Dashed lines represent 5% and 10% deviations from the ideal prediction.

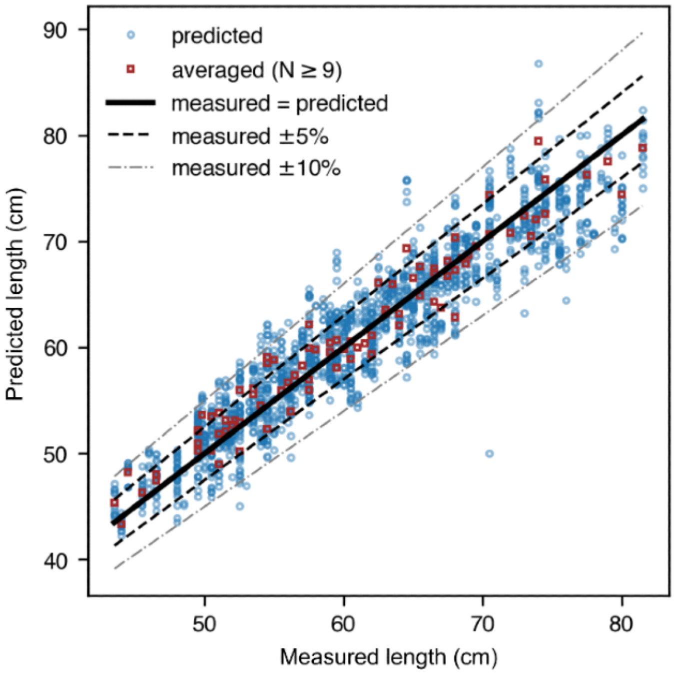

Figure 5. The overall distribution of errors (residuals) for individual image predictions (blue dots) and participant-averaged predictions made by the model. These were presented alongside published interobserver TEMs of "gold standard" length measurements from WHO (0.48 cm and 0.70 cm) and general clinics or community health settings (1.41 cm and 1.25-1.59 cm). The MAE of individual image predictions was 2.47 cm. When averaged, the predictions had an MAE of 1.77 cm, which approaches the TEM range reported in general clinics. MAE: mean absolute error; TEM: technical error of measurement; WHO: World Health Organization.

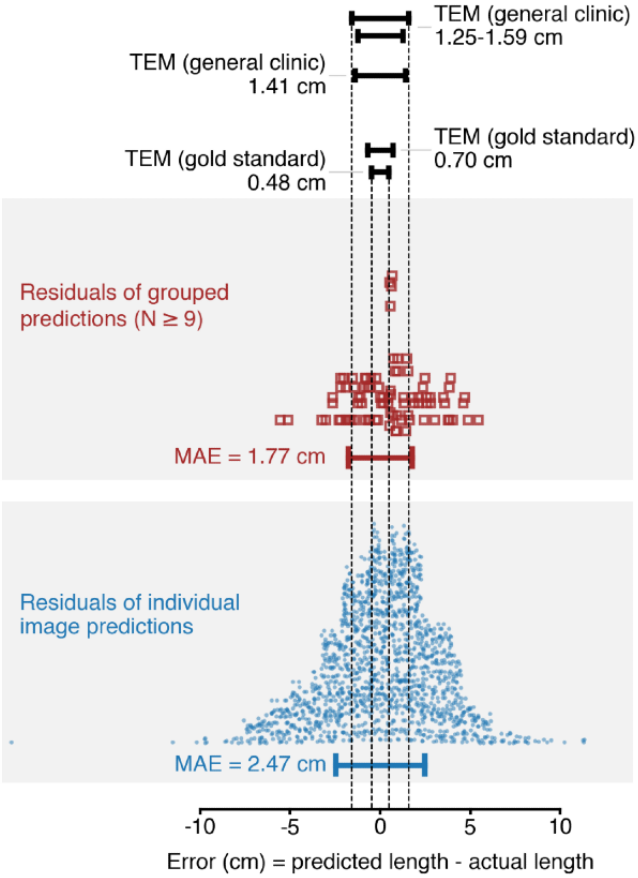

Figure 6. A plot illustrating the percentage of images available for length prediction and the corresponding MAE under varying scenarios where combinations of different warnings were ignored. Ignoring more warning types allowed more images to be used but yielded less accurate length predictions. Warnings: W0, card and body overlapping; W1, incorrect card aspect ratio; W2, improper card segmentation; W3, width, and height pixel size are too different. MAE: mean absolute error.

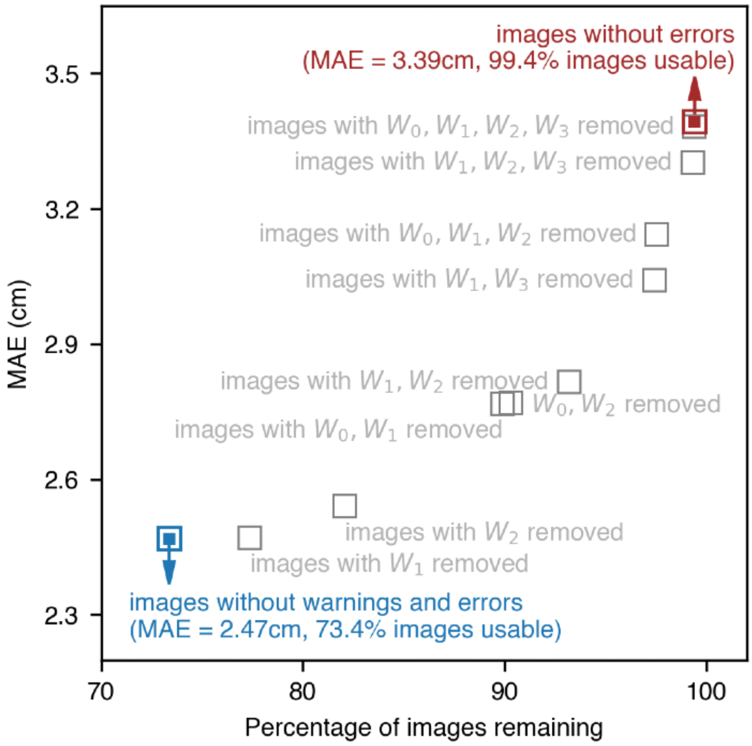
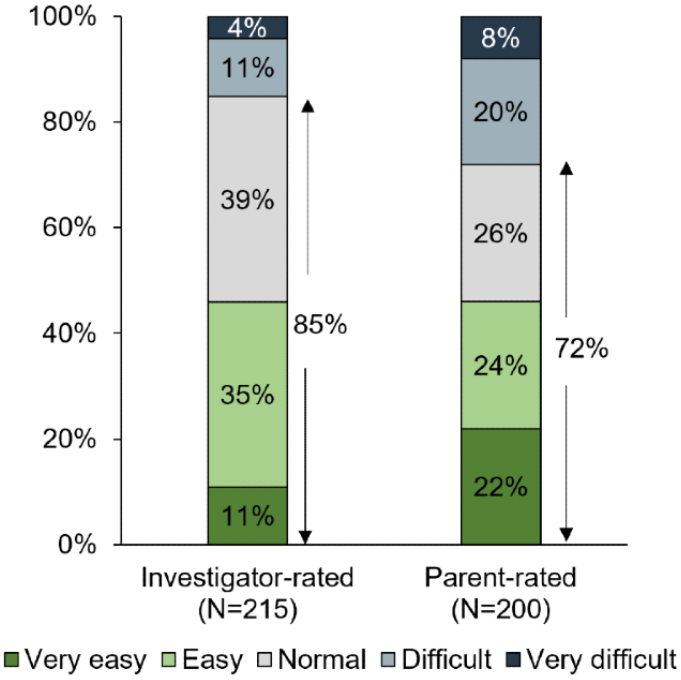


User Experience

In most cases, investigators and parents reported that they did not find it difficult to capture the required images (Figure 7). Investigators and parents rated the photo-taking process as very easy, easy, or normal for most participants (182/215, 84.7% participants, and 144/200, 72% participants, respectively).

Figure 7. Ease of collecting images as rated by investigators and by parents. N represents the number of participants for which the investigator or parent provided a rating.



User Feedback on the Use of a Digital Tool for Length Measurement

In total, 7 (88%) of 8 investigators indicated that they would be likely or very likely to use a digital tool that could automatically measure a child's length from an image, if available for clinical use (Multimedia Appendix 2). A similar proportion (7/8, 88% investigators) reported that they would be likely or very likely to recommend a digital length measurement tool to parents for home use, if available.

As for parents, most (143/196, 73% responses) were not currently taking length measurements regularly (at least once a month or more frequently) at home, whereas 57.1% (112/196) never measured length at home and 16.3% (32/196) measured less frequently than once a month (Multimedia Appendix 3). However, 91.5% (183/200) felt that a digital tool that could automatically predict length from an image would be useful or very useful for them to measure their child's length at home (Multimedia Appendix 3), and 88.5% (177/200) indicated that they would use such a tool at least once a month or more frequently (Multimedia Appendix 3).

Investigators and parents were asked about the magnitude of difference between standard clinic measurements and the length predicted by a digital tool that they would find acceptable in their typical use settings. For all investigators, only differences of ≤1 cm (4/8, 50% investigators) or ≤2 cm (4/8, 50% investigators) with respect to clinic measurements were considered acceptable (Multimedia Appendix 4). For most parents, differences of ≤1 cm (63/200, 31.5%) or ≤2 cm (93/200, 46.5%) were deemed acceptable, although a small proportion of parents considered differences of up to 5 cm acceptable.

Additional Desirable Features for an Automated Growth Measurement Tool

Apart from automated length measurement, investigators and parents highlighted several additional features that would be desirable in an image-based tool. Key desired features included estimating other anthropometric measurements, such as weight, head circumference, and growth-tracking functionality. Half of the investigators (4/8, 50%) suggested it would be useful to estimate other anthropometric parameters. A quarter (2/8, 25%) of investigators indicated that having a growth-tracking function would help detect growth abnormalities. In addition, 16% (32/200) of parents wanted the tool to be able to estimate weight or other anthropometric measurements. In total, 40% (80/200) of the parents wanted to be able to track their child's height, length, or both over time and have these measurements presented alongside the corresponding WHO height-for age and length-for-age charts.

Discussion

Principal Findings

Length measurement is challenging in clinical practice, especially among children younger than 2 years of age, where inaccuracy and interobserver variability in length measurements have been documented in primary care and community health settings [5,8,27]. Without proper equipment and training, it is impractical to expect parents and caregivers to take accurate and reliable length measurements at home regularly. Approaches for computer-assisted body length estimation from digital images have been proposed but involve elaborate requirements for data capture or procedures that may cause disturbances to the child [17,18] and limit their real-world feasibility and applicability. In contrast, the LAI algorithm was designed to have minimal requirements in terms of equipment and user training: only a smartphone and a readily available reference object (standard-size credit card) are required for data collection.

In our study, both parents and investigators found it easy to take the required photos for automated length estimation. Results from this proof-of-concept study suggest that the LAI algorithm, when trained on high-quality length measurements and image data, can predict children's body length with minimal systematic error and accuracy approaching that achieved in general clinics or community health settings. This indicates the potential for future implementations of the LAI algorithm to make growth monitoring more accessible to nonexpert users. The MAE for individual image predictions was 2.47 cm, and our results suggested that length prediction could be improved by averaging across multiple images of a child: participant-averaged predictions had a smaller MAE of 1.77 cm, which approaches the published interobserver TEM range (1.25-1.59 cm) reported in general clinics and community health settings [8,22]. Thus, the LAI algorithm would enable parents to estimate their child's length using images captured using their smartphones, with accuracy comparable to length measurements in general clinics or community health settings. Published reports indicate that the level of accuracy considered acceptable ranges from 0.5 cm to 2.0 cm, depending on the clinical indication for which length measurements are required [5,6,9,19-22,27]. For clinical growth monitoring, the WHO Multicenter Growth Reference Study protocols recommend interobserver differences of <0.7 cm for length [20], and the Standardized Monitoring and Assessment of Relief and Transitions (SMART) manual indicates an acceptable limit of <0.5 cm for height [28]. Growth measurement studies commonly report differences of ≤0.5 cm for expert anthropometrists [19-21,29]. This is consistent with the views of the study investigators, who indicated that they considered an accuracy of within 1 cm acceptable in an expert clinical setting.

Although smartphones greatly facilitate data collection for LAI algorithm, it is not always possible to consistently capture high-quality images of a child, which affects the accuracy of predictions. Commonly encountered image quality issues include the visibility of body landmarks obscured by clothing or limb position (Figure 2). Within the current LAI algorithm, we implemented a system that detects issues with uploaded images and generates warnings that these could affect length prediction (Table S1 in Multimedia Appendix 1). The settings can be tuned to ignore warnings and allow more images to be used for length prediction but at the cost of generating less accurate predictions. We envision that future versions of the tool will be integrated into a smartphone application that offers real-time feedback to guide parents or caregivers in positioning the baby and the standard-size reference object. Such feedback, including alerts about potential image quality issues and guidance on how to avoid or reduce key sources of error, would help users to take photos that are more likely to result in accurate predictions.

Other technologies, such as depth-of-field sensors available on some consumer devices, could potentially be integrated to further improve performance. Time-of-flight or light detection and ranging sensors can provide depth-of-field information that could be used with the current image-based algorithm to increase length prediction accuracy. Relevant practical considerations include the availability and accuracy of these technologies, especially for smaller participants like infants.

This proof-of-concept study collected images and corresponding length measurements and used these to explore the feasibility of a digital tool that can be used in home environments and in clinics to monitor growth over time. Due to the limited data available, a cross-validation approach was adopted to maximize the information that we could obtain about the tool's performance. This lack of an external validation sample may introduce limitations such as underestimation of error when the model is applied to new datasets, and systematic errors if the model's assumptions do not hold on to other datasets. Although care was taken to ensure that the reference measurements were as accurate as possible by using a standardized protocol (WHO method) and trained personnel, we have not formally accounted for the possibility of human error in the length measurements used for training.

Findings from our study have been used to refine the tool further, and projects to evaluate the feasibility and acceptability of the improved version are ongoing. At present, the proof-of-concept results suggest that the LAI algorithm's current performance may be compatible with personal use, such as general growth tracking at home, as its performance approaches that of manual length measurement in general clinics or community health settings [8,22]. Using the LAI algorithm, parents could record length measurements more frequently and conveniently at home. This idea is consistent with feedback from parents of the children in our study. Most parents reported that they did not measure their child's length at home; on the other hand, they indicated that an automated measurement tool was desirable and would be used at least monthly or more frequently. Besides automated length measurement, parents wanted a tool capable of estimating other anthropometric parameters and allowing them to track their child's growth with reference to WHO growth charts [3]. This user feedback provides valuable insights that can guide future development of the tool.

Conclusion

One of the main strengths of the current LAI approach is its simplicity and practicality for nonexpert end users. Data collection requires no specialized equipment or training; physical discomfort and disturbance to the child are minimized. This innovative approach explored the feasibility of image-based automated body length estimation that can be conveniently performed in a wide range of environments by any user. The potential value of such tools to nonexpert users is underscored by the range of studies that explore the possibilities of digital technology-assisted anthropometry [30,31]. The feedback collected from parents and clinicians in this study will inform future versions of the tool to better cater to the unique requirements of different users. It should be noted that the LAI algorithm's performance was evaluated only using data from healthy children (those without known growth-related conditions). Further studies with different populations will be needed to guide the design and optimization of the LAI algorithm for use in more specialized clinically oriented tasks such as monitoring for abnormal growth.

It should be noted that this was a proof-of-concept study to demonstrate the feasibility and acceptability of the LAI tool for estimating body length in young children (aged <18 months) in the home and similar environments. The performance achieved to date suggests that the current version of the LAI algorithm would not replace the standard clinical method used by health care professionals, but there is potential for future development to enhance its accuracy and applicability. Although the tool does not currently meet the requirements for highly accurate measurement in specialist clinical applications, our findings suggest that improving image quality is one way to increase length prediction accuracy. Integration of other technologies, such as depth-of-field sensors available on some consumer devices, could be explored to further improve performance. The current performance of the LAI algorithm, coupled with its ease of use, suggests it has the potential to be a feasible method of measuring a child's length for use by parents with accuracy approaching that of general clinic or community health settings.

Abstract

Background: The outbreak of COVID-19 has turned the care model of health systems around the world upside down. The health care crisis has led to opportunities for digital health to deliver quality care, and the system has been redirected toward telemedicine. In Catalonia, Spain, as of March 2020, the pattern of visits in primary care pediatric consultations changed, such that face-to-face visits decreased in favor of non–face-to-face visits.

Objective: This study aimed to analyze variations in the types of pediatric visits in primary care centers in Catalonia before and after the onset of COVID-19.

Methods: This was a descriptive observational study based on administrative data. The number and type of visits to primary care pediatric services in Catalonia between January 2019 and December 2022 were studied.

Results: A drop of more than 80% in face-to-face visits and an increase of up to 15 times in remote visits were observed as of March 2020 compared to the previous year. Subsequently, the face-to-face attendance rate began to recover, although it did not reach the same rate as before COVID-19. Non–face-to-face visits were maintained, representing more than 20% of the total after more than 2 years of the pandemic.

Conclusions: COVID-19 has been the trigger for a transition in the types of visits to primary care pediatric services. The COVID-19 pandemic was a clear catalyst for the integration of telemedicine in Catalan pediatric health care. In this context, although face-to-face consultations have recovered in absolute numbers, after the pandemic period, the weight of telemedicine has increased.

COVID-19; remote consultation; primary health care; digital health; pediatric; face-to-face; telemedicine

Introduction

The COVID-19 pandemic has turned the care model of health systems around the world upside down, causing a significant and often unexpected transformation or disruption in the way health care services are delivered and organized worldwide [1]. In Catalonia, Spain, the health care crisis has led to opportunities for digital health to deliver quality care, and the system has been redirected toward telemedicine [2,3].

Both primary care (PC) centers and hospitals in Catalonia and in many other countries had to adapt to the new situation, where in the face of uncertainty, people (including children) were recommended to not go to health centers in person unless strictly necessary [4,5]. Therefore, as of March 2020, the pattern of visits changed in PC pediatric consultations [6,7]. As with all other services, face-to-face consultations decreased considerably while non–face-to-face consultations increased significantly worldwide [8,9]. In Spain, the reduction in visits during the first months of the declaration of the state of alarm mainly affected child health program check-ups and acute demand due to infectious diseases [10]. In general terms, the acute infections that decreased the most once the strictest confinement started were respiratory and digestive infections [11]. At the same time, telephone consultations multiplied considerably. Later, in June 2020, despite the expected difficulties due to the fear of users and health care workers and the barrier of accessibility to PC, face-to-face attendance was not as low, as health care was managed more appropriately [12].

A multicenter study coordinated by the Spanish Association of Primary Care Paediatrics in June 2020 explains how PC pediatric services were organized during the first wave of COVID-19 and indicates that, in general, pediatricians followed the center's own contingency plan and that total consultations reduced by approximately 40% to 50% compared to the same period of the previous year [13]. There was a very significant increase in the rate of teleconsultations, such that more than 90% of pediatricians made teleconsultations as opposed to 38% who did so before the pandemic. In contrast, a decrease in on-site visits was noted, and these were mostly (88% of the cases) visits for the child health program.

In Catalonia, an autonomous community of the Spanish state with full competence in health matters, public health care coverage is guaranteed to all citizens through almost 400 PC centers. In pediatrics, in addition to visits for acute and chronic diseases and follow-up, the child health program called *Infància amb Salut* [14] is applied. It is a protocol developed by the Public Health Agency of Catalonia and includes actions that are carried out individually by the PC pediatric team for preventive visits and check-ups, scheduled between 0 and 14 years of age. It includes screenings, vaccines, and health education. It is implemented throughout the public health network of Catalonia. In this way, access to a high-quality child health service is guaranteed universally, that is, for all children and adolescents residing in Catalonia regardless of their socioeconomic situation or place of residence. These visits are called child health check-ups and have specific characteristics, which are different from the visits carried out for acute or chronic diseases or follow-ups.

A previous analysis conducted in Catalonia suggests that non–face-to-face visits (telephone and teleconsultation) increased threefold during the pandemic, while face-to-face visits fell by almost half. Despite this, there are no specific data on the evolution of the pattern of PC pediatric visits throughout the COVID-19 pandemic [15]. In this context, the objective of this study is to describe the quantitative evolution of different types of visits, both remote or electronic and on-site, from 2019 to 2022 in PC pediatric services in Catalonia.

Methods

Study Type

This was a retrospective, descriptive, and observational study in the Autonomous Community of Catalonia, Spain.

Population, Place, and Study Period

The study population comprised a sample of all the children who resided in Catalonia and accessed services between January 1, 2019, and December 31, 2022. This extended study period allowed for the collection of comprehensive data on the demand of child health care services over a period of 4 years.

Data were collected from the Information System of Information Technologies of the Primary Care Services of Catalonia database belonging to the Catalan Health Institute. Data regarding the number and type of visits between January 2020 and December 2022 were analyzed and compared to the corresponding period in the previous year (2019; ie, before the pandemic).

Variables

Three variables were considered: date of visit, number of visits in a given day, and type of visit; the latter is a categorical variable with 7 types of visits that are established in pediatric PC in Catalonia (9C, 9R, 9D, 9T, 9Ev, 9E, and 9Ec), which were reworked into 3 groups: face-to-face (9C, 9R, and 9D), synchronous non–face-to-face (9T and 9Ev), and asynchronous non–face-to-face (9E and 9Ec) visits. Table 1 summarizes the particularities of each visit type in relation to face-to-face attendance, duration, and synchronicity.

Table . Characteristics of the types of visits to pediatric primary care in Catalonia.

Designation	Types of visits	Face-to-face attendance	Average duration (min)	Synchronicity
9C	Spontaneous medical appointments	Yes	12	Yes
9R	Child health program check-up	Yes	20	Yes
9D	Home visit	Yes	30	Yes
9T	Telephone consultation	No	6	Yes
9Ev	Video call consultation	No	12	Yes
9Ec	Consultation through the eConsultation digital platform	No	6	No
9E	Non–face-to-face consultation (report, prescription, etc)	No	6	No

There are 3 types of face-to-face visits: short visits dedicated practically to acute demand (9C), child health program check-ups (9R), and home visits (9D). Synchronous non–face-to-face visits include telephone consultations (9T) and video call consultations (9Ev). Asynchronous non–face-to-face consultations comprise eConsultations (9Ec) through La Meva Salut, a personal digital health space, and non–face-to-face consultations (9E), which include consultations where the health care professional does not have direct contact with the user—often because it has been managed through administrative staff, involving procedures such as medication plan preparation, report writing, test evaluation, data management, interconsultation between professionals, and coordination with other services.

Statistical Analysis

To describe variables, we expressed continuous variables as means and SDs, and we summarized categorical variables as percentages. As for the *t* tests, a Welch unequal variances (2-tailed) *t* test was carried out to compare the mean of total pediatric visits made each month for 2019, 2020, 2021, and 2022, to check if there had been a recovery of total visits. Then, the same Welch test was performed for each group (face-to-face, remote synchronous, and remote asynchronous). Bonferroni correction has been applied to all *P* values. All statistical analyses were conducted using R software (version 4.1.0; R Foundation for Statistical Computing), and the significance level was set at 5%. To smooth the plots, a 14-day rolling average was performed.

Ethical Considerations

No ethical approval was required, as analyses were conducted only on aggregated data.

Results

General Evolution of Visits to PC Pediatric Services

Figure 1 [16,17] shows the evolution of the average number of daily visits made during the study period, between January 2019 and December 2022, to PC pediatric services in Catalonia, grouped according to the type of visit. The vertical stripes indicate the 8 waves of COVID-19 that can be defined in Catalonia with data from the Statistical Institute of Catalonia and the Information System for the Surveillance of Infections in Catalonia (*Sistema d'Informació per a la Vigilància d'Infeccions a Catalunya*; SIVIC) [16,17]. It is evident how during 2019, the volume of activity in PC pediatric services was predominantly through face-to-face visits and that this pattern changed completely after COVID-19.

Figure 1. Average number of daily visits by type (face-to-face, synchronous non–face-to-face, and asynchronous non–face-to-face) to pediatric primary care in Catalonia between January 2019 and December 2022. The vertical stripes indicate the 8 waves of COVID-19 in Catalonia.

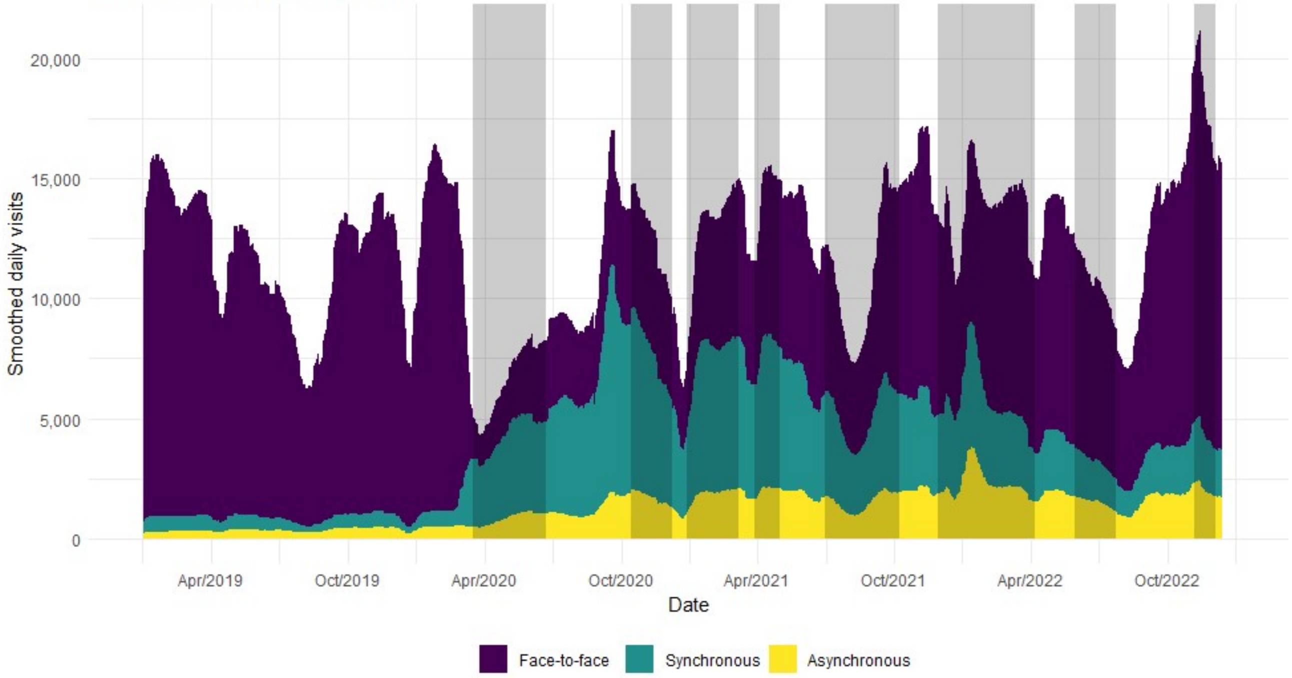

Figure 2 [16,17] shows the distribution of the 3 types of visits to PC pediatric services in Catalonia over the last 3 years. The drop in the relative weight of face-to-face visits with the outbreak of the COVID-19 pandemic is noteworthy. Later, they slowly picked up again but did not reach the 2019 proportion at the end of the study. Figure 2 shows that face-to-face visits had recovered in absolute numbers but not in proportion because telemedicine consultation had increased its weight. In parallel, synchronous and asynchronous remote visits grew and changed the pattern of consultation types during the months of the pandemic. At the end of the study period, non–face-to-face visits gained ground, clearly changing the distribution of the types of visits.

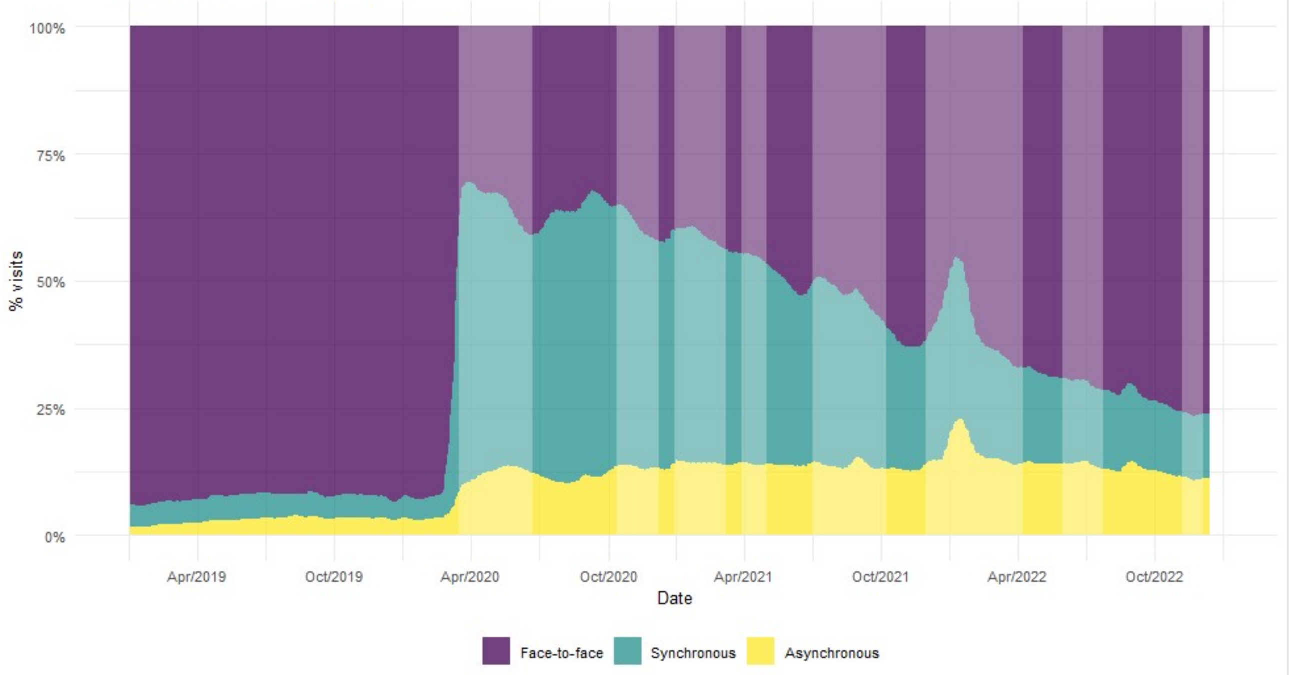
Figure 2. Distribution of daily visits by type (face-to-face, synchronous non–face-to-face, and asynchronous non–face-to-face) to pediatric primary care in Catalonia between January 2019 and December 2022. The vertical stripes indicate the 8 waves of COVID-19 in Catalonia.



Evolution of Visits According to the Type of PC Pediatric Services

Overview

The data corresponding to the results discussed below are shown in Multimedia Appendix 1, which shows the average daily number of visits in total and by types of visits, separated by month, to PC pediatric services in Catalonia between 2019 and 2022. The change, expressed as a percentage, was calculated with reference to the same period in 2019 and analyzed to see if it was statistically significant.

Total Visits

With the emergence of COVID-19 in March 2020, visits decreased significantly from the previous year. It can be observed that the number of daily visits decreased from 15,389 in the month of February 2020 (*P*=.32; vs February 2019) to 9515 in the month of March 2020 (*P*=.001; vs March 2019). The sharpest decrease relative to 2019 was in the month of April 2020 with 5102 visits per day on average (*P*<.001; vs April 2019). This represents a drop of more than 30% of total visits in March and more than 50% in April compared to the same months of the previous year.

In August 2020, compared to August 2019, the number of visits bounced back and the volume of daily visits did not show significant decreases again. In some months it was even significantly higher. The figure for November 2022 stands out, a month in which a maximum of 18,976 visits per day on average was reached (*P*=.002; vs November 2019), which is 40% more visits than the same period of the reference year (Multimedia Appendix 1).

Face-to-Face Visits

Regarding face-to-face visits, it can be observed that as of March 2020, there was a significant reduction that persisted until July 2022, the month from which a change in trend was observed and the levels of 2019 were recovered. In April 2020, this decrease was at its maximum and reached 85%, with 1604 visits on average per day compared to 10,987 in April 2019 (*P*<.001). Further on, the reduction was between 48% and 79% throughout 2020, between 17% and 67% in 2021, and between 13% and 47% in 2022, all with respect to 2019 (Multimedia Appendix 1).

Synchronous Non–Face-to-Face Visits

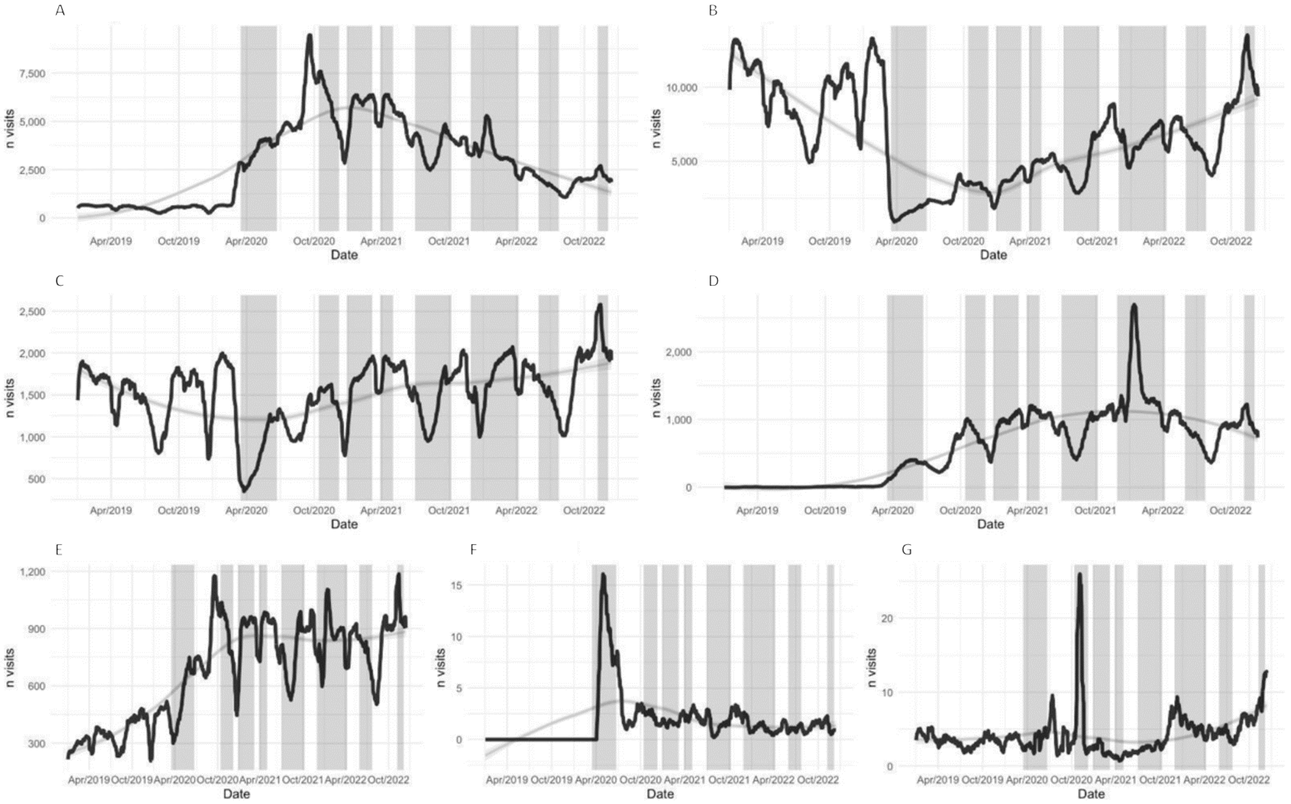
As for synchronous non–face-to-face visits, a statistically significant increase was noted starting in March 2020 that was maintained until the end of the study period. March 2020 saw a 200% increase in average daily visits and an increase from 620 daily remote visits in March 2019 to 2073 in March 2020 (*P*<.001). The increase was maintained, and synchronous remote visits went from representing 4.5% of total visits in 2019 to occupying 20% of total visits in 2022 (Multimedia Appendix 1).

Asynchronous Non–Face-to-Face Visits

Asynchronous non–face-to-face visits also experienced a statistically significant rise that had already been observed since January 2020 compared to the previous year. While in the first 3 months they had risen by around 60%, from April onward they rose by more than 90%, in May they rose by 154%, and they continued to increase during the following months. Growth continued and asynchronous remote visits increased from 2.8% of total visits in 2019 to 16% of total visits in 2022 (Multimedia Appendix 1).

Finally, Figure 3 [16,17] shows the evolution of the average number of daily visits according to the different subtypes (9C, 9D, 9R, 9T, 9Ev, 9E, and 9Ec).

Figure 3. Average daily visits by subtypes to pediatric primary care in Catalonia between January 2019 and December 2022: (A) 9T, (B) 9C, (C) 9R, (D) 9Ec, (E) 9E, (F) 9Ev, and (G) 9D. The vertical stripes indicate the 8 waves of COVID-19 in Catalonia.



Looking at face-to-face visits by subtypes, we can observe a marked reduction in face-to-face visits for acute diseases (9C) starting in March 2020, with a subsequent slow and progressive recovery that did not reach the previous values until November 2022. With respect to the check-ups of the *Infància amb Salut* (9R) program, a significant reduction was also detected as of March 2020, which recovered rapidly and practically completely during the second half of 2020. Pediatric home visits (9D) represented a very small volume with respect to total visits and did not undergo major changes during the years analyzed. However, a spike in these visits was noted during November 2020.

Regarding synchronous remote visits by subtypes, telephone consultations (9T) tripled from February to March 2020 and increased more than tenfold, peaking in September of the same year. Thereafter, a progressive decrease in the number of calls was observed, which at the end of the study period remained above the reference year. As for video call consultations (9Ev), although the values were also very low, we saw the emergence of this type of visit, with a sporadic peak between April and May 2020. Subsequently, they returned to a practically imperceptible level.

Regarding asynchronous remote visits, non–face-to-face visits (9E) already had a progressive growth before the pandemic, but it was between March and September 2020 when the sharpest increase was seen, which was maintained until the end of the period studied. Pediatric eConsultations (9Ec) rose slowly from March 2020 and stabilized at a higher position than before March 2020. A sporadic peak was detected in January 2022.

Discussion

Principal Findings

The aim of the study was to analyze the change in the types of pediatric visits to PC centers in Catalonia between 2019 and 2022, following the COVID-19 pandemic. In this context, we have been able to describe the evolution and coexistence between the different types of visits, both face-to-face and non–face-to-face visits, as well as the change in the pattern of pediatric consultations during this period. In summary, the results showed that non–face-to-face visits increased from around 10% of the total in January 2020 (before the pandemic) to almost 25% in December 2022 (after the pandemic). Half of these were telephone consultations and the other half were eConsultations.

Total visits to PC pediatric services fell from March 2020 and did not recover in overall number until September of the same year. From there, the overall volume resumed, with some subsequent fluctuations more or less in line with subsequent waves of COVID-19. In the first wave, there was a marked decrease in face-to-face visits and an increase in teleconsultations, in accordance with the literature. In a study conducted in a PC center in Madrid during the month of June 2020, it was observed that 51% of the visits were remote [18]. Other studies, both nationally and internationally, have also stated that between March and May 2020, the pattern of visits to PC centers changed [19,20]. There was a significant predominance of remote visits, especially by telephone, over face-to-face visits [21].

In the second, third, and fourth waves, face-to-face visits continued to decrease, while remote consultations continued to increase. During the fifth wave, defined by the Delta strain inmid-2021, there was a decline in both face-to-face and remote consultations, possibly because it was not a strain that affected the pediatric age group very much [22]. Nevertheless, remote visits continued to represent a significant part of the total number of visits. This fact changed with the sixth wave, starring the Omicron strain, between December 2021 and February 2022, which particularly affected children [23,24]. The corresponding peak of visits shows that more than half of the consultations at that time were non–face-to-face. During the seventh wave, in mid-2022, no change in the pattern of visits was detected. The eighth wave coincided with the marked increase in total visits, especially face-to-face visits, detected in pediatric services as of November 2022. The considerable increase in visits from November 2022 onward, which exceed prepandemic levels, could be due to the increase in infections reactive to ceasing use of protective measures against COVID-19. This phenomenon has been called immunity debt and may pose a risk for serious epidemics in the near future [25].

A breakdown of visits between face-to-face and non–face-to-face visits clearly shows a drop in the proportion of face-to-face visits and a rise in remote visits as of March 2020. Attendance recovered to prepandemic levels during November 2022 in absolute numbers but not in proportion. Although the number of total visits increased at the end of 2022 compared with 2019, the percentage of face-to-face visits decreased and the percentage of remote visits increased; thus, the results highlight that, during the pandemic, the pattern of the type of pediatric PC visits has changed, as seen in other studies [15,26].

In relation to acute demand (9C), the drop was very sharp, and the recovery was very slow, such that it was not until November 2022, two years later, that levels prior to March 2020 were reached again. This result is similar to the findings of other studies that detected a lower number of visits during the months following the onset of the pandemic, especially in acute infections [27-29]. This may be due to a lower circulation of pathogens other than the SARS-CoV-2 coronavirus. In general, it appears that the reduction in face-to-face attendance did not have much negative impact on urgent pediatric pathology care [30]. However, some studies have reported problems of diagnostic delays, such as an increase in complicated appendicitis cases [31]. On the other hand, an increase in overweight and obesity, technology use, sleep disorders, anxiety and distress, domestic violence, social isolation, and behavioral disturbances were also detected, especially in adolescents [32]. Likewise, due to the reduction in face-to-face attendance, an alteration in the circulation pattern of some respiratory viruses was observed during the subsequent season (2020-2021), especially for respiratory syncytial virus, which had an unusual peak of incidence in midsummer, as reported by the SIVIC [17].

As for the child health check-ups (9R) of the *Infància amb Salut* program, they recovered earlier than visits for acute diseases (9C). Although a drop was detected during March 2020, coinciding with the first wave of COVID-19 and stricter confinement, these visits recovered more quickly and were at the prepandemic level by the end of 2020. Quantification of the delay and losses of check-ups and vaccines showed that vaccination coverage decreased in all the autonomous communities of Spain by between 5% and 60%, depending on age and the type of vaccine [33]. The Spanish Society of Immunology, the Spanish Society of Paediatric Infectious Diseases, and the Spanish Association of Paediatrics published a document in April 2020 with complete information on the decreased uptake of vaccines, along with the criteria for the prioritization of childhood vaccination during the state of alarm carried out by the Ministry of Health [34]. Following the publication of similar figures, European pediatric societies called for the immediate recovery of vaccination programs, since compliance with the established vaccination schedule is one of the prerequisites for dealing with the resulting problems, such as immunity debt and the decreased uptake of vaccines [35].

Telephone consultations (9T), prior to March 2020, represented a minimal volume of total pediatric consultations. The onset of COVID-19 led to an exponential increase in the number of such consultations. They peaked during September 2020, probably coinciding with the start of that year's school year. Later, an oscillation in the number of calls was observed, although they remained at a higher value than in the period prior to the study. Therefore, the results suggest that telephone consultations have been one of the most widely used tools, both by users and professionals, to replace face-to-face visits during the pandemic [36]. This growth could be due to the ease of use of the telephone as well as to the organization of visits in PC centers, where it was established that the first patient assessment should always be made by telephone [37].

Regarding video call consultations (9Ev), the results have shown that they were used very little during the first wave of home confinement, and this is in agreement with the literature [38]. This low use could be explained by the limited technological resources for video visits, the technical difficulty it could pose for patients with lower digital literacy, and the fact that there was an impression that they did not add value to telephone consultations or eConsultations. Although they are currently practically not used in PC, the literature shows that they have a potential yet to be explored [39,40]. A systematic review conducted in 2021 on telemedicine in pediatrics, which includes 11 studies, concluded that care through call and video-call type visits in various pathologies (obesity, asthma, mental disorders, otitis media, and skin disease) can be comparable to, and in some cases even better than, face-to-face care; for these cases, it is necessary to improve user access and the effectiveness of services [41].

As for telemedicine consultations (9E), which are conducted without the patient being present, they were already on the rise before the pandemic but skyrocketed as of March 2020. One possible explanation is that since most of the COVID-19 cases in pediatrics were mild, many visits were probably made remotely, to indicate the result of the rapid viral detection test to administrative personnel, without ever having contact with health care personnel.

The pandemic was a clear catalyst for the use of eConsultation (9Ec). High use figures were reached and maintained at the end of the study period. In pediatrics, a peak of such visits was detected during January 2022, coinciding with the Omicron wave, which affected children in large numbers but had with low morbidity. Thus, the results of this paper and the literature suggest that eConsultation is here to stay [42].

It is also worth noting that although COVID-19 was a catalyst for the use of telemedicine in clinical practice, the Catalan health system has been promoting digital transformation through various "health plans" and different initiatives since 2011 [43-45]. In this context, the use of teleconsultation during the lockdown was essential to manage the health emergency at that moment. However, the Catalan health system had the digital infrastructure to cope with the situation and provide assistance. The population's experience of teleconsultation during the lockdown may have an impact on them, and the results also showed that currently, almost 25% of people used teleconsultation after the pandemic period.

During the COVID-19 pandemic, other modalities of pediatric telemedicine care for parents of patients were tested with good resolution and acceptance results, such as the creation of a Twitter (subsequently rebranded as X) profile called Equipo Pediatría HCSC (@EquipoHCSC) by a trained team of pediatricians in Madrid that resolved questions through private messages [46]. Another example is that of a health center in Zaragoza that had already developed an email consultation process, and they observed that during the strictest confinement, its use increased to the detriment of face-to-face consultations, although the most used modality was the telephone [47].

In relation to the use of information and communication technologies in pediatrics, there is the advantage, in general, that there is less of a digital divide on the part of users than in other areas. Several studies indicate that this is due to the age and education that parents usually have [48,49].

It was not only in pediatrics that a sharp reduction in face-to-face visits and a parallel growth in remote visits were detected. Equivalent results have been obtained from family and community medicine [50,51]. Telemedicine, however, has limitations in the human, technological, and economic spheres, and these must be understood by all parties involved. In addition, it is subject to current legislation based on the Organic Law on Data Protection and the doctor-patient confidentiality relationship. Thus, telehealth programs depend largely on the health care setting in which they are implemented. Conditions may change after the pandemic, and further studies will be needed [52].

In short, although the absolute number of face-to-face visits has recovered throughout the pandemic, telemedicine consultations established themselves as an important type of visit and made up almost a quarter of daily visits by the end of 2022. This indicates that some consultations that were previously carried out in person are now likely to be done remotely.

This analysis may contribute to a reorganization of the current model of PC pediatric services, which has been affected for years by the deficit and heterogeneous territorial distribution of professionals [53]. It can also help develop evidence-based guidelines for pediatric remote care focused on accessibility, quality, equity, and efficiency, as has been done in other territories [54,55]. It remains to be seen how, from now on, the application of digital health tools is managed in the field of PC pediatric services in Catalonia, as well as at a more global level, and whether it contributes to improving the current organization.

Limitations

This study has certain limitations that should be taken into consideration. First, the study did not examine the quality of care or patient outcomes that may have been associated with the changes in PC visits. Therefore, it is not possible to make conclusions about the overall impact of the changes on patient health. Second, the study did not take into account non–COVID-19–related factors that may have influenced PC visits during the pandemic. These factors include changes in patient behavior, such as reluctance to seek medical care due to the fear of contracting COVID-19, or changes in health care provider availability due to workforce shortages or redeployment to COVID-19 care. These factors may have contributed to the observed changes in PC visits and should be considered in future studies.

Conclusions

The COVID-19 pandemic has been a period of transition for the types of visits to PC pediatric services in Catalonia. It has undeniably accelerated the adoption of telemedicine in various health care systems, including pediatric care in Catalonia. In this context, although face-to-face consultations have recovered in absolute numbers, after the pandemic period, it is evident that telemedicine has gained prominence and plays a significant role in health care delivery. Thus, digital health tools are becoming a real possibility within current pediatric care, and it is difficult to imagine care without the technological integration acquired during the pandemic.

Multimedia Appendix 1

Average daily visits in total and for each type of visit (face-to-face, synchronous non–face-to-face, and asynchronous non–face-to-face), separated by month, to primary care pediatric services in Catalonia between January 2019 and December 2022. Percentage change with respect to the same period in 2019, SD, and *P* value are also shown.

Abstract

Background: Remote consultations (RCs) using videoconferencing was recommended by the General Medical Council as the method for clinicians to provide patient consultations during the COVID-19 pandemic. Facilitating this while providing high-quality care depends on the usability and acceptability of the technology.

Objective: This project aimed to investigate parents’ experiences of using videoconferencing technology for real-time RCs with children who had congenital heart defects during the COVID-19 pandemic lockdown.

Methods: This study’s design was quasi-experimental and was underpinned by the Unified Theory of Acceptance and Use of Technology model that seeks to explain and predict an individual’s intention to use a technology. Parents were informed of this study by the medical team, posters were made available in the wards and clinics, and leaflets were left for browsing. Clinician screening of potential participants led to the identification of 33 children and parents who were enrolled on this study. The intervention was a web-based RC by medical staff using a secure, interactive videoconferencing platform (Pexip). Each child and their mother or father received 8 RCs with the same specialist doctor or nurse. Measurements were taken using web-based questionnaires pre and post consultation at the first, middle, and last events; questions were focused on the acceptability, usability, and clinical applicability of RCs. Parents’ experiences were explored using recorded interviews and analyzed thematically.

Results: In total, 29 children aged 4 - 1052 (mean 95, SD 191.14) days completed the project, receiving a total of 189 RCs as part of their routine care. Parents’ prior experience of consultation via videoconference was low; however, as time progressed, their use and acceptance of the technology increased. The intervention was warmly received by all parents who found the face-to-face component particularly useful for discussion with their child’s medical team. Furthermore, parents noted the savings on time, money, and childcare.

Conclusions: While in-person consultations are considered the gold standard of patient care, increasing pressures on health services and staff reduce availability. Given the ease of access and additional benefits experienced by parents and their children, it is proposed that hybrid models of consultation and care provision are equal, if not superior, to in-person consultations in the management of children with severe congenital heart defects while reducing costs and pressure on the health service and parents.

Introduction

The Royal Belfast Hospital for Sick Children (RBHSC) is the only dedicated center for pediatric congenital heart disease (CHD) in Northern Ireland (NI) and provides a specialized service for the whole population. Since 2003, the RBHSC pediatric cardiology team has provided a sustainable home monitoring service for children with CHD post discharge from the pediatric cardiology unit [1-11]. This service has provided valuable ongoing contact and follow-up consultations between children and their parents and pediatric cardiology consultants and nurses, and it has reduced the need to travel to the hospital as frequently as would previously have been required. Considerable evaluation of the RBHSC pediatric cardiology remote consultations (RCs) using a videoconference service has already been conducted, and the data demonstrated an effective system providing reliable follow-up for babies or children assessed and monitored using audio and visual technologies [3,10]. This approach has been verified as effective and safe in a systematic review of telemedicine for pediatric cardiology [12]. RCs for pediatric care can offer a more timely response and enhanced quality of care when compared to in-person consultations [13-17]. Parents have reported a reduction in anxiety and an increase in satisfaction with services when receiving RCs compared to hospital consultations [6,10,13,18,19]. The evidence to support the use of telemedicine in general has been increasing over the last 2 decades, and there is now consensus on the benefits to children, their parents, health care staff, and the health service [7,13,20-23].

The COVID-19 pandemic presented major concerns for families regarding bringing children with CHD out of the safety of their home to the hospital, and the risk of exposing them to possible infection during travel or at their hospital appointment. Due to the COVID-19 pandemic, the use of telemedicine has been encouraged [24,25], and RC is ideal for patients, as it reduces the risk of exposure to infection [9]. Therefore, in order to meet the clinical needs of children and protect them and their families, the RBHSC service was expanded to offer remote pediatric cardiology RCs to children aged up to 16 years.

Initially, the RBHSC home monitoring service was facilitated by videoconferencing using Tandberg (Overland Tandberg) and Cisco (Cisco Systems, Inc) devices and software set up in the hospital videoconferencing suite and in the patient's own home. The device and, if required, broadband were installed in the patient's home by the Belfast Health and Social Care Trust. However, during the pandemic, engineers could not enter homes due to the risk of infection, and the Tandberg and Cisco infrastructure could no longer be installed in patients' homes. Therefore, as of April 2020, when in-person consultations were considered high risk, to maintain RCs and provide greater access, the RBHSC and parents of children with CHD started using a secure, videoconferencing platform (Pexip) with the aim of providing optimal RCs to assess, monitor, and manage condition progression during the pandemic.

The videoconferencing platform is accessed via the Pexip software application; can be downloaded to any internet-enabled device, including a smartphone, tablet, or computer; and provides a broad cloud-based, virtual meeting space that can only be accessed using a personal identification number code. The platform has a high level of interoperability, which allows access to users via a broad range of existing platforms. While increased accessibility may result in issues in terms of security, the developers state that the platform uses "formalized internal information security best practices," complies with ISO/IEC 27001:2103 and ISO /IEC 27701:2019 standards for information security and privacy and is General Data Protection Regulation compliant. It allows efficient bandwidth use regardless of where the meeting participants are located, ensuring high-quality video and audio. However, some people may experience technical challenges with, for example, the software and hardware, resulting in barriers to the adoption and acceptance of RCs [26]. New technologies in the clinical setting must be assessed and monitored to ensure they meet the ongoing needs of children, their parents or carers, and clinical staff. Therefore, the aim of this project was to evaluate parents' experience, perceived usefulness, usability, and acceptability of using a videoconferencing platform for remote pediatric cardiology consultations during COVID-19.

Methods

Study Design

This quasi-experimental cohort study ran from October 6, 2020, until April 27, 2022, and explored qualitative and quantitative outcomes of using a videoconferencing application for the delivery of 8 pediatric cardiology consultations to each patient to augment patient care during the challenges posed by the COVID-19 pandemic. Web-based questionnaires were developed using Qualtrics software. Based on the Unified Theory of Acceptance and Use of Technology (UTAUT) model [27], adapted for testing the videoconferencing application, the usefulness, usability, and acceptability of videoconferencing RCs were investigated. Parents provided feedback on their experiences of using videoconferencing and taking part in the project during interviews facilitated using WhatsApp (Meta Platforms) video calls.

Findings from this study relating to the number of attendances to the hospital, including both initiated and avoided attendances, as a result of RCs using videoconferencing have been presented elsewhere (Gillender et al, in press, December 2024).

Recruitment

Parents of children diagnosed with CHD were identified in the hospital ward, outpatient departments, or other pediatric cardiology satellite units within NI. Parents were approached by a pediatric cardiology clinician who informed them about the project and provided the participant information packs (PIPs). Parents provided written informed consent via email, WhatsApp, or post to 1 researcher (JEMM).

In order to minimize any risk of cross-contamination with coronavirus, the PIPs were printed and prepared while adhering to a strict protocol whereby a single masked operative, wearing gloves, prepared and packaged the PIPs. PIPs were delivered directly to the hospital where they remained in locked storage until required.

Parent or carers who had a child aged 0 - 16 years attending pediatric cardiology at the RBHSC were invited to participate and receive 8 RCs as part of their child's routine home monitoring care provision. The inclusion criteria included access to a device on which to download the videoconferencing application and ability to understand spoken and written English. The State Trait Anxiety Inventory (STAI) [28] was used as a screening tool, and parents with a score greater than 65 who chose to opt out of the project were excluded.

Parental anxiety levels were measured prior to the first RC and at the end of the project, using a web-based version of the validated self-completion STAI questionnaire [28], which indicates anxiety levels for a single point in time. The average STAI score for working adult females is 35.2 (SD 10.61), and for males, it is 35.72 (SD 10.40); the score is also age dependent [28]. However, given the nature of the medical condition under consideration, anxiety scores above the average for this population were expected. Based on previous research involving parents with children with CHD in NI [29] and a South American validation study of the STAI and the Beck Depression Inventory [30], the mean STAI scores for participants with anxiety was 52.8 (SD 11.42), giving a cutoff score of 65.

Videoconferencing Application

The videoconferencing platform can be easily accessed via the application, downloaded to any device, and used straight away. In most cases (21/32, 66%), participants were assisted with downloading and testing the application during an in-person discussion with the research doctor (JG). However, if children had already been discharged parents received an instruction sheet via email (Multimedia Appendix 1). RCs were carried out by JG and RB together or separately. Upon completion of the project children who continued to require home monitoring had further RCs.

Data Collection

Parents completed a baseline questionnaire at enrollment (T0) to collect demographic details and information about their use and experience of technology. Approximately 24 hours before and after the first (T1), fourth (T2), and eighth (T3) RC, parents were asked to complete the UTAUT questionnaire and details about their child's most recent RC. The UTAUT model is a theoretical framework that seeks to explain and predict an individual's intention to use a technology, as well as their actual use of that technology [27]. This questionnaire has been validated across a wide range of countries and for assessing different types of technologies [31,32]. Questions related to the quality of the technology interface based on work by Zhang et al [33] were also included. The UTAUT is designed to be adjusted to fit the technology under investigation, and therefore a certain amount of rewording was expected [27].

The UTAUT model is based on several key constructs:

1. Performance expectancy: An individual's belief that using a technology will lead to improved performance in a specific activity.
2. Effort expectancy: An individual's belief that using a technology will be easy and require minimal effort.
3. Social influence: The influence of others (eg, family, friends) on an individual's decision to use a technology.
