JMIR Pediatrics and Parenting

Impact Factor (2023): 2.1
Volume 8 (2025) ISSN 2561-6722 Editor in Chief: Sherif Badawy, MS, MD, MBA

Contents

Original Papers

Association Between the Parenting Competence and Quality of Life of Family Caregivers of Children Aged 0-3 Years: Cross-Sectional Study (e67872)
Wei He, Le-shan Zhou, Long-yi Hu. . . . 11

Examination of Chronic Sorrow Among Parents of Children With Disabilities: Cross-Sectional Study (e65754)
Samaa Al Anazi, Naseem Alhujaili, Dina Sinqali, Ftoon Al Heej, Lojain Al Somali, Samaher Khayat, Talah Ramboo. . . . 19

Practicality of the My Baby Now App for Fathers by Fathers: Qualitative Case Study (e64171)
Mathew Gaynor, Kylie Hesketh, Kidane Gebremariam, Karen Wynter, Rachel Laws. . . . 31

The Added Value of Parents Practicing in Virtual Reality to Illustrate the Use of Innovative Methods in Parent-Child Interaction Therapy: Single-Case Experimental Design (e60752)
Iza Scherpbier, Mariëlle Abrahamse, Samantha Bouwmeester, Robert Belleman, Arne Popma, Ramón Lindauer. . . . 43

Immediate Kangaroo Mother Care for Sick Newborns: Quality Improvement Implementation and Feasibility Study (e78207)
Belén Fernández-Monteaguado, Ana Peña-Moreno, Inés Ramírez-de Andrés, Patricia Barbero-Casado, Eduardo Zarzuela-NÚñez, Beatriz Bellón-Vaquerizo, Cristina Martin Arriscado-Arroba, María Moral-Pumarega, Salvador Piris-Borregas, Carmen Pallás-Alonso. . . . 65

The Practice of Shaking in Disciplining Young Children in Lower-Income Communities of Bangladesh: Cross-Sectional Exploratory Study (e64474)
Fahmida Tofail. . . . 71

The Maternal Support Framework Studying Mothers' Perceived Understanding and Support During Excessive Infant Crying: Exploratory Qualitative Study (e75669)
Oona Janssens, Anna Galle, Ineke De Kruijff, Katrijn Brenning. . . . 79

Analysis of Cough Factors and Quality of Life Score Among Children With Protracted Bacterial Bronchitis: Cross-Sectional Study (e82887)
Haonan Ning, Wenyu Zheng, Jinghui Zhang, Fuhai Li, Nana Qiao. . . . 92

Evaluation of the Use of a Novel Intelligent Diagnosis and Cost Control System on Pediatric Bronchopneumonia Outcomes: Retrospective Cohort Study (e74964)
Yanjun Wu, Kaijie Liu, Xinli Mao, Danjie Wu, Feng Zhu. . . . 107

Hospitalization and Mortality in Brazilian Children and Adolescents Due to COVID-19: Retrospective Study (e67546)
Ana Pereira de Godoy, Reinaldo Bulgarelli Bestetti. . . . 116

Exploring Stress and Stress-Reduction With Caregivers and Clinicians in the Neonatal Intensive Care Unit to Inform Intervention Development: Qualitative Interview Study (e66401)
Kristin Ginsberg, Jane Alsweiler, Jenny Rogers, Phoebe Ross, Anna Serlachius. 124

Implementing Diabetes Distress Screening in a Pediatric Endocrinology Clinic Using a Digital Health Platform: Quantitative Secondary Data Analysis (e65107)
Nicole Kahhan, Larry Fox, Matthew Benson, Susana Patton. 137

Enhancing Effect of eHealth Use on the Associations Between Social Supports and Well-Being in Japanese Employed Women Providing Childcare or Care: Bayesian Structural Equation Modeling Study (e68119)
Noyuri Yamaji, Daisuke Yoneoka, Daichi Suzuki, Kiriko Sasayama, Erika Ota, Etsuko Nishimura, Hisateru Tachimori, Eiko Saito. 146

Impact of Digitalization on Pediatric Practice and Childhood Health Care in Spain: Nationwide Survey Study (e75310)
Alicia Santamaría-Orleans, Luis Ortiz-González, Maite Pérez-Hernández, Cristóbal Coronel-Rodríguez. 159

Using WhatsApp for Nutrition Surveillance Among Children Under 5 Years in West Java, Indonesia: Cross-Sectional Survey and Feasibility Study (e58752)
Dewi Aisyah, Chyntia Mayadewi, Astri Utami, Fauziah Rahman, Nathasya Adriani, Erlangga Al Farozi, Meldi Sayoko, Aulia Chairunisa, Liza Restiana, Logan Manikam, Zisis Kozlakidis. 174

Parent-Child Mutual Influences on Sugar-Sweetened Beverage Consumption Behaviors: Actor-Partner Analysis (e76943)
May Lwin, Allison Seet, Seraphina Leo, Peter Schulz. 193

Monetary Valuation of Congenital Heart Disease in Indonesia: Economic Modeling Study (e80696)
Muhammad Iqhrammullah, Derren Rampengan, Ikhwan Amri, Surna Lastri, Starry Rampengan, Radityo Prakoso, Muhammad Habiburrahman.
2 0 5

Preliminary Effectiveness of a Postnatal mHealth and Virtual Social Support Intervention on Newborn and Infant Health and Feeding Practices in Punjab, India: Quasi-Experimental Pre-Post Pilot Study (e65581)
Garima Verma, Lakshmi Gopalakrishnan, Alison Ayadi, Nadia Diamond-Smith, Rashmi Bagga, Shashi Dhir, Pushpendra Singh, Navneet Gill, Vaibhav Miglani, Naveen Mutyala, Ankita Kankaria, Jasmeet Kaur, Alka Ahuja, Vijay Kumar, Mona Duggal. 225

Impact of a 6-Week Postpartum Text Messaging Program (Essential Coaching for Every Mother) at 6 Months: Follow-Up Study to a Randomized Controlled Trial (e62841)
Justine Dol, Marsha Campbell-Yeo, Megan Aston, Douglas McMillan, Amy Grant. 239

Fetal Birth Weight Prediction in the Third Trimester: Retrospective Cohort Study and Development of an Ensemble Model (e59377)
Jing Gao, Xu Jie, Yujun Yao, Jingdong Xue, Lei Chen, Ruiyao Chen, Jiayuan Chen, Weiwei Cheng. 249

An Online Family Literacy and Wellness Program for Latino Dual Language Learners: Pilot Randomized Waitlist Controlled Trial (e60764)
Kevin Guerrero, Lucia Lakata, Daniel Lima, Caroline Mendoza, Nila Uthirasamy, Lesley Morrow, Silvia Perez-Cortes, Maria Pellerano, Alicja Bator, Pamela Ohman Strickland, Benjamin Crabtree, Manuel Jimenez. 264

Parental Use of Social Media and the Internet in the Context of Their Child's Genetic Neurodevelopmental Disorder: Mixed Methods Study Nested in the GenROC Cohort Study (e76526)
Karen Low, Georgia Treneman-Evans, Sarah Wynn, Jenny Ingram, John Powell. 292

A Low-Cost, Social Media–Supported Intervention for Caregivers to Enhance Toddlers' Language Learning: Mixed Methods Feasibility and Acceptability Study (e66175)
Mollie Romano, Diana Abarca, Frances Baehman. 304

A Noninvasive Approach to Assess the Prevalence of and Factors Associated With Anemia Risk in Malaysian Children Under Three Years of Age: Cross-Sectional Study (e58586)
Muhammad Jalaludin, Ho Kiau, Suriati Hasim, Wai Lee, Angie Low, Nik Kazim, Jia Hoi, Sri Taher. . . . 320

Preoperative Anxiety Management Practices in Pediatric Anesthesia: Comparative Analysis of an Online Survey Presented to Experts and Social Media Users (e64561)
Armin Sablewski, Christine Eimer, Marcus Nemeth, Clemens Miller. . . . 334

Social and Environmental Determinants of Childhood Stunting in Indonesia: National Cross-Sectional Study (e68918)
Yuni Arief, Fildzah Yunita, Ferry Efendi, Fadhaa Murti, Rifky Pradipta, Lisa McKenna. . . . 346

Comparing Sociodemographic, Health Status and Resources, Macroeconomic Status, and Environmental Factors on Infant Mortality Rates in Bahrain, Kuwait, and Oman: Longitudinal Time-Series Study (e73203)
Mallak Al-Saqry, Rawaa Eltayib, Al-Hasan Al-Busaidi, Moon Chan. . . . 357

Parental Experiences of Administering Pediatric Tuina for Sleep and Appetite in Early School-Aged Children With Attention-Deficit/Hyperactivity Disorder: Qualitative Study in Hong Kong (e65471)
Shu-Cheng Chen, Kwai-Ching Lo, Han Li, Pong-Ming Wong, Lok-Yi Pang, Jing Qin, Wing-Fai Yeung. . . . 366

Evaluating the Reach, Usage, Human Support Needs, and Clinical Outcomes of Digital Parent Training for Child Oppositional Defiant Disorder Before and During Wartime: Longitudinal Study (e80420)
Amit Baumel, Or Brandes, Chen Saar. . . . 378

Enhancing Adherence and Mental Well-Being in Pediatric Growth Hormone Therapy: Feasibility Prospective Observational Study of a Family-Centered Digital Companion (e67102)
Antonio de Arriba Muñoz, Amalia García-Durán, Patricia Sanz-Aznar, Silvia Quer-Palomas, Ioannis Bilionis, Alba Xifra-Porxas, Joia Nuñez, Ricardo Berrios, Luis Fernández-Luque. . . . 392

Exploring the Acceptance and Opportunities of Using a Specific Generative AI Chatbot to Assist Parents in Managing Pediatric Rheumatological Chronic Health Conditions: Mixed Methods Study (e70409)
Cheryl Lau, Klaudia Kupiec, Polly Livermore. . . . 403

Evaluating the Impact of Pediatric Digital Mental Health Care on Caregiver Burnout and Absenteeism: Longitudinal Observational Study (e67149)
Darian Lawrence-Sidebottom, Kelsey McAlister, Aislinn Beam, Rachael Guerra, Amit Parikh, Monika Roots, Donna McCutchen, Landry Goodgame Huffman, Jennifer Huberty. . . . 416

Exploring Service Users' Experiences of a Community-Based Intervention to Improve Follow-Up at Bharatpur Eye Hospital in Nepal: Qualitative Study (e65023)
Manisha Shrestha, Gopal Bhandari, Sadhan Bhandari, Gudlavalleti Murthy, Ruchi Priya, Binod Pandey, Daya Chaudhary, Puspa Giri, Sureshkumar Kamalakannan, Operational Research Capacity Building Study Group. . . . 432

Perspectives of Adolescents and Young Adults With Inflammatory Bowel Disease on a Biopsychosocial Transition Intervention: Qualitative Interview Study (e64618)
Brooke Allemang, Ashleigh Miatello, Mira Browne, Melanie Barwick, Pranshu Maini, Joshua Eszczuk, Chetan Pandit, Tandeep Sadhra, Laura Forhan, Natasha Bollegala, Nancy Fu, Kate Lee, Emily Dekker, Irina Nistor, Sara Ahola Kohut, Laurie Keefer, Anne Griffiths, Thomas Walters, Samantha Micsinszki, David Mack, Sally Lawrence, Karen Kroeker, Jacqueline de Guzman, Aalia Tausif, Claudia Tersigni, Samantha Anthony, Eric Benchimol. . . . 440

Perspectives on Swedish Regulations for Online Record Access Among Adolescents With Serious Health Issues and Their Parents: Mixed Methods Study (e63270)
Josefin Hagström, Charlotte Blease, Arja Harila, Päivi Lähteenmäki, Isabella Scandurra, Maria Hägglund. . . . 455

Digital Health Program to Support Family Caregivers of Children Undergoing Growth Hormone Therapy: Qualitative Feasibility Study (e55023)
Alba Jiménez-Díaz, Maitena Pierantonelli, Patricia Morte Coscolín, Amaia Salinas-Uhalte, Silvia Quer-Palomas, Octavio Rivera-Romero, Rocío Herrero, Luis Fernández-Luque, Rosa Baños, Ricardo Berrios, Antonio de Arriba. 474

Community Caregivers' Perspectives on Health IT Use for Children With Medical Complexity: Qualitative Interview Study (e67289)
Farah Elkourdi, Onur Asan. 488

Content Development for a Multilevel Intervention to Operationalize Behavior Change Theory and Improve Parenting Behaviors for Physical Activity: Descriptive Study (e73510)
Breanne Wilhite, Erin Hennessy, Christina Economos, Jennifer Sacheck, Rachel Zive, Christine Odalen, Stephanie Herrick, Daniel Hatfield. . 5 0 0

Moderators of a mHealth Intervention for Adolescent Physical Activity: Intervention Refinement Study (e59334)
Christopher Cushing, Adrian Ortega, David Fedele, Calissa Leslie-Miller, Jordan Carlson, Ann Davis, Joshua Smyth. 514

Using a Consumer Wearable Activity Monitoring Device to Study Physical Activity and Sleep Among Adolescents in Project Viva: Cohort Study (e59159)
Yutong Zhang, Nicole Bornkamp, Marie-France Hivert, Emily Oken, Peter James. 523

Parental Perceptions of Priorities and Features for a Mobile App to Promote Healthy Lifestyle Behaviors in Preschool Children: Mixed Methods Evaluation (e65451)
Jessica Thompson, Summer Weber, Shelagh Mulvaney, Susanna Goggans, Madeline Brown, Anthony Faiola, Lynn Maamari, Pamela Hull. . . 5 3 4

The Role of Early Engagement in a Self-Directed, Digital Mental Health Intervention for Adolescent Anxiety: Moderated Regression Analysis (e60523)
Emma-Leigh Senyard, Arlen Rowe, Govind Krishnamoorthy, Susan Spence, Caroline Donovan, Sonja March. 550

Sex Differences in the Joint Trajectories of Depressive Symptoms and Body Mass Index From Adolescence to Early Adulthood: Longitudinal Observational Study (e72722)
Jing Chen, Rui Shan, Wen Yuan, Qiong Wu, Yang Yang, Yi-Hang Yang, Jing-Yao Liu, Wu-Cai Xiao, Shanghang Zhang, Li-Ming Wen, Xiao-Rui Zhang, Zheng Liu, Yi Song. 564

Adapting Cognitive Behavioral Therapy for Adolescents in Iraq via Mobile Apps: Qualitative Study of Usability and Outcomes (e67137)
Radhwan Ibrahim, Marghoob Yaas, Mariwan Hamarash, Salwa Al-Mukhtar, Mohammed Abdulghani, Osama Al Mushhadany. 575

The Impact of Parental Support on Adherence to Therapist-Assisted Internet-Delivered Acceptance and Commitment Therapy in Primary Care for Adolescents With Anxiety: Naturalistic 12-Month Follow-Up Study (e59489)
Anna Larsson, Sandra Weineland, Linnea Nissling, Josefine Lilja. 587

Changes in Internet Activities and Influencing Factors for Problematic Internet Use During the COVID-19 Pandemic in Korean Adolescents: Repeated Cross-Sectional Study (e66448)
Sol Kim, Jae-Chan Jin, Seo-Koo Yoo, Doug Han. 603

Effects of Web-Based Single-Session Growth Mindset Interventions for Reducing Adolescent Anxiety: Four-Armed Randomized Controlled Trial (e63500)
Shimin Zhu, Yuxi Hu, Di Qi, Samson Tse, Ko Chan, Jessica Sun, Paul Lee. 617

Developing Digital Mental Health Tools With Culturally Diverse Parents and Young People: Qualitative User-Centered Design Study (e65163)
Isobel Butorac, Roisin McNaney, Joshua Seguin, Patrick Olivier, Jaimie Northam, Lucy Tully, Talia Carl, Adrian Carter. . . . 636

Real-World Symptom Trajectories in Adolescents With and Without Suicide Risk Receiving Care from Rula Health: Retrospective Study (e81444)
Lara Baez, Kelsey McAlister, Douglas Newton, Sam Seiniger, Allie Woodhouse, Jennifer Huberty. . . . 658

Empowering Caregiver Well-Being With the Adhera Caring Digital Program for Family Caregivers of Children Living With Type 1 Diabetes: Mixed Methods Feasibility Study (e66914)
Antonio de Arriba Muñoz, Elisa Civitani Monzon, Maria Ferrer, Marta Ferrer-Lozano, Silvia Quer-Palomas, Joia Nuñez, Alba Xifra-Porxas, Francesca Aimée Mees Mlatiati, Ioannis Bilionis, Ricardo Berrios, Luis Fernández-Luque. . . . 673

Effects of the Jump Step Kids Program on Functional Movement and Self-Report Outcomes in Children Aged 7 to 12 Years With Chronic Ankle Instability: Randomized Controlled Trial (e81860)
Kitiyawadee Srisim, Supannikar Yingyongsaksri, Janya Chuadthong. . . . 682

Feasibility, Barriers, and Facilitators of Long-Term Physical Activity Tracking During Treatment: Interview Study Among Childhood Cancer Patients (e75322)
Emma den Hartog, Wim Tissing, Sebastian Bon, Patrick van der Torre, Emma Verwaaijen. . . . 694

Children's and Their Parents' Experiences With Home-Based Guided Hypnotherapy: Qualitative Study (e58301)
Ilse Ganzevoort, Adriëlla van der Veen, Manna Alma, Marjolein Berger, Gea Holtman. . . . 734

eHealth Literacy and Adolescent Health in Japanese Female High School Students in Sendai: Cross-Sectional Study (e73237)
Takashi Takeda, Kana Yoshimi, Sayaka Kai, Fumi Inoue. . . . 747

Advice for Improving the Experience of Web-Based Patient Portals: Qualitative Interviews With Caregiver-Adolescent Dyads (e72134)
Rachel Granberg, Jessica Goldberg, Alison Antes, Christine Bereitschaft, Fabienne Bourgeois, James DuBois, Bryan Sisk. . . . 761

Increasing Vaccination Awareness for Italian Primary Care Pediatricians: Game Design and Usability Study (e70049)
Federico Marchetti, Martino Barretta, Antonio Di Mauro, Marco Bona, Chiara Amerighi, Antonio D'Avino. . . . 775

A Companion Robot for Children With Asthma: Descriptive Development and Feasibility Pilot Study (e68943)
Jinnaphat Sangngam, Somsiri Rungamornrat, Rungnapa Santipipat, Kunchira Ponthanee. . . . 802

Guided Inhalation via Electronic Monitoring in Children With Uncontrolled Asthma (the IMAGINE Study): Randomized Controlled Trial (e78526)
Esther Sportel, Kris Movig, Bernard Thio, Mattienne Van der Kamp, Job Van der Palen, Marjolein Brusse-Keizer. . . . 810

Exploring the Impact of Perceived Parental Oversight on Problematic Smartphone Use Among Adolescents in the Digital Age: Database Analysis (e75837)
Mary Ho, Peter Schulz, Angela Chang. . . . 824

Novel Profiles of Family Media Use: Latent Profile Analysis (e59215)
Nicole Hamp, Jenny Radesky, Heidi Weeks, Alison Miller, Niko Kaciroti. . . . 843

Parental Perspectives on the Use of Smartwatch Activity Trackers by Young Children: Qualitative Study (e79851)
Raymond Davey, Amity Campbell, Amber Beynon, Charlotte Rasmussen, Danica Hendry, Sarah Stearne, Courtenay Harris, Leon Straker, Juliana Zabatiero. . . . 856

Exploring Parental Intentions to Use Digital Tools to Enhance Parent-Child Sexual Communication in Europe: Cross-Sectional Questionnaire Study (e75489)
Talia Hubble, Luca Carbone, Laura Vandenbosch, Jaan Toelen, David De Coninck. . . . 1046

Development of Chatbot-Based Oral Health Care for Young Children and Evaluation of its Effectiveness, Usability, and Acceptability: Mixed Methods Study (e62738)
Kittiwara Pupong, Jaranya Hunsrisakhun, Samerchit Pithpornchaiyakul, Supawadee Naorungroj. . . . 1065

Internet-Based Cognitive Behavioral Therapy for Children and Adolescents With Dental or Injection Phobia: 1-year Follow-Up Assessment (e80376)
Robert Schibbye, Erik Hedman-Lagerlöf, Viktor Kaldo, Göran Dahllöf, Shervin Shahnavaz. . . . 1081

Promoting Family Engagement With Early Childhood Developmental Screening via the Baby Steps Text Messaging and Web Portal System: Longitudinal Randomized Controlled Trial (e73443)
Hyewon Suh, Julie Kientz. . . . 1097

Usability Testing of an Internet-Based Responsive Parenting Program for Caregivers of Young Survivors of Childhood Cancer Living in Rural and Appalachian Communities: Mixed Methods Study (e70055)
Emily Moscato, Eva Darow, Jessica Quach, Adrien M Winning, Matthew Schmidt, Shari Wade, Cynthia Gerhardt, Emre Sezgin. . . . 1110

Evaluating a Digital Intervention to Reduce Aggression and Pro-Firearm Violence Attitudes Among Young Black Males: Pretest-Posttest Feasibility Study (e70048)
Chuka Emezue, Jessica Bishop-Royse, Andrew Froilan, Tara Wilkes, Niranjan Karnik, Wrenetha Julion. . . . 1126

Effects of Cold and Vibration on Venipuncture Pain Management in Children Aged 2-7 Years Old: Randomized Controlled Trial (e67918)
Zi-yun Zhou, Long-yi Hu, Ming-li Wang, Si-qi Li, Le-shan Zhou. . . . 1143

Supervised and Unsupervised Screen Time and Its Association With Physical, Mental, and Social Health of School-Going Children in Dhaka, Bangladesh: Cross-Sectional Study (e62943)
Shahria Kakon, Tanjir Soron, Mohammad Hossain, Rashidul Haque, Fahmida Tofail. . . . 1175

Effectiveness of Virtual Reality–Based Cognitive Control Training Game for Children With Attention-Deficit/Hyperactivity Disorder Symptoms: Preliminary Effectiveness Study (e66617)
Hyunjoo Song, Yunhye Oh, JongIn Choi, Seong-Yong Ohm. . . . 1187

Evaluating Telepsychiatric Assessment Satisfaction in Children and Adolescents With Autism Spectrum Disorder and Attention-Deficit/Hyperactivity Disorder and Their Caregivers: Randomized Controlled Trial (e69791)
Shunya Kurokawa, Yuko Kawade, Kensuke Nomura, Nana Hosogane, Takashi Nagasawa, Yu Matsumoto, Shuichi Morinaga, Yuriko Kaise, Ayana Higuchi, Akiko Goto, Naoko Inada, Masaki Kodaira, Taishiro Kishimoto. . . . 1199

Development of an eHealth Intervention in Pediatric Home Infusion Therapy: Interview Study of Needs and Preferences of Parents and Health Care Professionals (e63260)
Helena Hansson, Charlotte Castor, Hanne Larsen, Martha Topperzer, Mette Olesen. . . . 1208

Assessing the Impact of a Telemedicine Program on Caregivers of Children With Complex Chronic Conditions: Pre-Post Intervention Study (e62953)
Aurora Madrid-Rodríguez, María Peláez-Cantero, Alfonso Lendínez-Jurado, Ana Suárez-Carrasco, Elena Godoy-Molina, Antonia Gámez-Ruiz, Ana Corripio-Mancera, Yolanda Ramón-Telo, Ana García-Ruiz, Isabel Leiva-Gea. . . . 1221

Multilevel Factors and Indicators of Atypical Neurodevelopment During Early Infancy in Japan: Prospective, Longitudinal, Observational Study (e58337)
Daigo Kato, Akiko Okuno, Tetsuo Ishikawa, Shoji Itakura, Shinji Oguchi, Yoshiyuki Kasahara, Kenji Kanenishi, Yuzo Kitadai, Yoshitaka Kimura, Naoki Shimojo, Kazushige Nakahara, Akiko Hanai, Hiromichi Hamada, Haruta Mogami, Seiichi Morokuma, Kazuhiro Sakurada, Yukuo Konishi, Eiryo Kawakami. . . . 1231

Abstract

Background: The quality of life (QoL) for family caregivers significantly influences not only their own well-being but also the well-being of children aged 0 - 3 years. Competence stands out as a crucial subjective factor that impacts this QoL.

Objective: This study aimed to examine the factors affecting the QoL of caregivers of children aged 0 - 3 years and its correlation with parenting competency.

Methods: Caregivers of children aged 0 - 3 years from the child health department of a tertiary hospital in Changsha, Hunan Province, were chosen as the study sample through convenience sampling. The study investigated the relationship between parenting competency and the caregivers' QoL, utilizing general information, the parenting competency scale, and the family caregiver quality of life scale.

Results: In this study, 291 family caregivers, including 13 fathers and 278 mothers of children aged 0 - 3 years, were evaluated. The mean (SD) parenting competence score was 68.70 (9.816) and the mean (SD) QoL score was 56.81 (8.922). It was found that higher caregiver QoL scores were significantly associated with greater parenting competence (R=0.665, P<.001). Furthermore, each dimension of parenting competence demonstrated a significant positive correlation with each dimension of the QoL (P<.001).

Conclusions: The data suggest a notable association between parenting competence and QoL among family caregivers of children aged 0 - 3 years. This association has implications for improving fertility rates, as enhancing parenting competence may reduce childcare-related stress and thereby enhance the overall QoL.

Introduction

Quality of life (QoL) constitutes a subjective evaluation of one's place in life in the context of one's personal goals and value systems [1], spanning physical, social, spiritual, and psychological domains. The QoL of family caregivers for children aged 0 - 3 years not only mirrors the caregivers' own life quality, correlating with superior physical health and reduced incidence of anxiety or depression [2], but also influences the quality of care provided to the children [3]. Importantly, caregivers with a higher QoL tend to deliver improved care, which in turn enhances the life quality of children aged 0 - 3 years [4]. Consequently, evaluating the QoL is a crucial aspect in the study of family caregiving for this age group.

The QoL is profoundly influenced by a myriad of factors. Among these, for family caregivers, the challenges posed by childcare significantly impact their well-being. Parenting stress is associated with reduced life satisfaction, deteriorated mental health, and a diminished overall QoL [5]. The QoL is inherently subjective, and thus, subjective factors often provide more reliable indicators than objective ones [6]. A critical subjective factor is the sense of competence in parenting, which encompasses an individual's comprehensive assessment of their effectiveness within the parenting role, particularly in terms of parenting efficacy and satisfaction [7]. Parents with high parenting competence typically display greater confidence and motivation when addressing and resolving challenges that arise in the course of childrearing [8]. For children between the ages of 0 - 3 years—a crucial phase in developmental terms—the

XSL•FO
RenderX

pressures of parenting are acute. The research hypothesizes a correlation between the QoL and parenting ability, suggesting that enhancing parenting competence can alleviate parental stress and improve the QoL.

Recent studies on the QoL of child caregivers focused on parents caring for children with special needs or intergenerational caregivers [9]. However, they overlooked the experiences of typical parental caregivers. The purpose of this study was to explore the connection between parent competence and the QoL among caregivers of children aged 0 - 3 years. It also aimed to offer insights and guidance for the development of effective parenting strategies and interventions for families with children in this age group.

Methods

Design

The convenience sampling method was employed to select eligible family caregivers of children aged 0 - 3 years from the Child Health Department at a tertiary hospital in Changsha, for a questionnaire survey conducted from January to April 2024.

Participants

According to the widely recognized method for estimating sample size, it is recommended to have a sample size that is 5 to 10 times the number of variables under study [10]. This research encompasses 8 demographic and disease-related variables and 6 additional dimensions from the scale, resulting in a total of 14 variables. Consequently, an initial sample size of 70 to 140 participants is suggested. To accommodate a potential 10% loss of samples and the presence of invalid questionnaires, the minimum sample size should be adjusted to range from 77 to 154 participants. In this study, a total of 300 questionnaires were disseminated; 9 of them were excluded due to incomplete questionnaires.

The inclusion criteria were as follows: (1) guardians of children aged 0 - 3 years acting as primary caregivers; (2) possessing adequate cognitive communication skills; (3) consenting to participate in the study; and (4) capable of independently completing the survey. Conversely, exclusion criteria encompassed: (1) individuals with psychiatric disorders or those averse to collaboration; (2) family members of sick children; and (3) participants withdrawing for various reasons (for example, not having time to complete all the questionnaires, or unwilling to continue participating midway).

To guarantee the integrity of the data collection process, the investigator remained present to assist participants with any queries and to verify that the questionnaires were filled out completely.

Ethical Considerations

The study was approved by the Ethics Committee (No. E2023121). The data are anonymized. The participants were informed of the purpose and procedures of the study prior to participation, and we obtained informed consent from the parents. The participants did not receive any remuneration.

Data Collection and Measurements

General Information

This information encompassed the relationship with the child, marital status of the child's parents, family structure, child's age, identity of the primary family caregiver, physical health of both the child and the caregiver, method of the child's conception, and feeding practices employed.

Parenting Competence Scale

The Parenting Competence Scale was developed by Gibaud-Wallston and Wandersman [11] in 1978 and translated by Yang et al [12]. The scale comprises 17 items, bifurcated into two principal dimensions: efficacy and satisfaction. The efficacy component encompasses eight items that gauge parents' self-perceptions of their parenting skills, whereas the satisfaction component comprises nine items that assess parents' contentment with their role as caregivers. The scale ranged from "1: Totally Disagree" to "6: Totally Agree." The scores fluctuate between 17 and 102, with elevated scores mirroring enhanced parenting competence. The reliability of the scale is substantiated by a Cronbach α coefficient of 0.80.

Family Caregiver Specific QoL Scale

The Family Caregiver Specific QoL scale, developed by Nauser et al [13] and transcribed by Hyland Qian [14], was employed to assess the QoL in family caregivers. It comprised 16 items that span four dimensions: physical, social, spiritual, and psychological well-being. Four entries for each dimension. All domains carry equal importance. Employing a 5-point Likert scale, it allows respondents to answer with options ranging from "1: Strongly Disagree to "5: Strongly Agree." Items that were negatively expressed were reverse-scored. The scale scores spanned from 16 to 80, with higher scores suggesting an enhanced QoL for the caregiver. The Cronbach α for the Chinese version of the scale was 0.84, further confirming its reliability and validity. This scale has been applied in family caregivers for children with heart disease, premature infants, and newborns [15,16].

Statistical Analyses

Statistical analysis was conducted using SPSS software (version 24.0; IBM Corp). The general information was analyzed descriptively using frequency counts (component ratios). The QoL and parenting competence scores of family caregivers were characterized using means and standard deviations, provided they adhered to a normal distribution. One-way analyses were carried out to identify factors influencing QoL using *t* tests or ANOVA. The association between the QoL and parenting competence of family caregivers was assessed using the Pearson correlation analyses.

Results

General Information

A total of 300 parents participated in the survey, of which 291 responses were valid, yielding a questionnaire recovery rate of 97%. The participants comprised 13 fathers and 278 mothers, as detailed in Table 1.

Scores of Parenting Competence and QoL

In this study, we evaluated the parenting competence of family caregivers for children aged 0 - 3 years, finding an average (SD) score of 68.70 (9.816), while the average (SD) QoL score stood at 56.81 (8.922). Detailed scores for each dimension are depicted in Table 2.

XSL•FO

Discussion

Main Findings

The parenting competence scores of family caregivers for children aged 0 - 3 years exhibited a positive correlation with the caregivers' QoL (R=0.665, P<.001). Additionally, scores across all domains of parenting competence demonstrated positive correlations with scores across all dimensions of QoL (P<.001).

General Information on Family Caregivers

Composition of Family Caregivers

In this study, out of 291 participants, 278 were mothers (95.53%); therefore, mothers emerged as the predominant family caregivers. Consequently, efforts to enhance the QoL for family caregivers should prioritize understanding and addressing the experiences and sentiments of maternal caregivers. Out of 291 families, there are 170 nuclear families (58.4%) and 118 stem families (40.6%). Stem families refer to families where grandparents, parents, and children live together. This type of family is common. Although the mother is the primary caregiver, in China, grandparents are usually more involved in parenting. There may be differences in parenting concepts between parents and grandparents. Future research could explore the impact of grandparents' involvement in parenting on family dynamics.

Level of Caregiver Parenting Competence and QoL

Parenting Competence of Family Caregivers

The mean (SD) parenting competence score among family caregivers of children aged 0 - 3 years was 68.70 (9.816). This study is pioneering in investigating the parenting competence for this age group, as the majority of existing research has primarily concentrated on children age 1 years, particularly the

XSL•FO
RenderX

initial 42 days postdelivery, thereby limiting comparative analysis [17]. The present study revealed a medium level of parenting competence. The efficacy and satisfaction dimensions had different numbers of entries and were not comparable.

QoL of Family Caregivers

In this study, the mean (SD) caregiver QoL score was found to be 56.81 (8.922). Given the plethora of scales designed to measure caregiver QoL, particularly those catered to children with special needs, direct comparisons with other studies are challenging [18]. Among the four dimensions assessed, family caregivers exhibited the highest scores in psychological well-being. Parent-child interactions appear to bolster parent-infant attachment, especially during early development stages (0 - 3 y). Therefore, promoting these interactions within families could be an effective strategy for future interventions [19]. The social and psychological dimensions of QoL were notably deficient, so strengthening social support for caregivers of children aged 0 to 3 years and addressing their related psychological issues is a way to improve the QoL for caregivers [20].

Association Between Caregiver Parenting Competence and QoL

Impact of Parenting Efficacy on QoL

Research has consistently demonstrated a positive correlation between parenting efficacy and the QoL of caregivers [21-23]. Enhanced parenting efficacy not only bolsters cognitive and behavioral functioning but also catalyzes improvements in physical and mental health. Alam et al [24] found that caregivers are susceptible to physiological issues such as sleep disorders, weight loss, and fatigue due to their caregiving responsibilities. According to Bandura's theory [25], parents with a heightened sense of efficacy are more adept at self-regulation and self-management when confronted with challenging parenting scenarios, such as a decline in the child's health, thereby enjoying a higher physiological QoL. In terms of mental aspects, the task of caregivers is to manage the daily needs of children aged 0 to 3 years, take care of family members, and participate in decision-making, which may lead to mental health challenges. The research implies that individuals possessing a stronger sense of efficacy may exhibit an enhanced ability to mitigate the detriments of negative mental health [26]. Confronted with obstacles in parenting, such as disputes concerning educational philosophies, they are inclined towards adopting positive coping tactics to regulate their emotional state and promote superior mental health quality. From a social perspective, an unwavering focus on infants and toddlers might curtail a carer's independence, consequently posing adverse effects on their psychosocial development. Numerous investigations establish a linkage between social support and QoL [27-29]. Such findings indicate that the QoL could potentially intermediate the relationship between a collective sense of efficacy and parenting proficiency. In other words, caregivers possessing a stronger sense of efficacy are likely to be more assertive in pursuing social support, are more equipped to furnish social support, and possess a better overall social QoL. The psychological state of a caregiver is heavily influenced in their interaction with children aged 0 - 3 years [30]. Factors such as concern for the child's health, challenges in transitioning to caregiving roles, and understanding the child's expressions may catalyze anxiety and depression among caregivers. Loh et al [31] proposed that caregivers who are capable of effectively managing, adjusting to, and surmounting difficulties experience lesser burden and exhibit fewer symptoms of anxiety and depression. Furthermore, these caregivers tend to have a better social QoL due to their increased sense of efficacy.

Impact of Childcare Satisfaction on QoL

The positive correlation between childcare satisfaction and caregiver QoL has been well-documented. Numerous studies have examined the correlation between satisfaction and the QoL, typically comparing the two as indicators for assessing outcomes [32,33]. However, Sansó et al [34] postulated a direct correlation between life satisfaction and the QoL. Parenting satisfaction represents an individual's comprehensive evaluation of their parenting role. Physiologically, parents experiencing high levels of satisfaction are less inclined to engage in self-reproach, exhibit reduced susceptibility to fatigue and burnout while attending to children aged 0 - 3 years, and provide superior care, thereby enhancing their physiological QoL. Psychologically, these parents demonstrate a decreased likelihood of experiencing frustration and negative emotions when confronted with childcare challenges. Moreover, the subjective experience of well-being is recognized as a fundamental element for maintaining high mental health and satisfaction [35]. Consequently, parents who report satisfaction tend to exhibit a lower threshold for experiencing pleasure, reduced vulnerability to mental or psychological issues, and an elevated mental and psychological QoL. Socially, in line with societal expectations in many cultures, Chinese parents who fall short in their parenting duties are held accountable by various segments of society. Parents with high parenting satisfaction are more likely to cultivate higher-quality social connections, receive enhanced social support for their childcare responsibilities, and enjoy a superior quality of social life.

Limitations

This study employed a convenience sampling method from a single hospital, limiting its representativeness. Future research should consider stratified sampling across various countries, hospitals, and communities. Additionally, investigating the mediating factors between parenting competence and QoL may offer valuable insights for further studies.

Conclusion

The study found that family caregivers of children aged 0 - 3 years exhibit a correlation between parenting competence and QoL, with all dimensions showing significant correlations. Health care professionals have the potential to enhance QoL by fostering parenting competence.

Abstract

Background: Parents of children with disabilities face many challenges when providing care, along with persistent worry and fear about the child's health outcomes and the impact of the disability on their lives. These parents experience stressful situations and face many emotions, one of which is chronic sorrow (CS). Therefore, the theory of CS was introduced to examine and measure feelings of CS among parents. Little research has been conducted with Saudi parents with a child with disabilities and the utilization of CS theory in this population is limited.

Objective: This study aims to examine the application of CS theory on parents of children with disabilities in Saudi Arabia.

Methods: A cross-sectional design was used to obtain data from 89 participants who are parents of children with disabilities. A web-based questionnaire was distributed to measure CS.

Results: The study examined the concepts within CS theory. The concept of loss experience yielded a moderately high score (mean 3.3, SD 1.10); of all the variables measuring loss experience, parents scored high in feeling sad when thinking about their child's disability (mean 3.9, SD 1.24). Parents also reported a moderately high score (mean 3.3, SD 1.06) for the concept of disparity, specifically when their child does not meet the same developmental milestones as their peers (mean 3.8, SD 1.30). Feelings of CS also displayed a moderately high score (mean 3, SD 0.87), with the periodic nature of CS scoring the highest within the concept of CS (mean 3.6, SD 1.16). In addition, internal and external management methods that parents believe are effective were examined. Internal management of CS was believed to be of high importance (mean 4.6, SD 0.33), specifically the belief of fatalism (mean 4.8, SD 0.50). Parents also viewed external management as important in navigating their emotions (mean 4.5, SD 0.42), specifically social support from family and the community (mean 4.7, SD 0.55). This study identified strong positive relationships between sorrow and loss experience and disparity (both r=0.765 and P<.001). Lastly, the study found no relationship between CS and time elapsed since parents received their child's diagnosis (r=−0.009; P=.94).

Conclusions: This study applied the theory of CS to the parents of children with disabilities and they reported feelings of loss, disparity, and CS. Therefore, this population should be screened and provided with parental emotional care. Interventions to enhance parental mental health and well-being and support CS management should be developed and used by health care workers. Parental acceptance of their child's disability does not mean the absence of CS, as it is part of the normal grieving process. Anticipating CS triggers and applying internal and external management are essential to improving parental mental health and child health outcomes.

KEYWORDS

chronic sorrow; sadness; parent; disability; pediatric; infant; neonatal; children; youth; adolescence; Saudi Arabia

Introduction

Background

In 2017, the Saudi General Authority of Statistics issued a detailed report of people with disabilities who reside in Saudi Arabia, noting that a total of 1,445,723 people with varying degrees of disability (mild, moderate, or severe) reside in the country, of which 52.2% were males and 47.7% were females [1]. This illustrates that people with disabilities represent a substantial portion of the Saudi community and more attention should be directed to them and their families.

Parents of children with disabilities face numerous difficulties in their daily life when caring for their child, along with feelings of worry and stress about their child's long-term survival and

XSL•FO
RenderX

well-being [2]. The difficulties that the parents face may include their ability to deal with day-to-day challenges, transformation of their social interactions with relatives and friends, and modification of their daily activities [2]. Parents of children with disabilities worry about their child's acceptance in society, as well as the opportunities and resources that might not be available to them when caring for their child. As the child grows and their condition persists, parents become concerned about where and with whom their child will live when they are adults [3]. In addition, parents of children with disabilities experience emotions that are overwhelming and do not follow a predictable sequence. Their emotions can include sadness, anger, and frustration and be periodic in nature [4]. Multiple studies have aimed to measure chronic sorrow among parents of children with different health conditions. These include but are not limited to chronic illness and disabilities [4], autism [5,6], cancer [7], sickle cell disease [8], neurodevelopmental disorders [9], type 1 diabetes [10], and Down syndrome [11].

As a result, the concept of chronic sorrow emerged to explore the daily experiences of these parents. Roos [12] defined chronic sorrow as "a set of pervasive, profound, continuing, and recurring grief responses resulting from a significant loss or absence of crucial aspect of oneself (self – loss) or another living person (other – loss) to whom there is a deep attachment. The way in which the loss is perceived determines the existence of chronic sorrow. The essence of chronic sorrow is a painful discrepancy between what is perceived as reality and what continues to be dreamed of. The loss is ongoing since the source of the loss continues to be present. The loss is a living loss."

The Theoretical Framework of Chronic Sorrow

Chronic sorrow was initially proposed by psychiatrist Olshansky [13]. In his work with mentally challenged children, their parents, and family members, Olshansky observed that parents of children with disabilities display a widespread psychological response to the experience of having a child with disabilities [13]. The parents often had long-lasting, chronic sorrow because the loss they experienced lacked a clear end. It was also uncertain how long the loss would persist [14]. Parents who care for children with disabilities have described having profound emotional experiences. These emotions may be felt occasionally but they may not always be present. These intense emotions may include shock, disbelief, rage, irritation, a feeling of isolation, and a profound sense of sadness and loss. As a result, it is hypothesized that parents of children with disabilities are more likely to report experiencing persistent sadness [15].

Eakes et al [16] defined the variables of the theory of chronic sorrow as the following:

- Chronic sorrow: "ongoing disparity resulting from loss characterized by pervasiveness and permanence. Symptoms of grief recur periodically, and these symptoms are potentially progressive."
- Loss: occurs because of the discrepancy between the "ideal" or "imagined" situation versus the lived experience and occurs in the early stages of the child's diagnosis.
- Disparity: disparity follows the loss experience and can be classified as a trigger for chronic sorrow. The loss experience occurs in the early stages of the child's diagnosis, whereas disparity reemerges as time passes, when the child does not meet his or her developmental milestones like his or her peers, such as attending school graduations and birthday parties.
- Management methods: strategies used by parents or individuals to minimize the impact of sorrow. These methods can be internal (personal and individualized methods) or external (support from health care workers or institutions).

Studies that have addressed chronic sorrow among parents of children with disabilities are very scarce, especially in Arabic. The Kendall Chronic Sorrow Instrument was found to be useful in measuring the chronic sorrow of mothers of a child with disabilities [17]. Fernandes et al [18] analyzed the theory of chronic sorrow and found that the theory is well-defined and its concepts captured the phenomena under study. When measuring its concepts, they found that the theory had high reliability.

It is worth noting that parents experiencing chronic sorrow are usually overlooked and remain unexamined by society. Parents of children with disabilities must navigate their emotions of sorrow and an unending sense of commitment while maintaining their level of functionality [19]. The objectives of this study are important because parents of children with disabilities report multiple negative outcomes such as psychological distress, a sense of isolation, a lack of financial support, and the absence of tools to help them manage their child's condition [20].

Lastly, the theory of chronic sorrow can be used by nurses caring for parents of children with disabilities to help the parents identify and use management and coping strategies.

This descriptive study aims to explore chronic sorrow among parents of children with different types of disabilities in the Kingdom of Saudi Arabia. The objective of this study is to answer the following questions: With the use of chronic sorrow as a theoretical framework, what are the parental experiences of chronic sorrow in the context of caring for a child with a disability? Is there a relationship between the concepts of the theory of chronic sorrow, specifically between loss and disparity with chronic sorrow? Lastly, is there a relationship between the time elapsed since the child's diagnosis and parental feelings of chronic sorrow?

Methods

Design

A quantitative, descriptive cross-sectional study design will be used to conduct this study exploring chronic sorrow among parents of children with disabilities. We will also identify the strength of the relationships between the triggers (loss experience and disparity) of chronic sorrow. Lastly, we will investigate the impact of time since the child's diagnosis on parental feelings of chronic sorrow.

Instrument

Data were collected for this study through a web-based questionnaire. The questionnaire and consent form were sent

XSL•FO
RenderX

to the participants after obtaining institutional review board approval from King Abdullah International Medical Center.

The questionnaire was distributed electronically to participants via WhatsApp. The questionnaire consisted of parental demographic data (8 items), loss experience (5 items), disparity (3 items), chronic sorrow (9 items), and management of chronic sorrow (9 items). The chronic sorrow measurement was originally created by Kendall (Kendall Chronic Sorrow Instrument) [21], then the Arabic version of the same instrument was created by Baker et al [22], who confirmed that the internal consistency of the correlation coefficient of the scale was greater than 0.7, with a high degree of validity in the Loach method for all statements, with a score of 0.62. In addition, the Cronbach α was 0.8. All of the above parameters have met the psychometric properties of a valid and reliable instrument [22]. As a result, the Arabic version of the instrument was used for this study due to the proximity of the populations in both studies, both of which speak Arabic and have shared cultural characteristics and religious backgrounds.

For the measurement of chronic sorrow, every item in the scale had a total of 5 responses (5-point Likert scale), ranging from strongly disagree (score of 1 point), disagree (2 points), neutral (3 points), agree (4 points), to strongly agree (5 points). Scoring criteria were as follows: 1 - 2 indicated a low score of chronic sorrow, 2 - 3 indicated a moderately low score, 3 - 4 indicated a moderately high score, and 4 - 5 indicated a high score of chronic sorrow.

Sample, Setting, and Data Collection

Recruitment of study participants was done using nonprobability convenience sampling. The tool targeted parents with a child with disabilities currently residing in Saudi Arabia. The participants who were eligible for this study fulfilled the following criteria: the mother, father, or primary caregiver of a child with a disability, the child had a confirmed medical diagnosis, the parent could speak and read Arabic, and parental age was above 18 years.

For this descriptive study, the significance level of α was set at 0.05 with a power of 0.8 to calculate the sample size and estimate power analysis. The sample size was estimated by G*Power software. This study will be the first to examine the use of chronic sorrow as a theoretical framework among Saudi parents who have a child with a disability. As a result, no previously reported effect size was available for use in the power analysis. Cohen [23] stated that in cases like our study where effect size has not been previously reported in the literature, the estimation of effect size should be based on logic and judgment. Therefore, a medium effect size of 0.30, a power of 0.80, and α significance level of 0.05 were used to guide our statistical analysis, with a sample size of 64.

Potential participants were recruited via invitation through WhatsApp, Facebook, and X (formerly known as Twitter). Upon filling out the questionnaire, the researcher identified parents who met the inclusion criteria and enrolled them in the study. If the participant agreed to fill out the questionnaire after reading the consent form, they were directed to the questionnaire page. Consent was obtained from participants electronically; if the participant agreed to fill in the questionnaire, he or she was directed to an electronic informed consent form. After reading the consent form, the participant was required to sign the form electronically by clicking the “I agree to participate” box, after which the questionnaire would appear.

We used Microsoft Forms for its easy accessibility and user-friendliness for the general population to promote data collection and reduce missing data.

Data Analysis

Once data collection was complete, we entered the data into an Excel database for analysis. SPSS (version 30; IBM Corp) was used to analyze the data on a password-protected computer. Different types of analysis were proposed for this study. Descriptive statistics were calculated on all variables of interest, including means, standard deviations, frequencies, and percentages. Pearson correlation coefficients were used to examine the relationships among continuous variables. Statistical significance was based on the standard α level of .05.

Frequencies and percentages were used for analyzing descriptive data to evaluate the variables of chronic sorrow. Pearson correlations were used to analyze numerical data and assess the relationship between the triggers and the concept of chronic sorrow.

Ethical Considerations

This study received ethics approval from the institutional review board of the King Abdullah International Medical Research Center (SP23J/144/09) on October 16, 2023, and the data collection lasted for 6 months.

Various measures were undertaken to maintain the privacy and confidentiality of participants. Although there was minimal risk involved, all measures to protect participants’ information were taken. Participants’ responses to each survey item were not shared with other participants or individuals not associated with the research project. By accessing and completing the survey, participants gave their consent to take part in the study. Participation in the study was voluntary. Participants could withdraw from the study at any time. No compensation was provided to the participants.

Results

Participant Characteristics

As Table 1 shows, a total of 89 participants completed the survey. Of these participants, 78% (n=69) were mothers of a child with disabilities. Most of the participants (n=42, 48%) were aged 40-49 years. Many of the participants were caring for a child with a permanent disability (n=79, 89%) and most participants had a university level of education (n=54, 61%). Most of the children had been diagnosed for less than 1 year (n=45, 51%) and Down syndrome was the most reported disability (n=39, 44%).

XSL•FO

Table . The sample demographic characteristics (N=89).

Demographic variable	Participants, n (%)
People completing the survey	
Mother	69 (78)
Father	5 (6)
Nonparent	15 (17)
Age group (years)[a]	
20 - 29	5 (6)
30 - 39	20 (23)
40 - 49	42 (48)
50 - 59	16 (18)
60 - 65	4 (5)
Permanence of the child's disability	
Temporary disability	10 (11)
Permanent disability	79 (89)
Educational level	
Primary school	4 (4)
Intermediate school	5 (6)
High school	26 (29)
University	54 (61)
Time since the child was diagnosed with a disability (years)	
Less than 1	45 (51)
2 - 3	11 (12)
4 - 9	25 (28)
More than 10	8 (9)
Nature of the child's disability	
Down syndrome	39 (44)
Autism and attention-deficit/hyperactivity disorder	15 (17)
Mental retardation	8 (9)
Physical disability	21 (24)
Undisclosed disability	6 (7)

[a]There were 87 responses for this question (ie, 2 participants did not respond).

Descriptive Statistics of the Theory of Chronic Sorrow

The data in the following 5 sections illustrate the descriptive statistics of the participants toward the concepts of the theory of chronic sorrow, which is used to measure the following aspects: the triggers of loss experience and disparity, chronic sorrow, internal management, and external management.

Descriptive Statistics for Loss Experience

As shown in Table 2, the reported score of the loss experience that parents of children with disabilities face was a mean of 3.3 (SD 1.10). Of all the variables measuring loss experience, feeling sad when thinking about the child's disability was the highest (mean 3.9, SD 1.24) and a sense of overwhelming sorrow scored the lowest (mean 2.8, SD 1.40). The results showed that parents with children with disabilities reported moderately high loss experience.

XSL•FO
RenderX

Table . Descriptive statistics of loss experience (N=89).

Loss experience	Score, mean (SD)
It feels like the disability happened to me	3.5 (1.18)
Sorrow feelings when I think about my child's disability	3.9 (1.24)
The sorrow feeling remains the same as the day of the diagnosis	3.3 (1.43)
Urge to cry when I remember the disability	3.3 (1.42)
Overwhelming sorrow	2.8 (1.40)
Total score of loss experience	3.3 (1.10)

Descriptive Statistics for Disparity

As shown in Table 3, the total score of the concept of disparity reported by parents of children with disabilities had a mean of 3.3 (SD 1.06). The highest score among the disparity variables was the feeling of sorrow and sadness parents face when their child cannot meet developmental milestones, often associated with significant events or dates including birthdays, with a mean score of 3.8 (SD 1.30). On the other hand, the lowest score reported was the feeling of sorrow when thinking about their child without the disability (mean 2.7, SD 1.28). According to this study, the feeling of disparity experienced by parents of children with disabilities is moderately high, which is aligned with the experiences of loss.

Table . Descriptive statistics of disparity (N=89).

Disparity	Score, mean (SD)
Sorrow emerges when I remember my child's disability	3.3 (1.29)
I feel sorrow about things that do not matter for parents with healthy children (such as birthdays and entering school)	3.8 (1.30)
I feel sorrow when I picture my life without my child's disability	2.7 (1.28)
Total score of disparity	3.3 (1.06)

Descriptive Statistics for Chronic Sorrow

As shown in Table 4, the total score of the chronic sorrow reported by parents of children with disabilities had a mean of 3 (SD 0.87). Of the variables measuring chronic sorrow, the variable of sorrow and its nature of coming and going (ie, its periodic nature) had the highest score (mean 3.6, SD 1.16), along with reported energy to handle sorrow (mean 3.6, SD 1.11). On the other hand, the least reported variable within the chronic sorrow concept was parents reporting that their life is not what they imagined due to their child's disability (mean 2.6, SD 1.33), followed by feeling that parental desires and goals do not match what life has given them (mean 2.7, SD 1.32). Overall, parents reported moderately high levels of chronic sorrow, indicating that these feelings of sorrow are manageable and can be reduced or that its cyclic nature can be spaced out.

Table . Descriptive statistics of chronic sorrow (N=89).

Chronic sorrow	Score, mean (SD)
Sorrow regarding my child's disability comes and goes	3.6 (1.16)
I feel like my child's disability makes me give up some aspects of my life	3.4 (1.40)
I feel like I do not have control over my life	2.9 (1.36)
I feel like my life is not like I imagined due to my child's disability	2.6 (1.33)
The feelings of sorrow can transform into feelings of loneliness	2.8 (1.38)
I feel like I have energy to handle life's stressors	3.6 (1.11)
Sudden changes in my child's disability have led to exhaustion	3.0 (1.26)
I think that what I desired does not align with what life has given me	2.7 (1.32)
I feel older due to my child's disability	2.9 (1.34)
Total score of chronic sorrow	3.0 (0.87)

XSL•FO
RenderX

Descriptive Statistics of Internal Management of Chronic Sorrow

Table 5 presents the descriptive statistics of how parents of children with disabilities view the effectiveness of internally managing their child's disability as a means to overcome chronic sorrow. The total score of internal management had a mean of 4.6 (SD 0.33), which is a high score, highlighting the important role of internal management of chronic sorrow. Of all the variables measuring the internal management of chronic sorrow, accepting the child's disability as destined by God (also known in the Islamic religion as fatalism) demonstrated the highest score with a mean of 4.8 (SD 0.50), followed by the availability of resources that parents need to manage their child's disability (mean 4.7, SD 0.47). These were followed by feeling better when parents are more aware and can make independent decisions about the child's disability (mean 4.4, SD 0.62). The results of this study showed that internal management of a child's disability is crucial for reducing chronic sorrow and empowering the parents of children with disabilities to minimize their episodes of chronic sorrow, allowing them to provide the best care for their child.

Table . Descriptive statistics of internal management of chronic sorrow by parents of children with disabilities.

Internal management of chronic sorrow	Score, mean (SD)
I feel better when I am more aware of my child's disability	4.4 (0.62)
Making independent decisions about my child's disability is empowering for me	4.4 (0.62)
Accepting my child's disability as destined by God makes me feel better	4.8 (0.50)
The availability of resources (eg, financial and therapeutic) for my child induces a sense of relief	4.7 (0.47)
Total score of internal management	4.6 (0.33)

Descriptive Statistics of External Management of Chronic Sorrow

Table 6 shows results related to parents' external management of chronic sorrow, with the overall utilization of external management displaying great importance (mean 4.5, SD 0.42). Of all the variables measuring external management of chronic sorrow, feeling better when social support is provided displayed the highest score (mean 4.7, SD 0.55), followed by feeling better when the community is kinder and more considerate (mean 4.5, SD 0.56). The results of this study showed that both external and internal management of chronic sorrow are important tools that parents need to use and navigate to manage the periodic and unpredictable nature of chronic sorrow.

Table . External management of chronic sorrow by parents of children with disabilities.

External management of chronic sorrow	Score, mean (SD)
I feel better when doctors and nurses provide more information about my child's condition	4.4 (0.64)
I feel better when support is provided by family and the community	4.7 (0.55)
I feel better when I am allowed to express my emotions freely and without judgment	4.3 (0.71)
I feel better when I believe that we as a family have created a coping strategy that is specific to us	4.4 (0.62)
I feel better when more people in the community are considerate and kind to me and my child	4.5 (0.56)
Total score of external management of chronic sorrow	4.5 (0.42)

Association Between Chronic Sorrow and Parental Loss Experience and Disparity

Table 7 shows the Pearson correlation between chronic sorrow and the sense of loss experience and disparity. The study results showed a strong correlation between chronic sorrow and the concepts of disparity and loss.

As shown in Table 7, chronic sorrow is strongly and positively correlated with loss experience (r=0.765; P<.001). In addition, the same strong correlation emerged between chronic sorrow and disparity (r=0.765; P<.001). Lastly, another positive and strong correlation emerged between the concept of loss experience and disparity (r=0.791; P<.001).

XSL•FO
RenderX

Table . Pearson correlation between chronic sorrow and loss experience and disparity.

Variable	Chronic sorrow	Loss experience	Disparity
Chronic sorrow			
r	1	0.765	0.765
P value	—[a]	<.001	<.001
Loss experience			
r	0.765	1	0.791
P value	<.001	—	<.001
Disparity			
r	.765	0.791	1
P value	<.001	<.001	—

[a]Not applicable.

Association Between Chronic Sorrow and Time Since Diagnosis of the Child's Disability

Table 8 illustrates the results of the Pearson correlation between chronic sorrow and the amount of time elapsed since parents received their child's diagnosis. The correlation was negative and very weak (r=–0.009; P<.93), indicating that, as time passes, the feelings of chronic sorrow among parents do not subside. This study showed an inverse yet very weak relationship between time since diagnosis and the chronic sorrow score, indicating that time passing does not play a role or have an impact on the recurrent nature of chronic sorrow. It is also worth mentioning that an increase in chronic sorrow as time passes was not indicated. Therefore, health care workers need to assess parents for chronic sorrow whether the diagnosis was received recently or a long time ago, highlighting the importance of multiple interventions to manage and coexist with chronic sorrow.

Table . Pearson correlation between the concept of chronic sorrow and time since diagnosis.

Discussion

Principal Findings

Literature examining chronic sorrow among parents with a child with a disability was scarce in the international and Saudi literature alike. Therefore, this study was designed to examine the application of the theory of chronic sorrow by Olshansky [13] to Saudi parents with a child with a disability. The study examined the major variables in the theory including loss experience, disparity, chronic sorrow, and internal and external management. In addition, we attempted to examine the relationships between these variables and whether time since diagnosis decreased the sense of chronic sorrow. The results of the study showed that parents reported a moderately high level of loss experience, disparity, and chronic sorrow. On the other hand, management methods (internal or external) played a crucial role for these parents in adapting to and managing their child's disability. In addition, the reported concepts of loss experience and disparity had a moderately strong relationship with the feelings of chronic sorrow that the parents were experiencing. Lastly, time elapsed since the child's diagnosis did not have an inverse relationship with the feeling of chronic sorrow, indicting that time passing does not play a role in the feeling of chronic sorrow.

Parents of children with disabilities have experienced loss, which is different for every parent; in addition, different parents have different abilities to navigate emotions. Loss experience can be interpreted as the loss of the ideal child [24]. This study found a moderately high level of loss experience and that its consequences can trigger the feeling of chronic sorrow. Loss experience among parents of children with disabilities has been reported in previous studies, reflecting the results of our study despite cultural and religious differences between the study populations. A study by Phillips [25] examined loss among parents of children with disabilities, viewing loss as a consequence that they are not familiar with, and its ability to impact the family's well-being. Studies by Fernandez et al [18] and Fernández-Alcántara et al [24] examined loss and grief (eg,

XSL•FO
RenderX

related to loss of the ideal child, a traumatic experience, and shock) in the same population, and the concept of the theory of chronic sorrow emerged there as well. Loss experience among parents is a crucial step that parents undergo to explore their chronic sorrow, eventually leading to acceptance and hope for their child's future.

Disparity is one of the major concepts of the theory of chronic sorrow. It follows the feelings of loss experience and is triggered by certain developmental milestones that parents of children with disabilities observe in healthy children [8]. Multiple studies have illustrated the presence of disparity within parents; those results were congruent with the results of this study. A study by Nikfarid et al [26] examined chronic sorrow in parents of children who were diagnosed with cancer, while a study by Olwit et al [8] investigated chronic sorrow in parents with children diagnosed with sickle cell disease. In both of these studies, parents mentioned the presence of disparity and its role in triggering chronic sorrow, contributing to its ongoing nature. Lastly, a study by Masterson [27] explored parental chronic sorrow and disparity when a child with cerebral palsy becomes an adult. The study showed that mothers still experienced disparity, which triggered a loss of hope as the child aged without meeting milestones.

Chronic sorrow among parents with a child with a disability is different from the normal grieving process or sadness because it is characterized by its cyclic nature, and it can be triggered by feeling of loss and disparity [13]. Results from studies examining chronic sorrow among parents with children with disabilities have been similar to and consistent with the results of this study. The theory of chronic sorrow explains the realistic feelings and emotions encountered by these parents and that these feelings do not manifest the same way as grief or a single loss because they can appear after parental acceptance of the disability [26-29]. Studies by Olwit et al [8] and Hobdell [30] found that chronic sorrow among parents needs to be assessed by health care workers as it has the potential to affect parental health and parental management of their child's disability. In parents, chronic sorrow may present as reduced social interaction, psychological distress, anger, and even guilt [20,31,32].

Internal management of chronic sorrow that is effective and used by parents plays a crucial role in minimizing the recurrence of chronic sorrow episodes, particularly if it is used correctly [18]. This study illustrates that fatalism (accepting God's destiny regarding the child's disability) represents the most effective internal management strategy for chronic sorrow. Multiple studies have displayed similar results in spite of different religious or spiritual beliefs among the study participants. Studies by Mikołajczuk and Zielińska-Król [33] and Pillay et al [34] reported that parents of children with disabilities found that religion and accepting God's destiny were effective coping mechanisms that improved parental resiliency, acceptance, and management of daily challenges. The participants of this study were predominantly from the Islamic religion, and the concept of fatalism as a means to internally manage chronic sorrow was most reported in this population. Fatalism in the Islamic religion is the belief that the future of man is already determined by God and cannot be swayed or changed whether the destiny is good or bad, and man should accept god's destiny and surrender to his will. Khan et al [35] and Othman et al [36] studied Muslim parents of children with disabilities and their results—in which parents found comfort, hope, and resiliency when integrating religion and spirituality when caring for their children—are congruent with this study.

Its important to note that this study is the first to use the theory of chronic sorrow among Saudi parents of children with disabilities, and it is crucial to incorporate religion and the concept of fatalism into this framework to fully capture the phenomena of chronic sorrow as the role of religion in navigating emotions is important in this population. The role of religion and belief in this context was previously reported in the literature by Alqunaibet [37] and Çaksen [38], who illustrated that religion and spirituality play an important role in helping parents and caregivers manage sorrow and stress.

Our questions regarding the external management of chronic sorrow aimed to capture the most efficient method used by parents. The results of the study identified social support (from family and the community in particular) to be key to externally managing chronic sorrow. The results of the study correspond with those of Ha et al [39] and Felizardo et al [40], who investigated the role of social support from family and the community, which yielded similar results to this study. Mantri‐Langeveldt et al [41] conducted a scoping review to illustrate the important role of family support for parents with children with disabilities, reaffirming the importance of social support measurement by health care professionals.

This study identified a strong positive relationship between chronic sorrow and loss. The loss expressed by parents of children with disabilities is known as ambiguous loss as it is not definitive and not clearly visible as the child is alive, though not experiencing normal development. In addition, the loss associated with chronic sorrow in this population does not provide closure; the loss of the ideal child cannot be mourned because that child never existed [42]. Brown [43] conducted a study to capture the importance of sorrow and grieving in the healing process for mothers of children with intellectual disabilities. The results are similar to this study, as mothers experienced loss specifically after diagnosis and felt loss for their child and for their role as mothers. Senenac et al [44] described the parental experience of having a child with disabilities and the results identified that the themes of sorrow and loss are associated, along with other emerging concepts such as stigma and guilt.

This study identified a strong and positive relationship between chronic sorrow and disparity. Disparity, unlike loss, reemerges as time passes and the parents tangibly observe the inability of their child to meet developmental milestones like their peers, which triggers feelings of chronic sorrow [17]. Claassens et al [4] examined parental chronic sorrow among parents with children with disabilities. The results of the review yielded multiple findings, one of which was the strong relationship between chronic sorrow and disparity. The review identified events that parents undergo that trigger the resurgence of chronic sorrow and their role in reminding parents about the disparity and gap between the "idealized and hoped-for child" and "the

XSL•FO
RenderX

ill or disabled child" [4]. Multiple studies have found that the same phenomenon is seen with disparity and its role in triggering chronic sorrow in parents caring for children with different types of disabilities or diseases that require caregiving, such as autism spectrum disorder [45], sickle cell disease [8], and cerebral palsy [46].

This study examined the relationship between time elapsed since the child received their diagnosis and chronic sorrow among parents. The results of this study have shown that there is no relationship between time passing and chronic sorrow, indicating that time does not play a role in reducing or increasing feelings of chronic sorrow. The results of this study correspond with the literature. A study by Fernandez et al [18] found that loss and sorrow persist over time and therefore emotional interventions are crucial for the parents of children with disabilities. Fernández‐Ávalos et al [47] rationalized this phenomenon by explaining that parents are faced with daily challenges and worries when caring for their child. As a result, these challenges influence their perception of managing chronic sorrow and their quality of life. Therefore, delivering early interventions and realistic expectations of the child's development and disease prognosis are crucial, along with providing emotional care for parents. These interventions will play a role in managing chronic sorrow over time and eventually lead to acceptance, resilience, and enhanced mental health [48-50].

Limitations

This study collected data from parents primarily residing in Jeddah, Saudi Arabia. Therefore, the results of the study might not be generalizable to other countries or cultures. Another limitation was the type of disability that the children were diagnosed with, as much of the data were collected from parents with children with Down syndrome (44%), which limits generalizability to other types of disabilities that can be more severe or require less caregiving.

This study used nonprobability convenience sampling to recruit the parents of children with disabilities. This type of sampling has the potential to limit generalizability and therefore lacks external validity. It is worth noting that the study was conducted in Jeddah City, Saudi Arabia, and the majority of the participants reside in the western region of the country; we did not examine chronic sorrow in more rural areas of Saudi Arabia or other Middle Eastern countries that share multiple cultural aspects, which limits the generalizability of the study findings.

Another limitation was the study's cross-sectional design. Cross-sectional study designs create ambiguity about the direction of the causal relationship between study variables. Lastly, to overcome time and financial constraints that the researchers were faced with, data were self-reported via a web-based questionnaire. Therefore, the conditions in which parents filled out the survey were not controlled nor objectively measured.

Conclusion and Recommendation

The aim of this study was to examine the experience of parents of children with disabilities with chronic sorrow in Saudi Arabia using the theory of chronic sorrow. We found moderately high levels of loss experience, disparity, and feelings of chronic sorrow among study participants. Therefore, the results of this study highlight the importance of chronic sorrow management and the creation of interventions to enhance parental mental health and well-being. In addition, internal management of chronic sorrow played a crucial role. In particular, we demonstrated the importance of the concept of fatalism and religious and spiritual beliefs among Arab Muslim parents of children with disabilities. With regard to external management, parents reported that family and community support were pivotal for the management of chronic sorrow, highlighting the social responsibility of all members of the community to provide support to both parents and children. This study also identified a strong and positive relationship between the concepts of the theory of chronic sorrow, specifically between the identified triggers of loss and disparity and chronic sorrow. Lastly, the study results found no relationship between feelings of chronic sorrow and time elapsed since the parents received their child's diagnosis. Given the results of this study, parents of children with disabilities need to be periodically screened for chronic sorrow as these feelings and coping strategies need to be addressed. Parental acceptance of their child's disability does not signify the absence of chronic sorrow, as it is part of the normal grieving process, but rather the anticipation of the triggers of chronic sorrow. The use of management methods, both internal and external, is essential for promoting parental mental health and child health outcomes.

This study has the potential to provide the foundation for future studies navigating and investigating chronic sorrow among parents with a children with a disability. Future studies could include an investigation of chronic sorrow based on the severity of the disability among parents caring for adult children with a disability and could be expanded to extended family members and caregivers.

Abstract

Background: Evolving societal trends are resulting in fathers having an increasing influence on the health-related behaviors that children develop. Research shows that most fathers are committed to their role and when equipped with knowledge, can have a positive impact on their child's health. However, parenting resources typically target mothers, with fathers being excluded. While evolving mobile phone technology provides an efficient means for delivering parenting resources, many fathers find that mobile health (mHealth) technology does not provide material they can engage with.

Objective: This study aimed to explore how to make parenting apps more engaging and useful for fathers using an existing parenting mHealth resource, the My Baby Now app, as a case study.

Methods: A total of 14 purposefully selected, Australian fathers of 7 months to 5-year-old children took part in a qualitative study, comprising either focus groups or interviews. Recorded focus groups and interviews were transcribed verbatim, then coded using a combination of deductive and inductive methods. Reflexive thematic analysis was undertaken to identify patterns and themes.

Results: Current parenting apps provide parenting information that can be unappealing for fathers. To improve paternal engagement with mHealth resources, fathers highlighted the need for father specific information, with an increase in positive imagery and positive descriptions of fathers in their parenting role. There should be father-exclusive domains such as forums, and also push notifications to provide positive reinforcement and encouragement for fathers.

Conclusions: mHealth has the capacity to deliver information to fathers when needed. This reduces the risk of paternal frustration and disengagement from parenting. Further benefit will be gained by research to understand possible differences in mHealth app usage by fathers of differing socioeconomic position, cultural backgrounds, and family status, such as single fathers and same-sex couples.

Introduction

Parents have a central role in shaping children's long-term health behavior by the behaviors they promote and role model [1-5]. Changing societal trends of increasing rates of maternal participation in the workforce have resulted in child rearing activities in the home environment becoming increasingly shared with fathers [6,7]. Fathers are, thereby having an increasing

XSL•FO
RenderX

influence on the health-related behaviors that children develop [8]. Emerging research shows that when fathers are equipped with skills and knowledge, they can have a positive influence on the dietary and physical activity behaviors of their children [9,10]. However, many fathers lack knowledge and confidence about how to do engage with their children [10]. Multiple barriers that exist to gain skills and knowledge, including a lack of father-focused support, resources, and services are exacerbating this problem for fathers [3,11,12], lack of trained staff specifically to work with fathers [13], differing cultural beliefs toward fathers' roles [8], and a lack of father-specific, best practice guidelines [9,14]. In addition, paternal involvement in traditional parenting education programs has been low owing to fathers' full-time employment and not being available for parenting programs during traditional office hours [15], perceived attitudes of stoicism and self-reliance in fathers [16], and programs failing to engage fathers [17,18].

The proliferation of mobile phone usage may present an avenue to conveniently deliver relevant parenting resources and information to fathers [13]. Mobile phone ownership is pervasive in high income countries at over 90% [19] and increasing rapidly in low- and middle-income nations [20-22]. Through their personal mobile devices, parents now have at their disposal, a multitude of resources and information that can be accessed, including websites, social media and apps [23]. International trends for mobile devices being used to seek parenting information are increasingly becoming apparent, where for instance, recent Canadian research shows that 81% of parents rated their smart phone as a more important parenting resource than books (56%) [24].

International parenting research has shown positive results in providing perinatal health information to mothers through their mobile phone, whereby mothers found that they learned information in the perinatal period they otherwise would not have known without the use of texts to their personal phone [25]. Also, recent evidence in Australia and Africa has demonstrated increases in both maternal and paternal knowledge and confidence to breastfeed through the provision of a parenting app during the perinatal period [26,27]. Despite the convenience of parenting apps however, fathers have invariably experienced frustration in their use as a parenting resource, with information being predominantly mother-centric, and some even trivializing the roles of the fathers [28]. However, of the limited evidence of apps specifically targeting and providing information for fathers, positive experiences have been noted by fathers of being provided with convenient and nonjudgemental support [29,30]. Similarly, the Australian Milk Man app used such strategies as push notifications and social connectivity with other fathers to engage fathers with breastfeeding information [31]. This provided the impetus for increased conversations with partners about the benefits and facilitation of breastfeeding.

At present, despite research indicating that mobile health (mHealth) resources and apps are an effective tool for parents, there is a paucity of evidence examining the acceptability, usefulness, and effectiveness of such resources for fathers [32]. Evaluations of the limited number of apps for fathers (ie, Milk Man and mDad) have provided some evidence of the benefits of using these resources for support and guidance of fathers in limited areas of parenting, such as breastfeeding. However, there is a need to consult directly with fathers to gain greater understanding of their specific needs and preferences for mHealth resources promoting positive dietary and physical activity behaviors in young children. This will inform understanding of how mHealth parenting resources can be made more engaging for fathers to use. To our knowledge, no app exists exclusively for fathers to promote positive dietary and active play/physical activity behaviors in children aged 5 years or younger. Therefore, the aim of this study is to explore how to make parenting apps more engaging and useful for fathers using an existing app (My Baby Now) as a case study.

Methods

Study Context- Use of the My Baby Now App

This study used the My Baby Now (MBN) app as an example of an existing parenting app for fathers to provide feedback on. This app was chosen as it is currently being made available to parents as part of the roll out of the established Infant Feeding and Active Play and Nutrition (INFANT) program, which is a broader evidence-based group program that focuses on providing anticipatory guidance on feeding and play from birth to 18 months of age across Victoria, Australia [33]. The MBN app provides evidence-based information and support on infant feeding and active play from pregnancy to 18 months of age, in line with Australian Infant Feeding Guidelines and 24-hour Movement Guidelines for Early Years [34,35]. Presented as a parenting app with family imagery and language throughout, the MBN app has a strong focus on developing parenting confidence and skills. The app includes topics on feeding (breast, formula, mixed feeding and introduction to solids, and recipes) sleep and feed patterns, play, parental well-being, and dental care. Users receive 3 push notifications per week tailored to their child's stage of development and feeding mode (breast, formula, or mixed feeding). A facilitated forum to share experiences with other users is provided along with activities such as goal setting and quizzes to provide tailored feedback in areas such as feeding practices [26]. The app is informed by extensive formative research with mothers [36] and practitioners [37] and a feasibility study of an earlier version of the app, "Growing healthy" [38]. The app has been found to be acceptable and useful to mothers; however, it is less well used by fathers with the vast majority of participants being mothers [26].

Study Design

This study used qualitative inquiry in focus groups and one-on-one interviews to gain an understanding of fathers' views and experiences in using mHealth resources and to obtain fathers feedback on the MBN app. The overall methodology of this study was guided by a pragmatic research paradigm, which provides the flexibility to apply research methods best suited to answering a research problem [39]. In our study, qualitative enquiry [40] with thematic analysis [41], was deemed most suitable. In allowing for different worldviews of researchers and participants to be represented [42], the authors recognize that the data will be socially constructed.

XSL•FO
RenderX

Recruitment

All participants in this study were recruited from a larger, nationwide Australian study [9], that surveyed fathers about their perceived role, self-efficacy and support needs in promoting positive dietary and physical activity behaviors in early childhood. The survey was open to fathers or expectant fathers (aged 18 years or older) with children aged 5 years or younger residing in Australia, with sufficient fluency in English to complete the survey. At the completion of the survey, participants were asked if they would be interested in participating in further research. Email invitations were sent to those who had expressed interest in further research to invite them to participate in the focus groups and interviews. If participants did not respond to the initial email, 2 further reminder emails, at 1-week interval were sent. Once the participants replied to the original or a reminder email, confirmatory emails were sent with details of the zoom meeting and instructions on how to download the MBN app.

Depending on their availability or preference, participants were offered the choice of being in a focus group or having a one-on-one interview. Focus groups and interviews occurred 1-2 weeks after the confirmatory email was sent.

Data Collection

As part of the larger survey study [9], sociodemographic characteristics of participants were collected including, fathers' age, level of education, employment status, marital status, location, country of birth, languages spoken at home, number of children and children's age. Informed by the end user version of the mobile rating scale (uMars), which provides a reliable method to assess the quality of mHealth apps [43], a broad, semistructured focus groups and interview guide was used for this study (Multimedia Appendix 1). The guide was developed to explore fathers' perceptions of the appeal and usefulness of the solids, feeding, and play sections of the MBN app. After using the MBN app in the 1-2 weeks before the focus groups and interview, fathers provided feedback on their experiences seeking information in MBN, the functionality and aesthetics of MBN, their engagement with MBN, and their opinions of the information within the MBN app. The guide was reviewed by 2 researchers (MG and RL), and minor amendments were subsequently made to the wording of some questions to avoid using leading questions and to improve clarity.

In the confirmation email which participants received before their focus group, they were asked to download the MBN app to their phone before the meeting and were encouraged to explore the features of the app. Participants were advised that during their focus groups and interview, the solids and play sections of the app would be discussed in detail. All clients reported that they were able to download the app before their focus groups and interview as directed. During the focus groups and interviewss, participants used Menti (poll maker) to vote on the usefulness of a sample of 5 MBN app push notifications by selecting one of 5 options, very helpful, helpful, neutral, unhelpful, and very unhelpful. The Menti app enables multiple users to share knowledge and real-time feedback in meetings [44]. Participants voting provided impetus for further discussion on their subjective opinions on the positive or negative aspects of the notification and how it may be improved. The format for rating the push notifications was the same for both focus groups and interviews.

The lead author (MG) conducted the focus groups and interviews between April and May 2023, and these were recorded with the permission of the participants and transcribed verbatim. Each focus group had a primary facilitator, and an observer (KG), who completed reflexive notes.

Data Analysis

All focus groups and interviews were transcribed by an online platform (zoom) and then manually checked for accuracy by the interviewer. To minimize participatory burden on fathers, transcripts were not returned to participants for review. The interviewer (MG) and observer (KG) took notes throughout the interview and these notes were reviewed with the interview transcripts.

Reflexive thematic analysis was used to identify patterns and themes. Phases of analysis were based on Braun and Clarke's [41] 6-step method and were conducted by the first author. Initially, the data were coded deductively using uMars as a framework, and then inductive coding was used for data that did not align with uMars domains [45]. After initial coding by the first author, the coding framework was discussed with the research team with a sample of 2 transcripts, resulting in minor refinements. NVivo 11 (Lumivero) was used for coding and retrieval of data [46].

Researcher Reflexivity and Credibility

Qualitative research relies on nuanced judgements that require researcher reflexivity, to account for how subjectivity shapes their inquiry [47]. MG is a PhD candidate and a registered psychologist and is also a father of a young child and is motivated in role modelling positive health behaviors. However, MG has very little experience with using either general parental, or father specific parenting apps. MG did not have any involvement in the development of MBN app or any similar app, and this was made clear to the participants at the beginning of the focus groups and interviews. MG was conscious that some fathers will not share his knowledge and attitude toward the development of healthy behaviors and was careful not to judge participants in interviews [48].

Ethical Considerations

This study was approved by the Deakin University Human Research Ethics Committee (HEAG-H 30_2022). All participants were provided with an Aus $25 (US $15.6) supermarket or home hardware shopping voucher for their time. Written informed consent was obtained from all fathers before participation.

Results

Participants

Of the 200 surveys completed in the larger study, 58 participants expressed an interest in participating in this study and were invited to take part in the focus groups and interviews. Of these, 18 indicated interest in either the initial, or one of 2 reminders

XSL•FO
RenderX

to participate. After organizing time slots for focus groups and interviews, 4 of the participants cancelled their scheduled participation and did not reschedule an alternate time and were omitted from the study. A total of 5 participants chose to have an interview and 9 took part in one of 3 focus groups, which ranged from 2-5 participants. Interviews took an average of 51 (range 39-64) minutes, while focus groups lasted for an average of 58 (range 51-73) minutes.

The 14 participating fathers were on average around 40 years of age, had 1 or more children aged 5 years or younger with an average age of 2.4 years (Table 1). The majority of the fathers identified as Australian born (12/14) and all spoke English at home and were married. The majority of fathers were university educated (10/14) and were employed full-time (12/14). Participants in this study were broadly similar of survey participants; however, in contrast to participants in the survey who were 61.5% metropolitan based, the majority of fathers in the qualitative study (64.3%) were region or rural based (9/14).

Five key themes (and 19 codes) from the focus groups/ interviews relate to the previous parenting information seeking of the fathers, the functionality of the MBN app, fathers' engagement with the MBN app, the aesthetics of the MBN app, and fathers' perceptions of the information in the MBN app (Table 2).

Table 1. Characteristics of fathers participating in focus groups and interviews.

Characteristics	Fathers and children (N=14)
Father's age (years) mean (SD), range	40.2 (5.4), 51.1-31.5
Child's age (years) mean (SD), range	2.4 (1.9), 0.7-5.8
Father status	
1 or more children aged 5 years or younger	14 (100)
Age of children	
Infant (birth to 1 year)	5 (35.7)
Toddler (2-3 years)	4 (28.5)
Preschool (4-5 years)	5 (35.7)
Level of education	
High school	1 (7.1)
Trade certificate/ TAFE[a]	3 (21.4)
University	10 (71.4)
Employment

Table 2. My Baby Now (MBN) app focus groups/ interview themes, codes, and illustrative quotes.

Themes and codes	Example quotes
Previous information seeking	
Traditional	• We've got a local library, so we try and go there for information about development and stuff. (F1) • They [parenting groups] tend to fall back into that stereotype that moms are the primary carers. (F6)
App technology	• I do have an app that at a certain time every day is going to send me a message and you get used to it. (F10) • I've used one [an app], it did tell you what stage your baby's at, like okay, you're at week five, so you may notice this behaviour. (F2)
Social media	• They're absolutely great, there's a dad's one on Facebook. I like to know what other dads find challenging or have questions about. (F9) • There's a Facebook page - Advice for Dads. It became pointless, as every experience was different and just not that relevant to me. (F3)
Websites/YouTube	• It can be stressful, just going onto a parenting website and you get bombarded with pop-up windows and ads. (F1) • I want it to be accessible, so if I was cooking, you don't have to go into the app, you can just access it immediately on youTube (F14)
Functionality of the MBN app	
Ease of navigation	• That's good to be able to jump around, because you'll read something and then you'll get further down, and the reference is further away (MBN app). (F7) • I understand when you're in, it went to 3 to 4 months, it just takes you to that section within a really long sheet. I started scrolling around and then I realized I wasn't looking at 3 to 4 months (MBN app). (F10)
Useful tools	• So it's good that it tells you foolproof. It tells you how to safely set it up [play equipment] and what you'll need. I think those kinds of things are fantastic. (F14) • You look at it (MBN quiz), and go, bang, bang. You go tick, tick and then it's done…and you get the follow-up information straight away. (F12)
Fathers engagement with the MBN app	
Tools to bond	• I went to the video library, had a look at the video for chicken Bolognese. Easy to follow, the video was perfect. I was like, oh, that's easy. It's their favourite. (F6) • Having lots of different activities [in MBN] is fantastic, to be able to come up with new games and experiment with them and play with them (children) to help them create their own. (F4)
Customization videos	• Having some presented by a male would be advantageous. You're not feeling like you're being lectured to by mums. (F11) • In the recipe sections, the videos, it's all veggies and fruit. You could chuck meat on there because for dads, it's going to resonate with him. (F2)
Dads' sanctuary	• To engage a dad, you need other dads already there, so they feel more comfortable, and this is actually a space for dads. (F6) • Moms are always really keen if they think you're this bumbling idiot dad, and they can give you all the answers, but as soon as you have an opinion, the moms don't want you in their forum anymore. (F12)
Interactivity (push notifications)	• That American one (different app to MBN), you can imagine it was over the top, trying to pump you up. But it was good to get those kind of positive messages (reassuring/motivational messages for dads). (F4) • Age-based, just some prompts using the age, whether it was those age bands that you had earlier each month in the first 12 months and then probably less frequent after that depending how far out it goes. (F11)
Aesthetics of the MBN app	
Layout (clutter)	• Subheadings or something just to, because there's a lot there, it's quite comprehensive, but just to make it more intuitive to navigate. (F3) • if you've got a few minutes to have a look at this, but then you've got to go away for something, just to be able to go back to where you were and go on with what you were doing would be great. (F7)
Graphics	• The information's there plus the visual video too. So, there's a structured approach, that's tailored to how you learn, so you can go bang. (F9) • I like the pictures and stuff. That's how I've always picked up stuff [retained information]. (F2)

XSL•FO
RenderX

Themes and codes	Example quotes
Visual appeal	• I know it's probably going to be very hard, but so when you do look through a lot of pictures, there aren't really any men in any of the photo's. (F1) • I mean, that bottom photo with the pregnancy where the mom's in the pool laying on her back. I mean, she could be being held by her husband in the pool. Why not? (F13)
Fathers perceptions of information in the MBN app	
Specificity	• It breaks the recipe up and says, at this point you take the baby's portion out and then you'll add, spices chili or whatever else, which is quite handy when you are cooking for your family. (F9) • Quite a variety of topics [active play], I like that. Some apps, it just gives you a tiny bit of information and topics, but here [MBN], it puts it down for the different ages, what they should be doing. (F7)
Comprehensiveness	• We've had issues, if a bloke takes a child into a parent's room, there's a "what are you doing in here" attitude". You feel rejected. it'd be good to have advice there, how dads can manage that sort of thing. (F12) • Just prioritizing the topics based on the app. I think, although genders is one thing and roles. So, it could be, it's not just dad, mom, it's also - are you the primary care or secondary or what's your role? (F2)
Availability of info - breast-feeding	• The breastfeeding thing, even if it's not as relevant for dads. It would be great if there was a section that's like how to support your partner during breastfeeding. (F2) • Because in the early stages it's hard. The baby's not latching and you're just standing there useless as a dad. (F3)
Credibility of source	• Yeah, she obviously knows what she's on about [cooking video], but I can follow it ok. She's explaining it ok. (F3) • But, it's like, is this all kosher? Is it what the professionals recommend [play activities]. (F10)

Theme 1: Previous Information Seeking

This theme included the experiences of fathers so far in searching for information in their fatherhood journey. Although all fathers were proficient using modern technology, such as smart phones, most of the fathers also made use of traditional methods, such as hard copy books when searching for information. It was apparent that most fathers did not necessarily have a preferred source of information, they did however, want information to be credible. Many fathers had also involved themselves in parenting groups but highlighted negative experiences in these groups where invariably they felt they did not belong (subtheme 1.1). The majority of fathers had made use of apps on their smart devices and had found the experiences, such as getting age specific information through reminder texts, to be positive (subtheme 1.2). The majority of fathers used social media in some form for information seeking and many highlighted the reassurance they felt in learning of the experiences of other fathers. However, other fathers reported frustration in navigating the quantity and range in quality of information on social media (subtheme 1.3). Similarly, many fathers found the convenience and accessibility of the internet in seeking information on the internet to be positive, however they could feel overwhelmed by the amount and variable credibility of information they must process (subtheme 1.4). Across all sources of traditional or modern sources of information, fathers highlighted frustration that it was targeted more to mothers than fathers.

Theme 2: Functionality of the My Baby Now App

In this theme, fathers' spoke about what was important to them in regard to how the MBN app should function. Most fathers made comments about the importance of being able to navigate around the MBN app easily. However, some fathers highlighted some frustration with needing to scroll or swipe excessively, which resulted in them losing their place (subtheme 2.1). When able to locate and engage with the sections of the MBN app as desired, fathers spoke positively about the reassurance they felt from the information provided (subtheme 2.2).

Theme 3: Engagement With the My Baby Now App

In this theme, fathers spoke about the reasons why they may engage with the MBN app. Many fathers spoke positively about the combination of written and video information available, which provided ideas and strategies about how to engage with their children in areas such as pleasurable games and providing enjoyable food (subtheme 3.1). A consistent theme from fathers was for them to engage with the MBN app, it needs male imagery that could also include males presenting information in videos (subtheme 3.2). Fathers also highlighted the need for information in areas (such as male-only forums) where they could get information and exchange viewpoints without the threat of feeling out of place (subtheme 3.3). Fathers spoke positively about getting push notifications delivered to their smart devices, including specific health-related information about their child and simple messages of encouragement. However, the majority of fathers highlighted that daily push notifications would be too excessive, with some fathers preferring weekly or monthly notifications as the child ages (subtheme 3.4).

Theme 4: Aesthetics of the My Baby Now App

This theme provided fathers the opportunity to highlight how the presentation of the MBN app would affect their attraction and potential use of the app. Some fathers found that information in the MBN app can appear cluttered due to the amount of information and the lack of defined sections, such as information presented by age or stages of development. A number of fathers

XSL•FO
RenderX

stated that this could be remedied by the use of more subheadings (subtheme 4.1). In receiving information, fathers found the use of graphics and videos to explain information could facilitate a positive learning experience (subtheme 4.2). However, most fathers had negative perceptions about the distinct lack of visual images of fathers and lack of pictures that fathers would be interested in, such as more meat-based meals (subtheme 4.3).

Theme 5: Perceptions of the Information in the My Baby Now App

When discussing the type of information that they would like to see, fathers consistently made comments that they were appreciative of specific, relevant information that provided them with clear steps to follow, such as age-appropriate play activities and recipes (subtheme 5.1). However, many fathers also highlighted the need to have information in different areas of fatherhood that they were unfamiliar with, such as tips on the social etiquette of using baby change rooms and tips on food storage (subtheme 5.2). The majority of fathers highlighted that helping with the demands of breastfeeding was a constant source of stress and some thought a specific section for fathers and breastfeeding would be advantageous (subtheme 5.3). Fathers highlighted the need for factual information, with some fathers stating that they did not mind if a male or female presented information in videos, just as long as it was factual (subtheme 5.4).

Discussion

Principal Findings

This study adds to a limited pool of research that uses qualitative enquiry to gain fathers perspectives on how parenting apps can be improved to be more engaging for fathers [24]. From conducting focus groups and interviews with fathers, 5 themes emerged; previous parenting information seeking, functionality of the MBN app, fathers' engagement with the MBN app, the aesthetics of the MBN app, and fathers' perceptions of the information in the MBN app. The information gained from fathers about mHealth technology is important, as traditional and typical contemporary domains for fathers to find information on parenting, such as social media and parenting websites have typically targeted mothers, with few father-specific resources [49]. Indeed, some parenting apps to date have portrayed a dismissive attitude to fathers' roles and experiences and what they can contribute as a parent to children in early stages of development [28,50].

Findings from our study revealed that fathers have previously used a variety of traditional and contemporary sources of information, including books, social media, parenting groups, apps, with parenting websites and parenting material on YouTube (Google) being the most prevalent. This is in line with previous Australian research, which also found the web-based activities was the main resource fathers used to find information on their child's health, for reasons of convenience and speed, and this was particularly so in fathers of a higher socioeconomic position (SEP) [51]. Our sample consisted mostly of higher SEP fathers (by education) with over 70% of fathers being university-educated, and the preferences for internet usage highlighted by fathers is in line with a "digital divide" noted by Laws et al [51], whereby higher educated fathers are more likely to use parenting website activities for seeking information on children's health. Understanding differences in mHealth app usage by fathers seeking children's health information, delineated by SEP, remains unclear and will benefit from further research.

Despite being the prominent choice, seeking information through parenting websites and YouTube was widely reported to be a frustrating endeavor for fathers in our study, whereby many highlighted they could not locate what they desired due to being overwhelmed by excessive information of questionable quality. This led to some fathers having a negative perception of internet-based parenting information and resources and avoiding its use [52]. Similar findings were reported in the Australian qualitative study of Walsh et al [10], whereby fathers highlighted a desire to be better informed about their young children's diet and physical activity needs, but felt there was a lack of useable and credible information to guide them. Of fathers who had previously used apps in our study, not only was the convenience of the app in providing prompt information important, but also the value of an app in providing useful and credible information in the one area.

Many fathers in our study highlighted their negative perception of parenting information or imagery encountered previously, and also in the MBN app, that included only maternal content. Such perceptions are important considerations for the engagement of fathers, as it has been found that representations and languages that embed social norms of fathers not being involved in parenting duties, have led to paternal disengagement from parenting programs [53]. For fathers to be motivated to participate in parenting research and programs, research has highlighted the need for stratification, with fathers specifically named and targeted to garner paternal interest [54]. This need was present in the recommendations from fathers to improve the MBN, whereby it was unanimously highlighted that the MBN app needs greater father-specific information and imagery to appeal to and engage with fathers.

Further to the requests for greater father imagery and content, fathers also widely requested for there to be father-only forums. Evidence suggests that fathers engage with other fathers in a different style than mothers do, with more humor and less formality in their social media and chatroom interactions [55]. Their preference for male-only domains in apps may provide them with an opportunity to discuss sensitive matters while maintaining a perception of control through the use of humor while on an equal footing to other fathers [56]. Canadian research into engaging young fathers in parenting programs reveals that they will be more likely to engage if programs initially involve informal meetings in places of comfort with their male peers, such as sports fields [23]. This allows fathers to seek help in an environment of perceived security without looking "weak," as experienced in more formal settings such as traditional health care [55]. It was interesting to note in our focus groups and interviews, how positively and openly fathers engaged with each other, with regular humor evident, in discussing sensitive developmental issues without previous

XSL•FO
RenderX

contact with each other. Another potential benefit of men-only forums is that fathers who have had knowledge and previous experience with other children may be able to pass this knowledge onto younger or less experienced fathers who benefit from guidance [57].

Well-designed tools available through smart technology have the potential to provide fathers with the information they want [15,58], and fathers in our study were mostly able to navigate through app technology when seeking information. Similar to previous research [23,28], the fathers in our study reported that when they were able to find information, they could understand on the MBN app, and improved confidence and enjoyment was noted in their engagement with their child. Receiving notifications through smart phone technology has proven to be beneficial for mothers as well as fathers in gaining information [59,60], and fathers in our study were mostly positive about receiving push notifications from the MBN app, particularly in areas of low knowledge, such as breastfeeding. Push notifications, therefore present as a valuable strategy to deliver desired breastfeeding information to fathers wanting to be supportive, which is vital for mothers to facilitate the demands of breastfeeding [61]. Similar to Australian research into the effects of supportive text messages on new fathers' mental health [15], many of the fathers in our study expressed a belief that messages of support would be beneficial in managing parental pressures and lowering isolation. The pressures of raising young children are a stressful time where new demands are being put on parents [62], and many fathers in our study highlighted the significant impact of feeling useless and isolated had on their mood. In demanding times, if reassurance and guidance are not provided by others, mHealth technology presents as a valuable resource for fathers to use in their parenting journey.

While this paper highlighted the potential benefits of providing fathers with credible, evidence-based mHealth resources, it did not have the scope to explore the feasibility of developing and maintaining a usable app for fathers to use in their everyday lives. Recent American evidence suggests that it can take over 6 months and costs approximately US $ 270,000 for the development of an app, with ongoing maintenance costs an additional expense [63]. It was noteworthy in this study, that rather than advocating the need for father only apps, many fathers instead highlighted their desire to see father specific sections in current parenting apps. By having father specific sections in current parenting apps, the desired resources that fathers have raised in this study, such as positive male imagery, father only forums, and tailored push notifications, could be provided without the financial burden that a stand-alone app would encumber.

Strengths and Limitations

This study has a number of strengths and limitations. A key strength was the qualitative design, which allowed fathers' perspectives to be explored in more detail through focus groups and interviews, thereby providing a deeper understanding of fathers' experiences and viewpoints. The results of this paper provide qualitative evidence from fathers about what is needed in an mHealth resource for them to engage with it and find informative and useful. This is important for the promotion of coparenting, as more traditional methods of providing education to fathers, such as parenting classes, have not been an effective way to provide support fathers in paid employment [15]. Coparenting research has advocated the need for modern technology such as mHealth, to reach parents during the demanding postpartum period to promote greater coparticipation in the promotion of positive health behaviors [62]. Such co-operative parenting behaviors have in turn been shown to lead to such benefits as improving the child's obesity status [4] and the social-emotional well-being of the child [64,65].

In line with noted recruitment difficulties in existing paternal research [17,29,54], the recruitment of a desired number and varied sample of participants proved difficult for this study. In addition, the sample was limited by fathers being mostly higher educated, predominantly Australian-born, who by their interest in this study, were likely to be health conscious and committed fathers. While this may have contributed to social desirability bias in their responses, the fathers in our study were open and forthcoming with divulging their challenges and offered valuable insight and recommendations for improvement of the MBN app. Future research will benefit from the inclusion of a varied sample of participants, including fathers of low SEP and the inclusion of fathers of differing family status, such as single fathers and same sex couples. In addition, as this paper was predominantly made up of a culturally homogenous sample of participants, caution will need to be exercised in extrapolating the results internationally, as approaches and beliefs about fathering varies considerably across cultures [8].

Finally, many fathers were able to make themselves available only at select times, which precluded them from taking part in focus groups with other fathers, and instead took part in a one-on-one interview with a researcher. This denied some fathers the opportunity to engage with other fathers in a positive group setting and may have limited their opportunity to develop their views and opinions through group dynamic. The researchers do not believe that the quality of the information elicited in interviews lacked any of the richness of focus groups.

This qualitative study has provided unique insights from fathers in focus groups and interviews about how an mHealth parenting resource, in the form of app technology, can be improved to enhance the engagement of fathers in early childhood. While current parenting apps, such as MBN, have proved advantageous in delivering factual information to fathers expediently, the information can fail to appeal to the specific needs and wants of fathers. Fathers committed to the promotion of positive health behaviors to their children risk becoming frustrated and potentially disengaged if father-specific material is not provided. Through the promotion of father specific information, use of positive imagery and descriptives of fathers in their role, promoting father exclusive domains such as forums, and using positive reinforcements such as push notifications to support and give guidance to fathers in an area of uncertainty for them, app technology can be a valuable resource for fathers in their parenting journey.

Acknowledgments

The authors would like to thank all the fathers who contributed to this study. MG is supported by a Deakin University PhD scholarship, DUPR-GRANTS (PVC RSP; 0000018832). KDH is supported by a Heart Foundation Future Leader Fellowship (105929).

Data Availability

The datasets used and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors made a substantial contribution to this project and the manuscript. MG and KG conducted data collection. MG contributed to the analytical approach, results interpretation and had primary responsibility for manuscript writing. RL was the principal investigator and together with KW and KH contributed to the study design, analytical approach, and interpretation of results. All authors contributed to drafts and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Throughout years of research, the well-known behavioral parent training program, Parent-Child Interaction Therapy (PCIT), has been adapted and enhanced to tailor the treatment to the needs of families in community-based clinical care. This study wished to evaluate an add-on to PCIT that could be engaging for parents. As a way to enlarge practice opportunity and potentially allow parents to achieve positive treatment effects sooner, this study added virtual reality (VR) to PCIT.

Objective: This study aimed to increase positive parenting skills at a faster pace with the use of PCIT-VR, on the basis that practicing positive parenting skills in the VR tool would increase parents' overall practice time, thus leading to more confidence in their skills, which could consequently increase the pace of skill acquisition. Furthermore, we hypothesized that due to the overall increase in positive parenting skills, PCIT treatment effects such as diminishment of child disruptive behavior and parenting stress would decrease at a faster pace when VR was introduced.

Methods: Families were recruited from a specialized child and adolescent psychiatry clinical practice in the Netherlands. Using a single-case experimental design, 11 families, equating to 18 participants, signed informed consent forms and received the staggered introduction of VR to treatment. As is common with a single-case experimental design, visual inspection analyses and randomization tests were conducted. Group differences were evaluated with nonparametric tests and reliable change indices.

Results: Overall, our study reaffirmed that PCIT is an effective intervention for this population as there were positive treatment effects found in almost all cases. Nevertheless, there did not seem to be a clear relationship between the use of the VR tool and PCIT treatment effects, although positive parenting skills seemed to increase when VR was introduced to treatment for some parents. For all parents, questions and comments decreased with the introduction of VR. These findings tentatively suggest that practicing with VR could potentially increase positive parenting skills and also have an impact on other treatment-related outcomes, such as child disruptive behavior and parenting stress.

Conclusions: This was the first time that PCIT has been supplemented with VR. We provide preliminary evidence of its added value. We cautiously suggest that VR could provide added value to PCIT and increase confidence in parenting skills for certain parents, although there are complex factors that play into treatment success that must simultaneously be considered. These factors

XSL•FO
RenderX

include parents having the motivation and mental capacity to change and the complex psychological problems some families face. Although promising, we believe that due to the novelty of our VR practice tool and the variety of results from our study, more research is necessary into PCIT-VR to draw further conclusions on its effects.

Introduction

Background

Behavioral parent training (BPT) programs are an effective way to treat child disruptive behavior [1,2]. It is important to intervene at a young age for children exhibiting disruptive behavior to limit adverse outcomes later in life. Child disruptive behavior can lead to higher risks of aggressive behavior, criminality, internalizing problems, and other mental health–related problems later on [3]. Moreover, if persistent, long-term problems can arise in child development, family functioning, and other broader social factors, such as in parent-child relationships or educational delays [3,4]. We know that parents are the most important people in children's early lives [5-7], which indicates the importance of including parents in treatment. Parents should function as sensitive, responsive support figures for children. Furthermore, we know that child disruptive behavior can greatly increase parenting stress and strain the parent-child relationship [8]. Hence, BPT programs aim to diminish child disruptive behavior and parenting stress by focusing on the parent-child relationship with positive parenting skills [9].

With more than 40 years of evidence, Parent-Child Interaction Therapy (PCIT) is considered an effective BPT program for young children between the ages of 2 and 7 years and their parents, and has been widely disseminated [10]. PCIT aims to diminish child disruptive behavior and parenting stress, increase parents' positive parenting skills, and better the quality of the parent-child relationship [1,11]. Overall, PCIT is known to impactfully improve parental responsiveness and warmth [12]. PCIT includes 2 phases, the first phase is the child-directed interaction (CDI) phase and the second phase is the parent-directed interaction (PDI) phase. In the CDI phase, parents are taught to use positive parenting skills that affirm their child's behavior, which helps to build up the quality of the parent-child relationship. This phase lays the foundation for effective behavior change. In the PDI phase, parents are taught to set safe, consistent, and effective boundaries for their child's behavior. In this phase, the positive parenting skills that were previously taught still play an important role, allowing the parent-child relationship to continue improving over the course of the treatment [12]. To allow families to go at their own pace, PCIT has a nontime limited character, which means that treatment is completed only when certain parenting skills are met and parents feel confident in being able to manage behavior at home without the support of therapists [11].

Throughout the years, PCIT has been adapted and enhanced to tailor the treatment to the needs of families in community-based clinical care, though, for example, shortened versions of treatment or by adding incentives [13-18]. These studies demonstrated decreases in child disruptive behavior, a reduction in reports of child maltreatment posttreatment, and more positive parenting outcomes within community-based clinical samples. Notwithstanding, these studies commonly experienced high dropout rates that suggested only around 50% of families completed treatment [18]. When specifically looking at the difference between treatment completers and treatment dropouts, several factors were found that potentially predicted the dropout. These factors associated with the dropout were a lower education level, especially in combination with a female child gender, one-parent households, and internalizing problems for the mother [19,20]. Furthermore, a 3-year follow-up study showed that treatment completers reported substantially less child disruptive behavior and parenting stress than treatment dropouts [21]. It was also found that positive parenting skills increased more and negative parenting skills decreased more between pre and posttreatment when treatment was completed [19]. In addition, a crucial aspect of improving the parent-child relationship is parents using positive parenting skills [9] and skill practice was shown to be a good predictor for treatment outcomes [22]. Taken together, these studies infer that treatment should focus on increasing practice time for parents' skill use. This could in turn lead to better treatment outcomes, such as decreasing parenting stress and thereby dropout rates. With this in mind, this study strived to adapt PCIT in an attempt to increase skill practice at home. In other words, we attempted to tailor PCIT to the needs of this community-based clinical sample treatment receivers through creating an additional practice opportunity.

Adaptations to PCIT have previously been made with the common assumption that the treatment as is, did not fully extend to the needs of a target population, such as for clinical samples [23]. In addition, as there is a high attrition rate in community-based clinical samples, it is important to enlarge engagement opportunities for this target population and engage them in treatment right from the start. We know that positive treatment effects in PCIT can already be found if at least 4 treatment sessions are attended by families [17]. Accordingly, it could be helpful to prolong the effects of these sessions through, for example, a technological tool. In more recent years, digital adaptations, such as online PCIT and Pocket PCIT (ie, a web-based PCIT resource platform) have increasingly been used to better reach parents [12,24,25]. Pocket PCIT is a passive PCIT augmentation that provides an online and on-demand resource to families to practice CDI skills [24]. The first findings of Pocket PCIT indicated that the CDI phase was completed in fewer sessions when families had access to Pocket PCIT, although they did not complete the entire treatment in fewer sessions [12]. Moreover, parents were open to completing

XSL•FO
RenderX

additional homework in the form of Pocket PCIT, provided that the content was engaging, which indicates a high satisfaction rate with such a digital add-on [25]. Nonetheless, treatment-related outcomes such as child disruptive behavior and parenting stress did not differ significantly from standard PCIT, suggesting that there are only partial benefits gained from this on-demand resource [25]. This study wished to similarly create an add-on to PCIT that could be engaging for parents, but we decided to augment PCIT in a different way. As a way to enlarge treatment engagement through practice opportunity and potentially allow parents to achieve positive treatment effects sooner, this study sought to add virtual reality (VR) to PCIT [26]. VR can provide a sense of realness through immersion, which watching a video cannot. Therefore, practicing in VR would allow parents to not only be probed to think about the skills (similarly to previous digital add-ons), but it would also allow them to virtually experience using the skills [27].

In recent years, there has been an extreme increase in the use of VR in mental health care [28]. VR has been developed for new treatments but has also been used to boost or modernize treatments [29,30]. Among others, it has increasingly been implemented as a tool for internalizing problems in adults and children, such as the treatment of phobias, posttraumatic stress disorder, eating disorders, and anxiety disorders [31,32]. In these studies, VR has shown promising results with effect sizes varying from moderate to large [31,32]. Most commonly, VR has been used for exposure therapies and skills training [33]. Specifically, when VR was used as a skills trainer, a meta-analysis showed positive results in creating practice opportunities to increase knowledge-based skills [34]. Furthermore, a meta-analysis that supported the addition of VR to a variety of psychological treatments showed promising results and that it has the potential to support clinical populations [33]. In line with these findings, this study investigated the added value of VR to PCIT in a community-based clinical sample as a way to increase their practice opportunity [26].

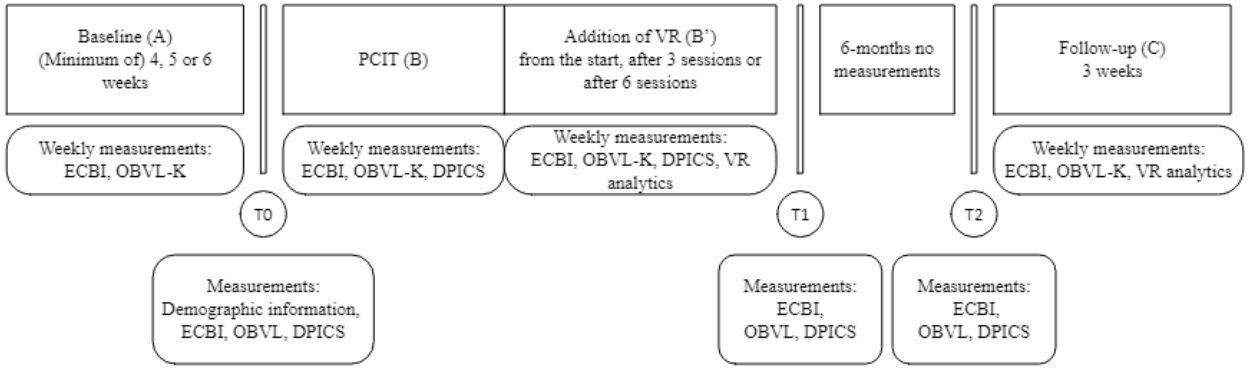
Due to the novelty of the VR tool and the fact that PCIT is measurement-driven and a nontime limited intervention, we used a single-case experimental design (SCED) to assess the added value of VR to PCIT. Using an SCED to evaluate a novel tool has multiple advantages. First, it is perfect to use in clinical practice as it can take into account individual changes because it compares the participant with him or herself [35]. More specifically, this can help take into account the variation of problems that are seen in a highly specialized clinical mental health care sample. Second, in an SCED, there are repeated measurements of the independent variable for one individual in different treatment phases, instead of evaluating the independent variable by assigning multiple individuals to different treatment groups. Third, in addition to prepost measurement strategies, an SCED can extensively examine the impact of an intervention due to its repeated measurements approach, not only within an individual, but also through repetition across participants. This allows for an insight into how, why, and when change happens during the intervention, which is done both individually and on a group level [36].

Objective

Therefore, through this SCED study, we evaluated the added value of VR to PCIT. Aside from measuring the effectiveness of PCIT in a community-based clinical sample, we took a closer look at individual patterns and how the staggered introduction of VR could influence treatment-related outcomes. We expected that PCIT-VR would increase positive parenting skills at a faster pace and increase treatment engagement. This is because if parents practiced positive parenting skills in the VR tool, we hypothesized that their overall practice time would increase, which could consequently increase the pace of skill acquisition. Moreover, we expected that with the addition of the VR tool, the scope would be enlarged (eg, it could be beneficial for split families with separated parents), as it provided the opportunity to practice in the absence of their child. Furthermore, we hypothesized that due to the overall increase in positive parenting skills, PCIT treatment effects such as diminishment of child disruptive behavior and parenting stress would also decrease at a faster pace when VR was introduced. Finally, we expected that the effects of PCIT-VR would be further maintained and engrained in the long run due to the additional skill training provided by our VR tool.

Methods

The Single-Case Reporting Guideline in Behavioral Interventions (SCRIBE), 2016 was followed to explain the design, methodology, and the results of this study [37,38].



Design

Type of Design

A randomized, nonconcurrent, multiple-baseline SCED across single participants (Figure 1) was applied. Intersubject replication, with weekly repetition, was used in this study [37]. Participants completed weekly measurements during a baseline phase (phase A, a minimum of 4, 5, or 6 measurements), an intervention period (phase B [PCIT] and phase B' [PCIT with the addition of VR]), and a follow-up phase (phase C with 3 measurements) that took place 6 months posttreatment. Between phases, a more extensive measurement took place as a way to assess pretreatment, posttreatment, and follow-up group differences as well (Figure 1). Researchers, therapists, and participants were not blinded to any components of the study. Nobody was blinded because researchers had to administer the VR component at the correct time, therapists could refer to the VR component during treatment, and participants were allowed to know when they would receive the add-on.

Figure 1. Set up of the design with phases and measurements per phase. DPICS: Dyadic Parent-Child Interaction Coding System; ECBI: Eyberg Child Behavior Inventory; OBVL-K: Dutch Parenting Stress Questionnaire-shortened version (Opvoedingsbelastingvragenlijst-Kort); PCIT: Parent-Child Interaction Therapy; T0: pretreatment measurement; T1: posttreatment measurement; T2: follow-up measurement; VR: virtual reality.

Randomization

Participants were randomized twice at the start of the study (Figure 1). As the waitlist for the treatment typically varied between 4 to 12 weeks, participants were randomized to phase A (ie, baseline) for a minimum of 4, 5 or 6 weeks, which means a multiple baseline design was used. Participants were contacted for participation while on the waitlist to start treatment. In this study, participants never remained on the waitlist longer to finish phase A, meaning clinical practice was not obstructed. Moreover, to allow for random sequencing of the intervention phase, the reception of VR was also randomized. Participants received VR either straight away, after 3 sessions, or after 6 sessions. This way, we could assess the added value of VR as we expected to see a direct difference in treatment results when VR was added. This limited the possibility of change occurring due to maturation and we could most relevantly attribute change to VR. In other words, both the baseline and intervention randomizations were done to control for potential time-related confounders [39]. The randomization of phases A and B/B' was done by a noninvolved researcher from the department, who would let the researcher know what randomization the participants had received. Phase C was not randomized, as all participants were contacted 6 months after treatment.

Procedural Changes

The original study protocol stated that 15 children would be included [26]. However, due to factors such as the COVID-19 pandemic; attrition; and losing therapists to, for example, other jobs; we were unable to include 15 children who completed all measurements. However, with an SCED, the amount of data per phase (ie, at least 3 to 5 data points) per participant are more important than the number of participants, as participants are merely compared within themselves. This amount of data per phase were adhered to in most cases. Refer to the *Participants* section for the final inclusion number and number of data points per phase per participant.

Moreover, in the original study protocol, there were no weekly measurements incorporated in the follow-up phase; this phase originally consisted of 1 single follow-up measurement. However, the third author (SB), who has expertise in SCED analyses, suggested adding additional weekly measurements to be able to compare that phase with previous phases. Accordingly, an amendment was written and subsequently granted by the medical ethical committee. This meant participants who had previously joined the study were asked to sign another informed consent form if they agreed to have 3 additional weekly measurements in phase C after the single follow-up measurement (Figure 1).

Participants

Participants Characteristics and Selection Criteria

Participants were recruited from a specialized child and adolescent psychiatry clinical practice in the Netherlands, after being referred through community channels. For the full selection procedure, please consult the study protocol [26]. The inclusion criteria for the study were as follows: (1) child disruptive behavior problems were a reason for referral, (2) children were aged between 2 and 7 years old, and (3) parents spoke Dutch or English. Participants were excluded from participation if any of the following criteria were met: (1) a child had a severe physical impairment, such as deafness; (2) a child had a mental disability (IQ <60); (3) an unsafe home situation, where home displacement was indicated; (4) a child or parent with problems requiring personal health care, such as suicidality, or parents with aggression regulation or addiction problems; and (5) parents known to have severe problems with motion sickness.

In total, 23 participants were screened to participate, of which 20 (87%) were approached as they met inclusion criteria. A total of 18 (78%) parents of 11 children were willing to participate in the study. Participants signed informed consent after receiving verbal and written information about the study, and after being able to ask all questions regarding the study to the researchers. If there was no wish to participate in the study, families would receive treatment as usual (PCIT without the addition of VR). A total of 1 (11%) couple dropped out during baseline. In total, we obtained data from all phases from 6 (33%) participants. The remaining 10 (56%) participants missed data in at least 1 phase of a measurement point, but were included in the analyses, nonetheless. In the *Results* section, we will go into detail on reasons for dropout per family.

Context

Setting

The specialized child and adolescent psychiatry clinical practice in the Netherlands used in this study has multiple locations in

XSL•FO
RenderX

and around Amsterdam. Depending on where participants lived and what team they were referred to, they were in clinical care in 1 of 3 locations. Another option was that they received treatment in-home, which was the case for 3 (%) families. All sessions were conducted by certified PCIT therapists according to PCIT International criteria. All pretreatment, posttreatment, and follow-up observations were conducted in-home by the first author (ICAS), and all the questionnaires were obtained digitally.

Ethical Considerations

This study was approved by the independent medical ethics committee of the Academic Medical Center of Amsterdam, the Netherlands (2020_143/NL74210.018.20). Furthermore, the principles of the World Medical Association Declaration of Helsinki [40], and the Medical Research Involving Human Subjects Act were adhered to.

Written informed consent was obtained from participants before the study and participation was voluntary. Data were anonymized. Participants received no compensation for participation apart from being able to keep the VR headset placeholder.

Intervention

PCIT Treatment

PCIT is an evidence-based treatment for young children with disruptive behavior problems aged between 2 and 7 years and their parents [1,11]. During the treatment, which consists of 2 phases, parents are coached live by therapists from behind a one-way screen through an earpiece. In the first phase, the CDI phase, parents follow their child's play while being coached to use child-centered interaction skills. In this phase, parents are being taught to use positive parenting skills, which include labeled and unlabeled praises, reflections, and behavior descriptions, as this positively reinforces the behavior their child is displaying. Parents are also taught to limit using questions, commands, and criticisms, as this can negatively impact the parent-child interaction. Ultimately, using positive parenting skills and limiting unwanted verbalizations leads to an improvement in the parent-child relationship. The second phase, the PDI phase, is reached when parents achieve the set amount of child-centered verbal skills (statements including 10 labeled praises, 10 reflective statements, and 10 behavior descriptions, and no questions, commands, or criticisms). During the PDI phase, parents learn to set effective and safe limits for their children. They are taught to give effective commands and how to respond consistently to their child's compliance and noncompliance. This allows for their child's behavior to be structured in a developmentally appropriate way. The treatment requires for parents to practice "special time" with their children 5 minutes every day at home. PCIT does not have a set number of sessions, parents rather progress at their own pace and naturally reach a subsequent phase when meeting the required skill criteria.

VR Component

As an additional skill training tool, parents could practice with VR at home. The VR component consisted of prerecorded 360-degree videos that portrayed a child actor playing with PCIT-appropriate toys in a PCIT playroom. The video showed the child playing, after which the fragment stopped and called for the parents to respond to a multiple-choice question. An instruction video explaining how the VR environment worked was optionally available to watch before starting to practice. In a VR practice session, parents were posed statements so they could practice positive parenting skills taught in PCIT (ie, labeled praises, reflective statements, behavior descriptions, and ignoring unwanted behavior). An example was "Describe her behavior," for which they had 2 options to answer with, such as "You put the yellow block on the green block," or "Put the block on the tower." An answer would only be selected when the pointer circle visible in the VR environment would increase in size for 3 seconds, as a way to warn participants about their imminent selection. Moreover, the selection was based on head movement rather than eye movement. After having selected an answer, parents received feedback on their respective answers. In the aforementioned example, if they selected the first option, they would see the following feedback: "That was a good behavior description." If they selected the second option, they would see, "That was a command. Try to describe her behavior. For example, 'you put the yellow block on the green block.'" The video resumed to the next fragment showing the child playing. The more the parents selected the correct answers that depict a positive parenting skill, the less examples they were offered of that particular positive parenting skill. Parents received more elaborate feedback (such as in the aforementioned example) if they did not select correct answers. After parents saw a few different scenarios, they were encouraged to practice different positive parenting skills out loud, without receiving feedback on every possibility. A VR practice session lasted approximately 10 to 15 minutes, depending on the answers given by parents.

Measures and Materials

Measures

All primary measures were completed weekly. The Dyadic Parent-Child Interaction Coding System (DPICS) [41], the Eyberg Child Behavior Inventory (ECBI) [42,43], and the Dutch Parenting Stress Questionnaire [44] were also completed before treatment, after treatment, and at 6 months follow-up. All measures apart from the DPICS were digitally obtained via Castor Electronic Data Capture (Castor Research Inc), which is a secure data management platform [45]. Demographic information was filled out solely at pretreatment.

Demographic Information

Parents were required to fill out a questionnaire regarding background information about their child and his or her family. Information regarding sex, age, origin, family composition, parental work situation, and education level were included.

DPICS Tool

The DPICS [41] is a reliable and valid behavioral observation coding system. It evaluates the quality of the parent-child interactions by coding open verbal and physical behaviors of both parents and children. The following DPICS categories were used: labeled praise, unlabeled praise, reflection, behavior

XSL•FO
RenderX

description, question, direct command, indirect command, and negative talk. These were subsequently categorized into the following 2 categories for the CDI phase: "positive following," which consists of labeled praise, unlabeled praise, reflection, and behavior description, and "negative leading," which consists of question, direct command, indirect command, and negative talk. To code with the DPICS, researchers must be trained to be able to achieve an 80% agreement rate on scored behaviors. All observations were transcribed verbatim to monitor interrater reliability. In this study, there are 2 ways the DPICS was used. First, researchers used the DPICS during the pretreatment, posttreatment, and follow-up assessment. Here, coding was done through 3 standard 5-minute play situations (child-led play, parent-led play, and clean-up). There was an average of 86% agreement between coders. Second, therapists scored a weekly 5-minute standardized observation moment at the start of every CDI session to monitor skill acquisition.

VR User Analytics

Each parent received a personalized link that automatically registered their use and progress in VR. The number of times (per week) that VR was used was monitored by the first author (ICAS) through a secure platform.

ECBI Questionnaire

The ECBI [42] is a questionnaire that addresses child disruptive behavior for children aged 2 to 16 years and is filled out by parents. The ECBI consists of 2 scales—one measuring the frequency of the problem behavior (Intensity scale: 7-point scale from 1 [never] to 7 [always]) and another that records the extent to which parents experience the behavior as a problem (problem scale: yes or no). The psychometric properties of the Dutch-translated version of the ECBI are good [43,46]. The ECBI was filled out weekly, in addition to being filled out at pretreatment, posttreatment, and follow-up assessments.

Dutch Parenting Stress Questionnaire (Shortened Version)

The Dutch Parenting Stress Questionnaire (Opvoedingsbelasting vragenlijst-Kort [OBVL-K]) [44] contains 34 questions that address 5 aspects of parenting stress. These are problems in the parent-child relationship, problems in parenting, depressed moods, role restriction, and health complaints. The total parenting burden score is calculated with a T-score. The psychometric properties of the questionnaire are good [44]. In the shortened version of the OBVL (ie, OBVL-K), there are 10 questions about the different aspects of parenting that together give a total score on parenting burden. The OBVL-K is used to assess weekly parenting burden, whereas the normal version is used before treatment, after treatment, and at follow-up.

VR Equipment

A head-mounted display that can house a smartphone was bought for all participants [47]. This study chose to use 360-degree videos that could be played on a smartphone device. This meant that participants could place their device into the headset and look around 360 degree from a singular point in the virtual environment, which in technical terms refers to 3 degrees of freedom. In other words, users could move their heads in all directions, simulating a natural look around, but did not have the capability of moving in a direction within the virtual space. This form of VR was inexpensive, easy to use with a protected personalized weblink, and allowed participants to practice in the comfort of their own homes. The videos were streamed over a network and played on a web browser, which allowed almost all devices with access to internet to be able to run the content. The raw videos were edited into fragments with key events that showed a multiple-choice question at the end of each fragment. The answer was selected by looking at the answer box with a built-in eye bullet for 3 seconds. The fragments were given in a nonlinear sequence, determined by the user's responses. This was done in a web-based scenario editor created by ICAS, the fourth author (RGB), and bachelor and master students from technology-based studies [48-52]. Before inclusion, a small amount of preliminary work was done. The product was tested by therapists before full development and use. Nonetheless, this study is the first to explore the addition of VR to PCIT with clinical participants.

Procedural Fidelity

Adherence to the treatment procedure was accomplished using the standard PCIT protocol for treatment sessions. Furthermore, ICAS was responsible for sending weekly questionnaires, which could be automatically done electronically via Castor Electronic Data Capture. A data monitor appointed by the Amsterdam University Medical Center was appointed to monitor the process with 2 monitoring visits throughout the project. The observational parts of the pretreatment, posttreatment, and follow-up assessments were also planned and coordinated by ICAS with the families. Although they received weekly reminders to fill out the questionnaires and practice with VR, it was the parents' responsibility to do this at home.

Analyses

Overview

Visual inspection analyses and randomization tests were conducted on a shiny app Single Case Design website [53]. Other analyses were conducted via R Statistical Software (version 4.2.1; R Core Team 2022) and SPSS Statistics (version 28; IBM Corp) [54]. We split the analyses up into 2 parts. First, we assessed the treatment effects of PCIT. Second, we analyzed the effects VR had on treatment outcomes.

Primary Measures

To evaluate the effects of the treatment per person, we conducted visual inspection analyses per person for the ECBI, OBVL-K, and DPICS. We expected to find that scores would decrease on the total score of the ECBI Intensity Scale and the T-score of the OBVL-K over time. For the DPICS, we expected an increase in positive following and a decrease in negative leading over time. Second, to evaluate the effect of the intervention on ECBI Intensity Scale and OBVL-K scores, randomization tests were performed complementarily to statistically test the difference in means [55,56]. First, for each individual participant the effect size, Cohen *d*, was calculated. Next, 1000 random samples were drawn from the individual scores, and for each of these samples, the Cohen *d* was calculated. The *P* value for the individual was defined as the number of random samples that had an effect size Cohen *d* that was as large or larger than the observed Cohen *d*

XSL•FO
RenderX

divided by 1000. To calculate *P* value for the group, the sum of the individual *P* values was calculated. The *P* value for the group was defined as the probability of finding the sum of *P* values given that the H0 (null hypothesis) distribution where the individual *P* values were uniformly distributed between 0 and 1. We calculated the overall *P* value for both the entire group and for the group of treatment completers.

Furthermore, to assess the added value of VR, vertical lines indicating the start of when parents received the addition of VR were added in the visual inspection analyses of the DPICS. We expected to find that when VR was added to treatment, the next measured positive following score would be higher and the next measured negative leading score would be lower. Therefore, we evaluated the hypotheses that the mean and median difference score between positive following before and after the use of VR was positive, while the mean difference score between negative leading before and after the use of VR was negative.

Secondary Measures

We secondarily evaluated the mean group differences from pretreatment to posttreatment and to follow-up in the DPICS categories of positive following and negative leading through a nonparametric Wilcoxon signed rank test. Effect sizes were calculated with Cohen *d*. We expected to find that positive following would significantly increase from pretreatment to posttreatment and remain stable at follow-up. Similarly, we expected to find that negative leading would significantly decrease from pretreatment to posttreatment and remain stable at follow-up. To evaluate DPICS per person, we evaluated their raw scores from pretreatment to posttreatment and to follow-up. Furthermore, reliable change indices (RCIs) were calculated to illustrate the change in the total scores of the Intensity and Problem scales in the ECBI and the total T-score on the OBVL-K from pretreatment to posttreatment and to follow-up. We expected to find that all 3 would reliably diminish from pretreatment to posttreatment and remain stable at follow-up. We expected scores to be less than the clinical range at posttreatment and at follow-up.

Results

Overview

First, we described the sample population with demographics, description per family, treatment trajectory, and research participation. Second, we analyzed the primary measures through visual inspection analyses and randomization tests. Third, we reported the secondary measures from pretreatment to posttreatment and to follow-up. We examined group outcomes of PCIT to show the effectiveness of the treatment for this entire sample. We looked at how often parents practiced with VR and what their DPICS scores were. In addition, we assessed their ECBI and OBVL scores through RCI.

Demographic Sample Population

Overview

To gain an understanding of the sample characteristics, see Table 1 for the relevant demographic information per participant. Moreover, Multimedia Appendix 1 presents an overview of per participant at baseline and VR randomization, what measurements were completed, and how many measurements were missed per phase as per the SCRIBE guidelines [37,38]. No participants reported adverse events during the study.

Table 1. Participants' demographics showing gender, relationship, custody status, family income, and child's gender and age.

Participant	Parent gender (per participant)	Relationship status	Custody status	Family income (€ per month[a])	Child's gender	Child's age (y)
01[b]	Female	Single parent	Sole	1000-2000	Male	4
02 and 03	Male and female	Divorced	Shared	Participant 02: >5000; participant 03: 2000-3000	Female	5
04	Female	Divorced	Sole	1000-2000	Male	6
05 and 06	Male and female	Married	Shared	3000-4000	Male	3
09	Female	Single parent	Shared	4000-5000	Male	6
10[b] and 11[b]	Male and female	Cohabiting	Shared	<1000	Male	5
12[c]	Female	Single parent	Sole	<1000	Male	5
13[b] and 14[b]	Male and female	Married	Shared	4000-5000	Female	4
15 and 16	Male and female	Married	Shared	>5000	Female	2
17[d] and 18[d]	Male and female	Divorced	Shared	Unknown	Male	7

Description of Each Participating Family

Reasons for referral and experiences with PCIT and VR are described per participant. All cases were referred for highly specialized clinical mental health care. Details of any family dropouts or significant events are also provided. Multimedia Appendix 1 supports the information for each trajectory.

Participant 01: a single mother who participated alone in the treatment with her 4-year-old boy. The child had contact with his father once a week and had 2 half-siblings that lived under the same roof. The mother had a history of psychiatric problems and was declared unfit to work. The child was clinically diagnosed with attention-deficit/hyperactivity disorder (ADHD), overall developmental delay, and parent-child relationship problems. Reason for referral was the child's disruptive behavior. He was impulsive, did not listen, and did not respond to punishment. The mother practiced with VR once, but indicated she was too tired to do it more often. The mother and child dropped out of treatment after 3 CDI sessions because it caused too much psychological burden and stress for the mother. She indicated willingness to be contacted for research purposes 6 months after treatment, but due to the child temporarily being placed out of home, no measurement took place. Due to dropping out, only descriptive and visual inspection was included from this family. They were excluded from pretreatment, posttreatment, and follow-up measurement analyses.

Participants 02 and 03: a divorced (with shared custody) father and mother participated together in treatment with their 5-year-old girl. The child, together with her sibling, alternated every 3 nights between her father and mother. The mother had a history of personal psychiatric problems for which she had been and still was in treatment. The child was clinically diagnosed with early relation-specific traumatic experiences, parent-child relationship problems (specifically with the mother), and disruptive behavior at home. These were also the reasons for referral. The father was positive about VR, although he experienced technological problems at first. The mother did not feel immersed in VR and stopped practicing with it due to that. Due to psychological stress, the mother only filled out questionnaires at the 6-month follow-up. Unfortunately, clinical DPICS scores were not registered for research purposes by the therapist and were therefore unavailable for this research project.

Participant 04: a single mother who participated alone in the treatment with her 6-year-old boy. Neither the mother nor the child had contact with the father. The child had no siblings. The mother had a history of psychiatric problems and had previously been in treatment. The child was clinically diagnosed with separation anxiety disorder (later in remission) and there were parent-child relationship problems. Reasons for referral were the diagnosed attachment problems and manipulative behavior of the child. They completed PCIT. The mother was positive about the results of PCIT and expressed VR helped her to constructively practice parenting skills. The therapist recorded 10 DPICS scores during the CDI phase and 2 DPICS scores during the PDI phase.

Participants 05 and 06: a married father and mother who participated together in treatment with their 3-year-old boy. The child had 1 sibling. The mother was recovering from burnout (ie, extreme physical and emotional exhaustion with mental health repercussions) at the start of the treatment. The father had a history of psychiatric problems for which he received treatment in the past. The child was clinically diagnosed with disruptive behavior and language delay. There were suspicions of autism spectrum disorder (ASD) and ADHD, but these were not officially diagnosed. The reason for referral was to lessen disruptive behavior and regain tranquility in the home environment. Upon completion of PCIT, the parents were positive about the results; their child's language had improved because of reflective statements and they saw that positive reinforcement helped in contact with their child. Both the parents practiced with VR, especially at the beginning of treatment. Later, they felt they gained more from practicing live. Due to the parents feeling overwhelmed with psychological care for their child, they only completed questionnaires at the 6-month follow-up. Unfortunately, clinical DPICS scores were not registered for research purposes by the therapist and were therefore unavailable for this research project.

Participants 07 and 08: while on the waitlist (baseline measurements, ie, phase A), the father and mother received intermediate psychological care for their child. This first caused PCIT to be postponed, and subsequently, it was concluded that PCIT was no longer necessary. No further information is known as they did not complete the T0 measurement. They will not be further discussed.

Participant 09: a single mother (with shared custody) participated alone in treatment with her 6-year-old boy. The father was aware and consented to the treatment, but did not want to fully commit. He participated in a few treatment sessions to gain an understanding of PCIT. The child was diagnosed early on with a genetic defect that could lead to neurological consequences. He was later clinically diagnosed with unspecified ADHD and unspecified intellectual disability. Originally, the child was referred by a pediatrician to diagnose ADHD and to treat it accordingly. Besides PCIT, the child also received medication (methylphenidate and melatonin) for his concentration problems. Upon completion of PCIT, the mother was positive about the reduced disruptive behavior and she was able to set effective limits for her child. She expressed that VR helped her to learn and practice the skills during the CDI phase, but that she missed the continuity of VR during the PDI phase. Unfortunately, clinical DPICS scores were not registered for research purposes by the therapist and were therefore unavailable for this research project.

Participants 10 and 11: a married father and mother participated in treatment together with their 5-year-old boy. The child had 2 half-siblings who he did not live with. The mother was simultaneously in treatment for personal psychological problems. The child was clinically diagnosed with ADHD combined type, a language delay, and there were parent-child relationship problems. The national institution that offers advice and support on matters concerning domestic violence and child abuse (in Dutch: "Veilig Thuis") was involved with this family due to reports of potential in-home violence. The reason for referral was to improve the parent-child relationship and to decrease behavior and parenting problems. The parents were

XSL•FO
RenderX

meant to receive VR but expressed that their burden and stress were too high to fit in time to practice with VR. They successfully completed the CDI phase of PCIT, but the intervention was temporarily paused. They did not restart PCIT due to experiencing a high psychological burden. No contact was achieved for T1 or T2. The therapist recorded 7 DPICS scores from the CDI phase. Due to dropping out, only descriptive and visual inspection was included from this family. They were excluded from pretreatment, posttreatment, and follow-up measurement analyses.

Participant 12: a single mother participated alone in treatment with her 5-year-old boy. The child was an only child and there was no contact with his father. The mother has a history of psychiatric problems for which she had been in treatment. During treatment, she was recovering from a recurring hernia. The child was clinically diagnosed with a disorganized attachment style, disruptive behavior, sleeping problems, and pica. The reason for the referral was to diagnose problem behavior and subsequently treat the respective diagnosed behavior with PCIT. The child had weekend foster care every 3 weeks. The mother and child dropped out of PCIT after a few CDI sessions, as the mother felt her child's behavior and their relationship had largely improved. Overall, the mother was positive about the treatment. She attempted practicing with VR but experienced nausea and dizziness. Even though she dropped out of treatment, she still completed both T1 and T2 measurements but did not want to complete the questionnaires in phase C anymore. The therapist recorded 5 DPICS scores from the CDI phase, with many weeks between sessions.

Participants 13 and 14: a married father and mother participated in treatment together with their 4-year-old girl. The father followed the treatment in Dutch and the mother in English due to her non-Dutch background. The father had a history of medical problems and substance abuse. The mother had psychological problems for which she started treatment during the PCIT trajectory. The child was clinically diagnosed with severe disruptive behavior, parent-child relationship problems, and parenting problems and there were suspicions of ASD. The child went to school 3 days a week upon request of the school due to hindrance from the disruptive behavior. They were referred to PCIT due to disruptive behavior at home and in school. The CDI phase was successfully completed (partially at home) and there were a few PDI sessions. The therapist recorded 5 DPICS scores from the CDI phase. The mother practiced with VR twice early on and said it helped her understand examples of how to use the skills. However, she later said it was not useful anymore. The father practiced once. Over the summer holidays, the child returned to their home country for 2 months, and PCIT was paused accordingly. In between, the parents were asked to practice with VR; however, they were unable to make time for this. PCIT was not restarted as they experienced enough improvement. Thus, they dropped out of treatment and the study. Due to drop out, only descriptive and visual inspection was included from this family. They were excluded from the pretreatment, posttreatment, and follow-up measurement analyses.

Participants 15 and 16: a married father and mother participated together in treatment with their 2-year-old girl. They received in-home PCIT. The parents experienced friction due to different views on parenting. The child had temper tantrums and exhibited crying fits and disruptive behavior. There were problems in the parent-child relationships. The reasons for referral were to lessen child disruptive behavior and parenting stress and the parents wished to improve their ability to react sensitively and responsively to their child. Upon completion of PCIT, they were positive about the results, although hesitant about some skills during the PDI phase. The father practiced a few times with VR but was not engaged in it. The mother was positive about practicing the skills in VR but found it difficult to make time for it. They both felt VR did not match their needs during the PDI phase. The therapist recorded 16 DPICS scores, all from the CDI phase.

Participants 17 and 18: a divorced father and mother participated together in treatment with their 7-year-old girl. The father was recovering from burnout and other psychological problems at the start of treatment. The mother had previously experienced burnout. The child was clinically diagnosed with ADHD, combined type, for which he received medication that was still being stabilized during the first few sessions of PCIT. There were parent-child relationship problems. Moreover, there were suspicions of oppositional defiance disorder and ASD. The child was referred for diagnostic assessment of oppositional defiance disorder and ASD and treatment for disruptive behavior. The parents originally did not want to participate in the study, but they did wish to practice with VR when their child was with the other parent. Upon completion of PCIT, the parents were positive about the results as the disruptive behavior decreased immensely, the child listened better, and parents were able to better understand their child. Moreover, both parents felt that the parent-child relationship had bettered during treatment. They mentioned that sudden changes or adaptations remained difficult for their child posttreatment. The father was positive about VR, although he experienced technological problems at first. The mother experienced nausea and dizziness when practicing in VR, so tried to do the videos on her phone without the head-mounted display headset. However, she did not feel it helped her and found the scenarios too simple. The parents were willing to participate in posttreatment and follow-up measurements and in phase C. The therapist recorded 11 DPICS scores, all from the CDI phase.

Primary Measures

Visual Inspection Analyses: VR, DPICS, ECBI, and OBVL-K

Multimedia Appendix 2 shows the visual inspection analyses per participant. In all figures, the horizontal axis represents the time in treatment expressed in weeks and the vertical lines represent the separation between subsequent phases and the addition of VR. Specifically, the gray line separates the baseline and CDI phase, the blue line separates the CDI and PDI phases, the purple line separates the PDI and follow-up phases, and the red dotted line represents the addition of VR. The visual inspection analysis of VR is shown for all participants except for participants 10 and 11 as they did not want to receive the addition of VR any longer. However, when they would have received VR is vertically presented. The visual inspection

XSL•FO
RenderX

analyses were only done for DPICS positive following and negative leading when DPICS scores were archived during treatment. This means that all participants except for participants 02, 03, 05, 06, and 09 were shown. We hypothesized that there would be a visible increase in positive following and a visible decrease in negative leading as soon as VR was introduced in treatment. For the ECBI and OBVL-K, visual inspection analyses were shown for all participants except for participant 14, as this participant did not fill out questionnaires due to the language barrier. We expected that the ECBI and OBVL-K would visually decrease over time, with a potential lag of 2 or 3 weeks behind the DPICS scores dependent on the respective increasing of positive following scores and decreasing negative leading scores.

Following visual inspection of the plots, little discernable change was apparent when looking at the moment VR was added to the treatment and the following DPICS scores. When examining the plots, participants 04, 17, and 18 appeared to show an increase in DPICS positive following scores when VR was added to treatment. Furthermore, participant 15 appeared to start using VR at around increment 10, and when looking at the DPICS positive following it appeared to increase at around the same time point. There was a visible upward trend in DPICS positive following (where everything >30 is considered good) for participants 04, 11, 12, 13, 14, 15, 16, 17, and 18. Participant 10 appeared not to show a steady pattern in DPICS positive following. There was also a visible downward trend in DPICS negative leading (where everything <5 is considered good) for participants 04, 10, 11, 12, 13, 14, 15, 16, and 18. No discernable change was visible for participant 17 in DPICS negative leading.

Following visual inspection of the plots for the ECBI, a visible decline in scores appeared for participants 01, 02, 03, 09, 12, 17, and 18. Participant 06 and 15 seemed to first decrease, but subsequently fluctuate in scores. There seemed no noteworthy changes in ECBI scores for participants 04, 05, 11, and 16. For participants 10 and 13, there appeared to be an increase in ECBI scores over time. No discernable change appeared between the use of VR and ECBI through visual inspection.

Following visual inspection of the plots for the OBVL-K, a visible decline in scores appeared for participants 01, 02, 06, 09, 12, 15, 17, and 18. The scores on the OBVL-K seemed to increase for participants 05, 10, and 13. There were no visible changes for participants 03, 04, 11, and 16 as scores seemed to remain stable or fluctuated a lot over time. No discernable change appeared between the use of VR and OBVL-K through visual inspection.

Randomization Tests: ECBI and OBVL-K

Table 2 shows the randomization tests of the ECBI Intensity Scale and the OBVL-K of all scores visible per participant in Multimedia Appendix 2. The effect size and individual *P* values are shown for both questionnaires. Only participants with at least 2 measurement points in phases A (baseline) and B (intervention) were included to assess treatment effects. This means that participants 17 and 18 were excluded as they did not participate in phase A.

The randomization test for the ECBI Intensity Scale revealed that there was no overall group significance in reports of child disruptive behavior for the entire group, nor solely for treatment completers. Only participant 09 showed a very large effect size complemented by a statistically significant decrease in reports of child disruptive behavior. Moreover, large or very large positive effect sizes were also found for participants 01, 02, 06, 11, 12, and 15, indicating that there were observed positive effects of their reports of child disruptive behavior, but these were not statistically significant. Nonetheless, this means that treatment positively impacted the reported levels of child disruptive behavior for a large number of participants. Participants 05 and 10 showed large to very large contratherapeutic effects in their reports of child disruptive behavior, although again not statistically significant. However, this means that for these 2 participants, their reports of child disruptive behavior were overall higher during the treatment phase than in the baseline phase, potentially due to amounting stressful circumstances described earlier.

The randomization test for the OBVL-K revealed that there were no overall group significance in reports of parenting stress. Again, participant 09 showed a very large effect size, complemented by a statistically significant decrease in parenting stress. Very large effect sizes were found for participants 06, 11, and 15, indicating that there were observed therapeutic effects of their reports of parenting stress, although these were not statistically significant. Nonetheless, this means that treatment positively impacted their reported levels of parenting stress. Participant 10 (who dropped out) demonstrated a nonsignificant very large contratherapeutic effect size in his reports of parenting stress, meaning that his parenting stress was higher during the treatment phase than in the baseline phase, potentially due to amounting stressful circumstances described earlier.

Virtual Reality

To investigate whether there was a visible effect in the use of parenting skills from one PCIT session to the next when parents used VR, we subtracted the number of tallied skills in a session from its previous session. As parents need to achieve a preestablished amount of positive parent skills, including 10 labeled praises, 10 behavior descriptions, and 10 reflections, we corrected for 30 tallied skills. This means that any number >30, was considered the same. All participants who had practiced with VR between 2 PCIT sessions, and where DPICS scores during the 5-minute observation at the start of both sessions were available, are included in Table 3. This table reflects how practicing with VR in between sessions contributes to the positive following and negative leading scores of parents. As DPICS scores were archived from varying sessions and parents practiced at varying moments in time, this table does not provide information regarding specific sessions and the effects of VR on those sessions. It does consider the number of times practiced between 2 sessions. Both the mean and median are shown. The median is more sensitive to outliers, which made it a more cautious analysis.

Table 3 shows that when parents used VR, all their negative leading scores decreased from one session to the next, both when looking at the median difference and the mean difference. In addition, only for 2 parents, the positive following skills increased from one session to the next when VR was used. This suggests that when parents practiced with VR in between sessions, it especially led to a decreased use of negative leading statements in the following session.

XSL•FO
RenderX

Table 3. Median and mean difference in positive following and negative leading skills from one session to the next when virtual reality was used in between sessions[a].

Participant	Median difference		Mean difference	
	Positive following	Negative leading	Positive following	Negative leading
04	7.00	0.00	3.00	−0.56
15	−14.50	−5.00	−9.00	−6.75
16	0.00	−2.00	−6.33	−0.33
17	0.00	−1.50	−1.13	−1.30
18	4.00	−2.00	4.00	−1.75

[a]Positive following is supposed to increase for wanted change to occur, and negative leading is supposed to decrease for wanted change to occur.

Secondary Measures

DPICS Group Outcomes

As the sample was too small to perform *t* tests, a nonparametric test (the Wilcoxon signed rank test) was performed to illustrate the changes in positive following and negative leading during the CDI phase according to the DPICS from pretreatment to posttreatment and follow-up (Table 4). Effect sizes were demonstrated with Cohen *d* [57].

Significant effects were found both in positive following and in negative leading from pretreatment to posttreatment, and from pretreatment to follow-up. No significant effects were found from posttreatment to follow-up. There was a general increase in mean in the use of positive following skills and a general decrease in the use of negative leading statements. Moreover, the effect sizes according to Cohen *d* indicated very large effects from pretreatment to posttreatment and from pretreatment to follow-up for positive following, as well as very large effect size for pretreatment to follow-up in negative leading.

Table 4. Changes in positive following and negative leading during the child-directed interaction phase in pretreatment, posttreatment, and follow-up measurements for parents who completed Parent-Child Interaction Therapy[a].

Measurements	Sample size, n	Wilcoxon signed rank test, mean (SD; range)	*P* value	Cohen *d*
Positive following				
T0[b]	9	5.11 (5.64; 0-18)	T0 to T1[c]=.01[d]	T0 to T1=1.84[e]
T1	10	32.10 (22.87; 11-89)	T0 to T2[f]=.04[d]	T0 to T2=2.96[e]
T2	7	32.00 (13.49; 13-51)	T1 to T2=.40	T1 to T2=0.01
Negative leading				
T0	9	30.44 (15.06; 5-56)	T0 to T1=.05[d]	T0 to T1=1.02[g,h,i]
T1	10	14.40 (16.41; 0-57)	T0 to T2=.04[d]	T0 to T2=2.27[e]
T2	7	6.43 (4.86; 1-15)	T1 to T2=.06	T1 to T2=0.68

[a]Positive following must increase and negative leading must decrease for wanted change to have occurred.

[b]T0: pretreatment measurement.

[c]T1: posttreatment measurement.

[d]Significance at <.05.

[e]Cohen *d* effect size: very large=1.20.

[f]T2: follow-up measurement.

[g]Cohen *d* effect size: large=0.80.

[h]Cohen *d* effect size: medium=0.50.

[i]Cohen *d* effect size: very small=0.01 to small=0.20.

VR, DPICS, and RCIs for ECBI and OBVL

To illustrate the number of times participants practiced with VR and whether this affected the primary outcomes of positive parenting skills, child disruptive behavior, and parenting stress, we examined the raw scores per person. Reliable change was not calculated for the DPICS, because there was not enough published information for the calculation of reliable change. Therefore, we have merely shown the raw scores of positive following and negative leading per measurement point. As this is a clinical sample, we deemed it important to show raw total scores and demonstrate whether or not participants fell into the clinical range at different time points (Multimedia Appendix 3; Table 5). To further illustrate changes in child disruptive behavior and parenting stress, we also performed RCIs (Table 6). We only included the participants who had completed ≥2

XSL•FO
RenderX

measurement points, which meant that participants who had dropped out of treatment and the study were not included (ie, participants 01, 10, 11, 13, and 14).

To assess whether there were differences on the DPICS, ECBI, and OBVL scores when VR was practiced, we split the group in 2 based on the median use of VR in the group. The median of practicing with VR was 6. Therefore, we split the group into participants who practiced with VR 6 or less times (group A) and who practiced with VR 7 or more times (group B; Tables 5 and 6). With this, we provided preliminary observations regarding practice time and treatment outcomes, but more evidence is necessary to draw any conclusions on relations with one another, as other factors may also have been of influence.

First, we observed that 3 of the 5 (60%) participants from group A did not participate in the follow-up measurement, whereas all participants from group B participated in posttreatment and follow-up. Second, results show that group A started with higher scores in positive following and negative leading than group B. Group A consistently scored higher in positive following than group B, but only group B showed progression in positive following from posttreatment to follow-up. However, for negative leading, group B showed lower scores on pretreatment and posttreatment than group A. Both groups decreased in negative leading from posttreatment to follow-up. Third, group A also started with higher reports on the ECBI Intensity Scale than group B and only group B had all scores less than the clinical cutoff score at posttreatment and at follow-up. Fourth, although group B started with a higher overall score on the ECBI Problem Scale, they diminished more than group B and remained below the clinical cutoff score at posttreatment and follow-up. Fifth, group A showed higher reports of total parenting stress in all 3 measurement points than group B. Overall, we observed more improvement for group B than for group A in child disruptive behavior and parenting stress, but group A applied more parenting skills than group B.

These results show that there are little discernable differences in terms of reliable change for the ECBI scales when splitting the group in 2 based on the median VR use. A total of 4 of 11 (36%) parents experienced a reliable change from pretreatment to posttreatment on the ECBI Intensity Scale. Two parents (both who practiced with VR >6 times) maintained that significant change at follow-up as well. For the ECBI Problem Scale, we observed that there were 6 (55%) parents with a reliable change from pretreatment to follow-up. Participant 16 experienced an increase in problems, which indicated contratherapeutic treatment effects. We were privy to the information that the child had experienced impetigo and chicken pox in the weeks before filling out the questionnaires, thus elevating her disruptive behavior, which could have influenced parent's reports. Participant 06 also experienced a deterioration from posttreatment to follow-up. Participants 02, 09, and 12 had reliable changes from pretreatment to follow-up and participant 02 also showed a large reliable change from posttreatment to follow-up, indicating that the treatment seemed to continue its effects.

For the OBVL, we observed that in the group that practiced with VR <6 times, all parents experienced a large significant change in parenting stress from pretreatment to follow-up. Participant 06 showed a significant negative reliable change from posttreatment to follow-up, indicating deterioration. This is in line with the fact that parents were unable to make time for the observation at follow-up, due to increased psychological burden at that moment in time. Her partner, participant 05, although not significantly changed, reported even higher levels of parenting stress at follow-up than participant 06. In the group that practiced with VR >6 times, all participants showed a reliable change from pretreatment to follow-up, except participant 04 who experienced contratherapeutic treatment effects. As mentioned before, participant 04 started working full time at the end of treatment and expressed feeling parenting stress as a result. Although participant 18 showed a negative reliable change from posttreatment to follow-up, the parent gave us relevant information that could have influenced the change index. Namely, in the specific week that the questionnaires were filled out, 3 family members had celebrated their birthdays, which meant that the normal routine had been disturbed. The parent expressed that her child was tired and irritable as a result, which in her eyes, was not representative of the months posttreatment.

XSL•FO
RenderX

Table 5. The total number of times practiced with virtual reality (VR) and the raw scores in pretreatment, posttreatment, and follow-up measurements in the Dyadic Parent-Child Coding System (DPICS), Eyberg Child Behavior Inventory (ECBI), and Opvoedingsbelasting vragenlijst (OBVL) per participant.

Participant	VR	DPICS						ECBI						OBVL

Discussion

Principal Findings

We experimentally examined the staggered addition of VR to PCIT with parents who followed treatment with their child who displayed child disruptive behavior. Our findings are presented in an SCED study on PCIT-VR in a community-based clinical sample. As this was the first time that VR was used supplementary to PCIT, we sought to give initial insights into the added value of this skill practice tool, and we examined the effects of additional practice time in VR and other treatment-related outcomes. Accordingly, we expected that the introduction of VR would increase positive parenting skills at a faster pace, and that this increase would subsequently lead to a faster diminishment of child disruptive behavior and parenting stress. This was partially confirmed as the relationship between practicing in VR and treatment-related outcomes varied among participants. Some participants seemed to benefit from the addition of VR, whereas it did not seem to impact treatment-related outcomes for other participants. We discuss the most important individual and group findings subsequently, after which we review strengths and limitations of the study and suggest future directions for research. Finally, we discuss clinical implications and conclude our findings.

With regards to the visual inspection plots and randomization tests, we found that overall, there did not seem to be a clear relationship between the use of the VR tool and PCIT treatment effects, as positive parenting skills did not noticeably change when VR was added in most of the cases. However, in 3 cases, positive parenting skills visibly seemed to increase when VR was introduced to treatment. This was confirmed through median and mean differences in skills between 2 sessions. Specifically, our study demonstrated that there seemed to be meaningful differences for more parents in changes in negative leading statements (ie, questions, commands, and negative talk) than in positive parenting skills (eg, labeled praises, reflective statements, and behavioral descriptions). Although our VR tool specifically targeted scenarios aimed at practicing positive parenting skills, some scenarios also targeted practicing ignoring unwanted behavior, while using positive parenting skills to re-engage the child in play. Although there is no clear reasoning behind why practicing in VR seemed to be associated more with decreased questions and commands in the following session, we can venture a guess as to why this pattern emerged. When parenting skills were sequenced, visible changes in increased positive parenting skills and decreased negative leading statements were seen during treatment sessions in a study by Hakman et al [58]. That study attributed this change to therapists providing immediate feedback to the parent to appropriately respond to child behaviors, and the therapist being able to tailor

XSL•FO
RenderX

the application of skills when problems arose during sessions. That described mechanism of feedback and tailoring responses is incorporated into our VR tool. Parents receive immediate positive feedback for correctly choosing to use positive skills and receive suggestions for alternative skill application when choosing to use questions and commands. Therefore, although they may not yet be fully proficient in applying positive parenting skills, practicing in VR may have given them enough alternatives to negative leading statements to limit those in the following sessions. While this was an incidental finding, we deem it an important benefit that pleads for practicing in VR as we know that negative parenting strategies can increase or maintain child disruptive behavior and other adverse outcomes [59].

Considering the number of missing questionnaires from parents and the amount of times VR was practiced with, our results indicate that the effect of VR may potentially be dependent on the level of engagement from parents in treatment. Parents who filled out >70% of questionnaires and did not drop out of either the treatment or the study, seemed to practice with VR more. This insinuates that when families have the drive, motivation, and capacity to change, in addition to having the mental space to take on the responsibility of change, they seem to take accountability for that change to happen. In other words, when they feel accountable for change, they do everything in their power, including increasing their practice time through VR, for the desired change to happen. This finding emphasizes treatment engagement of parents, which is considered an important predictor for treatment success [60]. In line with our study, previous research showed that lower income and high levels of parental stress were associated with lower treatment engagement [61,62]. Moreover, the more engaged parents were in treatment, the lower the child's disruptive behavior was at posttreatment and the more parents expressed understanding skills and how to use them appropriately [61]. In addition, Pocket PCIT found that treatment engagement was stimulated through their web-based resource platform for parents and they suggested this as a point of interest for future research [24]. Although we attempted to enhance treatment engagement through practicing with skills in VR, it may be that when the psychological burden is too high, parents are unable to benefit enough from the additional services offered to them. Another possibility is that due to the use of 360-degree videos and thus creating a 3-degree of freedom virtual environment, VR may not have been engaging enough for some participants who had previous experiences with VR. Where VR could have been perceived as an engaging way to practice skills, the static storyline could have quickly led to boredom [63]. This, in turn, could have led to less practice time in the virtual environment. Taken together, we believe that the VR practice could potentially work best as a suggested additional practice tool tailored to the needs, capacity, and motivation of individuals, rather than a mandatory addition to treatment.

We did not uncover conclusive changes between practicing with VR and child disruptive behavior, nor between practicing with VR and parenting stress, although therapeutic trends are visible in parenting skills, child disruptive behavior, and parenting stress. These were complemented by large effect sizes after receiving PCIT in most (n/N, %) cases. One parent, who had dropped out before treatment completion, showed contra therapeutic treatment-related outcomes, where both child disruptive behavior and parenting stress increased over time. These individual changes were also confirmed in the pretreatment, posttreatment, and follow-up measurements. Here, we found significant changes in increased positive parenting skills and decreased questions and commands from pretreatment to posttreatment as well as from pretreatment to follow-up for treatment completers. These were again complemented by very large effect sizes for receiving PCIT (-VR) in general. Our findings are in line with treatment effects found in other PCIT studies, including findings from a study in a similar Dutch community-based clinical sample [1,13,64]. This suggests that, regardless of the addition of VR, PCIT had the wanted therapeutic effects on the children and parents from this community-based clinical sample.

Furthermore, reliable decreases were found in parenting stress for all but 1 of the 11 (91%) treatment completers from pretreatment to follow-up, regardless of the number of times they had practiced with VR. This means that parenting stress decreased for all parents in our sample because of following PCIT (-VR). There was variability in reliable decreases of child disruptive behavior from pretreatment to posttreatment and to follow-up, where 5 (45%) parents reported reliable decreases from pretreatment to follow-up, and 1 (9%) parent reported a reliable increase, which was contra-therapeutic. Moreover, the participants who practiced with VR >6 times, reported their child's disruptive behavior to be below the clinical range at posttreatment, and all but 1 (83%) participant (who scored 131) remained below the clinical range at follow-up. This means that PCIT positively affected child disruptive behavior, but when VR was practiced along with it more than 6 times, the child disruptive behavior remained manageable at follow-up. These results were in line with treatment protocol because when positive parenting skills are correctly implemented, treatment-related outcomes such as child disruptive behavior should also decrease [11]. Although no group comparisons were statistically made and we must be very careful with this interpretation, participants that practiced with VR <6 times had higher initial reports of child disruptive behavior and parenting stress, and remained higher at posttreatment and follow-up, which could suggest that these participants represented more complex problems. When there are more complex problems, families in community-based samples are known to have lower homework completion rates, which is postulated to be related to barriers such as high levels of stress and busy schedules [19,65]. This confirms the trends seen in the individual outcomes, where treatment engagement may be contingent on the complexity of problems and their (mental) capacity. These findings suggest that the VR practice tool may not be the solution to engage these specific families in PCIT. This group might, for example, benefit more from other types of additional care, such as financial aid, to reduce life stressors. Moreover, more research is warranted to confirm the speculatory relationship between the complexity of problems and less practice time in VR.

XSL•FO
RenderX

Furthermore, we can see that skill acquisition largely increased at posttreatment and follow-up when VR was practiced >6 times. This is in line with the deliberate practice theory, which states that additional practice time can contribute to increased skill learning [66-68]. However, we cannot attribute this solely to practicing in VR, as parents who practiced <6 times with VR equally showed large increases in skills at posttreatment and follow-up. Moreover, PCIT is already known to stimulate increases in skill acquisition [1]. It is possible that the increased practice time in VR led to increased confidence in parenting in general, which was suggested by qualitative findings in PCIT-VR, which was a part of the study but published as a separate qualitative paper [63]. This implies that practicing parenting skills and receiving feedback in VR may have been beneficial for the confidence in skill application of these parents, which was reflected in showing more lasting treatment outcomes than the participants that practiced less with VR. Consequently, we believe that tailoring VR to the needs of parents could be of clinical relevance in PCIT because some parents from our sample visibly benefited from the additional practice time.

Strengths, Limitations, and Future Directions

This study allowed us to take an in-depth look at the varying change trajectories in the treatment-related outcomes in PCIT, while also investigating the novel VR practice tool. We uncovered interesting trends that demonstrated the complexity of a community-based clinical sample. Moreover, through VR, split families received an opportunity to practice in-treatment taught skills without the presence of their child. In our sample, we had 4 (participants for whom this was relevant and who profited from this. This was facilitated by the strong design that an SCED provides, as we could individually follow both parents and report their progress separately, but simultaneously. In addition, the simplicity of our VR tool with 360 degrees videos readily available on a personal smartphone meant that it was very accessible and easy to use. These points highlight the potential of VR to be tailored to an individual's needs, and that it could be implemented as an optional skill strengthener when necessary.

Although this study provides valuable initial insights into the added value of VR to PCIT, there are some limitations that must be addressed. We must first acknowledge that because of using an SCED design, parents were required to fill out weekly questionnaires at home, in their own time, rather than in the PCIT room before the start of treatment. Although this meant that we had data about child disruptive behavior and parenting stress from weeks that sessions did not take place, it also meant that this could be seen as additional homework by parents. In other words, on top of giving them additional practice time through VR, they may have felt that the weekly SCED questionnaires were an additional task or burden as well. This could potentially have influenced their practice time, because if they were short on time, they may have picked questionnaires over VR practice time. Moreover, we know that homework completion rates are already lower in community-based clinical samples [19,65], so adding questionnaires as a task may have impacted practice time, albeit live or in VR.

Another limitation was that a lot of DPICS data were missing in our sample due to archiving problems. Therefore, although we can very carefully draw conclusions about the effects practicing in VR had on treatment, we cannot say that it was the case for our entire sample, as we do not know. As mentioned, there seemed to be a trend that indicated that the more dedicated parents were to fill out questionnaires, which was translated into fewer missed values, the more they seemed to practice with VR. However, we missed DPICS data from some of these participants too (eg, participants 02 and 09). It would have been interesting to be able to report their change in positive following skills and negative leading behavior alongside VR as well. In the future, a better system for archiving DPICS data should be implemented.

Finally, this study had originally planned to evaluate the staggered addition of VR at the start of treatment, after 3 sessions or after 6 sessions. While the idea of such a design was strong, as we would be able to attribute changes in treatment outcomes on VR and not because of maturation, we were unable to include enough participants to be able to say anything on this in this study. Nonetheless, qualitative findings of PCIT-VR suggested that parents found particular added value in using VR at the start of treatment, as it provided them with a visual learning opportunity that complimented the verbal instructions from therapists. It also gave them examples of how to use specific skills, which they found helpful to apply to special time with their child [63]. With this knowledge, we believe in the potential VR has as a complementary tool to the instruction session. Therefore, it would be valuable to offer VR from the start for parents. A follow-up study with a similar design where DPICS scores are archived could help us confirm the initial suggestions that VR could help improve treatment outcomes.

Conclusions

First, our study provides additional evidence that PCIT in a community-based clinical sample results in positive treatment effects. Moreover, we gave valuable first insights into the added value of VR to PCIT. Although this study alone does not provide strong enough evidence to clearly state that there was added value of VR to PCIT, we believe that there are interesting trends that plead for a further investigation into PCIT-VR. These findings tentatively suggest that practicing with VR could potentially increase positive parenting skills, and it could potentially also have an impact on other treatment-related outcomes, such as child disruptive behavior and parenting stress. However, individual differences, such as treatment engagement, accountability, capacity for change, and complexity of problems, may play a role both in the number of times VR was practiced with over the course of the treatment and on individual treatment effects. In other words, creating a practical add-on for such a clinical target population is beneficial if it fits their respective complex and stressful lives, as this increases the chances of them being (able to be) engaged, and thus achieving treatment success. Overall, we can preliminarily suggest that VR could be of added value to PCIT to increase confidence in parenting skills for certain parents, while simultaneously considering complex factors that play into treatment success.

Acknowledgments

This research was funded by a grant from the Dutch Ministry of Health, Welfare, and Sport (in Dutch: Ministerie van Volksgezondheid, Welzijn en Sport). Information regarding the project funding can be found in the Amsterdam Medical Center, Amsterdam Medical Research B.V. (code 23378). The funding body had no role in the process of the study. In addition, the study protocol has not undergone peer review by the funding body.

The authors would like to thank all parents, children, and therapists who participated in the study. They would also like to thank the students who helped create the virtual reality tool and the students who helped code the Dyadic Parent-Child Interaction Coding System.

Data Availability

The datasets generated and analyzed during this study are not publicly available to protect the privacy of the participants and follow ethical guidelines, but they are available from the corresponding author on reasonable request.

Authors' Contributions

ICAS participated in conceptualization, data curation, data analysis, and writing the original draft, as well as reviewing and editing. MEA contributed to supervision and writing, major reviewing, and editing the manuscript. SB participated in the single-case experimental design experience; data analysis; and writing, reviewing, and editing the manuscript. RGB contributed to the virtual reality experience as well as writing, reviewing, and editing. AP was responsible for reviewing and editing. RJLL was responsible for funding acquisition and supervision, as well as reviewing and editing. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: A systematic separation of late preterm and/or sick newborns from their mothers and families continues to occur in most neonatal units around the world.

Objective: The aim of this study was to implement immediate kangaroo mother care for sick newborns from birth.

Methods: This study comprised preterm newborns at ≥34 weeks of gestational age and weighing ≥1800 g, term newborns with noninvasive ventilation, and newborns at ≥34 weeks of gestational age and weighing ≥1800 g with congenital anomalies that did not require urgent medical or surgical attention. Newborns were excluded in cases of advanced resuscitation or at medical discretion. The newborns in this study were maintained skin-to-skin for 120 minutes, preferably with the mother, and then transferred skin-to-skin to their destination unit.

Results: In this study, 60 newborns were included. The median time for immediate kangaroo mother care was 120 minutes for all newborns; 100% of the time was spent with the mother, even when respiratory support was required. Immediate kangaroo mother care was interrupted for 13 of the 60 newborns, and this was more frequent in newborns with heart disease (9/13, 69%), with the main cause being the neonatologist's concern. No causes of separation were related to maternal issues, hypoglycemia, or temperature instability, and no incidents such as hypothermia were observed during kangaroo mother care, either at birth or during transport.

Conclusions: Kangaroo mother care during the first 120 minutes of life in late premature or sick newborns is a safe and feasible practice.

Introduction

An increasing body of evidence supports maintaining the nuclear family unit at birth by promoting early newborn stabilization, prolonged uninterrupted immediate kangaroo mother care (iKMC) as soon as possible after birth, and initiating breastfeeding on the mother's bare chest, which is known as iKMC [1-3]. iKMC for preterm newborns has been associated with reduced mortality, nosocomial infections, and hypothermia in those weighing less than 1500 g [4]. It also improves breastfeeding rates [5,6], reduces parental stress and health care costs [7], and enhances long-term health outcomes [8]. Hence, the World Health Organization (WHO) recommends iKMC for neonates born after 28 weeks of gestation [9].

There is evidence regarding the feasibility and safety of iKMC in very premature newborns [10]. Nevertheless, there is a lack of clinical protocols or experiences explaining how to implement iKMC in other groups of ill newborns, particularly, late premature newborns, those requiring noninvasive respiratory support, or those with prenatal diagnoses. In many cases, there is very little evidence for these groups. This study aims to evaluate the feasibility and safety of iKMC at birth for sick newborns, thereby bringing the benefits of iKMC to a greater number of sick newborns and their families.

Methods

Study Design

This is a quality improvement study. The inclusion criteria comprised 3 gestational groups: (1) preterm newborns between ≥34+0 and <37+0 weeks of gestational age (GA) and weighing ≥1800 g with or without respiratory distress requiring or not noninvasive ventilation (group 1); (2) term neonates ≥37+0 weeks of GA with respiratory distress (group 2); and (3) term newborns ≥37+0 weeks of GA and preterm newborns ≥34 weeks of GA, weighing ≥1800 g, and having a prenatal congenital anomaly not requiring immediate medical or surgical intervention (group 3). The exclusion criteria were neonates needing intubation, cardiac massage, advanced resuscitation, noninvasive ventilation with FiO_2 (fraction of inspired oxygen) >40%, or with heart rate <100 beats per minute, as well as those excluded based on clinical judgment by the attending team. The iKMC protocol established a standardized duration of 120 minutes, irrespective of the delivery mode and was conducted in either the labor/recovery unit or the obstetric resuscitation area. Continuation of iKMC was permitted in the assigned maternal or neonatal unit depending on clinical stability. All training sessions were multidisciplinary, attended by neonatologists, resident doctors, neonatal nurses, midwives, and anesthetists.

A neonatologist or neonatal nurse was present at the initiation of skin-to-skin contact. In delivery rooms, newborns could be assessed either directly or via telemetry. Monitoring with pulse oximetry and temperature or glucose measurement was recommended, as appropriate. In cases of asymptomatic early mild hypoglycemia, breastfeeding during iKMC was encouraged to avoid mother-newborn separation. For cesarean deliveries, the physical presence of both a neonatologist and a neonatal nurse was mandatory. In all cases, the umbilical cord was cut after 1 minute. The temperature was measured immediately after birth and upon arrival at the neonatal intensive care unit. If at any time the temperature was below 36 °C, iKMC was interrupted. When the temperature was between 36 °C and 36.5 °C, additional measures were initiated, such as preheated cloths or increasing the maternal temperature with air convection blankets. Ideally, transport to the destination unit was performed with the mother using a bed or a wheelchair depending on her physical condition at the time. If the mother was not available, iKMC transport with the father or the other authorized caregiver was encouraged. A wheelchair was used for this purpose.

The primary outcome was the duration of uninterrupted iKMC (in minutes). Additional variables included patient demographics, the individual providing the care, need for respiratory support, and its discontinuation during iKMC. A formal sample size calculation was not conducted; however, a target of 50 patients was deemed sufficient to assess feasibility. Ultimately, 60 patients were included. Quantitative variables were summarized using mean and standard deviation or median (p50) and interquartile range (p25-p75), depending on the distribution assessed by the Shapiro-Wilk test. Categorical variables were reported as absolute counts and percentages. Group comparisons were performed using analysis of variance, Kruskal-Wallis, Mann-Whitney *U* test, 2-sided Student *t* test, chi-square, or Fisher exact test, as appropriate. Bonferroni adjustment was applied for comparisons among the 3 inclusion groups. All analyses were conducted using SAS software (version 9.4, SAS Institute), with statistical significance set at $P \leq .05$ and 95% CI.

Ethical Considerations

This study is a subproject of a larger project called “zero separation.” The larger zero separation project was submitted to the research ethics committee with all the subprojects. The ethics committee of the 12 de Octubre University Hospital approved the global project (approval 25/542). All families, including mothers and fathers, were informed verbally. No informed consent was required according to the recommendations of the ethics committee, and participants could opt out anytime. Data were anonymized, and no compensation was given to any participant.

Results

Between January and August 2024, 89 eligible newborns were admitted to the unit. Of these, 29 (33%) were excluded: 52% (15/29) were excluded due to respiratory distress with FiO_2 >40%, 35% (10/29) due to maternal factors, and 14% (4/29) for reasons such as advanced resuscitation or care overload. The final sample comprised 60 newborns.

The characteristics of the included newborns are shown in Table 1. Significant differences were observed among groups 1, 2, and 3 in the gestational weeks (median 35+0 [IQR 34+2 to 36+0] weeks vs 40+2 [IQR 39+2 to 40+6] weeks vs 40+0 [IQR 38+5 to 40+4] weeks, respectively; $P<.01$) and birth weight (2350 [IQR 2080-2940] g vs 3290 [IQR 3130-3660] g vs 3230 [IQR 2970-3550] g, respectively; $P<.01$). Among the different

XSL•FO
RenderX

congenital anomalies, 60% (14/24) were congenital heart diseases such as Tetralogy of Fallot or aortic coarctation, 20% (4/24) were neurological problems, and 10% (3/24) were other anomalies.

The characteristics of iKMC are presented in Table 2. The median duration was 120 minutes for all newborns, with no differences among the groups. All newborns received iKMC with their mothers. Notably, newborns in the respiratory distress group (group 2) more frequently required continuous positive airway pressure (CPAP) than groups 1 and 3 during iKMC (17/19, 90% vs 6/17, 35% vs 1/24, 4%, respectively; *P*<.01) and were more frequently transported in iKMC (16/19, 84% vs 8/17, 47% vs 10/24, 42%, respectively; *P*=.01).

Table 1. General characteristics of the sample of newborns recruited based on the inclusion criteria.

Variables	Late preterm newborns (n=17)	Term newborns with respiratory distress (n=19)	Newborns with congenital pathology (n=24)	*P* value

[a]CPAP: continuous positive airway pressure.

Table 3 summarizes the characteristics of iKMC among protocol participants. Among those with interrupted kangaroo care, the median duration was 20 (IQR 20-30) minutes. Early separation occurred more often in newborns with prenatal diagnoses of congenital anomalies (9/24, 69% vs 2/17,15% vs 2/19,15%, respectively; *P*=.02), although the median iKMC duration did not differ significantly between the groups.

Temperature instability and hypoglycemia were not reported as the causes of separation. Newborns who experienced iKMC interruption were less likely to be transported in iKMC (3/13,

XSL•FO
RenderX

23% vs 31/47, 66%, respectively; *P*<.01). No significant differences in interruption rates were observed across work shifts (morning: 3/13, 23%; afternoon: 3/13, 23%; night: 7/13, 54%; *P*=.47). Interestingly, newborns requiring positive pressure ventilation at birth (n=9) were less likely to have iKMC interrupted (2/9, 22% vs 7/9, 78%, respectively; *P*=.02). Some details related with the characteristics of breastfeeding during iKMC and at discharge were also studied, which are shown in Table 4.

Table 3. Characteristics of kangaroo care interruption in the contact protocol.

Variables	Late preterm newborns (n=17)	Term newborns with respiratory distress (n=19)	Newborns with congenital pathology (n=24)	*P* value
Kangaroo care interruption at some point (yes), n (%)	2 (15)	2 (15)	9 (69)	.02

Exclusive breastfeeding at discharge	7 (41)	10 (53)	10 (4)	.76

Discussion

This study represents the first experience published in Europe demonstrating the feasibility and security of iKMC for sick newborns and late premature newborns. Nearly 80% (47/60) of the newborns remained in uninterrupted iKMC for 120 minutes, with 100% of that time spent skin-to-skin with their mothers, even among those requiring positive pressure ventilation or respiratory support. No complications occurred during the process or during skin-to-skin transport.

No studies have been found with which to compare the outcomes of iKMC in patients with prenatally detected congenital anomalies. Walsh et al [11] evaluated singletons born vaginally at 35-36 6/7 weeks gestation who were randomized to be initiated with iKMC with a reported time of immediate kangaroo care of 60 minutes. Our median uninterrupted iKMC duration of 120 minutes is notably longer, likely reflecting heightened staff awareness and targeted training. iKMC was interrupted in 22% (13/60) of the cases, predominantly due to worsening respiratory status (4/13, 31%). No interruptions were related to maternal issues, hypoglycemia, or temperature instability, consistent with prior literature [12,13]. This underscores the role of health care providers, sometimes unintentionally, as the main cause of mother-newborn separation.

Technical or logistical issues accounted for only 2 interruptions. No significant differences in iKMC duration or interruption rates were observed across different shifts or patient subgroups. Numerous studies support the safety and benefits of KMC for newborns requiring respiratory support from birth [13,14]. However, only one prior study comprising premature newborns, including late premature ones, demonstrated safe respiratory stabilization by using noninvasive ventilation during skin-to-skin care, achieving 40.6% stabilization in kangaroo care [13]. In our study, this rate increased to 79% (47/60), with 38% (9/24) of the patients discontinuing CPAP during KMC, thereby reducing admissions. Differences in GAs between studies should be noted.

Notably, newborns requiring respiratory support were more frequently transported skin-to-skin, confirming the feasibility and safety of this method. This study extends existing evidence to preterm and sick newborns. Regarding breastfeeding, iKMC is known to promote early latch and initiation in healthy term newborns [13,15]. Our findings extend this to preterm and sick newborns, with 30% (18/60) achieving early colostrum latch and a greater breastfeeding rate at discharge (57/60, 95%), including exclusive breastfeeding in half of the cohort.

XSL•FO
RenderX

This study is the first to detail the way to apply implementation of iKMC in preterm and sick newborns, achieving greater recruitment and applicability. A limitation is that our study was conducted in a unit with extensive staff training and strong commitment to iKMC, which may limit generalizability without similar institutional support. Indeed, our unit has previously published its experience regarding the implementation of iKMC in preterm newborns born between 28 and 34 weeks of gestation [10].

In conclusion, iKMC with uninterrupted skin-to-skin contact and transport during the first 120 minutes of life in late preterm and sick newborns is safe and feasible. Newborns that required noninvasive ventilation with FiO_2 <40% could be initiated with iKMC. Early mother-newborn contact also improves breastfeeding initiation. This study represents a further step toward zero separation—a goal strongly desired by parents of hospitalized newborns and actively advocated by the Global Foundation for the Care of the Newborn Infant. To date, most scientific literature has focused primarily on very premature newborns. However, extending the practice of iKMC to newborns with higher GAs has the potential to benefit a much larger number of families by preventing unnecessary separation.

Abstract

Background: Disciplining a child is a complex, multidimensional aspect of parenting, involving emotional guidance, behavioral correction, and consistent communication. Disciplinary practices applied to children may vary due to social, cultural, and geographic contexts. Among these practices, child shaking and its potentially severe consequences, including traumatic brain injury and long-term neurodevelopmental impairments, are more frequently documented in high-income countries. Although child shaking also occurs in low- and middle-income countries, particularly among infants, where it is primarily triggered by persistent crying, it is rarely reported in formal studies. Moreover, primary caregivers, particularly mothers, may not perceive shaking as a form of punitive discipline, and maternal depression is often associated with their caregiving attitude toward children. Furthermore, notable functional variations are also observed in the parenting practices of low-income urban and rural mothers, often influenced by divergent socioeconomic and environmental factors.

Objective: This study aims to explore caregivers' use of shaking as a disciplinary practice with young children in lower-income urban and rural communities in Bangladesh and identify the underlying factors associated with this behavior.

Methods: This was a cross-sectional study in which we randomly interviewed 800 caregivers of children (aged <2 y) admitted to the hospitals of the International Centre for Diarrhoeal Disease Research, Bangladesh, in urban Dhaka (n=520, 65%) and rural Matlab (n=280, 35%). We collected detailed information on how they disciplined their young children (index children), with particular emphasis on shaking behavior. The questionnaires also explored perceived causes and common beliefs related to child shaking, in addition to collecting information on sociodemographic characteristics and caregivers' depression. All analyses were conducted using SPSS software.

Results: Child shaking was higher in lower-income communities of Dhaka compared to rural Matlab (n=265, 51% vs n=52, 19%; *P*<.001). Mothers, as the primary caregivers, mostly used shaking as a disciplinary practice with their young children (n=491, 61%). Overall, 27% (n=214) of primary caregivers reported ever shaking a child below 2 years; among these, 62% (n=133) reported shaking at least 3 to 5 times. Crying and fussing were the main triggering factors (Dhaka: n=107, 62% vs Matlab: n=26, 67%) for shaking behavior, particularly in infants aged younger than 6 months. Approximately 56.6% (n=99) of the mothers in Dhaka and 28.2% (n=11) of the mothers in Matlab believed that shaking was either definitely or probably harmless. Maternal depression was significantly correlated (adjusted odds ratio 1.03, 95% CI 1.01-1.04; *P*=.001) with shaking practices used by mothers.

Conclusions: Shaking young children as a form of discipline is quite prevalent in lower-income communities of Bangladesh, where poverty and other stressors are common. Caregivers are not fully aware of the harmful side effects of infant shaking. Positive parenting programs need to be strengthened to reduce these harmful behaviors toward children to support their developmental potential.

Introduction

Background

Shaking infants, commonly reported in Western countries, is a practice used by caregivers as a form of physical discipline or parenting for young infants and children. However, shaking can be the primary risk behavior for shaken baby syndrome (SBS) or abusive head trauma (AHT). Shaking infants or young children can cause a range of harms, from mild and transient effects to severe and potentially life-threatening injuries. Studies estimate that 10% to 12% of the infant deaths related to child abuse are attributable to SBS, with approximately 1 in 4 deaths due to grave injuries [1,2]. SBS is a severe form of child abuse caused by violent shaking, leading to brain injuries, such as subdural hematomas, diffuse axonal injury, and retinal hemorrhages, as well as fractures of the long bones or ribs, even when there might be little or no evidence of trauma [3]. Infants are particularly susceptible to injuries due to their anatomical and physiological characteristics, including a heavy head, weak neck muscles, a soft and rapidly growing brain, and a thin skull wall. With less control over their head and neck and limited mobility, they face an increased risk of permanent injuries. Globally, shaking is recognized as a common disciplinary act for children. In the United States, 2.6% of the parents of children aged younger than 2 years acknowledge shaking their child as an act of “discipline.” This indicates that the ratio of reported shaking to severe or fatal cases of SBS or AHT is 152:1 [4]. When data from 60 countries were analyzed, it was found to be 33% more common [5]. Despite the mortality rate for SBS and AHT ranging from 13% to 30% in high-income countries such as the United States [6-8] and Canada [9], its prevalence and long-term impacts in low- and middle-income countries (LMICs) remain underexplored. In Japan, the prevalence of self-reported shaking behavior at 1 month post partum was 16.8%, with caregivers continuing this behavior until the infants were aged 6 years [10]. Although several systematic reviews have been conducted on the impact and prevalence of SBS injuries in high-income countries, evidence from LMICs is unavailable. A parallel survey was conducted on parental child-discipline practices in 6 different countries that included a high-income country (the United States), upper–middle-income countries (Brazil and Chile), and lower–middle-income countries (Egypt, Philippines, and India). The study showed that almost half of the surveyed communities practiced shaking as a typical caregiving act, and more than 20% indicated using shaking to discipline their children before they were aged 2 years [11].

The consequences of such harsh punishments, particularly child shaking, are not well understood in LMICs, where poverty and other psychosocial stressors, such as violence, aggression, and caregivers’ depression, are quite common [12]. The long-term public health implications of child shaking remain largely unknown, emerging evidence suggests that it may contribute to the prevalence of learning disabilities and intellectual impairments in these settings [13]. Social and economic adversities may amplify the risks associated with such harsh caregiving practices, underscoring the need for further research and culturally appropriate interventions.

Common risk factors for the perpetrators of child shaking include an inability to cope with stress, poor impulse control, unrealistic child-rearing expectations, and rigid attitudes. In addition, caring for premature or high-needs infants may lead to heightened frustration, reduced tolerance, and resentment, increasing the likelihood of harmful responses [14]. In these situations, parents and caregivers often consider shaking to be less harmful than spanking. Environmental factors, such as low socioeconomic status, poverty, unemployment, low education, unsafe neighborhoods, poor prenatal care, single marital status, frequent moves, and the lack of social support, further compound the risk of infant shaking [15].

The long-term consequences of SBS are severe. Children exposed to SBS before the age of 2 years have exhibited developmental delays in 11% to 47% of the cases by the age of 5 years [16].

Objectives

Bangladesh, a densely populated, low-income country with more than 165 million people, is facing unique challenges in addressing harmful caregiving practices. In this study, we aimed to explore the descriptive epidemiology of caregiver-executed shaking behavior among young children residing in lower-income, resource-constrained urban and rural communities of Bangladesh.

The specific objectives of this study were to (1) estimate the overall burden of shaking in children aged between 0 and 24 months, (2) identify the common triggering factors for such behavior, and (3) understand caregivers’ descriptions of the act of shaking and their awareness of its potentially harmful effects.

Methods

Design

This cross-sectional survey was conducted among the mothers and other caregivers of children aged younger than 2 years who were admitted to the 2 big charity hospitals of the International Centre for Diarrhoeal Disease Research, Bangladesh. The 2 hospitals are situated in urban Dhaka and rural Matlab. Both hospitals primarily serve the economically disadvantaged surrounding communities. This study was conducted over 7 months, from June to December 2009. Children aged younger than 2 years with less severe diarrhea were enrolled in this study. We excluded all children who were critically ill (eg, children experiencing convulsions and those with tuberculosis, encephalitis, and meningitis) and those with obvious physical congenital anomalies or developmental abnormalities. Due to the variation in patient flow between the 2 hospitals, 2 interviewers at the Dhaka Hospital recruited up to 6 mother-child dyads per day (n=520), while one interviewer at Matlab Hospital recruited up to 3 dyads per day (n=280).

XSL•FO
RenderX

Measures

A questionnaire was adapted that included both open- and closed-ended items, designed to capture the experiences of caregivers with child discipline, specifically focusing on shaking behavior and their associated mental states, such as the extent of anger or frustration during these incidents.

A structured socioeconomic and demographic questionnaire was used to collect information on the number of family members, parental education and occupation, number of children aged younger than 5 years in the family, and the birth order of the index child. In addition, participants were asked about household income and expenditure balances over the previous months. The financial status of the families was classified into 4 categories: constant deficits, occasional deficits, balanced income, and surplus (excess of income over expenditure). The occupation categories were classified into 3 groups based on skill level and employment regularity: unskilled (eg, unemployed individuals and day laborers), low-skilled and irregular (eg, mechanics, electricians, and rickshaw pullers), and high-skilled job categories.

Questions on child discipline practices assessed whether the caregivers had ever disciplined their child and, if so, who else had been involved in the disciplinary process and what methods were used. *To capture caregiver-reported child-shaking behavior,* 5 *items were adapted* from the "Parent-Child Conflict Tactics Scale (CTSPC)" [17]. CTSPC includes subscales assessing various dimensions of the parent-child relationship, such as communication, power dynamics, discipline strategies, emotional expression, and relationship quality. Items are typically rated on a Likert-type scale (eg, from "never" to "always"), and subscale scores are calculated by summing the individual item responses.

The selected questions from this questionnaire included: (1) "Has anyone in the household ever shaken the child to discipline?" (2) "If yes, how many times in the past year or since birth was the child shaken?" and (3) "What was the mental status of the caregiver or others while they shook the baby?" Two additional items from a previous study were incorporated to assess contextual factors, assessed by the question, "What was the child doing right before you shook them?" and awareness of the potential consequences of shaking, assessed by the question, "Thinking about when you shook your child, did you think you might have hurt the child?" These items had previously been field-tested in the United States and other countries [11,17]. Maternal mental status and emotional well-being were assessed using 6 questions adapted from the Center for Epidemiological Studies Depression scale [5,18], which is widely used in community-based mental health research. In addition, caregiver-child interactions were assessed using the "Family Care Indicators," developed by the United Nations Children's Fund [19], which measure the frequency and type of stimulation and engagement provided by caregivers.

Data Collection

Once the children were settled after hospital admission and had received initial management, a trained interviewer briefed the caregivers about the project and built rapport. The interviewers were university graduates with previous experience in child health–related research. Informed written consent (signature or fingerprint) was obtained from the caregiver who agreed to participate in the study. Care was taken to organize the questionnaire to minimize the likelihood of caregivers feeling guilty, ashamed, or offended when responding to questions about shaking. For example, caregivers were first informed about common parental habits for disciplining their children. Then they were asked whether they had ever disciplined their children and, if so, how. The conversation was gradually guided to include shaking as one possible disciplinary behavior, after which the interviewer asked whether they had ever shaken their child as a form of discipline. Typical shaking was described as "back and forth" shaking, as used in the CTSPC. If the interviewers were convinced that a shaking incident was being described, additional details were collected. However, "mild" shaking, such as soothing, rocking, or tossing the child up in the air, was not counted as "typical shaking." The interviews were conducted in a private location in the ward, and the caregivers were offered snacks. One designated health worker or attendant looked after the child during the interview. The collected data were cross-checked by the supervisors on the day of the interview or the following day for any inconsistencies or missing information before data entry.

Analysis

Data were analyzed using SPSS software for Windows (version 20.0, IBM Corp). A simple descriptive analysis was conducted for this pilot study. Frequency distributions of all the items in the questionnaire were determined. The dichotomous "yes or no" information on whether the child had ever been shaken was calculated by combining the shaking histories reported by the primary caregiver and other family members. Sometimes a child was shaken, either by a caregiver or other family members, in the past year or since birth (if aged <1 year), and these instances were combined to calculate the total number of times the child had been shaken by someone. This variable was not normally distributed. Therefore, the Spearman correlation was conducted separately for the urban (n=520) and the rural (n=280) samples to examine the associations between various sociodemographic and maternal factors and the frequency of shaking the index child. An independent sample 2-tailed *t* test was conducted to compare the populations of the urban and rural areas. Finally, multiple logistic regression was computed to examine the factors associated with shaking as a disciplinary practice with young children. The model considered the following covariates in the analysis: family members (ie, number of persons eating from the same pot), number of children aged younger than 5 years in the household, family income-expenditure deficit, maternal depression, and geographic location (urban and rural). All statistical tests were performed using 2-tailed *t* tests.

Ethical Considerations

The institutional review board at the International Centre for Diarrhoeal Disease Research, Bangladesh, reviewed and approved this study (2009-007). We obtained verbal informed consent from all parents, and the principles of confidentiality and anonymity were upheld throughout the study. All participants were informed in Bengali about their rights

XSL•FO
RenderX

regarding voluntary participation and their freedom to withdraw from the interview at any point during the process.

Results

Description of the Population

A total of 800 mother-child dyads were enrolled from both hospitals (Dhaka: n=520, 65%; Matlab: n=280, 35%). Almost all (n=786, 98.3%) of the caregivers were biological mothers of the index children. A significantly higher proportion of fathers in rural areas were engaged in unskilled occupations compared to their urban counterparts (n=34, 10% vs n=45, 18%; *P*=.04). Multimedia Appendix 1 presents the socioeconomic, maternal, and child characteristics of the study populations. In addition, rural families tended to be slightly larger, and the fathers in these areas reported lower household incomes relative to those in urban settings. Across both groups, the mothers generally had a low level of educational attainment, reflecting limited access to formal education in these lower-income communities.

Approximately 15% (n=78) of the urban mothers and 19% (n=53) of the rural mothers completed education beyond high school. Although the mothers in the rural area were significantly better educated than their urban counterparts, they were more likely to be housewives. Approximately 29% (n=151) of the urban fathers and 30% (n=85) of the rural fathers studied beyond high school. Despite the urban-rural differences in living conditions, the monthly income and expenditure balances were not significantly different between the 2 groups. The percentage of mothers with higher depression scores (ie, median >25) was similar in both urban and rural contexts. A higher number of male children were admitted to and enrolled from the rural Matlab hospital than from the urban Dhaka hospital during the study period.

Shaking Practices in the Communities

In response to the question whether the child had ever been shaken to discipline them by anyone, 51% (n=265) of the respondents in Dhaka and 21% (n=60) of the respondents in Matlab hospital said “yes,” and the percentage was significantly higher (*P*<.001) in the lower-income urban communities of Dhaka compared to rural Matlab. The median number of shaking episodes reported in the past year was 5 (IQR 3-7) in Dhaka and 4 (IQR 2-7) in Matlab.

Responses to the question “How many times in the past year [or since birth if aged <1 year] have you shaken the child?” are illustrated in Multimedia Appendix 2, according to the percentage of children in different age groups who were shaken in Dhaka and Matlab.

Factors Triggering Shaking

To identify the source of disturbances that triggered shaking behavior, whether originating from the child or the caregiver, we asked specific questions to the caregivers. In most cases, caregivers reported that the shaking was triggered by the child’s behavior: 50.6% (n=134) in Dhaka and 18.3% (n=11) in Matlab. However, 12% (n=32) of the caregivers in Dhaka and 50% (n=30 in Matlab reported that there was no provocation from the child; rather, they were disturbed and stressed for some other familial reasons and expressed their frustrations by shaking the child.

When we asked about specific activities of a child that elicited shaking behavior, caregivers from both Dhaka and Matlab reported that crying and fussing were the most common triggers (n=133, 62.4%) for shaking, particularly in infants approximately aged 6 months (Multimedia Appendix 3). Disruptive behavior of children during feeding (eg, not eating and throwing food) and playing (eg, hitting other children or making a mess) also appeared to be important triggers.

Persons Involved in Shaking Behavior

In these communities, children’s biological mothers, as the primary caregivers, shook their children the most (Multimedia Appendix 4). Approximately 43% (n=113) of the mothers in urban Dhaka and 60% (n=36) of the mothers in rural Matlab acknowledged that they were the only caregivers who shook the child. Sometimes more than 1 caregiver shook the child (n=77, 29.1% of the cases in Dhaka vs n=4, 6.7% of the cases in Matlab), and in most cases, these caregivers were fathers, grandparents, older siblings, or neighbors, along with the mothers.

A comparatively smaller proportion of biological fathers reported shaking their children: only 8% (n=21) in Dhaka and 5% (n=3) in Matlab. In Dhaka, 20% (n=54) of the children were shaken by nonparent caregivers; among them, 14% (n=37) were siblings, cousins, neighbors, and housemaids, 4% (n=12) were aunts and 2% (n=5) were grandmothers. Similarly, in Matlab, 28% (n=17) of the children were shaken by nonparent caregivers; among them, 10% (n=6) were siblings, 17% (n=10) were aunts, and 2% (n=1) were grandmothers.

Caregivers’ Beliefs Regarding Child Shaking Behavior

When caregivers were asked about their beliefs regarding shaking, 56.6% (n=85) of the mothers in Dhaka and 28.2% (n=10) of the mothers in Matlab stated that they considered shaking to be harmless for children (Multimedia Appendix 5).

Factors Associated with Shaking

Finally, to identify the factors associated with shaking as a disciplinary practice in young children, we conducted a multiple logistic regression analysis (Multimedia Appendix 6). The variables included were age and sex of child, parental education (ie, years of schooling), parental occupation, and total number of family members. After adjusting for potential covariates, child age in months was significantly associated with increased odds of being shaken (adjusted odds ratio [AOR] 1.06, 95% CI 1.02-1.10; *P*=.001), showing that older children were more likely to be subjected to this form of discipline. No significant associations were found for child sex, parental occupation, family size, number of children, and parental education. Although male children had higher odds of being shaken compared to female children (AOR 1.13, 95% CI 0.83-1.55; *P*=.44), the association was not statistically significant. Similarly, low-skilled paternal occupation (AOR 1.07, 95% CI 0.75-1.51; *P*=.72) and maternal housewife status (AOR 1.23, 95% CI 0.77-1.98; *P*=.39) were not statistically significant predictors. However, maternal depressive symptoms were

XSL•FO
RenderX

positively associated with shaking behavior; each 1-point increase in the depression score was associated with a 3% increase in the odds of shaking (AOR 1.03, 95% CI 1.01-1.04; *P*=.001). In addition, children residing in Dhaka had significantly higher odds (5 times more) of being shaken compared to those in Matlab (AOR 5.32, 95% CI 3.62-7.82; *P*<.001).

Discussion

Principal Findings

The practice of shaking as a form of disciplining children, particularly those aged between 6 and 12 months, was found to be unexpectedly high in lower-income rural and urban households. Around 27% (n=214) of the primary caregivers (mothers) of the children surveyed had practiced it. This study was designed to document the occurrence of shaking and not its severity.

One possible explanation for the high prevalence of caregiver-reported shaking behavior among those aged between 6 and 12 months is the increased caregiving demands during this developmental period, including heightened crying, mobility, and feeding difficulties. Children require more attention and care during this critical time as they transition to complementary feeding; learn new developmental skills, such as motor activities (eg, crawling and sitting); and begin to explore their surroundings. Moreover, infants at this age experience frequent illnesses (eg, diarrhea, respiratory infections, and fever) due to the waning of maternally acquired immunity and increased exposure to infectious agents. Consequently, caregivers become increasingly anxious and stressed, which can contribute to “shaking” as a response to perceived child distress or behavioral challenges. Unlike studies from high-income countries, shaking behavior does not appear to be prevalent during early infancy (ie, aged <6 months). One explanation could be the culture and social structure that exists between neighboring families in Bangladesh. Families in these communities tend to live closely together, offer mutual support, and form very intimate bonds. Such connections may serve as a buffer against caregiver stress during the first months of childcare. In rural Matlab, 3 to 5 households share a common courtyard [20], and in Dhaka slums, as many as 8 to 10 individuals share a 1-room dwelling [21]. Thus, there are several household members available to help with childcare during the early months.

The peak prevalence of shaking is similar in urban and rural households, although the practice was significantly higher in the slums of Dhaka city. Both groups have experienced extreme poverty, but there are important differences as well. Urban mothers are more likely to be wage earners and have a higher level of education. Unlike in other LMICs, where maternal education had a negative correlation with shaking behavior [22], we found no significant association between maternal education and shaking practices, although it was higher in urban mothers. However, maternal depressive symptoms showed a significant association with shaking practices for disciplining [23]. This indicates the importance of maternal mental well-being as the primary caregiver.

Similar to other studies, we found crying and fussing to be common triggering factors for shaking, particularly in young children. However, the timing of crying is outside the normal cry curve, which peaks at around 3 months of age in high-income countries [24]. Among 33 infants aged younger than 3 months, only 4 (12%) in Dhaka and none in Matlab experienced shaking.

We also tried to assess the mental status of the caregivers during shaking by asking questions about how frustrated or angry they were and why. Approximately 50% (n=162) of the mothers reported that they were disturbed or frustrated at the time of their last shaking episode due to different reasons (eg, a quarrel with their husband or mother-in-law). In our study, depression was positively correlated with the shaking behavior of mothers.

According to one study in Ethiopia, female primary caregivers were significantly associated with a higher use of harsh physical punishment compared to male caregivers [23]. We found female caregivers (eg, mothers, aunts, sisters, and grandmothers) to be the main perpetrators of shaking behavior. This contrasts with studies published from high-income countries, where in 65% to 90% of the cases, young male individuals—either the baby’s father or the mother’s boyfriend—are the main perpetrators [25]. This could be due to the cultural norms in this part of the world, where mothers and other female relatives are expected to look after children at an early age.

However, consistent with studies from many other countries, half (n=85, 56.6%) of the mothers in Dhaka hospital and a third (n=10, 28.2 %) of the mothers in Matlab believed that infant shaking is harmless. Interestingly, when we interviewed mothers to learn how they discipline their children, not a single mother spontaneously mentioned shaking as a disciplining behavior. However, when asked specifically whether they shook their child for discipline, they reported that they did so sometimes. This indicates that, culturally, shaking is not considered a very dangerous or cruel behavior in child-rearing in Bangladesh.

In general, this pilot study aimed to explore the prevalence of shaking behavior among caregivers toward their young children residing in lower-income communities as well as the possible biological and sociodemographic factors associated with it. We collected information from the aforementioned 2 popular diarrhea hospitals because a large number of people from lower-income communities with mild to moderate illnesses are admitted to these hospitals. Therefore, selecting cases from these hospitals allowed us to estimate the prevalence of shaking in lower-income, stressed, and vulnerable communities of urban and rural Bangladesh.

Limitations

Our main limitation was the selection of a biased sample of mothers of children who were hospitalized with illness. To minimize this, we included only the mothers of children with less severe illness who were admitted to longer-stay units, so that after settling their children, they could talk to us. Most of the reported studies on infant shaking interviewed mothers of children diagnosed with SBS and thus were easier to interpret. Here, based on the mother’s report, we do not know how severe the shaking was and whether it impacted the child. The report

XSL•FO
RenderX

of maternal depression was also confounded by the concurrent illnesses of the children.

Apart from these limitations, this quick exploratory study on 720 participants revealed the context of infant-shaking behavior in an LMIC such as Bangladesh. The key observations were that shaking behavior exists in lower-income communities in Bangladesh and is alarmingly high, but the patterns are different from those reported in high-income countries. The age range for children who were shaken is different from that in the Western context, as shaking occurs when children are slightly older. Although similar to other countries, crying and fussing triggered shaking behavior in most cases; this does not fall within the normal crying curve of infants aged 2 to 3 months. Mothers are the main perpetrators of infant shaking because of their frequent contact with children, and in many cases, they are unaware of the hazardous outcomes.

Furthermore, qualitative and quantitative studies are needed to determine the actual burden of this problem. In Bangladesh, child abuse and neglect are becoming a growing concern [26]. A screening program on 2576 children in Bangladesh showed that up to 70% of the children are living with mild to moderate disabilities [27]. It is also important to examine the relationship between early shaking and future child development in low-income countries to understand the long-term consequences of infant shaking and the resulting social and public health burden.

Comparison with Prior Work

There has been no study conducted in Bangladesh with which we can compare our results.

Conclusions

This study provides insights into the differences in disciplinary acts experienced by children from their caregivers in 2 types of communities in Bangladesh. We recommend more research on this topic, considering cultural beliefs or social practices. It is very important to examine the association between shaking behavior and child development. In addition, we found that maternal depression was correlated with certain disciplining practices, which, as we hypothesize, may affect child development. Children living in lower-income urban communities are more prone to these practices. However, the long-term effects of disciplining children through shaking practices are still unknown. We need to help parents understand how such behavior impacts their children. As the world shifts into a new era, some social aspects of raising children need to be revised for the betterment of society.

Acknowledgments

I extend my heartfelt gratitude to Centre for Community Child Health Research of the Child and Family Research Institute, and BC Children's Hospital, Canada for their generous financial assistance. I am also grateful to Dr Hasanat Alamgir (Simon Fraser University) and Dr Charles Larson (British Columbia Children's Hospital, Canada) for their invaluable support throughout this work. My sincere thanks go to Dr Ron Barr (Department of Pediatrics, UBC Faculty of Medicine, Canada), and Drs Adam J Zolotor and Desmond K Runyan (The University of North Carolina, USA) for their extensive guidance and technical support. Great appreciation to Nur-E Salveen, Goutam Kumar Dutta, Mahbub Elahi, Sk Rafia Islam Mitu, and Kaniz Fatima for their support in preparing the manuscript. The author is grateful to the study participants who gave their valuable time and information for this research. icddr,b is also grateful to the Governments of Bangladesh and Canada for providing core/unrestricted support.

Abstract

Background: Excessive infant crying affects approximately 20% of families and can lead to parental distress, anxiety, and strained relationships. Despite its prevalence, many parents report feeling misunderstood and unsupported during these challenging periods.

Objective: This study aimed to gain in-depth insight into mothers' perceptions of being understood and supported in the context of excessive infant crying, focusing on three key stakeholder groups: partners, the personal network, and health care professionals. Based on these results, the study sought to develop a maternal support framework regarding excessive crying that could guide future research and practice, as well as support strategies.

Methods: Using a qualitative approach supplemented by quantitative measures, through an online survey, three open-ended questions were included on how mothers would like to be understood and supported by the three stakeholder groups (ideal situation) and six 6-point Likert scales on mothers' current perceived understanding and support regarding the three stakeholder groups (current situation). Descriptive statistics were used to examine current levels of understanding and support, and an inductive thematic analysis was applied to identify the ideal key support elements.

Results: Data were collected from 432 mothers (n=238, 55.1% Dutch; n=194, 44.9% Flemish; mean age 33 years, range 21-45 years). Regarding the current situation, mothers rated health care professionals lowest in perceived understanding and support, with 50.6% (n=219) feeling little or no understanding and 47.1% (n=203) reporting little or no support. Similar patterns were found in the personal network (n=184, 42.6%, and n=164, 38%, respectively). Partners were perceived as most supportive, with only 17.6% (n=76) of mothers reporting little or no understanding and 21.8% (n=94) reporting little or no support. Based on the thematic analysis of the qualitative data, the ideal situation was framed in the newly developed maternal support framework. This framework identifies 25 distinct support forms, of which 12 (48%) are common support forms (partner, personal network, health care professionals, eg, listen actively), 6 (24%) are related to partners (eg, be physically present), 6 (24%) concern the support of health care professionals (eg, refer appropriately), and 1 (4%) is specific to the personal network (cope with the crying).

Conclusions: This study underscores the need for holistic, family-centered approaches to supporting families with excessively crying infants. The proposed maternal support framework offers a foundation for developing tailored interventions that reflect the diverse roles of partners, personal networks, and health care professionals in maternal well-being.

KEYWORDS

excessive crying; infant; maternal support; parental distress; framework; maternal support framework

Introduction

Infant crying is an essential aspect of early development, serving as the primary mode of communication during the first months of life [1,2]. Although crying is typical behavior, it becomes a concern when approximately 20% of infants exhibit excessive crying [3]. Traditionally, excessive crying has been defined using objective criteria, such as Wessel's rule of threes (crying for at least 2 hours per day, 3 days per week, for 3 consecutive weeks [4]), and, more recently, the ROME-IV criteria (recurrent, unexplained crying or irritability in infants under 5 months old that cannot be soothed by caregivers [5]). Although ROME-IV incorporates caregiver reports, its focus remains on observable infant behavior and colic specifically, offering limited attention to parental distress or the broader psychosocial context. Recent research emphasizes the limitations of such symptom-based classifications, highlighting the need to consider parents' subjective experiences, such as stress and helplessness [6,7]. Indeed, Reijneveld et al [7] emphasize the importance of definitions that integrate both crying duration and the distress experienced by parents. Additionally, some researchers distinguish between "excessive crying," which is based on parents' subjective perception that their baby cries too much and signals a potential problem, and "prolonged crying," which refers to a measurable duration [8]. This dual perspective highlights the growing recognition of parental perceptions and the intricate interplay between infant behavior and parental mental health. This is a positive development, as it underscores the importance of adopting a biopsychosocial perspective and approach to excessive crying [9], particularly given that a medical cause is identified in fewer than 5% of cases [1].

The experience of having an excessively crying infant can profoundly affect parents, leading to heightened levels of distress, anxiety, and depression, as well as difficulties bonding with their child [3,6,10-12]. These psychological challenges are often compounded by practical issues, such as early cessation of breast feeding, overfeeding, and, in some cases, long-term developmental risks for the infant. Although more research is still needed on the long-term consequences of excessive crying, excessively crying infants seem to be at increased risk of developing psychological, behavioral, and allergic disorders. In addition, there might be a higher incidence of headache and migraine later in life in children who cry excessively [13]. In severe instances, excessive crying might also increase the risk of shaken infant syndrome [9-11,14]. These far-reaching effects underline the necessity of addressing excessive crying, not merely as an infant issue, but also as a family-centered concern that prioritizes the well-being of parents [6].

A qualitative study by Garratt et al [6] explored UK parents' experiences of having an excessively crying baby. Their study showed that parents often have disrupted expectations and experiences of parenthood, perceive stigma and social isolation, and seek support and validation of their experience [6]. This sense of isolation is further amplified by dissatisfaction with health care; research shows that 55% of the participating Dutch mothers in a study by van der Veek et al [15] felt that they received inadequate information about their infant's crying and available health care support. Therefore, proactively providing comprehensive information during pregnancy or shortly after birth might better equip parents to manage the challenges associated with excessive crying [6]. In the same vein, Harskamp et al [16] explored the types and format of health care support parents with excessively crying infants need. They identified four key themes: (1) the need for confidence in health care professionals, (2) the need to investigate potential somatic causes of crying, (3) the need for acknowledgment of their baby's crying, and (4) the need for support to break the cycle of exhaustion and self-doubt [16]. These findings underscore the importance of holistic, family-centered care that addresses not only the crying itself but also the emotional and practical challenges faced by parents. Providing tailored support is essential for preventing cascading difficulties and fostering positive parent-infant interactions [17].

Even though health care professionals are thus critical in providing support and care for parents with an excessively crying baby, an integrative approach involving the entire support system of parents with an excessively crying baby is essential. Moreover, existing research often isolates specific aspects of excessive crying, such as health care interventions, for example, manual therapy [18,19], probiotics [20], parental coping [6], or soothing techniques (eg, swaddling [21]). Furthermore, studies on excessive crying are often small in scale, and an integrative care framework for parents with excessively crying infants is lacking.

To optimally identify the needs of parents with excessively crying infants, it is crucial to assess both their current experiences and their perceptions of an ideal support situation. Previous research has shown that mothers often feel they are not taken seriously or that the severity of their situation is not adequately understood or acknowledged [15]. Additionally, receiving insufficient or inadequate support has been highlighted as a key issue by van der Veek et al [15]. Importantly, being understood and receiving support represent two distinct but interrelated needs for families facing excessive infant crying. Building on this, this survey study investigated mothers' perceived understanding and support from their partners, personal networks, and health care professionals (current situation). Moreover, building on the needs for support expressed by mothers (ideal situation), this study aimed to develop a comprehensive conceptual framework—the maternal support framework—that can serve as a foundation for future research and interventions designed to support families with excessively crying babies.

Methods

Sample

Recruitment began in January 2024. Using a cluster sampling technique, invitations to participate were distributed via specific Facebook groups for parents, such as "Mama's," "Mama's onder

XSL•FO
RenderX

elkaar," and "Onder mama's." Additionally, invitations were also shared in more specialized groups focusing on excessively crying infants, such as "Reflux Baby," "Crying Baby Parents," "Crying Baby Support Center," and similar communities. A link was available to participate in the study. The relatively homogeneous sample, including only mothers who had experienced having a crying baby themselves (without a specific quantification of the crying amount, as our main focus was on parental perception) allowed for an in-depth exploration of the phenomenon of excessive crying and, more specifically, parents' perceptions of understanding and support during this life phase. Although there is no gold standard for determining the sample size in qualitative research, we aimed to recruit and collect data until we reached data saturation. However, 432 participants completed the survey within a week, which could be seen as an exceptional response rate, so we decided to include all data, thereby further strengthening the validity of the study.

Ethical Considerations

When interested mothers wanted to participate, they could click an anonymous link that directed them to a questionnaire. The study received approval from the Ethics Committee of Ghent University (reference number: 2023-141W). Prior to commencement of the questionnaire survey, written informed consent was obtained from all participants after providing them with comprehensive information about the study goals, study flow, etc. Additionally, participants acknowledged a privacy statement at the beginning of the questionnaire, which provided comprehensive information regarding General Data Protection Regulation (GDPR) compliance and the handling of their data. No incentives were provided. A brief overview of the sample can be found in the *Results* section.

Data Collection

A questionnaire was developed in Qualtrics. The questionnaire was based on previous research indicating a gap in knowledge about the perceived understanding and support of mothers' direct environment (partners, personal networks, and health care professionals). First, the invitation was posted in the aforementioned Facebook groups to test the questionnaire and ensure the questions are clear. Three mothers pilot-tested the questionnaire using a think-aloud procedure where they could write down their concerns regarding the questions. However, no ambiguities was identified, as expected, as the questions were straightforward and concise. Therefore, the final questionnaire consisted of 11 questions that were a combination of qualitative and quantitative measures. Nine items concerned perceptions of the current (six items) and the ideal (three items) situation, one item was an open-ended question on which health care professionals they consulted during this period, and one item was on the general daily duration of crying. Participants were included based on maternal characteristics—specifically, having experienced a baby who cried excessively at the time of the study or in the past.

Qualitative Measures

To encourage deep insights and strengthen our qualitative research approach by data triangulation, a combination of open-ended questions and Likert scales was used. The qualitative part existed of asking participants how they wanted to be understood and supported by each of the groups (partners, personal networks, and health care professionals in general=ideal situation). Finally, they were asked which health care professionals they consulted during this period.

Quantitative Measures

In addition to answering the open-ended questions, participants scored six Likert scales that assessed their perceptions (current situation) of understanding (three questions) and support (three questions) from their (1) partners, (2) personal networks (parents, grandparents, friends, colleagues, etc), and (3) consulted health care professionals (health care disciplines not specified). These questions used a 6-point Likert scale with the following verbal anchors: perfect (1), very good (2), good (3), fair (4), poor (5), and none (6). The use of these verbal anchors avoids numeric values and clearly defines the scale in verbal terms. We chose 6 points to prevent consistently selecting the neutral midpoint [22-25]. Finally, a scale with predefined time categories (in hours) was used to assess the duration of crying in different parts of the day as part of the demographic data. The complete questionnaire can be found in Multimedia Appendix 1.

Data Analysis

This study used a qualitative research approach (open-ended questions) supplemented by quantitative measures (Likert scales).

Qualitative Measures

Open-ended questions that explored how participants wished to be supported and understood were analyzed using an inductive content analysis approach in NVivo [26]. Given the exploratory nature of the study and the straightforward structure of the data, a single experienced coder conducted the initial coding. Thereby, the data were first thoroughly read multiple times to gain a deep understanding of the content. Following this, the organizing process began, which included open coding, theme development, and abstraction [27]. The final phase of abstraction involved creating overarching concepts. Afterward, an independent reviewer examined the themes to eliminate ambiguity, overlap, and potential misinterpretations, thereby enhancing credibility and reducing potential bias. This approach ensured a balance between analytical consistency and critical validation. Additionally, the frequency with which each theme emerged in the data was calculated to assess how well the integration of themes resonated with participants. This approach allowed for an estimation of the importance and prevalence of the identified themes, ultimately contributing to the development of a framework for the overarching concept of "care for parents with an excessively crying baby," referred to as the maternal support framework [28].

Quantitative Measures

Analysis of the Likert scales involved descriptive statistics to calculate frequencies, as well as minimum, maximum, and mean values.

Results

Participant Details

A total of 432 mothers fully completed the questionnaire. Of these, 55.1% (n=238) resided in the Netherlands, while 44.9% (n=194) were from Flanders (Belgium). Additionally, 0.5% (n=2) of the participants reported living in other countries, specifically France or Italy. The average age of the participants was 33 years (range 21-45). The number of children per participant varied from 1 to 5, with a mean of 1.77 children per parent.

Descriptive analyses showed that the 432 participating mothers consulted a total of 1111 different health care professionals at least once during the period their baby cried excessively. On average, each mother consulted 2.7 health care professionals due to their infant's excessive crying. These health care professionals included pediatricians, general practitioners, midwives, child health nurses, osteopaths, pharmacists, physiotherapists, psychologists, chiropractors, dentists, radiologists, parenting coaches, lactation consultants, surgeons, dietitians, and occupational therapists. The most frequently consulted health care professionals were pediatricians (305/408, 74.8%, mothers), general practitioners (212/408, 52%, mothers), child health nurses (153/408, 37.5%, mothers), osteopaths (121/408, 29.7%, mothers), and midwives (112/408, 27.5%, mothers). Table 1 provides a detailed overview of consulted health care professionals and the number of mothers who consulted them.

Excessive crying, on average, began approximately 2 weeks and 1 day after birth. Parents reported that they typically noticed their baby's crying was above average around 4 weeks and 2 days after birth. Participants estimated that their babies cried for nearly 12 hours (mean 11.97 hours, SD 5.2) each day, with the most significant crying occurring in the evening, averaging 6.6 hours (SD 5.3). This was followed by crying in the afternoon, which averaged 5.5 hours (SD 5), while mornings saw the least crying, averaging about 4.4 hours (SD 4.7).

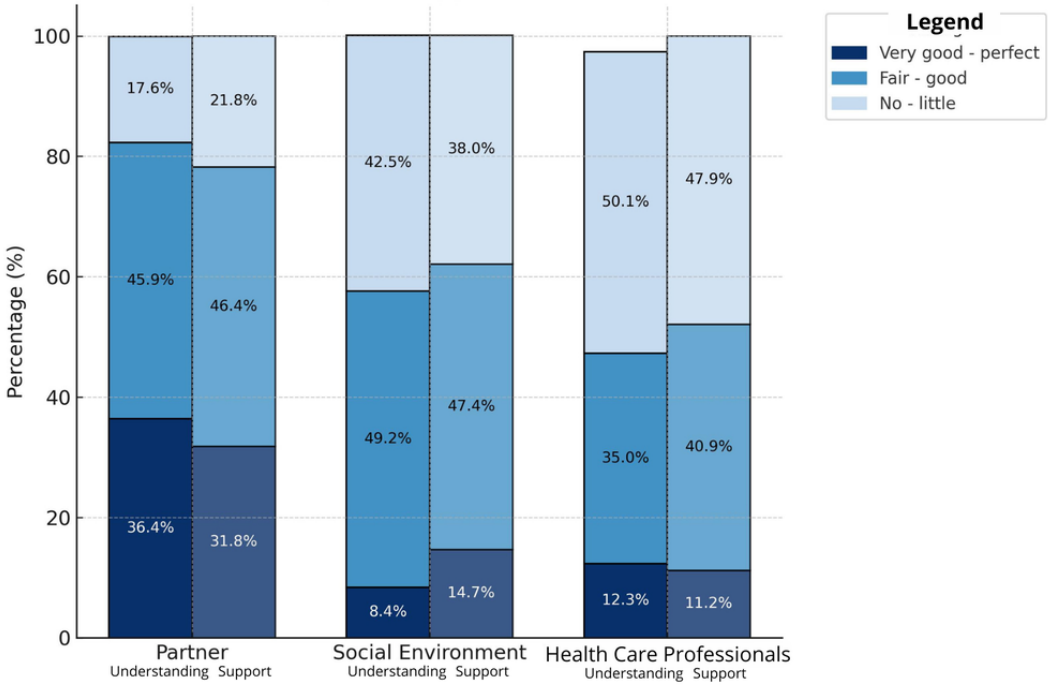
Table 1. Overview of consulted health care professionals (N=1111).



Health care professionals	Mothers (N=432), n (%)
Missing (participant did not specify consulted health care professionals)	24 (5.6)
None	1 (0.2)
Pediatrician	305 (70.6)
General practitioner	212 (49.1)
Child health nurse: *Kind en Gezin* (Belgium) or *Consultatiebureau* (the Netherlands)	153 (35.4)
Osteopath	121 (28.0)
Midwife	112 (25.9)
Child physiotherapist	31 (7.2)
Other alternative medicine practitioner (eg, homeopath, acupuncturist)	27 (6.3)
Emergency doctor	23 (5.3)
Lactation consultant	22 (5.1)
Psychologist	22 (5.1)
Chiropractor	12 (2.8)
Dietitian	9 (2.1)
Manual therapist	6 (1.4)
Allergist	6 (1.4)
Baby therapist	5 (1.2)
Sleep coach	5 (1.2)
Manual therapist	5 (1.2)
Nurse	5 (1.2)
Foot reflexologist	5 (1.2)
Speech therapist	5 (1.2)
Dermatologist	3 (0.7)
Ear, nose, and throat specialist	3 (0.7)
Mesologist	3 (0.7)
Neurologist	2 (0.5)
Dentist	2 (0.5)
Psychiatrist	2 (0.5)
Pedagogue	2 (0.5)
Neonatologist	1 (0.2)
Orthomolecular therapist	1 (0.2)

Current Situation of Understanding and Support

Based on the quantitative measures, mothers' perception of understanding and support from *health care professionals* was the lowest, with a score of 4.4 and 4.3, respectively, on a 6-point Likert scale (ranging from 1=perfect understanding/support to 6=no understanding/support). Half of the parents (n=216, 50%) felt they perceived no to little understanding from their health care professionals. The same was seen for perceived support, where 47% (n=203) of the parents felt they perceived little to no support. However, it is important to note that no differentiation was made among the health care professionals involved. The results therefore offer a general overview of health care professionals as a whole. Although parents' perceptions of understanding and support from health care professionals were the lowest, there is also room for improvement in the understanding and support from parents' partners and personal networks. A large group of parents reported receiving little to no understanding (n=76, 17.6%; mean=3.1/6) and support (n=94, 21.8%; mean score=3.3/6) from their *partners*, as well as little to no understanding (n=184, 42.6%; mean score=4.2/6) and support (n=164, 38%; mean score=4/6) from their *personal networks*. An overview can be found in Figure 1.

XSL•FO

Figure 1. Visualization of mothers' perceptions.

Ideal Situation of Understanding and Support

Of the 432 participants, 423 (97.2%) responded to the open-ended questions about how they want understanding and support from their partners, personal networks, and health care professionals to be improved. It was striking that when people were asked to name their needs, they tended to focus not on their active needs but rather on negative experiences in which their needs had not been met. These narratives shed light on the unmet expectations and frustrations of mothers navigating the challenges of excessive infant crying. For example, one mother shared:

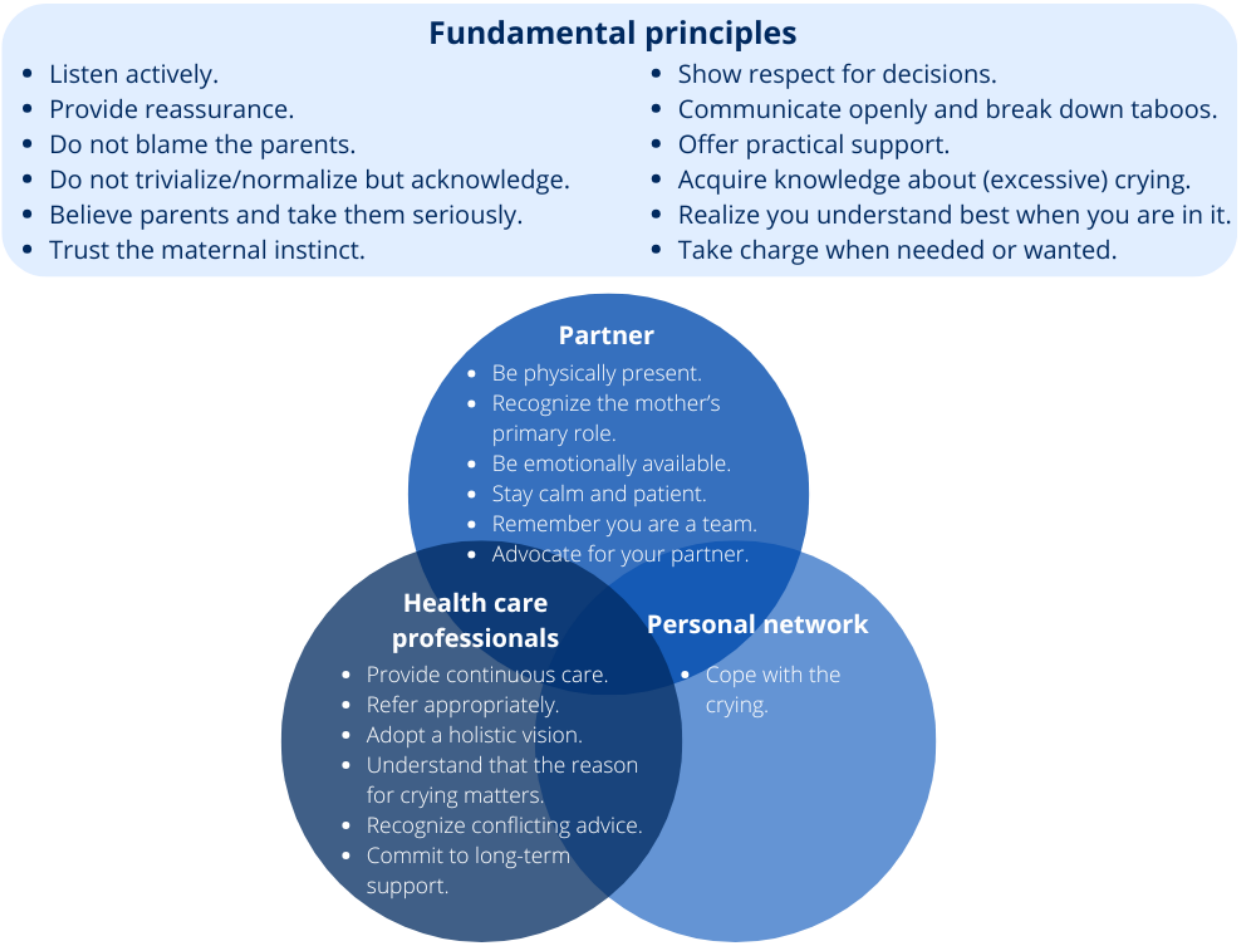
> *I wish certain people would have acknowledged it. And that they wouldn't accuse me of keeping my child away from family while I was acting in my child's best interest, and they were unwilling to adapt.* [The Netherlands, 29 years old, consulted a general practitioner, a child health nurse, a pediatrician, and a dermatologist]

Another mother noted:

> *They dismissed me as a young mom, ignorant, first child, and all that.* [Belgium, 26 years old, consulted several pediatricians and general practitioners]

These experiences, although painful, were crucial in identifying the gaps in support and helped shape the themes and subthemes, after which the overarching themes were transformed to support forms. Overall, the findings revealed that although some forms of support were shared across groups and incorporated as fundamental principles, others were more specific to the roles of partners, personal networks, or health care professionals. These forms of support were integrated through an in-depth analysis into the maternal support framework presented in Figure 2.

A total of 25 support forms or themes were identified, of which 12 (48%) were common across all three groups and were therefore labeled as *fundamental principles*, such as "communicate openly and break down taboos." A participant's quote below emphasizes the taboo around admitting struggles during early parenthood while she points out a lack of support options:



> *It's a shame that there is still so much taboo around this, and that having a baby is still expected to be mostly "joyful," while in reality, when you truly talk to people, you realize that many parents struggle and that for a lot of them, their "cloud" is more gray than pink. It's also frustrating that society expects you to be back at work three months after giving birth, functioning just as before—whether you have a high-needs baby, sleep deprivation, or not. Additionally, there are very few support options or places where you can seek help for yourself and your baby. You can talk to a psychologist, but even there, waiting lists are always an issue.* [Belgium, 35 years old, consulted a midwife, a general practitioner, and a psychologist]

Another lamented the lack of acknowledgment of their struggles:

> *Since the baby was growing well, there was no problem. My own struggles were not acknowledged.* [Belgium, 38 years old, consulted a pediatrician]

XSL•FO
RenderX

Figure 2. Maternal support framework.

Although many support forms were shared across groups (fundamental principles), some were specific to particular groups. For example, mothers expressed distinct expectations from their *partners*, such as "stay calm and patient" and "remember you are a team." This resulted in the development of six specific partner support forms. One mother recounted:

> *My partner had no patience with our crying baby. It frustrated him a lot, and he took it out on me. It would have been really helpful if he could have stepped in with patience and acceptance sometimes.* [The Netherlands, 29 years old, consulted a child health clinic]

Another mother highlighted the value of teamwork, stating:

> *My partner and I have really been a team during this challenging time. He has pulled me through, and I have done the same for him.* [The Netherlands, 27 years old, consulted a child health clinic, a general practitioner, and a pediatrician]

These accounts underscore the critical role of partners in alleviating the mental and emotional burden of excessive infant crying.

Similarly, the support forms directed at *health care professionals* were particularly distinct, with six support forms specific to this group, for example, "provide continuous care" and "refer appropriately." One mother expressed frustration, saying:

> *It is important that these parents feel heard. Don't let them struggle on their own. I only realized later that my baby was a high-needs baby, even though I had asked the consultation clinic for help so many times. I felt so alone. It turned out that our hospital had a special clinic for crying babies—they probably could have helped much sooner. This might have spared me from depression.* [The Netherlands, 37 years old, consulted a general practitioner and a pediatrician "too late"]

These examples highlight the need for health care professionals to go beyond surface-level assessments and consider both parents' and infants' physical and emotional well-being.

The *personal network*, although less distinctive and showing more overlap with the other support forms, is also a critical source of either comfort or frustration. The most important theme related to the personal network that distinguished itself from the other two groups was to cope with crying. This was illustrated, for example, in the following quote:

> *When they came to visit and saw that he wouldn't stop crying, they often couldn't leave fast enough.* [Belgium, 38 years old, consulted a midwife, a pediatrician, and a general practitioner]

However, concerning their personal networks, mothers also called for several fundamental principles such as "offer practical support." For example, one mother shared:

XSL•FO
RenderX

> *Avoid giving generic advice—just listening is enough. Offer to watch the baby for a few hours so they can recharge, take over household chores, or prepare dinner.* [Belgium, 28 years old, consulted a general practitioner, a pediatrician, an osteopath, a homeopath, and a physiotherapist]

Discussion

Principal Findings

This study, using a qualitative approach supplemented with quantitative measures, explored maternal perceptions of understanding and support when faced with an excessively crying baby (current situation), as well as the key forms of support the mothers would like to receive (ideal situation). With 432 participants, it offered a robust and diverse dataset, enabling nuanced insights into support needs and identifying potential forms of support from partners, personal networks, and health care professionals. These findings informed the development of the maternal support framework.

Crying Duration

The reported average of nearly 12 hours of infant crying per day appears unusually high compared to existing epidemiological data, even for excessively crying infants. This likely reflects a combination of recall bias, parental misinterpretation of crying versus fussing or general wakefulness, and the low coping ability of parents. Parent-reported measures, although practical for large-scale studies, are known to diverge from objective recordings. The Barr's Baby Diary validation study found moderate correlations between diary reports and audio recordings for crying (r=0.67) but low or no correlation for fussing (r=0.45 for crying+fussing; r=0.01 for fussing alone [29]). As Vermillet et al [6] noted, this may be due to parents' sensitivity to visual signs of distress not captured by audio, as well as the more fragmented nature of fussing behavior. As capturing the objective crying duration of these infants was not the main purpose of this study, these findings reflect perceived, not actual, cry durations, yet they remain valuable for understanding parental experience, which plays a crucial role in early caregiving and stress [2].

Consulted Health Care Professionals

Before turning to the study's central research questions on current and desired support, we highlight one key finding regarding health care use among mothers of excessively crying infants. The level of health care use, reflected in an average of 2.7 health care professionals consulted during periods of excessive crying, was relatively high in this study and aligns with previous research [15]. One reason for this is that many mothers feel a strong need to find an explanation for their baby's excessive crying. However, in 95% of cases, no medical cause is found [1,30], and crying often decreases by the time the baby is 3-4 months old [31,32]. This suggests that the reduction in crying may be due to other factors, not just the health care professionals parents consult, and "finding the cause" of excessive crying is not the primary reason for its reduction [1,33,34]. For example, the months wherein parents consult different health care professionals might cover the natural peak of infant crying [2]. Consulting various health care professionals likely gives parents a sense of control, as they hope for a quick fix, which for them often means receiving a medical label [35]. However, this high health care consumption in combination with the low satisfaction of parents regarding health care delivery also highlights a lack of continuous and solid support, leaving parents feeling that they must take charge in the search for a cause, since they seem to believe that without a medical cause, there is no solution to excessive crying.

As for the specific health care professionals consulted, mothers most frequently sought help from a pediatrician, a general practitioner, child health nurses, an osteopath, or a midwife. Remarkably, no mother mentioned consulting an infant mental health (IMH) specialist—a health care professional with additional training, skills, and experience in working intensively with young children and families through a comprehensive, relationship-based approach [36]. One possible explanation is that parents, given the recent development of this field, are not yet aware of the existence of these specialized professionals. Another possibility is that parents are aware of a professional's IMH training but simply do not specify it. Lastly, parents may have consulted such specialists without realizing their additional expertise. However, future research could help demonstrate the added value of such specialists in cases of excessive crying, as current research lacks a clear link to this issue, even though the existence and role of these specialists are increasingly being acknowledged [37].

Current and Ideal Situations of Understanding and Support

Mothers of excessively crying babies reported the lowest levels of understanding and support from health care professionals, with half feeling they received little to no understanding and support. These numbers are in accordance with previous research indicating that 55% of mothers feel they receive inadequate information regarding their baby's crying and their caregiving role [15]. Although health care professionals showed the greatest need for improvement, mothers also experienced significant gaps in support and understanding from their partners and personal networks. This suggests widespread challenges in securing sufficient support networks for mothers.

This brings us to the qualitative data, which provided deeper insight into mothers' perceived support needs. An in-depth analysis of the data led to the development of a maternal support framework consisting of 25 maternal support forms divided into common maternal support forms or fundamental principles and specific maternal support forms. Twelve general maternal support forms were identified, which applied to each of the groups (partners, personal networks, and health care professionals). Six maternal support forms were only detected toward health care professionals, six were identified toward mothers' partners, and one was specified for their personal networks.

First, *common maternal support forms* were identified. The support forms identified in this qualitative study generally align with various needs previously reported in the literature. For example, the theme *communicate openly and break down taboos* corresponds to the stigma surrounding excessive crying, often

XSL•FO
RenderX

exacerbated by societal taboos, which leaves mothers feeling isolated and unsupported. Clearly, insufficient social recognition and a lack of open communication can significantly increase maternal distress [6,7]. Moreover, prior research states that excessive crying often disrupts parental identity and generates stigma [6]. This highlights the critical need to explicitly address the taboo and blame surrounding infant crying in intervention programs, as doing so may reduce stigma, foster parental acceptance, and encourage seeking support. Furthermore, *practical support*, such as household tasks or caregiving assistance, was another recurrent theme. Many mothers reported that small gestures, such as offering to babysit or prepare a meal, could have alleviated their overwhelming burden. This resonates with studies advocating for community-based interventions to enhance family resilience during challenging periods [16].

Second, the findings regarding current and ideal levels of understanding and support by *health care professionals* highlight critical areas for improving health care delivery. Indeed, mothers expressed dissatisfaction with fragmented or dismissive health care, where excessive crying was trivialized or attributed to "normal" infant behavior without thorough investigation. Despite frequent consultations, health care professionals seem to underperform in meeting parental needs during episodes of excessive infant crying. This may be due to a predominant biomedical approach focused on ruling out disease or normaliz*ing* the crying behavior, rather than addressing the emotional and informational needs of parents [15,16]. Harskamp-Van Ginkel et al [16] stated that through the development of eight consecutive steps in the assessment of an excessively crying infant, *taking parents seriously* while demonstrating medical expertise and *offering a practical plan* is the way to go. However, *providing care continuity* with *appropriate referral* to health care professionals who can offer the most appropriate care at the time of the request for help and a *holistic vision* of both the baby's and the mother's well-being can improve mothers' satisfaction and families' well-being, as also shown in previous research [38]. The study underscores the need for a holistic screening approach that goes beyond quantifying crying episodes. Incorporating emotional and contextual factors into assessments could facilitate targeted interventions and foster greater understanding among health care professionals. Such approaches would align with calls in the literature for more family-centered care models that prioritize both infant well-being and parental mental health [7,39]. A great example of such a good practice, where a multidisciplinary approach is used with a focus on continuity of care, is the care model described by de Graaf et al [40], which is currently being further developed at the Sint-Antonius Hospital in the Netherlands. This integrated model supports families with excessively crying infants by combining psychosocial support, timely medical consultation, and structured follow-up across disciplines. It involves early intervention through clear guidance on soothing techniques and access to reliable (digital) information about excessive crying for all parents. In cases where a medical cause is suspected, parents are offered a joint consultation with both a pediatrician and a medical pedagogical professional within 5 working days. This close collaboration ensures that both medical and psychosocial aspects are addressed simultaneously. To safeguard continuity of care, a follow-up handover takes place within 2 weeks via a video call in the presence of the parents, allowing the referring professional to remain involved and ensuring a warm and informed transfer of care [40]. Accordingly, the recently validated Infant Crying and Parent Well-Being (ICPW) screening tool could serve as a starting point for a more nuanced approach to identify parents whom have a problem with the excessive crying of their infant. This ICPW screening tool is a brief, five-item instrument designed to identify parents who are struggling with their infant's crying (example item: "Has your baby's crying or fussing been a problem or upsetting to you recently?" Yes/No). It quickly and efficiently identifies families that are in need of extra support in comforting their child, considering parent-specific stressors, such as parenting stress. Its simplicity and clinical relevance make it well-suited for routine use in early infancy to guide timely support and referrals [41,42].

Third, the findings shed light on the forms of support that mothers consider important to receive from their *partners*. Participants highlighted the importance of a unified approach, where *partners act as advocatesand teammates* in managing the situation. The strain of excessive crying often amplified the mental load for mothers, particularly when partners were perceived as less *present*, *engaged*, or understanding. Conversely, where strong partner support was present, mothers reported greater emotional stability and a sense of shared responsibility. These findings support the literature emphasizing the protective effects of strong partner relationships in mitigating stress [39]. However, having an excessively crying baby might cause marital stress, arguments, and feelings of resentment toward the partner, which confirms our findings [39].

Fourth, the forms of maternal support from the *personal network* were explored. Mothers often felt that their networks failed to grasp the intensity of their experiences, leading to feelings of alienation. *Experiential knowledge* where social contacts had faced similar challenges was perceived as enhancing understanding and empathy. This suggests a potential benefit of peer support programs or initiatives that connect parents with others who have navigated similar challenges [43]. Given that mothers indicated their personal networks often had difficulty *coping with their baby's crying*, and considering the lack of research on this topic, increasing awareness and knowledge, as well as conducting further investigation, may be warranted.

The results of this study also highlight gaps in research and practice. Existing studies often focus on isolated elements of the parent's environment, such as partner support or health care delivery, while neglecting the broader support system. This fragmented nature of current research also limits generalizability. The findings of this study provide a first step in expanding the scope of research to encompass a fuller spectrum of maternal experiences. However, including the role of societal pressure, for instance, could yield valuable insights into developing comprehensive support systems. In addition, the results emphasize the importance of *fostering greater knowledge* and understanding of excessive crying among different central stakeholders—parents, personal networks, and health care professionals. Enhancing awareness could *reduce stigma*, *improve acknowledgment* of parental struggles, and ultimately lead to better care and support. Such efforts could

XSL•FO
RenderX

transform excessive crying from an isolating and distressing experience to an opportunity for building stronger family and community resilience. Finally, the findings of this study underscore the need for a *holistic and context-sensitive approach* to understanding and addressing excessive crying, both in research and in practice.

Practical Implications

The maternal support framework may serve as a valuable foundation for the development of new support programs or the optimization of existing ones. By offering a clear representation of the support needs of the target population, the framework can enable health care professionals and program developers to assess which needs are already being addressed and to identify how to broaden their interventions in line with unmet parental support needs. For example, the framework's emphasis on fundamental principles, such as "listen actively," "believe parents and take them seriously," and "provide reassurance," shows the need for interventions to create safe spaces where parents can share their feelings without judgment, reducing the taboo and blame associated with infant crying; the framework's emphasis on trusting the maternal instinct could help develop family-centered interventions focusing on parent empowerment by validating their choices and providing them with knowledge and tools to make informed decisions.

Limitations

Although this study has several strengths, certain limitations should be acknowledged, alongside some recommendations for future research. First, the study included both participants who currently have an excessively crying baby and parents who experienced excessive crying in the past. Perceptions may differ between mothers currently coping with excessive crying and those reflecting retrospectively on a past experience. Nevertheless, both perspectives are highly relevant: the immediate experience offers insight into present challenges, while retrospective accounts provide valuable reflections. Although this approach introduces certain limitations, the diversity of the sample enriches the findings by incorporating unique viewpoints. These varied experiences offer additional insights that might otherwise be overlooked.

Second, there may be sampling bias, as mothers who were dissatisfied with the perceived understanding and support might have been more likely to participate than those without issues. Moreover, this study only involved *mothers* with excessively crying babies. This might be seen as a limitation as fathers, comothers, and same-sex fathers are equally important groups. Fathers experience a lot of distress and have a high chance of developing depression when having an excessively crying baby [12]. Therefore, future studies and interventions need to include other primary caregivers. However, the focus on mothers did ensure a consistent and homogeneous sample, reducing variability in responses that could arise from differences between mothers and fathers or comothers and same-sex fathers.

Third, we have no information about the age of the babies at the time of the excessive crying complaints. This lack of age-specific data is unfortunate, as perceptions of excessive crying and the need for support are likely to vary depending on the infant's age and developmental stage. Not accounting for this variable may have affected how mothers reflected on their experiences and expressed their needs. However, this broad inclusion strategy was a deliberate choice, as it allowed us to explore general themes that are widely shared across the population. Given the exploratory nature of this study, capturing a broad range of experiences was valuable in identifying common patterns and concerns among mothers.

A fourth limitation is that we did not collect information about the cultural or ethnic backgrounds of the participants. Although the recruitment strategies (eg, Dutch language online communities in Belgium and the Netherlands) suggest that most participants were likely part of a Western European cultural context, we cannot draw firm conclusions about the cultural diversity within the sample. This limits the transferability of the findings to mothers from other cultural backgrounds, whose perceptions and support needs around excessive infant crying may differ. Future research should aim to include and differentiate between diverse cultural perspectives to gain a more inclusive understanding [44,45].

Finally, another potential limitation is related to the measurement instrument. Specifically, the use of "perfect" as the positive anchor on the Likert scale is less common in previous research. Although we deliberately chose to capture participants' perceptions of an ideal or optimal experience, the word "perfect" may have been perceived as an unattainable ideal and therefore selected less frequently. Future research might consider using a more moderate and relatable term (such as "excellent") to capture positive evaluations more accurately.

Finally, we did not use any existing/adapted items from validated tools as we believed there did not exist any fitting items in existing tools. However, as a compensation, we used a pilot test (n=3).

In addition to the aforementioned limitations, several final recommendations for future research can be proposed to further advance understanding in this field. For instance, future studies could investigate the association between perceived understanding and support and the specific type of health care professional involved. Given the considerable variation in approaches, treatment methods, and patient interactions across health care disciplines, such an examination would clarify the unique contributions and challenges associated with each. Further, future research might focus on the validation of the conceptual maternal support framework, while considering the previously stated stakeholder groups, so that the maternal support framework can be expanded to the parental support framework.

Conclusion

This study highlighted the significant challenges faced by mothers of excessively crying infants, emphasizing the critical role of understanding and support from their partners, personal networks, and health care professionals. Findings indicate that health care professionals provide the least understanding and support, followed by personal networks, while partners offer more consistent support and understanding.

XSL•FO
RenderX

Qualitative insights further underscore the emotional and practical support needs of mothers, including a desire for more empathy, respect for their decisions, and tangible support. The maternal support framework developed in this study offers a comprehensive guide to understanding and addressing maternal support forms. It calls for greater collaboration among partners, personal networks, and health care professionals to alleviate the mental and emotional burdens of parents, ultimately improving the well-being of both parents and infants. Future interventions should focus on bridging the gaps in understanding and support, fostering a more supportive environment for families dealing with excessive crying.

Data Availability

The complete codebook, including the fundamental principles (shared support forms) and specific support forms, supplemented with the ad verbatim codes, which stayed close to the original words, will be available upon request. A list of support forms and subforms, each with a verbatim quote, will also be available upon request.

Abstract

Background: Protracted bacterial bronchitis (PBB) is a leading cause of chronic wet cough in children. Misdiagnosis and inadequate treatment may lead to the progression of diseases.

Objective: The objective of this paper was to analyze factors influencing the cough duration prior to the diagnosis and assess health-related quality of life in children with PBB.

Methods: Children diagnosed with PBB in the Qilu Hospital of Shandong University from November 2021 to November 2022 were included in this study. Clinical data were collected; parents completed the Parent-Proxy Cough-Specific Quality of Life (PC-QOL) questionnaire and the simplified Cough Symptom Score. Children aged 6 years and older completed the Leicester Cough Questionnaire in Mandarin-Chinese (LCQ-MC).

Results: As of November 2022, we enrolled 88 patients. Place of residence (B=9.35, 95% CI 0.36-18.35; *P*=.04) and rest status during the coughing episode (B=7.87, 95% CI 0.36-15.38; *P*=.04) were significantly associated with cough duration prior to the diagnosis. PC-QOL scores (physical: mean 3.10, SD 1.36; psychological: mean 3.32, SD 1.57; social: mean 3.67, SD 1.53; total: mean 10.09, SD 4.21) showed physical-social differences (t_{174}=−2.58, *P*=.01). PC-QOL posttreatment scores were significantly higher than pretreatment scores (physical: t_{18}=–6.05, *P*<.001; psychological: t_{18}=–4.42, *P*<.001; social: t_{18}=−4.79, *P*<.001; total: t_{18}=–5.25, *P*<.001). However, the scores of each PC-QOL domain were significantly lower than those of the LCQ-MC (physical: t_{34}=8.31, *P*<.001; psychological: t_{34}=6.58, *P*<.001; social: t_{34}=5.09, *P*<.001; total: t_{34}=8.11, *P*<.001).

Conclusions: Place of residence and rest status during the coughing episode were significantly associated with cough duration prior to the diagnosis**.** Furthermore, PBB significantly reduces quality of life in physical, psychological, and social aspects.

KEYWORDS

protracted bacterial bronchitis; duration of cough; sCSS; PC-QOL; LCQ-MC; simplified Cough Symptom Score; Parent-Proxy Cough-Specific Quality of Life; Leicester Cough Questionnaire in Mandarin-Chinese

Introduction

Cough is a prevalent symptom of respiratory disorders among children, with children presenting with cough constituting 70% of primary complaints in outpatient visits to pediatric respiratory clinics. Notably, chronic cough, defined as a cough lasting more than 4 weeks, accounts for 10% of these outpatient cases [1-3]. Chronic cough in children originates from various factors, and its etiology varies based on the child's age. Common causes of cough include respiratory infections, postinfectious cough, cough variant asthma, upper airway cough syndrome, and protracted bacterial bronchitis (PBB) [4-6].

PBB was initially proposed in 2006 [7], representing a chronic bacterial infection of the endobronchial membrane. This condition manifests as a persistent wet cough in children and may account for up to 42% of chronic cough cases [8,9]. Studies have indicated that the protracted duration of chronic cough is linked to respiratory dysfunction, impaired lung function, and potential development of bronchiectasis [10-13]. The incidence of cough-related complications escalates with both the prolongation of the disease and increased cough frequency, with a more than 2-fold increase in complication rates when symptoms persist beyond 8 weeks [14]. Inadequate treatment of PBB can result in irreparable damage to the bronchial mucosa,

XSL•FO
RenderX

potentially progressing into chronic suppurative lung disease or bronchiectasis [15]. A recent study [16] indicates that a significant proportion of children experience respiratory symptoms many years later; some have an objectively reduced lung function and structural changes of the bronchial wall despite adequate initial therapy. Additionally, PBB profoundly affects the quality of life of both affected children and their families [17].

Therefore, PBB not only affects the physical health of children but also undermines their psychological, social, and familial functioning. The Clinical Practice Guide for Diagnosis and Treatment of Cough in Chinese Children underscores the significance of pediatricians in China focusing on children's quality of life, advocating for the development and validation of a Cough-Specific Quality of Life Scale tailored for domestic children [18]. According to the 2015 Chest Guidelines [19], the Leicester Cough Questionnaire (LCQ) [20] and Parent-Proxy Cough-Specific Quality of Life (PC-QOL) questionnaire [21] have emerged as reliable and efficacious metrics for assessing quality of life in children experiencing chronic cough. Presently, there are few reports addressing the quality of life of children experiencing PBB. Highlighting this aspect of cough management is crucial for raising clinical awareness. To gain a deeper insight into PBB, this study dissected the clinical profiles of children with PBB, delved into the reasons behind their protracted disease trajectory, and evaluated the detrimental effects of chronic cough on their quality of life.

Methods

Participants

A comprehensive study was conducted on 88 pediatric patients diagnosed with PBB, who were admitted to the Pediatrics Department of Qilu Hospital, Shandong University, between November 2021 and November 2022. In total, 88 pediatric patients were included from outpatient and inpatient departments, and we obtained written consent from their guardians. All enrolled participants must meet the diagnostic criteria for PBB established by the American College of Chest Physicians (CHEST) Guidelines and Expert Panel [22].

The relevant definitions are as follows:

- Clinically based PBB: children aged ≤14 years with chronic wet or productive cough unrelated to an underlying disease and without any specific cough pointers (eg, coughing with feeding and digital clubbing) and whose cough resolves within 2 weeks of treatment with antibiotics targeted to local antibiotic sensitivities.
- Microbiologically based PBB: children aged ≤14 years with PBB with lower airway (bronchoalveolar lavage or sputum) confirmation of clinically important density of respiratory bacteria (≥10^4 CFU/mL).

The exclusion criteria were as follows: (1) the presence of acute respiratory symptoms, such as fever or rapid breathing before enrollment; (2) chest X-ray or chest CT scans indicating pneumonia after hospitalization; (3) specific cough symptoms or signs, such as chest pain, suspected history of foreign body inhalation, hemoptysis, repeated sinus lung infections, history of tuberculosis exposure, dyspnea, chest deformities, wet rales on lung auscultation, changes in chest imaging, abnormal lung function, etc; (4) the coexistence of severe underlying diseases, including but not limited to neuromuscular disorders, immunodeficiency, chronic corticosteroid use, congenital heart disease, and delayed growth and development; and (5) inability to obtain written informed consent from the children or their legal guardians.

General Information

The characteristics of the included children, such as their age, sex, duration of coughing prior to the diagnosis, characteristics of their cough (eg, wet, dry, or accompanied by wheezing), residential area, the presence of siblings, their parents' age and educational attainment, their primary caregiver's status, underlying health issues, exposure to smoking environments, and previous medical diagnoses and treatments, were comprehensively collected. Furthermore, the diagnoses and treatments provided to the children both in and out of the hospital during our research, including the type of antibiotics, length of treatment, and the efficacy of antibiotic therapy (Multimedia Appendix 1). For pediatric patients with PBB who showed inadequate response to empirical antibiotic therapy administered externally, electronic bronchoscopy was performed after hospitalization to identify pathogens and rule out potential underlying diseases. The pathogens found in bronchoalveolar lavage fluid were recorded.

Simplified Cough Symptom Score

The simplified Cough Symptom Score (sCSS; Table S1 in Multimedia Appendix 2) [23], which is determined based on the description of the frequency and intensity of daytime and nocturnal coughing, and its effect on daily activities and sleep patterns, is categorized into 4 distinct grades based on symptom severity. This scale is a simplified version developed based on the Cough Symptom Score (Table S2 in Multimedia Appendix 2). Research [24] shows that the sCSS is a reliable and valid instrument for assessing cough symptoms. A higher sCSS indicates a more severe cough, which negatively affects children. Using the sCSS obtained during the initial visit, guardians were subsequently contacted through outpatient follow-ups and telephone interviews to monitor the fluctuations in the sCSS over 2 and 4 weeks of treatment, including at night. The scores were interpreted as follows:

1. A score of 0 meant the complete resolution of cough symptoms.
2. A decrease in the sCSS compared to the initial visit without reaching 0 indicated improvement in the cough symptoms.
3. No change in sCSS meant no significant change in cough symptoms.
4. An increase in the sCSS compared to the initial visit indicated a worsening of the cough symptoms.

The Quality of Life Scale

The Leicester Cough Questionnaire in Mandarin-Chinese (LCQ-MC) [25] and PC-QOL questionnaire [21] were used to evaluate the impact of cough and disease experience on both children's and parents' overall quality of life (Tables S3-S5 in Multimedia Appendix 2).

XSL•FO
RenderX

The LCQ-MC and PC-QOL questionnaires were used to evaluate the frequency and severity of coughing episodes, their impact on the sleep patterns of both patients and parents, and the overall quality of life in children. The LCQ-MC scale is validated for children aged 6 - 14 years old and consists of 19 items, and the PC-QOL is validated for children aged 0 - 14 years old and consists of 27 items; both assess physical, psychological, and social functioning domains. The total score is calculated by summing the scores from each domain. The higher the accumulated score, the better the quality of life and the less the detrimental effects of coughing on children.

Statistical Analysis

Measurement data with normal distribution are presented as means and SDs, and between-group comparisons were conducted using an independent sample *t* test or ANOVA. Measurement data without normal distribution are expressed as median (IQR), and nonparametric tests were used for intergroup comparisons. Count data are expressed as percentages, and chi-square tests were used for intergroup comparisons. Normally distributed variables were analyzed using Pearson correlation analysis, whereas variables without normal distribution were subjected to Spearman correlation analysis. Difference analysis and multivariate linear regression analysis were used to investigate the factors affecting the cough duration prior to the diagnosis in children. *P* values obtained from univariate comparisons were adjusted for multiple testing using the Benjamini-Hochberg false discovery rate (FDR) correction method, with a significance threshold set at Q<.05. Statistical analysis was conducted using IBM SPSS 26.0 software, with a *P* value of less than .05 exhibiting statistical significance. The FDR correction was carried out using the R statistical programming language (version 4.5.1; R Core Team).

Ethical Considerations

This study was approved by the Ethics Committee of Qilu Hospital, Shandong University, under the ethical number KYLL-202111-118-1. Written informed consent was meticulously obtained from all participating children or their guardians. All data are anonymous.

Results

Sample Characteristics

As of November 2022, we enrolled 88 patients with PBB. Among these 88 enrolled children, there was a male predominance, with a male-to-female ratio of 1.84:1 and a median age of 60 (IQR 48 - 78) months. The median cough duration prior to inclusion in this study was 8 (IQR 4.5 - 16) weeks. Overall, 38% (33/88) of patients lived in rural areas, while 63% (55/88) of patients lived in urban areas. Furthermore, 51% (45/88) of patients had siblings and 49% (43/88) were only children. Parental education levels indicated that 28% (25/88) of patients had a high school education or below. In contrast, 72% (63/88) of patients had postsecondary education. The cohort analysis further demonstrated that 24% (21/88) of children were primarily cared for by their grandparents, while 76% (67/88) of children received primary care from their parents. Environmental tobacco smoke exposure was reported in 16% (14/88) of children, contrasting with 84% (74/88) of children without such exposure. Furthermore, regarding activity patterns during illness, 63% (55/88) of children continued attending school and physical activities despite cough symptoms, whereas 38% (33/88) rested at home. Parents' assessment of the nature of the cough indicated that 16% (14/88) of parents mistook a wet cough (a cough producing phlegm) for a dry cough. Meanwhile, 84% (74/88) of parents correctly identified it.

All 88 children had prior outpatient visits at external health care facilities before enrollment in this study. Health care–seeking behavior analysis showed that 49% (43/88) of children visited a municipal-level or higher hospital, 13% (11/88) of children had more than 5 repeated visits. Diagnostic accuracy assessment revealed that 33% (29/88) of cases were initially misdiagnosed with cough variant asthma or bronchial asthma, and 65% (57/88) of children were incorrectly diagnosed with bronchitis or bronchopneumonia and were treated with antibiotics and Chinese patent medicine before study participation (Table S1 in Multimedia Appendix 3).

Complete pre-enrollment medication records were unavailable for some participants in this study. Of the 73 children with documented antibiotic use, 48 (66%) received β-lactam antibiotics (amoxicillin, clavulanate potassium, cefaclor, etc), with only 4 (5%) having treatment durations longer than 2 weeks. Additionally, 33 (45%) children were treated with macrolides, including azithromycin and erythromycin; among them, only 5 (7%) had a treatment duration exceeding 2 weeks (Table S2 in Multimedia Appendix 3).

As for microbiological findings, following enrollment in this study, 63 pediatric patients were hospitalized for treatment and underwent bronchoscopy and bronchoalveolar lavage. Pathogen tests, such as bronchoalveolar lavage fluid culture, polymerase chain reaction, and metagenomic next-generation sequencing analysis, were also conducted. Of the 63 patients, 39 (62%) were positive for pathogenic bacteria. Of the 39 patients, 17 *Streptococcus pneumoniae* (44%), 7 *Haemophilus influenzae* (18%), and 6 *Staphylococcus aureus* (15%) were the most frequently detected pathogens. Additionally, 36% (18/39) of patients were coinfected with viral infections. Rhinovirus had the highest detection rate among viruses. Fungi were detected in 2 patients, namely Candida albicans; Pseudomonas aeruginosa, a bacterium, was also identified (Table S3 in Multimedia Appendix 3).

All the children were prescribed oral antibiotic therapy after enrollment in this study. Forty-seven patients were treated with Cefditoren Pivoxil Granules (3 mg/kg, 3 times a day), with a mean treatment duration of 2.7 (SD 0.7) weeks; 27 patients received Faropenem Sodium Tablets (5 mg/kg, 3 times a day), with a mean duration of 3.0 (SD 1.1) weeks; and 22 patients were administered Linezolid Tablets (10 mg/kg, 3 times a day), with a mean treatment course of 2.5 (SD 1.3) weeks. Among these cases, 2 patients who showed inadequate response to Cefditoren Pivoxil Granules achieved cough resolution after switching to Faropenem Sodium Tablets; 4 patients who failed initial Cefditoren Pivoxil Granules therapy successfully transitioned to Linezolid Tablets with subsequent symptom disappearance; 2 patients received combination therapy with

XSL•FO
RenderX

Faropenem Sodium Tablets and Linezolid Tablets, and 1 patient required antifungal medication. The median duration of anti-infective therapy after evaluation at our institution was 3 (IQR 2 - 4) weeks. Treatment duration distribution was as follows: 31% (27/88) of children received 2 weeks of therapy, 33% (29/88) completed 3 weeks, 27% (24/88) required 4 weeks, and 9% (8/88) needed extended therapy beyond 4 weeks. Complete resolution of cough symptoms was achieved in all cases (Tables S4 and S5 in Multimedia Appendix 3).

Analysis of Factors Affecting Cough Duration Prior to the Diagnosis

Ten potential influencing factors were screened through univariate analysis. Given that multiple comparisons increase the risk of Type I error, we applied the Benjamini-Hochberg method to control the FDR by adjusting the *P* values. A Q value <.05 after correction was considered statistically significant. The corrected results demonstrated statistically significant differences among groups for the following 4 factors: place of residence (z=−2.72; P=.006; Q=.045), parental education level (z=−2.37; P=.02; Q=.045), parental assessment of the nature of the cough (z=−2.46; P=.01; Q=.045), and whether the individual rested during the cough episode (z=−2.50; P=.01; Q=.045). In contrast, no significant differences were observed for other variables; detailed data are presented in Table 1.

[a]The nonparametric test was conducted with the duration of cough prior to the diagnosis as the dependent variable.

To explore the independent effects of each variable on cough duration prior to the diagnosis after controlling for other factors, the 4 variables that showed significant associations ($P<.05$) in the univariate analysis (including residence, parental education level, parental assessment of the nature of the cough, and rest status at disease period) were included in a multivariate linear regression analysis model. The assignment of each variable is presented in Table 2. Specifically, place of residence (B=9.35, 95% CI 0.36-18.35; $P=.04$) and rest status during the coughing episode (B=7.87, 95% CI 0.36-15.38; $P=.04$) were significantly associated with cough duration prior to the diagnosis. In contrast, parental educational level (B=2.83, 95% CI −6.36 to 12.01; $P=.54$) and parental assessment of the nature of the cough (B=7.39, 95% CI −2.59 to 17.38; $P=.15$) were not significantly associated with the outcome. The analysis revealed that the regression model was statistically significant ($F_{4,83}=3.98$; $P=.005$). The 4 predictor variables collectively explained 12.1% of the variance in the interval between symptom onset and diagnosis (adjusted $R^2=0.121$) (Table 2).

Correct Antibiotics Significantly Reduced Daytime and Nocturnal Cough Scores

At the first visit, all 88 children were scored by their parents based on the symptoms. At the first visit, 5% (4/88) of patients only had night cough, 23% (20/88) of patients only had daytime cough, and 20% (18/88) of patients had frequent daytime cough affecting their daytime life. There were 32% (28/88) patients with frequent nocturnal cough affecting sleep, and 13% (11/88) patients with frequent daytime and nocturnal cough affecting daily life (Table S6 in Multimedia Appendix 3). At the first visit, there was no significant difference in daytime cough symptom score and nocturnal cough symptom score between the two groups (z=−0.52; *P*=.60; Table S7 in Multimedia Appendix 3).

The daytime and nocturnal scores at 2 weeks and 4 weeks after diagnosis were assessed via outpatient examination and telephone follow-up. Fortunately, all parents and caregivers of the enrolled patients completed the assessment of their children's cough symptom scores at both the 2nd and 4th weeks of treatment. At the 2nd week of follow-up, daytime cough disappeared in 38% (33/88) of patients, nocturnal cough disappeared in 70% (62/88) of patients, and the cough symptoms completely disappeared in 31% (27/88) of patients. At the 4th week of follow-up, daytime cough symptoms disappeared in 90% (79/88) of patients, night cough symptoms disappeared in 98% (86/88) of patients, and cough symptoms completely disappeared in 90% (79/88) of patients (Tables S8 and S9 in Multimedia Appendix 3).

Daytime cough did not completely disappear in 9 patients after 4 weeks of treatment. Cough disappeared in 7 patients after 5 to 6 weeks of antibiotic therapy, aggravated in 1 patient and improved after adding antifungal drugs in the hospital, and 1 child did not continue treatment. The nocturnal cough did not completely disappear in 2 children at 4 weeks of treatment, and the duration of treatment was prolonged to 5 weeks (Tables S8 and S9 in Multimedia Appendix 3).

PBB Reduced the Quality of Life in Children

In total, 35 PBB children older than 6 years old completed the LCQ-MC. The results showed no significant difference in the physical, psychological, and social scores of LCQ-MC among children with PBB ($F_{2,102}$=0.13; *P*=.88; Table S10 in Multimedia Appendix 3 and Table 3).

XSL•FO
RenderX

Table . Score of the Leicester Cough Questionnaire in Mandarin-Chinese (LCQ-MC) and Parent-Proxy Cough-Specific Quality of Life (PC-QOL).

Scale and domain	Score, mean (SD)	*F* test (*df*)	*P* value
LCQ-MC (n=35)		0.13 (2,102)	.88
Physical	4.90 (0.89)		
Psychological	4.99 (1.28)		
Social	4.85 (1.37)		
PC-QOL (n=88)		3.20 (2,261)	.04
Physical	3.10 (1.36)[a]		
Psychological	3.32 (1.57)[a,b]		
Social	3.67 (1.53)[b]		

[a]Data were analyzed by repeated-measures ANOVA followed by Bonferroni post hoc test. Within each scale, different superscript letters denote statistically significant differences at $P<.05$ in the post hoc pairwise comparisons.

[b]Data were analyzed by repeated-measures ANOVA followed by Bonferroni post hoc test. Within each scale, different superscript letters denote statistically significant differences at $P<.05$ in the post hoc pairwise comparisons.

The reliability and validity of the PC-QOL scale were measured among 88 children at the first visit. Cronbach α coefficient was higher than 0.8, suggesting good internal consistency and high reliability. Cronbach α coefficients of physical, psychological, and social components were all higher than 0.8, suggesting that the scale had high reliability. Kaiser-Meyer-Olkin (KMO) >0.8 was suitable for factor analysis. The overall KMO of PC-QOL was 0.90, and the KMOs of physical, psychological, and social components were all >0.8, suggesting that the scale exhibited good construct validity (Table S11 in Multimedia Appendix 3). The results showed a significant difference between the scores of the physical domain and social domain among children with PBB ($t_{174}=-2.58$, $P=.01$; Table 3), and the score of the physical domain was significantly lower than that of the social domain.

In total, 19 parents of children with PBB completed the PC-QOL scale at baseline and after treatment. The results showed significant differences in the overall distribution of each domain and the total score of PC-QOL between baseline and after treatment (Table 4). The scores of physical ($t_{18}=-6.05$, $P<.001$), psychological ($t_{18}=-4.42$, $P<.001$), and social domains ($t_{18}=-4.79$, $P<.001$) and total scores ($t_{18}=-5.25$, $P<.001$) after treatment were significantly higher than those before treatment.

Table . Parent-Proxy Cough-Specific Quality of Life scores were compared before and after treatment using the paired samples *t* test (n=19).

Domain	Before treatment, mean (SD)	After treatment, mean (SD)	*t* test (df)	*P* value
Physical	2.86 (1.35)	5.48 (1.24)	−6.05 (18)	<.001
Psychological	3.38 (1.54)	5.69 (1.17)	−4.42 (18)	<.001
Social	3.63 (1.60)	5.89 (1.06)	-4.79 (18)	<.001
Sum	9.87 (4.26)	17.06 (3.22)	-5.25 (18)	<.001

Thirty-five children with PBB aged more than 6 years were included in this study. Pearson correlation analysis and difference analysis showed a good correlation between the scores and total scores of PC-QOL and LCQ-MC (physical: $r=0.57$, $P<.001$; psychological: $r=0.48$, $P=.004$; social: $r=0.58$, $P<.001$; total: $r=0.66$, $P<.001$) (Table S12 in Multimedia Appendix 3). The scores and total scores of PC-QOL were significantly lower than those of LCQ-MC (physical: $t_{34}=8.31$, $P<.001$; psychological: $t_{34}=6.58$, $P<.001$; social: $t_{34}=5.09$, $P<.001$; total: $t_{34}=8.11$, $P<.001$) (Table 5).

Table . Paired sample *t* test was used for the Leicester Cough Questionnaire in Mandarin-Chinese (LCQ-MC) and Parent-Proxy Cough-Specific Quality of Life (PC-QOL) among children aged ≥6 years (n=35).

Domain	LCQ-MC, mean (SD)	PC-QOL, mean (SD)	*t* test (df)	*P* value
Physical	4.90 (0.89)	3.24 (1.43)	8.31 (34)	<.001

Discussion

Principal Findings

This study examined factors contributing to the prolonged clinical course of PBB and evaluated the impact of chronic cough on quality of life in children with PBB. Using multiple regression analysis, this study identified place of residence and whether the child was resting or active during coughing episodes as significantly associated with prediagnosis cough duration. Furthermore, PBB substantially impairs multiple dimensions of children's well-being, including physical, psychological, and social functioning.

Analysis of Factors Affecting Cough Duration Prior to the Diagnosis

PBB is a common cause of chronic wet cough among preschool children aged 0 - 6 years [26,27]. The 2019 multicenter study on the proportion of the causes of chronic wet cough in children [28] showed that PBB was the 4th cause of chronic wet cough among children in China. It was also the leading cause of chronic wet cough among children younger than 1 year. Early diagnosis and treatment of PBB can reduce the duration of persistent cough, improve clinical symptoms, prevent its progression to bronchiectasis, and reduce morbidity and mortality [27,29].

Residence in rural areas demonstrated the strongest correlation with prolonged cough duration prior to PBB diagnosis, underscoring a core issue of inequitable distribution of medical resources. Compared to urban residents, rural families likely face several barriers, including limited access to specialized diagnostic facilities and expertise. PBB was recognized as a diagnostic name worldwide in 2008 [30]. In 2013, PBB was first included in the guidelines for chronic cough in China [4]. However, the Australian scholar Laird et al [31] conducted a survey of local medical workers in towns and remote communities and found that approximately one-third of local medical workers did not know the guidelines for chronic wet cough and had little knowledge about chronic wet cough, PBB, and chronic suppurative lung disease. They normalized chronic wet cough. The long-term complications of chronic wet cough and the need for timely assessment and therapeutic intervention have been largely neglected. Therefore, the cough duration of children with PBB who live in rural areas is longer than that of those living in urban areas, which is closely associated with the lack of knowledge about PBB in primary medical institutions in rural areas of China. Residents in rural areas may experience significant delays within the local health care system. They often undergo multiple rounds of ineffective empirical treatments at primary care facilities before receiving a definitive diagnosis. A study including 190 children with PBB diagnosed after referral to secondary care institutions [32] reported that more than 80% of the children had visited a doctor 5 or more times in the past 12 months, and 53% (101/190) had visited a doctor 10 or more times before referral. Therefore, there is a lack of awareness of PBB-related treatment options in primary care institutions. Geographical barriers: accessing medical centers that provide specialized pediatric respiratory care requires considerable financial resources and time; this poses a substantial barrier to timely diagnosis. The family in rural residents had insufficient awareness of disease prevention and control and had less knowledge about chronic diseases of the respiratory system. Due to the economic conditions of families, parents more often choose the nearby diagnosis and treatment facilities or buy drugs based on their choice rather than going to professional medical institutions for treatment. When the child's condition does not improve, they will seek more professional treatment. In addition, parents in rural areas have less energy to take care of their children, which limits the implementation of medical advice and affects the treatment effect. Perhaps in the future, we will be able to introduce advanced technology such as cough sound classifiers [33], eHealth systems and interventions [34,35] to offer a promising solution for the early detection and efficient management of PBB in primary care institutions.

Prior to the diagnosis of PBB, inadequate rest during the coughing episode was significantly linked to a prolonged duration of the cough. In this study, 63% (55/88) of the children continuously went to school after the onset of cough symptoms. Among daycare children, those who receive care because of a cough are 13 times more likely to develop a chronic cough than those who stop caring for children at home [36]. The incidence of infectious diseases among children in daycare or preschool education is 2 to 3 times that of ordinary children [37,38], and the large population density in the classroom can easily lead to cross-infection of viruses among children. Common respiratory pathogens, such as respiratory syncytial virus, influenza A virus, and rhinovirus, upregulate the bacterial adhesion molecules of epithelial cells in children, which can also lead to mucociliary clearance disorders and damage epithelial cells, affect the clearance efficiency, promote bacterial invasion of host cells and tissues, and enhance bacterial growth and colonization. This damage can take weeks to repair [39-41]. Cross-infection provides insufficient time to repair the airway mucosa, and repeated infection worsens airway inflammation, further exacerbating airway inflammation, thus forming a vicious circle, which is conducive to the formation of bacterial biofilm [42], promotes the development and progression of PBB, and prolongs cough symptoms. However, due to work requirements and social and family tasks, it is difficult in many families in our country for parents to terminate school and nursery care for children with a persistent cough. In contemporary society, seeking medical care for children often entails practical constraints such as taking time off work or arranging leave from school. Consequently, families tend to prioritize health care visits only when symptoms become sufficiently severe to cause significant functional impairment, that is, when the child must rest and daily routines are substantially disrupted.

Parents play critical roles in the treatment of children with respiratory diseases [43]. Studies have found that the low education level of primary caregivers is a risk factor for the incidence of recurrent upper respiratory tract infections among children [44,45]. A low education level is a risk factor for the low awareness of respiratory infection prevention and control among parents of preschool children [46]. At the same time, in the process of treatment, parents with higher education levels will provide accurate information, have better compliance, and

XSL•FO
RenderX

will not arbitrarily stop the drug. Nevertheless, parental education showed no significant association with diagnostic delay in the multivariate model. One possible explanation is that parental education influences the disease course indirectly through various health behaviors and environmental factors. Research shows that a mother's education level is a factor influencing children's susceptibility to illnesses [47-49]. Families with higher levels of parental education are more likely to seek professional medical care when their children are ill, possibly because higher education enhances health knowledge and the ability to access health care resources. This influence may be reflected in variables such as urban versus rural residence and the frequency or severity of cough symptoms. When variables such as residence and cough characteristics are included in statistical models, the independent effect of parental education becomes attenuated or statistically insignificant.

Moreover, this study indicated that parental judgment of the nature of the cough was not significantly associated with the duration of cough prior to diagnosis. Like parental education level, parental judgment may be influenced by mediating effects and potential collinearity with other variables. These factors could reduce its independent explanatory power. Furthermore, this result suggests that even when parents are able to recognize key symptoms such as "wet cough," this recognition does not necessarily translate into timely health-seeking behavior. Foreign studies have shown that local Australian residents believe that isolated chronic wet cough does not need medical management [50], which often delays treatment. Some parents may also rely on self-management approaches based on previous illness experiences. Specifically, a productive cough may be mistaken for a mild condition that resolves on its own, such as the recovery phase of a common cold, rather than being recognized as a symptom that requires professional medical evaluation.

Quality of Life Score Among Children With PBB

Frequent cough during the daytime can affect children's learning and life, and nocturnal cough can affect children's sleep, lower daytime energy levels, and affect children's health. Long-term cough can also lead to anxiety, embarrassment, and other psychological problems, and repeated medical treatment and physical discomfort can also affect the progress of school life. Chronic cough affects children's physical, sleep, and mental health and school performance. It can also cause anxiety in parents, interfere with work and other plans, and increase family expenditure. The decreased quality of life caused by cough may be the direct cause of patients' visits.

The LCQ scale [20] was first proposed by SSB in 2003, which assesses the effects of chronic cough on 19 items across 3 domains: physical, psychological, and social domains. The LCQ scale is highly reproducible and responsive to change. It is a reliable and valid measurement tool for assessing cough-specific health status and can be used to evaluate the effects of cough on different aspects over time, with a minimal clinically important difference of 1.3 [51]. Gao et al [25] translated the LCQ scale into Mandarin Chinese in 2014 using the forward-backward translation method, creating the LCQ-MC. There were no significant differences in the conceptual content between the back-translation and the original English version. This was verified by S.S. Birring (SSB), the author of the English LCQ. This study confirmed that the LCQ-MC effectively assessed the severity of cough symptoms in patients with bronchiectasis. Research by Xu et al [52] indicated that the LCQ-MC can assess cough severity after thoracoscopic surgery in patients with pulmonary disease. The Chinese National Guideline on Diagnosis and Management of Cough (2021) [53] also recommends using LCQ-MC to assess cough-related quality of life, supporting these findings.

The PC-QOL scale [21] was developed by Newcombe PA in 2008. The questionnaire was set according to the opinions of experts in child respiratory medicine and psychology. It comprises 27 items involving physical, psychological, and social aspects. The parents' feelings (15 items) and concerns (12 items) about the severity of cough in children with chronic cough were evaluated to reflect the effect of children's cough on parents and parents' perception of their children's quality of life. In 2010, Newcombe et al [54] confirmed that the questionnaire was a reliable and valid measure, with a minimally important difference of 0.9 [55], capable of assessing childhood cough-related quality of life over specified periods. But over the last 10 years, minimal research has been conducted on the creation, application, and cultural modification of QOL evaluation instruments for chronic cough in children [56].

The scores of 35 children who completed both LCQ-MC and PC-QOL at the first visit were analyzed to explore the consistency of quality of life assessment between children and their parents. Correlation analysis showed a good correlation between PC-QOL and LCQ-MC in physical, psychological, and social domains and total scores. After cough remission, the scores of each domain and the total score of the PC-QOL scale significantly increased in children with PBB, suggesting that the scale has good therapeutic responsiveness and can be used to assess treatment effects. A randomized controlled trial [57] also showed that the PC-QOL score of children with PBB increased by 2.1 and 1.9 after 2 or 4 weeks of treatment with amoxicillin clavulanate potassium, respectively. A study [58] also indicated that PC-QoL scores were significantly improved postintervention. The improvement in the PC-QOL score suggests an improvement in the quality of life of children and their caregivers. The pressure and concerns of parents will disappear when the children's cough stops [32]. The treatment of PBB not only relieves the cough symptoms of children and solves the physical discomfort of children but also significantly improves the psychological and social effects of cough on children and their caregivers.

In this study, the average scores of the physical, psychological, and social domains of the LCQ-MC scale were mean 4.90 (SD 0.89), mean 4.99 (SD 1.28), and mean 4.850 (SD 1.37), respectively, and the average total score of each domain was mean 14.74 (SD 3.11). In the study conducted by Reynolds et al [59], the average scores of physical, psychological, and social domains of LCQ were mean 6.53 (SD 0.39), mean 6.83 (SD 0.34), and mean 6.87 (SD 0.27), respectively. The total scores of LCQ ranged from 17.05 to 21, with an average score of mean 20.23 (SD 0.85). The study suggested the following scores as the lower limits of a normal LCQ score: physical domain: 5.36; psychological domain: 5.81; social domain: 6.06; and total

XSL•FO
RenderX

score: 17.68. In our study, the scores of each domain and the total score of the LCQ-MC scale among children with PBB were lower than the lower limit of normal scores suggested by the above studies, suggesting that PBB can decrease the physical, psychological, and social quality of life in children.

The scores of PC-QOL were significantly lower than those of LCQ-MC. The differences in scores between PC-QOL and LCQ-MC could be attributed to the characteristics of parents and children in families. Parents' response is affected by their expectations and attention to their children, the burden of care, their own mental health, and family responsibility [60]. Children's quality of life score was higher than that of parents' evaluation. Consistently, previous studies have found that the self-rated quality of life scores of children with attention-deficit hyperactivity disorder syndrome, sickle cell anemia [61], and ataxia telangiectasia [62] were higher than those of their parents.

On the LCQ-MC scale, the lowest score was observed in the social domain, and the highest score was observed in the psychological domain. However, on the PC-QOL scale, the lowest score was observed in the physical domain and the highest score was observed in the social domain. Parents are more concerned about the effects of cough on the body of children, while the social function of children is more affected, suggesting that parents of children with PBB may ignore the effect of chronic cough on the social function of children. For children, it is critical to achieve good peer relationships, and children with chronic diseases more frequently report that their health problems impair their participation in group activities and affect their quality of life [63-65]. For children with PBB, chronic cough is often considered a sign of being unhealthy and infected. Children themselves worry about the effect of cough on peers, care about the views of classmates and teachers, and are unwilling to go to school. In addition, frequent absences in school and group activities due to repeated medical visits and exacerbation of cough symptoms subsequent to respiratory tract infection also limit the time of children to participate in social and recreational activities, thus decreasing their social communication skills. At the same time, the parent-child relationship between the children and their parents will also be affected, and the parents' requirements, control, and overprotection of the children will increase, and parents of the children will have to complete work tasks to earn sufficient money for taking care of their children, which can induce a negative feeling. Negative attitudes toward children can affect communication with children, and some parents even give their children to others because they cannot cope with their children's diseases, which affects children's psychosocial function [66]. Based on the bio-psycho-social medical model, people's health not only represents their normal physical function, but also the health and harmony of physiological, psychological, and social functions. Medical workers should not only solve the physical pain of patients but also improve their quality of life.

Therefore, clinicians should pay more attention to children with PBB who live in rural areas and whose parents have a low education level. Parents should consider the rest time at home for children with PBB to shorten the duration of the cough. PBB can seriously affect the physical, mental, and social functions of children. While treating the physical diseases of children, doctors and parents should also pay attention to the detrimental effects of cough on the psychological and social functions of children and strengthen psychological counseling and communication to help children improve their quality of life.

Limitations

Of course, this study has several limitations. First, the adjusted R^2 value of 0.121 suggests that a considerable proportion of the variance in cough duration remains unexplained. This indicates the potential role of unmeasured confounding factors, such as specific pathogens, the child's atopic predisposition, and variations in both the accuracy of primary care diagnoses and the level of awareness among primary care providers. Additionally, only Chinese participants were included in this study. No analysis of cultural or social influences related to racial or ethnic differences was conducted. Second, all measures, including symptom data and clinical assessments, relied on subjective information, which is susceptible to measurement bias, such as recall or reporting bias. Third, the relatively small sample size may limit the statistical power of the analyses, and the cross-sectional design precludes causal inference between variables. As a result, the findings are preliminary. Future studies should use longitudinal designs and recruit larger samples. They should also incorporate laboratory-confirmed bacterial diagnoses and environmental assessments to validate these findings and better elucidate the biological and sociobehavioral mechanisms influencing the course of PBB in children.

Conclusions

Based on univariate analysis, 4 variables potentially associated with cough duration prior to PBB diagnosis were identified and included in the multivariate regression model. The final model revealed that "place of residence" and "rest status during the coughing episode" were significantly associated with cough duration. Nevertheless, the model also indicated that a substantial proportion of the variance remains unexplained, suggesting the involvement of additional unmeasured factors that warrant further investigation. Moreover, our findings indicate that PBB significantly impairs children's physical, psychological, and social quality of life. Notably, changes in social functioning are often overlooked by both clinicians and parents during the diagnosis, treatment, and daily care of affected children.

Multimedia Appendix 1
Patients' demographics assessments with a case report form.
[PDF File, 326 KB - pediatrics_v8i1e82887_app1.pdf]

Multimedia Appendix 2
Questionnaires of simplified cough symptom score, cough symptom score, Leicester Cough Questionnaire, Leicester Cough Questionnaire in Mandarin-Chinese, and Parent-Proxy Cough-Specific Quality of Life.
[PDF File, 237 KB - pediatrics_v8i1e82887_app2.pdf]

Multimedia Appendix 3
Characteristics of 88 children, usage of antibiotics outside the hospital, pathogen detection in the bronchoalveolar lavage fluid, antibiotic use, duration of antimicrobial therapy, sCSS at first visit, comparison of CSS between day and night, efficacy evaluation of daytime cough, efficacy evaluation of nocturnal cough, LCQ-MC score, the reliability and validity of PC-QOL, and correlation analysis of LCQ-MC and PC-QOL scores among children aged ≥6 years. LCQ-MC: Leicester Cough Questionnaire in Mandarin-Chinese; PC-QOL: Parent-Proxy Cough-Specific Quality of Life; sCSS: simplified Cough Symptom Score.

Abstract

Background: Health care systems face challenges of inconsistent quality, inefficiency, and rising costs. Fragmented applications of clinical decision support systems (CDSSs), clinical pathways (CPs), and diagnosis-related group (DRG) payment systems have limited their synergistic potential.

Objective: This study proposed a CDSS-CP-DRG closed-loop model enabled by digital health technologies; specifically, the CDSS optimized CP execution through real-time data, the CP standardized workflows to support DRG cost control, and DRG payment pressures drove iterative improvements in both technology and processes. This research aimed to validate the model's effectiveness in clinical efficacy, cost control, and standardized diagnosis and treatment of bronchopneumonia in children and provide evidence for value-based health care transformation.

Methods: A total of 4543 children with bronchopneumonia were selected and divided into the experimental or control group based on whether the intelligent diagnosis and cost control system was used in the diagnostic process. Chi-square test, 1-way analysis of variance, paired *t* test, multiple regression analysis, and other mathematical statistical methods were used to verify the difference between the outcomes of the two groups of patients.

Results: This study demonstrated comparably high cure rates in both groups ($P>.05$). However, the experimental group exhibited a 0.4-day reduction in average length of stay, 12.3% lower total hospitalization costs, RMB 135.3 (US $19) higher medical insurance reimbursement surplus, and a reduction of 0.16 defined daily doses of antibiotic use intensity versus the control group ($P<.05$ for all significant differences).

Conclusions: The novel intelligent diagnosis and cost control system demonstrated significant improvement in clinical effect, cost control, and standardized treatment for pediatric bronchopneumonia, but the CP for pediatric pneumonia requiring intensive care still needs further attention and adjustment.

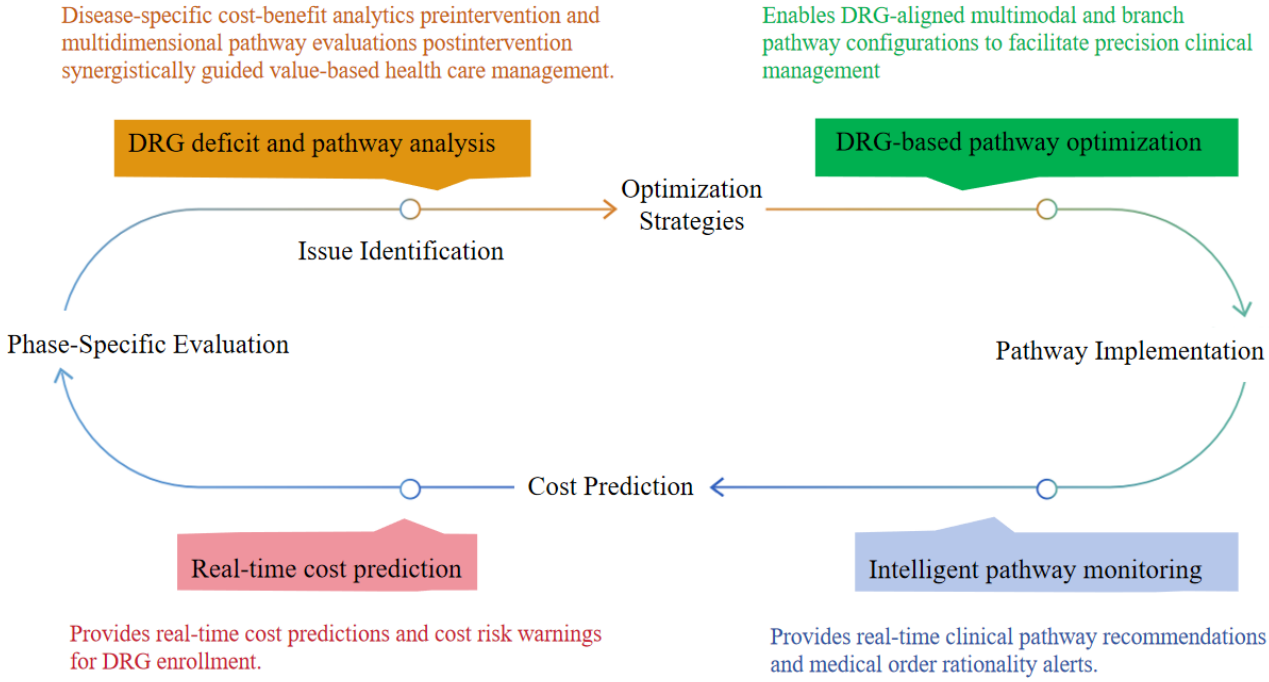
Introduction

Background

Bronchopneumonia, a prevalent lower respiratory tract infection, exhibits high incidence in children globally [1], with approximately 150 million annual cases among those aged 0‐5 years. Severe cases requiring hospitalization account for 12.82% of affected children [2,3], imposing substantial health burdens and socioeconomic costs [4].

Clinical decision support systems (CDSSs) integrate patient-specific data with computerized knowledge bases to generate evidence-based recommendations through software algorithms, representing a pivotal advancement in health informatics [5,6]. Pediatric applications demonstrate the capacity of CDSSs to enhance diagnostic accuracy, reduce errors, and improve workflow efficiency via intelligent alerts [7]. In addition, standardization of treatment through the use of clinical pathways (CPs) has proven to be an effective way to streamline

XSL•FO
RenderX



care in a way that minimizes errors and cost while improving outcomes [8].

Although these information-based systems hold transformative potential for global health care digitalization, rigorous economic evaluations and real-world effectiveness analyses remain scarce, with most evidence derived from narrative reviews rather than empirical data.

The Design and Implementation Path of a Novel Intelligent Diagnosis and Cost Control System

As shown in Figure 1, the artificial intelligence (AI)–driven CP optimization and cost containment system uses generalizable identification mechanisms and data-intelligent decision-making, integrating natural language processing, data mining, and machine learning technologies. It is integrated with core hospital information systems including electronic medical records, the laboratory information system, and the picture archiving and communication system. The system constructs disease-specific smart CPs that synchronize treatment quality assurance with expenditure control. This machine learning–powered architecture enables granular diagnosis-related group (DRG) adaptation, achieving precision treatment protocols (dynamic pathway optimization based on real-time patient status monitoring), intelligent cost governance (automated detection of billing deviations through natural language processing–based charge item analysis), and quality-cost balance (continuous learning from multisource clinical data to maintain care standards while reducing low-value services).

Figure 1. Closed-loop management framework of the intelligent decision and cost control system. DRG: diagnosis-related group.

Implementation Pathway and Core Functions

The intelligent diagnosis and cost control system (IDCCS) operates through a streamlined workflow, integrating multisource data from hospital systems (eg, hospital information system, laboratory information system, picture archiving and communication system, electronic medical records), followed by automated data cleaning and standardization. It features customizable CPs with DRG-based treatment branches and preimplementation cost simulations using historical data. The system establishes baselines through retrospective data analysis, then automatically enrolls eligible patients into pathways. During treatment, it provides real-time clinical decision support with deviation alerts requiring clinician confirmation, while monitoring prescription appropriateness and forecasting costs with early warnings. Posttreatment multidimensional analytics evaluate pathway efficacy, supporting continuous optimization.

Study Goal

This retrospective study analyzed the clinical outcomes, cost containment, and treatment standardization metrics of children with bronchopneumonia in a tertiary hospital in Eastern China (May 2023 to November 2024) and compared the difference of using or not using the IDCCS on these treatment outcome indicators. The findings provided empirical evidence for developing specialized and systematic intelligent CDSSs integrating cost-effective quality control in pediatric respiratory treatment.

Methods

Study Design

We designed a retrospective cohort study to analyze the differences in the results of 3 dimensions of treatment outcomes of hospitalized children with pneumonia for whom the IDCCS was used or was not used. The specific indicators of the 3 dimensions were as follows. The indicator of clinical efficacy was whether the disease improved. The economic indicators included length of hospital stay, total hospitalization expenses, proportion of drugs and consumables in expenses, and medical insurance settlement balance. The standardized diagnosis and treatment index was the volume of antibiotics dispensed (defined daily dose [DDD]).

XSL•FO
RenderX

Antibiotic therapy remains pivotal in pediatric pneumonia management [9]. The selection of DDD for evaluating antibiotic therapy compliance and normative treatment aligns with international guidelines [10,11]. This metric demonstrates superior validity in quantifying adherence to evidence-based protocols while balancing clinical relevance, operational feasibility, and comparability across multicenter studies [12]. The quantitative indicators including length of stay and health care costs can serve as economic end points to further validate the IDCCS's beneficial effects on treatment outcomes through cost analysis and resource utilization evaluation. These metrics' integration with CDSSs enables real-time feedback.

IDCCS Evaluation

Participants and Setting

This study was carried out at a tertiary hospital in Eastern China. The deployment of the IDCCS in December 2023 served as a natural intervention. Accordingly, patients retrospectively enrolled from the preimplementation phase (January to November 2023) comprised the control group. Conversely, patients from the postimplementation phase (the corresponding period in 2024) comprised the experimental group.

Information was collected for patients admitted to the hospital with the diagnosis of "bronchial pneumonia" and aged <14 years. The experimental group consisted of patients for whom the IDCCS was used (n=1658), and the control group consisted of patients for whom the IDCCS was not used (n=2885).

Cases were excluded if their medical records had home pages with incomplete information or important fields missing, home pages with errors, hospitalization expenses with outliers, hospitalization expenses below 100 yuan (US $13.95), hospitalization days below 0.1 days; ultimately, records for 4543 children were retained.

Data Collection

All the data were extracted from the hospital's internal database. To describe the population included in the study, the following variables were extracted at baseline: age, sex, diagnosis, with coinfection or not, and treatment result.

Statistical Analysis

Statistical analyses were conducted using SPSS for Windows (version 23.0; IBM Corp). Categorical data were denoted in numbers and percentages, while continuous variables were represented as means and SDs. Data normality and homoscedasticity were preliminarily verified before executing each statistical analysis.

The χ^2 test was used to compare the differences in categorical variable indicators between the experimental group and the control group (gender, diagnosis results of disease severity, concurrent infections, treatment outcomes). Paired *t* test and 1-way ANOVA were used to test the differences in continuous variables of the research subjects (length of hospital stay, total hospitalization cost, proportion of drug and consumable costs in the total cost, balance of medical insurance settlement, DDD).

For all tests, a *P* value ≤.05 was considered statistically significant.

Furthermore, in the comparison of treatment outcome differences, we not only conducted the analysis of the overall experimental group and intervention group, but also further divided the patients based on whether they required intensive care and whether they had severe complications or comorbidities, and then conducted further analysis separately.

Ethical Considerations

This study, conducted in accordance with the Declaration of Helsinki, received approval from the institutional review board of Taizhou Hospital of Zhejiang Province (K20250873). As it was a retrospective study involving the analysis of existing, anonymized data, the requirement for informed consent was waived by the ethics committee. To ensure data security and patient confidentiality, all personally identifiable information was removed prior to analysis. The data were accessed strictly for research purposes and stored on secure, password-protected hospital servers [13].

Results

Overview

Among the 4543 patients included in the study, 1658 were in the IDCCS-used (experimental) group, and 2885 were in the IDCCS-without (control) group. Data on demographic characteristics, discharge diagnosis, coinfection with or without, and treatment outcomes of the patients are provided in Table 1. No statistically significant differences were observed in age or sex distribution between the experimental and control groups (*P*>.05).

Clinical Efficacy

Participants were stratified into 3 diagnostic subgroups: pediatric pneumonia, pediatric pneumonia requiring intensive care, and pediatric pneumonia with severe comorbidities and complications. Statistical analysis revealed no significant differences in treatment outcomes between the intervention and control groups across these subgroups (*P*>.05) (Table 2).

Table . The differences in treatment outcomes among participants in different diagnostic subgroups.

		Control (n=2554)	Experimental (n=1647)	Chi-square (*df*)

Economic Indicators

As shown in the analytical data in Table 3, following the implementation of the IDCCS, the experimental groups demonstrated a statistically significant reduction in the length of stay by 0.4 days (*P*<.001), with total hospitalization expenses decreasing by 12.2% (RMB 508.56 [US $71.43]) and medical insurance settlement balance increasing by RMB 135.3 (US $19; both *P*<.001).

Further group analysis found that the previously mentioned indicators of patients with pneumonia in the experimental group were improved. However, no significant differences were observed in the pediatric pneumonia subgroup requiring intensive care (*P*>.05).

Pediatric pneumonia requiring intensive care	715.0	–5.0	381.6 to 1052.1	2704.7	12.4	135.8 to 5335.7	6.1 (1)	.01

Standardized Diagnosis and Treatment

Table 4 demonstrates that while the experimental group showed a modest reduction in mean antibiotic prescribing intensity (−0.1 DDD) compared to the control group, this system-wide effect was not statistically significant (*P*=.21). However, in the pediatric pneumonia subgroup that leveraged the clinical decision support features of the IDCCS, we observed a statistically and clinically meaningful reduction in antimicrobial exposure intensity (−0.2 DDD; *P*=.002), representing a 6.8% decrease compared to the control group.

Discussion

Principal Results

Our findings demonstrate that implementing the IDCCS CDSS significantly reduced treatment costs and improved standardized treatment in pediatric pneumonia management [14]. The digital intervention was associated with a reduction in the length of stay, a decrease in total hospitalization expenses, an increase in the medical insurance settlement balance, and a reduction in antibiotic prescribing volumes [15].

These results highlight the dual benefits of AI-driven decision support in enhancing value-based treatment while maintaining normative treatment quality.

However, within our study, in the pediatric pneumonia subgroup requiring intensive care, the aforementioned outcome metrics demonstrated no statistically significant improvement, suggesting that the current CP algorithms in the intelligent diagnosis assistance system require further optimization for use in critically ill patient populations.

Interpretation and Comparison With Prior Work

Extensive international research demonstrates that health information technology, characterized by accessibility, feasibility, and efficiency, significantly reduces antibiotic resistance rates, antimicrobial therapy mortality, and health care costs [16-19].

Christensen et al [20] put forward that CDSSs were designed according to the “Five Rights” principle: delivering the right information to the right recipient at the right time, through the right channel, in the right format. As a tool for auxiliary diagnosis, CDSS can improve the quality and efficiency of diagnosis. Düvel et al [21] demonstrated in a qualitative study that CDSS holds promise for optimizing antibiotic stewardship, while current systems lack AI technology integration.

Umoh et al [22] proposed the future development of CDSS in clinical treatment and management; a comprehensive tool that is precise and user-friendly would improve clinical decisions and efficiency.

Farkas et al [23] revealed that the use of CPs could reduce unnecessary diagnostic testing in hospitalized patients, which is consistent with the conclusion of our study. Jaafar et al [24] found that the implementation of DRG policy and CPs significantly enhanced health care resource utilization. However, evidence evaluating the effectiveness of CPs using real-world data remains limited in current literature. As noted by Bakel et al [25], most hospitals were unable to measure their pathway outcomes or demonstrate improvement in care.

In these prior studies, CDSS, CP, and DRG payment systems were mostly applied and evaluated separately, and the fragmented application greatly limited their synergy potential. Current literature lacks real-world data studies investigating the integration of CDSSs with CPs.

This study innovatively proposed a CDSS-CP-DRG closed-loop model enabled by digital health technologies, where CDSS optimized CP execution through real-time data, CPs standardized workflows to support DRG cost control, and DRG payment pressures drove iterative improvements in both technology and processes. Their integration promoted evidence-based practice, reduced clinical variation, and curbed overutilization, particularly in resource-sensitive pediatric settings.

Strengths and Limitations

DRG is a well-known type of hospital payment system that aims to establish the reference interval of medical expenses. It can effectively reduce costs, decrease the difficulty of standardized management of the medical diagnosis and treatment, and facilitate the macroprediction and control of medical expenses.

The ultimate goal of the DRG cost pathway is to achieve optimal medical value [26]. In this study, we integrated CDSS with CP systems using AI technology to develop the IDCCS, and the framework established a closed-loop quality and cost control process spanning preimplementation DRG-based deficit analysis and CP optimization, intraimplementation execution with real-time alerts, and postimplementation statistical analytics. This system ensures standardized diagnosis and treatment while managing and controlling health care costs for hospitalized patients through the establishment of defined insurance payment

XSL•FO
RenderX

quotas. As a result, hospitals are incentivized to reduce medical costs proactively, shorten hospital stays, and minimize unnecessary expenditures in pursuit of economic profitability. This approach facilitates cost control and promotes the rational and standardized use of medical resources [27]. Ultimately, it aims to achieve low-cost, high-quality, efficient, and health-oriented value-based treatment [28,29].

Conclusion

This study innovatively integrated a CDSS with CPs to optimize DRG-based case management. An AI-driven CDSS-CP framework was developed for pediatric pneumonia, demonstrating scalability for diverse clinical contexts. AI-optimized CPs enhanced cost-effectiveness (ie, reduced medical expenditures) and care standardization, further validating its role in health care system reform. The model contributed to evidence-based global health care practices and population health improvement. However, CPs for critical cases or other diseases require continuous optimization and adaptation to enhance health care resource utilization and standardize clinical practices.

Abstract

Background: COVID-19 is currently one of the most important medical challenges as it affects the entire population, with children and adolescents being infected as easily as adults.

Objective: The objective of this study was to evaluate the prevalence of mortality in children and adolescents aged <19 years, compared to that of adults.

Methods: This retrospective, observational study analyzed the medical records of all patients diagnosed with COVID-19 by real-time reverse transcription–quantitative polymerase chain reaction who were hospitalized at Hospital de Base and the Infant and Maternal Hospital of São José do Rio Preto, São Paulo, Brazil. Out of a total of 8986 hospitalized patients who were COVID-19 positive, 383 (4.26%) were children and adolescents aged <19 years (group 1), and 8603 (95.74%) were adults (group 2).

Results: Overall, mortality was significantly higher (P<.001) in group 2 (2185/8603, 25.4%) compared to group 1 (12/383, 3.1%). A total of 11 (92%) of the 12 patients in group 1 that died had associated diseases. The mortality rates by age group were as follows: infants aged <1 year, 1.6% (2/123); children aged 1-4 years, 4% (4/95); children aged 5-9 years, 2% (1/47); adolescents aged 10-14 years, 2% (1/40); and adolescents aged 15-19 years, 5% (4/78).

Conclusions: Mortality from COVID-19 in children and adolescents was significantly lower than that in adults and was associated with other comorbidities.

Introduction

COVID-19 is currently one of the most important medical challenges as it affects the entire population, with children and adolescents being infected as easily as adults; children and adolescents often remain asymptomatic or have mild complaints due to their immature immune systems [1]. Advanced age and comorbidities such as hypertension, diabetes, ischemic heart disease, vascular disease, renal failure, obesity, dyspnea, and dementia have been reported to be associated with a greater risk of death among older people infected with COVID-19. Some studies have described pathophysiological insights into COVID-19–induced coagulopathy, endothelium disease, and angiogenesis-associated defects [2-4]. Most children and adolescents with COVID-19 have mild symptoms; however, coagulopathies have been associated with multisystem inflammatory syndrome—a postinfectious complication—in young patients [2].

A study in Sergipe, Brazil, describing COVID-19 cases and deaths in children and adolescents reported 37 deaths before September 20, 2020, corresponding to a rate of 4.87 deaths per 100,000 of the population aged <19 years. Most children and adolescents had comorbidities such as chronic neurological diseases (n=7, 19%) and prematurity (n=4, 11%). Furthermore, most children and adolescents who died (n=18, 49%) were not admitted to intensive care units. This was possibly related to the great regional inequalities in health care [5].

A study in England reported that 4% (1408/35,200) of tests performed in children and adolescents aged <16 years were positive for SARS-CoV-2, compared to 19.1% to 34.9% in adults [3]. A review of pregnant women with COVID-19 reported that SARS-CoV-2 was detected in 4.3% (19/444) of newborns at birth. Elevated levels of immunoglobulin M and G serum antibodies were reported in one case, but the swab test was negative [4]. Mortality in children is higher in those with existing diseases compared to those without comorbidities [6].

XSL•FO
RenderX

Regarding the prognosis, metabolic acidosis, hyperlactatemia, hyperglycemia, altered liver function parameters, and hypoproteinemia are biochemical markers associated with the severity of the disease in children infected with SARS-CoV-2. Anemia and ketoacidosis are important risk factors for death in the pediatric patient population who are infected [7]. Gastrointestinal involvement is common in children hospitalized for acute COVID-19 infection and multisystem inflammatory syndrome, but gastrointestinal involvement is not associated with critical illness, length of hospital stay, or mortality in acute cases of COVID-19 [8].

In a study of pediatric COVID-19 epidemiology, Sousa et al [9] highlighted the presence of comorbidities in patients aged <2 years, in particular those related to congenital heart disease, Down syndrome, obesity, and asthma. Furthermore, these authors reported differences in morbidity and mortality due to regional disparities, with higher rates in regions with less resources, as is the case in the economically less favored northern and northeastern regions of Brazil. In their analysis of 2020 deaths of children that occurred throughout Brazil, 42% occurred in children aged <2 years and 43% occurred in adolescents aged 10 - 19 years, with children aged 2 - 10 years being relatively protected. A total of 58% of deceased patients had at least one comorbidity. It is noteworthy that 69% of deaths were observed in Black or multiracial patients, 25.5% in White patients, and 5% in Indigenous patients, with approximately 60% occurring in the northern and northeastern regions of Brazil.

It is also worth remembering the prolonged symptoms that are associated with COVID-19—notably, fatigue, headaches, drowsiness, and difficulty concentrating—as well as the impact of social isolation, which can cause psychosocial disorders and learning gaps that can have a major impact on children's education [10,11].

An American study reports that pediatric patients with a recent relapse of cancer have a higher chance of all-cause mortality when infected with COVID-19 [12].

The objectives of this study were to evaluate the mortality of children and adolescents and compare it with that of adults in a cohort of 8986 patients hospitalized for COVID-19 in a university hospital complex in Brazil.

Methods

Patients and Setting

A retrospective, observational study was performed to analyze the medical records of all patients diagnosed with COVID-19 who were hospitalized at Hospital de Base and the Infant and Maternal Hospital of São José do Rio Preto, São Paulo, Brazil, from March 2020 to July 2023.

All patients diagnosed with COVID-19 by reverse transcription–quantitative polymerase chain reaction and admitted to these hospitals were included in this study. Patients hospitalized for other illnesses and those who tested negative for COVID-19 during this period were excluded.

Patients aged <19 years were categorized as children or adolescents (group 1), and those aged ≥19 years were categorized as adults (group 2). Group 1 was further subdivided by age: <1 year, 1 - 4 years, 5 - 9 years, 10 - 14 years, and 15 - 19 years. The monthly occurrence of COVID-19 was evaluated, with mortality in children and adolescents being compared to that in adults. Existing diseases and the occurrence of other viral infections were identified over the same period in patients aged <19 years who were COVID-19 positive.

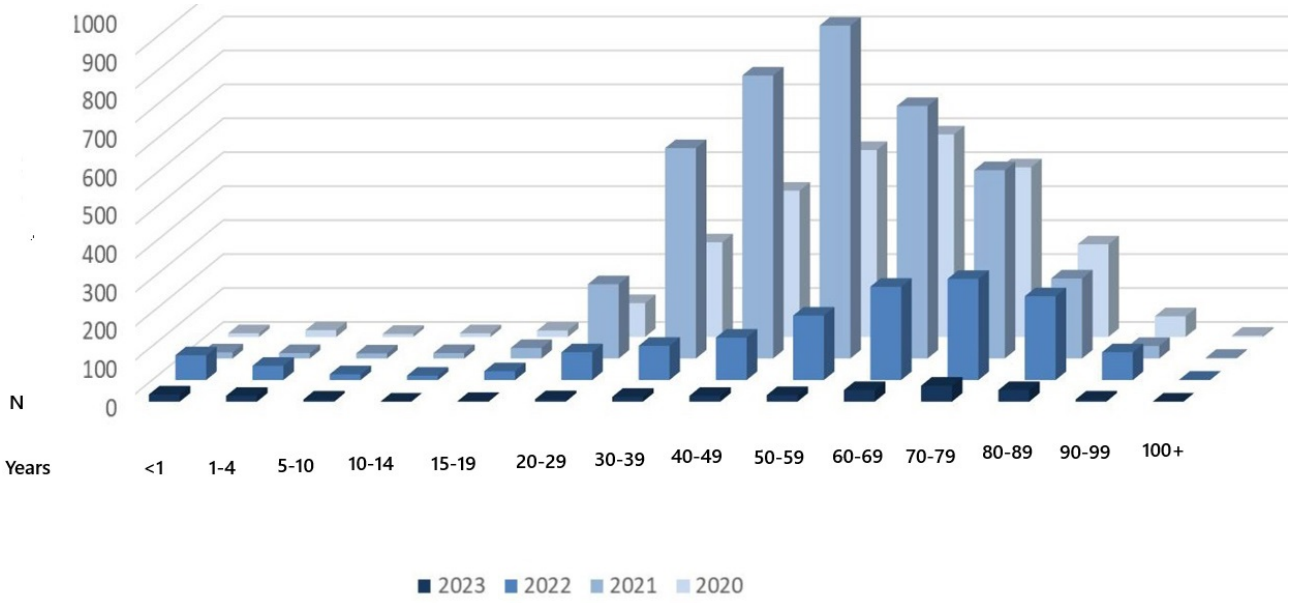
Ethical Considerations

The study was approved by the ethics committee of the Medical School in São José do Rio Preto under approval 6.086.468 (CAAE 67915723.3.0000.5415; date approved: May 29, 2023).

For this study, the institution permitted the analysis of these records, guaranteeing the use of data only in this research protocol. Absolute confidentiality was maintained during the data collection and use thereof. Safeguards were taken to collect data from medical records in the institution's own archives department; patient charts were not removed for any reason.

The signed consent form was authorized by the ethics committee to be waived, because these were medical records and due to the impossibility of contacting family members and those who have died. Thus, the authors guaranteed the privacy and confidentiality of the data obtained, fully preserving the anonymity of the participants in accordance with the Declaration of Helsinki.

Statistical Analysis



Data were tabulated in Microsoft Excel spreadsheets, with statistical analysis conducted using StatsDirect 3 software (StatsDirect Ltd). Descriptive statistics, Fisher exact test, chi-square test, and odds ratio were used considering an α error of 5% ($P \leq .05$).

Results

Between March 2020 and July 2023, a total of 8986 patients who were COVID-19 positive were hospitalized, 383 (4.26%) of whom were aged <19 years and 8986 (95.74%) were aged ≥19 years (mean age 57.66 y; Figure 1). Overall, 12 children and adolescents died, that is, 3.1% of the 383 patients in this age group. The number of deaths in group 2 (adults) was 2185, that is, equivalent to 25.4% of the 8603 hospitalized adults and 99.45% (2185/2197) of overall deaths. Mortality was significantly higher for adults than children and adolescents aged <19 years (Yates-corrected χ^2 test=98.127501, $P<.001$; odds ratio 10.317, 95% CI 5.793 - 18.374).

Figure 1. Patients hospitalized with COVID-19 by age group and year.

Regarding the different age groups of children and adolescents, the mortality rates were as follows: infants aged <1 years, 1.6% (2/123); children aged 1-4 years, 4% (4/95); children aged 5-9 years, 2% (1/47); adolescents aged 10-14 years, 2% (1/40); and adolescents aged 15-19 years, 5% (4/78). There were no statistical differences between the different age groups (Fisher exact test: *P*=.30; Table 1 and Figure 2). Figure 3 shows the main viral infections of the patients who were COVID-19 positive in the 2 hospitals, emphasizing the importance of this disease. Table 2 shows the associated diseases of the 12 children who died from COVID-19.

Discussion

Principal Findings

This study reports on the general mortality of children and adolescents aged <19 years and adult patients in a single university hospital complex from March 2020 to July 2023. Of the 8986 patients hospitalized with COVID-19, a total of 383 (4.26%) were children and adolescents treated at the children's hospital. Deaths in this age group represented 0.55% (12/2197) of all deaths from COVID-19 in the institution and 3.1% (12/383) of all hospitalized patients aged <19 years. No significant difference was detected in mortality between the age groups of children and adolescents. A multicenter study in Latin America reported a mortality rate of 14% in 210 children, with

XSL•FO
RenderX

67% of those who died being treated in an intensive care unit [13].

Observational studies in the pediatric population have shown that the presence of comorbidities is a risk factor for severe disease. Obesity, genetic disorders (such as sickle cell anemia), neurological disorders, hematological diseases, congenital heart diseases, diabetes, chronic kidney disease, asthma, and other lung diseases are pathologies that have already been associated with the severity of COVID-19 in previous studies [14]. In this study, heart disease was the main disorder reported in the children and adolescents who died.

Regarding the age of the children and adolescents, there is no consensus on which age group has the highest or lowest severity of disease, included mortality; however, severity does seem to be linked to the presence of preexisting clinical factors. A review study reported that younger children and those with specific comorbidities, such as obesity, diabetes, heart diseases, chronic lung diseases, epilepsy, and immunocompromised conditions, are at higher risk of infection and potentially more severe consequences of COVID-19 [15,16].

One interesting Brazilian study that analyzed a large nationwide database of hospitalized children and adolescents with laboratory-confirmed COVID-19 showed that death was associated with being aged younger than 2 years or between 12 and 19 years. Indigenous ethnicity, living in the poorest microregions, and the presence of comorbidities were also correlated with the severity of the disease. Therefore, health care disparities and social inequalities, exacerbated by interweaving comorbidities, might have contributed synergistically to magnifying the COVID-19 burden for more socioeconomically deprived and vulnerable individuals [17]. Due to uncertainties in epidemiological data on children, there is still much to learn about the manifestations of COVID-19 in this population.

In this study, no significant differences with respect to mortality were detected between age groups of the children and adolescents; however, the number of patients is too small to arrive at any definite conclusion.

In North America, mortality was higher in children younger than 1 year, followed by adolescents aged between 15 and 19 years [18]. In 2021 and 2022, a study in Java, Indonesia, analyzed 6441 patients aged ≤18 years who were positive for COVID-19 and reported that 2.7% of deaths occurred with other associated factors; in this study, the rate was 91.67%—a difference that may be related to the different conditions (socioeconomic factors and access to health care) in the 2 countries [19].

Regarding mortality, since the beginning of the pandemic, newborns, children, and adolescents are less prone to this emerging condition compared to adults. Most of them experience mild symptoms; hospitalization and death of pediatric patients are rare, with deaths usually being explained by associated complications [20].

In Ecuador, a study on mortality from 2020 to 2021 reported that out of 34,001 confirmed cases of COVID-19, a total of 258 were children and adolescents aged between 0 and 19 years and that 127 died due to COVID-19. In the same period, the study found that most deaths occurred in children aged 0 to 1 year, representing 44% (n=114) of the total deaths reported [21].

In Brazil, in 2020, a total of 14,638 children were diagnosed with SARS, resulting in 1180 (8.06%) deaths. Being younger than 2 years was a risk factor for higher hospitalization and mortality rates [22]. In 2021, an increase in the number of cases of pediatric patients was noted; according to data from the Brazilian Ministry of Health, there were 17,644 occurrences of SARS-CoV-2 with 1263 (7.15%) deaths. This rise is related to greater knowledge of the disease, a simpler diagnosis, the larger quantity of diagnostic tests performed, and the emergence of new variants (Delta and Omicron) [9].

Pediatric patients with comorbidities are at higher risk for hospitalization and mortality. Among the reported comorbidities, the following should be highlighted: Down syndrome, asthma, obesity, immunosuppression, and heart disease. Morbidity and mortality due to COVID-19 are not similar to other etiologies of acute respiratory distress syndrome. This is because fulminant activation of coagulation cascades can occur in COVID-19, resulting in widespread microvascular thrombosis and the consumption of clotting factors [9,22-25]. It appears that inflamed lung tissues and pulmonary endothelial cell damage may result in the formation of microthrombi that contribute to the high incidence of thrombotic complications, such as deep vein thrombosis, pulmonary embolism, and arterial thrombotic complications.

Another important factor that must be highlighted is the possibility of long-term symptoms such as fatigue, headaches, drowsiness, and difficulty concentrating, all of which have implications in social and educational spheres, leading to important concerns regarding the impact of the pandemic on future education levels.

Another point to be considered is related to the risk of the long-term effects of COVID-19 on the health of the general population. Post–COVID-19 coronary changes and the presence of multisystem inflammatory syndrome were identified in some pediatric patients. Therefore, although children and adolescents represent a low percentage of COVID-19 cases in Latin America and worldwide, major social, economic, and cultural implications are linked to the disease in this population. In truth, COVID-19 has disrupted all spheres of life, including country risk factors, such as exposure to multidimensional risk drivers.

Socioeconomic and political factors significantly influence health care conditions and directly impact the response to pandemics, including the allocation of resources for immediate health care needs. Studies analyzing the influence of demographic, economic, and political conditions in different countries and continents show a significant difference between countries with a low Human Development Index and those with a high Human Development Index. This has influenced, and continues to directly influence, human health care [26,27].

It should be remembered that the dynamics of infections and deaths related to COVID-19 differ from country to country and are constantly changing throughout Latin America. Management requires political leadership, financial resources, and social

XSL•FO
RenderX

equality, as well as the existence of informal and regional economies directed toward disadvantaged populations that traditionally have had limited access to health services. In this study, COVID-19 was the most common viral infection identified in this period. Mortality from COVID-19 in children and adolescents was lower than that in adults and was generally associated with existing diseases, with the main one being heart disease.

This study shows results consistent with our hypothesis and with the results of studies published in MEDLINE. Thus, predicting the outcome of COVID-19 is of vital clinical importance to better allocate medical resources and provide individualized treatment for patients. The availability of clinical characteristics and parameters with potential prognostic implications will be of value for effective prevention and intervention.

Conclusion

Mortality from COVID-19 in children and adolescents was lower than that in adults. A second interesting finding was that these deaths were generally associated with existing diseases.

Data Availability

All data generated and analyzed during this study have been included within the paper.

Abstract

Background: Parents and caregivers with preterm babies in the neonatal intensive care unit (NICU) experience high levels of distress and are at an increased risk of anxiety, depression, and acute stress disorders. Effective interventions to reduce this distress are well described in the literature, but this research has been conducted primarily in Europe and North America. To our knowledge, few interventions of this sort have been developed in Australasia, and none have been developed or tested in Aotearoa New Zealand.

Objective: The primary aims of this study were to explore sources of stress with caregivers and clinicians in a NICU in Aotearoa New Zealand and gather participant ideas on ways to reduce caregiver stress to inform intervention development.

Methods: This qualitative design used an essentialist and realist methodology to generate findings aimed at future intervention development. Overall, 10 NICU clinicians (neonatologists, nurses, and mental health clinicians) and 13 caregivers (mothers, fathers, and extended family members) of preterm babies, either currently admitted or discharged from the NICU within the last 12 months, were recruited to participate in interviews exploring stress and stress-reduction in the NICU.

Results: The 23 participants included 10 clinicians (all female, with an average of 15 years of experience in the NICU) and 13 parents and caregivers (majority of them were female; 10/13, 77%) of preterm babies. We identified 6 themes relevant to intervention development. Three themes focused on caregiver stress: the emotional "rollercoaster" of NICU; lack of support, both culturally and emotionally; and caregivers feeling "left out" and confused. Three themes focused on participant-proposed solutions to reduce stress: caregiver empowerment, improving emotional support, and communication on "my" terms (ie, digitally).

Conclusions: Participants reported high levels of caregiver stress in the NICU, and they proposed a range of stress-reducing solutions, including increasing caregiver empowerment and improving emotional and cultural support. Clinicians and caregivers also strongly agreed on providing more information for caregivers in digital, mobile-friendly formats.

Introduction

Parents with babies in the neonatal intensive care unit (NICU) have described the NICU experience as "terrifying" and "traumatic" [1], and they frequently experience high rates of stress, anxiety, depression, and acute stress disorders [2,3]. These effects can last well after discharge, with long-term negative effects including problems with parent-child bonding and attachment [4].

The most common cause of admission to the NICU is preterm birth (born at less than 37 weeks gestational age). Preterm birth affects an estimated 1 in 10 births annually around the world and is the leading cause of death for children under 5 years of age [5]. In Aotearoa New Zealand, a diverse, bicultural country,

XSL•FO
RenderX

preterm birth is estimated to occur in 8.9% of annual births [6]. New Zealand Europeans experience fewer preterm births, perinatal deaths, and maternal deaths than Māori, the Indigenous people of Aotearoa New Zealand who make up 17.3% of the population [7]. They also experience fewer adverse perinatal outcomes than Pacific Peoples and Indian minority groups in Aotearoa New Zealand [8]. Additionally, New Zealand European babies are less likely to be admitted to NICU than these 3 groups [9].

Effective interventions to reduce the distress of parents with babies in the NICU are well described in the literature, but this research has been conducted primarily in Europe and North America, and mostly with Caucasian mothers [10,11]. To our knowledge, few interventions of this sort have been developed in Australasia, and none have been developed or tested in Aotearoa New Zealand. As a recent study of services showed, psychosocial support for caregivers in the NICUs in Aotearoa New Zealand is highly limited, with no formalized support programs, limited cultural support services, and fewer staff members available to provide support to parents with babies in the NICU [12]. Given the limited resources available to support this highly distressed population, clinically feasible and culturally appropriate interventions for use in the NICU should be developed for the Aotearoa New Zealand context.

A few qualitative studies have explored the experiences of families in Aotearoa New Zealand NICUs [13,14], including for Māori whānau (families) [15]. However, no intervention research focused on reducing distress has been conducted with caregivers in the NICUs of Aotearoa New Zealand.

Therefore, the main objectives of this study were to gather feedback from caregivers and clinicians in the NICU on sources of caregiver stress and ways to reduce that stress to inform future intervention development.

Methods

Study Design

We conducted a qualitative study using semistructured interviews with caregivers and clinicians from September 2022 to April 2023 in a level 3 NICU in Auckland, Aotearoa New Zealand. We analyzed the data using thematic analysis (framework method).

Ethical Considerations

The Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist was followed to report the qualitative study findings. The Auckland Health Research Committee provided ethical consent (#AH24458). Informed written consent was provided by participants in advance of their participation in this study. Individuals were provided with a NZ $50 (US $28) gift voucher to a local store as thanks for their participation. To ensure confidentiality, all identifying details were removed from the data, and participant transcripts were issued numeric codes.

Setting

This study was conducted at Te Toka Tumai Auckland Starship Child Health NICU, a level 3 NICU and one of Aotearoa New Zealand's largest NICUs. Most rooms are shared, with 40 cots in the unit and an average of 900 infant admissions per year. The unit is a regional specialty center with a diverse patient population. In 2023, 29% of babies in the unit were New Zealand European, 19% were Other Asian, 17% were Indian, 17% were Pacific Peoples, and 16% were Māori. Common causes of admission were preterm birth (42%), respiratory distress (25%), and congenital abnormalities (14%) [16].

All participants in our study had admissions in the NICU during the COVID-19 pandemic. COVID-19–related visitor restrictions in the unit varied during this study's time period, with parents recruited earlier in the study experiencing more restrictive conditions than those recruited later in the study. NICU visitor restrictions included limiting visitors in the NICU to one parent at a time, not allowing extended family visitors without special permission, and requiring all visitors to wear facial masks in the unit.

Participants and Recruitment

We sought to collect a range of perspectives on caregiver stress and support in the NICU, so we recruited both currently admitted and discharged parents and legal guardians of preterm babies in the NICU. We also aimed to include other types of caregivers in this study, such as extended family members who had spent significant time in the NICU. This is important in the Aotearoa New Zealand cultural context, as grandparents and other extended family members (such as aunts and uncles) often play important caregiver roles in many cultures, including Māori [15].

Caregivers were eligible for the study if their baby was currently admitted to the NICU or discharged within the previous 12 months and had an admission lasting at least 2 weeks. Participants also had to be 18 years of age or older and be able to read and speak English.

Clinicians were eligible for the NICU clinician group if they were currently employed by Te Toka Tumai Auckland Starship Hospital and interacted closely with caregivers in the NICU as a standard part of their job. Eligible roles included nurses, neonatologists or pediatricians, and mental health clinicians, including social workers and psychotherapists.

An experienced research nurse in the NICU recruited parents with babies currently admitted in the unit. Parents of discharged babies were introduced to the study by clinicians using convenience sampling in an outpatient follow-up clinic for NICU graduates. Parent participants were encouraged to invite their extended family members to participate if they had spent significant time in the NICU.

Clinicians in the NICU were recruited via voluntary response sampling. Study promotion flyers for clinicians were displayed in the unit staff room and distributed by email.

Recruitment for this study was closed after data saturation was reached in both groups. Data saturation was defined as the point at which little or no relevant new categories were found in the data [17]. The final study sample size (N=23) also met the recommended sample size guidelines for achieving rigor in qualitative research of this type [18].

XSL•FO
RenderX

Interview Schedule

The open-ended interview questions (Multimedia Appendix 1), with a caregiver version and a clinician version, were developed by the research team and based on existing literature about the sources of stress and support for parents with babies in the NICU. In the caregiver interview, part 1 included open-ended questions about sources of stress (ie, "What situations did you find most stressful in the NICU?") and support (ie, "What helped you manage your stress most in the NICU?"). In part 2, caregivers were shown examples (websites, apps, and printed materials) of NICU education materials and evidence-based stress-reduction activities from a range of sources (both local and international) and asked for their feedback on usefulness and feasibility. Questions were a mixture of open and closed questions in part 2 (ie, "Would you have used this type of intervention in the NICU? Why or why not?").

In the clinician interview, in part 1, clinicians were asked questions about their work with caregivers and what was most stressful and supportive from their perspective (ie, "In your experience, what types of support, education, or staff roles are most helpful in reducing stress for parents and family members?"). In part 2, clinicians were asked about their ideas on stress reduction tools and what they would like to see included (ie, "What are some features of a stress-reduction intervention that you would like to see for parents in the NICU?"). They were also asked about potential challenges involved in the implementation and feasibility of a new stress-reduction intervention.

The interview schedules were piloted with a researcher with lived NICU experience and a NICU clinician uninvolved in this study. Based on that feedback, the order of questions was changed to improve the interview flow, and some questions were simplified.

Procedure

After expressing interest in the study, participants were contacted by a researcher who introduced them to the study and sent them a link to study enrollment materials. Participants provided informed consent and completed a demographic survey through the web-based research tool REDCap (Research Electronic Data Capture; Vanderbilt University).

Participants chose their preferred interview method (in-person or on Zoom), and families were invited to participate in interviews either individually or as a group. Each participant was given a voucher as a gift of thanks at the start of the interview.

Interviews lasted an average of 45 minutes for clinicians and 60 minutes for caregivers. Interviews were audio-recorded (if in-person) or via Zoom's recording feature.

Two researchers conducted interviews and had no prior relationship with any of the participants. One interviewer (JR) was an experienced female Māori nurse and qualitative researcher who holds leadership roles in equity and Māori engagement. She is a mother of 5 children and grandmother of 7. The other interviewer (KHG) was a European, female, health psychology PhD candidate, licensed mental health clinician who specializes in perinatal mood disorders, and mother of 2 children.

Participants who self-identified as Māori were offered the choice of being interviewed by the non-Māori or Māori researcher. The Māori researcher conducted interviews in alignment with tikanga Māori (Māori protocols).

Interviews were transcribed using automatic speech recognition tools (Zoom and Whisper.AI [19]) and checked and corrected for accuracy using audio or video recordings. To ensure confidentiality, all identifying details were removed, and participant transcripts were issued numeric codes. Participants could review transcripts if they wished within 2 weeks after completing an interview.

Qualitative Methodology

This study's methodology was grounded in an essentialist and realist epistemology (that a reality exists independently of researcher beliefs or interpretations) [20] and informed by existing stress theory, including the situational stress model [21], on which the validated PSS:NICU (Parental Stress Scale: Neonatal Intensive Care Unit) was developed [22]. We used the framework method of thematic analysis, a qualitative method commonly used in applied health research [23]. The framework method allows for both a deductive approach, led by existing theory and predetermined concepts organized into a "framework," and an inductive approach, exploring new concepts based on the data [17].

Data Analysis

Anonymized interview transcripts were imported into the qualitative data analysis software NVivo (release 1.3, Lumivero). Data were then analyzed using the five-step process of the framework method: (1) familiarization with the data, (2) creating a coding framework, (3) indexing (coding), (4) charting (sorting and grouping of coded data), and (5) mapping and interpreting (creating themes) [23].

The initial coding framework for the caregiver dataset was developed a priori from the interview schedule and existing research on NICU parental stress using a deductive approach. It was piloted on 3 transcripts by KHG and PR. During that process, codes were also added as needed in an inductive, data-driven fashion in accordance with the framework method, which allows for both inductive and deductive approaches [17]. The same method was used to create the clinician framework. All investigators discussed and agreed on the final codes and frameworks.

Working independently and using the frameworks, 2 researchers (KHG and PR) coded transcripts, charted (grouped) the data into categories, and developed initial minor and major themes. Then, they used a collaborative approach to create the final themes, working together to compare theme ideas against transcripts and reevaluate when needed.

Initially, themes were created separately for the caregiver and clinician groups. However, after both researchers identified nearly identical themes in the 2 groups independently and shared the results with the investigative team, the decision was made to merge the datasets together. This agreement between datasets

XSL•FO
RenderX

also provided triangulation, which helps ensure data rigor and credibility in qualitative research [24].

The Māori researcher (JR) also reviewed themes and example quotes for cultural understanding for the Māori participant transcripts. The final themes were reviewed and refined by all coinvestigators.

Results

Participant Characteristics

We interviewed 23 participants, conducting 13 interviews on Zoom (including 2 with couples) and 8 in-person: at a university (n=5), in the NICU (n=1), and, for caregivers, at participants' homes (n=2). Three babies were present during these interviews.

Thirteen caregivers (12 parents and 1 grandparent) completed interviews and experienced NICU stays with 10 infants (8 singletons and 1 set of twins). Although we aimed to recruit multiple types of caregivers (ie, parents, grandparents, aunts, and uncles) in this study, only 1 nonparent caregiver was successfully recruited. This was likely due to COVID-19–related restrictions in the unit that ran throughout the study period and only allowed nonparent or legal guardian family members into the unit with special permission (such as to support a single mother) and did not allow children (siblings). All study families had infants admitted to the NICU due to preterm birth, and the majority of babies (6/10, 60%) had stays of 8 weeks or more.

We also interviewed 10 clinicians, who were all female and who had an average of 15 years of experience in the NICU (Table 1). Seven parents completed enrollment paperwork but did not schedule interviews and were removed from the study.

Themes

Stress and Support Themes

We identified 6 themes centered on stress and stress-reduction that we considered relevant to future intervention development. Three themes focused on caregiver stress: (1) the emotional "rollercoaster" caused by the NICU experience, (2) insufficient emotional and cultural support, and (3) caregivers feeling "left out" and confused. Participant-proposed solutions to reduce stress were to (1) empower caregivers through education, (2) improve emotional support, and (3) communicate on "my" terms (ie, digitally) (Textbox 1).

Textbox 1. Themes.

Sources of stress*Emotional "rollercoaster"*

- Fear and anxiety
- Overwhelmed and helpless
- Grief and loss

Left out and confused

- Mixed messages
- Not informed about medical care
- Lack of information

Unsupported

- Forgotten fathers
- Limited emotional and cultural support
- Lack of empathy

Participant-proposed solutions

Empower caregivers

- Provide basics about premature birth, the neonatal intensive care unit, and common medical procedures
- Educate on how to care for premature babies

Communicate on "my terms"

- Deliver information digitally
- Make mobile phone-compatible
- Simplify information

Improve emotional support

- Peer support, including father- and cultural-specific support
- Foster online forums and support groups
- Teach stress-reduction skills

XSL•FO
RenderX

Theme 1: Emotional "Rollercoaster" of the NICU

Nearly all the parent participants in our study described their time in the NICU as significantly stressful and highly distressing.

> *It's an emotional rollercoaster, with lots of crying.* [Mother #9]

Multiple participants described it as the most stressful event of their lives.

> *It's a massive test of your emotional resources, certainly the biggest of my life, and I felt like I was having an existential crisis.* [Mother #1]

Many parents reported ongoing episodes of fear in the NICU, related to the highly medicalized NICU environment and concerns about their babies' survival.

> *It's terrifying to be in NICU. It's terrifying because of so many things…seeing my baby in pain and needing so much life support to keep him alive.* [Mother #13]

Consistently, parent participants also reported feeling overwhelmed and helpless in the NICU because of the intensity of the environment and their inability to help their babies. Fathers also shared explicit feelings of helplessness.

> *My partner gave birth and can express [milk] and do all that stuff, and I can't do any of that.* [Father #10]

Participants also reported feelings of grief and loss throughout the NICU experience. While parents whose babies died in the unit were not part of our study, 4 participants reported sharing rooms with or befriending other families whose babies died in the unit.

> *I feel like being in NICU, you not only have your own experiences, which can be quite scary, but you are also forced to take on other family's difficult experiences too.* [Mother #1]

Some participants also felt cultural traditions were not considered after a baby's death.

> *We felt quite unstable after a baby had passed [in the same room], and another baby just turned up. For us, it's very tapu [sacred, with complex spiritual restrictions] when someone's passed away. So spiritually... we felt unsafe.* [Mother #5]

Theme 2: Insufficient Cultural and Emotional Support

While some parents stated they felt emotionally supported by staff in the NICU, most reported that they felt their needs were secondary.

> *If you weren't dying, you weren't a priority.* [Mother #1]

Clinicians agreed that they often do not spend much time talking to parents about their well-being.

> *We don't finish a visit by saying [to parents], "How are you feeling? Are you doing ok?" We just don't have time.* [Clinician #8]

Multiple parents also felt that some medical staff did not respond to their emotional needs in helpful ways.

> *Something had gone wrong and the doctor told me about it. And then he went on to talk about other things that could go wrong [in the future]. And I was like, that was information I needed to know, but it wasn't information I needed to know right then. Eventually, I was like, "I want you to leave because I want to get upset in private."* [Mother #12]

Additionally, 3 fathers participated in our study, and most reported they felt "forgotten" and treated differently than mothers.

> *I felt like [some staff] didn't expect the dad to ask questions or be involved. Gender expectations were quite out of date.* [Father #2]

A few mothers also commented on this, expressing frustration on behalf of their babies' fathers about a lack of consideration for them.

> *I used to joke to [baby's dad], "you're at the bottom, no one really cares about you." It's terrible, actually, I mean, talk about the gender disparity.* [Mother #1]

All the Māori and minority participants in this study reported mixed levels of cultural support in the NICU. Three parents reported speaking their first or Indigenous language to their babies in the NICU and all expressed concerns that they were making English-speaking staff uncomfortable by doing so. The Māori participants in our study also reported concerns that staff did not understand cultural practices that were important to them.

> *Because I'm brown, I felt like people were thinking, "Oh, is she capable?" I also wondered if they were treating me differently because of my skin color.* [Mother #1]

One clinician (#5) commented on unconscious bias as a barrier to appropriate Māori cultural support, which she noted is a requirement of the Te Tiriti o Waitangi (Treaty of Waitangi), New Zealand's founding document signed by Māori and the British Crown in 1840.

> *I'm always reminding staff that we work within Te Tiriti, and that's the place we need to start from, particularly for Māori.* [Clinician #5]

Some participants also detailed gaps in cultural support for Asian families, including limited translation services and a lack of understanding about some cultural practices.

> *So we have this cultural thing that for the first 30 days after delivery we are not supposed to go out of the house, but immediately I'm traveling between NICU and home, so that's gone out of the window. And on the days when I wasn't going, the nurses were ringing me like, "Are you coming today?" And I was like, "I will come tomorrow." You have this pressure on you.* [Mother #8]

XSL•FO
RenderX

Theme 3: Caregivers "Left Out" and Confused

Caregivers reported significant confusion and uncertainty in the NICU due to a lack of information, which they reported increased their stress. Many reported having unanswered questions about day-to-day procedures in the NICU, who the staff were that cared for their babies, and what they could expect in the future.

> *When I went into labour, I didn't know how early you could have a baby, or what the survival rate was. I didn't know what NICU was! I wish someone had explained it all to me more clearly.* [Mother #6]

A few caregivers also noted that it was difficult for them to take in information early in their baby's admission due to the suddenness of their baby's birth and the feelings of fear and overwhelm they were experiencing.

> *We're almost three months into our admission, and I'm probably only now just getting to a point where I can mentally understand everything that happens in NICU and communicate about it clearly. It was just a real shit show for a long time, and of course I had to recover from birth. It probably took me eight weeks to feel like myself.* [Mother #12]

Some mothers also reported feeling nervous about asking questions of the medical team.

> *I know at the start, I remember sitting there and wanting to say things [to the doctors]. But even just asking something was nerve-wracking and overwhelming.* [Mother #8]

Similarly, a few clinicians expressed the concern that the information they were providing was not always understood by caregivers, and they attributed this to both a lack of time they had available to talk to families and potential power differentials between medical providers and caregivers.

> *The [medical] hierarchy is sometimes an issue for people to speak up and ask more questions. They may come back later and say, "Look, I actually didn't understand a word." Or they may come back and ask a nurse but not the doctor.* [Clinician #4]

Participants also mentioned feeling more stressed when they received conflicting information from different staff members.

> *[My baby] couldn't latch properly, and the machine would start beeping [about his oxygen], and I had different messages from the nurses. So some nurses say "it's totally fine," and then some nurses will say, "If he drops then you need to stop breastfeeding and let him breathe." The mixed messages gave me a lot of anxiety.* [Mother #8]

Concerningly, many parents also reported stressful situations in which they were not informed about their babies' medical care. One mother (#6) reported a "really scary" incident when she was not told that her baby had stopped breathing, which she reported "made me lose my mind." Additionally, 2 participants reported being told "at the last minute" or without their knowledge that their babies were moved to a different section of the unit.

> *So before we moved from Level 3 to Level 2, we were told, "It's not going to happen for a while." But then we're told over the phone that now she's in Level 2. That was very stressful for us. The doctor had given us clear plans, yet the transition happened without us.* [Mother #5]

Clinicians also reported stressful situations when parents were "left out of the conversation," attributing this to time constraints and frequent staff changes.

> *If we had more staff, that would give me more time to talk to parents, rather than thinking, "Oh, but I've got these 3 other babies to think about." If the staff is not stressed, then everybody can be less stressed.* [Clinician #3]

Theme 4: Empower Parents

Overwhelmingly, participants expressed an interest in learning more about the NICU and learning how to better care for and respond to their preterm babies in the NICU. Generally, caregivers wanted information that would help them feel more confident and empowered in the NICU.

> *The things at the top of my education wish-list would be on breastfeeding and pumping, which was so stressful; how to hold your baby; the importance of skin-to-skin and any other developmental tools I could use; and understanding your baby's behaviour.* [Mother #9]

Clinicians echoed this idea and felt it important to emphasize the importance of caregiver involvement and partnership with the medical team in the NICU.

> *I think an intervention that would include solid medical information and highlight ways for parents to be involved in NICU would be really helpful. It needs to have a big focus on what parents can do, because there's so much already taken away from them. And focus much more on the message, 'this is your baby,' and emphasize that they are part of the medical team.* [Clinician #4]

Participants also had many specific ideas about the types of NICU information that would be helpful to them, as well as a desire to receive personalized information about their babies.

> *I wanted to know more about everything. How long does my baby need to be on the incubator, how long for the overall stay, the timing of things. Also, their growth, their weight, are they on track?* [Mother #8]

Some participants had specific information requests, from standard medical procedure timelines to developmental week-by-week guides.

> *It would be nice to have a brief timeline of when babies will get the brain scans, when they'll get their first eye checks. It would be good to know when things are going to happen before, instead of after, so you can ask if you should be there and know to ask about the results.* [Mother #11]

XSL•FO
RenderX

Some parent participants also commented on the lack of information available to them about their babies' medical care through the hospital's electronic health record system, and one suggested an "integrated" web-based approach to include both NICU education and updates about their babies' medical care.

> *It'd be great to have education about NICU in an app form that also includes the doctor's notes from the day. I'd like to have more information that keeps you updated when you aren't there.* [Mother #11]

Theme 5: Provide More Emotional Support

Most participants stated they wanted more emotional support, including more empathy from staff and more ways to destress. Participants also mentioned a desire to connect with other caregivers "like me," such as fathers or caregivers from the same cultural group.

> *It would have been nice to chat with a few more dads. If there was some way that brought people together in a casual format, that'd interest me.* [Father #10]

Some participants expressed a desire to connect both in-person and via online support groups with caregivers from the same NICU.

> *It'd be great if there was an online forum or group for parents from this NICU. I found connecting to other NICU parents helped online, even if their baby is no longer in NICU or was in another city. Also, if they can invite some ex-NICU parents [to the unit], I think that would be really good too.* [Mother #8]

Clinicians also commented on the strength of support parents could provide to each other.

> *It's all very well for us as professionals to say "I've been here for years, and this is what 25-week-old babies do." But that doesn't make a parent feel better sometimes. But if another parent who had a 25-week-old maybe two years ago can say, "Look, now I have a healthy child," that's hugely helpful.* [Clinician #1]

In addition to peer-support as a source of stress reduction, many caregivers also expressed an interest in learning specific stress-reduction skills that they could use while in the NICU.

> *It would be quite nice to put on headphones and do some breathing exercises or to listen to a guided meditation.* [Caregiver #7]

Clinicians expressed an interest in having more ways to help parents reduce stress.

> *We know parents are really stressed, and it'd be great to be able to say, "Here are some tools to reduce your stress."* [Clinician #2]

A few participants also noted that there is a lot of downtime in the NICU, and having stress-reducing activities to try would be more helpful than "doom scrolling" on a phone.

> *Based on my experience, I spent a lot of time in NICU just sitting there not doing anything, especially in my baby's early days. So I would have tried some stress-reduction activities if someone had given them to me, because hopefully they'd help me feel better, but also to give me something to do.* [Mother #9]

One mother stated that she and her partner had a session with a psychotherapist during their baby's admission, which she reported helped reduce her stress. However, she noted that scheduling these sessions was challenging and privacy was limited within the unit. (Clinicians also noted similar challenges in this regard.) She recommended complementing this type of in-person therapy with resources and activities that could be done at home.

> *The therapist gave us self-reflective questions to think about, and those were really helpful for us to talk about later. Like, what was most important to us as parents in NICU? It's hard to get perspective when you are in the midst of it, and those reflective questions really helped us do that. I think a list of those types of questions could be really useful for other parents, too.* [Mother #12]

Participants also recommended ways to improve cultural support, including more diverse staffing and staff training on cultural traditions.

> *I think it'd be helpful to have really good information in different languages and then basic info for staff [on cultural traditions], like this is something a family might want to do, and here's how to support them.* [Clinician #1]

Two Māori participants also recommended specific cultural practices around stress reduction.

> *I'm always interested in karakia (Māori ritual chants/incantations) and ones to do with breathing. For me, it's really helpful in stressful situations and really important that I keep doing it in the NICU.* [Mother #13]

Theme 6: Communicate on "My" Terms (ie, Digitally)

Many caregivers and clinicians expressed an interest in authoritative, reliable web-based resources for information about the NICU and premature baby development, and they commented that the printed resources currently provided in the unit were "not helpful."

> *I've spent more than a decade dedicated to the NICU, and I wouldn't read our pamphlets. Also, we're all on our phones. That's how we communicate. So I think digital is way better.* [Clinician #6]

Another clinician agreed, observing that younger parents in particular prefer digital information.

> *Digital is the way to go. The younger parents never read a printed pamphlet. They take out their phone, and they find their answers, good or bad. I think content needs to be short, sharp, and ideally, more video rather than lots of text. I think it should also be easy to navigate so that when they are hopefully sitting at the bedside or expressing milk, they can look at it when they have a few minutes.* [Clinician #4]

XSL•FO
RenderX

While 2 caregivers preferred printed materials over web-based, the majority of caregivers wanted information delivered in digital formats and specifically mobile-friendly.

> *I never open my laptop. I'm always on my phone. You want it to be easy to read and less words and more videos. But you do want to find the right information that's accurate for your baby.* [Mother #12]

Three participants brought specific app and blog ideas they had brainstormed to their study interviews because they felt "so frustrated" by the lack of information they felt they received about the NICU and premature babies. They also noted they wanted to be able to access information regardless of the time of day.

> *I want more information about my baby and NICU, and I want to be able to work things out in my own time, online, even if it's at 2 am.* [Father #2]

Discussion

Principal Findings

Our study explored caregiver stress in the NICU and solicited participant ideas on ways to reduce stress to inform future intervention development. Broadly, our stress themes highlight how the majority of caregivers felt devalued in the NICU and that their emotional needs were not a priority. They expressed a desire to be treated as partners in their babies' medical care and seen as individuals, with unique values and strengths that were vital to their babies' health and well-being.

These findings align with stress theory, which posits that stress occurs in response to specific components of a situation as well as an individual's perceptions of that environment and their ability to cope within it [21]. The PSS:NICU [22], which was developed based on this theory, measures parental perceptions' of stress in response to four specific components of the NICU environment: (1) "sights and sounds of the NICU," (2) "infant behavior and appearance," (3) "parental role alteration" (with examples such as "not being able to hold my baby" and "feeling helpless"), and (4) "staff communication and behaviors."

Our study data contain examples of all of the categories measured by the PSS:NICU. Importantly, the majority of our data about parental stress can be organized within the category of "parental role alteration." In particular, our themes around parents feeling left out of decisions about their babies' medical care, uniformed, and unsupported emotionally highlight how parents felt disempowered in the NICU. This is important, as a meta-analysis of studies from around the world using the PSS:NICU found that "parental role alteration" is the most significant factor in parental stress in the NICU, with higher perceptions of changes in the parental role leading to higher rates of parental stress [25].

The stress themes in our study highlight problematic gaps in emotional and cultural support for families that led to feelings of parental isolation and disempowerment. While some parents stated they were supported in the NICU, the majority reported stressful interactions that made them feel devalued, confused, or judged as parents. Fathers, in particular, reported feeling "less important" than mothers in the NICU. Fathers' needs have long been understudied in the NICU, with many studies focusing exclusively on mothers [5]. However, recent studies have demonstrated that fathers can experience high levels of distress in the NICU, including elevated rates of depression and posttraumatic stress disorder compared to non-NICU fathers, and specialized interventions in the NICU can help [26].

In total, 30% (7/23) of our study participants self-identified from Māori and other minority cultures. These participants all reported mixed experiences of cultural safety (such as feeling judged by speaking a non-English language to their baby in front of medical staff), which are similar to findings reported in previous studies internationally with minority families [27] and in Aotearoa New Zealand with Māori families in the NICU [15].

Cultural support is a critical area for improvement and should be considered an important component of parental empowerment in the NICU [28] and an avenue for future intervention development. As a systematic review of Indigenous populations' birth outcomes in New Zealand, Australia, Canada, and the United States found, Indigenous groups experience significantly higher rates of preterm birth and neonatal death than non-Indigenous populations [29], and a growing body of international research has also documented a strong dose-dependent relationship between experiences of discrimination and health outcomes [30]. Few studies have explored experiences of discrimination and health outcomes within the NICU [31] or how cultural support can affect outcomes, and these are much-needed avenues of future research.

All participants shared ideas on ways to reduce parental stress in the NICU and what they felt would be helpful in a future intervention. Participants overwhelmingly agreed on the need for caregivers to feel more confident and empowered in the NICU. This idea has significant support in the literature, with decades of evidence documenting the benefits for parents and babies of increased parental involvement and engagement in the NICU [32]. As our study highlights, however, this knowledge can be difficult to translate into practice. Formalized "empowerment" interventions in the NICU have been designed to address this challenge, and most involve multimodal intervention programs that include hands-on caregiver education and changes in clinical practices. These have been found effective in reducing parental stress and depression [32].

Caregiver participants were interested in learning about education topics in 2 categories: how to care for their baby in the NICU and understanding the NICU environment, which was new and unfamiliar to all the families in our study. This desire is backed by research: educational interventions for parents with babies in the NICU have been shown to improve parenting confidence and decrease parental anxiety [33]. Clinicians echoed this need, and most participants wanted information to be provided in "short and sharp," easy-to-understand text and video. Participants also overwhelmingly agreed on the need for digital, mobile-friendly delivery of information (both for education and about their babies).

XSL•FO
RenderX

Digital interventions are a worthwhile avenue for future exploration, as evidence has demonstrated the effectiveness of digital interventions with pregnant and postnatal women. A 2024 meta-analysis examined 31 randomized controlled trials testing digital intervention effects on postpartum anxiety and depression and found significant reductions in symptoms compared to treatment as usual, particularly for interventions that incorporated psychotherapy such as cognitive behavioral therapy or mindfulness [34]. Despite this evidence base, to our knowledge, no digital mental health interventions have been evaluated for parents with babies in the NICU.

Participants also proposed a range of strategies to improve emotional support, including through parent-to-parent support (both in-person and through online support groups). Participants also wanted improved cultural support, including increased staff training on diverse cultural traditions, hiring more Māori and minority staff, and creating more ways for parents to connect with other parents from similar cultures. This personal connection aligns with the Māori concept of whakawhanaungatanga, which emphasizes building meaningful, trusting relationships.

Strengths, Limitations, and Future Research

To inform future intervention development, this study explored sources of stress and solicited ideas about ways to reduce stress with caregivers and clinicians in a level 3 NICU in Aotearoa New Zealand. Soliciting participants' ideas on caregiver stress reduction in the NICU is an uncommon approach in the literature and a strength of the study.

This study is qualitative, and therefore its findings are not generalizable but may be transferable to similar populations. Our results are reflective of one participant group, in which the majority of participants were female, self-identified as European in ethnicity, and most were tertiary-level educated and employed. The study interviews were also conducted during the COVID-19 pandemic, which may have influenced participants' perceptions of stress and contributed to their ideas about stress reduction (such as more interest in digital sources of information).

In the recruitment process, 7 parent participants completed enrollment paperwork but did not schedule interviews. We do not know the reasons for this change in participation interest; however, we were aware of possible barriers, including parental hospitalization, a transfer out of the unit, and a lack of access to a mobile phone, limiting interview scheduling.

Future studies should strive to reduce barriers to participation in research for all caregivers with babies in the NICU, and they should aim to recruit more fathers and minority participants, who are underrepresented in the literature [5]. Caregivers and clinicians in the NICU are also valuable, knowledgeable resources for intervention development and design. Involving stakeholders such as parents, extended family members, and clinicians in intervention development is likely to improve patient-centered care, improve engagement in interventions, reduce inefficiencies in research, and improve research outcomes [35].

Conclusions

This study explored sources of parental stress in the NICU with caregivers and clinicians, and gathered participants' ideas and feedback on ways to reduce stress to inform future intervention development. Proposed solutions by participants focused on increasing parental empowerment, improving emotional and cultural support, and providing information in digital, mobile-friendly formats. This formative study was essential in identifying the unique needs and views of both caregivers and clinicians working in the NICU. It has since informed the development of a digitally delivered psychoeducational program that we are currently evaluating in a randomized controlled trial [36].

Acknowledgments

We would like to thank the participants in this study for sharing their stories and opinions with us. We would also like to thank Sabine Huth for her assistance in recruitment.

Abstract

Background: Type 1 diabetes (T1D) management requires following a complex and constant regimen relying on child or caregiver behaviors, skills, and knowledge. Psychological factors such as diabetes distress (DD), depression, and burnout are pertinent considerations in the treatment of pediatric T1D. Approximately 40% of youth and 61% of caregivers experience DD. Implementation of DD screening as part of clinical best practice is recommended and may facilitate treatment referral, perhaps leading to improved health or well-being for youth with T1D and their caregivers. By building on existing institutional infrastructure when available, screening via digital health platforms (applications, or "apps") may allow for timely screening of, and response to, DD.

Objective: This work details the creation, implementation, and refinement of a process to screen for DD in youth and their caregivers in the context of routine T1D care using a digital health platform.

Methods: DD screening was implemented in an outpatient endocrinology clinic over 1 year as part of a larger screen-to-treat trial for children aged 8 - 12.99 years and their caregivers. Validated measures were sent via digital health platform to be completed prior to the clinic visit. Results were initially reviewed manually, but a digital best practice alert (BPA) was later built to notify staff of elevated scores. Families experiencing DD received resources sent via the digital health platform. For this secondary analysis, child demographics and glycated hemoglobin A_{1c} (HbA_{1c}) were collected.

Results: During the screening period, absolute completion rates were 36.78% and 38.83%, with adjusted screening rates at 52.02% and 54.48%, for children and caregivers, respectively. A total of 21 children (mean HbA_{1c} 8.04%, SD 1.39%) and 26 caregivers (child mean HbA_{1c} 8.04%, SD 1.72%) reported elevated DD. Prior to BPA development, resources were sent to all but 1 family. After BPA implementation, all families were sent resources.

Conclusions: Early findings indicate that DD education, screening, and response can be integrated via digital platforms in a freestanding outpatient endocrinology clinic, thereby facilitating timely treatment referral and provision of resources for those identified with distress. Notably, in the observed 1-year screening period, screening rates were low, and barriers to implementation were identified. While some implementation challenges were iteratively addressed, there is a need for future quality improvement initiatives to improve screening rates and the identification of, or response to, DD in our pediatric patients and their families.

Introduction

Rates of type 1 diabetes (T1D) in youth aged 19 years or younger have been increasing in recent years, from approximately 1.48 per 1000 youth in 2001 to 2.15 per 1000 youth in 2017 [1]. Rates increased at the highest levels in non-Hispanic White and non-Hispanic Black children [1]. Health-promoting management of T1D requires following a complex and constant treatment regimen with tasks relying on child and caregiver behaviors, skills, and knowledge [2]. Given the complexity and constancy of diabetes management, it is not surprising that psychological factors such as distress, depression, anxiety, and burnout are highlighted as pertinent to consider in the management of pediatric T1D [2-4].

Diabetes distress (DD) is the "emotional distress that results from living with diabetes and the burden of relentless daily

XSL•FO
RenderX

self-management" that can be seen across the life span, as well as in caregivers of those with diabetes [5]. It occurs at rates of approximately 25% in adults with T1D [6]. In children aged 8 - 12 years, as many as 40% of youth and 61% of their parents or caregivers experience at least some DD [7]. Notably, DD is occurring at higher rates, on average, than depression in pediatric populations with diabetes [8,9]. Increased levels of DD relate to deficits in diabetes self-management behaviors, increased glycated hemoglobin A_{1c} (HbA_{1c}), and negative impacts on mental health and well-being [4,6]. DD differs from burnout, defined as the physical or emotional exhaustion associated with continuous DD and management needs, and depression, although these can co-occur [10,11]. Implementation of DD screening (and subsequently, treatment of DD) as part of clinical best practice may facilitate treatment referral and could lead to improved health and well-being for youth and their caregivers [6].

The American Diabetes Association (ADA) Standards of Care in Diabetes recommends DD screening starting at 8 years of age, with the parent, child, and adolescent versions of the Problem Areas in Diabetes (PAID) highlighted as validated assessment tools in this domain [2]. Similarly, the International Society for Pediatric and Adolescent Diabetes (ISPAD) recommends that age-appropriate and validated assessment tools be used routinely to monitor and guide conversations specific to the psychosocial well-being of all youth with diabetes as well as their caregivers [4]. Despite these recommendations, 1 recent publication reported that less than half of surveyed pediatric diabetes clinics screened for mental health problems of any kind using a validated tool [12]. In contrast, another survey of T1D exchange participants reported that 96% of pediatric centers included use at least 1 standardized measure of patient reported symptoms or needs. However, measures included in this study were more broadly inclusive of mental health, transition readiness, and structural determinants of health, among other domains, with <30% of centers reporting screening for DD [13].

In line with best practice recommendations, we sought to implement standardized DD screening for youth aged 8 - 12 years and their caregivers in an outpatient endocrinology clinic in a large, freestanding, pediatric medical center. Screening was completed using validated surveys sent prior to children's clinical visit via digital health platform. Thus, by building on existing infrastructure, it was possible to conduct DD screening and deliver a response to elevated scores using the institutional app, which we anticipated would be a highly scalable process.

Methods

Participants

This project occurred in the pediatric endocrinology clinic at Nemours Children's Health-Jacksonville, which serves more than 1000 children with T1D. The reported results focus on screening procedures initiated and tested from April 1, 2022, through March 31, 2023. Children eligible for screening were aged between 8 and 12.99 years, with any diagnosis of diabetes (broadly identified by visit type, because at the time of implementation, the system could not differentiate between T1D, type 2 diabetes, or another diabetes), and able to read and understand English. Adolescents aged 13 years and older were excluded from DD screening because they were already participating in another screening initiative at our institution (depression screening). Eligible parents or caregivers had a child who met the eligibility criteria, were signed up to use the Nemours app for health care management, and were able to read and understand English. The Nemours app is a stand-alone app created by the larger Nemours Children's Health system. Families were encouraged to sign up for this app beginning in August 2019 to access child health records, manage appointments, message providers, complete paperwork and payments, receive resources, and participate in telehealth visits. At the start of the screening period (April 2022), approximately 68% of families followed in the endocrinology clinic were signed up for the Nemours app, although this increased to 78% by month 12 (Table 1). Of note, 30.7% of families on average who started previsit questionnaires in the app (the "GetReady" process) did not complete their questionnaires and were able to attend clinic visits despite outstanding paperwork.

Ethical Considerations

Given the use of retrospective chart reviews for data collection, the authors obtained institutional review board approval (2057003) for secondary (exempt) research prior to the collection of data. The institutional review board determined based on the methods, proposed analyses, and the researcher's ability to work with deidentified data that informed consent or assent was not required for this project. Compensation was not provided as part of this secondary research.

Procedure

In line with standard of care recommendations from the ADA and ISPAD [2,4], and as part of a larger screen-to-treat trial, the pediatric endocrinology clinic at Nemours Children's Health-Jacksonville, implemented a screening program to detect symptoms of DD in school-aged children and their parents. The clinic used automated processes, a digital health platform, and validated screening tools to minimize any negative impact on clinic flow and to capitalize on the existing system for paperwork completion via the Nemours app. Per the screening protocol, the automated system assigned the DD screening tools to children, aged at least 8 years and younger than 13 years, with a visit type "Diabetes NP (new patient) w/Care Team" or "Diabetes FP (follow up patient) w/Care Team" and the clinic location in Jacksonville, Florida. Children and parents received the DD screeners every 6 months via the Nemours app "GetReady" feature along with other clinic surveys (eg, intake form) up to 10 days before their scheduled clinic visit. Regular reminders to complete paperwork were provided prior to the visit through an automated messaging system. Once completed, the Nemours app automatically scored the DD screeners and uploaded the screener results into the child's electronic health record (EHR). Initially, each week, a diabetes psychologist would manually review the completed DD screeners and send messages in the EHR to the visit provider when a child or parent had an elevated DD screen. Furthermore, for each elevated DD screen, the psychologist manually sent families a message via the EHR, which (1) thanked the family for completing screening; (2) defined and normalized DD; and (3) listed local resources including community diabetes groups and camps, web-based resources, relevant web pages, ways to access mental health services (including within their institution from psychology and social work providers), and information about the larger

XSL•FO
RenderX

screen-to-treat DD trial so that families could reach out to learn more if interested. This resource list was created collaboratively between endocrinology physicians, psychologists, and a licensed clinical social worker assigned part-time to the endocrinology clinic. Eventually, to automate the process more fully, the clinic technology team built a best practice alert (BPA) into the EHR so that clinical providers associated with an upcoming visit and the diabetes psychologist would receive an automated alert flag for elevated DD scores. This feature made it possible for providers to engage in standard of care practices to address elevated DD screening results with families directly during the clinic visit and to include a resource list in their electronic after-visit summary. The psychologist also continued to review screening BPAs and send families a local resource list via an EHR message.

Measures

We selected 2 validated DD screening tools, the Problem Areas in Diabetes-Child (PAID-C) and the Parent Problem Areas in Diabetes-Child (P-PAID-C) to screen for child and parent symptoms of DD, respectively. The PAID-C is an 11-item survey of DD symptoms specifically designed and validated for children aged 8 - 12 years [7]. The PAID-C yields a total score that ranges from 11 to 66, with higher scores reflecting more distress. The P-PAID-C is a 16-item survey of DD symptoms specifically designed and validated for parents of school-aged children [7]. Like the child form, the P-PAID-C yields a single total score. The P-PAID-C total score can range from 16 to 96, and higher scores reflect more distress.

We collected child demographics (eg, age, biological sex, race, and ethnicity) and examined these within the larger eligible clinic population; the subpopulation who participated in the screening program; and the group who had elevated DD screening results. We also collected child HbA_{1c} levels from the visit associated with DD screening captured between April 1, 2022, and March 31, 2023. For children's HbA_{1c}, the clinic uses instruments certified by the National Glycohemoglobin Standardization Program and traceable to reference methods from the Diabetes Control and Complications Trial.

Data Analyses

We used approved tools to retrieve all EHR data. We report the percentage of eligible families screened for DD out of all eligible families in the clinic population (absolute percentage screened) and the percentage of eligible families screened for DD out of all eligible families with a completed clinic visit between April 1, 2022, and March 31, 2023 (adjusted percentage screened). To analyze these data, we examined the screening rate by each month and the average across the year. We also examined the rate of EHR documentation of follow-up resources being sent to families with elevated screening results. To identify elevated DD, the clinic applied a clinical cut point of ≥41 for children and a cut point of ≥64 for parents or caregivers [7]. Descriptive statistics and HbA_{1c} were examined for both the population who completed DD screening and the families who had elevated screening results. Given that the screening period took place over a 12-month period, some families received and completed the screening measures on more than 1 occasion. If a child or a caregiver was identified as having elevated DD on multiple screenings, he or she was sent resources each time; however, for the purposes of data analysis, only the first elevated screen that also had a clinic visit with an associated HbA_{1c} was included for analyses.

Results

Participants

Children who completed any DD screening (eg, child and parent or caregiver completed, child-only completed, and parent or caregiver-only completed) were 55.2% female, 44.8% male, and had a mean age of 10.22 (SD 1.36) years. With respect to their self-reported race, 1.8% were Asian American and Pacific Islander, 0.75% were American Indian or Alaskan Native, 0.8% were Asian Indian, 19.6% were Black or African American, 64.16% were White, 5.0% reported more than 1 race, 8.0% reported other/unspecified, and 1.0% reported "prefer not to say." For their self-reported ethnicity, 12.1% identified Hispanic/Latinx, 86.4% identified not Hispanic/Latinx, and 1.5% reported "prefer not to say" (Table 2).

Primary Outcomes

Screening Completion Rates

During the 1-year screening period, the institutional app system automatically assigned a total of 590 PAID-C questionnaires and 649 P-PAID-C questionnaires to children aged 8 - 12.99 years and their caregivers, respectively. A higher number of caregiver questionnaires than pediatric questionnaires were assigned, as some pediatric patients had multiple caregivers associated with their account in the institutional app. Of those, 396 PAID-C and 435 P-PAID-C questionnaires assigned were associated with attended clinic visits. Absolute percentage screened (questionnaire completion out of all assigned) were 36.78% (217/590) and 38.83% (252/649), respectively. Screening rates (questionnaire completion) for those who attended their clinic visits (adjusted percentage screened) for children or caregivers were 52.02% (206/396) and 54.48% (237/435), respectively. Completion rates were relatively stable over the 12 months of DD screening.

DD Rates and Resource Provision

In total, 10.2% (21/206) PAID-C and 11.0% (26/237) P-PAID-C surveys scored as elevated during the 1-year screening period, with 1 child and 3 caregivers completing the measure with an elevated score at multiple clinic visits. During this period, 11 child and caregiver dyads scored as elevated on both measures of DD, with 4 of these dyads including a child with a diagnosis of type 2 diabetes or prediabetes, and the remaining dyads with a child diagnosed with T1D. All other elevated screens were present in only a caregiver or a child, who was not part of a parent and child dyad. Of those who were identified as having DD, resources were sent in the app to families in response to 91.7% of elevated PAID-C scores and 100% of elevated P-PAID-C scores; only 1 patient who screened as elevated was not flagged by manual processes and did not receive resources. This occurred before the automated BPA system was put in place. After the BPA was established, all families with elevated parent or child DD scores were sent resources electronically.

DD, Demographics, and HbA_{1c}

Mean HbA_{1c} was calculated for youth with T1D who also attended the clinic visit associated with the date of elevated DD screening (15 PAID-C and 17 P-PAID-C scores were included). Youth with type 2 diabetes or prediabetes were not included in this subsample. For this subsample including all youth with DD, mean HbA_{1c} was 8.04% (SD 1.39%) and mean child HbA_{1c} for those with caregivers screening elevated for DD was 8.04% (SD 1.72%). This subsample of youth was 68% female (17/25),

XSL•FO
RenderX

32% male (8/25), and had a mean age of 10.4 (SD 1.44) years. With respect to their self-reported race, 8.3% were Black or African American (2/24), 70.8% were White (17/24), 8.3% reported more than 1 race (2/24), and 12.5% reported other/unspecified (3/24). For their self-reported ethnicity, 12.5% identified as Hispanic/Latinx (3/24) and 87.5% identified as not Hispanic/Latinx (21/24).

Discussion

Principal Findings

This study details the creation, implementation, and refinement of a process to routinely screen for DD in youth with T1D and their caregivers using a digital health platform. Furthermore, we present descriptive information for those who completed screening. During the 1-year screening period, screening rates for DD were relatively stable, and lower than our initial goals. Approximately 10% of youth and 11% of caregivers who completed screening were identified as having elevated DD. Most of these families were appropriately sent resources via EHR when DD was identified, with 1 patient not flagged prior to an automated BPA being placed. Iterative processes allowed for improvements to be made in the way families with DD were screened and identified using our institutional app, and for resources to be appropriately shared in the families through the digital health platform. Additional suggestions for quality improvement (QI) processes to increase DD screening as well as relevant clinical implications can now be trialed based on findings and lessons learned during this initial 1-year screening period.

Challenges with Screening Implementation

We identified several challenges to screening families using our institutional app, some that were corrected and others that inform future QI initiatives and clinical research. First, while the automated system was coded to assign the DD screening tools to children aged at least 8 years and those younger than 13 years, for a brief period the questionnaires were incorrectly sent to all pediatric patients or parents seen for diabetes associated visit types in endocrinology. Once identified, this error was corrected. However, the error reoccurred following a later system update and because the system assigns questionnaires at the time an appointment is scheduled (sometimes 6 or more months in advance), the clinic experienced a backlog of incorrectly assigned questionnaires intermittently throughout the first 9 months of the screening period. For the current analyses, children and parent or caregivers who incorrectly received the questionnaires due to age were not included. Nevertheless, the error had clinical implications in that some children and parents or caregivers who were outside of the PAID-C normative age range were identified as distressed and sent electronic resources in line with our procedures.

Second, with our institutional app and its supporting automated system, we could only assign the DD screening tools to children aged 8 - 12.99 years (and their caregiver) with a visit type "Diabetes NP w/Care Team" or "Diabetes FP w/Care Team". These visit types are not coded to differentiate between different diabetes diagnoses. Although DD is also observed in persons with type 2 diabetes, the screening tools we used are not validated for families of youth with type 2 diabetes. In the 1-year screening period, there were 4 elevated PAID-C surveys and 4 elevated P-PAID-C surveys associated with youth with type 2 diabetes or prediabetes. These could represent false-positive results. Thus, if using an automated system to assign a clinical screening tool, it may be important to identify a solution for assigning screeners with greater specificity.

Third, while the initial system for manually reviewing screening results and sending electronic resources to families who had an elevated screen was generally effective, 1 child was not immediately identified and therefore did not receive resources in response to his or her elevated score in a timely manner. Although this represented <5% of total population that screened as elevated, it highlighted the need for an automated BPA process in the EHR to promote greater accuracy and improve response time when sending resources to families. Unfortunately, upon implementing the automated BPA, we identified a new problem, as clinical providers had the ability to close the BPAs without sending families electronic resources. Thus, the lesson learned was also the value of providing ongoing provider education about screening processes in clinic so that these alerts could be appropriately responded to.

Fourth, while 73.6% of families in the endocrinology division were signed up for the Nemours app during the screening year, 30.6% of families who started the "GetReady" paperwork did not complete it before their appointment, thus limiting the number of families screened for DD. While specific reasons for incomplete paperwork were not collected, it can be hypothesized that the length of time to complete "GetReady" paperwork, which included our DD screeners, as well as other standardized paperwork, may have exceeded family availability. Also, as part of the "GetReady" system, we learned that new surveys added to the system are placed at the end of the queue and the order cannot by adjusted. Thus, it is likely that the DD screeners were at the end or near the end of the package of surveys assigned to families. It may be more effective to use an institutional app for routine DD screening if it is possible to toggle the order of surveys so that the clinic can ensure that families receive the screeners earlier in their web-based paperwork.

Notably, the number of families signed up for our institutional app has increased in 3 years since becoming available (from about 25% of families enrolled to current rates). In part, the Covid-19 pandemic and related concerns [14] spurred enrollment, as telehealth functionality is built directly into the app; and many divisions at this institution, including endocrinology, have set annual goals to increase app enrollment. However, it warrants comment that to create and support a process to routinely screen for DD in youth with T1D and their caregivers using a digital health platform, it is important to select a digital health platform that families are willing to use.

Future Directions

We plan to (1) implement a series of QI cycles to increase DD screening rates (these QI cycles will focus on current screening processes in the institutional app, as well as processes that are not app reliant if feasible, for example, integrating screening during clinic appointments); (2) expand screening to other

XSL•FO
RenderX

endocrinology clinic locations within our multisite medical system; (3) create and implement a system to track follow-through on resources or recommendations sent to those with elevated DD; and (4) include options for Spanish-language speakers to receive and complete DD screening, with the eventual goal for this to be integrated into the institutional app when the app is available in Spanish. Our third goal is of particular importance given the increasing rates of T1D among Hispanic/Latinx children [1], and Hispanic youth have been identified as having the highest rates of mental health needs per Youth Risk Behavior Surveillance data [15]. The Problem Areas in Diabetes Survey—Pediatric Version (PAID-Peds) was recently normed for Spanish speakers [16], with the Spanish version of the Problem Areas in Diabetes Survey—Parent Revised (PAID-PR) also validated [17]. Improving distress screening in Spanish-speaking youth and families may assist in decreasing disparities in treatment access for mental health needs.

Relatively low rates of elevated DD were observed for the children or the caregivers in the current report. In the future, a less stringent cutoff for DD may be needed to better identify families and direct provision of referrals and resources; cut point studies may be warranted. Furthermore, given challenges previously noted specific to completion rates, it is possible that those families experiencing higher levels of distress were less likely or able to complete GetReady paperwork. Alternative methods to screen families who do not complete previsit paperwork may be necessary to improve completion rates and to identify or respond to DD. It will be important to increase buy-in at the institutional and provider level to increase opportunities to complete screening during clinical visits.

Conclusions

DD screening is recommended by the ISPAD and the ADA as part of standards of care [2]; however, it is not consistently applied across institutions (currently, the US News & World Report review of pediatric health systems tracks only the inclusion of depression screening in youth aged 13 - 18 years [18]). Given that depression is identified at lower rates than DD in populations with T1D, especially for preadolescent age groups [8,9], that DD and depression screening are not interchangeable, and that DD may play a stronger role in predicting HbA_{1c}, many pediatric endocrinology clinics are missing valuable screening opportunities to direct patient care and impact health outcomes if they are screening only for depression. Our findings indicate that DD education, screening, and response can be integrated via digital platforms in a pediatric endocrinology clinic, facilitating timely treatment referral and provision of resources for those identified with distress. Of note, mean child HbA_{1c} for those with elevated DD in our sample (mean 8.04%, SD 1.72%) was higher than the mean HbA_{1c} for the larger sample of youth aged 8 - 12.99 years with T1D seen in the endocrinology clinic (mean 7.75%, SD 1.46%), and higher than the clinical target of <7.0% recommended by the ADA [2]. This further emphasizes the importance of evaluating DD and providing appropriate resources and interventions in pediatric endocrinology settings.

Abstract

Background: The increasing prevalence of information and communication technologies has made health-related information and social support more accessible on the web. However, limited evidence exists on how eHealth and social support affect the well-being of employed women who also serve as caregivers in Japan.

Objective: This study aimed to assess the relationship between social support and well-being among employed Japanese women providing childcare or caregiving and explore eHealth use's role in enhancing this relationship.

Methods: We conducted a cross-sectional study using secondary data analysis from a nationwide web-based questionnaire survey of 10,000 employed women aged 20-65 years, administered from February 28, 2023, to March 7, 2023. The primary study used a quota random sampling approach based on age and geographic area from the research company's panel. For this analysis, we focused on a subgroup of 2456 women who reported either caring for children less than 7 years old or providing other caregiving responsibilities. We employed a Bayesian structural equation model to estimate the enhancing effect of eHealth on the relationship between social support and 4 well-being indicators: life satisfaction, worthwhileness, happiness, and anxiety.

Results: Among the 2456 employed women included, 1784 (72.6%) received social support and 1635 (66.6%) obtained health-related information via eHealth. Bayesian structural equation model analysis revealed that the standardized total effects of social support on well-being were 0.20 (95% CI 0.13-0.27) in the group without eHealth use and 0.47 (95% CI 0.45-0.50) in the group with eHealth use.

Conclusions: The findings suggest that eHealth may enhance the positive impact of social support on the well-being of employed Japanese women providing childcare or caregiving. This study highlights the potential of eHealth interventions in supporting social support and well-being among working women with caregiving responsibilities in Japan.

KEYWORDS

eHealth; social support; well-being; women's health; caregivers; working women

Introduction

Well-being is defined as a multifaceted concept encompassing happiness, satisfaction, personal growth, fulfillment, and contribution to the community [1]. It includes physical, emotional, and social dimensions and is a key factor in determining women's productivity and quality of life. While employment has been shown to improve women's well-being [2], it also exposes them to adverse effects from work-family conflict [3]. Women in the prime of their working lives face various health challenges, including mental health issues, work-related illnesses, and reproductive health concerns [4]. Working women with childcare or older adult care responsibilities must balance their work and home lives, and this double burden affects their well-being [5,6].

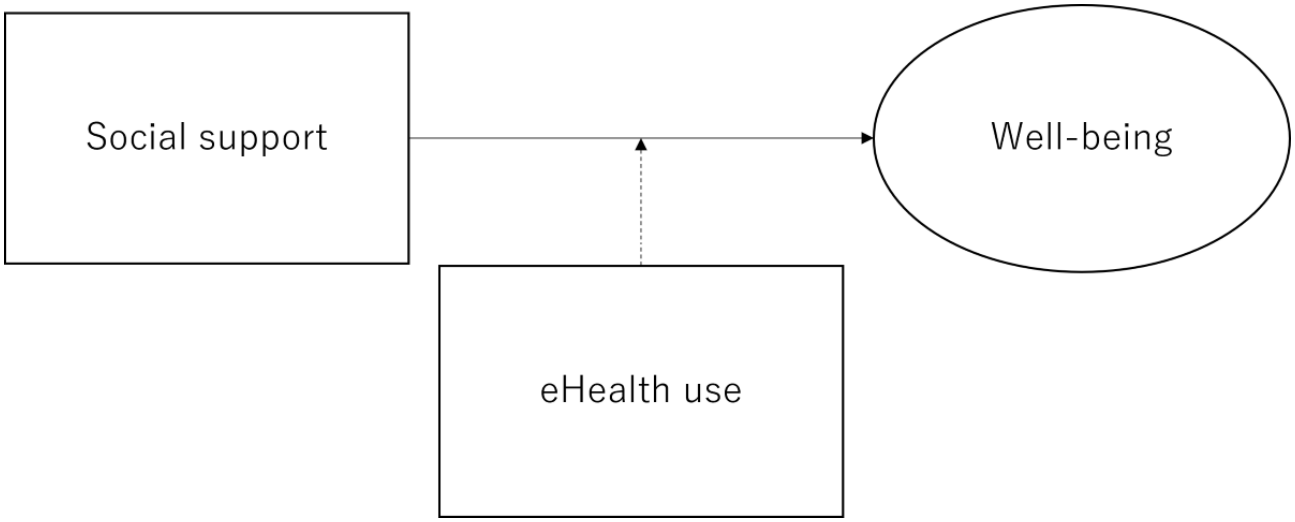
Social support, a key factor in maintaining well-being, traditionally comes from family, friends, and the community [7]. Social support from family and friends plays a pivotal role in maintaining physical and mental health. This multifaceted concept revolves around interpersonal interactions, wherein individuals perceive reliable connections with friends or family members on whom they can depend during favorable and challenging circumstances [8]. Good social relationships provide emotional and practical resources essential for feeling nurtured and esteemed, consequently fostering healthier lifestyles [9]. Social support has protective physical and mental effects [10]. Although social support from partners is essential [11], approximately 90% of households with children in Japan are nuclear families [12]. The traditional sources of social support may be limited for many working women. This situation creates a need for alternative forms of support, particularly for those balancing work with childcare or older adult care responsibilities.

The rapid digitalization of Japanese society has also opened new avenues for addressing this need. In Japan, with over 90% of the working-age population using the internet and about 80% engaging with social networking services [13], eHealth has emerged as a promising solution. eHealth refers to the cost-effective and secure use of information and communication technologies (ICT) to support health and health-related fields [14]. The dissemination of health information via the internet has expanded in recent years and information on social support has also increased [15]. Recent trends indicate that social support is being increasingly accessed and provided on the web through various digital platforms and social networks. For example, several interventions have been developed that incorporate social support content using group phone calls or applications [16,17].

This shift reflects a broader societal change toward digital communication, which enables individuals to access information and community and emotional support without geographical constraints [18]. Internet-based social support has shown potential in enhancing well-being by providing immediate access to resources and reducing social isolation [19]. It is also known as an important form of social support. These eHealth tools may provide crucial social support and be valuable for working women facing time constraints and the social stigma associated with seeking help. However, these tools are primarily designed for specific groups, such as pregnant women or women with health issues. Few studies specifically targeting working women exist.

In addition, cultural differences must be considered when implementing eHealth interventions. Cultural perspectives on the self differ between Western and Eastern societies. In Western cultures, there is a tendency to view individuals as autonomous entities. Conversely, Eastern cultures often conceptualize the self as intrinsically interconnected with others, emphasizing social relationships and collective harmony [20]. This fundamental difference in self-perception influences various aspects of social behavior. A previous study found cultural differences in the emotional correlates of social support receipt across countries, highlighting the importance of considering cultural context when examining social support interventions. In addition, seeking social support might help the Japanese reduce loneliness [21].

Given Japan's unique cultural and societal context, including its high technological adoption rate, it is necessary to understand how social support and eHealth use interact to influence the well-being of working women with caregiving responsibilities. However, there have been limited studies on the relationship between social support and well-being among employed women raising children or caring for them and the relationship between the use of eHealth medical information in Japan. Therefore, this study aimed to fill this gap by evaluating the relationship between social support and well-being among employed women providing childcare or caregiving and the enhancing effect of eHealth use on this relationship. We hypothesized that individuals who use eHealth services will have improved well-being because they receive support from internet-based communities in addition to support from close family and friends. In this study, we hypothesized that the enhancing variable, "eHealth use," would influence the direct effect of "social support" on "well-being."



Methods

Study Design

This is a cross-sectional study using secondary data from a web-based nationwide questionnaire survey conducted from February 28, 2023, to March 7, 2023 [22]. Figure 1 illustrates the hypothetical model of the Bayesian structural equation model (BSEM).

XSL•FO
RenderX

Figure 1. Hypothetical model.

Participants and Data

The data used in this study were obtained from a nationwide survey of 10,000 employed women aged 20-65 years in Japan using a questionnaire developed for the previous study [22]. This primary study included participants who met the following criteria: (1) being 20-65 years old, (2) being employed, and (3) being able to provide informed consent. Students were excluded. A research company conducted recruitment and data collection using a web-based questionnaire. This company used its extensive nationwide panel, which includes women from diverse backgrounds across all 47 prefectures of Japan. A link containing the study introduction and the questionnaire was sent to the company's research panel. We stratified the age categories and prefectures for recruitment to improve sample diversity. A questionnaire was distributed using the web-based platform of a professional research company. The first page of the questionnaire contained an informed consent form and the participants could access the questionnaire by checking the agreement button at the end of the page. A structured questionnaire contained questions about demographics (eg, age, sex, and comorbidities), socioeconomic status, social support, health status, well-being, and eHealth. All monetary values originally reported in Japanese yen were converted to US dollars using the average exchange rate at the time of data collection, which was 1 JPY=0.0069 USD. The participants required approximately 10-15 minutes to complete the entire questionnaire. Eligible participants could then choose to respond to the questionnaire.

From the initial 10,000 respondents, participants for this study were selected based on the following criteria: women raising or caring for children aged <7 years were included in the analysis. Those who met these criteria were included in the final analysis.

Measures and Outcomes

Well-Being

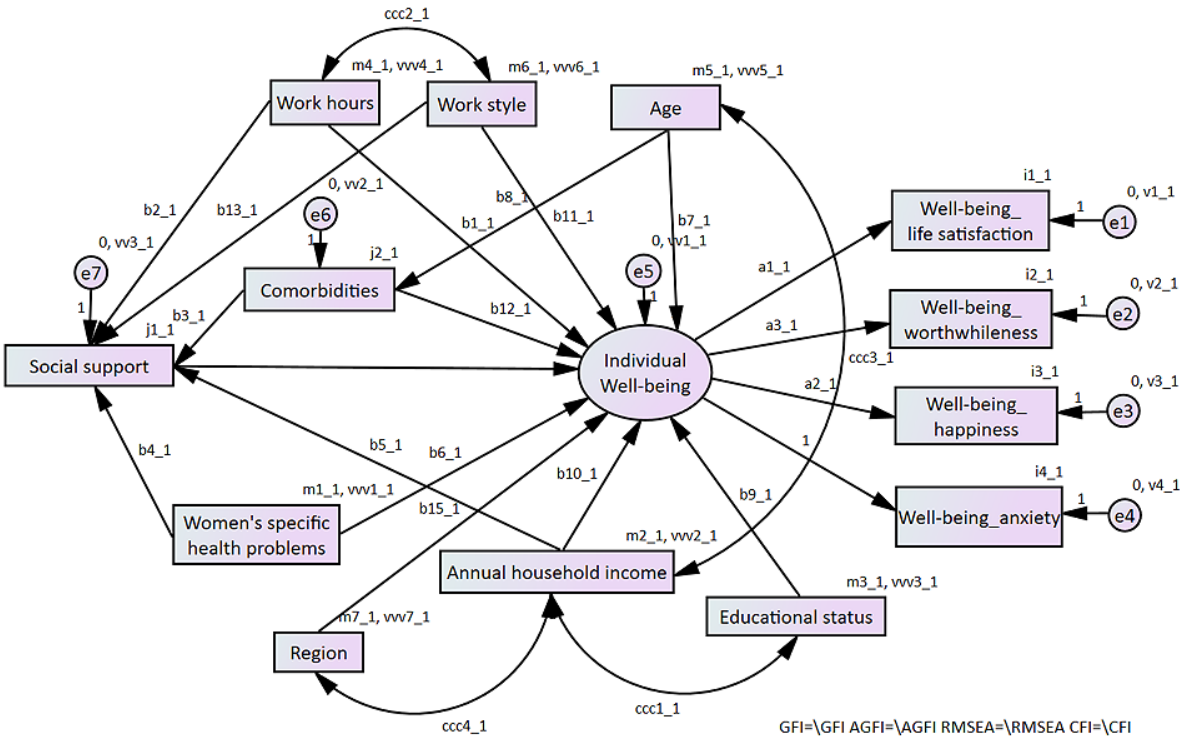
The Office for National Statistics (ONS)-4 questionnaire, developed by the United Kingdom Office for National Statistics, was used to measure personal well-being [23]. This questionnaire consists of 4 items: life satisfaction, worthwhileness, happiness, and feelings of anxiety. The participants were instructed to rate their well-being on a scale of 0-10. For life satisfaction, feeling that things done in life are worthwhile and happiness scores are categorized as low (0-4), medium (5-6), high (7-8), and very high (9-10). Feelings of anxiety were categorized as very low (0-1), low (2-3), medium (4-5), or high (6-10). The scores were analyzed using these threshold categories [23].

Social Support

The participants were asked multiple-choice questions about the people or groups who supported them in child and nursing care, which we calculated using dichotomous data: yes or no support.

Usage of eHealth

In this study, eHealth use was defined as obtaining health-related information through ICT. The participants were asked how they obtained health-related information. The choices included medical professionals, health events, books (newspapers, scientific journals, and scientific papers), television, internet news, internet search engines, social network services, medical information sites, blogs, information from the government and local government, family, friends, and others. If the participants selected ICT-enabled health care services from the options (eg, internet news, internet search engines, social network services, medical information sites, and blogs), we recorded them as dichotomous data for eHealth use (yes or no).



Statistical Analysis

First, a descriptive analysis was performed to examine participant background characteristics and well-being. The Kendall rank correlation coefficient was used to confirm the latent variables that should be considered in addition to the hypothetical model. We selected confounders shown in previous studies to be associated with well-being and social support [24-30], including age, region, educational status, annual household income, work style, work hours, comorbidities, and specific health problems (Figure 2). A BSEM was used to assess the enhancing effect of eHealth usage on the relationship between social support and the 4 well-being items. We adopted

XSL•FO
RenderX

the BSEM approach because it accommodates smaller sample sizes [31] and allows for a natural and explicit representation of Likert scales and binary latent variables [32,33]. The BSEM assumes one latent variable encompassing 4 well-being items and their correlated residuals (Figure 2). Based on the structure, we grouped the participants using eHealth and presented the results separately. We estimated the parameters in the BSEM for the groups with and without eHealth use, respectively. In addition, the ONS-4 data are ordinal scale, and treating them as normally distributed metric values is considered inappropriate. Therefore, we analyzed them using an ordered probit model, assuming the latent variable follows a standard normal distribution, which is appropriate for modeling binary outcomes. The prior distribution was set as a standard normal distribution, reflecting the assumption that the coefficients are centered around zero. We estimated the total standardized effects as path coefficients and their 95% CIs. The standardized total effect normalized the total effect by considering the ratio of the SDs of social support to well-being. The posterior distribution was derived using the Markov Chain Monte Carlo algorithm. The path coefficient was considered significant if the 95% CI excluded zero. The maximum number of iterations was set to 100,000 with 500 burn-in iterations. We judged that the algorithm converged after 100,000 sampling iterations, as determined by a convergence statistic below the threshold of 1.002 [34]. The estimated model was evaluated by the deviance information criterion. Finally, we performed the sensitivity analysis concerning model specifications involved in testing alternative model structures by omitting paths and latent variables to ensure the robustness of the results. Specifically, we confirmed that the standardized coefficients among well-being, eHealth, and other variables did not significantly change by omitting region and work hours and the paths that were linked to them, respectively. All statistical analyses were performed using the SPSS Statistics (version 29.0.1; IBM Corp) software and SPSS Amos (version 29.0; IBM Corp), and a *P* value of <.05 was considered statistically significant.

Figure 2. Preidentified structural model.

Ethical Considerations

This study was approved by the Research Ethics Committee of St. Luke's International University (reference number 22-A089). All participants provided informed consent on the web and the study data were collected anonymously. The research company offered the participants shopping points as rewards.

Results

Demographic Characteristics

Table 1 presents the demographic characteristics of the 2456 women who met the inclusion criteria. The table includes information on age, occupation, region, educational status, annual household income, work style, daily working hours, comorbidities, and women's specific health problems.

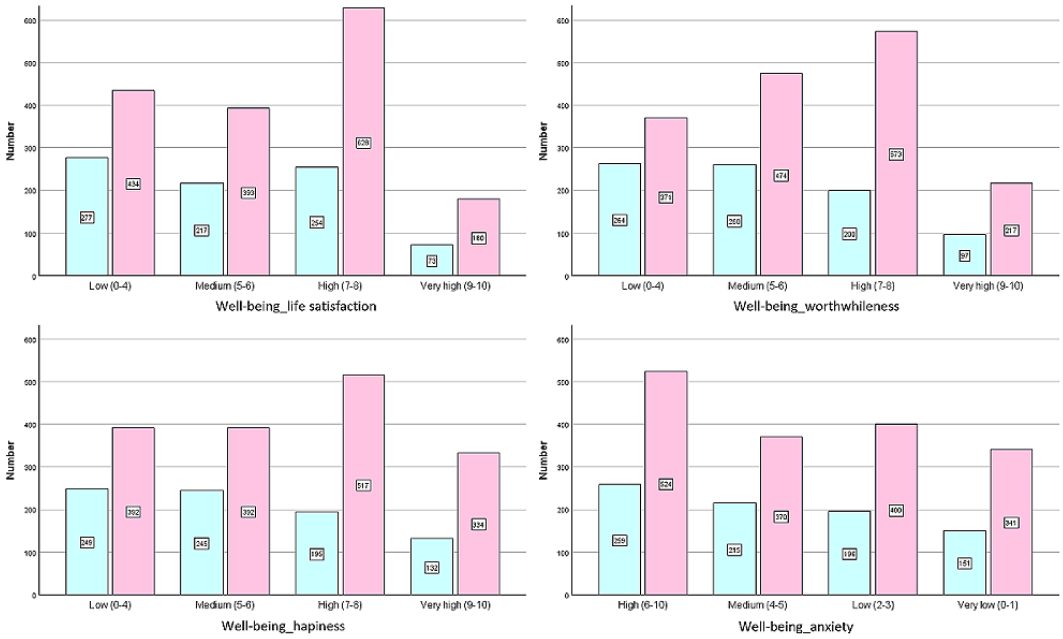
[a]As of May 2025, a currency exchange rate of 1 JPY=US $0.0069 was applicable.

[b]Not available.

[c]Comorbidities include hypertension, heart disease, atherosclerotic disease, diabetes mellitus, hyperlipidemia, and chronic kidney disease.

[d]Women's specific health problems include menstrual symptoms and illnesses, premenstrual syndrome, cancers common in women (eg, cervical, uterine, ovarian, and breast cancer), pregnancy- and childbirth-related symptoms, menopausal disorders, mental disorders, insomnia, infertility, endometriosis, benign female tumors, blood flow disorders, anemia, gastrointestinal disorders, headaches and migraines, underweight status, nutritional disorders, autoimmune diseases, and pelvic floor symptoms and diseases.



Approximately 70% of the participants were in their 30s and 40s. About 40% of participants were employed by a company and worked full-time. Most participants lived in the Kanto region, followed by Kinki, with the fewest residing in Tokai and Shikoku. Approximately half of the participants had graduated from graduate school or university. Most participants reported middle-class household incomes, with the most common range being upper-middle income (4-6 million yen [US $27,600-41,400] annually). This was followed by households with middle-high income (6-8 million yen [US $41,400–55,200]) and lower-middle income (2-4 million yen [US$ 13,800-27,600]). A notable portion, 372 (15.1%) participants, belonged to high-income households, earning over 10 million yen (over US $69,000) annually. The Kanto region had a higher concentration of high-income households, with 194/879 (22.1%) of participants from this area reporting annual incomes over 10 million yen (over US $69,000). Approximately 204/2456 (8.3%) participants worked night shifts, and 548/2456 (22.3%) participants worked an average of ≥8 hours per day. A total of 521 out of 2456 (21.2%) participants had comorbidities. More than half of the participants (1620/2456, 66% women) answered that they were experiencing symptoms that are common in women, such as premenstrual syndrome, female-specific cancers (uterine cancer and breast cancer), pregnancy-related issues, menopausal disorders, and mental disorders. Of the 2456 participants, 2123 (86.4%) had obtained health-related information in some form, including through means other than the internet, and 1635 out of 2456 (66.6%) had obtained health-related information through eHealth. The breakdown of eHealth sources was as follows: search engines (1003/2456, 40.8%), internet (851/2456, 34.6%), social networking service (744/2456, 30.3%), medical information sites (137/2456, 5.6%), and blogs (126/2456, 5.1%).

Profiles and Correlations of Measures

In terms of well-being, 711 out of 2456 (28.9%) participants reported low life satisfaction, 635 out of 2456 (25.9%) felt their lives were less worthwhile, and 641 out of 2456 (26.1%) had low happiness. Conversely, 253 out of 2456 (10.3%), 314 out of 2456 (12.8%), and 466 out of 2456 (19.0%) participants reported high scores for life satisfaction, feeling worthwhile, and happiness, respectively. In addition, 783 out of 2456 (31.9%) participants experienced high anxiety, whereas 492 out of 2456 (20.0%) reported low anxiety (Figure 3). Social support was reported by 1784 out of 2456 (72.6%) women. Table 2 presents the correlation coefficients between eHealth use, social support, and well-being measures. Significant correlations were found between well-being, social support, and eHealth use, although the effect size was small (Table 2).

Enhancing Effects of eHealth Use

The direct effects of associations between well-being and social support, as BSEM, differed depending on eHealth use. Among participants without eHealth use, the standardized total effects were 0.20 (95% CI 0.13-0.27, SE 0.00, SD 0.03), with a convergence diagnostic value of 1.00. In contrast, for those with eHealth use, the standardized total effect was higher at 0.47 (95% CI 0.45-0.50, SE 0.00, SD 0.01), with the same convergence diagnostic value of 1.00. The posterior predictive distribution *P* value was .50 and the deviance information criterion was 19,262.24, suggesting strong predictive validity of the model. The sensitivity analysis showed that the key relationships in the original model were robust to these changes as the estimated path coefficients and factor loadings varied only marginally. This result suggests that the model's conclusions are not dependent on specific assumptions regarding the model structure.

Discussion

Summary of Study Findings

This study examined the characteristics of participants and the relationship among well-being, social support, and eHealth use among employed women providing childcare or care. In this study, eHealth use enhanced the relationship between social support and well-being, with higher standardized total effects observed in the group that used eHealth compared to those that did not. Our findings align with recent research on eHealth interventions, demonstrating their positive impact on social support and well-being. A study suggested that social media use was positively associated with perceived responsiveness in internet-based social networks, which improved perceived social support and was linked to reduced loneliness and increased life satisfaction [19]. Furthermore, DeHoff et al [35] showed that internet-based social support might enhance participants' belief in being supported, leading to improved health behaviors. These findings suggest that eHealth use may contribute to improved well-being by facilitating access to social support and enhancing

XSL•FO
RenderX

individuals' perception of being supported. It might be particularly effective for working women who have limited time due to childcare or caregiving responsibilities.

Social support refers not only to the receipt of support but also to an individual's perception of support from family, friends, and significant others in their lives [36,37]. Current research suggests that family and close friends are positively associated with emotional well-being, even when they are far away [38]. Furthermore, recent research has shown that internet-based resources allow individuals to connect with and receive social support from people other than family and close friends [18]. The results of this study also support this hypothesis, as internet-based connections with individuals or organizations may lead to social support and improve individual well-being. A study investigating internet-based social support for parents of children with medical needs also showed that, through internet-based support, they receive support from peers, learn the information they need, and acquire the ability to deal with the associated emotional challenges [35]. As nuclear families make up the majority of households in Japan [12], women involved in the care of children and older family members need to be supported effectively using the internet as a tool for exchanging information about these fields and creating social connections for support. For Japanese people, who place great importance on social relationships and group harmony, this intervention might enhance their support-seeking behavior and reduce loneliness [21].

Previous research has demonstrated that cognitive factors such as age [39], education level, income [40], gender, occupational status, and marital status influence eHealth literacy [41]. In addition, a previous study indicated that higher health literacy levels positively influence health-seeking attitudes and social support [42]. Our study found minimal differences between groups based on eHealth usage. This result may be attributed to the data collection method, which was an internet-based survey, and our focused sample of employed Japanese women aged 20-65 years engaged in childcare or caregiving activities [43]. Most participants were in their 30s and 40s, with approximately half having completed higher education. These individuals are not older adults, have a higher level of education, and are employed women. Therefore, they are likely to belong to a group with a relatively high rate of eHealth usage. Regarding income, the participants in this study were employed women whose annual household income exceeded the average income in Japan (5,242,000 yen [US $36,368.68]). This is likely because the survey was conducted among working women, many of whom belong to dual-income households. The lack of comparative data makes it difficult to make a general statement. As many studies have shown a relationship between annual household income and well-being [44,45], the participants in this study may represent a group with a relatively high level of well-being. Health-related conditions, such as high blood pressure and female-specific conditions, were prevalent among the participants. Other well-being surveys in the United Kingdom have shown that the well-being of Japanese people tends to be relatively low [46]. Compared with the British survey using ONS-4, participants had a lower life satisfaction rate and a higher percentage of individuals with high anxiety [46]. As a previous study has pointed out, social support interventions should account for cultural context and cognitive factors and be developed and implemented as tailored eHealth interventions for a similar population.

In addition, when implementing eHealth, factors that might influence its use should be considered. Previous studies have not reached a consensus on the association between eHealth service use, including social media, and well-being. Although some studies have reported a positive association with well-being [36,47], others have suggested that social media use negatively affects well-being [48,49]. Given the complex factors influencing eHealth literacy and well-being, it is important to consider how eHealth service use may impact well-being outcomes across different populations [50]. Previous studies have suggested that interactive methods may have positive effects and that internet-based information exchange and positive social interaction enhance perceived social support and well-being [49]. However, we could not clarify the specific methods for obtaining information via eHealth in this study. Future studies should investigate how individuals obtain information through eHealth services.

Implications for Future Practice and Research

These findings suggest that eHealth use can play a significant role in enhancing well-being among women, particularly those providing childcare or caring for someone else. Labor participation by women has increased globally, benefiting individuals and society worldwide [51]. Japan is no exception, with the number increasing by more than 4 million over the past decade [52]. However, gender inequality exists in Japan's working environment. In 2023, the World Economic Forum assessed the state and evolution of the gender gap across 4 key dimensions (economic participation and opportunity, educational attainment, health and survival, and political empowerment). The World Economic Forum ranks Japan 125th among 146 countries [53]. Various issues were identified, including the gender pay gap, a lack of female executives, and a decline in the number of women in regular employment after their 30s [54]. Women's progress in social advancement is closely linked to changes in daily life and overall well-being. Using internet-based social support to enhance women's well-being could promote their social advancement, improve the next generation's health, and address gender equality. This finding suggests that health care providers and policy makers should consider promoting eHealth platforms to improve mental and physical health outcomes. Moreover, they must support women in accessing required information via eHealth services. Future studies can further explore the mechanisms through which eHealth influences social support and well-being, potentially focusing on the most effective eHealth interventions or platforms. eHealth interventions should be developed to address the specific needs of employed women providing childcare or caregiving and to assess their benefits and harms. In addition, longitudinal studies can provide insights into the long-term effects of eHealth use on well-being and other health outcomes.

Strengths and Limitations

This study is unique in that it examined the relationship among well-being, social support, and eHealth use among a large

XSL•FO
RenderX

sample of working women raising or caring for children. The use of BSEM allowed for a robust analysis of the data, providing CIs and a sensitivity analysis that strengthened the validity of the results. Focus on the use of eHealth provides valuable insights into an emerging area of health intervention that is particularly relevant in today's digital age. However, this study has some limitations. First, the cross-sectional design restricted the ability to infer causality between eHealth use and well-being. Second, our study did not use validated scales specifically designed to measure social support, work-life balance, job satisfaction, and caregiver burden, which could have provided more robust and standardized assessments of these crucial variables. In addition, we did not investigate perceived social support in this study. However, it is important to consider that the mechanisms linking social support and well-being are complex and involve multiple correlated factors. Including perceptions of social support may provide a more comprehensive understanding of how these elements interact and contribute to overall well-being. Third, we only assessed the use of ICT to obtain health-related information, such as the usage of eHealth, and could not evaluate social support through ICT. The frequency or intensity of use was also not evaluated. As eHealth encompasses a broader range of concepts, further studies should include this in evaluating ICT for support in health and health-related fields. Fourth, these data were collected through a self-reported questionnaire, and response biases may be present.

Conclusion

This study suggests that using eHealth services for employed women raising children or caring for someone may enhance the impact of social support on their well-being. However, the complexity of the relationship between eHealth use, social support, and well-being necessitates further investigation. Further studies should investigate the following points while considering cultural contexts and individual differences in eHealth literacy: the mechanisms underlying the relationship among social support, well-being, and eHealth use; the potential benefits and harms of eHealth interventions; and the long-term effects of eHealth interventions on social support and well-being. In addition, further research is needed to develop customized eHealth interventions that address the specific needs of working women with caregiving responsibilities. Deepening our understanding in these areas would allow for the implementation of more effective eHealth interventions, contributing to the improvement of working women's well-being.

Acknowledgments

This study was supported by the Japan Agency for Medical Research and Development (grant 22rea5221030001) and Japan Science and Technology Agency (PRESTO grant JPMJPR21RC, Japan). Funders were not involved in any of the processes, such as study design, participant recruitment, data collection, analysis, or manuscript writing. We thank Editage for editing the English language.

Data Availability

The data used in this study are not publicly available because of privacy and confidentiality concerns. Consequently, external parties cannot share the data.

Authors' Contributions

NY, DY, and KS were responsible for the conceptualization of the study. All members accessed and verified the data. The investigation was conducted by NY, DS, SK, EN, and EO. The methodology was developed by NY, DY, KS, and ES. The original draft was written by NY. Supervision was provided by DY, EO, HT, and ES who reviewed and edited the manuscript. The corresponding author had full access to all the data in the study and assumed the final responsibility for the decision to submit the manuscript for publication.

Abstract

Background: Health care digitalization and pediatric information and communication technology have facilitated the use of telemedicine and digital communication tools in pediatric practice, improving accessibility and efficiency. Meanwhile, artificial intelligence (AI) is emerging as a promising tool in medicine. However, the rapid adoption of these technologies has raised concerns regarding reliability and ethics.

Objective: This study examines the level of digitalization in pediatric consultations and explores the perspectives of health care professionals (HCPs) on digital technologies in patient care, analyzing differences by age group, health care management, and institution type.

Methods: An observational, cross-sectional survey was conducted among Spanish HCPs dedicated to pediatric care. Participants completed an 18-question web-based questionnaire evaluating their use of digital communication tools, perceptions of online health information, and opinions on AI in clinical practice. Statistical analyses compared responses across age groups, health care management type, and institution type.

Results: A total of 495 pediatric specialists participated (female: 273/495, 58.2%; aged >45 y: 324/495, 69.8%). Most participants worked in urban settings (409/469, 87.2%), in primary care (243/313, 77.6%), and in the public sector (253/464, 54.5%). The telephone remained the most used communication channel (462/481, 96.1%), followed by email (290/481, 60.3%) and WhatsApp (139/481, 28.9%). Private-sector HCPs used digital platforms more frequently than public-sector HCPs, including email (136/206, 66% vs 135/247, 54.7%; *P*=.02), Instagram (23/206, 11.2% vs 5/247, 2%; *P*<.001), WhatsApp (105/206, 51% vs 26/247, 10.5%; *P*<.001), and Facebook (18/206, 8.7% vs 3/247, 1.2%; *P*<.001). Nearly all respondents (417/437, 95.4%) believed that parents were increasingly seeking health information online, yet a considerable proportion (158/458, 34.5%) reported that parents rarely consulted them about reliable sources. Overall, 85.4% (410/480) agreed that the internet and social media raise many questions among parents, while only 7.5% (35/465) believed that the information found is generally reliable. Nearly half of the participants (232/443, 48.5%) proactively suggested trustworthy digital resources, while 44.1% (211/443) did so only when asked. Younger respondents (*P*=.002), public-sector HCPs (*P*=.005), and primary care specialists (*P*=.004) were significantly more likely to offer this guidance, with scientific society resources being the most frequently recommended (402/430, 93.5%). We found that 78.6% (369/470) of participants were familiar with AI, with private-sector HCPs demonstrating greater knowledge than public-sector HCPs (*P*=.003). Overall, 59.6% (279/468) agreed that AI could significantly improve medicine, a view more commonly held by private-sector HCPs (*P*=.005). However, 94.8% (306/323) expressed ethical concerns, and 89.8% (422/470) wished to receive AI-related training.

XSL•FO
RenderX

Conclusions: The survey highlights the increasing use of digital communication tools in pediatric practice, with private-sector HCPs leading adoption. While AI is viewed as promising, ethical dilemmas remain, underscoring the need for training. Limited confidence in online health information highlights the importance of strengthening digital literacy among both HCPs and parents to optimize patient care.

KEYWORDS

health care digitalization; information and communication technology; ICT; pediatric ICT; artificial intelligence; AI; telemedicine

Introduction

Background

Technological development in recent decades has facilitated digital transformation, defined as the integration of digital solutions to create or modify existing organizational structures, resources, and social relationships [1,2]. Medicine has similarly undergone significant transformation through advances in this field. The adoption of innovative tools in health care, including pediatric information and communication technology (ICT), has expanded the provision of medical services via telecommunications, commonly referred to as telemedicine [3,4]. These services encompass telephone calls, instant messaging apps, videoconferencing, websites, mobile apps, and blogs [5]. These telemedicine options offer substantial benefits and have gained widespread user acceptance by facilitating access to information and enhancing physician-patient communication. In regions with limited health care accessibility, these solutions are particularly valuable, as they reduce travel constraints and optimize time utilization [6-8].

Although telemedicine had been steadily growing, it was the COVID-19 pandemic that triggered its rapid acceleration and widespread implementation [9]. Restrictions on hospital access during the pandemic created major challenges for patient monitoring and treatment adherence, prompting health care professionals (HCPs) to adopt digital solutions within online environments [10,11]. Unfortunately, the increasing use of the internet and social media by patients has generated new concerns. While these platforms can improve access to knowledge, not all content is reliable, which may result in the spread of misinformation. Thus, ensuring content quality control and appropriate regulation of these platforms is crucial [12,13]. In this context, HCPs could play a key role by leveraging social media as educational platforms when appropriate and guiding patients toward reliable sources of information [14].

More recently, the development of artificial intelligence (AI) has emerged as one of the most significant scientific and technological advances of our time, with applications extending across all sectors of society [15]. In medicine, AI is already being used to support specialists in various capacities, including big data analysis, medical image interpretation, workflow management systems, and clinical diagnostics. The implementation of AI has the potential to significantly improve the accuracy, efficiency, and overall quality of patient care [16-18]. Despite these benefits, AI lacks essential human attributes such as empathy and compassion, which are critical skills in health care. These limitations highlight the need for patients to feel that consultations remain under human oversight. As a result, ethical concerns regarding the use of AI continue to persist [19].

Telemedicine in Pediatrics

Pediatrics is among the medical fields most influenced by new ICTs. Parents often seek immediate information and support, for which telemedicine and the internet offer convenient options [20]. During the COVID-19 pandemic, telemedicine use considerably increased in both ambulatory and hospital environments, suggesting that it is likely to become an integral component of routine pediatric care if such services remain available [21,22]. In Spain, most pediatricians reported using digital technologies to communicate with patients during the pandemic and believed that digital consultations would continue to play a role in the future [23].

Therefore, this survey aimed to examine and evaluate the digitalization of pediatric consultations and HCPs' perceptions regarding the use of digital technologies in parenting.

Methods

Study Design

An observational, cross-sectional, descriptive survey was designed to obtain information on pediatric specialists' perspectives regarding communication channels with patients, the quality of information available online, and the potential impact of AI in medicine. In addition, the survey analyzed and compared responses by age group, type of management, and type of institution to identify possible divergences within the system.

HCPs involved in pediatric care, from a sample of 5187 specialists registered in the database of Laboratorios Ordesa, a Spanish company specializing in nutrition and food supplements, were invited to participate. All individuals in this database had previously provided informed consent, in accordance with the Spanish Data Protection and Digital Rights Act, to be contacted by the company for informational purposes. An email invitation describing this study and containing a link to the questionnaire was sent to all members of this database, and the same invitation was also disseminated through the company's social networks (X [formerly known as Twitter] and LinkedIn). No reminders were sent. Of the 5187 HCPs invited to participate, 495 (9.54%) completed the questionnaire. Explicit refusals were not recorded; thus, nonresponders were defined as those who did not reply to the invitation. Participants included HCPs from both the public and private sectors in Spain. No specific inclusion criteria were applied. Participants completed the questionnaire between September 2023 and June 2024.

XSL•FO
RenderX

The survey was developed by a team of HCPs with experience in questionnaire-based studies after a comprehensive literature review (Multimedia Appendix 1).

Since 2017, the research team has progressively explored key topics in communication between pediatricians and families through regular consultations with professionals in the field. This ongoing collaboration helped identify and refine the most relevant questions over time. The final structure and content of the questionnaire were based on a previously published survey that addressed similar topics [23]. In addition, a new section on AI was introduced, given the growing interest and limited existing data in pediatric settings. The questions in this section were developed with input from experts and inspired by recent findings in the field [24].

The questionnaire consisted of 18 questions across 3 sections. The first section included 7 items on sociodemographic data, including workplace location (rural vs urban). This classification was based on population size: rural (<2000 inhabitants), semiurban (2000-10,000 inhabitants), and urban (>10,000 inhabitants).

The second section focused on evaluating the digitalization of pediatric consultations and included 6 closed-ended questions measuring the level of agreement.

The third section assessed the impact of AI in clinical practice through 5 closed-ended questions. Responses regarding the influence of the internet and social media on parenting were rated on a scale ranging from 1 (completely disagree) to 10 (completely agree) and grouped into 4 categories according to Likert scaling: disagreement (1-3), neutral (4-6), agreement (7-10). In parallel, responses were analyzed by age group (29-45 y and >45 y), type of management (public or private), and type of institution (hospital or primary care).

Data Analysis

Descriptive statistics (means and SDs) were calculated for quantitative variables, while frequencies and percentages represented categorical variables to describe the sample characteristics. The Fisher exact test was used to assess associations between qualitative variables, and the Mann-Whitney *U* test was used to compare quantitative variables between 2 independent groups. Statistical analyses were conducted in SAS (version 9.4; SAS Institute), with statistical significance defined as $P<.05$.

Ethical Considerations

This study was exempt from formal ethics committee approval in accordance with the Spanish Organic Law 3/2018, of December 5, on the Protection of Personal Data and the Guarantee of Digital Rights. Participation was entirely voluntary. Pediatricians were informed about the objectives of the study, the voluntary nature of their participation, and the anonymous handling of their data prior to completing the questionnaire. Consent was implied through prior registration in the recruitment database and the voluntary completion of the online survey. No personally identifiable information was recorded, thereby ensuring participant privacy and confidentiality. The study did not involve patients, minors, or other vulnerable populations.

Results

Sociodemographic Data

Of the 5187 HCPs invited to participate, 495 (9.54%) completed the questionnaire. Of the 495 respondents, 273 (58.2%) were female, and the mean age was 52.2 (SD 10.9) years, with 324 (69.8%) aged more than 45 years. Most of the participants (409/469, 87.2%) worked in urban areas; 54.5% (253/464) were public-sector HCPs, while 77.6% (243/313) worked in primary care (Table 1).

Digitalization of Pediatric Consultations and the Use of the Internet and Social Media

When asked about communication methods with patients, 96.1% (462/481) of the participants reported using the telephone, making it the most common channel. However, nearly 90% (429/481) also relied on ICTs such as email (290/481, 60.3%) and WhatsApp (139/481, 28.9%). Statistically significant differences were observed across subgroups: older HCPs (aged >45 y) were more likely to use WhatsApp (P<.001), while private-sector HCPs more frequently used digital communication methods, including email (P=.02), Instagram (P<.001), WhatsApp (P<.001), and Facebook (P<.001), compared to public-sector HCPs. By contrast, public-sector HCPs primarily relied on telephone communication (P=.01), and specialists working in hospitals used WhatsApp significantly more than those working in primary care (P=.002). These results are summarized in Table 2.

Regarding digitalization in information seeking, most of the respondents (n/N, 95.4%) believed that parents have increased their search for parenting information over the past year (Table 3). Table 4 presents the respondents' recommendations on reliable digital sources of parenting information.

However, 34.5% (158/458) of the participants stated that parents had not consulted them about reliable digital sources of parenting information. The only significant difference was observed by age: younger specialists (aged 29-45 y) were more frequently asked about reliable sources of information (Table 5).

Table 5. Responses of health care professionals in pediatric practice to the survey question "Do parents ask you for reliable sources of information to learn about raising their children in the digital media?" *P* values were calculated with the Fisher exact test. Italicization indicates values that met the threshold for significance.

	Total (n=458), n (%)	Analysis by age (y), n (%)		*P* value	Analysis by type of management, n (%)		*P* value	Analysis by type of institution, n (%)		*P* value
		29-45 (n=129)	>45 (n=305)		Public (n=236)	Private (n=198)		Hospital (n=65)	Primary care (n=227)	
Responses				*.03*			.42			.99
Yes	300 (65.5)	95 (73.6)	191 (62.6)		150 (63.6)	134 (67.7)		45 (69)	158 (69.6)	
No	158 (34.5)	34 (26.4)	114 (37.4)		86 (36.4)	64 (32.3)		20 (31)	69 (30)	

When asked whether they recommend "reliable digital sources of parenting information," 48.5% (232/443) of the HCPs responded that they normally do so even if parents do not ask, while 44.1% (211/443) provided recommendations only when asked. Grouped analysis indicated that younger respondents (*P*=.002), public-sector HCPs (*P*=.005), and primary care specialists (*P*=.004) were significantly more likely to provide such recommendations (Figure 1). The most frequently recommended sources were those from scientific societies, cited by 93.5% (402/430) of the HCPs, followed by blogs and digital content (142/430, 33%). Among the recommended options, younger professionals were more likely to propose blogs and digital content from other HCPs (*P*=.005), whereas private-sector physicians were more likely to recommend their own materials (*P*=.004; Table 4).

For the statements "The internet and social media raise many questions among parents" and "In general, the information found on the internet and social media is reliable," the mean scores were 8.10 (SD 0.81) and 3.8 (SD 2.0), respectively. The corresponding percentages are shown in Figure 2.

The only significant differences were observed by type of management, with private-sector HCPs being more likely to believe that the internet and social media raise many questions among parents (*P*=.03; Table 6). Table 7 presents the respondents' perceptions on whether, in general, the information found on the internet and social media is reliable.

Figure 1. Proportions of health care professionals in pediatric practice who proactively recommend, recommend only when asked, or do not recommend trustworthy digital sources to parents, stratified by age group, type of management, and type of institution. Total responses: "yes"=48.5% (232/478); "only when asked"=44.1% (211/478); "no"=7.3% (35/478). The statistically significant *P* values (*P*<.05; Fisher exact test) are shown in bold.

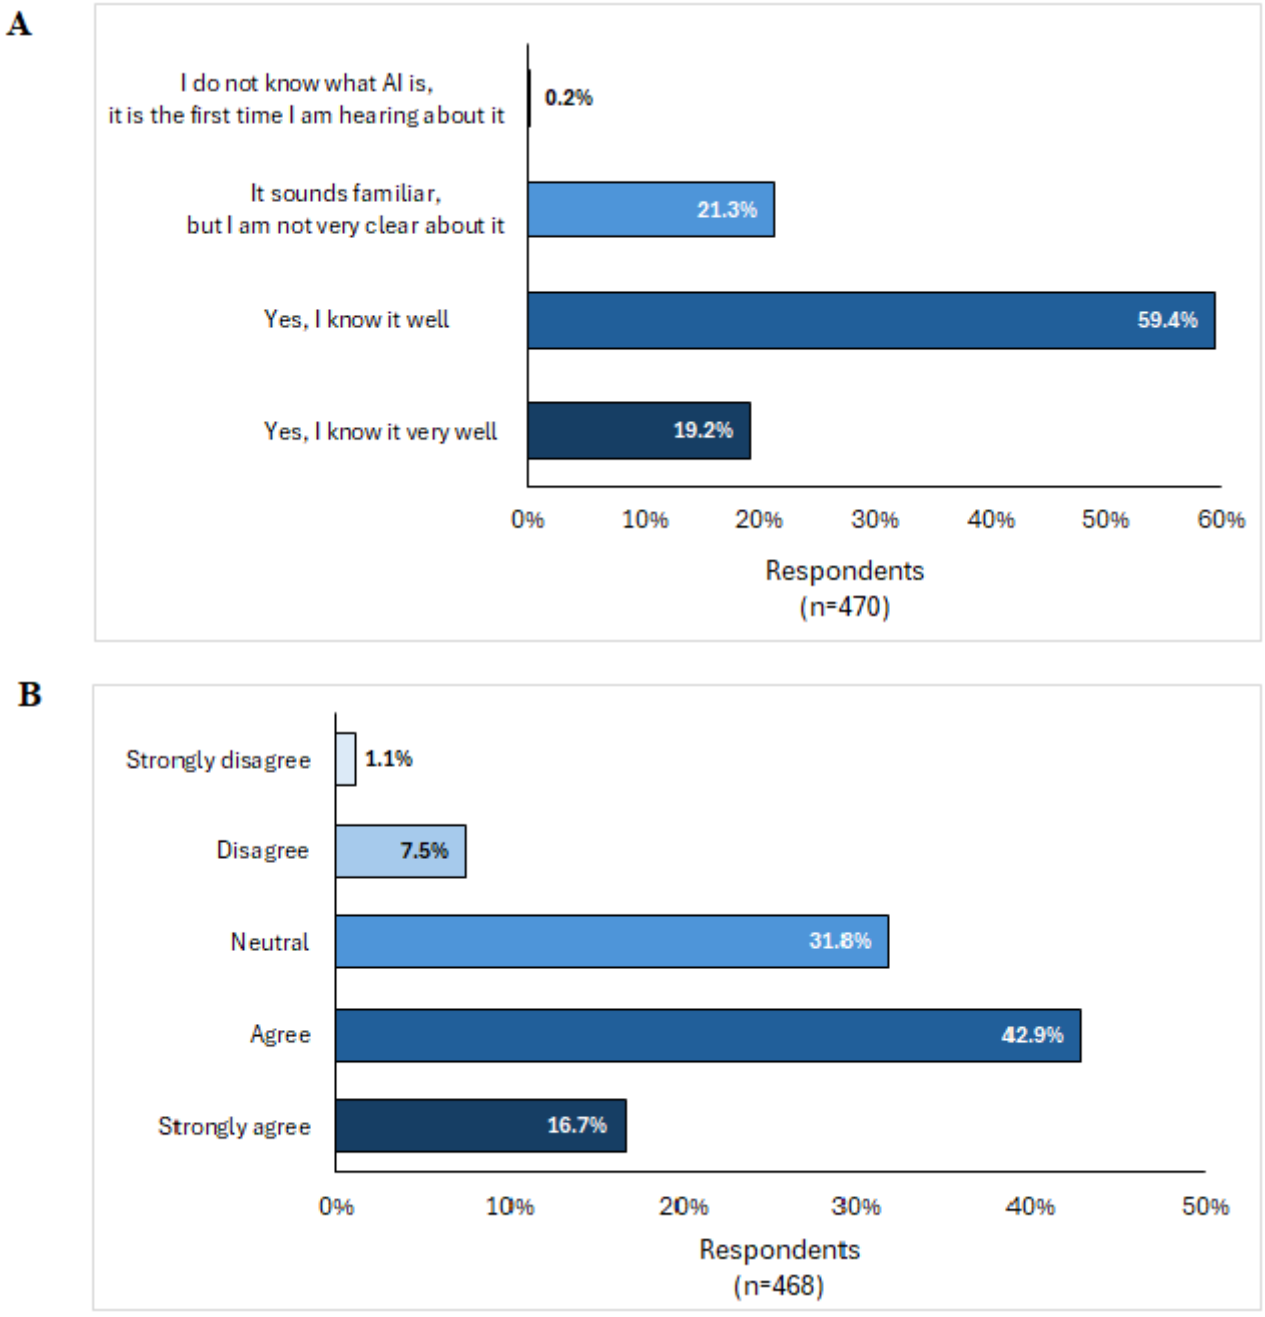
Impact of AI in Medicine



Participants were asked to share their opinions on recent advancements in AI and AI's potential impact in medicine. Nearly 75% (369/470) of the HCPs reported knowing well (279/470, 59.4%) or very well (90/470, 19.2%) what AI is, while 21.3% (100/470) indicated that AI sounded familiar but that they were not very clear on what it entails (Figure 3A). Regarding the statement "I believe AI could lead to significant improvements in medicine," more than half agreed (201/468, 42.9%) or strongly agreed (78/468, 16.7%), while 31.8% (149/468) remained neutral (Figure 3B). Regarding the medical areas where AI is perceived to offer the most improvements, respondents highlighted diagnostic assistance, medical training,

XSL•FO
RenderX

and enhanced health care access in regions lacking specialists. The first 2 options were selected by approximately half of the HCPs (254/472, 53.8% and 228/472, 48.3%, respectively; Table 8).

Grouped analysis revealed several significant differences. Private-sector HCPs demonstrated greater knowledge of AI (*P*=.003; Table 9) and were more convinced than public-sector HCPs that AI could bring important advancements to medicine (*P*=.005), a view also strongly shared by hospital-based HCPs (*P*=.02; Table 10). Regarding areas of improvement, pediatric specialists aged more than 45 years were more likely to believe in AI's potential to assist and contribute to diagnostic support (*P*=.02), as were hospital-based HCPs (*P*=.04); however, public-sector HCPs were more likely to believe that AI could enhance medical training (*P*=.04) and improve treatment adherence (*P*=.02; Table 8).

Figure 3. Health care professionals' perspectives on artificial intelligence (AI) in pediatric practice. (A) Self-reported knowledge of AI among respondents (n=470), expressed as the percentage of participants in each category. (B) Level of agreement (n=468) with the statement "AI will significantly improve medicine."

Disagree	7 (5.2)	25 (8)		22 (8.9)	10 (4.8)		1 (2)	3 (1.3)	
Strongly disagree	2 (1.5)	3 (1)		3 (1.2)	2 (1)		0 (0)	0 (0)	

Regarding the ethical and legal aspects of AI, more than half of the participants admitted to being moderately (92/323, 28.5%) or highly (214/323, 66.3%) concerned, with no statistical differences between groups (Figure 4). In addition, most of the HCPs (422/470, 89.8%) stated that they would like to receive

XSL•FO
RenderX

training on AI and its potential applications in medicine (Table 11), again with no significant group differences.

Figure 4. Health care professionals' concerns regarding ethical and legal aspects of artificial intelligence. The bars represent the distribution of responses by age group, type of management, and type of institution. Total responses: "yes, very much"=66.3% (214/323); "yes, somewhat"=28.5% (92/323); "indifferent"=4.6% (15/323); "no, hardly"=0.3% (1/323); "no, not at all"=0.3% (1/323).

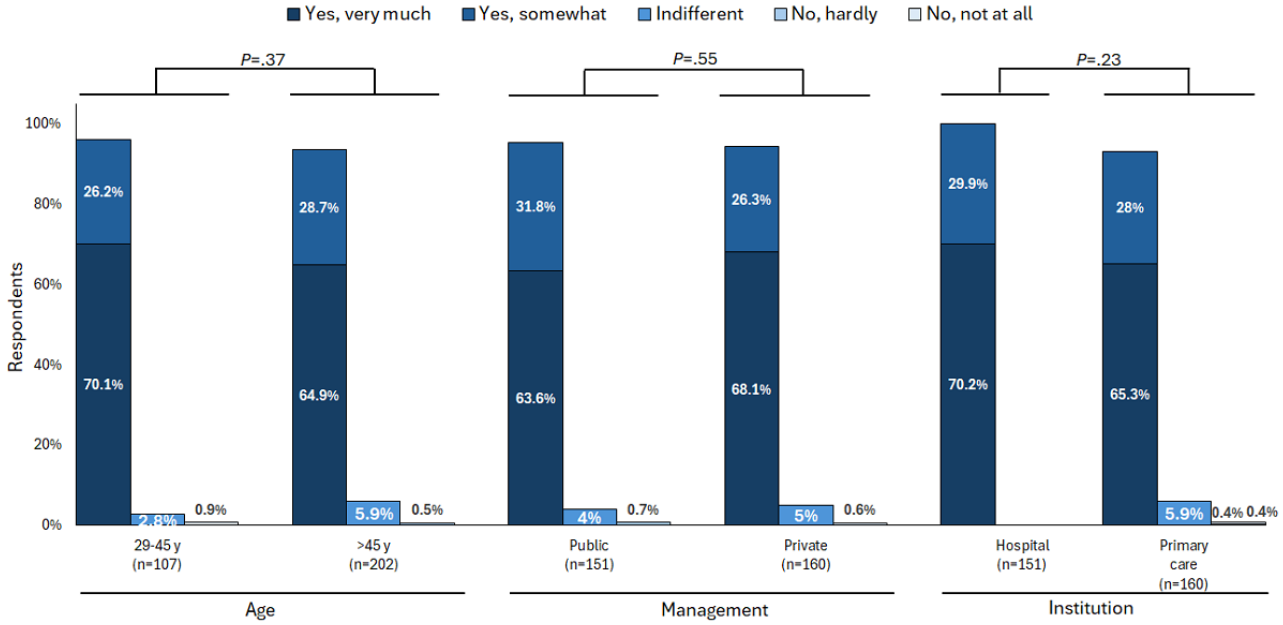

Table 11. Responses of health care professionals in pediatric practice (n=470) to the survey question "Would you like to receive training on AI and its potential applications in the field of medicine?" *P* values were calculated with the Fisher exact test.

Discussion

Principal Findings

The integration of AI and digital tools is transforming medical practice, driving advancements in diagnostics, patient management, and health care accessibility [22]. In pediatrics, ICTs have become especially valuable, enhancing physician-parent communication [25] and providing immediate access to medical advice [26].

To the best of our knowledge, this survey is the first to examine the impact of health care digitalization across both public and private sectors and between hospitals and primary care services in Spain. It highlights a high prevalence of telephone use and digital communication tools such as WhatsApp and email among pediatric HCPs. These patterns may reflect the predominantly urban settings of the participants, as urban areas typically offer better digital infrastructure, high-speed internet, and more resources for digital health integration compared to rural regions [27]. Nevertheless, these results emphasize the widespread adoption of virtual communication models between parents and HCPs, consistent with previous reports from Europe [28,29].

Notable variations in digital tool use were observed, aligned with prior research indicating that adoption rates depend on the management system (public vs private) and the age of HCPs [30,31]. According to Rotaru and Edelhauser [30], private health care institutions generally implement digital solutions more quickly than public systems, which often encounter bureaucratic and financial barriers. Supporting this, the *Observatorio de Digitalización en la Sanidad Privada: Madurez Digital y Casos de Éxito* (*Digitalization Observatory in Private Health Care: Digital Maturity and Success Stories*) report underscores that private health care in Spain is leading the charge in digitalization, providing more accessible and personalized services [32]. Indeed, this is reflected in the higher use of digital platforms such as Instagram, WhatsApp, and Facebook by private-sector HCPs. It should be noted that in the Spanish public health care sector, the use of informal communication channels such as WhatsApp or Instagram between HCPs and patients is generally discouraged due to concerns regarding

XSL•FO
RenderX

confidentiality, data protection, and professional boundaries [33].

Interestingly, private-sector HCPs preferred email communication more frequently than public-sector HCPs. This preference may be related to email's ability to maintain formal records, align with structured consultation schedules, easily transfer digital images and documents, and facilitate asynchronous communication [34]. Nevertheless, telephone use remained dominant among public-sector HCPs, possibly due to centralized call systems or accessibility for families with limited digital resources. In addition, primary care physicians demonstrated a lower tendency to use digital tools overall compared to hospital-based HCPs, suggesting existing barriers or constraints in the use of digital health [35]. Notably, the Spanish Ministry of Health has implemented a digital health strategy aimed at transforming primary and community care in Spain, which is expected to help address these challenges [36].

Age has long been considered a key factor in the adoption of digital tools, with younger physicians typically seen as digitally literate and comfortable using digital platforms [31]. However, middle-aged adults (those aged 30-60 years) now also exhibit varying but significant levels of digital literacy, depending on their exposure to technological tools [31]. The simplicity and widespread use of WhatsApp, which has become an integral part of daily life for most people [37,38], likely explains its higher adoption among older HCPs.

Regarding parental use of digital media, most of the participants (417/437, 95.4%) reported that parents are increasingly turning to digital platforms for child-rearing advice. This finding aligns with previous research [39-41] indicating that social media is becoming a primary source of health information for both parents and HCPs [40]. This shift underscores the growing responsibility of HCPs to guide parents toward evidence-based resources. At the same time, concerns about misinformation have escalated, with many participants expressing skepticism about the reliability of online content, often due to the overwhelming volume of unverified information [25,40]. As a result, HCPs must strengthen their presence on social media, recommending curated and credible resources to counter misinformation and improve child health outcomes.

Most of the HCPs (402/430, 93.5%) reported recommending resources from scientific societies. This could be expected, as these institutions provide peer-reviewed, evidence-based information, which ensures content accuracy, reliability, and absence of commercial bias, making them trusted sources of medical advice [42]. Interestingly, private-sector HCPs, in addition to recommending scientific societies, were more likely than their public-sector counterparts to recommend their own online sources. This trend can be attributed to the fact that private hospitals often focus on increasing patient numbers and adherence [43]. Unlike their public-sector counterparts, who usually rely on institutional platforms and officially endorsed guidelines, private HCPs often operate in settings that require greater autonomy and visibility. Recommending personal or practice-specific resources may allow them to reinforce patient trust, provide tailored information, and enhance professional identity, while also compensating for the lack of centralized institutional tools available in the public system.

Evaluating how pediatric specialists are adapting to this digital era is critical for identifying areas of improvement and optimizing integration to ensure high-quality, patient-centered care. Indeed, the survey found that private-sector HCPs are generally more familiar with AI than their public-sector counterparts, likely due to greater investment in AI tools [32], more access to training [43,44], higher patient demand for technologically advanced services, and fewer bureaucratic obstacles to AI adoption [30].

Nearly half of the participants (82/135, 60.7%) believed that AI could significantly enhance medicine, especially in diagnostics and medical training. These results align with previous studies highlighting the role of machine learning in pediatric health care, particularly in supporting complex diagnoses and improving clinical decision-making [45]. However, this study identified differences in preferred areas of AI improvement: public-sector HCPs valued AI more for medical training and treatment adherence, whereas hospital-based HCPs (vs those working in primary care) prioritized diagnostic assistance. This trend was also seen among older HCPs. The reasons for these differences were not explored in the survey, but they may be explained by (1) AI's role in continuing education, especially in underfunded public health systems; (2) AI's potential to support treatment adherence—through automated reminders and multilingual resources—in populations considered vulnerable and attending public hospitals; (3) the ability of AI to automate monitoring; and (4) the potential to democratize access to therapeutic support tools in public health systems. Among older HCPs or those based in hospitals, the preference possibly reflects the need to address more complex or rare cases.

Previous studies have highlighted several concerns among HCPs regarding the integration of AI into health care. Key issues include fears of job displacement, particularly in specialties such as radiology, where AI may reduce the need for human workers. Such concerns are often linked to a lack of understanding of AI, with HCPs reporting superficial knowledge of this technology but still expressing skepticism about its potential. In addition, specialists lack trust in AI's ability to address human emotions, which may degrade the patient-physician relationship, and they worry that overreliance on AI could undermine critical thinking, especially among younger professionals who may not have enough practical experience [46-49]. In this study, although approximately 90% (422/470) of the participants expressed interest in receiving AI training, concern about the legal and ethical aspects of AI was unanimous, regardless of age and type of management. Furthermore, a large proportion of respondents (30/133, 22.6%) reported neutral opinions regarding their knowledge of AI. These findings underscore the need for structured outreach, more reliable educational resources, and awareness campaigns on the role of AI in medicine.

Given the increasing role of digital tools and AI in pediatric care, integrating structured training programs for HCPs is essential to optimize their effective and ethical use. This could

XSL•FO
RenderX

enhance health care efficiency, improve patient outcomes, and help address existing disparities among professional groups. Moreover, efforts should be directed toward establishing guidelines to ensure the reliability of online health information, given its growing influence on parental decision-making. Pediatricians should play a key role in this process by guiding families toward evidence-based resources.

Although this study focuses on Spain, its findings are in line with international trends in pediatric digitalization and AI adoption. Future research should explore cross-country comparisons to identify best practices and potential areas for policy improvement. In addition, further studies should evaluate the long-term impact of digitalization on pediatric health outcomes, as well as the effectiveness of AI-driven solutions in improving clinical decision-making and patient education.

Strengths and Limitations

This study benefits from a large sample size that includes HCPs from different regions, age groups, health care settings, and professional backgrounds, providing a broad overview of current practices and perceptions regarding digital communication and AI in pediatrics. The questionnaire was specifically designed to capture both the use of digital tools and attitudes toward AI, and the stratified analyses offer valuable insights into differences by age, type of management, and type of institution. Although digital health technologies evolve rapidly, the survey was conducted over a relatively short period (September 2023-June 2024), making it unlikely that substantial shifts in professional perceptions occurred during data collection.

However, some limitations should be acknowledged. Recruitment through Laboratorios Ordesa's database and social media channels may have introduced selection bias, favoring HCPs with higher digital literacy or stronger professional ties to the private sector. In addition, the relatively low response rate (495/5187, 9.54%) raises the possibility of nonresponse bias, as participants who completed the survey may differ from nonrespondents in their engagement with digital tools or interest in AI. This could limit the generalizability of the findings to those less engaged with digital platforms. To mitigate this, the study sought participation from professionals across diverse health care settings and sectors, aiming to capture a heterogeneous sample.

Reliance on self-reported data may have introduced recall bias or social desirability bias, potentially leading to overestimation of AI knowledge or frequency of digital tool use. The cross-sectional design also limits the ability to establish causal relationships between variables, as it captures data at a single point in time. Nonetheless, the survey provides a valuable snapshot of current perceptions and practices among HCPs, allowing for the identification of relevant trends and areas for future longitudinal research. In addition, rural HCPs were underrepresented (11/469, 2.3%), which may limit the applicability of the results to rural practice contexts, where resources, infrastructure, and digital adoption present greater challenges. Public-sector participants were also underrepresented, which may not fully reflect their predominance in Spain [50]. There are no similar published works with which our data can be directly compared. Finally, the absence of a mandatory requirement to respond to all questions may have introduced some data gaps, potentially biasing the results.

Conclusions

The findings of this study highlight a significant level of digitalization in pediatric consultations, with widespread adoption of ICTs among pediatric specialists, particularly in urban settings. In addition, AI knowledge among HCPs seems to be relatively high, with many recognizing its potential benefits in diagnostics and medical training. However, concerns about misinformation as well as the ethical and legal aspects of AI continue to persist.

To enhance health care efficiency, improve patient outcomes and education, and help address existing disparities among professional groups, structured training programs on digital tools and AI, together with guidelines to ensure the reliability of online health information, are warranted.

Acknowledgments

This research was funded by Laboratorios Ordesa SL. The funder had no role in the study design; data collection, analysis, and interpretation; or manuscript preparation. The authors thank all pediatricians who participated in this study, K Access Health Projects for support with statistical analysis, and Meisys for assistance with manuscript editing and editorial support.

Data Availability

The datasets generated and analyzed in this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors made substantial contributions to this study. AS-O and CC-R conceptualized the study and oversaw the project. LO-G and AS-O contributed to the study design. LO-G, AS-O, MP-H, and CC-R oversaw data collection and interpretation. LO-G performed data analysis. LO-G, AS-O, MP-H, and CC-R contributed to manuscript preparation and interpretation. All authors approved the final manuscript.

Conflicts of Interest

AS-O and MP-H are employees of Laboratorios Ordesa SL. All other authors declare no conflicts of interest.

Abstract

Background: Large-scale programs involving nutrition-specific interventions have been carried out in Indonesia as a community-based approach at the primary care level across cities and districts, throughout the age-specific target population (ie, children under 5 years).

Objective: The aim of this paper is to describe the potential use of WhatsApp as a tool for recording and monitoring the growth of children under 5 years by Posyandu (Pos Pelayanan Terpadu or community-based health service post), investigating its potential in enhancing health programs and services.

Methods: Data were collected from Posyandu cadres in Bogor District, West Java, from March to June 2022. The anthropometric measurement data were reported in real time through a WhatsApp chatbot, automatically analyzed by the system, and presented in a structured dashboard. A qualitative assessment was carried out using a cross-sectional survey conducted from March to July 2022.

Results: The study involved 42 Posyandu in 3 villages, engaging 282 staff, and the WhatsApp chatbot recorded anthropometric data for 4571 children under 5 years. The qualitative assessment indicated widespread system utilization, with 50% (45/90) affirming comprehensive data input. Additionally, 66.4% (83/129) found the system easy to use, and 66.7% (82/123) expressed clarity in comprehending variables. Moreover, 75.6% (93/123) found the data input flow easily understood, and 74% (91/123) suggested that the system contributed to enhancing Posyandu activities and the quality of data reporting. Regarding staff proficiency, 63.5% (80/126) affirmed their adeptness in using the system, and 71% (88/124) asserted their high capability in providing training to colleagues.

Conclusions: The potential use of WhatsApp as a surveillance tool for recording children's nutritional status is promising, suggesting broader applications within health programs. Nonetheless, this expansion requires additional improvements, including human resource preparation, Posyandu infrastructure development, and strong regulatory support.

Introduction

Stunting is a condition described as a linear growth failure in which children are too short for their age, and it has been deemed a significant public health issue globally [1-3]. Children with stunted growth are at heightened risk of irreversible loss of growth, suboptimal cognitive development, and elevated risk of morbidities and mortalities in adulthood [3,4]. Suboptimal cognitive development leads to lower cognitive skills, resulting in poor academic performance and lower incomes [4,5]. Although there was a significant decrease in prevalence within the last decade, 148.1 million (22.3%) children under 5 years (CU5) were estimated as having stunted growth in 2022 [1]. According to the Indonesian Nutritional Status Survey (Survei Status Gizi Indonesia) in 2023, the prevalence of children with stunted growth in Indonesia in 2022 was 21.6%, thus similar to the global burden [1,6,7].

To accurately describe a population's nutritional status, particularly the at-risk groups, establishing a nutritional surveillance system becomes pivotal [8]. Such a nutritional surveillance system needs to collect data on nutrition risk factors in a regular and timely manner from various sources, such as growth monitoring in health facilities, nutrition surveys for the population, as well as community-based sentinel monitoring [8-10]. In Indonesia, community-based sentinel sites for growth monitoring for CU5 are conducted through Posyandu (Pos Pelayanan Terpadu; community-based health service post), where the anthropometry measurements are done routinely to help obtain cohort nutritional status information of the children [11,12]. Posyandu serves as a community-based public health outreach initiative, managed and organized in partnership with the community, linking the latter to public health centers (Pusat Kesehatan Masyarakat [Puskesmas]), with the goal of improving access to basic health services, particularly for reducing maternal and child mortality rates [13]. Posyandu itself is integrated into the village social institutions, contributing to enhanced health services for the community [14].

Posyandu undertakes a comprehensive range of health services, consisting of but not limited to maternal and child health care, including immunization services; adolescent reproductive health services; older adult health services; disease control; environmental sanitation; promotion of healthy lifestyles; and diversification of food consumption [11]. These activities are carried out by dedicated and trained community health workers, also referred to as cadres, who are community members voluntarily devoting their time and efforts to organizing Posyandu activities [11]. Indonesia currently possesses a substantial network of more than 213,000 Posyandu, with an estimated 1,039,684 active volunteers nationwide [15]. Trained community health workers play a crucial role in the success of Posyandu and the reduction of malnutrition [16]. In 2021, a presidential decree by the Indonesian government focused on the acceleration of stunting reduction and emphasized the importance of growth and development monitoring services at Posyandu [17].

In general, the reporting process in Posyandu begins with the cadre registering the children and mother in the Posyandu's registration book. It is then followed by the measurement of the height and body weight of the children, which are recorded in the Maternal and Child Health book as well as the Posyandu book [11,12]. After the child and the mother are given health education and other health services as needed, the data are input into an Excel file (Microsoft Corp). The file is then sent to the Puskesmas (public health center), where the workers begin inputting the data into the nutrition surveillance system. This process creates a delay in generating the nutritional status of the children and presents challenges such as difficulty for the cadres to plot the growth chart, possibility of loss of records, and potential inclusion of errors.

Mobile phones and internet usage are increasingly used for health programs, service delivery, and public health messaging [18]. Young adults are very likely to use mobile apps and the internet for health purposes [19]. Furthermore, in low- and middle-income countries (LMICs), mobile phone technologies are promising tools for enhancing primary health care services [20]. In 2021, 125.6% of the total population in Indonesia possessed a mobile phone (ie, there is more than 1 phone per person) [21], while in 2022, 66% of the population had used the internet [22], with the majority of apps used falling within the social and communication spectrum [23]. As of 2023, WhatsApp reached 120.35 million users in Indonesia with an average use time of 29 hours per month, making it the most used app nationally [24]. Aside from being a communication tool, WhatsApp is used for other purposes such as facilitating education (as a supporting tool for e-learning), as well as for health purposes such as for diagnostic and telemedicine support [25-31], though WhatsApp's use as a survey tool remains limited.

Indonesia is considered a digital force in Southeast Asia [32], with highly advanced digital health services integration. With the launch of the Digital Health Transformation Blueprint, the government committed to enhancing public health through the means of digitization [33]. One of these digitization programs involves improving the quality and reach of surveillance of the nutritional status of CU5 conducted by community health workers. To this end, the Digital Transformation Office – Pusat Data dan Informasi (DTO-Pusdatin) team at the Ministry of Health carried out a pilot project using WhatsApp as a data input tool to monitor the growth status of CU5 during Posyandu activities. This paper investigates the potential use of WhatsApp as a tool for recording and monitoring the growth of CU5 in Posyandu and evaluates its application within the national framework of providing an improved national surveillance service.

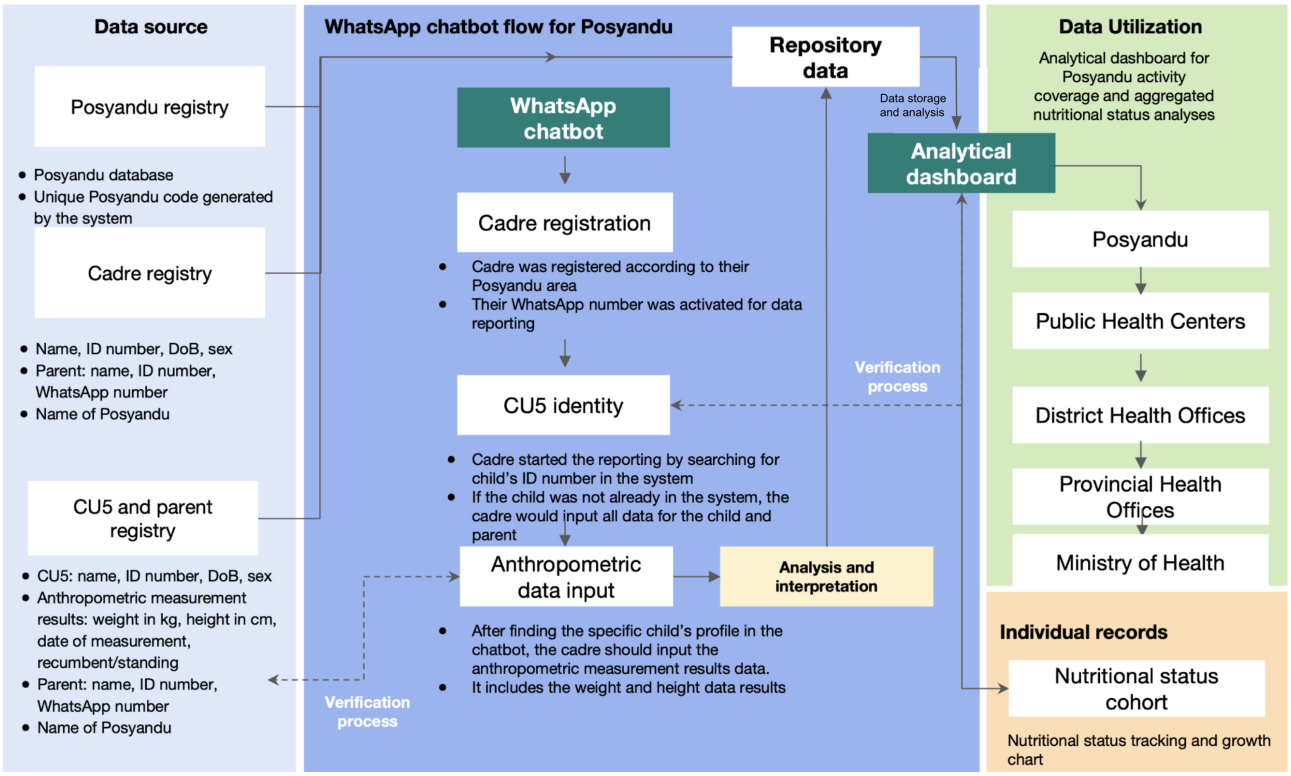
Methods

Using WhatsApp for CU5 Nutrition Surveillance

Overview



There are varying capacities among Posyandu's cadres in Indonesia with respect to technology; not all are acquainted with or adept at using mobile apps or information systems for nutrition surveillance recording and reporting. To address this, a novel approach is required to simplify the process of recording and reporting nutrition surveillance in Posyandu, especially that which is to be done by the cadres. In response to this need, the DTO-Pusdatin Ministry of Health introduced an innovation by creating a WhatsApp chatbot specifically designed for inputting CU5 measurement results by the cadres at Posyandu. A feasibility study to test the reporting system through the WhatsApp chatbot was conducted from March to June 2022 at the Ciderum Puskesmas, located in Bogor District, West Java Province, Indonesia.

The process of recording the nutritional data using the WhatsApp chatbot involved several stages (Figure 1).

Gathering the Basic Data of CU5 and Parents or Caregivers

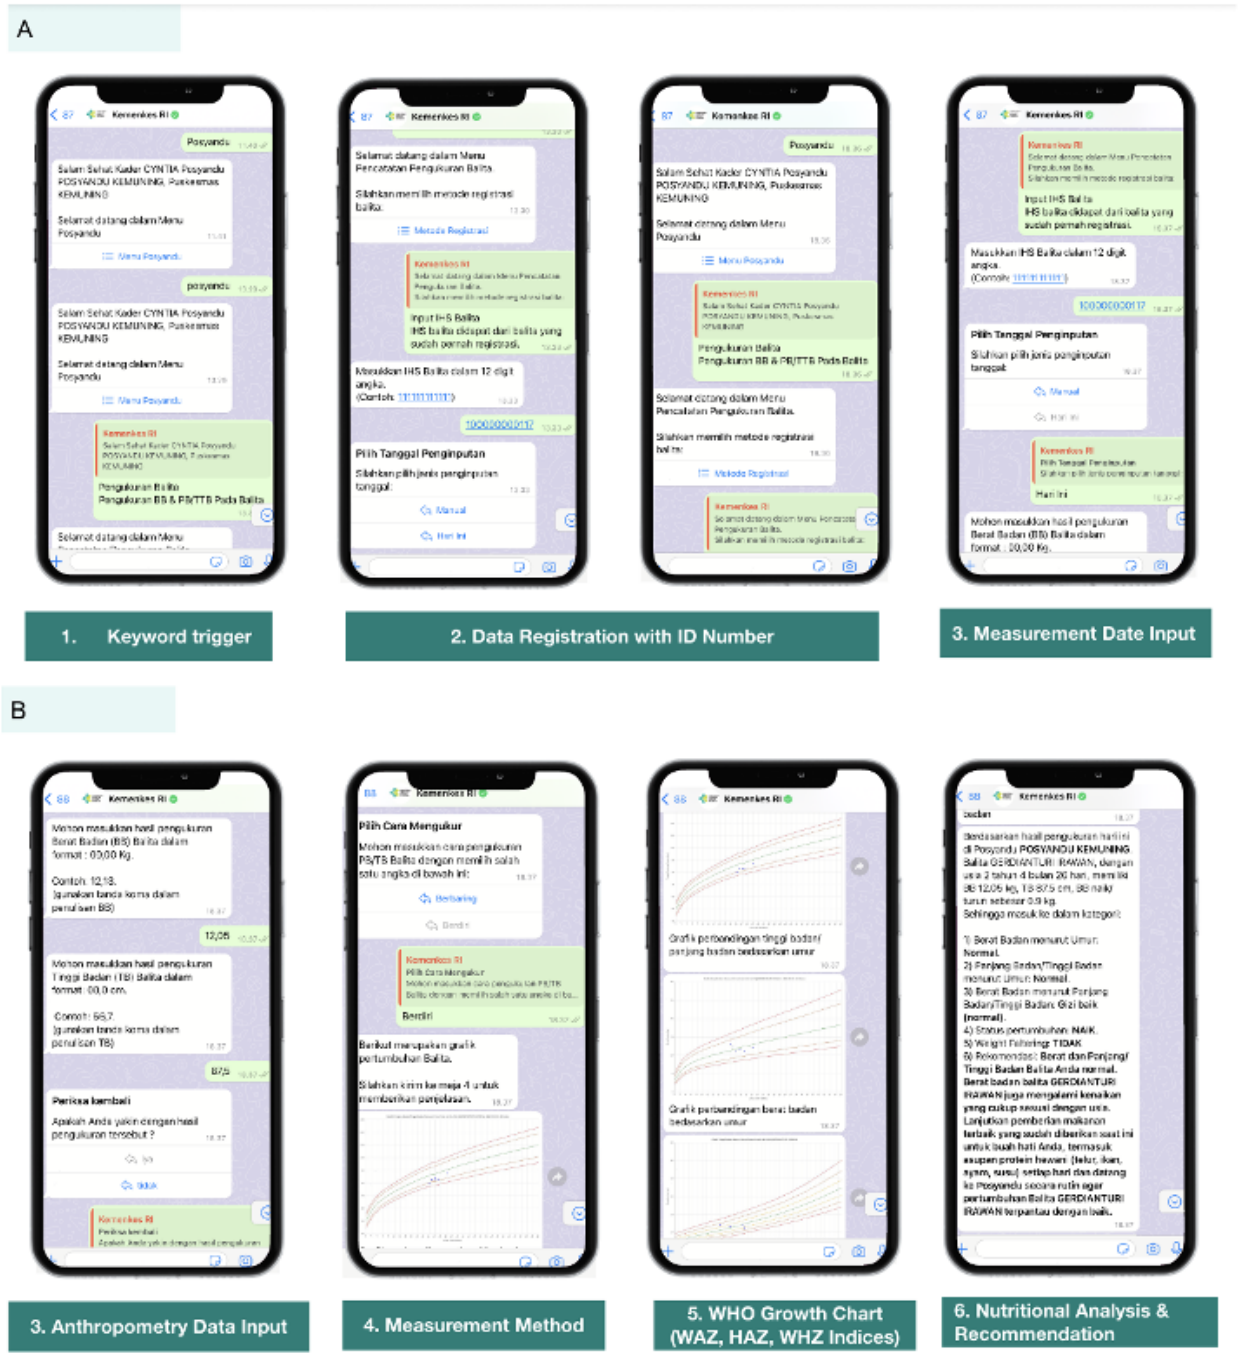
Basic data were gathered about the CU5 and their parents, including the child's full name, national identification number (Nomor Identitas Kependudukan; NIK), date of birth, gender, parent's name and ID number, and lastly the Posyandu ID. For the parent's data, it was only asked that either the father or mother's information was entered; in some cases, this information would be that of a grandmother or another caregiver. This manual dataset was then imported into the system.

Figure 1. Input, process, and output flow of the WhatsApp chatbot system for nutrition surveillance in Posyandu. CU5: children under 5 years; DoB: date of birth.

Cadre Registration

The account registration was done to enable the cadres to record the data in the WhatsApp chatbot. The registration required the cadres' data including their full name, ID number, date of birth, the name of Posyandu they work in, and an active WhatsApp number. This data already existed at Puskesmas, and it was used to validate the input data. The registered cadres' profiles could be monitored through the operational dashboard, which also served as the user management feature for the WhatsApp chatbot. Only DTO-Pusdatin Ministry of Health and Puskesmas Ciderum Teams had the authority to register and edit the cadres' accounts.

Data Input and Validation



After the cadres were registered and their WhatsApp number was activated, the cadres could start to report data by sending "posyandu" as the trigger keyword to activate the data reporting flow of the chatbot (Figure 2). Once the flow started, the variables that should be filled in by the cadres were separated into 3 main sections: child's data, parent/caregiver's data, and measurement data. For each variable, automatic validations were set in order to prevent human error in data recording.

For the first section, the child's name, ID number, date of birth, and sex were required. For the parent's section, their name, their ID number, and an active WhatsApp number were required. Both the child's and parent's ID number were nonmandatory, as some of them may not have had an ID number. Lastly, the measurement section required the date of measurement, weight

XSL•FO
RenderX

result (kg, 2 decimals), height result (cm, 1 decimal), and method of measuring height (recumbent or standing).

Figure 2. The WhatsApp chatbot interface including (A) starting the flow and child identity data input and (B) anthropometry data input, WHO growth chart, and results analysis. HAZ: height-for-age z-score; WAZ: weight-for-age z-score; WHO: World Health Organization; WHZ: weight-for-height z-score.

Individual Nutritional Status Analysis

After the cadres completed inputting the requested data, the chatbot system automatically sent the results of 3 nutritional status indices, which included the weight-for-age z-score (WAZ), height-for-age z-score (HAZ), and weight-for-age height z-score (WHZ) (Textbox 1).

Each recorded CU5 was provided with an evaluation of their nutritional status using 3 nutritional indices, accompanied by a growth chart for each index. These growth charts are similar to the World Health Organization (WHO) growth chart, making it easy for the cadres to quickly determine the child's nutritional status by plotting the growth chart.

XSL•FO
RenderX

Textbox 1. Nutritional indices and the classifications for each index according to the Ministry of Health Decree Number 2/2020 about Children Anthropometry Standard.

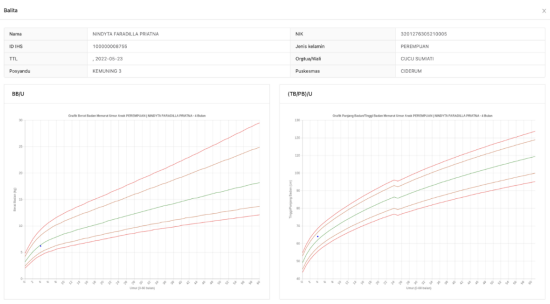
1. Weight-for-age z-score (WAZ)

- Severely underweight (less than –3 SD)
- Underweight (–3 SD to less than –2 SD)
- Normal (–2 SD to +1 SD)
- Risk of overweight (greater than +1 SD)

2. Height-for-age z-score (HAZ)

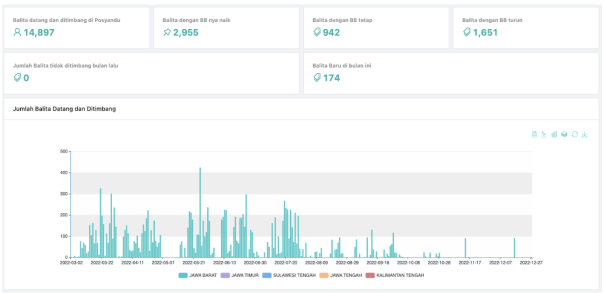
- Severely stunted (less than −3 SD)
- Stunted (–3 SD to less than –2 SD)
- Normal (–2 SD to +3 SD)
- Tall (greater than +3 SD)

3. Weight-for-height z-score (WHZ)



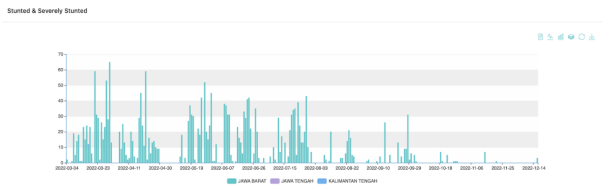
- Severely wasted (less than –3 SD)
- Wasted (3 SD to less than –2 SD)
- Normal (–2 SD to +1 SD)
- Overweight (greater than +2 SD to +3 SD)
- Obese (greater than +3 SD)

Analytics Dashboard

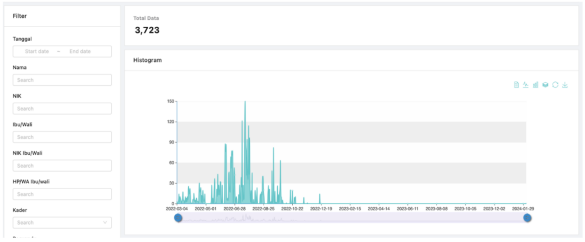


In order to provide nutritional status interpretations, the reporting system offered individual recording outcomes and aggregate analyses through a dashboard (Figure 3). The analysis dashboard was divided into four sections, including (1) cohort of individual measurement results, (2) aggregated measurement analysis, (3) analysis of nutritional problem magnitudes, and (4) malnutrition management feature (Figure 3).

Figure 3. Analytical dashboard features.



(A) Cohort of individual measurement results



(B) Aggregated measurement analysis

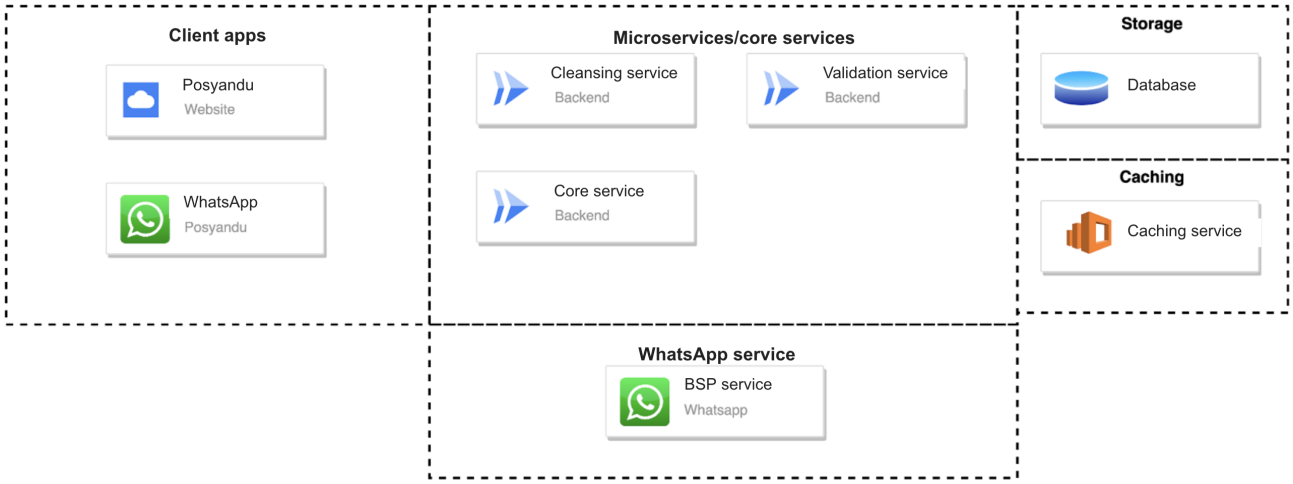
(C) Nutrition problem magnitude analysis

(D) Malnutrition management feature

Excel Download for Cadres

For cadres who completed inputting weighing results at Posyandu, the chatbot flow offered the option to download the recorded data in Excel format. Selecting “YES DOWNLOAD” prompted the system to send an Excel file containing weighing results not only from one cadre but from all cadres who input data for all CU5 attending the same Posyandu within the same

XSL•FO
RenderX



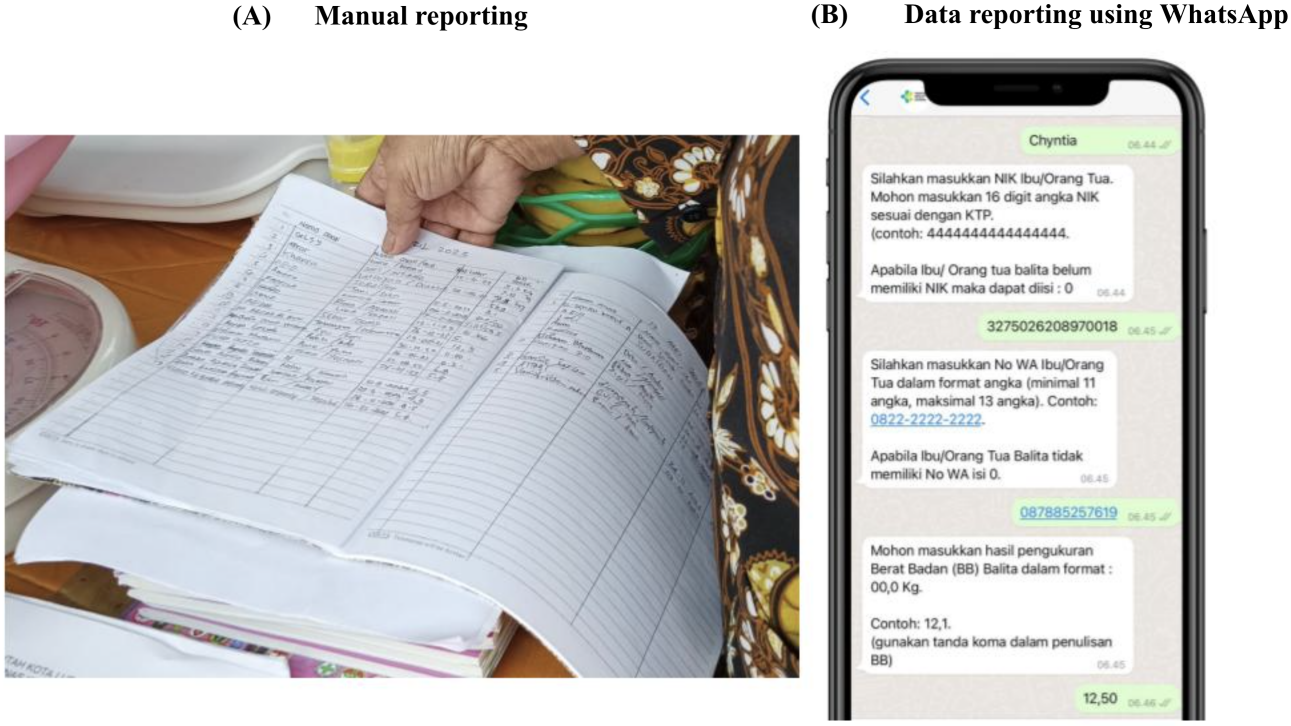
time frame. This excel data served as a simple way to check the number of recorded CU5 in the system, especially for the Puskesmas, which mostly required timely reports of recent Posyandu activity.

System Architecture

Client applications, microservices, and the WhatsApp service, storage, and caching are the 5 components that make up the architecture used for this chatbot development (Figure 4). A website and a WhatsApp client (chatbot) are the components that make up the client apps. For the purpose of facilitating the submission of data from the WhatsApp chatbot, the website functions as a front-facing interface for cadres and system administrators. Additionally, it is able to process and change the master data that is going to be used by the WhatsApp chatbot, such as Posyandu data. The information that is stored in each of these front-facing interfaces is stored in a MySQL database. As a result of the large amount of data that is processed, an additional caching service was designed in order to speed up the look up and processing of data within the database.

The microservices model allows for communication between the storage and the front-facing interface. The front-facing client and the database are connected through a number of microservices, which act as the gateway for the exchange of data between the two. In addition, these services incorporate logics and rules that are in accordance with the standards set forth by the World Health Organization (WHO) in order to process the information that is received from the front-facing interface before saving it in the database. Additionally, WhatsApp possesses its very own microservice, which is responsible for communicating the outcome of the computation and the data from the database to the chatbot before it is displayed to the user.

Figure 4. WhatsApp chatbot system architecture. BSP: business service provider.



Data Analysis

The cadre entered individual data by entering the child's 16-digit NIK or Individual Health Status (IHS) number. The cadre was then asked to enter the child's height and weight measurements, as well as how the measurements were taken (standing or recumbent). After all the data were entered, the system calculated the measurement results to be included in the growth chart (Figure 5): based on body height/length and body weight, based on body height/length and age, and based on body weight and age [34]. After that, recommendations for parents were displayed based on the child's nutritional status. Data collection was carried out from March 1 to June 30, 2022, at 42 Posyandu in 3 villages in the Puskesmas Ciderum work area in Bogor District, namely Ciderum Village, Ciherang Pondok Village, and Pancawati Village.

Before the recording was carried out by cadres, a training session was carried out for one cadre from each Posyandu, with a total of 42 participants, in February 2022. To make it easier for cadres to carry out training for other Posyandu cadres, a booklet and tutorial video were provided. The system trial phase was carried out for 1 month by visiting the Posyandu in each village and an evaluation was carried out at the end of March. In the following 3 months, assistance was provided at 42 Posyandu with 2 evaluation processes through a WhatsApp coordination group with cadres. The Puskesmas officers monitored the input results through the analysis dashboard.

XSL•FO
RenderX

Figure 5. Posyandu reporting before (left) and after (right) using the WhatsApp chatbot.

The results of anthropometric data (weight and height) were automatically processed by the system and presented in a structured dashboard, accessible for Puskesmas, District Health Offices, Provincial Health Offices, and the Ministry of Health at the national level. The data could be queried using a set of predetermined variables. The analyses generated were the frequency and percentage of children being measured based on demographic characteristics (sex, age, domicile address), nutritional status (WAZ, HAZ, WHZ), and spatial analysis on nutritional burden. Trends in service outcome were depicted using time series graphs. The comparative results of Posyandu services at the village level were generated, including analysis by sex and age groups.

Qualitative Assessment

To collect feedback from users, a series of qualitative assessments were carried out on March 31, May 31, and July 4, 2022, using a roundtable discussion method with a total of 48, 41, and 42 participants in the sessions, respectively [35]. This qualitative assessment was done during monitoring evaluation meetings with health cadres who had been trained and joined the pilot program since February 2022.

The participants of the survey were health cadres from 3 villages (Ciderum, Ciherang Pondok, and Pancawati) in Bogor District. The qualitative assessments started 1 month after the pilot project was implemented, and they were repeated at monthly intervals an additional 2 times. The survey used the Mentimeter online platform, enabling participants to answer and show the cumulative, anonymized results directly. The questionnaire consisted of four sections: (1) system usage, (2) data input, (3) overall user feedback, and (4) cadre's ability.

Ethical Considerations

We declare that the data collected for this paper do not require ethical approval as no individual data are presented and informed consent was obtained during the survey implementation. The participants were able to opt out at any point during participation in this study. This exemption is regulated in Indonesia Ministry of Health's National Guidelines and Standards for Ethical Research and Development in Health year 2017, which states that studies are exempt from the ethical review process due to no or minimal potential risk/harm of the studies, and if the information being used was publicly available, including procedures such as surveys or interviews or observations of public behavior. It further specifies that research that is conducted by a department or agency, with the purpose of studying, evaluating, or assessing the benefits of public programs or services, does not require ethics approval [36]. This study ensured that the entire process adhered to ethical principles, including respecting participants' autonomy, promoting their well-being, and avoiding any harm. These principles were upheld by obtaining informed consent, maintaining the confidentiality of participants' information, and minimizing any potential risks. Additionally, no compensation was provided to the participants involved in this study.

Results

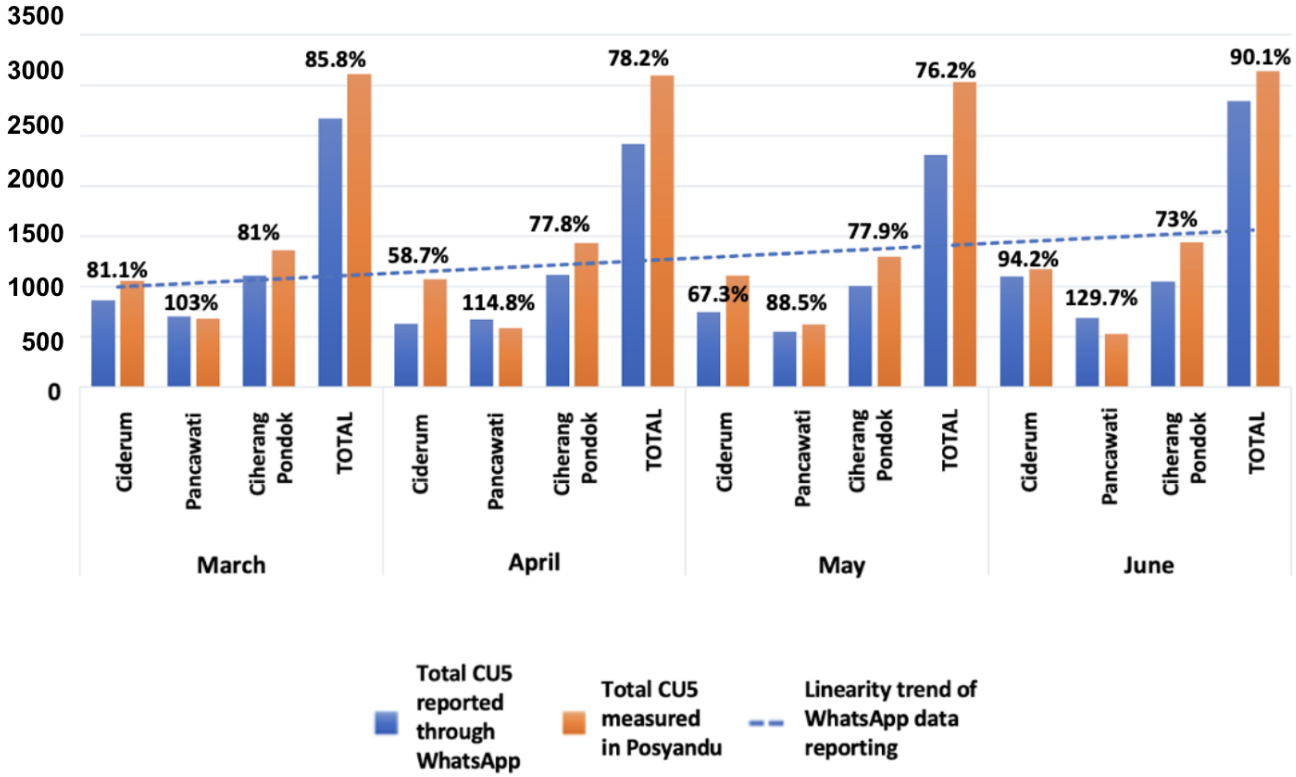
Overview

This study of a WhatsApp chatbot for nutrition surveillance data recording and reporting was done in 3 villages in Bogor District, West Java Province, Indonesia, specifically Ciherang Pondok, Ciderum, and Pancawati. These 3 villages have different characteristics in terms of sociodemographics, facilities, and level of support by local leaders (Table 1).

XSL•FO
RenderX

Table . Characteristics of the 3 study area villages.

Characteristics	Ciherang Pondok	Ciderum	Pancawati	Total
Children under 5 years, n (%)	1642 (36)	1352 (30)	1577 (34)	4571
Number of Posyandu	13	14	15	42
Number of cadres	65	56	60	282
Internet infrastructure	Good	Fair	Poor	N/A
Support from village leader	Very good	Neutral	Neutral	N/A



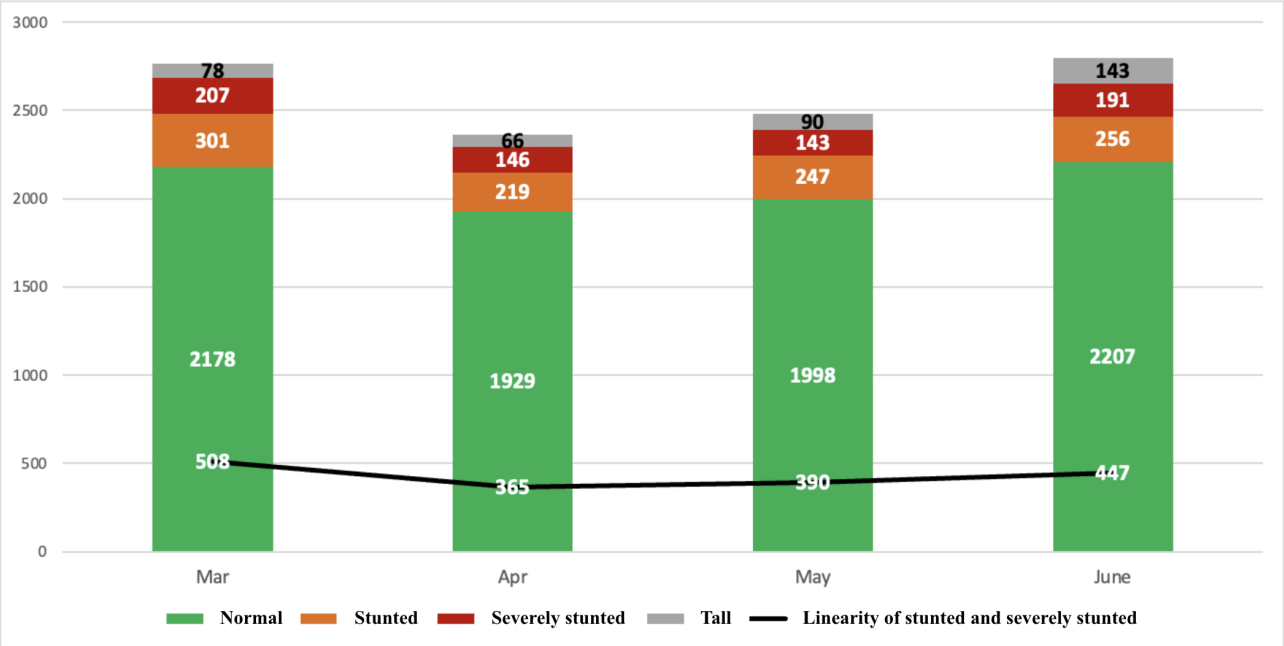
[a]N/A: not applicable.

Results of CU5 Posyandu Weight and Height Measurement Services

During the study, cadres successfully adapted to the new WhatsApp chatbot for reporting CU5 height and weight measurements, transitioning from manual to digital recording. Implementing the WhatsApp chatbot for data reporting presented a novel experience for the cadres.

Generally, it was found that the total number of CU5 measurements input into the chatbot was lower than the total number of children weighed at the Posyandu (Figure 6). The highest proportion of measurements input was in June (n=3144, 90.1%), followed by March (n=3113, 85.8%), April (n=3095, 78.2%), and May (n=3032, 76.2%). In April and May, fewer results were entered due to Ramadan and Eid al-Fitr affecting how well cadres could input data. Toward the study's end, a reminder was sent to cadres by DTO-Pusdatin Ministry of Health and village leaders about data entry.

Figure 6. The comparison of total CU5 being measured and those reported through WhatsApp, and the linearity trend of total WhatsApp data reporting month by month. CU5: children under 5 years.



In terms of each village's performance of inputting data, Pancawati had the highest number, followed by Ciherang Pondok and Ciderum. However, the data show that Pancawati had more children entered into the system than the number of children actually weighed. In March, April, and June, the percentage of CU5 weighed exceeded 100%, possibly because the chatbot recorded CU5 not just from the monthly weighing but also from those weighed outside the Posyandu area. Additionally, some data might have been entered twice, thus increasing the total number of records, but not affecting individual recordings.

Further analysis on HAZ was done, categorizing children into severely stunted, stunted, normal, and tall according to the Ministry of Health Decree Number 2/2020 about Children Anthropometry Standard guidelines (Figure 7). In general, the majority of CU5 had a normal nutritional status based on their HAZ compared to other nutritional statuses. Following the "normal" status, the next highest counts were for "stunted,"

XSL•FO
RenderX

"severely stunted," and "tall" statuses. This sequence of HAZ nutritional statuses remained consistent throughout the 4-month observation period.

Figure 7. Measurement result data analysis based on the height-per-age z-score.

User Feedback on WhatsApp Usage for the Posyandu Reporting System From Cadres

The qualitative exploration of the system usage shows that all participants used the system (129/129, 100%). Regarding the data input, half the users (45/90) self-reported that all data had been input into the system, followed by 25.6% (23/90) reporting that three-quarters of the data had been input into the system, and 24.4% (22/90) reporting that half or less of the data had been input into the system.

Most respondents suggested the system was easy to use (118/125, 94.4%) and only 5.6% of respondents (7/125) stated that the system was difficult to use. Regarding the variable in the system, none of the respondents stated that the variable (data required including child and parent identity and weight and height measurements) was difficult to understand. Two-thirds (82/123, 66.7%) of the respondents stated the variable was easy to understand, and 33.3% (41/123) stated the variable was very easy to understand. None of the respondents stated that the flow of data input was difficult to understand. Most respondents (93/123, 75.6%) suggested that the flow of data input was easy to understand and 24.4% (30/123) of respondents said that the flow of data input was very easy to understand. Related to the impact of the usage of the system, 74% (91/123) of respondents suggested that the system was improving Posyandu activities and data reporting quality, while 26% (32/123) suggested that the system only improved data reporting quality.

The other aspects explored in the assessment were about the cadre's ability to train other cadres about the system. In general, 36.5% (46/126) of respondents stated that they were fairly competent at using the system, and 63.5% (80/126) stated that they were proficient at using the system. Regarding the ability to train the other cadres, 0.8% (1/124) of respondents stated that they were uncertain about their ability to train the other cadres, while 28.2% (35/124) stated that they were capable of training other cadres with preparation. The other 71% (88/124) stated that they were very capable at giving training to the other cadres (Table 2).

Characteristics		Values, n (%)
	Capable with preparation	35 (28.2)
	Very capable	88 (70)

SWOT Analysis

The use of WhatsApp for recording and reporting Posyandu results means that cadres do not need to download new apps, but instead can use a popular existing app. This makes Posyandu recording using WhatsApp easy to use and easy to teach to cadres, thereby speeding up the Posyandu monthly reporting process. This is in line with the evaluation results where, in the first evaluation, cadres still had difficulty inputting Posyandu data; conversely, in the next two evaluations, cadres found it easy to use WhatsApp to report the results of weighing CU5.

Cadres can also input data on toddlers from different Posyandu in the same subdistrict. The Excel data input over the last month remains downloadable and this makes it easier for cadres to report to the village midwife and Puskesmas. Moreover, the digital record helps cadres to plot CU5's nutritional status in a precise manner, allowing them to produce an accurate plot.

Based on the evaluation results, connection problems are the number one challenge in Posyandu reporting using WhatsApp; Table 3 presents a SWOT (strengths, weaknesses, opportunities, threats) analysis. Limited internet connectivity and the absence of an offline input feature prevented cadres from reporting. Additionally, some cadres could not input data in real time, especially for areas with high target data, with a large volume of work related to inputting data in real time. Finally, there are several features that should be considered for future updates, such as a reminder feature for inputting Posyandu results data, or other features that suit the program's reporting needs.

XSL•FO
RenderX

Table . WhatsApp chatbot SWOT[a] analysis.

Category	Strength	Weakness	Opportunity	Threat
Data input process	Cadres can input data for children from different Posyandu within the same subdistrict (Puskesmas).	It depends on the signal; offline data input is not yet possible.	In cases where the number of target children is not high, real-time data input by cadres is feasible.	Slow responses from the chatbot can discourage cadres from inputting a large amount of data.
System utilization	No need to download an app, simply save the chatbot WhatsApp number.	Limitation on providing various features for user through chatbot flow mechanism	Additional features can be introduced based on the reporting program's needs.	If incorrect information—such as birth date, gender, and weighing results—is input, it can lead to inaccurate interpretation of nutritional status.
Sustainability	Easy to be taught to cadres with low digital literacy	N/A[b]	The sustainability of Posyandu nutritional surveillance data reporting depends on cross-sectoral collaborations from related ministries and stakeholders to support the Puskesmas and Posyandu in implementing the Maternal and Child Health program and recording and reporting data while ensuring data quality. Stakeholders include the National Population and Family Planning Board, the Ministry of Public Works, and the Ministry of Villages, Development of Disadvantaged Regions, and Transmigration.	Depending on server capacity, scalability considerations are essential for national implementation.
Data quality	Validation and verification during data input to minimize errors	Regular data monitoring and evaluation are necessary to support data reporting.	After completing data entry, there is an Excel file containing the weighing results for the last month, facilitating reporting to the village midwife and Puskesmas.	Cadres often input child data with different national identification numbers and Individual Health Status numbers, leading to potential data duplication for a single child in the database.
Significance of innovation	Data security is maintained as cadres can only input data and cannot edit it.	N/A	The interpretation of nutritional status provided at the end of each recording helps cadres to plot nutritional status accurately.	The performance of the chatbot is influenced by the specifications of the cadre's mobile phone.

[a]SWOT: strengths, weaknesses, opportunities, threats.

[b]N/A: not applicable.

Both support from local regional leaders to encourage cadres to input data and regular monitoring and evaluation of reporting are necessary to encourage cadres to input measurement data. If the recording is complete, cadres can report individual weighing results that have not been reported yet.

Cadres' ability to carry out anthropometric measurements in the correct way and anthropometric tools that are not available or have not been calibrated were some of the challenges in this trial. Not all cadres have devices with high specifications, which slows down the chatbot's response. This makes cadres unwilling to input large amounts of data. Double data also often occurs because there are discrepancies when inputting the NIK and IHS numbers. If a cadre enters the wrong gender or date of birth, there will be an error in the nutritional interpretation such that the information obtained will be incorrect. In addition, regarding server capacity, it is necessary to consider how such a program could scale up and be implemented nationally.

Discussion

Principal Findings

WhatsApp has been used for various health-related purposes [28-34]. This paper demonstrates the feasibility of WhatsApp as a tool for data input and data recording in childhood health programs in Indonesia, where it can be used for inputting data, real-time monitoring of nutritional status, generating plotted growth charts, and automatically generating reports on the activities and performance of the cadres in Posyandu.

XSL•FO
RenderX

Current WhatsApp utilization includes aiding in the preparation for professional medical licensing examinations and facilitating online-mediated learning [37,38]. It serves as a data collection tool for health questionnaires related to conditions like Williams-Beuren syndrome and acts as a survey tool for patients with COVID-19 and cancer [39,40]. In biomedical and health care settings, it is used to support processes like neurosurgery assessments, to monitor the application of braces for clubfoot, in laboratory management systems, and to facilitate patient-related communication [41-44]. Additionally, it plays a role in health programs, including initiatives for smoking cessation, patient follow-up care, online health information services for the prevention of stunting, and various peer-support interventions [45-48]. Despite its demonstrated versatility in many contexts, there is currently limited utilization of WhatsApp as a data input tool.

During the 4 months of this pilot study, there was a significant narrowing of the gap between the number of CU5 receiving measurements at Posyandu and the number of data points reported by cadres through WhatsApp. Recording Posyandu activities with WhatsApp can be considered user-friendly and practical because the cadres are already familiar with the app, as are large parts of the population [49,50]. The frequent use of WhatsApp has made cadres accustomed to its interface, features, and services, making it easier for them to follow recording and reporting instructions.

Any app featuring a well-designed user interface contributes to user comfort when using the app and WhatsApp has been shown to fulfill the memorability and usability aspect of an app [51]. The architectural design of the WhatsApp client is also crafted to deliver a seamless and user-friendly experience [52,53]. From an economic perspective, WhatsApp provides an easily adoptable alternative solution. The majority of cadres are housewives [54,55]. Although employment status does not affect the motivation of cadre contributions, it can pose a challenge because they tend to have limited resources, such as owning a smartphone with limited internet data for digital recording. WhatsApp is a freely downloadable app, so cadres do not need to incur subscription costs to use it [56,57].

During the final stage of the pilot, 15.9% (n=447) of CU5 were reported as having stunted growth. This number was lower than the 2022 estimated prevalence of children with stunted growth obtained through a national survey in Indonesia, which amounted to 21.6% at the national level and 20.2% for West Java Province [7]. The number was also lower than the prevalence of children with stunted growth in Bogor District, which was reported to have reached 24.9% in 2022 [58]. It is unclear if this discrepancy was due to a more accurate reporting methodology, a lack of recording for the more affected children, or other reasons. However, it demonstrates that, even within a pilot application, the use of this tool provides a representative picture.

However, there are several challenges to its nationwide implementation: access to an internet connection, data validity, system capacity, hardware support, and external support. To activate a conversation with the chatbot, an adequate internet connection needs to be established. Despite the increasing adoption of 4G networks and up to 73% internet penetration, disparities in internet access persist in the eastern part of Indonesia [59].

To mitigate challenges related to internet access, it is crucial to support efforts to expand internet quality across all provinces. Efforts that could reduce this gap in the digital divide include but are not limited to: partnering with local business to provide internet in low-resource settings, engaging with multisectoral stakeholders to develop policy frameworks and funding support for targeted areas, as well as encouraging innovation in technology related to internet access [60,61]. Currently, the Indonesian Ministry of Health is exploring the possibility of cooperation with Starlink (a satellite internet provider) to provide internet access in Puskesmas located in remote, frontier, and outermost areas [62]. Aside from that, continuous collaboration with relevant stakeholders such as the Ministry of Communication and Information Technology is needed.

As an alternative, developing offline features would allow for data entry without an internet connection. A previous study showed that offline features in a mobile app could aid data collection in a decentralized registry [63]. Mobile apps with offline functionality such as Research Electronic Data Capture (REDCap) have also been tested for their usefulness in collecting field survey data in areas with low access to the internet [64]. Additionally, offline functionality could also be used for educational purposes to inform mothers in rural areas about their children's nutrition status [65].

Several studies pointed out the need for attention to the standard operating procedure for anthropometric measurements (especially for body height, which had the highest technical error of measurement), maintenance of instruments, training, and measurement resampling to ensure the accuracy of the data [62,66,67].

To tackle the disparities in anthropometric instruments across the country, the Ministry of Health is striving to equip all Posyandu with anthropometric devices, aiming to distribute 313,737 anthropometric devices to 303,416 Posyandu nationwide by the end of 2024 [68]. Regular calibration must be carried out by an assigned technician to ensure instrument quality; equipment such as infantometers and stadiometers must be calibrated weekly [69]. Another study showed that, to achieve the same accuracy of anthropometric measurement as a medical student, cadres must be trained intensively and receive regular education [70,71]. Capacity building can be carried out as a means to train cadres to conduct anthropometric measurements and digitally report data [72,73].

In order to record individual data, having a NIK number is an integral part of the reporting process. This identification number is able to provide information on location such as province, city/district, and subdistrict, as well as date of birth [74]. Even so, a subpopulation of around 5.3 million people in Indonesia still do not have access to NIK as an identification number [75]. A study by the Ministry of Home Affairs highlights that disadvantaged groups such as individuals living in poverty, indigenous communities, religious or ethnic minorities, remote populations, older individuals, persons with disabilities, refugees, and individuals with nonpermanent housing or high

XSL•FO
RenderX

mobility are those having a hard time accessing and obtaining digital identification [76]. Providing legal identification since birth is an area of focus of the Sustainable Development Goals; therefore, to tackle the gap mentioned above, as well as part of a strategy to participate in providing legal identity for all, civil registration data can be linked and integrated with vital statistics such as birth registration data [77,78].

To prevent data duplication, the government shall implement a central database that connects a unique identifier generated by the Ministry of Home Affairs (NIK), Ministry of Health (IHS number), and Immigration Directorate General (passport number) [79-81]. The system shall implement robust data validation mechanisms that could include automated cross-checking against a central database before final submission. This interoperable check of the central database ensures that an individual's data are recorded through a single, streamlined thread, effectively reducing the risk of duplication and maintaining health data quality [82].

Considering that anthropometric measurement is carried out as a routine activity in Posyandu, it is crucial to ensure that the system is capable of meeting user needs related to inputting data, and that it has the capability to store, file, abstract, and retrieve records seamlessly [83]. Server availability is also one of the crucial components of infrastructure readiness [84]. Another technicality that needs to be considered is the compatibility of the hardware to the software, meaning that to use WhatsApp, potential users need to at least have a device that supports Android OS 5.0 or iOS 12 [85]. Consequently, older devices that were released before 2015 might not be compatible with WhatsApp [85-87].

Taking into consideration that ease of use affects the adoption of apps and/or health systems, developers also need to ensure that the data reporting flow remains simple and the app size is compact [88,89]. Adding features like reminders for data input and providing visual feedback on data consistency could motivate cadres and improve adherence to data entry protocols. Studies have shown that electronic reminders had a great impact on health worker adherence to implementing certain health protocols [90]. Adding monitoring features and feedback loops can also help in identifying cadres who are facing challenges and ensuring targeted support [90].

Aside from the technical support aspect, external support is also pivotal for the implementation of the data input process. Support from the village midwife, Puskesmas, as well as the village leader plays a role in motivating cadres to use the WhatsApp chatbot and input data. It is undeniable that stakeholders such as professional health workers and governmental bodies have a role to play in adequately managing health information systems [91]. Legislative, regulatory, and coordination support are also deemed to be a prerequisite step for optimal and functional health information systems [83]. Having strong cross-sectoral collaborations with relevant ministries and stakeholders, such as the Ministry of Villages, Development of Disadvantaged Regions, and Transmigration; the Ministry of Home Affairs, the National Population and Family Planning Board, and the National Development Planning Agency (Bappenas), will strengthen the broader implementation.

Strengths and Limitations

The strength of this study lies in its pioneering exploration of digitizing Posyandu records through WhatsApp, representing the first-ever development of such a method with substantial potential for diverse data input approaches, particularly in low- and middle-income countries. However, certain limitations must be acknowledged: (1) data input at Posyandu is dependent on internet access, (2) data validation relies on the standards of measurement tools and the capacity of the cadre, and (3) there exists a potential for record duplication due to discrepancies in the input of NIK and IHS numbers by the cadres. Nevertheless, this study provides a nuanced understanding of the potential application of WhatsApp as a tool for monitoring the nutritional status of CU5 in developing countries such as Indonesia.

Conclusions

The utilization of WhatsApp holds promise as a tool for recording surveillance data related to the nutritional status of children. This study provides the first evidence of the implementation of such a tool in community-driven health care settings. In the future, there is potential for expanding the application of WhatsApp to encompass broader data recording functions within health programs. However, such an expansion requires concurrent enhancements in features, involving the preparation of human resources, infrastructure at Posyandu, and robust regulatory support. This entails a comprehensive approach that addresses not only the technological aspects but also considers the human, infrastructural, and regulatory dimensions for the effective integration of WhatsApp into health programs, ensuring its optimal and sustainable use.

Acknowledgments

The authors would like to thank the Digital Transformation Office, Ministry of Health, Republic of Indonesia for supporting the study implementation and developing the WhatsApp (Meta) chatbot. The authors also thank Posyandu Desa Ciherang Pondok, Posyandu Desa Ciderum, Posyandu Desa Pancawati, Ciderum Public Health Centres, and Bogor District Health Office in West Java Province, who participated in the study.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

DNA led the study design and built the paper concept, main structure, and methodology. CAM, AU, FMR, NHA, LR conducted quantitative and qualitative assessment and accessed and analyzed the data. DNA, CAM, AU, FMR, and NHA wrote the first draft of the paper. EAF developed the chatbot infrastructure. MHS and AC provided support in chatbot development. ZK and LM validated the study and critically revised the manuscript content. DNA, CAM, and LR had primary responsibility for the final content. All authors read and contributed to reviewing the study data and manuscript design. All authors provided approval of the final manuscript.

Conflicts of Interest

Although 2 authors are affiliated with Aceso Global Health Consultants Pte Limited, a private company, we declare that this research project did not receive funding from Aceso Global Health Consultants. The company did not have a role in the study design; data collection and analysis; decision to publish; or preparation of the manuscript. LM is the director of the company and DNA is a consultant of the company. However, both of them contributed to this paper on a pro bono basis. Where authors are identified as personnel of the International Agency for Research on Cancer/World Health Organization, the authors alone are responsible for the views expressed in this article and they do not necessarily represent the decisions, policy or views of the International Agency for Research on Cancer/World Health Organization. The other authors declare no conflicts of interest.

Abstract

Background: Childhood obesity remains a significant global public health issue, with consumption of sugar-sweetened beverages (SSBs) recognized in scientific studies as a key contributing factor. While family influences on children's dietary behaviors and their effects on obesity risk are well-documented, the dynamics between parents and children in shaping SSB consumption remain underexplored.

Objective: Drawing on social influence theory, this study examines how parent-child perceptions and consumption intentions regarding SSBs are interrelated and the potential mediating role of attitudes. We also studied how engagement with food-related content on social media may relate to consumption intentions.

Methods: We conducted a face-to-face survey of 250 parent-child dyads (N=500) living in public housing in Singapore, a country tackling overweight in its population. Dichotomous items were used to measure cognitive perceptions and attitudes toward SSBs. Both parent and child participants self-reported their intention to consume SSBs. Based on the World Health Organization (WHO) definition of SSBs, visuals of culturally relevant drink products were used in the survey to visualize SSBs. Dyadic data analysis using the MEDYAD tool was conducted to test the actor-partner interdependence model (APIM) and examine the impact of the parent-child dyadic relationship on individuals' intention to consume sugary drinks.

Results: Pearson correlation results indicated positive associations between parent and child cognitive perceptions and intentions to consume SSBs. Path analysis revealed strong actor effects with both parents' (β=.52, *P*<.001) and children's (β=.43, *P*<.001) own perceptions predicting their attitudes and subsequent intentions to consume SSBs (parent: β=.32, *P*<.001; child: β=.31, *P*<.001). Partner effects also emerged: parental perceptions influenced children's intentions (β=.20, *P*=.01), while children's perceptions shaped parental attitudes (β=.20, *P*=.02), highlighting the reciprocal nature of influence. While digital food media engagement was positively associated with consumption intentions, its effects were relatively modest and not central to the dyadic pathways.

Conclusions: Our study findings highlight the reciprocal effects of both parents and children in influencing healthier behaviors and hence provide insights to aid obesity prevention efforts. By addressing the interdependent associations of parent-child dynamics, this research bridges theory and health communication practice, offering a novel framework for combating obesity through family-centered approaches.

Introduction

Background

The rising prevalence of childhood obesity has become a significant public health issue, with rates among Singapore's school-aged children (aged 6-18 years) increasing from 11% in 2013 to 16% in 2021 [1]. This rapid upward trend is evident even among primary 1 (grade 1) students, the youngest entrants into Singapore's school system, where national data from the Singapore Department of Statistics indicate a steady increase in the proportion of overweight and severely overweight children in this age group—from 9.8% in 2014 to 12.1% in 2022 [2]. As childhood obesity becomes more prevalent, it is no longer solely a pediatric issue, but a pressing public health crisis at the national level.

Among the various dietary contributors, the frequent consumption of sugar-sweetened beverages (SSBs) has been consistently identified as a major risk factor for childhood obesity, with growing scientific evidence linking high sugar intake to adverse weight outcomes in early childhood [3-5]. This concern is similarly echoed in national dietary data showing that Singaporean adults consume an average of 60 grams of sugar daily—exceeding the recommended intake by 10 grams—with more than half of this sugar derived from SSBs [6]. Excessive sugar consumption, particularly through SSBs, has been associated with increased caloric consumption, greater adiposity, and a higher risk of developing noncommunicable and metabolic diseases such as type 2 diabetes, hypertension, and nonalcoholic fatty liver disease [7-9]. With these dietary patterns, unsurprisingly, Singapore has reported one of the highest rates of diabetes among developed countries [10]. The implications are far-reaching—from higher hospitalization rates to reduced work productivity and an increased risk of developing other chronic diseases [11]—and place a burden on public health resources.

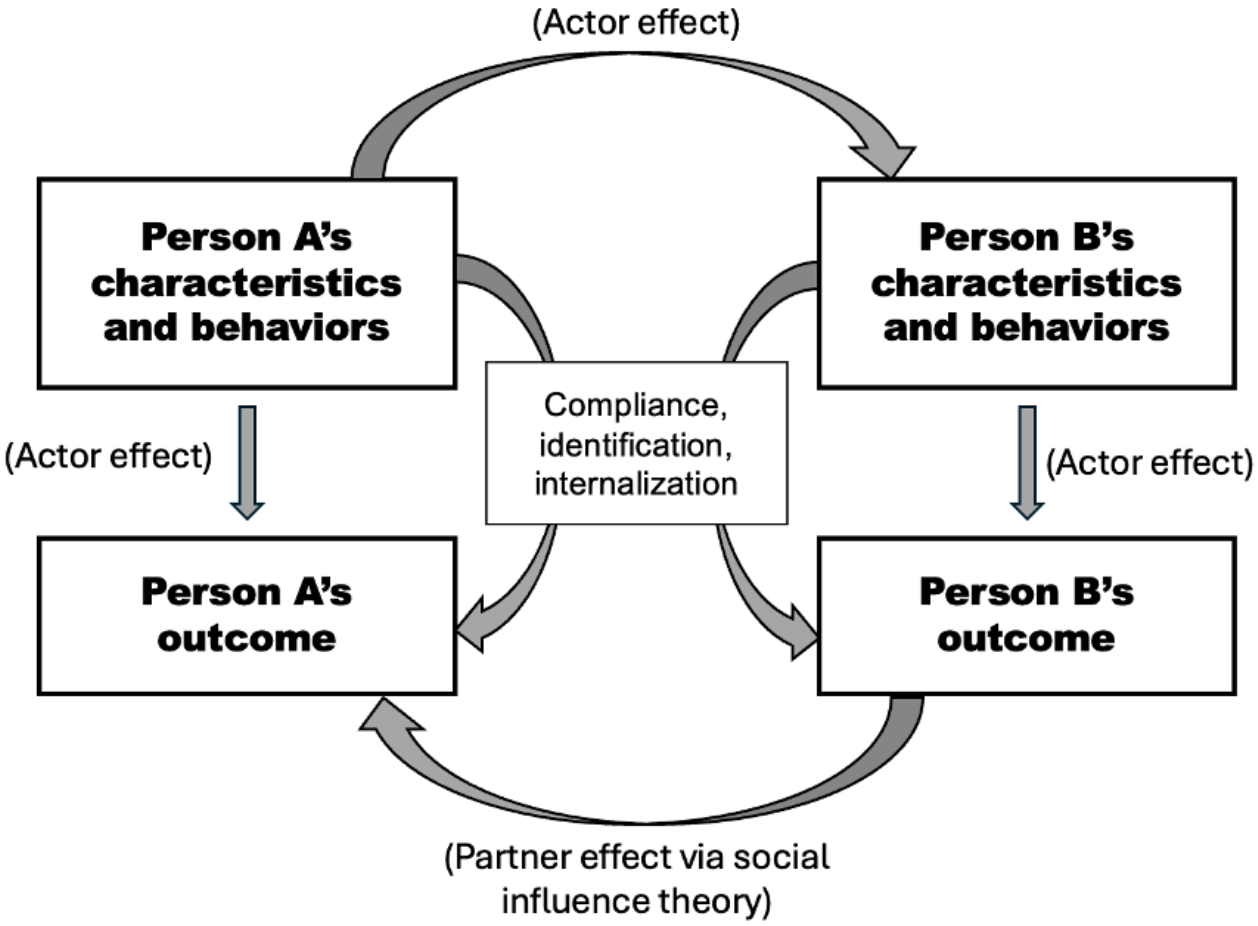
Globally, the intake of SSBs among children and adolescents is also rising, increasing alarmingly by 23% over the past 3 decades [12]; this trend is raising concerns over the impact of SSB consumption on nutritional quality and future health outcomes. Frequent consumption of SSBs during childhood is associated with elevated blood pressure, dental caries, and unhealthy dietary habits, factors that, as discussed earlier, can contribute to the early onset of noncommunicable and metabolic diseases such as obesity and type 2 diabetes. Moreover, these patterns often persist into adulthood [12,13], potentially reinforcing a life-course trajectory of poor health outcomes. In Singapore, the widespread popularity of sugar-laden drinks—such as the highly popular bubble tea (often sweetened with high-fructose corn syrup), carbonated soft drinks, and sweetened fruit juices—coupled with pervasive advertising of SSBs has contributed substantially to the growing burden of childhood obesity [14]. Children and adolescents today are immersed in social media environments saturated with food-related content, often encountered passively through algorithm-driven feeds, influencer promotions, and peer sharing. Evidence suggests that such incidental exposure can subtly shape adolescents' cravings, food preferences, and consumption behaviors over time, including increased inclination toward energy-dense, nutrient-poor products such as SSBs [5,15]. Considering this, reducing SSB consumption through key socializing agents is critical for obesity prevention and health promotion strategies targeted at younger populations.

Children's dietary behaviors are not formed in isolation but rather through complex social interactions embedded within their daily environments. While social influence theory highlights the role of multiple agents (eg, peers, teachers, and the media), the family unit is considered one of the earliest and most influential socializing agents in shaping children's health behaviors [16-20]. Parent-child interactions related to broader dietary norms and health-related behaviors serve as a foundation through which children begin to interpret, model, and internalize parental attitudes, beliefs, and practices about food, nutrition, and health [21]. As primary socialization agents, parents play a critical role, often acting as gatekeepers of the home food environment and influencing children's eating patterns and dietary choices from an early age; in this way, parents provide guidance and set expectations for healthy consumption. As such, parental attitudes and behaviors toward SSBs can directly affect children's consumption patterns.

Previous studies have investigated the links between parental modeling and children's food consumption, as well as between media exposure and dietary intake in parent-child dyads [18,22]. However, most existing research has focused on unidirectional influences from parents to children, with comparatively less attention given to bidirectional or reciprocal effects such as how children's own preferences, attitudes, or media exposure might influence parental perspectives and behaviors surrounding SSB consumption. Moreover, studies that systematically examine the bidirectional dynamics in parent-child dyads specifically in the context of SSB consumption are lacking. In particular, the psychological mechanisms that drive and sustain these dynamics, such as the role of cognitive perceptions and positive attitudes toward SSBs, are still unclear.

Emerging perspectives informed by social influence theory challenge the notion that children are passive recipients of parental influence [23], instead highlighting their active role in shaping and responding to social cues related to food and health behaviors. This includes influencing household norms and practices through reciprocal interactions with their parents. Building on Kelman's foundational work [23], contemporary social influence research has expanded to encompass a broader set of cognitive mechanisms, including normative-informational influence, central-peripheral information processing, and unconscious or automatic pathways [24-26]. These developments underscore the multifaceted nature of social influence, which operates at both conscious and subconscious levels, shaping children's dietary behaviors across diverse interpersonal contexts.

There is a clear gap in knowledge regarding the reciprocal influence between parents and children in understanding parents' and children's dietary behaviors in the current age of digital media. In today's media-saturated environment, children and adolescents' food preferences and consumption habits are increasingly shaped—and often reinforced—by food-related



XSL•FO
RenderX

content on social media. As children mature and become more independent, their opinions and preferences can contribute to household decision-making, including food-related choices such as grocery selections and meal planning. Such exposure not only influences their own individual consumption patterns, but can also indirectly influence parental attitudes, grocery purchasing decisions, and potentially shift household dietary norms. In the Singaporean context, where educational milestones are closely tied with distinct social development stages, children's evolving roles within the family—across primary, secondary, and post-secondary levels—may reflect varying degrees of influence over family dietary behaviors and food-related decision-making, and vice versa.

Objectives

To examine the reciprocal nature of influence within parent-child actor-partner relationships, this research draws upon the actor-partner interdependence model (APIM), situated within the broader theoretical lens of social influence theory. APIM allows us to disentangle the extent to which an individual's perceptions affect their own behavior (*actor effects*), as well as how those perceptions influence the behavior of the other dyad member (*partner effects*). In the context of SSB consumption, this framework enables a more granular understanding of how attitudes, perceptions, and intentions for SSB purchase are shaped by parent-child relationships across different stages of social development. Figure 1 presents a self-developed conceptual framework illustrating potential actor-partner effects in dyadic relationships using APIM [27,28].

Figure 1. Conceptual framework depicting potential actor-partner effects in dyadic relationships using the actor-partner interdependence model.

The overarching aim of this study is to examine how SSB-related attitudes, perceptions, and behavior intentions are associated within parent-child dyads in Singapore, exploring patterns of mutual influence using a cross-sectional dyadic framework. It further examines how the influence of the parent-child dynamic on SSB consumption intent varies across children's developmental stages and social media exposure. This research is thus guided by the following overarching research questions: (1) how do parents' and children's perceptions of SSBs influence each other's attitudes and behavioral intentions, and (2) how do these effects vary across developmental stages and digital media exposure levels.

Hypotheses

To address the research objectives, the following hypotheses were proposed based on social influence theory:

Hypothesis 1

Hypothesis 1 (H1) is related to actor effects via intrapersonal pathways:

XSL•FO
RenderX

- H1a (parent actor effect) is that parents' perceptions of SSBs relate to their behavioral intentions to consume these beverages, with this relationship mediated by their attitudes toward SSBs.
- H1b (child actor effect) is that children's perceptions of SSBs relate to their own behavioral intentions to consume these beverages, with this relationship mediated by their attitudes toward SSBs.

Hypothesis 2

Hypothesis 2 (H2) is related to partner effects via interpersonal pathways:

- H2a (parent-to-child partner effect) is that parents' perceptions of SSBs are expected to predict their children's behavioral intentions to consume these beverages, with this relationship mediated by the children's attitudes toward SSBs.
- H2b (child-to-parent partner effect) is that children's perceptions of SSBs are expected to predict their parents' behavioral intentions to consume these beverages, with this relationship mediated by the parents' attitudes toward SSBs.

Hypothesis 3

Hypothesis 3 (H3) is related to moderators of partner effects:

- H3a (moderation by developmental stage) is that the child-to-parent partner effect is expected to be stronger for older children than younger children.
- H3b (moderation by social media exposure) is that the child-to-parent partner effect is expected to be stronger for children with higher levels of social media exposure.

Methods

Study Design and Population

The cross-sectional, in-person survey was conducted in Singapore, targeting parent-child dyads. Participants were recruited using a multistage cluster sampling procedure based on a compiled list of government primary and secondary schools, stratified by region according to the Singapore Urban Redevelopment Authority's zoning. This approach ensured geographic diversity and representation across urban planning districts in Singapore. The targeted child age range (8-19 years) corresponds to key developmental stages from late childhood through adolescence, during which independent dietary preferences begin to form and parental influence remains critical.

Within each region of the country, schools were randomly selected. The public housing estates feeding the selected schools were then identified, and data collection began from the top floor of the lowest-numbered apartment block adjacent to each school, proceeding door-to-door. From there, participants were recruited through snowball sampling. Eligibility criteria included (1) being a Singaporean citizen or having permanent resident status, (2) parents and children residing in the same household, and (3) children being aged between 8 and 19 years. Each household contributed one parent-child dyad. In families with more than one eligible child in the targeted age range, the participating parent was given the discretion to select one child to take part in the study. While this approach may introduce some selection bias, no additional controls were applied for within-household selection, consistent with protocols in comparable dyadic studies prioritizing feasibility in field-based recruitment.

Both parents and children completed parallel versions of the survey assessing their perceptions, attitudes, and intentions regarding SSB consumption. The survey was administered in person in English. Survey items were designed to be age appropriate, with simple and clear language used throughout to accommodate younger participants. Prior to data collection, the research team conducted internal pilot testing and cognitive walk-throughs to ensure item clarity and relevance. Where necessary, terminology was simplified or rephrased to enhance understanding. For younger participants, researchers were present to guide them through the survey to ensure they could complete it independently, thereby minimizing parental influence on the children's responses.

As part of the survey, both parents and children were shown 4 unbranded images of commonly consumed beverages in Singapore: a glass of cola, bubble tea, a sports drink, and a bottle of orange juice (Multimedia Appendix 1). These images were presented simultaneously at the start of the relevant survey section and served as visual references for participants when responding to questions on cognitive perceptions and attitudes toward SSBs. The images were selected based on the WHO definition of SSBs and adapted for cultural relevance [29].

Ethical Considerations

Informed consent was obtained from both parents and children prior to participation. Participants were informed that they could withdraw from the study at any point during data collection without any consequences, and that doing so would not affect their relationship with the university. The study protocol was approved by the University's Institutional Review Board (IRB-2022-320) and data collection took place between 2023 and 2024. No personal identifiers were collected. Instead, each dyad was assigned a unique identification code used during data analysis to maintain confidentiality. Upon completion of both the parent and child surveys, each household received a $40 supermarket voucher.

Survey Measures

The measurement of parent-child dyads' perceptions and attitudes toward SSBs was adapted from previous validated studies [30-32]. Perceptions toward SSBs were measured using 4 dichotomous items on a 5-point semantic differential scale ("unhealthy" to "healthy," "unsafe" to "safe," "unnatural" to "natural"). One item with low factor loading was excluded from the analysis. Internal consistency for the final 3-item scale was acceptable, with the McDonald ω values exceeding the commonly recommended threshold of 0.70 (ω=0.71 for parents, ω=0.76 for children). In comparable samples of children aged 9-12 years, Lwin et al [31] reported high reliability for a similar 4-item scale assessing views on unhealthy foods, including sugary drinks (Cronbach α=0.93).

Positive attitudes toward SSBs were measured with four 5-point semantic differential items ("not at all happy" to "very happy," "not at all satisfied" to "very satisfied"). Internal consistency

XSL•FO
RenderX

was excellent in the current sample (ω=0.96 for parents; ω=0.94 for children). In another comparable study by Lwin et al [32] involving 210 parent-child dyads (children aged 9-15 years), a similar attitude scale toward healthy food yielded Cronbach α=0.87.

Intention to consume SSBs was measured using a single item, adapted from previously validated instruments [32], asking participants to rate their agreement with the statement "I intend to drink these beverages in the next week" on a 5-point Likert scale from "strongly disagree" to "strongly agree." This item had previously demonstrated predictive validity in studies of adolescent dietary behavior.

In addition, children's exposure to food-related content on social media was measured by their self-reported frequency of seeking such content, using a 5-point Likert scale ranging from "strongly disagree" to "strongly agree."

Demographic data were collected from both parents and children, including age, sex, and ethnicity. Children's school grade levels were used to classify them into three social age groups reflective of the Singapore education system: (1) ages 8-12 years, (2) ages 13-16 years, and (3) ages 17-19 years. This categorization captures key educational transitions in Singapore and was used as a covariate in regression analyses to account for developmental differences in autonomy, social influence, and decision-making relevant to dietary behaviors.

Statistical Analysis

Data analyses were conducted using SPSS Statistics (version 29; IBM Corporation) along with the MEDYAD tool developed by Coutts et al [33]. Descriptive statistics were computed to summarize participant demographics. Pearson correlation coefficients were calculated to explore bivariate associations among key study variables.

To examine the dyadic associations between perceptions, attitudes, and consumption intentions, the APIM was applied using path analysis with 1000 bootstrap samples [33,34]. Standardized regression coefficients (β) were reported for all effects. A 2-tailed significance level of $P<.05$ was used to determine statistical significance.

Results

Sample Characteristics

A total of 250 parent-child dyads participated in the study, totaling 500 respondents (Table 1). The average age of parent participants was 43.7 (SD 5.77) years, with 82% (205/250) being female and 86.8% (217/250) being of Chinese ethnicity. Among child participants, the mean age was 12.1 (SD 3.52) years, with almost equal sex distribution (female: 126/250, 50.4%; male: 124/250, 49.6%). The majority of children were Chinese (219/250, 87.6%), followed by Indian (18/250, 7.2%), Malay (8/250, 3.2%), and other ethnicities (including Burmese, Eurasian, Filipino, and Indonesian; 5/250, 2%).

Children's grade levels, classified by social age groups, showed that 141 of 250 (56.4%) were in primary school (grades 1-6), 77 of 250 (30.8%) were in secondary school (grades 7-10), and 32 of 250 (12.8%) were in post-secondary school (grades 11 and 12).

Table 1. Demographic information of study participants.

Characteristics	Parents (n=250)	Children (n=250)
Age (years), mean (SD)	43.7 (5.77)	12.1 (3.52)
Sex, n (%)		
Female	205 (82)	126 (50.4)
Male	45 (18)	124 (49.6)
Ethnicity, n (%)		
Chinese	217 (86.8)	219 (87.6)
Malay	8 (3.2)	8 (3.2)
Indian	18 (7.2)	18 (7.2)
Other[a]	7 (2.8)	5 (2.0)
Grade, n (%)		
1-6	—[b]	141 (56.4)
7-10	—	77 (30.8)
11-12	—	32 (12.8)

[a]Other ethnicities included Burmese (n=1), Eurasian (n=1), Filipino (n=2), Indonesian (n=2), and Russian (n=1) for parents and Burmese (n=1), Eurasian (n=2), Filipino (n=1), and Indonesian (n=1) for children.

[b]Not applicable.

Correlations Between Variables

Table 2 summarizes Pearson correlation coefficients between key study variables. Notably, parents' cognitive perceptions of SSBs were positively associated with their positive attitudes toward ($r=0.35$, $P<.001$) and intentions to consume ($r=0.21$, $P<.001$) SSBs. A similar pattern was observed among children:

XSL•FO
RenderX

children's perceptions were positively correlated with their attitudes (r=0.36, P<.001) and intentions (r=0.14, P=.03).

Table 2. Correlations between study variables (n=250).

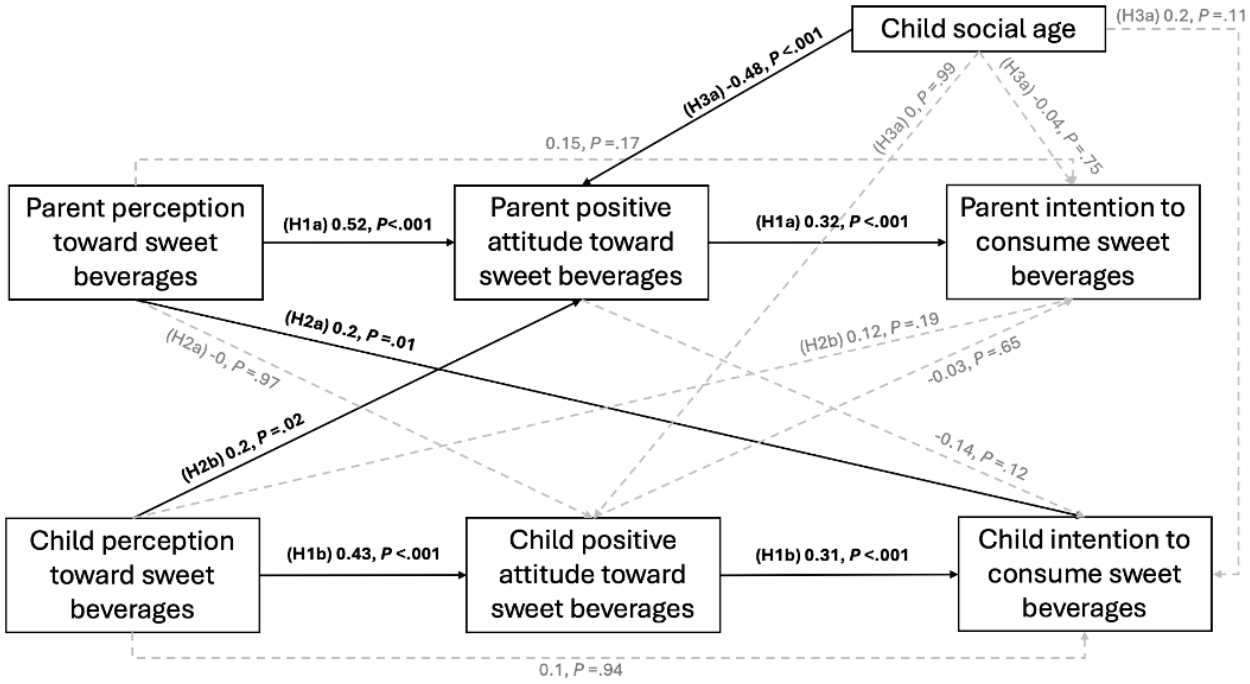
[a]SSBs: sugar-sweetened beverages.

[b]The correlation is significant at the P<.01 level (2-tailed).

[c]The correlation is significant at the P<.05 level (2-tailed).

[d]Not applicable.

Our overarching research objective questioned the links between parents' and children's perceptions of SSBs and their influences on each other's attitudes and behavioral intentions. The data revealed that significant associations between parents and children emerged in their perceptions and behaviors. Parents' and children's perceptions of SSBs were weak but still significantly correlated (r=0.15, P=.02), while their consumption intentions showed moderate correlation (r=0.33, P<.001). Children's social age group showed a positive correlation with their perceptions of SSBs (r=0.15, P=.02), suggesting that older children held more favorable views of these beverages. Interestingly, social age was negatively correlated with parents' positive attitudes toward SSBs (r= –0.26, P<.001), indicating potential shifts in parental attitudes as children mature. Although children's food-related media exposure was positively correlated with both their parents' (r=0.18, P=.004) and their own (r=0.17, P=.008) intentions to consume SSBs, the effect sizes were small. While these findings indicate some individual-level associations, the food media exposure variable was not directly tied to the dyadic framework central to the APIM. To preserve the theoretical integrity and parsimony of the APIM, which is designed to capture reciprocal interpersonal effects within dyads, children's food-related media exposure was excluded from the final model, as its role as an individual-level predictor was not



XSL•FO
RenderX

conceptually aligned with the model's core assumptions. Hence, H3b, which aimed to assess the influence of social media exposure, was excluded from further analysis.

Path Analysis (APIM) and Regression Analysis

To examine H1a (parent actor effect), H1b (child actor effect), H2a (parent-to-child partner effect), and H2b (child-to-parent partner effect), we conducted path analysis of our APIM model. Additional regression analysis was further conducted to the test moderation effects of H3a (moderation by developmental stage). The results are summarized in Figure 2.

Figure 2. Path analysis results using the actor-partner interdependence model. Standardized regression coefficients and P values are reported. H1: hypothesis 1; H2: hypothesis 2; H3: hypothesis 3.

H1 proposed actor effects via intrapersonal pathways for both parents (H1a) and children (H1b). Actor effects demonstrated that both parents' and children's cognitive perceptions strongly predicted their own positive attitudes toward SSBs (parent: β=.52, *P*<.001; child: β=.43, *P*<.001). In turn, these positive attitudes were significantly associated with higher intentions to consume SSBs (parent: β=.32, *P*<.001; child: β=.31, *P*<.001).

H2 proposed partner effects via interpersonal pathways, with H2a predicting a parent-to-child partner effect and H2b predicting a child-to-parent partner effect. Data analysis showed that partner effects further illuminated patterns of mutual associations between parents and children. Specifically, parents' cognitive perceptions significantly predicted their children's intentions to consume SSBs (β=.20, *P*=.01). Notably, children's perceptions also positively influenced their parents' attitudes toward SSBs (β=.20, *P*=.02), highlighting the reciprocal nature of influence within the dyad. Overall, the model supports the hypothesized pathways of H1 and H2, with both actor and partner effects influencing SSB consumption intentions in parent-child dyads.

To further explore how parents' and children's perceptions relate to consumption intentions, we ran multiple regression analyses, as shown in Table 3. Initially, we included both parents' income and education level as covariates to control for socioeconomic status. However, neither variable was statistically significant (income: β=–.008, *P*=.52; education level: β=–.062, *P*=.12), and their inclusion did not meaningfully change the results. Therefore, these covariates were excluded from the final model.

When it came to predicting the intention of parents to consume SSBs, both their own perceptions (β=.214, *P*<.001) and their child's perceptions (β=.127, *P*=.05) were significant predictors. Like findings from the APIM analysis, this suggests that parents who view SSBs in a more positive light, and whose children also hold favorable views, are more likely to intend to consume such beverages. In contrast, when predicting children's intention to consume SSBs, only the child's own perception was a significant predictor (β=.136, *P*=.03), while the parent's perception was not statistically significant (β=.102, *P*=.11).

Discussion

Principal Findings

This study set out to examine the interdependent associations between parents and children in shaping intentions to consume SSBs, drawing on social influence theory and using APIM. Our findings confirmed significant actor and partner effects (H1 and H2), underscoring the reciprocal nature of influence within parent-child dyads. Notably, children's cognitive perceptions of SSBs significantly influenced their parents' attitudes, providing novel insight into the evolving role of children as active contributors to family health behaviors.

While active engagement with food-related content on social media was positively associated with both parent and child SSB consumption intentions, these effects were relatively small and outside the primary scope of our dyadic model (proposed H3b). To preserve the conceptual integrity of the APIM, which is designed to assess reciprocal interpersonal influence, this variable was excluded from the final model. Instead, our focus remained on mutual influences within the parent-child relationship, where actor and partner effects provide a more meaningful framework for understanding shared dietary behavior.

To our knowledge, this is the first study to apply APIM to investigate the reciprocal pathways underlying SSB consumption within parent-child dyads. By simultaneously modeling actor and partner effects, APIM offers a more nuanced understanding of intrapersonal and interpersonal processes than traditional unidirectional models. When integrated with social influence theory, this approach was able to capture both the mechanisms of behavioral persuasion and the dynamic flow of influence between family members. This is especially relevant in contemporary applications of the theory, which now recognizes the roles of normative versus informational influence, central versus peripheral processing, and unconscious social mimicry. These mechanisms are especially salient in family contexts, where both overt communication and subtle social cues co-shape health behaviors.

Our findings reaffirm established evidence that individual cognitive perceptions strongly predict positive attitudes and behavioral intentions (H1a and H1b were supported), consistent with health behavior models such as the theory of planned behavior [22,35-37]. These effects underscore the enduring role of individual beliefs in shaping dietary intentions and reinforce the need to address personal cognition in health promotion efforts.

Importantly, our results extend the current literature by quantifying interpersonal dynamics using data from dyadic sources. While previous studies examined the impact of parental influence on children's dietary choices, they typically relied on unidirectional frameworks, where children are treated as passive recipients of parental modeling [17,38,39]. By contrast, this study demonstrates that children's perceptions can shape parental attitudes, supporting the idea of upward social influence within the family. This finding offers a statistically grounded contribution to an emerging body of work that recognizes children as socializing agents rather than passive recipients of health messaging.

Parents' perceptions were positively associated with their children's intentions to consume SSBs (H2a was supported), a finding consistent with the literature on parental modeling and household food norms [18,40]. More strikingly, children's positive perceptions also influenced parental attitudes (H2b was supported), suggesting a shift in traditional influence patterns. As children develop preferences and exert greater autonomy, particularly for popular drinks like bubble tea or isotonic beverages, parents may recalibrate their attitudes to accommodate their child's views, consciously or otherwise [35,36].

These patterns are especially relevant in the context of Singapore, where children's educational levels correspond with key developmental stages. Our data show that older children tended to hold more favorable views of SSBs, potentially amplifying their influence on household attitudes (H3a was supported). This aligns with social development theory, which posits that adolescents become more persuasive in family decision-making as they gain autonomy [37]. For health promotion and communication practitioners, this suggests that behavior interventions may benefit from tailoring content by age group while recognizing children's emerging role in shaping household consumption norms.

Implications

Our findings contribute to the broader application of social influence theory by empirically demonstrating interdependent associations in family health decision-making. While earlier applications of the theory have predominantly emphasized top-down parental influence (parental modeling), more recent expansions have acknowledged reciprocal and automatic forms of influence. By applying APIM, we capture both actor and

XSL•FO
RenderX

partner effects within the same analytical framework, offering a more complete understanding of shared health behaviors and extending the application of social influence theory beyond individual-level outcomes.

From a practical perspective, these insights carry implications for obesity prevention strategies. Family-centered interventions that engage both parents and children simultaneously may be more effective than those targeting individuals in isolation. This could include school-based nutrition programs, multigenerational health workshops, or community-based campaigns. Specifically, empowering children with nutrition knowledge and fostering critical thinking around beverage choices could generate spillover effects that reshape parental attitudes and, by extension, household norms. Our findings are also potentially relevant for existing public health policies such as Singapore's Nutri-Grade labeling system, introduced in 2022 to inform consumers about sugar and saturated fat levels in beverages [41]. While the Nutri-Grade framework targets individual decision-making at the point of purchase, our results suggest that its impact could be magnified through family-based educational efforts. By incorporating parent-child dialogue into nutrition labeling initiatives, health authorities could promote more meaningful engagement with the system and improve long-term dietary behaviors.

Limitations and Future Research

Some limitations should be considered when interpreting the findings of this study. First, the cross-sectional design limits the ability to draw causal inferences. While the APIM offers a powerful framework for assessing dyadic associations, longer-term observations via longitudinal or experimental designs would allow for a more precise understanding of how the strength and directionality of influence evolve over time, particularly as children mature and gain autonomy and parental control shifts.

Second, the use of self-reported measures may be subject to recall bias or social desirability effects, especially in relation to dietary intentions and perceptions. Future research could benefit from incorporating objective consumption data (eg, food diaries or purchase records) to complement self-reports and enhance measurement accuracy.

Third, although culturally relevant images of SSBs were used to aid recognition, the omission of specific brand names or labels may have influenced participants' perceptions and engagement with the stimuli. Future studies could experimentally manipulate branding or use ecologically valid consumption scenarios to examine how commercial cues interact with attitudes and intentions.

Additionally, while this study focused specifically on SSBs within parent-child dyads, it is important to consider how other types of familial relationships—such as siblings or grandparents—as well as peer networks may shape children's dietary behaviors. These wider social influences warrant further exploration in future dyadic or network-based analyses.

Furthermore, our exclusive focus on SSBs represents only one aspect of children's dietary patterns linked to obesity. Other food categories associated with excess calorie intake and poor nutrition, such as fast food or ultraprocessed snacks, were not examined but may be equally or more salient in shaping health risks. Future research could extend the dyadic framework to examine how parent-child interactions influence consumption of these foods and how such patterns contribute to broader dietary and obesity-related outcomes.

Conclusion

Despite its limitations, this study strongly advances the current understanding of the reciprocal dynamics between parents and children regarding SSB consumption intentions. By identifying both actor and partner effects, the findings underscore children's active role in shaping parental attitudes and contribute valuable insights for designing more holistic, family-centered health communication strategies. As childhood obesity continues to challenge an already-strained global public health system, leveraging reciprocal family influences offers a meaningful and actionable pathway for promoting sustainable behavior change related to beverage consumption.

With this study's findings, we aim to extend existing knowledge on family dynamics in dietary behaviors and present practical insights for health communication strategies targeting both parents and children, particularly within the Singaporean context, with potential for adaptation across other health care systems. By applying the APIM to a health communication context, this study contributes to the broader effort to develop family-centered interventions for obesity prevention, focusing on the interplay of perceptions, attitudes, and intentions that shape beverage consumption decisions.

Looking forward, future research could explore how these parent-child dynamics operate across dietary domains beyond SSBs, such as fast-food consumption or snacking behaviors, which are also known contributors to childhood obesity. Additionally, examining diverse family structures and extending dyadic analyses to peer or sibling relationships could offer deeper insight into the broader social networks that influence children's eating behaviors. As digital media continues to shape youth culture and food choices, future studies could also investigate how digital exposure intersects with family influence over time, particularly through longitudinal designs that capture developmental shifts in autonomy and influence.

Abstract

Background: Congenital heart disease (CHD) constitutes a significant health and economic burden in low- and middle-income countries, including Indonesia. However, its macroeconomic impact across provinces remains poorly quantified.

Objective: This study aims to estimate the economic burden associated with premature death and disability due to CHD in Indonesia, with a focus on regional and gender disparities.

Methods: Using data from the Global Burden of Disease 2019 study, we assessed the value of lost welfare (VLW) attributable to CHD across all 34 Indonesian provinces. Economic valuation was conducted using 3 approaches: the US Department of Transportation model, a method based on the Organisation for Economic Co-operation and Development, and a national wage–based estimate. Analyses were stratified by sex and derived from both disability-adjusted life years (DALYs) and years of life lost. We examined disparities using two approaches: (1) gender disparity was measured as the relative difference in VLW between males and females, and (2) geographical disparity was quantified using both location quotients (for raw VLW) and a disparity index (for VLW-to–gross domestic product ratios).

Results: The national CHD-related VLW derived from DALYs was estimated at US $16.83 billion (US Department of Transportation), US $11.41 billion (Organisation for Economic Co-operation and Development), and US $9.03 billion (wage-based). West Java recorded the highest provincial VLW (US $1.60 billion), followed by East Java (US $0.83 billion), North Sumatra (US $0.80 billion), and Central Java (US $0.79 billion), indicating a concentration of burden in populous provinces. In contrast, Yogyakarta (US $0.04 billion), North Kalimantan (US $0.04 billion), and West Papua (US $0.06 billion) had the lowest estimates. In several provinces, male-attributed VLW was more than 150% higher than female VLW, with extreme gaps observed in Riau Islands (281.25%), Aceh (166.10%), and Banten (145.86%). These patterns were consistent across both DALY- and years-of-life-lost-based estimates. Based on the location quotients, provinces such as Papua (2.42), West Sulawesi (2.37), Maluku (1.78), East Nusa Tenggara (1.75), and Central Sulawesi (1.66) bore VLW burdens far greater than their population share. The

XSL•FO
RenderX

burden was disproportionately high in several eastern provinces, including East Nusa Tenggara (3.35%), Maluku (2.61%), and West Sulawesi (2.66%).

Conclusions: CHD is a macroeconomically manageable burden across most of Indonesia. However, the presence of deep gender disparities and geographically concentrated burdens in eastern and underserved provinces calls for targeted pediatric cardiac health investments.

burden of disease; economic burden; health economics; health equity; pediatric cardiology

Introduction

Despite a 56.2% global reduction in mortality, congenital heart disease (CHD) continues to cause more than 200,000 childhood deaths annually, remaining one of the leading contributors to mortality among children younger than 5 years worldwide [1]. This global progress, however, has not been equitably realized across all nations. In Indonesia, CHD-associated disability-adjusted life years (DALYs) rose from 96.3 (72.4-126.8) per 100,000 population in 2019 to 113.2 (86.6-143.7) in 2021, indicating a concerning reversal of global trends [2].

Clinical data from a national registry of 1012 pediatric patients identified secundum atrial septal defect as the predominant diagnosis, accounting for more than 70% of cases, with over three-quarters already exhibiting signs of pulmonary hypertension at the time of diagnosis [3]. The consequences of CHD extend beyond cardiovascular morbidity, encompassing significant impairments in growth and development. Previous studies have shown that children with CHD frequently present with underweight, stunting, and wasting [4]. Independent risk factors for undernutrition include cyanotic CHD, delayed diagnosis, congestive heart failure, and pulmonary hypertension [4]. In a separate cohort, nearly half of the children were aged 0-2 years, with 18.5% demonstrating developmental delays; cyanotic CHD was significantly associated with poor nutritional status [5].

Despite well-documented clinical, developmental, and survival implications, the long-term economic burden of CHD—particularly the loss of productivity due to premature mortality and disability—remains underexamined in Indonesia's national health planning. Valuing lost life years provides a critical framework to translate disease burden into economic terms. Previous research has demonstrated the applicability of value of lost welfare (VLW) approaches to quantify the economic impact of mortality shifts in low- and middle-income countries (LMICs), reinforcing its utility in appraising health sector investments [6].

The VLW, derived from the broader concept of the value of a statistical life (VSL), provides a standardized monetary valuation for years lost to premature death or morbidity. When applied to DALYs and years of life lost (YLLs), VLW enables the conversion of epidemiological estimates into economic burden, thereby enhancing the evidence base for strategic resource allocation and policy prioritization. The increasing use of disease burden estimates in shaping national policy, such as in the European Union's legislative decisions, underscores their practical influence [7].

Several methodologies for estimating the VSL exist, each carrying distinct policy implications. The US Department of Transportation (US DOT) model reflects valuations typical of high-income settings [8], the Organisation for Economic Co-operation and Development (OECD)–based model offers a global median, and wage-based models generate context-specific estimates more aligned with national economic realities [9]. In Indonesia, where regional disparities in income and health care access remain pronounced, disaggregating VLW by province and valuation model allows for a more nuanced understanding of both absolute and relative economic burden [10,11]. For macroeconomic assessments, Global Burden of Disease (GBD) estimates can capture regional inequalities, as reported previously in studies quantifying disparities in population health [12,13]. Previous studies have used GBD estimates to capture the trend in various causes of death in global, regional, and even national contexts [12-16]. Accordingly, this study sought to quantify the economic burden of CHD in Indonesia by estimating VLW and VLW-to–gross domestic product (GDP) per capita ratios across provinces using GBD 2019 data and 3 established VSL frameworks.

Methods

Ethical Considerations

This study used publicly available, deidentified data from the Global Burden of Disease 2019 study. As all data were anonymized and aggregated, no additional ethical approval was required. The data were used in accordance with the Global Burden of Disease data use policy.

Study Design

This study quantified the economic burden associated with congenital heart anomalies (CHAs) in Indonesia by monetizing health losses using the VLW framework. We drew upon the GBD 2021 dataset, which provides comprehensive and methodologically harmonized estimates of disease burden across countries and regions. Two principal health metrics were used: DALYs—a composite of years lived with disability (YLDs) and YLLs due to premature mortality—and YLLs alone, to isolate mortality-specific economic losses. VLW was estimated by applying 3 established benchmarks of the VSL. Analyses were conducted at both national and provincial levels, stratified by sex, to examine geographic and demographic variation in the health-related economic burden.

XSL•FO
RenderX

Data Sources

Burden estimates were extracted from GBD 2021, focusing specifically on the CHAs subcategory. YLDs were calculated by multiplying condition-specific prevalence by disability weights reflective of the severity of health loss. YLLs were estimated from mortality counts and the GBD standard life expectancy for each age group. DisMod-MR 2.1, a Bayesian meta-regression framework, was used to ensure epidemiological consistency across parameters. Additionally, Spatiotemporal Gaussian Process Regression was used to account for spatial and temporal heterogeneity in disease patterns. All estimates were disaggregated by gender and province. In provinces with limited empirical data, estimates were refined using covariate adjustments and comparisons with analogous regions. Full methodological specifications are available in the GBD technical documentation [17,18]. To contextualize the economic burden, 2021 provincial GDP per capita data were sourced from Badan Pusat Statistik (BPS, Indonesian Statistic Agency). Reported values in Indonesian Rupiah (IDR) were converted to US$ using the average 2021 exchange rate (IDR 14,308=US $1) and expressed in trillions to match the national economic scale. DALYs and YLLs of CHD and GDP per capita across Indonesian provinces are available in Multimedia Appendix 1.

VSL Benchmarks and Economic Valuation

To monetarily quantify the societal burden associated with premature mortality from CHAs, we applied 3 benchmark estimates of the VSL. The primary benchmark was a nationally derived, wage-based VSL specific to Indonesia, estimated at US $950,000. This estimate reflects labor market trade-offs between income and occupational fatality risk, as captured through a hedonic wage model [19]. The model used data from the 2019 Survei Angkatan Kerja Nasional National (Labor Force Survey) conducted by BPS, alongside occupation-specific fatality rates provided by the Badan Penyelenggara Jaminan Sosial Kesehatan Ketenagakerjaan (Social Security Administrator for Labor) [20,21].

Multivariable linear regression was used to estimate wage differentials associated with varying levels of occupational risk, adjusting for confounding factors including industry classification, educational attainment, and demographic characteristics. To address potential selection bias—where individuals may self-select into higher-risk or better-compensated occupations—a Heckman [22] 2-stage correction model was applied. The choice of 2019 as the base year was intentional, ensuring that VSL estimates reflect stable labor market conditions before disruptions caused by the COVID-19 pandemic.

Two additional benchmarks were adapted from international reference values originating in high-income countries: one from the OECD and another from the US DOT. Both were recalibrated to the Indonesian context using the income transfer method, which adjusts VSL values according to relative national income levels. This ensures that the transferred VSLs remain consistent with Indonesia's economic reality. Specifically, the recalibrated values were derived using the standard benefit transfer formula (equation 1):

(1)

In this equation $VSL_{Indonesia}$ denotes the income-adjusted value of a statistical life for Indonesia; $VSL_{Reference}$ corresponds to the original benchmark value from either the OECD or the US DOT; $GDP_{Indonesia}$ and $GDP_{Reference}$ represent per capita GDP values (in purchasing power parity terms) for Indonesia and the reference country, respectively; and ε (elasticity coefficient) indicates the income elasticity of VSL. Following established methodological practice for LMIC settings, we assumed an ε of 1.0, consistent with World Bank and OECD recommendations for cross-national health valuation exercises.

Using 2021 GDP per capita data, the income-adjusted VSL estimates for Indonesia were calculated as US $1.2 million (based on the OECD benchmark) and US $1.77 million (from the US DOT benchmark). These adjusted values reflect economic conditions specific to Indonesia while preserving the relative scale of the original reference values. Each of the 3 benchmark VSLs—including the nationally derived, wage-based VSL—was subsequently transformed into a VLW by dividing the respective VSL by the standard age-specific life expectancy at death, enabling alignment with GBD metrics. These VLWs were applied to DALY- and YLL-derived estimates of CHAs to produce monetized estimates of VLW, stratified by province and sex. This dual disaggregation enabled a granular evaluation of the economic burden and its association with geographic and demographic disparities.

Monetization of DALYs and YLLs Through VLW

To quantify the economic burden associated with CHAs in Indonesia, we used a monetization approach anchored in the concept of the VLW, applying it to both DALYs and YLLs in absolute counts. To convert DALY and YLL rates into absolute counts, we multiplied them by the population estimated by the GBD (Multimedia Appendix 1). This approach leverages DALYs and YLLs as proxies for health-adjusted life years lost, facilitating economic valuation based on the VSL framework [23,24]. Following established methodological conventions [24,25], we used the inherent age stratification provided by the GBD study to retain age-specific granularity in estimating disease burden. For each province (*i*), sex (*s*), and valuation model (*m*), we derived VLW estimates by multiplying age-disaggregated DALYs or YLLs with a standardized value of a statistical life year (VSLY), which was computed by dividing VSL by life expectancy at age of death. We used separate life expectancy estimates for males and females, allowing sex-specific adjustment of VSLY in accordance with the demographic profile of each death. According to BPS, the average life expectancy in 2021 was 73.5 years for the total population, with sex-specific values of 60.67 years for males and 73.55 years for females. Three VSLY estimates were applied, corresponding to the VSL benchmarks sourced from the US DOT, the OECD, and the nationally derived wage-based estimate. The economic valuation formula is expressed as follows (equations 2 and 3):

XSL•FO
RenderX

(2)

or,

(3)

Where α denotes the age group; $DALY_{i,s,\alpha}$ or $YLL_{i,s,\alpha}$ represent the disease burden (ie, DALYs or YLLs) in age group α for province *i* and sex *s* and $VSLY_m$ corresponds to the life-year valuation under model (USDOT, OECD, or wage-based). Finally, to contextualize these figures within local economic capacity, we calculated the VLW-to-GDP ratio for each province, defined as follows (equation 4):

(4)

Disparity Estimation

We estimated gender and geographic disparities in the economic impact of CHD across Indonesia. Gender disparity was quantified using the male–female relative difference in VLW, expressed as a percentage (equation 5). This gender disparity metric reflects the proportional excess burden among males relative to females. Geographic disparity was assessed using 2 measures. First, we calculated the location quotient (LQ), defined as the ratio of a province's share of national VLW to its share of the national population (equation 6). This metric is suitable for raw VLW data because both the numerator and denominator represent shares of national totals, allowing a valid comparison of economic burden relative to population size. An LQ greater than 1 indicates that a province bears a disproportionate share of VLW relative to its population. Second, we computed a disparity index by dividing the provincial VLW-to-GDP ratio by the national average. This approach is more appropriate for ratio-based metrics such as VLW-to-GDP, as using an LQ on these values can lead to inflated results due to the low national reference value. The disparity index quantifies how much greater (or lesser) the economic burden is in a province relative to the national benchmark, offering a stable basis for interprovincial comparisons.

(5)

(6)

(7)

Data Processing and Visualization

All calculations and data integration were performed using Python 3.11, with the Pandas library used for structured data manipulation, including the aggregation and merging of health burden estimates (from GBD 2021) and provincial economic indicators. Final estimates of VLW were expressed in billion US$, computed under both DALY- and YLL-based paradigms, and stratified by sex (male, female, and combined) to reflect sex-specific differentials in health-related economic loss. To classify provinces by levels of disparity, we applied k-means clustering on both gender and geographic disparity indices, allowing unsupervised grouping into quartile-based clusters. To visually convey the geographic heterogeneity of the burden, we used Tableau Desktop 2024.1 (Tableau Software, LLC) to develop spatially resolved choropleth maps, highlighting provincial-level VLW and VLW-to-GDP ratios. This visual framework enabled the identification of regions exhibiting disproportionately high economic losses relative to their GDP, facilitating targeted policy interpretation and public health planning.

Results

Economic Burden Based on DALY-Derived Estimates

The DALY-based VLW estimates for CHD in Indonesia are presented in Table 1. At the national level, the total VLW burden reaches US $16.825 billion using the US DOT benchmark, US $11.407 billion using the OECD benchmark, and US $9.03 billion using the national wage benchmark. Based on the national wage–based estimates, West Java reported the highest provincial VLW at US $1.599 billion, followed by East Java (US $0.831 billion), North Sumatra (US $0.797 billion), and Central Java (US $0.793 billion). Together, these 4 provinces accounted for over 44% of the national burden. Other notable contributors include Banten (US $0.475 billion), Papua (US $0.381 billion), and South Sumatra (US $0.363 billion). In contrast, provinces such as North Kalimantan (US $0.036 billion), Yogyakarta (US $0.042 billion), and West Papua (US $0.055 billion) reported the lowest VLW.

Economic Burden Based on YLL-Derived Estimates

Indonesia's overall estimated VLW reaches US $16.13 billion using the US DOT benchmark, US $10.936 billion under the OECD benchmark, and US $8.658 billion based on the national wage model (Table 2). To reflect local relevance, the national wage benchmark is prioritized in the following interpretation. The highest provincial VLW was observed in West Java (US $1.533 billion), followed by East Java (US $0.777 billion), North Sumatra (US $0.776 billion), and Central Java (US $0.742

XSL•FO
RenderX

billion). Collectively, these 4 provinces contributed more than 40% of the national burden. Other significant contributors include Banten (US $0.459 billion), South Sumatra (US $0.351 billion), and Papua (US $0.374 billion). In contrast, provinces such as North Kalimantan (US $0.035 billion), Yogyakarta (US $0.037 billion), and West Papua (US $0.054 billion) reported the lowest VLW estimates (Table 2).

Table 2. Economic burden of congenital heart disease in Indonesia estimated from years of life lost (YLL), using the United States Department of Transportation (US DOT), Organisation for Economic Co-operation and Development (OECD), and wage-based models (value of lost welfare [VLW] in billion US$).

In most provinces, the DALY-based values exceeded YLL-based values by less than 5%. For instance, the gaps were 2% in Papua, Maluku, North Maluku, Southeast Sulawesi, and West Sulawesi; 3% in Central Sulawesi, Central Kalimantan, East Nusa Tenggara, North Kalimantan, South Kalimantan, and West Nusa Tenggara; and 4% in Aceh, Bengkulu, Lampung, South Sulawesi, and West Java. Only a few provinces demonstrated higher differences, such as Bali (6%), Central Java (6%), East Java (6%), Jakarta (7%), and Yogyakarta, which had the largest gap at 12%. Nationally, the average DALY–YLL gap was approximately 4%.

Productivity Loss Based on DALYs

The estimated CHD-related economic burden in Indonesia stands at 1.35% of GDP using the US DOT benchmark, 0.91% under the OECD benchmark, and 0.72% using the national wage benchmark (Table 3). Provincial-level insights using the national wage benchmark reveal that East Nusa Tenggara (3.08%), West Sulawesi (2.47%), Maluku (2.40%), and Gorontalo (1.93%) bear the highest CHD-related economic burden relative to their regional GDP. In contrast, Jakarta (0.07%), East Kalimantan (0.13%), Riau (0.22%), and Riau Islands (0.23%) report the lowest VLW-to-GDP ratios. Other populous provinces such as West Java (0.76%), Central Java (0.58%), and East Java (0.35%) fall at or below the national average.

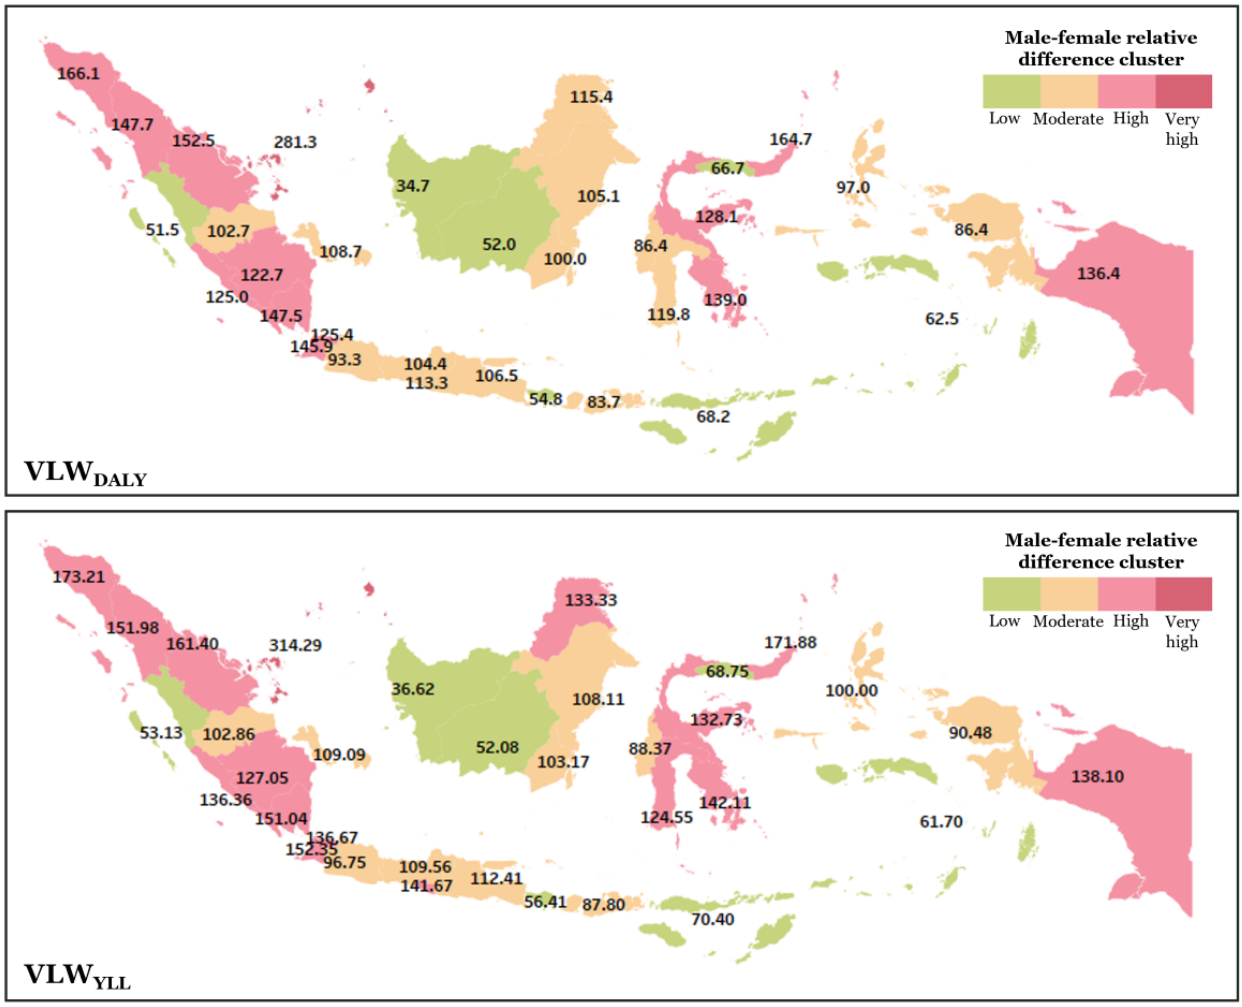
[a]VLW_{DALY}: value of lost welfare–disability-adjusted life years.

[b]VLW_{YLL}: value of lost welfare–years of life lost.

Productivity Loss Based on YLLs



Corresponding estimates based on YLL are detailed in Table 3. Nationally, CHD-related productivity loss accounts for 1.35% of GDP using the US DOT benchmark, 0.91% with the OECD benchmark, and 0.72% under the national wage model. According to the national wage benchmark, East Nusa Tenggara records the highest VLW-to-GDP ratio at 3.64% (males=5.16% and females=3.03%), followed by West Sulawesi (2.92%), Maluku (2.84%), Gorontalo (2.28%), and West Nusa Tenggara (1.93%). In contrast, Jakarta (0.08%), East Kalimantan (0.16%), Riau (0.26%), and Riau Islands (0.27%) exhibit much lower VLW-to-GDP ratios. As populous provinces, West Java (0.90%), Central Java (0.67%), and East Java (0.40%) fall at or below the national average.

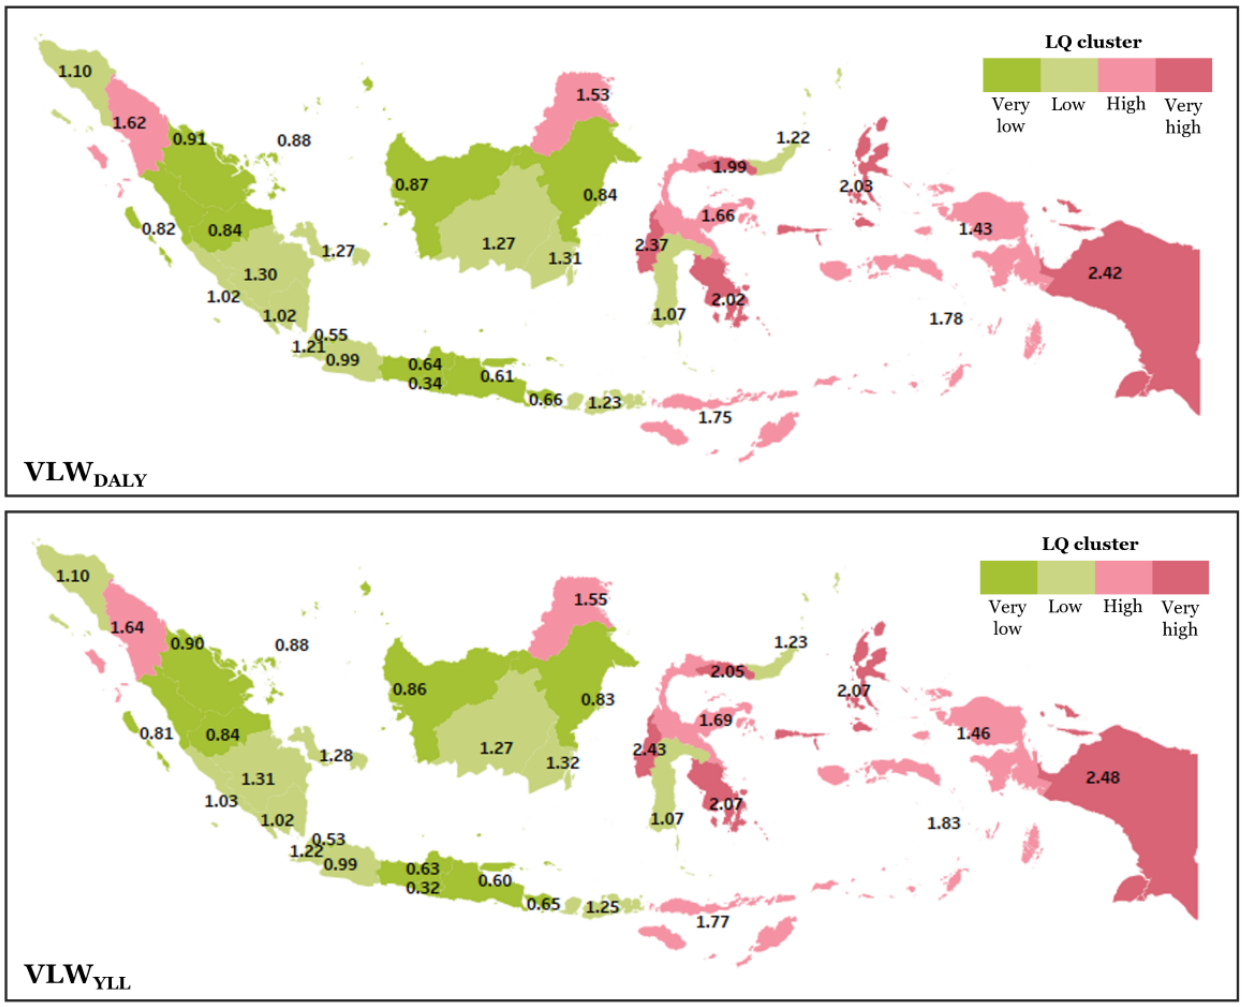
XSL•FO
RenderX

Gender Disparity

High gender disparities across Indonesian provinces, revealed by the male–female relative difference, are presented in Figure 1 and Multimedia Appendix 2. Based on the gender disparity in VLW_{DALY} (value of lost welfare–disability-adjusted life years), provinces such as Riau Islands (281.25%) stand out in the very high disparity category. A significant number of provinces fall into the high disparity cluster, including Aceh (166.10%), Banten (145.86%), Lampung (147.52%), North Sumatra (147.71%), and Papua (136.43%), reflecting consistently male-dominated VLW in both western and eastern regions. The moderate disparity group encompasses provinces such as Central Java (104.41%), East Java (106.51%), South Kalimantan (100%), and Yogyakarta (113.33%). Meanwhile, the low disparity cluster, with relative differences below 70%, includes Bali (54.76%), Central Kalimantan (52.00%), West Kalimantan (34.67%), Maluku (62.50%), and East Nusa Tenggara (68.22%).

Figure 1. Male-female relative difference showing gender disparities across Indonesia, estimated from VLW_{DALY} (value of lost welfare–disability-adjusted life years) and VLW_{YLL} (value of lost welfare–years of life lost).

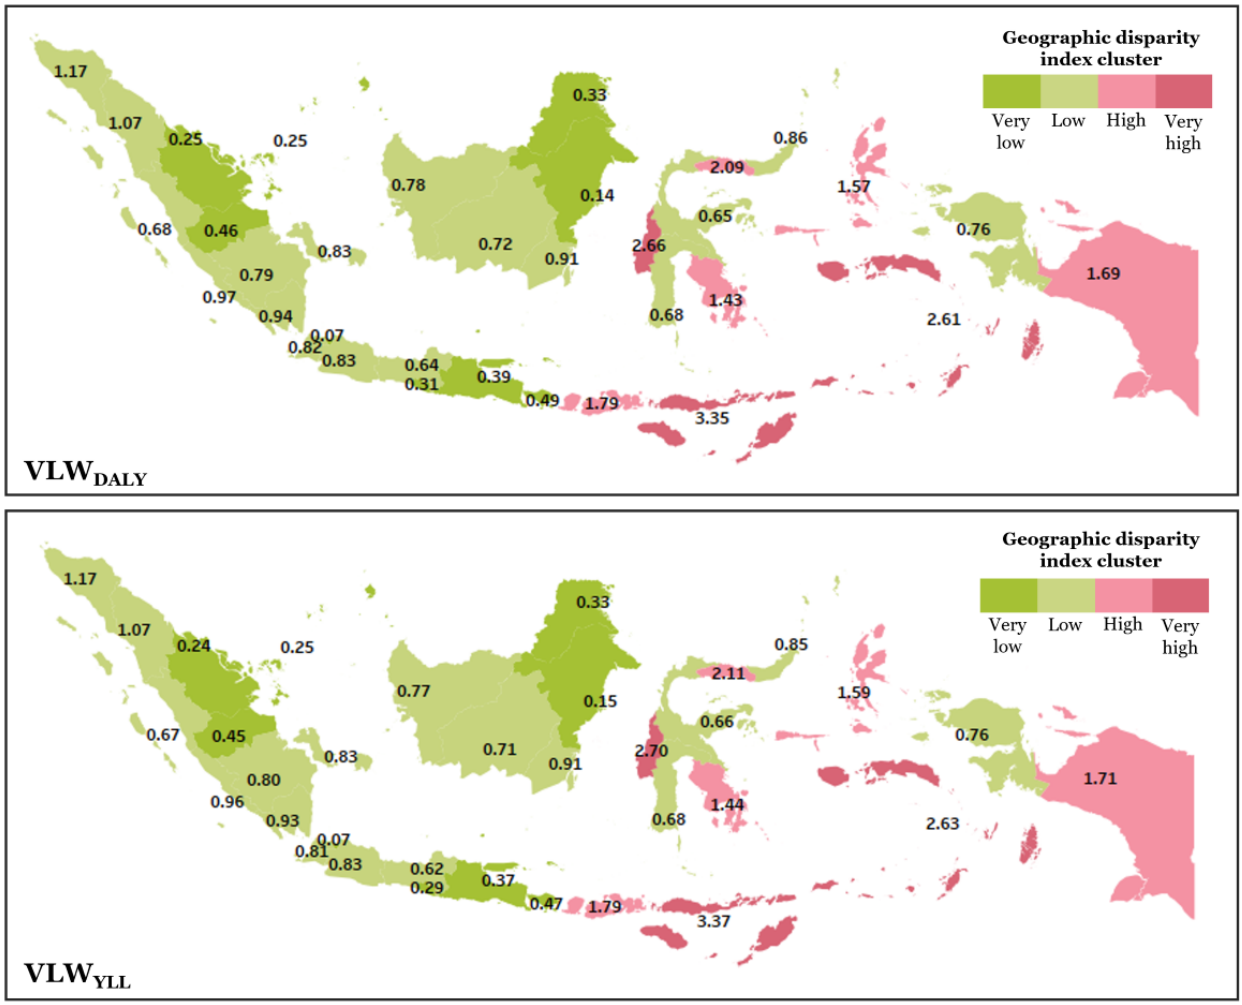
The VLW_{YLL} (value of lost welfare–years of life lost) gender disparity reveals substantial variation in male-to-female differences across Indonesia. The most extreme case is seen in the Riau Islands, with a relative difference of 314.29%. A large group of provinces falls into the high disparity category, including Aceh (173.21%), Banten (152.35%), North Sumatra (151.98%), Lampung (151.04%), Papua (138.10%), and Yogyakarta (141.67%). The moderate disparity group features provinces such as Central Java (109.56%), East Java (112.41%), South Kalimantan (103.17%), and North Maluku (100%). In contrast, the very low disparity cluster includes Bali (56.41%), Central Kalimantan (52.08%), West Kalimantan (36.62%), and East Nusa Tenggara (70.40%). The gender disparity patterns in VLW_{DALY} and VLW_{YLL} for CHD are consistent. However, North Kalimantan and Yogyakarta are 2 provinces categorized as moderate disparity in the VLW_{DALY} but rise to high disparity in the VLW_{YLL}.



Geographical Disparity

The geographical analysis of economic CHD burden in Indonesia reveals notable spatial disparities in the VLWs (Figures 2 and 3; Multimedia Appendix 2). Based on the VLW_{DALY} LQ, most provinces fall into the low (LQ=1.0-1.3) and very low (<1.0) categories, indicating that their share of CHD-related welfare loss is roughly proportional—or even lower—than their population size. Notably, Yogyakarta (0.34), Jakarta (0.55), East Java (0.61), Central Java (0.64), and Bali (0.66) fall under the very low group. In contrast, provinces such

XSL•FO
RenderX



as Central Sulawesi (1.66), East Nusa Tenggara (1.75), Maluku (1.78), and North Sumatra (1.62) are in the high group, while Gorontalo (1.99), North Maluku (2.03), Papua (2.42), Southeast Sulawesi (2.02), and West Sulawesi (2.37) are in the very high group. Similarly, the VLW_{YLL} LQ follows a consistent trend. Provinces with very low LQs include Yogyakarta (0.32), Jakarta (0.53), East Java (0.60), Central Java (0.63), and Bali (0.65). Meanwhile, high disparity is observed in Central Sulawesi (1.69), East Nusa Tenggara (1.77), Maluku (1.83), and North Sumatra (1.64). The very high group again includes Gorontalo (2.05), North Maluku (2.07), Papua (2.48), Southeast Sulawesi (2.07), and West Sulawesi (2.43).

Figure 2. Location quotient (LQ) showing the economic burden of congenital heart disease (CHD) relative to the share population across Indonesia, estimated from VLW_{DALY} (value of lost welfare–disability-adjusted life years) and VLW_{YLL} (value of lost welfare–years of life lost). An LQ greater than 1 indicates a disproportionately higher economic burden relative to population share.

XSL•FO
RenderX

Figure 3. Geographic disparity index of the CHD economic burden across Indonesia, estimated from VLW_{DALY} (value of lost welfare–disability-adjusted life years) and VLW_{YLL} (value of lost welfare–years of life lost).

VLW_{DALY}-to-GDP disparity revealed that the majority of provinces in Indonesia (20 of 34) fall into the "low disparity" group, with ratios ranging from 0.636 in Central Java to 1.174 in Aceh, indicating that while the burden exists, it is proportionate to local GDP. Provinces such as Banten (0.816), North Sumatra (1.067), and West Java (0.834) also belong to this group. The "very low disparity" cluster includes 9 provinces, such as Jakarta (0.072), East Kalimantan (0.143), Riau and Riau Islands (both 0.251), and Yogyakarta (0.314), showing minimal economic strain from CHD-related welfare loss. In contrast, 5 provinces fall into the "high disparity" category, including West Nusa Tenggara (1.793), Papua (1.694), and North Maluku (1.569), where the economic burden is disproportionately high relative to GDP. Most critically, East Nusa Tenggara (3.352), Maluku (2.608), and West Sulawesi (2.662) are classified under "very high disparity."

Even though similar to the VLW_{DALY}-to-GDP, where the indices of most provinces (21 of 34) fall into the "low disparity" category, discrepancies exist in the trend. The value was lowest in Central Java (0.620) and in highest in Aceh (1.166). Provinces such as Banten (0.814), Lampung (0.935), and North Sumatra (1.073) belong to this group. The "very low disparity" cluster includes 9 provinces, including Jakarta (0.074), East Kalimantan (0.148), Riau (0.241), and Yogyakarta (0.287). Conversely, 5 provinces are classified under "high disparity," with indices ranging from 1.444 in Southeast Sulawesi to 2.110 in Gorontalo, indicating a disproportionate burden relative to their GDP. Notably, 3 eastern provinces—East Nusa Tenggara (3.369), Maluku (2.628), and West Sulawesi (2.702)—fall into the "very high disparity" group.

Discussion

Overview

This study estimated the economic burden of CHD across all 34 Indonesian provinces, highlighting substantial national losses as well as marked regional and gender disparities. The VLW-to-GDP ratio across provinces exceeds 1 million ($\times 10^{-}$), underscoring the significant burden of premature mortality and disability associated with CHD. This widespread productivity loss represents not only an urgent public health challenge but also a constraint on equitable economic development. High-income provinces such as Jakarta, East Kalimantan, and the Riau Islands reported some of the largest absolute VLW estimates, frequently exceeding US $10 billion even under conservative wage-based valuations. However, their

XSL•FO
RenderX

VLW-to-GDP ratios remain modest due to their larger economic output. Nonetheless, the absolute magnitude of these losses highlights a substantial, and perhaps underappreciated, burden of disease. The persistence of CHD-related productivity losses in economically advantaged provinces points to systemic inefficiencies in health care delivery; despite higher income levels and relatively advanced health infrastructure, these regions continue to experience significant losses in human capital.

Overall, the CHD-related VLW-to-GDP ratio remains under 5% in most provinces, suggesting a modest economic burden nationally. However, the relative burden is considerably higher in economically vulnerable eastern provinces, where limited health infrastructure and geographic barriers amplify the impact of premature mortality and disability. In contrast, higher-income provinces such as West Java, East Java, North Sumatra, and Jakarta reported the highest absolute VLW_{DALY} estimates, ranging from US $0.79 billion to US $1.60 billion under wage-based valuations. However, due to their stronger economic output, these areas exhibited modest VLW-to-GDP ratios. These provinces also had LQ values <1.0, suggesting their share of VLW is proportionate to—or even smaller than—their population size. Nonetheless, the absolute magnitude of these losses—despite higher health infrastructure—suggests systemic inefficiencies in health care delivery and delays in diagnosis or treatment within CHD care pathways.

This phenomenon aligns with the Preston Curve, in which higher GDP does not automatically translate into better health outcomes without commensurate health system performance [26]. Similar patterns have been observed in coronary heart disease, where economic losses persisted despite macroeconomic gains, estimated at US $33.3 billion nationally [27]. In this context, the high VLW in affluent provinces may reflect missed opportunities in prevention, early detection, or effective intervention—rather than resilience. Conversely, resource-limited provinces, particularly in eastern Indonesia—East Nusa Tenggara (3.35%), Maluku (2.61%), and West Sulawesi (2.66%)—though reporting lower absolute VLW (US $0.1-US $0.3 billion), experienced disproportionately high relative burden and LQ values (2.4-2.7). This suggests structural fragility: limited pediatric cardiology services, fragmented referral networks, and geographic barriers all magnify the consequences of delayed care [28,29]. The findings thus illuminate a dual burden: in wealthier, urbanized provinces, absolute VLW losses suggest inefficiencies in service delivery, whereas in poorer, rural areas, high VLW-to-GDP ratios and elevated LQ values highlight acute economic vulnerability from preventable losses. Collectively, these patterns underscore the need for nuanced, region-specific policy responses.

Burden Patterns: DALYs Versus YLLs

Our provincial analysis in this study revealed that the difference between VLW_{DALY} and VLW_{YLL} is small—generally under 5% across most regions, with only Yogyakarta exceeding a 10% gap. This finding indicates that premature mortality remains the dominant contributor to productivity loss from CHD in Indonesia, rather than chronic morbidity. It also suggests that while rehabilitation and long-term care are important, the most immediate policy priority in many provinces remains the prevention of early deaths through improved detection and timely intervention. Many infants do not survive CHD—largely due to late diagnosis, limited surgical access, and insufficient intensive neonatal and postoperative care [4,30]. In remote regions, care-seeking is often delayed due to low health literacy, poor transportation, financial hardship, and cultural beliefs [28,31]. As a result, many congenital anomalies remain undetected until they cause serious complications or early death [31]. In line with the previously reported economic evaluations of congenital anomalies, strengthening early detection and intervention is thus essential to reduce VLW_{DALY} [27]. In Bali, Central Java, East Java, or Jakarta, persistent premature mortality likely affects marginalized subgroups within otherwise well-equipped provinces. Similar patterns have been reported in the United States, where CHD mortality remains unequally distributed despite overall health system strength [32,33]. Yogyakarta's relatively higher DALY-to-YLL difference likely reflects both effective early detection and follow-up care systems [34,35], as well as a sociodemographic structure with a lower concentration of underserved populations compared to megacities such as Jakarta [36].

Geographic Divide

This study introduces 2 complementary indicators of geographic burden: the VLW-to-GDP disparity index and the VLW LQ. While both indicators reveal a consistent east–west divide, they offer distinct perspectives. The VLW-to-GDP disparity index classifies 20 of 34 provinces as "low disparity" and 9 as "very low," indicating that in most regions, the CHD-related economic burden remains relatively proportional to local GDP. However, East Nusa Tenggara (3.35%), Maluku (2.61%), and West Sulawesi (2.66%) fall into the "very high disparity" cluster, pointing to severe strain relative to their limited economic capacity. These findings support previous reports highlighting chronic health care underdevelopment and financial vulnerability in these eastern provinces [37,38]. Residents of Maluku are significantly less likely than even those in Papua to use hospital services, with an adjusted odds ratio (OR) of 0.827 (95% CI 0.820-0.835), reflecting both structural and access-related barriers to care [38]. Such disparities in hospital use emphasize how systemic underutilization of formal health services may contribute to both the progression of undiagnosed CHD and increased long-term economic burden in these regions. In addition, comparable regional gradients have been observed in China's poverty and population distribution using remote sensing–based spatial models [12,13]. These parallels highlight how geospatial approaches can uncover hidden structural inequities, reinforcing the need for province-specific strategies in Indonesia.

The LQ, by contrast, measures each province's share of the national CHD-related burden relative to its population size. Provinces such as Gorontalo, North Maluku, Papua, Southeast Sulawesi, and West Sulawesi had LQ values exceeding 2.0, suggesting that their per capita contribution to national VLW is disproportionately high. Other regions, including East Nusa Tenggara, Maluku, North Kalimantan, and North Sumatra, also fall into the "high" category. In contrast, economically stronger and densely populated provinces such as Jakarta, Yogyakarta,

XSL•FO
RenderX

Central Java, and East Java show consistently low LQ values (0.32-0.64), indicating a lower per capita burden. This may reflect underlying disparities within otherwise well-resourced provinces, where marginalized or socioeconomically disadvantaged subpopulations continue to face barriers to timely diagnosis and treatment. Previous research in high-income contexts, including the United States, has similarly demonstrated that CHD-related mortality is unequally distributed across populations, with persistent service gaps and socioeconomic deprivation contributing to avoidable deaths [32,33].

When DALY-based and YLL-based disparity indices are compared, the results show broadly similar geographic patterns but also important differences. Both measures consistently flag East Nusa Tenggara, Maluku, and West Sulawesi as high-disparity regions, while Jakarta, East Kalimantan, Riau, and Yogyakarta appear in the very low cluster across both metrics. However, DALYs, which include YLDs, tend to be higher in provinces such as West Nusa Tenggara, where survival is often accompanied by long-term morbidity. Conversely, Gorontalo and North Maluku exhibit higher YLL-based indices, suggesting early death as the dominant burden component.

Gender Disparities and Economic Impact Severity

Across all provinces and valuation models, males consistently contributed a greater share to the total VLW than females, underscoring persistent gender-based disparities in the economic impact of CHD. This pattern aligns with prevailing socioeconomic structures in Indonesia, where men dominate formal labor markets and are typically regarded as primary income earners [39]. As a result, premature death or long-term disability in males translates into greater economic loss, particularly in contexts where male productivity is central to household income and community stability [40].

In this study, the magnitude of this disparity varies considerably by province. Riau Islands exhibited the most extreme male-dominant burden, with a VLW-to-GDP gender difference of 281.25% (DALY-based) and 314.29% (YLL-based). Several other provinces, such as Aceh, Banten, North Sumatra, Lampung, and Papua, consistently fall into the high-disparity category (≥130% higher in males), spanning both western and eastern regions. In contrast, provinces such as Bali, Central Kalimantan, West Kalimantan, Maluku, and East Nusa Tenggara showed much lower disparities, with male VLW contributions below 70% higher than female, suggesting either more balanced socioeconomic structures or more equitable access to care.

While the overall pattern is consistent across DALY- and YLL-based measures, some provinces, such as Yogyakarta and North Kalimantan, demonstrated higher disparity in YLL-derived estimates, indicating that male premature mortality plays a more dominant role than long-term male disability therein. Given that CHD prevalence also remains higher in males (0.96%) than in females (0.72%) [2], targeted policy responses must consider sex-specific vulnerabilities to reduce both health and economic consequences, particularly in provinces with extreme gender disparity.

Implications and Policy Recommendations

Our dual analysis using VLW-to-GDP disparity indices and LQ reveals distinct yet overlapping geographical patterns, underscoring the need for a province-specific strategy that balances financial, systemic, and service-based interventions. In lower-resource provinces, elevated VLW_{DALY} reflects the economic consequences of survival without adequate recovery, highlighting fragmented care pathways and limited rehabilitative infrastructure. Conversely, in more affluent regions, high VLW_{YLL} underscores that income alone does not ensure early diagnosis or optimal outcomes. These findings point to persistent system inefficiencies that allow both preventable mortality and long-term disability to persist across disparate socioeconomic contexts.

Timely diagnosis is central to effective CHD management, yet screening remains inconsistently implemented nationwide. Although feasibility studies in Yogyakarta have demonstrated successful integration of pulse oximetry into newborn care [4], national scale-up has been hindered by logistical and workforce barriers. School-based screening using auscultation and electrocardiography has also shown promise [3] but remains fragmented and pilot-driven. A recent national review highlights the absence of a cohesive CHD screening strategy, contributing to diagnostic delays, often until complications such as pulmonary hypertension or irreversible cyanosis arise [41]. Screening strategies should be prioritized in light of existing evidence showing that universal neonatal pulse oximetry screening is not only effective but also highly cost-effective [42]. Beyond clinical access, the economic burden of CHD is not gender-neutral. As findings of this study suggest, male children represent a larger share of projected productivity losses due to their expected roles in the formal labor market. Provinces such as Riau Islands, Aceh, and Papua reveal extreme disparities in male-to-female VLW, suggesting that male early mortality or disability carries greater economic implications, especially in socioeconomically vulnerable areas.

To effectively reduce geographic inequities, interventions must be tailored to the burden profile of each province. Regions such as East Nusa Tenggara, Maluku, and West Sulawesi, which show both high local strain (limited resources) and moderate contribution to the national CHD-related economic burden, warrant comprehensive support. These provinces present a strategic opportunity for high-return investment: their low baseline health care capacity means that even modest improvements in screening, referral, or access to surgical services can yield substantial health gains [43,44]. As previously reported, deep learning–assisted prenatal ultrasound is highly cost-effective, generating more than 1200 additional quality-adjusted life years at a cost of just US $1720 per quality-adjusted life year [45]. Moreover, alleviating the burden in these areas reduces both localized economic strain and the national VLW [46]. Targeted interventions here not only address vulnerability but also improve overall system efficiency, making them particularly cost-effective. In contrast, provinces such as West Nusa Tenggara and Bengkulu, despite contributing less to the national burden, still experience significant local impact. These areas require strengthened local infrastructure and the

XSL•FO
RenderX

continuation of full coverage by Indonesia's Universal Health Coverage system, covering surgery, diagnostics, and long-term follow-up, to shield households from out-of-pocket costs and prevent untreated cases from progressing into costly long-term disabilities [47].

Other areas, such as Papua, North Maluku, and Gorontalo, contribute significantly to the national VLW through high premature mortality, suggesting the need for enhanced early detection, community engagement, and strengthened referral systems. However, such efforts will remain insufficient without addressing the chronic shortage and unequal distribution of pediatric cardiologists and cardiac surgeons in these regions [48]. Evidence from cost-effectiveness studies consistently supports the value of expanding surgical access in LMICs [49]. Strengthening pediatric surgical capacity in Indonesia would therefore not only reduce preventable mortality but also represent an efficient use of limited health resources.

To reduce preventable mortality and economic loss, targeted investments are needed to expand local specialist capacity, develop regional cardiac centers, and implement remote consultation systems such as telecardiology [50,51]. Task-shifting approaches, such as training nurses or midwives to perform point-of-care cardiac ultrasound, have demonstrated effectiveness in resource-limited settings by enabling earlier detection and timely referral for CHD [52]. While challenges remain, including training costs, limited internet connectivity, and unstable electricity supply, these models have been proven to address the limited specialist availability [52].

Meanwhile, well-performing provinces such as Jakarta, Central Java, and Yogyakarta can serve as national innovation hubs to accelerate progress in CHD care. These regions are well-positioned to support interprovincial partnerships and lead pilot projects for digital health integration, including the development of artificial intelligence (AI)–based models for early CHD detection and risk stratification [53-55]. Their advanced clinical infrastructure allows for the implementation of high-impact interventions, such as zero-fluoroscopy atrial septal defect closures [56], transesophageal echocardiography–guided balloon-assisted percutaneous closures in complex cases (including during pregnancy) [57], and percutaneous palliative stenting for adults with unrepaired Tetralogy of Fallot [58]. Furthermore, these provinces can spearhead trials on advanced therapies, remote robotic-assisted surgery, and AI-assisted procedural planning [59,60], while also serving as training centers for pediatric cardiologists and interventional specialists [48].

Limitations

This study is subject to several limitations, chiefly stemming from its reliance on the GBD 2019 dataset. While the GBD framework provides standardized, internationally comparable estimates of disease burden, its modeled nature may not adequately reflect the subnational heterogeneity in CHD prevalence, health care access, and mortality reporting that characterizes Indonesia's archipelagic geography. Provinces with limited health surveillance infrastructure, particularly in eastern and remote regions, may exhibit substantial discrepancies between modeled and actual disease burden, introducing uncertainty into provincial-level estimates. Furthermore, the use of age-standardized data, though essential for international comparability, may obscure local demographic nuances, such as regional fertility rates, health-seeking behaviors, and differential survival trajectories—factors particularly salient in the context of pediatric conditions.

In addition, the valuation methods used, although grounded in established economic frameworks (eg, US DOT, OECD, and wage-based models), may inadequately account for informal labor contributions, gendered economic roles, and intrahousehold productivity, all of which are significant in the Indonesian context. Nevertheless, the GBD remains among the most comprehensive sources for cross-provincial disease burden estimation and provides a rigorous foundation for quantifying the economic impact of CHD across diverse settings. The triangulation of estimates across multiple valuation models further strengthens the robustness of the findings and highlights important spatial and sociodemographic disparities.

Conclusion

Our findings reveal that CHD imposes a macroeconomically nonsignificant burden in Indonesia, accounting for up to 1.35% of GDP using the highest valuation model. Similar to patterns observed in other LMICs, this economic impact is primarily driven by premature death. Across provinces, the gap between DALY- and YLL-based estimates is typically under 5%, indicating that YLLs dominate the productivity losses from CHD. Notably, gender disparities are prominent, with provinces such as the Riau Islands showing very high male–female relative differences in both DALY- and YLL-based losses. In Yogyakarta and North Kalimantan, the disparity is more pronounced in YLL-derived estimates, suggesting that premature mortality among males is a key contributor. Geographic disparities further reveal that provinces such as East Nusa Tenggara, Maluku, and West Sulawesi—which experience both high local strain and moderate national burden—warrant comprehensive and fundamental support. Meanwhile, provinces with low VLW-to-GDP ratios, including Jakarta, Central Java, and Yogyakarta, can serve as innovation hubs, facilitating specialist training, piloting AI-assisted interventions, and supporting interprovincial knowledge exchange to reduce national inequities.

Abstract

Background: We evaluated a pilot mobile health (mHealth) intervention aimed at improving postnatal maternal and infant health. The intervention featured provider-led group sessions for education, health care communication, in-person care referrals, and virtual mHealth support for postpartum mothers through weekly calls, texts, interactive voice response (IVR), and a phone app.

Objective: We aimed to assess the preliminary effectiveness of the pilot mHealth intervention, *MeSSSSage* (*Maa Shishu Swasthya Sahayak Samooh*, which means maternal and child health support group), on infant health knowledge, behaviors, and outcomes at 6 months post partum. We focus on maternal knowledge of infant danger signs and optimal young child feeding practices at 6 months post partum and also evaluate maternal care-seeking behaviors for infants, adherence to age-appropriate immunization, and infant and young child feeding practices such as early initiation of breastfeeding and complementary feeding.

Methods: We evaluated the preliminary effectiveness of an intervention on maternal health knowledge among 135 participants in Punjab, India, who completed pre- and postintervention surveys. The intervention, led by research personnel with backgrounds similar to community health officers, aimed to empower society and support universal health coverage if successful. We assessed changes in knowledge of maternal danger signs and the appropriate age for introducing different food groups over 6 months post partum. Additionally, we examined postintervention differences in health-seeking behavior for infants, adherence to age-appropriate immunizations, and adoption of breastfeeding and complementary feeding practices among women in the synchronous (group call), asynchronous (IVR and app), and control arms.

Results: Of 12 infant risk factors, maternal knowledge of infant danger signs remained low (mean range: 1.85-2.31 preintervention and 1.81-2.22 postintervention). Participants in the synchronous arm had a statistically significant higher mean increase (mean difference: 0.87, 95% CI 0.06 - 1.69) compared to the control arm. Participants in synchronous arms had nearly 3-fold increased odds of infant health checkup by a clinical provider than asynchronous arm participants (odds ratio [OR] 2.72, 95% CI 1.02-7.23).

XSL•FO
RenderX

No significant differences were noted in age-appropriate vaccine coverage among infants between arms, though vaccination coverage was more than 80% across all arms. Early initiation of breastfeeding remained low across all arms (~47%).

Conclusions: Our pilot study on group-based mHealth education and virtual social support during the postnatal phase showed modest yet promising results. Rigorous testing is crucial to strengthening the limited evidence base for group-oriented mHealth approaches.

Introduction

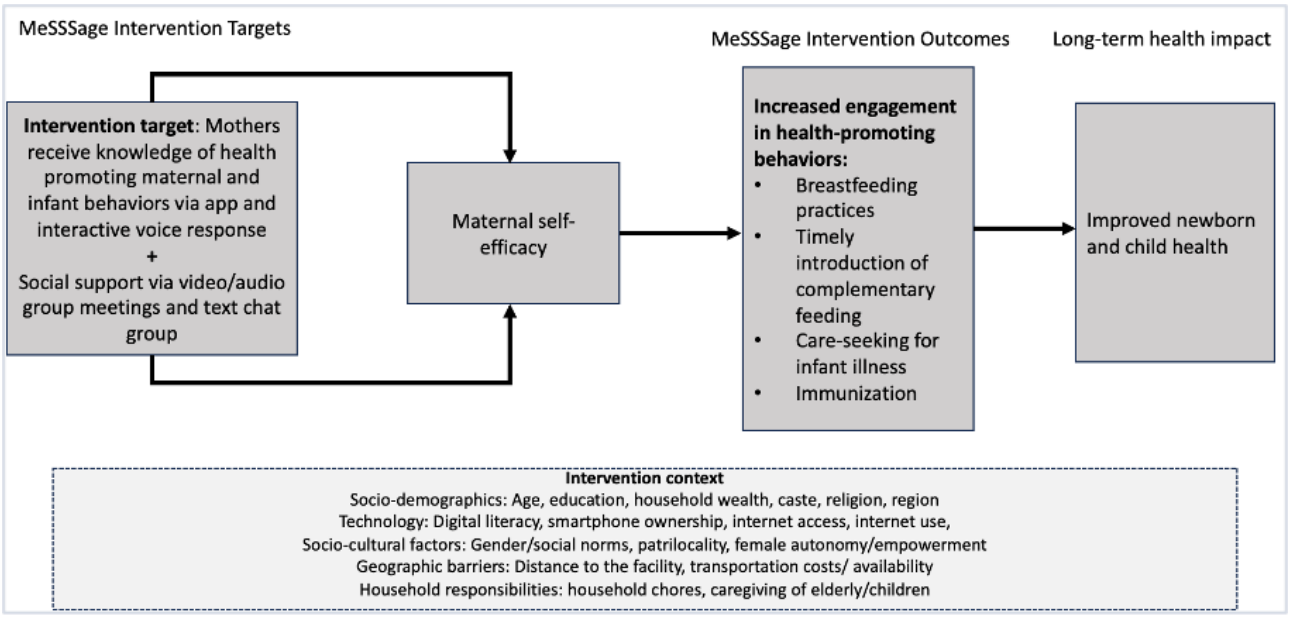
Background

India has made substantial improvements in child survival through a 54% reduction in neonatal mortality rate from 52 per 1000 live births in 1990 to 23.7 per 1000 live births in 2017 [1,2]. About 75% of newborn deaths occur in the first week of life, highlighting the importance of intervening in the early postnatal period [3]. Further, child undernutrition accounts for over 20% of deaths and remains a major risk factor for disease burden in children younger than 5 years in India [2,4]. The latest national survey suggests that 35.5% of children in India are stunted, 32.1% are underweight, and 19.3% are wasted with substantial variation both across and within Indian states [5].

There is a robust evidence base of interventions spanning the continuum of care from pregnancy through post partum and through the first 1000 days of life, including appropriate infant and young child feeding practices to improve newborn, and child health and nutrition outcomes [6,7]. India, backed by a two million+ female community health worker program, has adopted a comprehensive and universally available package of maternal and neonatal evidence-based interventions through its multiple national government programs, including the Integrated Child Development Services, the National Health Mission, and the National Nutrition Mission [8,9]. However, national surveys suggest that coverage of nutrition interventions, particularly in the postnatal and newborn period, remains low. Only 41.8% of children were breastfed within an hour of birth, 46% of children 6 - 8 months were initiated on complementary food, and 11% of children below 6 - 23 months received adequate diet with disparities by geographical region, socioeconomic status, and rural-urban residence [5].

Prior research from India suggests that postnatal care is associated with reduced neonatal mortality [10], and appropriate care for sick infants and children is correlated with reduced risk of severe wasting [11]. Postnatal education is an evidence-based strategy to improve newborn health and nutrition and maternal knowledge of general infant health and care [12]. While national data suggest that 79% of infants receive a postnatal checkup by skilled health personnel within 2 days of childbirth [5], a recent study of 13,000+ respondents from 3 large Indian states (including Punjab, one of our study states) highlights that 55% of mothers receive no postnatal education, with considerable knowledge gaps in appropriate newborn care practices, including skin-to-skin care, cord care, warning signs of infant illness, among other related topics [13]. Beyond postnatal education, enhancing social support for mothers through interpersonal connections is associated with reduced risk of postpartum depression [14,15], improved maternal self-efficacy [16,17], higher postnatal care attendance of mothers and infants [18], increased healthy maternal physical activity and nutritional intake [14], and better infant and young child feeding practices [19]. However, various barriers hinder postnatal care in India, including logistical challenges exacerbated by geographic distance and cultural factors [20-22]. Factors such as lower levels of women's autonomy, restricted freedom of movement, and social isolation further compound these challenges, particularly during the postnatal period when women are traditionally confined to their homes for 40 days after delivery [23]. Additional barriers include poverty, limited education, lack of male involvement, absence of health insurance, financial constraints, and perceptions of inadequate quality or lack of benefit of services [24-26].

Leveraging mobile health (mHealth)–based interventions holds promise in addressing barriers to postnatal care and improving postnatal maternal knowledge, social connectedness, and maternal and child health-related behaviors given increasing mobile phone ownership and internet access. A scoping review of 28 studies across low- and middle-income countries (LMICs) found improved immunization coverage and increased adherence to immunization schedules through mHealth-based text and voice message reminders [27], while another systematic review of 16 studies in LMICs found mHealth education interventions to increase perinatal interactions between young mothers and health care workers [28]. Individual studies reporting on mHealth interventions using text and voice messaging have improved perinatal care attendance [29], early initiation of breastfeeding and exclusive breastfeeding [30-32], protein consumption [33], general infant and young child feeding practices [34], knowledge of child immunization [35], and better adherence to child immunization schedules [36].



Key gaps in the evidence base on the impact of mHealth interventions on postpartum and neonatal health in India include fewer interventions focused on this topic area, with most targeting frontline health and nutrition workers to improve service delivery [37-40], limited interactions and social support provision among those targeting beneficiaries [30-32,41], and

XSL•FO
RenderX

the need for more rigorous studies [28,30,37,40]. Group-oriented mHealth interventions combining group-based learning and social support may overcome prevalent barriers given the convenience, feasibility, acceptability, and preliminary effectiveness in improving postnatal maternal and infant health outcomes [32,42-47]. However, the combined impact of interactive group-based social support delivered via mHealth modalities such as group voice calls or Zoom has been understudied in LMICs.

To address these gaps, we designed a provider-facilitated group perinatal mHealth intervention called *MeSSSSage* (*Maa Shishu Swasthya Sahayak Samooh*, which means maternal and child health support group). Informed by the capabilities and motivation constructs of the COM-B (Capability, Opportunity, and Motivation Behavior) framework [48,49], the intervention was designed to enhance maternal knowledge of health-promoting behaviors and promote maternal self-efficacy and empowerment to improve health-related knowledge, behaviors, and maternal and child outcomes (Figure 1). The intervention aimed to improve knowledge, facilitate referrals to in-person care, and foster connections with a virtual social support group for postnatal mothers with infants of similar ages through various mHealth modalities, including weekly group calls and text chat. Our development process included 2 iterative rounds of pilot testing—the first to inform the mHealth components and design factors [50] and the second to understand the feasibility and acceptability of our revised intervention [51] and explore preliminary effectiveness on health outcomes.

Figure 1. Conceptual framework of intervention context, *MeSSSSage* intervention targets and outcomes, and anticipated long-term impacts. *MeSSSSage*: *Maa Shishu Swasthya Sahayak Samooh* (which means maternal and child health support group).

Objective of This Study

In the current analysis, we aimed to assess the preliminary effectiveness of the pilot mHealth intervention, *MeSSSSage*, on infant health knowledge, behaviors, and outcomes at 6 months post partum. We focus on maternal knowledge of infant danger signs and optimal young child feeding practices at 6 months post partum and also evaluate maternal care-seeking behaviors for infants, adherence to age-appropriate immunization, and infant and young child feeding practices such as early initiation of breastfeeding and complementary feeding.

MeSSSSage Intervention

The *MeSSSSage* intervention was administered to women from late pregnancy through 6 months post partum. It included weekly audio or audio-video group calls, group text chats, and audio educational content provided via automated interactive voice response (IVR) or *MeSSSSage* app (Table 1 and Figure 2). Groups and group-based content (ie, audio-video group calls and group text chats) were facilitated by trained intervention moderators with backgrounds in public health or social work and supported by a gynecologist and neonatologist. The detailed description is published elsewhere [51].

XSL•FO
RenderX

Table . *MeSSSSage*[a] intervention modalities.

mHealth[b] modalities or arms	Description
Audio-video group sessions	Trained moderators led weekly group sessions focusing on increasing education and social support. These sessions incorporated icebreakers and group-building activities, facilitated discussions based on weekly themes (Figure 2), and allowed open questions and discussion sessions. Prenatally, a gynecologist participated in one call per month, while postnatally, both a gynecologist and a neonatologist participated in one call per month. Participants could choose to connect to their group via audio-only sessions on the TATA platform or video sessions on the Zoom platform.
WhatsApp-based group text chat	Trained moderators led weekly WhatsApp-based group chats by sharing audio and visual messages based on themes (Figure 2). Group participants were expected to engage by asking questions, and group discussion was facilitated.
MeSSSSage mobile app	Weekly educational audio messages focus on key information regarding weekly themes (Figure 2). The mobile app structured sections for these weekly audio messages, offering women the flexibility to access health education content at their convenience.
IVR[c]	IVR calls were scheduled to reach participants once a week at designated days and times. To maximize the chances of participants receiving the calls, they were sent out 3 times within a 15-minute interval. These brief audio calls, lasting between 5 and 10 minutes each, addressed essential topics concerning perinatal, neonatal, and child health. IVR calls persisted up to 6 months postdelivery.

[a]*MeSSSSage*: *Maa Shishu Swasthya Sahayak Samooh* (which means maternal and child health support group).

[b]mHealth: mobile health.

[c]IVR: interactive voice response.

Figure 2. Weekly maternal and neonatal content of *MeSSSSage* intervention. IVR: interactive voice response; *MeSSSSage*: *Maa Shishu Swasthya Sahayak Samooh* (which means maternal and child health support group).

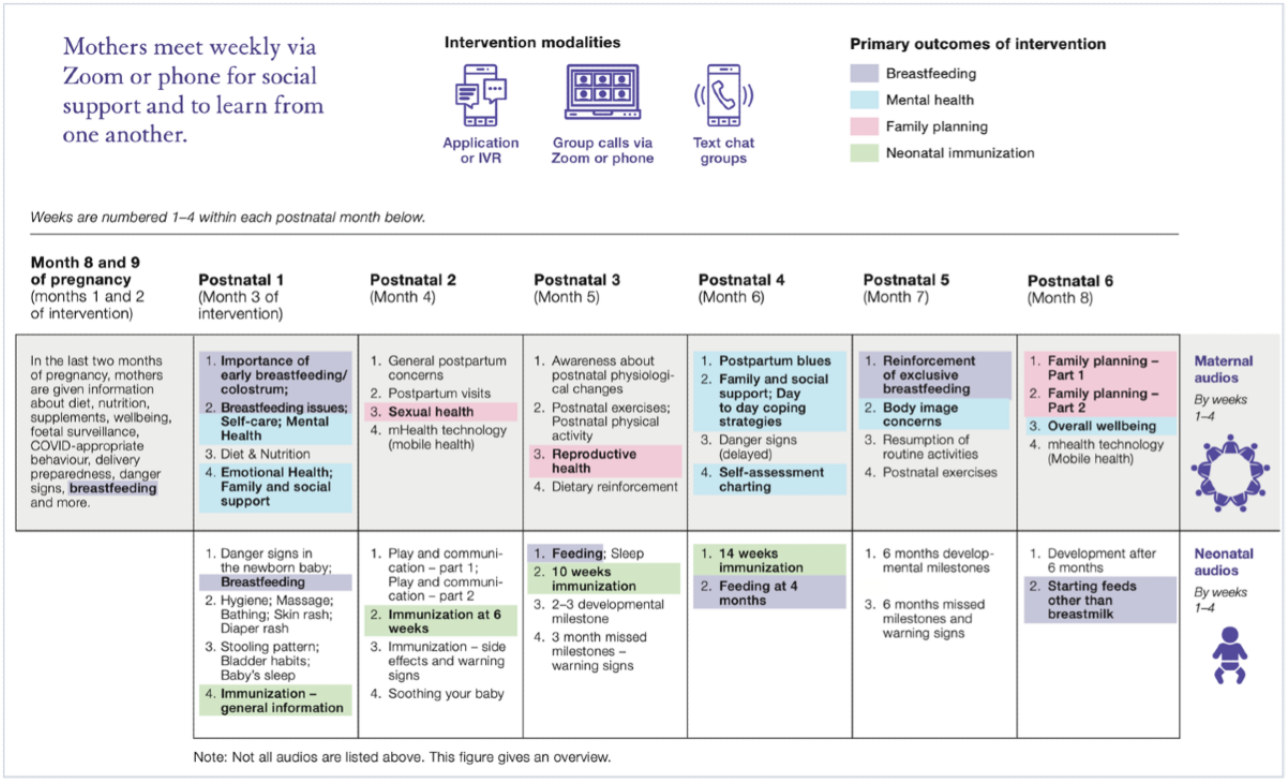


Figure 2 provides a summary of the intervention plan. While this table offers the general structure of IVR calls and audio-video group discussion topics, the audio-video group discussion topics were dynamically adjusted based on the queries and concerns shared by the new mothers, ensuring a responsive and participant-focused approach.

Methods

Study Design

This open-label pilot study on an mHealth-based perinatal health support intervention targeted women in late pregnancy through 6 months post partum in the Boothgarh block of the state of Punjab, northern India. We used a pretest-posttest nonrandomized control group design. Quantitative survey data were collected at study enrollment and intervention completion (approximately 6 months post partum).

Study Participants

Participants were eligible for inclusion in the study if they met the following criteria: (1) aged 18 years or older, (2) between 28 and 32 weeks pregnant, (3) residing in the study area, and (4) not experiencing a serious maternal complication. Participants with high-risk pregnancies and parity of more than 2 were ineligible.

Study Procedures

Our study team used antenatal clinic registry data maintained by community health workers to prescreen pregnant women in the seventh month of gestation. We then contacted these potential participants over the phone, screened them, and if found eligible, invited them to participate. We led them through an informed consent process, which included discussing study procedures, risks, and benefits. All participants provided informed consent verbally.

Out of the 397 women we tried to reach, we successfully recruited a total of 180 participants. These participants were then sequentially assigned to one of five arms: (1) app only (n=20), (2) IVR only (n=20), (3) group call+WhatsApp+app (3 separate arms, n=60), (4) group call+WhatsApp+IVR (3 separate arms, n=60), and (5) finally the control arm (n=20) at baseline. All participants, including the control arm, received the standard of care, which, in this setting, comprised community health worker–led home visits, counseling, and immunization services. Reasons for nonenrollment included being unable to reach the potential participant over the phone, as their phone was either switched off or out of service. Some women provided false information, while others were no longer pregnant due to a miscarriage or preterm birth. A few participants also described having irregular access to mobile phones since they used either their husband's or an immediate family member's phone and only had access to it in the evening when their husband or family member returned home from work. Some individuals did not respond to our calls, while others faced language challenges.

After enrollment, the 8 groups or arms were formed in a staggered fashion, leading to a study timeline from August 2021 to November 2022. Participant engagement in the intervention spanned a total of 8 months. Enrollment of participants and administration of the baseline survey occurred between August and December 2021. Intervention implementation spanned from August 2021 to July 2022, and our endline quantitative survey was conducted between May and December 2022. All data were collected through interviewer administration over the phone and directly entered into the REDCap (Research Electronic Data Capture) data collection application. For individuals who were not able to be reached for the endline survey, local ASHAs (Accredited Social Health Activists) were engaged to facilitate in-person quantitative survey administration.

Study Measures

Based on existing research on IVR and apps for maternal and child health in India, we focused on examining the supplementary impact of group calls. We anticipated that participants engaged in group calls would experience higher levels of social connectedness compared to those using the educational app or IVR, as the former allowed for direct interaction with others, fostering a sense of community and support. For analysis, we consolidated study participants into 3 intervention categories: a synchronous arm (combining arms 3 and 4 described above, comprising all group call participants), an asynchronous arm (combining arms 1 and 2 described above, comprising those in the app and IVR), and a control arm.

The primary outcomes of this analysis were the change in maternal knowledge of infant danger signs and maternal knowledge of infant and young child feeding practices between pre- and postintervention. Knowledge of infant danger signs was defined as women's ability to recall symptoms indicating infants may require medical attention within the first month of birth. We developed a cumulative score based on women's recall of various danger signs, including diarrhea, fever, cough or cold, difficulty breathing, absence of crying, chest problems, blue tongue and lips, lack of milk intake, failure to gain weight, premature birth, jaundice, coldness to touch, and others (scores ranging from 0 to 13). Women's knowledge of infant and young child feeding practices was assessed by their correct reporting of the appropriate age for introducing the following foods: water, rice, bread, legumes (dal), green leafy vegetables, pumpkin, carrot, fruits (banana, papaya, mango, and orange), meats (chicken, mutton, and fish), eggs, and different types of milk (cow, goat, powdered, etc). Women who correctly identified 6 months or older as the appropriate age for introducing all food groups except cow's/goat's milk (12 months) were coded as 1; otherwise, they were coded as 0. We developed a cumulative score based on women's correct responses.

Additional outcomes assessed postintervention included infant health status, access to health care, infant vaccination status, and infant feeding behaviors. Infant postnatal health characteristics were assessed through various questions. Postnatal care was assessed based on women's self-reports regarding whether their infants received a checkup within 6 weeks of birth, the frequency of these checkups, and the type of provider conducting the checkup (clinical or community). Infant vaccination coverage was determined by whether the infant had received all age-appropriate vaccines. Infant and young child feeding practices were evaluated through breastfeeding, early initiation of breastfeeding (defined as within 1 hour of birth), and complementary feeding (defined as whether other liquids or foods had been introduced to the infant). All variables were coded as indicator variables (yes/no).

Participant sociodemographic characteristics collected during preintervention included age, relationship status, educational attainment, religion, caste, ration card and type, parity, and mobile phone ownership.

XSL•FO
RenderX

Analysis

At baseline, 120 participants were in the synchronous arm, 40 participants in the asynchronous arm, and 20 in the control arm. At endline, we had 94 participants (78.3% retention rate) in the synchronous arm, 28 participants (70% retention rate) in the asynchronous arm, and 13 (65%) in the control arm. With our primary focus on temporal change, we restricted the analytic sample for this paper to participants with both baseline and endline data, resulting in a sample size of 135 participants.

We compared the sociodemographic characteristics of the 3 analysis arms (synchronous, asynchronous, and control arm) by identifying standardized differences [52]. Due to significant disparities across arms in the distribution of age, age at marriage, household composition, educational attainment, household income, ration card possession, mobile phone ownership, and smartphone access, we used inverse probability weighting to ensure comparability of participants across arms. This approach, similar to direct standardization, balanced preintervention discrepancies in sociodemographics between the arms [53,54].

We summarized sociodemographic characteristics using proportions and means of the matched, reweighted study population surveyed pre- and postintervention stratified by 3 arms (synchronous, asynchronous, and control). We then assessed the association of being in each intervention arm on primary outcomes (changes in maternal knowledge of infant danger signs and knowledge of infant and young child feeding practices) using mixed effects linear regression, including a random intercept for participants with robust standard errors to adjust within individual clustering due to the longitudinal structure of the data. The difference-in-difference coefficient (β) is the interaction term between a categorical variable denoting the time (before vs after the intervention was implemented) and the intervention arm (synchronous vs asynchronous modes, synchronous vs control, and asynchronous vs control). We interpreted this term as the differential change over time associated with being in each intervention arm compared to the reference group. For outcomes collected only at endline, we analyzed the differences between the arms (synchronous vs asynchronous modes, synchronous vs control, and asynchronous vs control) using logistic regression. Differences where $P<.05$ were considered statistically significant. All analyses are presented using weighted estimates. Data entry was done through REDCap, and all statistical analyses were conducted using Stata 15 (StataCorp LLC).

Ethical Considerations

This study received approval from the Indian Council of Medical Research and senior health authorities of the Government of Punjab and the Mission Director, National Health Mission, India. The study protocol was approved by the University of California San Francisco Institutional Review Board (19 - 299723), the ethics committee of the Postgraduate Institute of Medical Education and Research (IEC-03/2020 - 1567), the Collaborative Research Committee of the Postgraduate Institute of Medical Education and Research (79/30-Edu-13/1089 - 90), and the Indian Council of Medical Research (ID 2020 - 9576). All study participants were deidentified, engaged in a thorough informed consent process and provided written confirmation of informed consent at enrollment.

Results

Sociodemographic Characteristics

At study enrollment, participants had an average age of 26.8 years, and almost all (99.3%) were married (Table 2). The majority had either a high school education (44.8%) or higher education (44.3%). Nearly two-thirds of the sample belonged to the Sikh religion (65.3%), and one-third of the sample belonged to a marginalized caste (scheduled caste and scheduled tribe; 36.4%). Less than half possessed a ration card (48%), an official government document given to eligible poor families to get subsidized food grains from government fair price shops. Parity was one (53.3%) or more (46.8%). Mobile phone ownership at the household level was near-universal (99.2%), and most women owned their own phones (92.5%).

Maternal Knowledge of Infant Danger Signs

Despite increases noted across time, maternal knowledge of infant danger signs remained relatively low (Table 3). Of the 12 infant risk factors, the mean number known across arms ranged between 1.85 and 2.31 preintervention and 1.81 and 2.22 postintervention (Table 3 and Multimedia Appendix 1). Being in the synchronous arm was associated with a small but significantly greater increase in the mean number of infant danger signs known when compared to those in the control arm (mean difference 0.87, 95% CI 0.06 - 1.69; Table 3). No differences were identified between synchronous versus asynchronous arms or between asynchronous versus control arm participants.

Postintervention	7.89 (7.77 - 8.01)	7.56 (6.95 - 8.18)	6.51 (4.74 - 8.28)	—	—	—

[a]Full model output for these analyses with corresponding *P* values is presented in Multimedia Appendix 1.

[b]Combining all participants assigned to weekly group calls.

[c]Combining those participants assigned to the app and interactive voice response.

[d]Not applicable.

Maternal Knowledge of Appropriate Infant and Young Child Feeding Practices

Maternal knowledge of appropriate initiation of varied food groups was high preintervention, and no increase was observed over time (Table 3). Of 9 food groups in total, the mean number of food groups that women reported the correct knowledge for ranged from 6.48 to 7.56 preintervention and 6.51 to 7.89 postintervention. No group differences were identified.

Infant Health Checkup and Infant Vaccination

Table 4 presents a postintervention comparison of outcomes. Over 50% of participants in the synchronous arm and 40% of participants in the asynchronous arm reported receiving a health checkup for their infants, compared to 28.9% in the control arm. However, no statistically significant difference was noted between arms. Regarding receipt of infant health checkups by a clinical provider, a higher proportion (53.2%) of participants in the synchronous arm reported receiving a health checkup from a clinical provider compared to the other 2 arms. Participants in the synchronous arm had 2.72 times greater odds ratio (OR 2.72, 95% CI 1.02-7.23; $P<.05$) of infant health checkup by a clinical provider compared to the asynchronous arm. There were no statistically significant differences between the synchronous arm and control arm or between the asynchronous arm and control arm. The coverage of all 4 age-appropriate vaccines—BCG (Bacillus Calmette-Guérin), polio, DPT (diphtheria, pertussis, and tetanus), and hepatitis B—was high across all arms, ranging from 89% in the synchronous arm, 84% in the asynchronous arm, and 80.3% in the control arm. No differences were noted in the postintervention between-arms comparison.

Breastfeeding and Complementary Food Introduction

Initiation of breastfeeding within the first hour after birth was low across all arms (Table 4). The intention to breastfeed for more than 24 months was highest in the asynchronous arm at 37.6%, followed by 19.8% in the synchronous arm and 14.9% in the control arm. No differences in breastfeeding initiation or intention were noted in the postintervention between-arms

XSL•FO
RenderX

comparison. A greater proportion of participants in the synchronous arm (92.6%) and the asynchronous arm (95.3%) had introduced complementary foods by 6 months postnatal, compared to the control arm (52.2%).

Discussion

Principal Findings

Our pilot study on the preliminary effectiveness of the *MeSSSSage* mHealth education and virtual social support intervention found that synchronous arm assignment had a beneficial impact on participants' knowledge regarding infant danger signs and odds of obtaining an infant health checkup from a clinical provider when compared to control participants. We also noted no differences by arm in maternal knowledge of appropriate infant and young child feeding practices, number of infant health checkups, and early initiation of breastfeeding. Given the pilot nature of this investigation, including our study design limitations, in conjunction with our previously reported results supporting intervention feasibility and acceptability [51], these findings support continued investigation into the effectiveness of mHealth-based interventions targeting postnatal maternal and newborn health using robust research designs.

Our findings that the *MeSSSSage*'s synchronous arm that included group calls on education and social support increased maternal knowledge of infant danger signs are consistent with existing literature. Previous literature has demonstrated the effectiveness of mHealth interventions in empowering mothers to recognize infant danger signs [28], while interventions layering health education within women's self-help groups have shown promise in improving maternal knowledge across a range of outcomes [55,56]. Group-based mHealth education and social support interventions can promote health-seeking behaviors through the mechanism of "positive psychological support" among mothers [57]. On the other hand, we found less improvement in participants assigned to asynchronous modes of mHealth intervention, potentially due to unidirectional messaging and lack of social support. Our findings underscore the potential for integrating mHealth delivery into comprehensive interventions that combine both social support and health education, thereby enhancing their impact and effectiveness.

Our study findings noted no difference between pre- and postintervention on maternal knowledge of appropriate infant and young child feeding practices, though scores were high (7 out of 9) at preintervention. It is possible that high baseline levels of maternal knowledge precluded changes over time. A similar lack of effect was also noted in another Indian evaluation of an mHealth intervention for maternal knowledge of infant and child feeding practices [39] and other global studies [37]. Moreover, large-scale evaluations of mHealth interventions in India have failed to observe changes in infant and young child feeding practices [38,39]. Nonetheless, insights from another evaluation in India, including those using innovative approaches like audiovisual tools and interactive messaging, highlight the potential for future mHealth interventions to effectively impact maternal knowledge and practices concerning infant and young child feeding [58].

The synchronous arm of our mHealth intervention demonstrated the greatest impact, particularly in improving infant health checkups by clinical providers. In contrast, our asynchronous intervention arm, comprising solely audio educational messages, showed lower effectiveness. This could be attributed to various factors such as missed calls, insufficient attention to messages, or competing household obligations, resulting in null results for the intervention. Additionally, the absence of impact from the asynchronous modality may also be attributed to instances where participants' phones were with their husbands during the day, rendering it impossible for them to listen to the IVR messages. Similar challenges were encountered in a study conducted in Punjab, North India, where participants faced connectivity issues and missed messages due to household chores or not having access to their shared phone at the time [50,59]. To address these challenges, future research should identify the optimal timing for sending messages and IVR calls, and devise strategies to enhance engagement and participation in mHealth interventions, such as exploring incentives such as discounted call rates to motivate participants to carefully listen to all messages, as suggested in a study conducted in Afghanistan [60]. Given these challenges, combined effectiveness and implementation designs for mHealth research are likely to be more informative, particularly those that engage qualitative research methods.

The primary objective of our overall study was to assess the feasibility and acceptability of the intervention rather than robustly evaluating its effectiveness; thus, the preliminary effectiveness analysis reported here represents a secondary objective of the study, and the interpretation of these findings should consider the study's limitations. The sample size was determined for our feasibility and acceptability outcomes, resulting in significant differences in sociodemographic characteristics between the 3 intervention groups at baseline. While weighting techniques were used to address this imbalance, more robust experimental designs with a larger sample size will allow for a better assessment of effectiveness and potential mechanisms of impact. We also noted differential retention across the study by intervention group, which may have influenced our findings. Furthermore, our study design also limited our ability to assess whether intervention effectiveness differed by sociodemographic characteristics, and considering the important influence of social and structural factors on women of reproductive age and their influence on perinatal health, future research should focus on understanding the potential of interventions to specifically mitigate health disparities.

Conclusion

The postnatal period presents a critical opportunity to engage new mothers in enhancing their knowledge and practices concerning infant and young child feeding, infant health checkups and care-seeking behaviors, child vaccinations, and providing social support. Our pilot study on the *MeSSSSage* mHealth education and virtual social support intervention delivered mostly in the postnatal period yielded modest results and offered promising insights into its preliminary effectiveness. Such interventions, integrating mHealth-based education and communication with social support, hold significant promise but warrant further exploration to optimize their impact. With

XSL•FO
RenderX

smartphones and social media platforms like WhatsApp increasingly prevalent even in low-resource settings, there is an urgent need for more rigorous experimental research to comprehensively evaluate the impact of mHealth interventions and their underlying mechanisms. Our team is currently conducting a fully powered randomized controlled trial to examine the effectiveness and potential mechanisms of impact of an mHealth educational and social support intervention for perinatal women across multiple sites in India, with results expected in the coming years.

Abstract

Background: Essential Coaching for Every Mother is an SMS text messaging program that positively improved parenting self-efficacy and reduced postpartum anxiety when measured immediately after intervention at 6 weeks postpartum. However, the impact of a short-term postpartum intervention over time is unknown.

Objective: This study aims to compare parenting self-efficacy, postpartum anxiety symptoms, postpartum depression symptoms, and perceived social support at 6 months postpartum for mothers in the Essential Coaching for Every Mother trial.

Methods: Participants (n=150) were randomized to Essential Coaching for Every Mother or control (usual care). Data were collected on parenting self-efficacy (primary outcome, Karitane Parenting Confidence Scale), postpartum anxiety symptoms (Postpartum Specific Anxiety Scale), postpartum depressive symptoms (Edinburgh Postnatal Depression Scale), and perceived social support (Multidimensional Scale of Perceived Social Support) at enrollment and 6-months postpartum. Data were analyzed using analyses of covariance and chi-square analysis.

Results: A total of 139 women completed the primary outcome at 6 months and 136 completed secondary outcomes. At 6 months, there were no statistically significant differences between mothers in the intervention group and mothers in the control group on any of the outcomes. More mothers in the intervention group had higher postpartum anxiety scores (31/68, 45.6%) than mothers in the control group (16/68, 23.5%; *P*=.007).

Conclusions: At 6 months postpartum, all mothers had similar scores on parenting self-efficacy, postpartum anxiety symptoms, postpartum depression symptoms, and social support. Thus, Essential Coaching for Every Mother improved parenting self-efficacy and reduced postpartum anxiety at 6 weeks, with all mothers having similar scores at 6 months postpartum.

Introduction

Background

The growth of digital health interventions to address mental health and maternal health outcomes has grown significantly over the past decades [1,2]. Despite this growth, the extent to which preventative digital health interventions improve or maintain outcomes after the intervention has concluded is unclear. This is known as the maintenance effect, which is essential to behavior change interventions and measures the impact of the intervention on outcomes after the treatment has taken place [3]. To date, evidence is mixed as to whether the positive effects of digital health interventions are maintained over time for a variety of health areas including obesity or weight loss [4], smoking [5], and increasing physical activity

XSL•FO
RenderX

[6]. However, a meta-analysis on the maintenance effect of SMS text messaging–based interventions found that even after the intervention ends, there is a significant maintenance effect [4]. Furthermore, in the postpartum period, there have been mixed findings as to which type of interventions can maintain behavior change in maternal physical and mental health outcomes [7,8]. Thus, there is a need for reporting follow-up periods of digital health interventions to determine the effectiveness of maintenance postintervention [9] to facilitate the understanding of potential factors that lead to greater maintenance effects and whether ongoing follow-up is needed to maintain effects.

This study reports on the postimplementation outcomes of a 6-week postpartum SMS text messaging program called Essential Coaching for Every Mother. This program was designed to send daily SMS text messages to birthing people during the first 6-weeks postpartum who are living in Nova Scotia to improve parenting self-efficacy and perceived social support and to reduce postpartum anxiety and depression symptoms. Essential Coaching for Every Mother was developed through iterative testing with mothers/birthing people (eg, individuals who are physically capable of giving birth) and postpartum health care providers as an evidence-based, SMS text messaging program [10]. In the published results of this randomized controlled trial (RCT), it was found that primiparous women who received the Essential Coaching for Every Mother program had higher parenting self-efficacy at 6 weeks postbirth than those who did not receive the intervention [11]. Additionally, all mothers (regardless of parity) who received the intervention had lower postpartum anxiety symptoms than mothers who did not receive the intervention [11]. This success highlights the effectiveness of the Essential Coaching for Every Mother program to improve immediate parenting self-efficacy and reduce postpartum anxiety symptoms. However, outcomes were measured immediately after completing the intervention at 6 weeks postpartum, and thus, exploration of whether the study effects were maintained is needed to determine whether a short-term intervention has longer-term effectiveness and to determine whether ongoing follow-up is required to maintain positive outcomes.

Aim

This study aimed to compare parenting self-efficacy, postpartum anxiety symptoms, postpartum depression symptoms, and perceived social support at 6 months postpartum for mothers in the Essential Coaching for Every Mother trial.

Hypotheses

The following were our hypotheses:

1. Mothers who received Essential Coaching for Every Mother would have higher parenting self-efficacy and lower postpartum anxiety mean scores at 6 months compared with the control group.
2. Mothers who received Essential Coaching for Every Mother would be more likely to have clinically high parenting self-efficacy scores and clinically low postpartum anxiety scores at 6 months, compared with the control group.
3. Given that no significant differences were found in the original trial on postpartum depression symptoms and perceived social support, no differences at 6 months are hypothesized.

Methods

Participants

Birthing persons from Nova Scotia, Canada, were recruited remotely through SMS text messages between January 5, 2021, and August 1, 2021. Additional details are available in the study by Dol et al [11].

Ethical Considerations

This study was approved by the IWK Health Research Ethics Board (#1024984) and Nova Scotia Health Research Ethics Board (#1026534) and is registered with the ClinicalTrials.gov Protocol Registration System (NCT04730570). All participants provided informed consent and were able to opt out at any time.

Design

This is a follow-up evaluation of a 2-group, stratified, parallel arm RCT which followed a predefined protocol [12]. Participants were recruited from Nova Scotia, Canada via social media advertisements and research study posters at local hospitals and family practice clinics. Participants initiated contact by texting a study phone number to complete a preprogrammed eligibility screening process. All recruitment and onboarding occurred through standardized SMS text messages.

Upon enrollment, participants were first stratified by parity (primiparous and multiparous) and then using a 1:1 allocation, participants were randomized into the intervention or control group. Participants were not blind to their allocation, but hospital staff were. Researchers were aware of allocation but due to the nature of the randomization and remote data collection process, this did not increase any risk of bias.

Intervention

The Essential Coaching for Every Mother program includes standardized evidence-based SMS text messages that provide information related to newborn care and maternal mental health in the first 6-weeks postpartum [10]. Participants allocated to the intervention are sent messages from birth to 6 weeks postpartum based on the age of their newborn, with 2 messages sent per day in the first 2 weeks (one at 10 AM and one at 5 PM) and a daily message (at 10 AM) for weeks 3 through 6. Participants allocated to the control group did not receive any SMS text messages aside from recruitment and survey requests. No changes to regular care were implemented and no study contact occurred between the 6-week and 6-month surveys.

Outcome Measures

Participants were invited to complete a survey hosted on Research Electronic Data Capture (REDCap) [13] via SMS text message at enrollment/baseline (preintervention), 6 weeks postpartum (postintervention), and 6 months postpartum (follow-up). For the purposes of this study, only the baseline and 6-month data were used. The primary outcome was parenting self-efficacy measured using the Karitane Parenting Confidence Scale [14]. This 15-item scale assesses the perceived

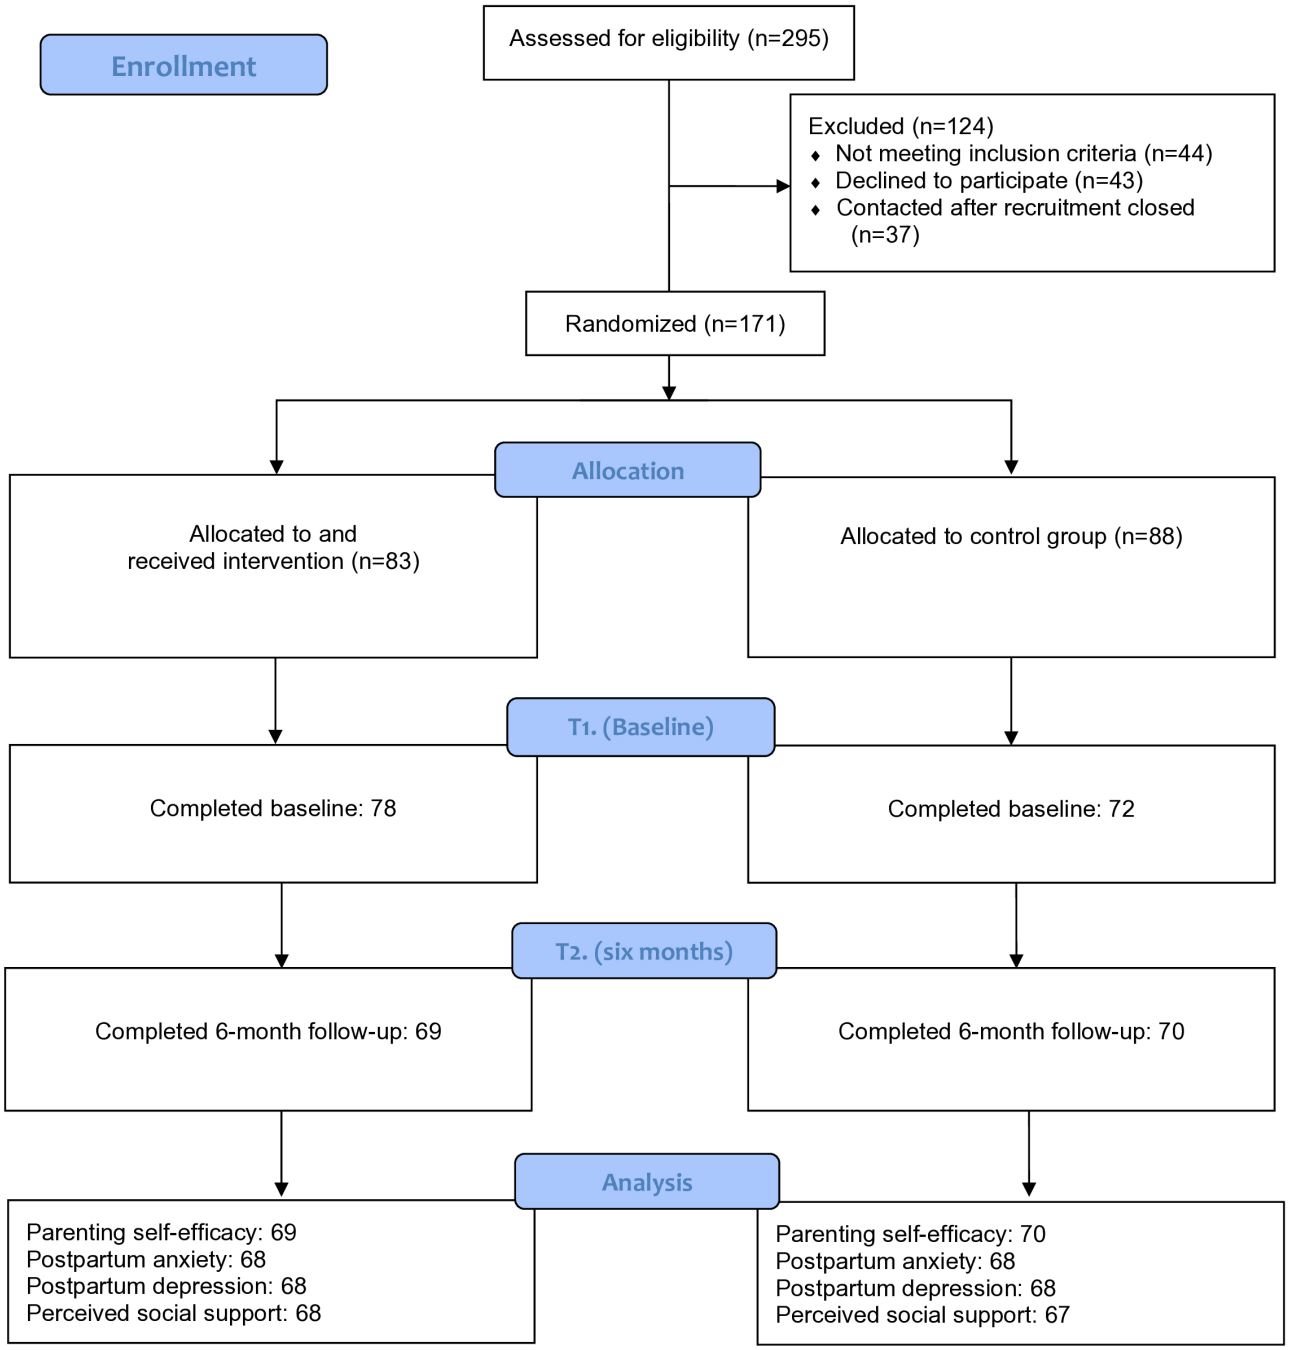
XSL•FO
RenderX

self-efficacy of mothers with newborns from birth to 12 months of age. Scores can range between 0 and 45 and a score of 39 or less is considered to be clinically low perceived parenting self-efficacy [14]. Secondary outcomes included postpartum anxiety symptoms (Postpartum Specific Anxiety Scale [PSAS] [15]), postpartum depression symptoms (Edinburgh Postnatal Depression Scale [EPDS] [16]), and perceived social support (Multidimensional Scale of Perceived Social Support [17]). For the PSAS, the clinical cut-off for postpartum anxiety symptoms is 112 out of a possible 201 [15] and for the EPDS, a score of 9 or above indicates depressive symptoms in a community sample and 13 or greater indicates probable clinical depression [16,18]. Therefore, higher scores in both the PSAS and EPDS indicate higher symptomology of postpartum anxiety and depression, respectively. No clinical cut-off scores are available for the Multidimensional Scale of Perceived Social Support.

Data Analysis

Data were analyzed on a per-protocol analysis, excluding women who requested to stop receiving the messages or did not return the 6-month follow-up survey. A series of analyses of covariances were conducted to examine the effects of the intervention on the outcomes of interest at 6 months postpartum considering allocation. In all analyses of covariances, parity, maternal age, and scores on the respective outcomes at baseline were entered as co-variates (ie, when analyzing parenting self-efficacy, parity, maternal age, baseline parenting self-efficacy scores were included as co-variates).

Chi-square analysis was conducted to compare whether participants scored above or below the clinical cut-off that identifies low parenting self-efficacy or high postpartum anxiety and depression symptoms. For the chi-square analysis, all participants who completed the outcome survey at 6 months were included. A *P* value of .05 was considered significant for all outcomes. SPSS (version 29.0; IBM SPSS Statistics) was used for analysis.



Results

Overview

Of the 171 participants randomized, 150 participants completed the baseline survey and were enrolled in the study. Of those enrolled, 139 (81.2%) participants completed the 6-month follow-up survey and were included in this analysis (Figure 1). All participants identified as cis-gendered females and as mothers; thus, the term “mother” will be used in describing the sample. Mothers were predominantly married, White, and had an undergraduate degree or higher. At 6 months, the groups were similar in all demographics, except for race, with mothers in the control group being more likely to identify as White compared with mothers in the intervention group. This differed from baseline, as there was no difference in race but mothers in the control group were significantly older than mothers in the intervention group (*P*=.053) [11]. At baseline, there were no differences between the groups on any of the primary outcomes [11]. Additional demographic details are available in Table 1 and Dol et al [11].

Parenting Self-Efficacy

Based on the 139 mothers who completed parenting self-efficacy measures at 6 months, there was no statistically significant difference in parenting self-efficacy at 6 months postpartum based on allocation ($F_{1,134}$=0.112, *P*=.74, partial η^2=0.001) (Table 2). A chi-square analysis was conducted to determine whether the proportion of mothers who had high (≥40) or low parenting self-efficacy scores (≤39) at 6 months were different based on group allocation. There were no differences in the proportion of mothers with high or low parenting self-efficacy scores based on allocation at 6 months postpartum (χ^2_1=0.091, *P*=.76) (Table 3).

Table . Adjusted means scores based on allocation at 6 months postpartum.

Outcome	Intervention, mean (SD)	Control, mean (SD)	*P* value
Parenting self-efficacy (n=139)	40.14 (3.73)	40.11 (3.94)	.74
Postpartum anxiety scores (n=136)	106.71 (20.97)	99.35 (19.13)	.30
Postpartum depression scores (n=136)	10.01 (4.66)	8.19 (4.94)	.20
Social support (n=135)	5.82 (0.95)	5.82 (1.12)	.79

Postpartum Anxiety Symptoms

Based on 136 mothers who completed the postpartum anxiety measure at 6 months postpartum, there was no statistically significant difference in postpartum anxiety scores at 6 months postpartum ($F_{1,131}$=1.077, *P*=.30, partial η^2=0.00) (Table 2). These findings differed in the chi-square analysis, where mothers in the intervention group were more likely to have clinically high (≥112) postpartum anxiety scores (31/68, 45.6%) compared with those in the control group (16/68, 23.5%) (χ^2_1=7.315, *P*=.007) (Table 3).

Postpartum Depression Symptoms

Based on the 136 mothers who completed the postpartum depression measure at 6 months, there was no statistically significant difference in postpartum depression mean scores at 6 months postpartum based on allocation ($F_{1,131}$=1.680, *P*=.20, partial η^2=0.013) (Table 2). In the chi-square analysis comparing mothers with scores ≥9 to ≤8, there were no differences in the proportion of mothers with high or low postpartum depression symptoms at 6 months postpartum (χ^2_1=2.408, *P*=.12). Additionally, comparing participants who scored ≥13 or ≤12, there were no differences in the proportion of mothers with high or low postpartum depression symptoms (χ^2_1=3.043, *P*=.08).

Perceived Social Support

Based on the 135 mothers who completed the perceived social support measure, there was no statistically significant difference in perceived social support scores at 6 months postpartum based on allocation ($F_{1,130}$=0.071, *P*=.79, partial η^2=0.001) (Table 2).

Discussion

Principal Results

This study sought to explore mothers' parenting self-efficacy, postpartum anxiety symptoms, postpartum depression symptoms, and perceived social support at 6 months postpartum, after receiving Essential Coaching for Every Mother, a 6-week postpartum SMS text messaging intervention immediately after birth. At 6 months, all mothers, regardless of their allocation, had similar scores on all outcomes. Mothers in the intervention group were slightly more likely to have high postpartum anxiety symptoms compared with mothers in the control group. The implications of these findings are discussed below.

For the primary outcome of parenting self-efficacy, the hypotheses were not supported in the analysis. The hypotheses were that mothers who received Essential Coaching for Every Mother would have higher mean parenting self-efficacy scores compared with mothers in the control group and would be more likely to have parenting self-efficacy scores that would be considered high (≥40). While there were no significant differences in scores or differences in high scores, both the intervention and control groups had mean scores that would be considered "high" parenting self-efficacy. In the RCT measuring immediate intervention effectiveness [11], primiparous women who received the Essential Coaching for Every Mother program had a greater increase in parenting self-efficacy than those who did not receive the program. This may suggest that Essential Coaching for Every Mother was able to improve parenting self-efficacy during the earlier postpartum period, particularly for primiparous women, showing potential to improve immediate parenting self-efficacy during an early critical period. Given the relatively high parenting self-efficacy scores at 6 months postpartum, it is clear that parenting self-efficacy increases over time in the first 6 months as mothers become more comfortable and confident in their parenting role [19].

XSL•FO
RenderX

Early interventions for primiparous mothers may be helpful in bridging the gap to achieve earlier parenting self-efficacy.

In relation to postpartum anxiety symptoms, the original RCT found that postpartum anxiety symptoms decreased at 6 weeks for women who received the Essential Coaching for Every Mother program, regardless of parity, compared with the control group [11]. Thus, the hypothesis was that mothers who received Essential Coaching for Every Mother would have lower mean postpartum anxiety scores at 6 months as well as more mothers would have clinically low postpartum anxiety scores compared with the control group. Like parenting self-efficacy, there were no significant differences at 6 months between the groups on average postpartum anxiety scores. However, mothers in the intervention group were more likely to have a clinically high postpartum anxiety score compared with mothers in the control group. Postpartum anxiety symptoms have been found to be higher in mothers with an infant 4 - 6 months than mothers with an infant 0 - 3 months [20], suggesting that perhaps there may be factors that influence a later emergence of anxiety symptoms during the postpartum period. Additionally, it has been suggested that postpartum anxiety may have a u-shaped relationship, with mothers who have higher anxiety levels during pregnancy experiencing a dip when their infant is born and then continue to increase back up to pregnancy levels up to 24 months postpartum whereas mothers with low anxiety levels during pregnancy tend to stay low across the postpartum period [21]. In this study, anxiety scores at baseline were higher for the intervention group, so there may be an influence of self-referral bias whereby mothers who were more anxious were interested in enrolling in the study. Particularly since the COVID-19 pandemic, the loss of support and ability to consult with health care providers or friends has also been associated with higher levels of mental health concerns [22]. Combined with normal fluctuation that occurs in the postpartum period along with decreased social support and potentially being predisposed to higher anxiety, there may be factors other than the Essential Coaching for Every Mother program that resulted in increased anxiety symptoms for intervention mothers. Despite the higher levels in the Essential Coaching for Every Mother group, both groups had a mean below the clinical cut-off for high levels of postpartum anxiety. At the individual level, it is important to ensure that birthing people have access to ongoing mental health support throughout the postpartum period.

Last, no differences in postpartum depression symptoms and perceived social support at 6 months were hypothesized since there were no significant differences found in the original trial at 6 weeks postpartum. This was found in both analyses, with no differences in postpartum depression symptoms and social support at 6 months. Despite the lack of significant findings, mothers in the intervention group did have higher postpartum depression mean scores, and more mothers were in the >9 group than mothers in the control group. During the recruitment for the RCT, participants were not excluded if they were currently experiencing mental health concerns or had a history of mental health concerns. While randomization is expected to equalize this between groups by design, this may not have been sufficient to balance this across groups as the intervention group had higher, yet not significant, postpartum depression symptoms at baseline as well [11]. Additionally, the intervention group had a higher, although again not significant, difference in having a history of mental health concerns (24/69, 34.8% vs 18/70, 25.7%) which may have influenced their postpartum depression symptoms at 6 months postpartum.

Limitations

This follow-up analysis is limited by the small sample size and loss of follow-up, which may have impacted the ability to be sufficiently powered in the analyses. While the original study was sufficiently powered, this follow-up study lost some power as participants who did not complete the 6-month timepoint were removed. This study was carried out in Canada in English, and findings may be different in other populations. We were unable to explore other variables that influenced mothers' psychosocial and mental health scores across the postpartum period. Mothers who participated in the study may not be fully representative of the population, as they were predominately White, highly educated, and high-income earners. Additionally, our sample may have been influenced by self-referral bias, as participants were remotely recruited and signed themselves up for participation and there was a greater number of participants in the control group who dropped out before completing the baseline questionnaire [11]. Given these limitations, the findings should be interpreted in this light.

Comparison With Prior Work

Questions remain about the appropriate dose and engagement of postpartum SMS text messaging interventions to improve psychosocial and mental health outcomes. The first year after an infant is born is associated with significant changes in physical and emotional outcomes for mothers. Risk factors for postpartum depression and anxiety are wide-ranging and include, but are not limited to, having depression during pregnancy [23-25], having a history of depression [23,26], or experiencing abuse or marital conflict [24,25]. Additionally, evidence shows that postpartum anxiety varies across the first 6 months of the postpartum period, ranging from 14.8% to 17.8% [27]. In addition, well established is the comorbidity between anxiety, depression, social support, and parenting self-efficacy in the postpartum period [19,28], suggesting that postpartum adjustment is multifaceted and interdependent. More research is needed to understand whether ongoing support throughout the postpartum period may be able to alter mental health outcomes as well as other interventions that may address additional risk factors. Given that Essential Coaching for Every Mother was designed primarily to improve parenting self-efficacy, it is important that other supports are available to mothers that target mental health outcomes beyond the initial 6-weeks.

There is a challenge with designing interventions that improve mental health outcomes in the postpartum period, particularly in regard to universal support to women considered low risk [29]. In a recent scoping review analyzing 70 unique evidence-based universal interventions to support parents between conception and 12 months postpartum, only half reported evidence of effectiveness against their reported outcome measures, suggesting a need for a multifaceted approach to support parent well-being across the perinatal period [30].

XSL•FO
RenderX

Another review examining digital health interventions for postpartum anxiety and depression found that digital health interventions significantly reduced postpartum depression and postpartum anxiety symptoms [31]. It is also important to consider what might make an intervention effective beyond the treatment period. In analyzing the maintenance effectiveness of physical activity and dietary interventions for adults, Fjeldsoe et al [32] found that intervention characteristics that were associated with maintenance effects were those of longer duration (>24 weeks), face-to-face contact, the use of a variety of intervention strategies, and the use of follow-up prompts. Examining parent training more broadly, providing booster sessions or intermittent contact postintervention, have been suggested as potentially effective strategies to maintain intervention effects over time [33].

While digital health interventions are desired and accepted by postpartum mothers [34], interventions designed for implementation during the postpartum period should take into consideration how interventions can maintain positive impacts over time. In a meta-synthesis of what women want in the postpartum period, Finlayson et al [35] clearly summarize: "To cope with this period of adjustment women express the need for practical, emotional and psychological support from family members, peer groups and online sources, as well as from health providers. Women also want information and reassurance from health providers delivered in a consistent manner by authentic, familiar providers who recognise the mother's as well as baby's needs, within a well-resourced and flexible healthcare system that respects their cultural context". Given the multiple challenges that emerge for mothers during the postpartum period, both in-person and digital support from reliable sources of information that respond to mothers' needs and infant development is needed. Engaging patients in the development of perinatal digital health solutions is important to improve health outcomes but is not yet common practice [36-38].

Future Directions

Future work should explore the potential to expand the timeline of the Essential Coaching for Every Mother program beyond the immediate 6-week period, as there are clearly challenges parents experience beyond this time frame that are impacting their psychosocial and mental health. Additionally, future work should consider the population that may be in most need of such an intervention, such as primiparous mothers or those with higher postpartum anxiety and depression scores at baseline. Future work should identify at-risk groups and determine whether any differences between low-risk and high-risk groups can be improved with the Essential Coaching for Every Mother program.

Conclusions

In conclusion, mothers, regardless of whether they received Essential Coaching for Every Mother, a 6-week postpartum intervention, had similar scores on parenting self-efficacy, postpartum anxiety symptoms, postpartum depression symptoms, and social support at 6 months. This suggests that the Essential Coaching for Every Mother program was able to improve parenting self-efficacy for primiparous mothers and reduce postpartum anxiety symptoms in the immediate postpartum period. At 6 months, both groups were similar, indicating that support during the immediate 6-week postpartum period is critical to ensure early intervention.

Acknowledgments

This work was supported by an IWK Mentored Grant and an IWK Ross Fund grant held by JD and MCY.

Authors' Contributions

JD and MCY researched the literature and conceived the study with input from MA and DM. JD led protocol development, gained ethical approval, patient recruitment, and data analysis. AKG provided statistical guidance on the analysis. JD wrote the first draft of the manuscript. All authors reviewed and edited the manuscript and approved the final version of the manuscript.

Abstract

Background: Accurate third-trimester birth weight prediction is vital for reducing adverse outcomes, and machine learning (ML) offers superior precision over traditional ultrasound methods.

Objective: This study aims to develop an ML model on the basis of clinical big data for accurate prediction of birth weight in the third trimester of pregnancy, which can help reduce adverse maternal and fetal outcomes.

Methods: From January 1, 2018 to December 31, 2019, a retrospective cohort study involving 16,655 singleton live births without congenital anomalies (>28 weeks of gestation) was conducted in a tertiary first-class hospital in Shanghai. The initial set of data was divided into a train set for algorithm development and a test set on which the algorithm was divided in a ratio of 4:1. We extracted maternal and neonatal delivery outcomes, as well as parental demographics, obstetric clinical data, and sonographic fetal biometry, from electronic medical records. A total of 5 basic ML algorithms, including Ridge, SVM, Random Forest, extreme gradient boosting (XGBoost), and Multi-Layer Perceptron, were used to develop the prediction model, which was then averaged into an ensemble learning model. The models were compared using accuracy, mean squared error, root mean squared error, and mean absolute error. International Peace Maternity and Child Health Hospital's Research Ethics Committee granted ethical approval for the usage of patient information (GKLW2021-20).

Results: Train and test sets contained a total of 13,324 and 3331 cases, respectively. From a total of 59 variables, we selected 17 variables that were readily available for the “few feature model,” which achieved high predictive power with an accuracy of 81% and significantly exceeded ultrasound formula methods. In addition, our model maintained superior performance for low birth weight and macrosomic fetal populations.

Conclusions: Our research investigated an innovative artificial intelligence model for predicting fetal birth weight and maximizing health care resource use. In the era of big data, our model improves maternal and fetal outcomes and promotes precision medicine.

Introduction

The assessment of fetal birth weight for the purpose of fetal growth monitoring is essential in contemporary prenatal care, as anomalies in growth are linked with negative consequences for both the mother and the fetus [1,2]. For instance, the birth of a macrosomic fetus is associated to unfavorable delivery outcomes (operative vaginal, caesarean delivery, or shoulder dystocia), trauma (maternal severe birth canal laceration and postpartum hemorrhage, fetal clavicular fracture, brachial plexus injury, neonatal hypoglycemia, and birth asphyxia) [3]. Infants with low birth weight may present a greater risk of acute or chronic hypoxia, acidemia, fetal demise, neonatal death, neonatal morbidity, and abnormal neurodevelopmental outcome, which are more likely to be admitted to a neonatal intensive care unit (NICU) and to have lifelong illnesses [4]. Consequently, precise fetal birthweight prediction helps clinical decision-making, such as appropriate prenatal treatments and acceptable mode of delivery selection, which might assist to enhance pregnancy outcomes [5].

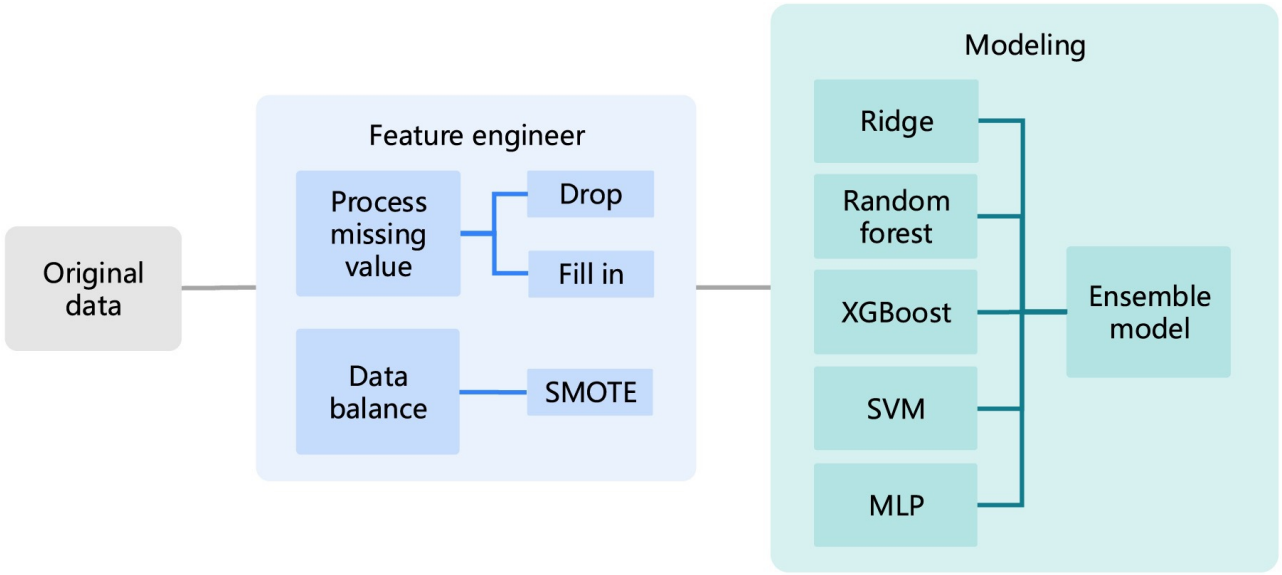
Ultrasonographic evaluation based on biometric measurements and regression equations is the method of choice in obstetrics

XSL•FO
RenderX

due to its objectivity and convenience. However, the majority of ultrasonic formulae are based on western populations, and there are biases when applied to Chinese as fetal birth weight after 20 weeks varies significantly by race [6]. Predictions of macrosomia and low birth weight infants based on estimated fetal weight are significantly less accurate [7,8]. A meta-analysis of 29 studies reveals that the pooled sensitivity of the Hadlock formula for fetal weight estimation was only 0.56. (95% CI 0.49 - 0.62) [9]. Inaccurate estimations may result in inappropriate interventions, so alternative approaches to precision estimation are urgently required.

With more ability than traditional statistical methods of handling complex, nonlinear, and multidimensional clinical data, machine learning (ML) has been explored successfully in several obstetrics domains, including gestational diabetes mellitus (GDM) [10], preterm birth [11], and postpartum hemorrhage [12]. Currently, there are only a few of published models using ML to estimate fetal birth weight before delivery, such as Wang et al [13]. used a Random Forest Algorithm to predict macrosomia and Gao et al [14] proposed a fetal weight prediction model based on genetic algorithm to improve back propagation (GA-BP) neural network. However, their simple size was too small and the feature parameters were insufficient; consequently, the performance of published models was unreliable and differentially robust.

In this study, we aimed to analyze the vast clinical data of a large cohort of pregnant women and create predictive models for the prediction of fetal birth weight using a variety of ML algorithms. Compared to the preexisting ultrasound formula, our novel ML models are anticipated to achieve an advanced result with a high degree of accuracy and offer convenient service to both medical staff and families of pregnant women in the future.



Methods

Study Design

This is a retrospective observational study using ML algorithms to increase the accuracy of fetal birth weight prediction based on real-world data. The process included feature engineering and modeling, as depicted in Figure 1 and described in detail in this section. This project established a simplified model suitable for maternal self-testing or clinical staff rapid prediction and transformed this model into a mobile application for use in clinical practice. Previously, there existed a model suitable for medical electronic record system with more detailed features, and the results will be improved.

This research was reported in accordance with the Transparent Reporting of a multivariable prediction model for Individual Prognosis or Diagnosis (TRIPOD) statement. The official TRIPOD checklist is shown in Table S1 (Multimedia Appendix 1).

Figure 1. The whole process of fetal birth weight prediction. SMOTE: Synthetic Minority Over-sampling Technique; SVM: support vector machine; MLP: multilayer perceptron.

Study Population and Data Source

International Peace Maternity and Child Health Hospital (IPMCH), a tertiary first-class hospital in China, is the source of the data. The following were the criteria for inclusion: (1) gestational weeks of less than 28, (2) a singleton pregnancy, and (3) a normal pregnancy outcome (no or severe fetal malformations, stillbirths, or neonatal deaths). We searched for predictors of fetal birth weight that were repeatedly reported in studies or systematic reviews, can be easily ascertained in different settings with various clinical experiences, and are part of the routine examination during pregnancy. It includes samples of 18,837 pregnant women who gave birth between January 1, 2018 and December 31, 2019, including parental demographics, clinical characteristics, ultrasound information, and laboratory tests. Concerning the height and weight of the husband were oral reported by pregnant women, both the reliability and filling rate were extremely low, so we only included the age and education level information of the husband. A total of 59 characteristics, was shown in Table S2 in Multimedia Appendix

XSL•FO
RenderX

1. The measurement data's extreme and error values were eliminated, and the categorical data were standardized and coded.

At the first prenatal visit, between 9 and 13 weeks of gestation, we gathered parental data on the demographics, reproductive history, and medical history. Parental age was calculated through the date of birth and double checked by interviews. Face-to-face interviews were used to record maternal weight, height, parity, gravity, parental educational level, and baseline blood pressure (diastolic blood pressure [DBP] and systolic blood pressure [SBP]). Gestational weight gain (GWG) throughout pregnancy was measured by subtracting prepregnancy weight from the woman's weight at her final prenatal checkup. Gestational age was derived from sonographic measurement of the fetal crown-rump length or biparietal diameter. In the first trimester, between 9 and 14 weeks of pregnancy, samples of the mother's fasting lipid serum were collected in vacutainer tubes of 10 mL and centrifuged. Triglycerides (TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL), and total cholesterol (TC), were among the laboratory indices. The glucose index was derived from a 75-g oral glucose tolerance test (OGTT) between pregnancy weeks 24 and 28—including fasting plasma glucose (FPG), 1-hour glucose (GLU-1H), 2-hour glucose (GLU-2H), and hemoglobin (HGB). Attending physicians with more than 5 years of obstetric ultrasound experience performed routine sonographic evaluations of the fetal abdominal circumference (AC), head circumference (HC), biparietal diameter (BPD), humerus length (HL), transverse trunk diameter (TTD), femur length (FL), amniotic fluid index (AFI), and anteroposterior trunk diameter (APTD). Only ultrasound data within 2 weeks before delivery were collected. Each neonate's birthweight (in gram) was measured routinely by registered midwives using an electronic weighing scale within half an hour of delivery. Those newborns with birth weights <2500 g or ≥4000 g were defined as low birth weight or macrosomia, separately. Shinozuka's formula [15] was used to estimate fetal weight since it has been shown to be most suitable for weighing Asian fetuses.

$$(1) y=1.07*BPD3+3.42*APTD*TTD*FL$$

During the modeling process, four-fifths of the sample is picked at random as train data, and one-fifth is used as test data. Each model is trained on the same dataset partition.

Model Training and Validation

The Model Training and Validation process involved feature engineering steps, including handling missing values, filtering outliers, creating new features, selecting important features, and balancing the dataset. Pearson correlation coefficient, Ridge, and XGBoost methods were used for feature selection. The dataset imbalance was addressed by dividing the samples into categories and performing up-sampling using the SMOTE algorithm. Ensemble learning with bagging was used, averaging results from benchmark models, which included Ridge, Random Forest, support vector machine (SVM), k-nearest neighbor (KNN), and Multilayer Perceptron (MLP). Evaluation metrics such as relative error (RE), absolute error (AE), mean squared error (MSE), root mean squared error (RMSE), and mean absolute error (MAE) were used. The process aimed to optimize the model's accuracy in predicting fetal birth weight.

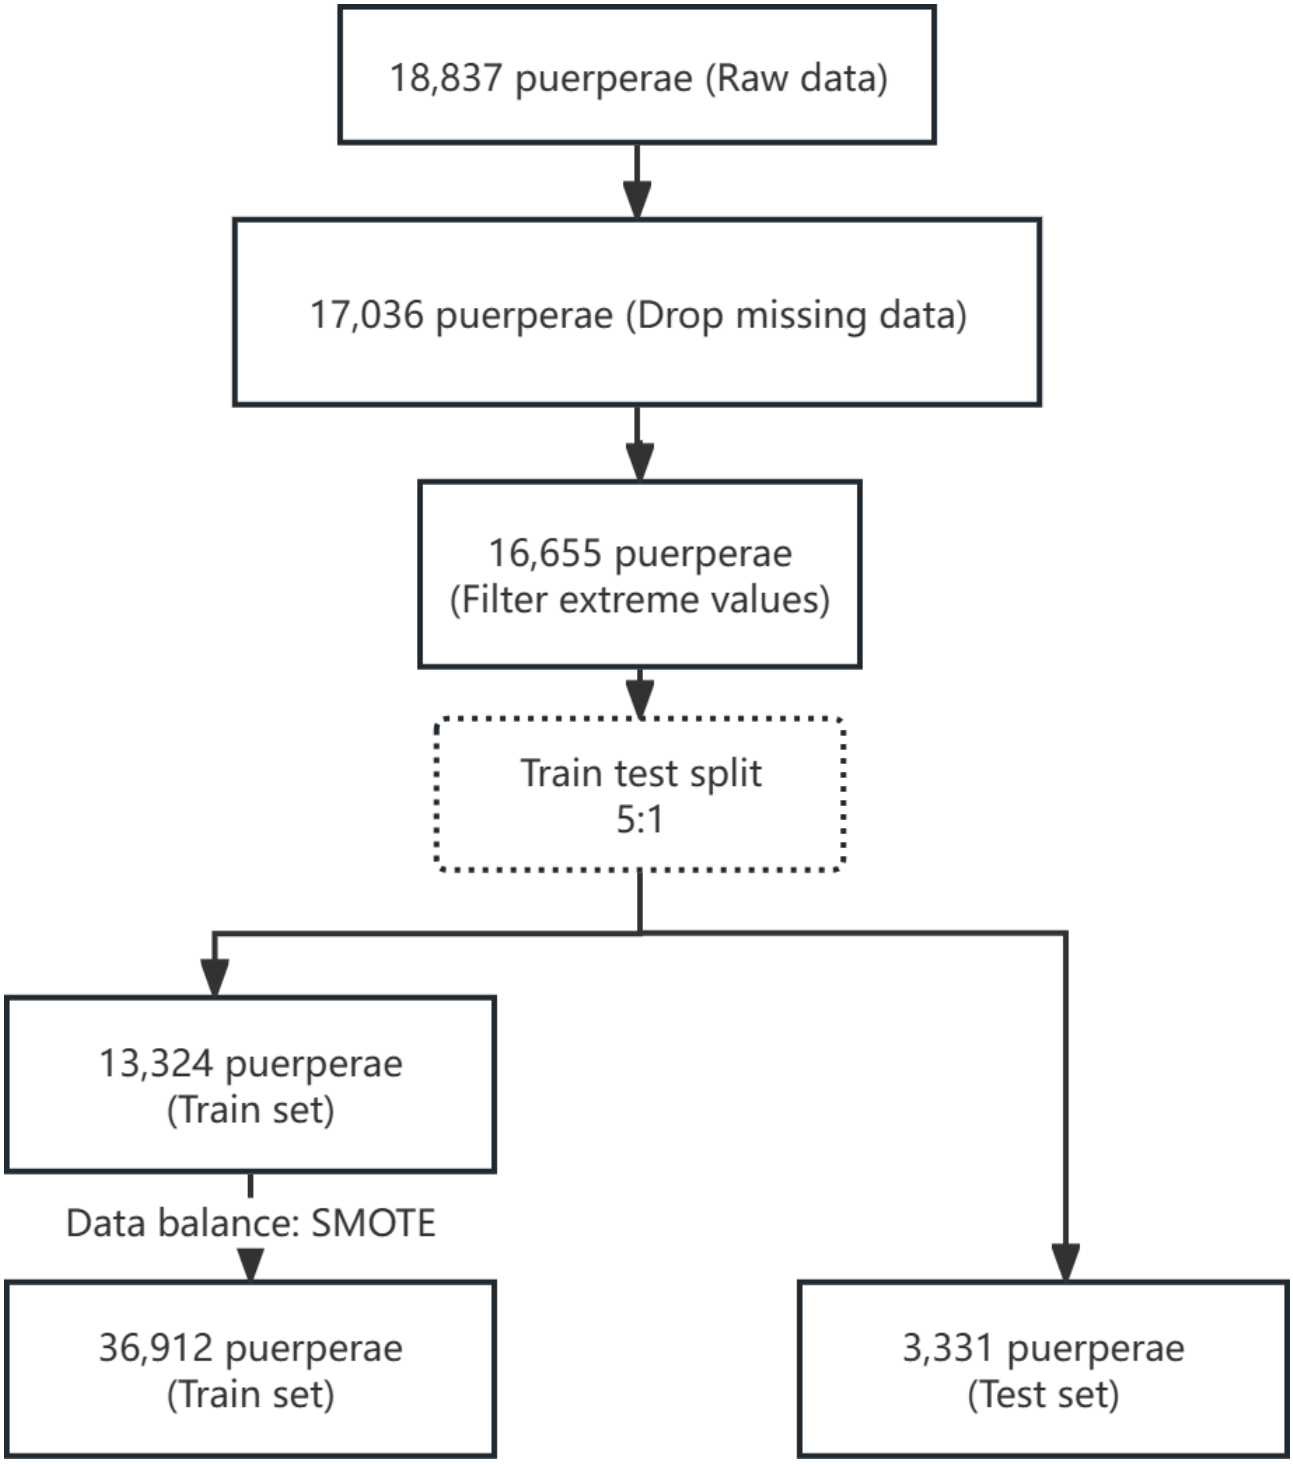
Statistical Analyses

The classification index expressed in numbers and percentages (%). The continuous data were shown as mean (SD). Kolmogorov-Smirnov (KS) divergence were used to measure whether there is a significant difference between 2 sets of data distributions, a *P* value less than .05 was deemed significant.

Ethical Considerations

International Peace Maternity and Child Health Hospital's Research Ethics Committee granted ethical approval for the usage of patient information (GKLW2021-20). We ascertained that the International Peace Maternity and Child Health Hospital's Ethics Committee waived informed consent since the research was reviewed.

Results



Sample Size and Clinical Features

A total of 16,655 individuals were enrolled in our study after application of inclusion criteria and data cleaning; 13,324 cases were included in the train dataset, and 3331 cases were included in the test dataset (Figure 2).

Table 1 provides an outline of clinical characteristics. The incidence of low birth weight and macrosomia did not differ statistically between the train dataset and the test dataset (low birth weight 1.79% vs 1.92%; *P*=.24; macrosomia 5.87% vs 5.88%; *P*=.98). There is generally good data consistency between the training dataset and the testing dataset (Table 1).

Variable Setting

Table S2 (Multimedia Appendix 1) displays 59 alternative variables, including sociodemographic characteristics, ultrasound measurements, and laboratory indices. In order to facilitate fetal birthweight prediction in the real world, a number of feature selection models were used to evaluate feature significance, as depicted in Figure 3. Due to the significance of features and the difficulty of obtaining them in the real world, few variables were eliminated before engineering implementation. A total of 17 variables were selected into our "few feather model," including "Parity," "pre_weight," "maternal_weight_last," "days_last_ul_to_delivery," "BMI," "GWG," "GA," "GWG_Inspect_Preg_Days," "GDM," "BPD," "HC," "FL," "HL," "AC," "TTD," "APTD," and "AFI" (Table 2). Those variables can be verbally responded to by pregnant women or extracted through an ultrasound report, instead of the blood test report requiring careful checking, which is convenient for clinical use and saves time.

[a]Not available.

The Development and Performance of Prediction Model

The basic models, with the exception of KNN, were substantially superior to the ultrasound formula. Therefore, KNN was omitted from the ensemble model, which was a bagging ensemble model based on the results of the remaining 5 models. Using a variety of models, including basic models and an ensemble model, to predict fetal birthweight, and comparing the results of these models to those calculated by the original ultrasound formula, while keeping only a few essential and easily-obtained variables. The ensemble model with 17 variables predicted fantasy performance displayed in Table 3 with an accuracy of 81.84% (RE≤10%） and 66.98% (AE≤250 g) , and the MSE, RMSE, and MAE were the lowest when compared with other methods. (Table S3 in Multimedia Appendix 1, and Figures 4 and 5). The results demonstrated that the effect of the final ensemble learning is greater than that of the ultrasound formula and other single models.

In addition, a segmented evaluation of the final prediction results was conducted, with division values of 2500 g and 4000 g for the 3 segments. Displaying the range of 10 percent metrics was selected. It demonstrates that the prediction effects of various models in various weight intervals were quite distinct. Some models performed better in the low weight interval, such as XGBoost and Random Forest, while others performed better in the high weight interval, such as Ridge and SVM. In addition, the MLP performed better in the normal weight range. The Ensemble Model combines the benefits and drawbacks of these distinct algorithm models, which has no serious shortcomings. The predictive effect of our established ensemble learning method significantly outweighs that of ultrasound. The accuracy for low birth weight can reach 70.30% (RE≤10%) and 73.44% (AE≤250 g). With 81.12% (RE≤10%) and 61.22% (AE≤250 g), the accuracy of macrosomia has also increased significantly (Figures 4 and 5). Besides, during the training process, trying to use more features (31 features) did not bring much improvement to the results with an accuracy of 83.49% (RE 10%) and 69.71% (AE≤250 g; Table S2, and Figure S1a and S1b in Multimedia Appendix 1). This group of controlled experiments shows that the 17 features are considered to be able to maintain good results, and to select easy obtain variables is of great significance for practical use.

Discussion

Principal Findings

As a key parameter for monitoring fetal development in utero, fetal birth weight can be used to evaluate fetal growth trends and screen for abnormal growth. Predicting the fetal birth weight in late gestation can effectively guide clinical decisions and reduce adverse pregnancy outcomes, such as increasing the survival of infants with intrauterine growth restriction and decreasing maternal-fetal complications in macrosomia delivery. Consequently, an accurate estimation of the fetal birth weight is crucial. Unfortunately, it is not possible to measure the fetal birth weight directly. Clinicians lack confidence in the estimation of the formula fetal birth weight at present due to the large variation in the accuracy of estimation results obtained through abdominal palpation or ultrasound measurement.

ML is based on clinical data, and the ML method is used to optimize health care resource use. The established ML algorithm model has high accuracy and is straightforward to implement; it is a win-win project that benefits patients, hospitals, and society; and it will have a major impact on the future of reproductive health.

In this study, data on pregnant women, including outpatient prenatal visits and hospital deliveries, was subjected to necessary feature processing and imbalanced data handling. A total of 5 ML methods were used as basic models for modeling through ensemble learning, which effectively balances the prediction effects of all models on fetuses in different weight ranges, achieving promising performance in predicting the different birth weights of newborns (low weight infants, normal weight infants, and macrosomia infants). The defining characteristic of ensemble learning is “Learn from the best.” First, it prevents underfitting by combining all the weaker learners and obtaining superior models through collective intelligence (in this case, like expert consultation, more complex learning models are obtained from advice from experts in different fields). Second, the integrated model prevents over-fitting: by combining all the results, it is simple to develop a more moderate model, thus avoiding some extreme case. Although it is not the best in all weight estimation ranges, the overall effect is the best, reducing the likelihood of large errors in a particular weight range.

In this study, the maternal sociodemographic characteristics and sonomicrometry data were inputs, and the predicted fetal birthweights were outputs of machine learning algorithms. Age, parity, mode of conception, education, prepregnancy weight and BMI, weight gain during pregnancy, gestational age, and GDM were the sociodemographic variables of the mothers. These variables are readily accessible in clinical practice and do not involve specific, difficult-to-obtain clinical indicators such as blood glucose, lipids, and protein levels, etc. In published prediction models, the input indicators usually include data such as uterine height [16] and pelvic measurements [13], which are subjective and prone to risk of bias.

Ultrasound as a direct method for measuring fetal size contributes significantly to the estimated fetal weight. Sonography is a time-saving, non-painful, and radiation-free tool that is widely used in obstetrics. In the third trimester, term-pregnant women in Shanghai undergo more than 2 or 3 ultrasound examinations. In our model, all ultrasonographic input data come from a reliable and accurate ultrasound report. In our model, we accounted for the time between the acquisition of ultrasound data and maternal delivery outcomes, which may have contributed to the model’s accuracy. However, Lu et al [16] and Shigemi et al [17] abandoned ultrasound data to benefit pregnant women in clinical practice, considering limited medical resources, whereas, at the expense of lower accuracy (the accuracy of Lu’s model is only 64.3%). Ultrasonography has become the most common auxiliary examination in obstetrics because of its security. In the vast majority of patient populations, ultrasound data need not be discarded. Our predictive model maximizes the clinical use of ultrasound and has significant implications for antenatal monitoring, antenatal assessment, intrapartum decision-making, and postpartum care. On the contrary, Ye et al [18] established an ensemble model, only used ultrasonographic measurements based on 26 different empirical ultrasonographic formulas. The risk factors associated with macrosomia were not collected thoroughly; therefore, the model did not provide the greatest benefits.

Compared with previously published predicted models, our model predicts fetal birth weight ranges with greater precision. Gao et al [14] adopted back propagation neural network model with the accuracy rate of 76.3%. Another previously published model reveals that the genetic algorithm-optimized neural network model’s accuracy is 74.9% [19]. In addition, 1 study found that the accuracy of prediction was only around 80% among GDM pregnant women [20]. Both low birth weight (2500 grams) and macrosomia (≥4000grams) are major public health concerns. In contrast to ultrasound’s poor performance in estimating extreme fetal weight, our model not only has excellent predictive performance in normal weight, but also in estimating extreme fetal weight. Although numerous studies

XSL•FO
RenderX

have been conducted in the field of predicting extreme body weight, many prediction models consist only of simple binary variables ("Yes or No") and do not provide quantitative results [13,21-23]. In our model, the evaluation metrics for accuracy were based on predicting birth weight within ±10% or ±250g, which are two of the most commonly used metrics in the existing literature. For larger birth weights, the ±250g metric may better reflect the accuracy of the model, while for smaller birth weights, the ±10% metric is more appropriate for assessing the model's precision. In our study results, the ensemble learning model demonstrated satisfactory predictive performance in both the <250 g and >4000 g subgroups. In contrast, other models exhibited better predictive ability in only one of the extreme weight categories. Our model's accurate estimation of fetal birth weight values will improve clinical decision-making and have significant clinical application value.

In order to turning our ML model into practice, we transformed the simple optimization model into a mobile application with a visual page to provide pregnant women, obstetricians, and midwives with a real-time, efficient method for fetal birthweight estimation (Figure S2 in Multimedia Appendix 1). In the future, with the purpose of improving the accuracy of fetal weight estimation, we will embed the original model into the doctor's medical record workstation so that it can cover more variables and retrieve the relevant data automatically.

Limitations

This model is primarily designed for monitoring the fetal growth trend in the third trimester, not the second. The subsequent research can further expand the data set (including the first and second trimesters) in order to optimize the ML algorithm for estimating the fetal weight at various gestational ages.

Fetal birthweight is also closely associated with genetic predisposition. In our study, we lack the husband or partner's more relevant information, such as weight, height, and weight gain during pregnancy. Provided it is possible, we can also obtain the parental birth weight. For further study, we can invite the husband or partner to join our first interview for more details.

Conclusions

Assessment of the fetal birth weight in late-pregnant women before delivery presents numerous challenges, but also presents an opportunity for the advancement of ML in the obstetric field. In our study, 5 fundamental algorithms (Ridge, SVM, Random Forest, XGBoost, and Multi-Layer Perceptron) and an ensemble learning model were investigated to determine the algorithm with the best performance in fetal birth weight prediction. As anticipated, ensemble learning performed the best and was chosen to create a mobile application for pregnant women and obstetric staff. We believe our model will promote precision medicine and improve the quality and efficiency of maternal and fetal health care, despite the need for additional experiments.

Abstract

Background: Early childhood interventions can simultaneously promote positive health and early language experiences, but implementation and health equity often receive insufficient attention during the development process.

Objective: We apply a health equity lens to refine and pilot-test a family literacy and wellness program designed for Latino dual language learners (DLLs) entering kindergarten and their caregivers.

Methods: In collaboration with a parent and community advisory board, we refined an 8-week family literacy and wellness program and conducted a pilot randomized controlled trial (RCT) with a waitlist control. The program, specifically designed by our interprofessional team for Latino DLLs, uses health topics (ie, nutrition, physical activity, sleep, and social-emotional development) to (1) introduce foundational language and literacy skills to children; (2) empower families to engage in health and home literacy activities using a strengths-based approach; and (3) encourage maintenance of families' home language. We assessed reach by collecting sociodemographic information; attendance and acceptability using a parent survey; and preliminary effects on home literacy activities through a validated parent-report instrument ($StimQ_2$ quantity, quality, content, and concepts subdomains) and on child literacy skills using investigator-developed assessments. We analyzed quantitative data using descriptive statistics and regression analyses.

Results: Parents and community advisors informed the program content. A total of 32 parent-child dyads were enrolled in the pilot RCT. All parents identified as Latino, and half had not completed high school, indicating that we reached the intended audience. Parents rated the program as highly acceptable, and 23 (72%) participants attended at least half of the sessions. After participation, group 1 had higher $StimQ_2$ quality scores (effect size 0.99, P=.02) and higher quantity scores (effect size 1.01, P=.04) compared with group 2.

Conclusions: Similar interprofessional collaborations may be a promising strategy to promote equity in early language experiences for Latino DLLs and their families.

Introduction

Education is critically important for health and well-being, yet this social driver of health has received insufficient attention in health care settings [1]. Kindergarten performance is a strong predictor of health risk behaviors and indicators of well-being, such as college education [2-4]. As a result, existing inequities in kindergarten readiness [5,6] pose a threat to long-term health and well-being at both individual and population levels.

The US Department of Health and Human Services and the US Department of Education define dual language learners (DLLs) as children with a home language other than English who are learning 2 or more languages simultaneously or learning a second language while still developing their first language [7]. Latino DLLs are a rapidly growing segment of the population who face discrimination and unequal opportunities, predisposing them to poor educational, occupational, and health outcomes [8,9]. Sustainable interventions to support this population are therefore urgently needed.

Pediatric clinicians are in a unique position to implement early childhood interventions that promote optimal school readiness, given their near-universal access to young children, frequent contact with families, and opportunities to build and leverage strong parent-clinician relationships [10-12]. Several programs are designed to be embedded within early childhood settings to promote early language development among DLLs [13,14]. However, early childhood interventions can simultaneously promote both physical and academic school readiness. Interventions focused on family literacy offer a clear example. Family literacy can be defined as the way families use literacy in their homes and communities, including during typical routines [15-17]. Families already engage in a wide range of literacy activities that are present in many health-related routines (eg, reading food labels). Embedding these practices into family literacy programs may provide a more ecologically valid intervention—one rooted in existing rather than entirely new practices and one that embraces cultural diversity. Few early childhood interventions take advantage of these opportunities. One example is a program that uses culturally sensitive, typical family food routines to support children's language and literacy skills, such as vocabulary, decoding, and writing [18]. Programs can adopt this approach to engage families and build cross-sector partnerships between pediatric professionals and educators—partnerships that find synergy in their complementary expertise. Despite their potential to promote equity through family engagement, such cross-sector partnerships remain rare.

Implementation often receives insufficient attention early in the development of health promotion interventions. This is critical, as a limited understanding of community context and partner priorities can potentially diminish—or even eliminate—an intervention's impact [19]. Baumann and Cabassa [19] identified key elements that can support the integration of an equity lens early in implementation research, including a focus on reach from the outset and the intentional design of interventions with historically marginalized populations in mind. Partnered approaches from the earliest stages of intervention design and refinement can help promote health equity, yet they remain rare. To our knowledge, few early childhood interventions have leveraged this strategy.

To address these gaps, we applied implementation science with a health equity lens to refine and pilot-test an online family literacy and wellness program designed for Latino DLLs entering kindergarten and their families. Using community-engaged research strategies, we partnered with parents to refine the program and subsequently conducted a pilot randomized controlled trial (RCT). Consistent with the approach proposed by Baumann and Cabassa [19], we intentionally focused on intervention reach, design, and equity-relevant implementation outcomes. These insights can inform similar cross-sector education-health care partnerships that aim to promote equity for Latino DLLs and their families.

Methods

Study Design and Registration

We conducted a pilot study using an RCT with a waitlist control design.

Ethical Considerations

The Rutgers Health Institutional Review Board approved this study (approval number Pro2021001575). All participants provided informed consent. Data were deidentified. Participants received a US $25 retail gift card for each study visit completed. The study was registered before enrollment of the first participant at ClinicalTrials.gov (NCT05339464). We followed CONSORT (Consolidated Standards of Reporting Trials) guidelines for reporting clinical trials [20].

Study Population and Setting

We recruited Latino DLLs (aged 4 - 6 years) and their parents from Eric B. Chandler Health Center, a local Federally Qualified Health Center, and the surrounding greater New Brunswick area. Eric B. Chandler Health Center primarily serves Latino individuals from underresourced communities. Clinicians at the center referred potentially eligible participants to the study team. We also advertised the study with our local community partners using recruitment flyers and word of mouth. Eligibility criteria included primary caregivers aged ≥18 years (referred to as parents for the remainder of this article) of children entering kindergarten who identified as Latino, used Spanish at home, owned a cellphone, and were willing to receive SMS text messages and be randomized. We excluded children with multiple anomalies or genetic disorders, as well as those with previously identified developmental delays.

Program Refinement

We partnered with our parent advisory board through a series of community engagement studios that helped refine the program throughout the project [21]. The parent advisory board consists of parents who participated in past iterations of the family literacy and wellness program. All parents identify as Latino and prefer Spanish as their primary language for communication. Their children are in kindergarten, first grade, or second grade, providing a range of scholastic experiences and perspectives on their children's needs. We conducted 7

XSL•FO
RenderX

community engagement studios with our parent advisory board from January 6, 2021, to January 30, 2023. We adapted the community engagement studio concept from the approach developed by the Meharry-Vanderbilt Community Engaged Research Core [21] to facilitate meaningful participation and engagement. Each studio focused on a specific aspect of the program. Bilingual team members presented relevant information about the program, and a bilingual research coordinator then facilitated dialogue to elicit parents' feedback on the content and procedures. Through this process, parent advisors provided substantive input on the program's mission, intervention content, and logistics. The project also includes a community advisory board composed of local community leaders, including educators, a pediatrician, a librarian, and a community health expert, that meets regularly to advise the team on outreach and engagement strategies, as well as program content.

Study Conditions

All parent-child dyads participated in the family literacy and wellness program, Ready and Healthy for Kindergarten. Parent-child dyads were enrolled and randomized 1:1 to either the first group (June-July) or the second group (July-August). The randomization schedule was computer generated by the study biostatistician (POS). Allocation concealment was maintained using the REDCap (Research Electronic Data Capture; Vanderbilt University) randomization module. Participants in both groups received a book bag with school supplies, an activity kit, and program books at enrollment. The program was specifically designed by our interdisciplinary team (ie, education, linguistics, and pediatrics) for Latino DLLs, using health topics (ie, nutrition, physical activity, sleep, and social-emotional development) to (1) introduce and reinforce foundational language and literacy skills to children, (2) empower families to engage in health and home literacy activities using a strengths-based approach, and (3) encourage the maintenance of families' home language and cultural traditions [22,23]. The program is designed to be strengths-based by building on families existing routines and inviting caregivers to incorporate new ones that support their goals and the objectives listed above. For example, during the nutrition topic, teachers may highlight how following a family recipe during meal preparation, whether written or recalled from memory, offers embedded opportunities for sequencing tasks, storytelling, and interaction. During the physical activity topic, teachers may point out how everyday simple family activities, such as walking to the bus stop, can include literacy-rich moments like reading street signs. Each session follows a predictable structure that draws out families' existing routines. Teachers use language flexibly and authentically, in alignment with the families' preferences, to tacitly normalize bilingualism and position home language maintenance as the standard, thereby empowering participation. In addition, the social-emotional unit includes a dedicated session focused on cultural pride, honoring one's heritage, and highlighting the advantages of multilingualism, explicitly encouraging the maintenance of the home language.

We first offered the program in person at Eric B. Chandler Health Center in 2019 [22]. This initial iteration established the program structure, which included (1) 8 parent-child workshops; (2) take-home kits, including a book bag with school supplies, activity kit, and program books, to support at-home extension activities that reinforced session content; and (3) reminder SMS text messages that reinforced in-class content [22]. In 2020, in response to the COVID-19 pandemic, the workshops shifted to an online format using videoconferencing software [23]. We retained the virtual format for the 8 parent-child workshops, which we then refined and pilot-tested in this study.

Data Collection

Trained bilingual research assistants collected data online via secure videoconference software at 3 time points: enrollment (study visit 1); approximately 2 months after enrollment, after group 1 completed the program and before group 2 began (study visit 2); and approximately 4 months after enrollment, after group 2 completed the program (study visit 3). Recruitment began in March 2024, the first study visit occurred on May 9, 2022, and the last study visit took place on September 25, 2022. In this paper, we focus on between-group differences in parent literacy and language activities and child outcomes at study visit 2, which captures the period after group 1 completed the program and before group 2 began.

Implementation Outcomes

Reach

As noted by Baumann and Cabassa [19], equity research requires attention to reach, that is, who is included in and participating in research. To assess whether the program reached its intended audience, we examined demographic characteristics of parent-child dyads, including ethnicity, parent education, and self-reported English proficiency.

Attendance

To understand the extent to which parents and children would use the program, we examined session attendance. A study team member documented attendance at each session.

Acceptability

Acceptability can be defined as users' perception of the extent to which a treatment or service is satisfactory [24]. In this study, we assessed acceptability using the Acceptability of Intervention Measure (AIM) [25], a validated 4-item survey that evaluates participants' perceptions of program acceptability.

Parenting and Child Outcomes

Parenting Outcomes

The $StimQ_2$ is a validated parent-report measure of the home cognitive environment, available in both English and Spanish [26]. In the validation sample, 93% of caregivers identified as Latino, 76% completed the surveys in Spanish, and 91% were classified as having low socioeconomic status based on the Hollingshead Four Factor Index. We used the $StimQ_2$ READ scale to explore the program's effects on parent-home literacy activities, focusing on subdomains that assess quantity, quality, content, and concepts. We used the $StimQ_2$ Parent Verbal Responsivity (PVR) scale to examine verbal responsivity during parent-child interactions. Both the READ and PVR subscales demonstrate good reliability (Cronbach α=0.753 and 0.790,

XSL•FO
RenderX

respectively) and strong validity, as indicated by correlations with assessments of child language, cognitive ability, and social-emotional skills.

Child Outcomes

We used investigator-developed assessments to explore the program's effect on child outcomes. These assessments were administered by a bilingual research assistant in the child's preferred language. Here, we focus on tests of children's development in letter identification, letter sound identification, thematic vocabulary identification, and book awareness. To assess book awareness, children were asked to identify different print concepts (ie, front and back cover, title page) using a book of their choice. The examination of letter and sound identification involved an untimed task in which children were asked to identify 10 different letters (presented in upper and lower case) and to produce their corresponding sounds. Vocabulary identification, focusing on words discussed during the workshops, such as healthy habits, foods, and family routines, was assessed using a picture-based vocabulary recognition task.

Sample Size

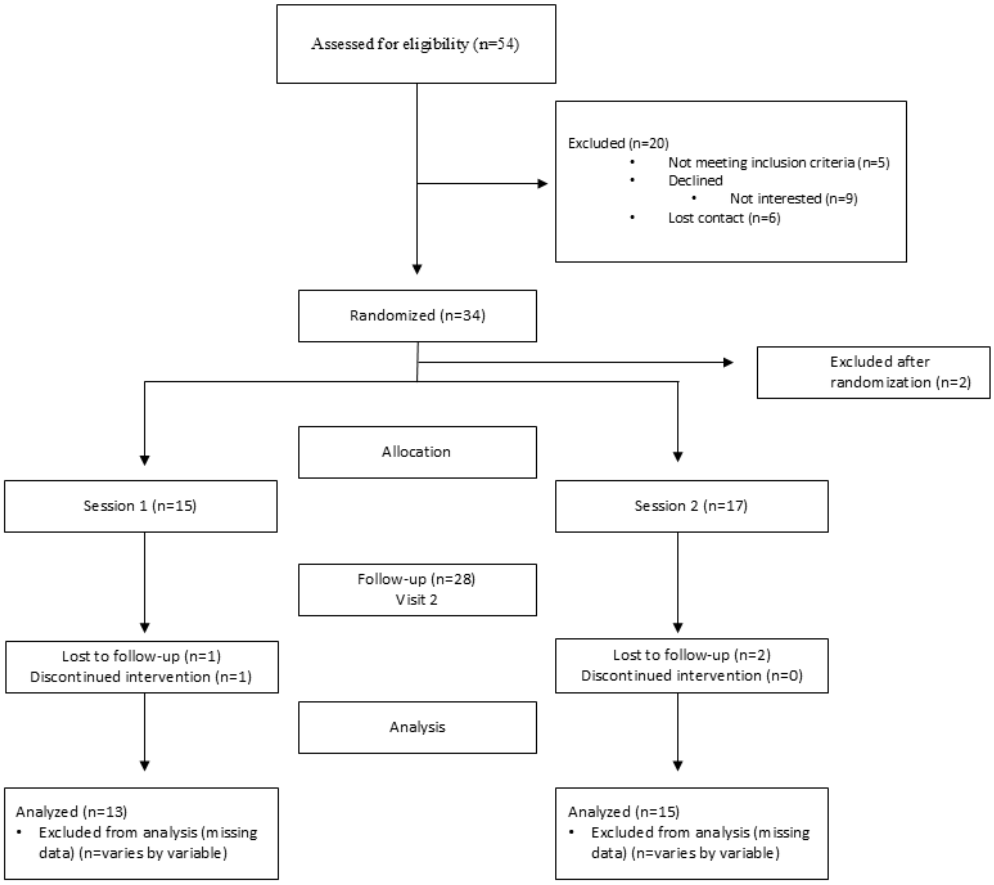
In determining our sample size, we considered the main objective of this pilot study, to examine equity-relevant implementation outcomes such as reach, engagement, and acceptability, and to explore the program's preliminary effects on parenting and child outcomes in an exploratory manner. We also followed best practice recommendations [27,28]. Based on these factors, our goal was to randomize at least 24 participants (12 per arm). The recruitment response exceeded our expectations, and we enrolled more participants to avoid turning interested families away.

Data Analysis

We first calculated means and SDs or percentages for continuous or categorical variables to examine reach using sociodemographic data, engagement using attendance logs, and acceptability using AIM survey responses. Participants were analyzed according to the group to which they were originally randomized. Participants who discontinued or were lost to follow-up were excluded from analyses. We used regression models to explore between-group differences in home literacy activities measured by the $StimQ_2$ READ scale total score and its subdomains, quantity, quality, diversity of concepts, and diversity of content, as well as responsive verbal interactions assessed by the $StimQ_2$ PVR. In addition, child literacy skills were evaluated using investigator-developed assessments focused on letter identification, letter-sound knowledge, vocabulary, and book awareness. We adjusted for the following important a priori–identified covariates: baseline scores, child age, child language, and parent education. To enable comparison across outcomes, we calculated effect size estimates by dividing the treatment coefficient from the regression models by the residual SD of each outcome.

Results

Program Refinement



The parent advisory board helped shape the program's logistics and content. Drawing on their experience with the program, parents provided specific feedback that guided decisions about session length, program duration, and optimal dates and times for the online sessions. Synthesizing this feedback, we kept sessions under 1 hour, offered multiple evening options on weekdays, and scheduled Saturday sessions in the late morning or around noon. Parents also provided guidance and feedback on recruitment strategies and materials, which helped enhance reach. During meetings, they also offered input that informed adjustments to instructional pace, use of materials, and routines for parent-child interactions. Key considerations were whether the materials were easy to read and use at home. For example, children enjoyed opportunities to draw pictures starting with the session's focus letter, and parents shared that their children liked cutting out cards to practice letter sounds. As a result, we adapted the session content and at-home activity kits to include more opportunities for these activities. Families found the at-home extension activities enjoyable and identified them as a strength. Parents also reported that the school supplies sent home in the backpack were useful for their home learning environment.

Pilot Study

A total of 54 parent-child dyads initially expressed interest in participating; however, 5 of these dyads did not meet the inclusion criteria, 6 were lost to contact, and 9 declined participation. The most common reason for declining was lack of interest. Ultimately, we randomized 34 parent-child dyads (Figure 1). Two parent-child dyads were later excluded for not meeting eligibility criteria, resulting in a final enrolled sample of 32 dyads. Among these, 3 parent-child dyad groups were lost to follow-up, and 1 dyad discontinued participation, leaving 13 dyads in group 1, and 15 dyads in group 2.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flowchart.

Reach

Demographic characteristics are summarized in Table 1. All participants identified as Latino (N=32), with 16 of 32 (50%) reporting Mexican origin; 29 out of 32 (91%) reported speaking English less than very well, and 17 (53%) had not completed high school. At enrollment, children were on average 4.5 years old, and 20 (63%) were identified as native-like Spanish speakers. These characteristics suggest that the program reached the intended audience.

High school diploma or greater	15 (47)	10 (67)	5 (29)

[a]Parents' response to "How well do you speak English?"

Attendance

Program attendance is summarized in Table 2. Seventy-two percent of parents (23/32) attended at least half of the sessions. Timing appeared to influence attendance, with lower participation observed in the second half of the summer. Some families reported traveling internationally or taking on additional

XSL•FO
RenderX

seasonal work during this period, which may have impacted their ability to attend.

Table . Number of workshops attended by participants during the family literacy and wellness program (n=32).

Number of sessions attended	Number of participants
0	4
1	1
2	2
3	2
4	3
5	2

7	5
8	8

Acceptability

On average, parents agreed that the program met their approval, it was appealing, they liked the program, and they welcomed what they learned (Table 3).

Table . Acceptability of intervention survey among the study population (n=25 parents).

AIM[a] question	AIM score, mean (SD); range[b]
The program met my approval.	3.5 (0.5); 3-4
The program was appealing to me.	3.5 (0.5); 3-4
I liked the program.	3.5 (0.5); 3-4
I welcome what I learned in the program.	3.5 (0.5); 3-4

[a]AIM: Acceptability of Intervention Measure.

[b]0=completely disagree, 1=disagree, 2=neither agree nor disagree, 3=agree, and 4=completely agree.

Parenting Outcomes

Results of the $StimQ_2$ READ and PVR scales are presented in Table 4. Although not statistically significant, there was a moderate difference on the total $StimQ_2$ READ scale between group 1 (ie, those who completed the program) and group 2 (ie, those who had not yet begun; Cohen *d*=0.55; *P*=.23). However, there were large and statistically significant differences between the groups on the quantity and quality subdomains (Cohen *d*=1.01; *P*=.04 and Cohen *d*=0.99; *P*=.02). By contrast, the between-group difference on the PVR scale was small and not statistically significant (*P*=.75).

Table . Effects of Ready and Healthy for Kindergarten participation (group 1) compared with waitlist control (group 2) on the Home Literacy Environment and Parent Verbal Responsivity scale scores.[a]

Measures	Group 1, effect size estimate (95% CI)	*P* value
$StimQ_2$ READ scale[b]		
Total score	0.55 (−0.44 to 1.10)	.23
Subdimensions		
Book reading quantity	1.01 (0.05 to 1.52)	.04
Book reading concepts	−0.20 (−1.41 to 0.52)	.66
Book reading content	0.02 (−1.09 to 0.68)	.95
Book reading quality	0.99 (0.18 to 1.41)	.02
$StimQ_2$ Parent Verbal Responsivity Scale[b]	0.14 (−0.92 to 0.76)	.75

[a]Linear regression analyses were conducted, adjusting for baseline scores, child age, child language, and parent education. Effect size estimates were calculated by dividing the treatment coefficient from the regression models by the residual SD of each outcome.

[b]Subscale of the $StimQ_2$-Preschool, a parent-report questionnaire that assesses the cognitive home environment for children aged 36-72 months.

RenderX

Child Outcomes

Child outcomes are summarized in Table 5. Between-group differences in letter identification, letter-sound knowledge, and vocabulary were either minimal or in an unexpected direction. However, a moderate-to-large effect, though not statistically significant, was observed for book awareness (Cohen *d*=0.82; *P*=.11).

Table . Effects of Ready and Healthy for Kindergarten participation (group 1) compared with waitlist control (group 2) on child skills.[a]

	Group 1, effect size estimate (95% CI)	*P* value
Letters identified	0.07 (−1.07 to 0.71)	.88
Letters sounds identified	−0.03 (−1.18 to 0.64)	.95
Vocabulary words identified	−1.68 (−5.84 to 0.21)	.10
Book awareness	0.82 (−0.23 to 1.35)	.11

[a]Linear regression analyses were conducted, adjusting for baseline scores, child age, child language, and parent education. Effect size estimates were calculated by dividing the treatment coefficient from the regression models by the residual SD of each outcome.

Discussion

Principal Findings

In this study, we refined an online family literacy and wellness program using parent feedback. During pilot testing, we found that the program effectively reached and engaged Latino DLLs and their families. We also observed promising improvements in parent home literacy activities after participation. The intentional involvement of families and community partners throughout the research process, along with a deliberate focus on reach and other early implementation outcomes, provided valuable insights into applying a health equity lens to early childhood interventions. These findings offer guidance for interdisciplinary teams aiming to build cross-sector collaborations and move beyond siloed efforts in the pursuit of equity.

The US Centers for Disease Control and Prevention defines health equity as “the state in which everyone has a fair and just opportunity to attain their highest level of health” [29]. The Robert Wood Johnson Foundation elaborates that achieving health equity “requires removing obstacles to health such as poverty, discrimination, and their consequences, including powerlessness and lack of access to good jobs with fair pay, quality education and housing, safe environments, and health care” [30]. Such obstacles drive health inequities, and health care organizations have developed programs in response to growing evidence that social needs impact health [31]. However, health care interventions have largely missed the opportunity to address educational achievement, an important social driver of health that underlies both social and health outcomes [32]. As a cross-sector partnership between health and education, Ready and Healthy for Kindergarten aims to promote health equity by coaching families on how to implement healthy routines early, while supporting children’s development of literacy and numeracy skills that foster health literacy and wellness throughout their life course.

All caregivers in our sample identified as Latino, and half had not completed high school, indicating that the program successfully reached the intended audience. The family literacy and wellness program was designed to address the specific needs of this population, with careful consideration of their linguistic and ethnic backgrounds. Central to this approach, our program is bilingual, supporting children’s language development while honoring and accommodating parents’ linguistic preferences. The focus on families from Latino backgrounds encompassed not only the language of implementation but also the cultural aspects embedded in the program. Meta-analyses support that family literacy programs increase parent literacy activities and improve child emergent literacy [33,34]. However, low participation and engagement among Latino parents from underresourced communities have been major weaknesses of these programs [35]. There are important modifiable program design weaknesses [18]. First, similar programs have been criticized for taking a deficit approach and imposing dominant cultural activities on families without building on their unique strengths [35,36]. Such approaches do not take into account parents’ experiences with activities such as reading, which may be negative [37]. Second, while bilingual programs are emerging, most do not build on families’ heritage language, which is a major issue [38-41]. Third, there is a paucity of studies focused on engagement with Latino families from underresourced communities [18]. By engaging parents as partners throughout the research process and refining the program based on their feedback, we were able to overcome many of these barriers and reach the intended audience with high attendance levels.

Consistent with previous work, we found that the online family literacy and wellness program was well attended and highly acceptable to families [22,23]. This study extends our prior work by demonstrating promising patterns in both the quantity and quality of home literacy activities. Although we did not identify differences in letter identification, letter-sound knowledge, and vocabulary, it is possible that 8 weeks is not sufficient time to detect these differences. Although not statistically significant, the moderate to large effect on book awareness aligns with the enhanced quantity and quality of home literacy activities. One possibility is that by increasing parent literacy activities during the summer before kindergarten, improvements in child outcomes may be observed later. Future studies will need to follow children for a longer period to test this hypothesis—an issue we are currently addressing in our ongoing work.

This work is subject to certain limitations. First, while pervasive inequities in school readiness and wellness provide a strong rationale for focusing on Latino DLLs and their families, our

XSL•FO
RenderX

findings may not generalize to all settings or other populations. Future work is needed to tailor program content for participants from different racial and ethnic backgrounds. Second, as this was a pilot study, the primary focus was on examining equity-focused implementation outcomes including reach, attendance, and acceptability. While a sample size of 32 aligns with recommendations for pilot studies [27,28], it is possible that the statistical analyses did not have adequate power to detect differences in parent and child outcomes that may be meaningful. Further, we were unable to examine a threshold for the dose of the intervention necessary to affect outcomes; we are addressing this limitation in our ongoing work. Third, we relied on parent-report measures for home literacy activities and health routines, which may be subject to recall bias and social desirability. Future work should incorporate observational measures to help address this limitation. Fourth, engagement with an intervention goes beyond usage and must capture the relationship between the program and the intended goal of the intervention [42], in this case empowering caregivers to build on their existing strengths and support their children's physical health and school readiness. While this was beyond the scope of this pilot study, we plan to address it in future work.

Conclusion

We found that a family literacy and wellness program designed for Latino DLLs reached the intended audience, achieved strong attendance, and showed promising patterns in home literacy activities. While additional work is needed to definitively test the program's effects and identify optimal implementation strategies, these findings suggest that such interdisciplinary collaborations could be a promising approach to promote equity in children's early language experiences.

Acknowledgments

This project was funded under grant number R18HS028574 from the Agency for Healthcare Research and Quality (AHRQ), US Department of Health and Human Services (HHS). The authors are solely responsible for this document's contents, findings, and conclusions, which do not necessarily represent the views of AHRQ. Readers should not interpret any statement in this report as an official position of AHRQ or HHS. None of the authors have any affiliation or financial involvement that conflicts with the material presented in this report. We thank our partners who contributed to the development and delivery of this program. The parents on the Parent Advisory Board generously contributed their time and ideas to refine the program and set its priorities. The board included the following parents: Morena Castillo, Nely Chanes, Sofia Gonzalez, Aleyda Elias, Gabriela Zepeda, Glennys Cruz, and Romina Jimenez. The sessions were facilitated by two dedicated teachers, Lirizell Johnson and Diana Galindo. They contributed to the refinement of the sessions, built positive relationships with the children and their families, and brought enthusiasm to each session. We also acknowledge the support from the staff at Greater Brunswick Charter School, especially Lilia Fabila-Guilbot and Hector Alvarez, for their contributions to this program and their commitment to promoting child and family well-being. Additionally, we thank pediatricians Drs. Usha Ramachandran and Shilpa Pai for their support.

Abstract

Background: The prevalence of and growth in digital technology present opportunities for educational and social enrichment; however, there are also many health and digital safety risks for children engaging with digital technology. While there is a growing body of research on digital safety programs to enhance children's digital safety through parental support, evidence regarding the effectiveness of such interventions remains limited.

Objective: This study aimed to evaluate the effectiveness of digital safety interventions on parental practices related to safeguarding children's digital activities.

Methods: The review was conducted following the Joanna Briggs Institute methodology for systematic reviews and has been reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. A comprehensive search was performed in May 2024 in MEDLINE, CINAHL Ultimate, PsycINFO, Web of Science, The Allied and Complementary Medicine Database, ProQuest Central, and IEEE Xplore databases to identify peer reviewed articles that were (1) published in English, (2) included parents as participants, and (3) reported on programs or interventions designed to enhance parents' knowledge and skills to safeguard children's digital safety.

Results: A total of 11 published studies between 2012 and 2024 were included in the review. Data from 8 studies were included in the meta-analysis. A significant effect (Hedges g=–0.47; 95% CI –0.85 to –0.08; P<.001) was observed in children's screen time in the 5 randomized controlled studies, while a large effect size was observed in 3 quasi-experimental studies (Hedges g=1.90; 95% CI –4.36 to 8.16; P<.001). A substantial level of heterogeneity was evident in the randomized studies (I^2=87.95%). The quasi-experimental studies exhibited no heterogeneity (I^2=0%). Overall, parents' digital safety knowledge and skills improved as a result of the digital safety interventions. Notably, children's screen time (P=.04) and parents' own screen time (P=.001) decreased following the digital safety intervention.

Conclusions: Parents who participate in digital safety interventions report higher levels of knowledge and skills related to digital safety, as well as a shift in attitudes, including the intention to implement strategies to safeguard their children engaging with

XSL•FO
RenderX

technology. The enhanced knowledge and skills reported in these studies led to measurable reductions in both parents' and children's screen time. Future research should identify strategies that address community norms and other digital safety risks beyond screen time and bullying, which were predominant outcomes in these studies.

KEYWORDS

child; parental mediation; digital safety; parental education; meta-analysis; intervention effectiveness; screen time; digital technology; digital literacy

Introduction

Technology has transformed the way children learn, socialize, and interact with the world. Internet and digital technology have made access to new information from afar more accessible and immediate [1,2]. Digital technology is embedded in the school system [3] and this means that children spend a significant portion of their time engaging with and using digital technologies to perform daily tasks such as homework, to form and nurture friendships, and for entertainment [1]. These digital advancements offer a wealth of opportunities for educational and social growth, with evidence indicating that moderate use of digital technology can positively impact children's learning, development, and mental well-being [4,5], mainly through enhancing children's literacy and numeracy skills, manual dexterity, and visuo-spatial working memory [6]. The rapid integration of digital technologies into daily life has increased the use of digital technology in schools and at home, with parents admitting being obligated to embrace the digital world that is often new to them, as their children now access web-based school learning resources, such as homework and timetables [7]. Digital technology use has impacted children of all ages, including children less than a year old, who spend time on digital media privately or independently [5]. However, in Australia, digital technology use and access to digital platforms increase with age, with adolescents (13-17 years) having access to various social media platforms, such as YouTube (86%), Facebook (75%), Snapchat (67%), and Instagram (70%) [8].

Healthy digital use among children has been debated, with Suresh and Tiwari [5] recommending minimal technology use of 1 to 2 hours a day for children aged 3 to 8 years. The American Academy of Pediatrics reinforces this stance, and they further recommend that children younger than 2 years should not engage in screen time [9]. In 2016, the Canadian Society of Exercise Physiology released the 24-hour movement guidelines tailored for children and young people aged 5 to 17 years, which are intended to assist parents and educators to promote appropriate daily levels of physical activity, manage screen time, and ensure adequate sleep duration [10]. Various countries, including Australia [11], South Africa [12], and New Zealand [13], along with international bodies such as the World Health Organization [14], have adopted these guidelines. However, experts from the Australian Research Council Centre of Excellence for the Digital Child have contended that while limiting screen time is often recommended in these guidelines, such restrictions may overlook potential developmental benefits [15].

Recent evidence indicates that children report spending up to 4 hours or more (outside their digital classes) of screen time on their technological devices, such as computers, television, smartphones, video games, and other mobile devices such as iPads [1]. Alongside its countless benefits, the digital space can pose several risks, particularly for children who lack the experience and understanding to navigate it safely. Scholars argue that the increasing use of digital technology among children has amplified their exposure to a broad spectrum of web-based risks, including cyberbullying, exposure to inappropriate content, privacy violations, digital addiction, and online sexual exploitation [16,17]. These threats can impact children's mental well-being and lead to mental disorders, such as depression or anxiety [18,19]. Parents are tasked with the primary role of protecting their children's well-being, and this now needs to encompass digital safety: defined in this review as safeguarding children from web-based risks such as cyberbullying, exposure to inappropriate content, privacy violations, online sexual exploitation and the inappropriate use of digital technologies including excessive screen time that can lead to digital addiction and negative mental health outcomes [20,21]. However, the digital landscape offers a high level of anonymity and accessibility that complicates direct oversight, making parents feel unequipped to navigate the vast and rapidly evolving digital space [22].

Therefore, it is essential to position parents as active participants in mitigating potential harm by developing effective digital safeguarding practices that facilitate children's safety [23,24], giving parents a primary role in moderating the use of technology by monitoring, guiding, and supervising their children [5,24]. Banić and Orehovački [23] emphasize that parents must participate in their children's digital technology usage. This means parents need to be equipped with the knowledge, skills, and values necessary to foster safe and responsible navigation of the digital landscape by children while safeguarding their well-being [1]. However, despite the wide embrace of digital platforms, the capacity of parents to effectively safeguard their children's digital activities remains inconsistent, often constrained by varying levels of digital literacy, awareness of web-based risks, and access to appropriate resources.

Various digital safety interventions have been developed to equip parents with the knowledge and tools to protect their children in the digital space. Despite this growing number of digital safety interventions available to parents, there remains a lack of comprehensive evidence regarding their effectiveness in improving parental knowledge, skills, and practices and, ultimately, enhancing child safety on the web. Recent reviews

XSL•FO
RenderX

have highlighted the significance of parental mediation through strategies such as educational programs, digital monitoring tools, parental controls, and strategies for fostering open communication between parents and children about web-based risks [23,25-27].

Existing reviews on the topic predominantly focused on the effects of digital literacy practices on children's learning, identifying parental mediating strategies, and factors affecting parental mediation strategies [23,25-29]. None of the existing reviews has evaluated evidence on the effectiveness of the approaches in increasing the knowledge and skills of the parents, as well as enhancing the safe practices of using digital technology by their children. Aggregating evidence through a systematic review and meta-analysis has the potential to inform decision-makers by providing a comprehensive and critically evaluated synthesis of evidence while also uncovering research gaps. The rigorous statistical analysis involved in measuring the size of effect, examining the heterogeneity, and identifying possible sources of bias enhances the reliability of the synthesis. Therefore, this systematic review and meta-analysis evaluated the effectiveness of digital safety interventions in improving parental practices related to safeguarding children's digital activities. The primary research question for this review was "What is the effectiveness of digital safety interventions on parental literacy and practices in increasing parental knowledge and skills on digital safety?"; the secondary review question was "What is the effectiveness of parental digital safety interventions on children's digital safety?"

Methods

Design

The systematic review was conducted following the Joanna Briggs Institute (JBI) methodology for systematic reviews [30]. The review involved developing a clear and focused review question, establishing explicit inclusion and exclusion criteria, a systematic search of relevant databases, a critical appraisal of included studies, and a synthesis of findings. These steps adhered to the a priori protocol that was developed before commencing the study. The protocol was discussed by the members of the research team before being registered in the Open Science Framework [31].

Eligibility Criteria

To be included in this review, peer reviewed articles published from database inception to 2024, were required to meet the following criteria: (1) population included parents or primary caregivers responsible for children aged 0-17 years; (2) irrespective of the delivery methods, interventions included resources, programs or interventions designed to enhance parents' knowledge, and skills to safeguard children's activities when interacting with digital technologies; (3) control groups received no intervention or were waitlisted for the intervention following the conclusion of the study; (4) primary or secondary outcomes on effectiveness of the intervention on parental practices and children's digital safety were explicitly reported; and (5) interventional studies including randomized controlled trials (RCTs), non-RCTs, and quasi experiment. Articles were excluded if they were published in a language other than English and if they did not meet the inclusion criteria outlined above.

Search Strategy

A 3-step search strategy was used in this review. The first phase of the search involved a limited exploratory search in 2 databases: MEDLINE (PubMed) and CINAHL (EBSCO). This preliminary search aimed to identify key articles that would inform subsequent search stages. The text words contained in the titles and abstracts of relevant articles and the index terms used to describe the articles were used to develop a comprehensive search strategy. The full search strategy was applied to the following databases: MEDLINE, CINAHL Ultimate, PsycINFO, Web of Science, The Allied and Complementary Medicine Database, ProQuest Central, and IEEE Xplore (Table 1).

XSL•FO
RenderX

Table 1. Search strategy.

Search 1	(Parent* OR famil*)
Search 2	((cybersafe* OR “cyber safe*” OR “digital* safe*” OR “digital security” OR “digital risk” OR “e safety” OR esafety OR “internet safe*” OR “internet security” OR “internet risk*” OR “online safe*” OR “online risk*” OR “online security” OR “safe technolog*”))
Search 3	(((MH “Child”) OR (MH “Child, Preschool”)) OR ((MH “Minors”)) OR ((MH “Adolescent”)) OR (child* OR minor* OR adolescen*))
Search 4	((“Parent* education” OR “Parent* knowledge” OR “Parent* support” OR “Parent* mediation” OR “famil* education” OR “famil* knowledge” OR “famil* support” OR “famil* mediation”))
Search 5	S1 AND S2 AND S3 (Parent* OR famil*)AND (cybersafe* OR “cyber safe*” OR “digital* safe*” OR “digital security” OR “digital risk” OR “e safety” OR esafety OR “internet safe*” OR “internet security” OR “internet risk*” OR “online safe*” OR “online risk*” OR “online security” OR “safe technolog*”) AND (((MH “Child”) OR (MH “Child, Preschool”)) OR ((MH “Minors”)) OR ((MH “Adolescent”)) OR (child* OR minor* OR adolescen*))
Search 6	S2 AND S3 AND S4 (cybersafe* OR “cyber safe*” OR “digital* safe*” OR “digital security” OR “digital risk” OR “e safety” OR esafety OR “internet safe*” OR “internet security” OR “internet risk*” OR “online safe*” OR “online risk*” OR “online security” OR “safe technolog*”) AND ((MH “Child”) OR (MH “Child, Preschool”)) OR ((MH “Minors”)) OR ((MH “Adolescent”)) OR (child* OR minor* OR adolescen*) AND ((“Parent* education” OR “Parent* knowledge” OR “Parent* support” OR “Parent* mediation” OR “famil* education” OR “famil* knowledge” OR “famil* support” OR “famil* mediation”))

The databases were searched systematically using the identified keywords and MeSH (Medical Subject Headings) terms. No date or language limitations were applied. The Boolean operator “OR” was used to combine similar search terms, while “AND” was applied when combining different search terms. Two reviewers searched each database independently and then compared findings for similarities or any divergences. Last, a hand search of the reference lists of included studies, along with the use of the Scite artificial-powered research tool, was conducted to identify additional articles. The database search was conducted between May and August 2024.

Study Selection

Identified citations were uploaded into EndNote (version X9; Clarivate) Reference Management System and duplicates removed [32]. The remaining titles were imported into the JBI System for the Unified Management, Assessment, and Review of Information (JBI SUMARI) [33]. Titles were then screened independently by 2 reviewers. Titles and abstracts deemed eligible were retained for level 2 screening, where full texts were retrieved and assessed independently by 2 reviewers. Disagreements occurring between the 2 reviewers at both screening levels were resolved with a discussion in the presence of team members to reach a consensus.

Assessment of Methodological Quality

In this review, eligible studies underwent a rigorous critical appraisal conducted by 2 independent reviewers. The evaluation of the RCTs was performed using the JBI checklist for randomized controlled studies, which has 13 appraisal questions to assess bias related to selection and allocation of participants, administration of the intervention, assessment / detection / measurement of the outcome, participant retention, and data analysis [34]. Nonrandomized studies were assessed by 7 questions in the checklist (Multimedia Appendix 1) for quasi-experimental studies, and these questions assess bias in the domains of temporal precedence, selection and allocation of participants, confounding factors, administration of intervention, assessment/detection/measurement of the outcome, retention, and statistical validity [35]. The response options to each question are “Yes” (scores 1), “No” (scores 0), or “Unclear” (scores 0). The total score was converted into a percentage, and based on previous research [36], each study was ranked according to 3 levels of bias: high (for scores between 0% and 49%), moderate (for scores between 50% and 79%), and low (for scores between 80% and 100%). The specific questions used to assess the methodological quality of the included studies are detailed in Tables 2 and 3, which highlight the criteria followed during the appraisal process. In instances where discrepancies arose between the 2 reviewers, resolutions were achieved through collaborative discussion or a third reviewer to reach a consensus.

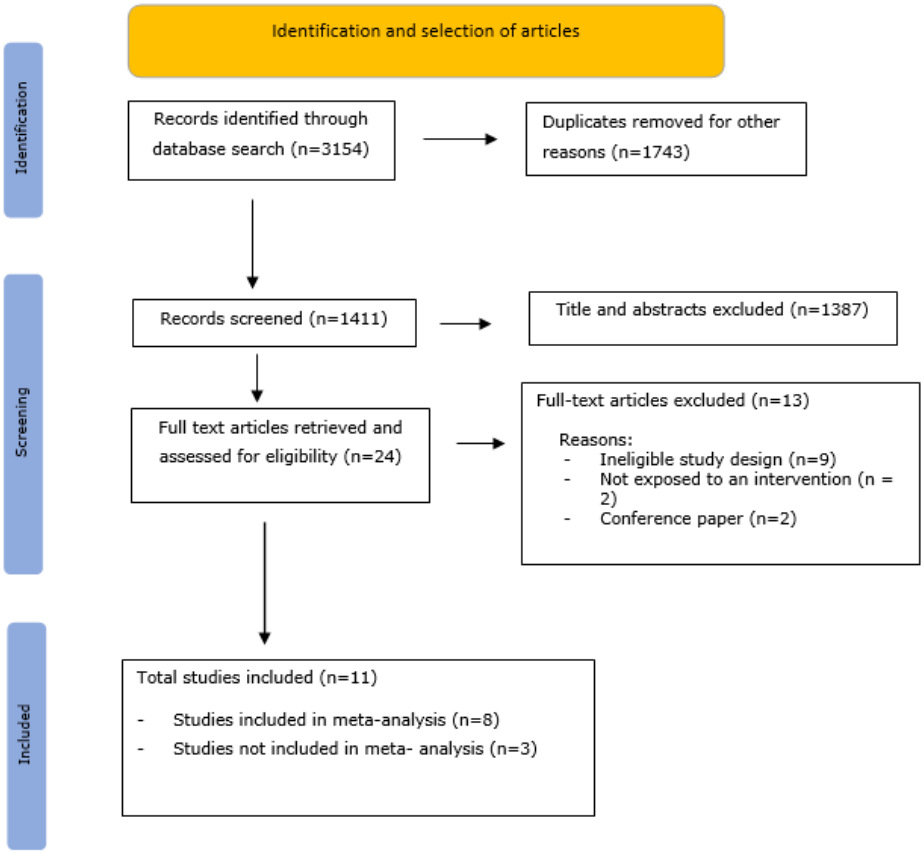
Data Extraction

Data were independently extracted using the standardized JBI RCT data extraction forms by 2 independent reviewers and then crosschecked by a third reviewer. The extracted information included (1) attributes of the study: author, geographical location, year of publication, economic background, setting, study aims; (2) methodological qualities: study design, sample size/ population, characteristics of intervention, statistical analyses; and (3) findings and conclusions (Multimedia Appendix 2 [37-49]).

Data Synthesis

Data synthesis was conducted through meta-analysis and narrative synthesis. Meta-analysis was conducted when studies demonstrated a sufficient degree of homogeneity in terms of participants, interventions, and outcomes. Based on these criteria, a meta-analysis was conducted specifically for the outcome of children's screen time. Forest plots were generated to show mean differences with 95% CIs and funnel plots. Random-effects meta-analyses using the restricted maximum likelihood method were used to pool the data. Heterogeneity was assessed using an I^2 test, with values <50% considered nonsubstantial. The outcome was deemed statistically significant if the P value was less than .05. Effect sizes were interpreted according to GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) recommendations: small (<0.5), moderate (0.5-0.8), and large (> 0.8) effects [50]. Sensitivity analyses using the leave-one-out approach were performed to explore sources of heterogeneity. Subgroup analyses and meta-regression were not conducted due to the insufficient number of studies in both RCT and quasi-experimental meta-analyses. For other outcomes (eg, parental awareness, attitudes) with substantial conceptual heterogeneity measured by different instruments, a narrative synthesis was undertaken with supporting tables due to the inappropriateness of statistical pooling. Publication bias was evaluated through funnel plot visualization, Egger regression test, and trim-and-fill analysis. All analyses were conducted using Stata (version 17.0; StataCorp LLC).



Results

Study Selection

After removing duplicates from a total hit of 3154, a total of 24 potentially eligible titles and abstracts were retained from 1411 records. Following a full-text assessment of 24 articles, 13 were excluded based on the following exclusion criteria: ineligible study design (n=9), lack of intervention exposure (n=2), incompatible participant characteristics (n=1), ineligible outcomes (1), conference proceedings (n=2). Eleven studies were included in this systematic review and meta-analysis, and details are provided in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Methodological Quality

Overall, the risk of bias score for RCTs was low to moderate (average score of 82%; range 69% to 100%; Table 2). Three articles scored moderate risk [37-39], and another 3 articles scored low risk [40-42]. Studies that had a moderate risk were either unclear in their description or did not (1) conceal allocation of intervention groups, (2) blind participants to intervention groups, (3) blind those delivering interventions, and (4) outcome assessors were not blind to intervention assignment [37-39]. All quasi-experimental studies scored 100% except one article, which scored 85% [46], representing the lowest risk of bias (Table 3).

Characteristics of Included Studies

The review included 11 studies published between 2012 and 2024. Study designs consisted of RCTs (6/11, 54.5%) and quasi-experimental studies (5/11, 45.5%). Studies were conducted across 8 countries: Turkey (2/11, 18.2%), Iran (2/11, 18.2%), the United States (2/11, 18.2%), and one study each from Thailand, Belgium, Canada, Malaysia, and Taiwan (1/11 each, 9.1%). Sample sizes ranged from 28 to 360 parent-child dyads. Regarding intervention delivery formats, studies used face-to-face sessions (5/11, 45.5%), online/web-based delivery (4/11, 36.4%), and combined web-based and face-to-face delivery (2/11, 18.2%). Participants were primarily parents (with mothers comprising >80% in most studies) and children ranging from toddlers (18 months) to adolescents. The duration of interventions varied from a single session to 9 weeks. The follow-up periods ranged from immediate postintervention to 4 months. The contents of interventions mainly focused on 3 domains: cyberbullying prevention (3/11, 27.3%), screen time management (5/11, 45.4%), and gaming-related parenting practices (3/11, 27.3%). Detailed characteristics of the included studies are presented in Multimedia Appendix 2 [37-49].

Summary of Effects of Digital Safety Interventions on Parental Outcomes

Parental Digital Safety Knowledge, Attitudes, and Skills

Six studies reported the effectiveness of digital safety interventions in improving parents' digital safety knowledge and skills (Table 4) [37,42-45,47]. For cyberbullying-related outcomes, significant improvements were observed in both parental awareness [43] and various communication intentions [37] (all $P<.05$). Screen time management interventions showed mixed results: while parental attitudes demonstrated significant improvements ($P<.05$), changes in intentions and subjective norms remained nonsignificant [44]. Raj et al [42] in their larger study (n=360) found significant enhancements in parental knowledge and self-efficacy for screen time reduction ($P<.001$). However, De Lepeleere et al [45] found no significant improvements in parental self-efficacy for either modeling or permission concerning gaming ($P>.05$), suggesting limited intervention effectiveness in this domain. Overall, the interventions appeared most effective in enhancing cyberbullying-related competencies, moderately effective for screen time management, but showed minimal impact on gaming-related outcomes.

XSL•FO

Parents' Behavioral Outcomes

Based on data from 6 studies [37,42-45,47], including 827 participants, collectively examining behavioral outcomes, digital safety interventions showed mixed results in changing parents' behaviors (Table 5). Only 2 outcomes demonstrated significant improvements: parents' immediate screen time reduction (for child) behaviors (*P*=.05) and parents' own screen time at 3-month follow-up (*P*=.001) [42,44]. However, interventions showed no significant effects on cyberbullying incidents and victimization, television and gaming-related parenting practices (rules, modeling, monitoring, and explanations), or technology-specific parenting (all *P*>.05), suggesting limited effectiveness in achieving sustained behavioral changes (Table 5).

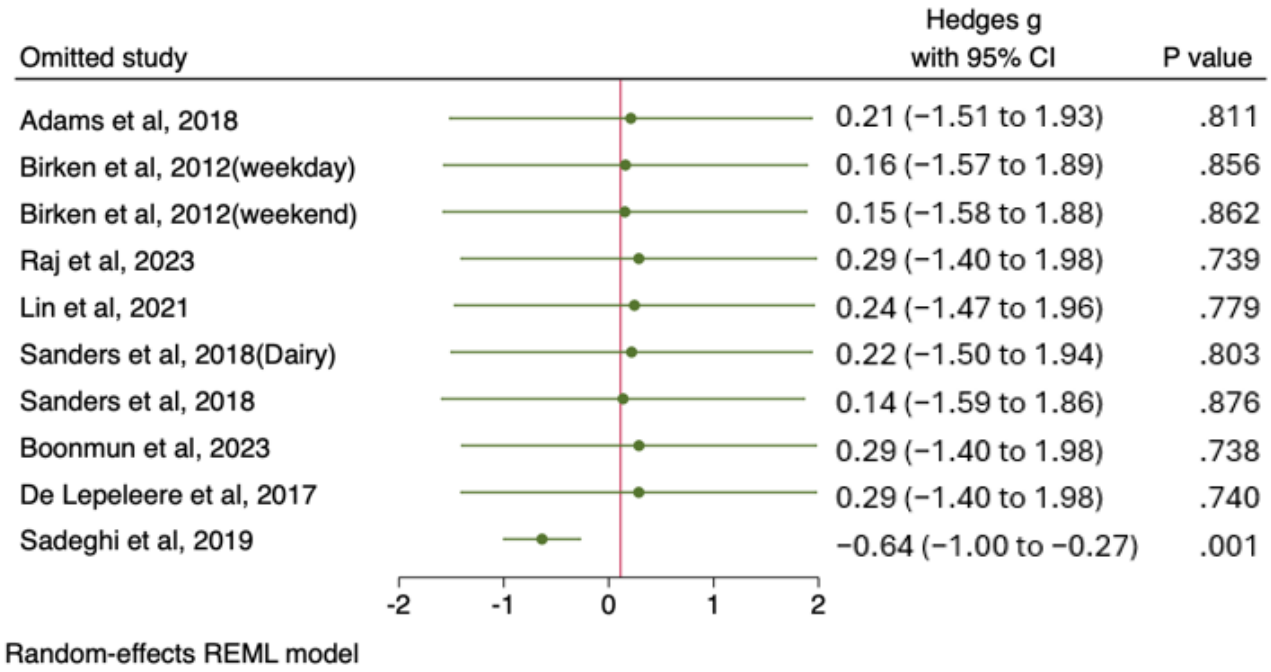
Meta-Analysis Results

Effects of Digital Safety Interventions on Children's Screen Time

Figure 2 [38-42,44-46] presents a forest plot from a meta-analysis comparing treatment and control groups across 2 study types: quasi-experimental designs and RCTs. The quasi-experimental studies, comprising 3 studies and 151 participants, demonstrated a large effect (Hedges g=1.90; 95% CI –4.36 to 8.16; P<.001) with substantial heterogeneity (I^2=99.71%). Conversely, the RCTs, comprising 5 studies (7 datasets) and 1091 participants, revealed a smaller yet significant effect (Hedges g=–0.47; 95% CI –0.85 to –0.08; P<.001) with substantial heterogeneity (I^2=87.95%). The statistical analysis of group differences (Q=0.55, P=.46) indicates no significant disparities between the quasi-experimental and RCT designs.

Figure 2. Meta-analysis of randomized controlled trials and quasi-experimental studies on the effects of digital safety interventions on children's screen time [38,40-44,46,47]. REML: restricted maximum likelihood.

Descriptive Comparison by Control Group Type and Delivery Mode



Among the 5 RCTs (7 datasets) included in the meta-analysis, formal subgroup analyses could not be conducted due to most subgroups having fewer than 2 studies. Therefore, effect size was compared descriptively by intervention delivery modes and control group types, with results interpreted cautiously given these limitations. Studies using waitlist controls [38,41,42] showed effect sizes ranging from –0.59 to –1.22, whereas studies with an active control [39] and standard care control [40] yielded effect sizes of –0.51 and –0.05, respectively. Regarding the mode of delivery, face-to-face interventions [38-41] showed variable effects (–0.05 to –0.83), while a single web-based intervention [42] demonstrated an effect size of –1.22 (Figure 2 [38-42,44-46]).

Sensitivity Analysis

The leave-one-out sensitivity analysis demonstrated the robustness of the meta-analysis findings for children's screen time, with Hedges g values ranging from 0.14 to 0.29 and all 95% CIs crossing zero (P>.05), except when Sadeghi et al [46] was excluded (Hedges g=–0.64, P=.001) (Figure 3 [38-42,44-46]). The most pronounced effect was observed when the studies by Raj et al [42], Boonmun et al [44], Birken et al [40], or De Lepeleere et al [45] were excluded (Hedges g=0.29), while the smallest effect was noted when the study by Sander et al [38] or were omitted (Hedges g=0.14). These results indicate that the overall findings are not disproportionately influenced by most studies, except for Sadeghi et al [46], which appears to have a significant impact on the pooled effect estimate.

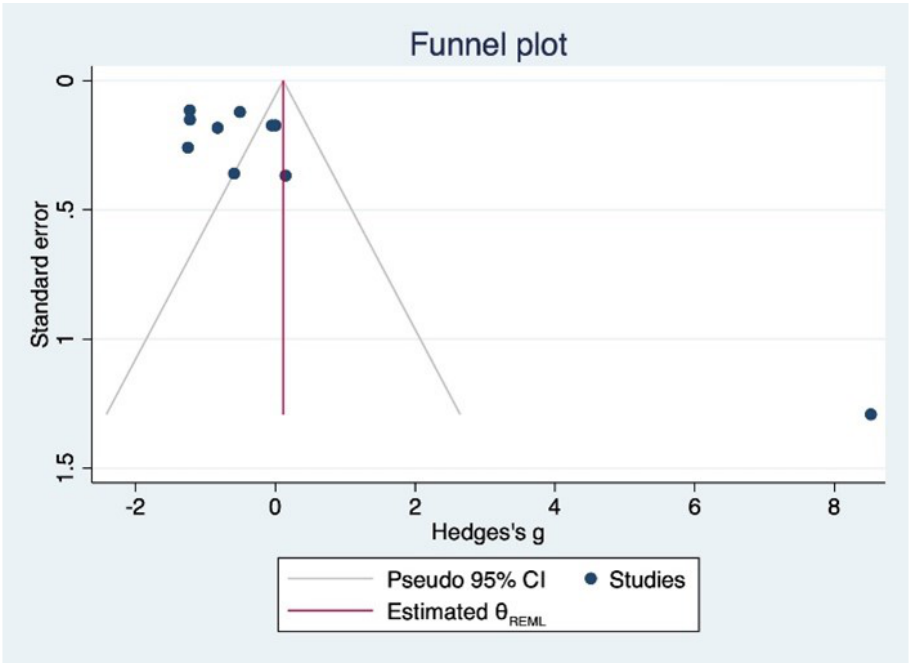

Figure 3. Leave-one-out sensitivity analysis on children's screen time [38,40-44,46,47]. REML: restricted maximum likelihood.

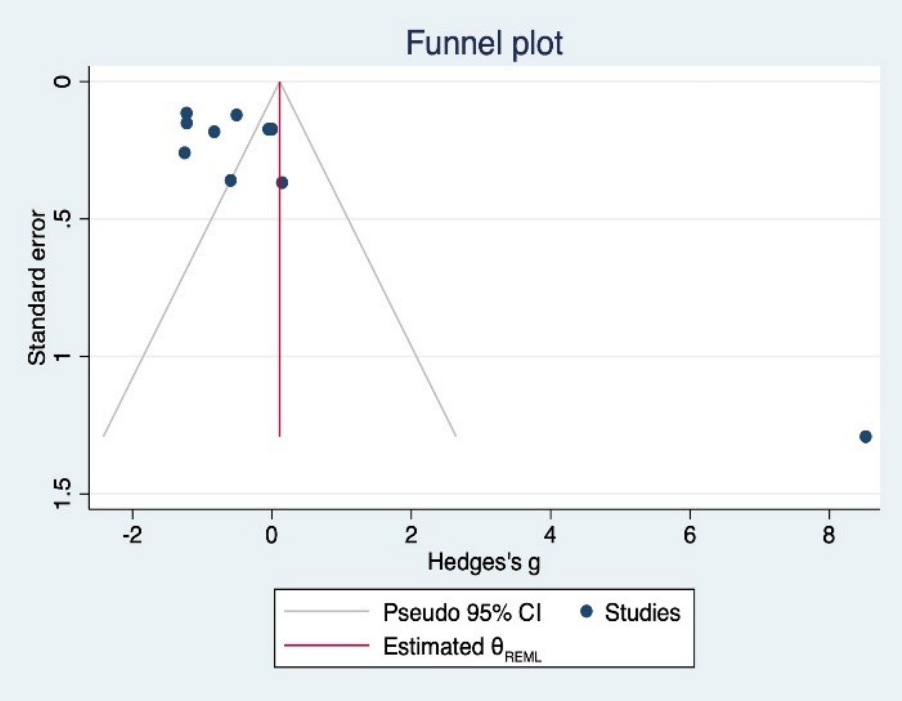
Publication Bias



Visual inspection of the funnel plot from the random-effects restricted maximum likelihood model (Figure 4) showed relative symmetry, and the Egger test indicated no significant publication bias (t=2.04, P=.08). The trim-and-fill analysis yielded an identical funnel plot (Figure 5) with zero missing studies, further confirming the absence of publication bias. The test of residual heterogeneity was significant (Q-res=83.64, P<.001). This suggests that while there is substantial heterogeneity in the included studies, there is no significant indication of publication bias in our meta-analysis.

Discussion

Principal Results

To the best of our knowledge, this is the first meta-analysis to assess the effectiveness of digital safety interventions on parental practices related to safeguarding children's digital activities. This systematic review and meta-analysis identified 6 RCTs and 5 quasi-experimental studies to evaluate the impact of digital safety interventions on parental practices. Based on the comprehensive search of available studies, this area of research has been given limited attention. Nonetheless, the results provide evidence that parents who participate in digital safety interventions have a higher chance of increasing digital safety knowledge and skills, with a positive change in attitudes, including intentions to use strategies to safeguard their children engaging with technology.

Findings demonstrate that interventions targeting parents' knowledge related to digital safety were more effective in intervention groups compared with control groups. While increased knowledge is associated with a behavior change [51,52], knowledge alone does not necessarily translate to a change in behavior [53,54]. Theories of Behavior Change [55] such as the Theory of Planned Behavior, emphasize that an individual's likelihood of changing their behavior depends on their attitudes, social norms (which refer to beliefs about what others think regarding certain behaviors), and behavioral control (the individual's ability to act) [56]. Similarly, the Social Cognitive Theory by Albert Bandura highlights personal (individual's self-efficacy towards behavior), environmental (situational influences), and behavioral (having the ability to perform the behavior) factors as important elements in changing one's behaviors [57]. Therefore, the effectiveness of an intervention such as those aimed at promoting parental support in safeguarding children engaging in digital technology relies not only on knowledge but also on enabling a shift in social norms and addressing contextual factors that influence behavioral control. While it is commendable that 7 of the 11 articles used either a model, a theory, or a framework to underpin their interventions, the inclusion of social norms or environmental influences in the targeting interventions remains insufficient. Future studies and interventions should consider strategies that can address community norms around the digital safety of children.

In this review, some included studies evaluated either knowledge or behavioral outcomes independently, and all studies used educational sessions as an intervention (or part of the interventions). These educational sessions were delivered through different approaches, including videos, infographics, presentations face to face, role play, in groups, or via web. It is, therefore, limiting to isolate the effect of an individual approach to parent education to influence their knowledge or behavior. Regarding the behavior outcomes, while the desired direction of effect is noted in most of the reported effect estimates, the majority were not statistically significant, except for 2 outcomes: parents' own screen time [42] and children's screen time [44], which reduced after exposure to digital interventions. Similar findings were reported in a previous meta-analysis, where the behaviors of youths did not change after exposure to anti-bullying interventions [58]. To further the understanding of the effectiveness of digital interventions, future research should consider evaluating the individual effects of components of the intervention. In addition, interventions predominantly targeted cyberbullying and screen time. Considering that digital safety encompasses broader outcomes beyond cyberbullying and screen time, we recommend that interventions targeting digital safety should adopt a holistic framework rather than addressing isolated components where applicable. There is a need for additional research that can measure digital safety outcomes that have not been included in

XSL•FO
RenderX

these studies, albeit important, such as exposure to inappropriate content, web-based grooming or sexual exploitation, and digital citizenship.

Small effect sizes were also observed on giving an explanation concerning TV ($F_{1,80}$=0.10; P=.75) or gaming ($F_{1,66}$=0.29; P=.59), cyberbullying incidents (t/z=−1.124; P=.26), and rules concerning TV ($F_{1,105}$=0.00; P=.97). The findings suggest an influence of the study design on the observed effect sizes as indicated in the significant difference between quasi-experimental studies and RCTs (Q=10.72, P<.001). The larger effect observed in the quasi-experiment could be because of the lack of randomization in these studies [59]. This potential bias, along with the detected substantial heterogeneity observed in RCTs, limits the reviewers' ability to draw conclusions based on this finding. Therefore, further investigations, with an improved study design that involves implementors and outcome assessors, are required to understand the effect of digital interventions on children's screen time and other studied outcomes.

Overall, the outcome of the analysis indicates that articles included in this review and meta-analysis were of high quality, with the majority (n=8/11) considered to have a low risk of bias. Another strength of the study lies in the systematic and robust search strategies used to identify the included studies. Just like other systematic reviews and meta-analyses, our study has some limitations. The search for articles did not extend to gray literature databases, which may have missed relevant studies conducted by reputable organizations and government agencies [60]. Results from the sensitivity analysis demonstrate a significant influence of one article [46] on children's screen time despite a small sample size of 12; therefore, its validity should be interpreted with caution. Last, studies published in languages other than English were excluded due to time and financial constraints associated with translation, which may limit generalization of the outcomes.

Conclusions

To the best of the reviewers' knowledge, this is the first review to evaluate the effectiveness of digital safety interventions on parental practices related to safeguarding children's digital activities. Several interventions were identified, with educational sessions being the most common intervention across the studies. The analysis for this study indicates that the identified interventions effectively increased parents' knowledge and skills to safeguard their children while engaging with technology. Future research should use more robust designs that include blinding of outcome assessors and consider environmental factors. There is a need to focus on examining the effect of individual approaches to educational sessions on parents' practices.

Abstract

Background: Social media groups (SMGs) enable individuals with rare diseases to connect with one another and access instant support and advice. Accelerated diagnoses of genetic neurodevelopmental disorders (NDDs) over the last decade have driven rapid expansion of gene-specific SMG membership. Limited literature regarding parental use of SMGs in the context of managing their child's NDD exists.

Objective: The objective of our study was to determine and describe how parents use social media and the internet in the context of their child's NDD.

Methods: We undertook a mixed methods study of 477 parents within a cohort of children with NDDs (Genetic Rare Disease: Observational Cohort Study; GenROC). A total of 359 parents provided quantifiable survey responses regarding their use of social media. We also interviewed 17 parents to understand how they use SMGs and their views on the data held within these groups.

Results: Our survey found 359/475 (75.7%) of parents use SMGs related to their child's genetic disorder, and of these, 98.5% (354/359) are on Facebook. Most SMGs are closed, international, have more than 200 members, are specific to the NDD, and are associated with a corresponding charity or foundation. In total, 191/312 (61.2%) parents could not recall what they had consented to when joining the group with respect to the use of their posted data. Most parents trust the data (Likert scale 1 - 10; mean 7.03, SD 1.98) that are shared but acknowledged the anecdotal nature of them. Parents found the most valuable element of the SMG to be shared lived experience with other families. Interview data from 17 parents were coded and analyzed thematically. A total of 4 main themes were identified: (1) SMGs for support and shared lived experience; (2) possible harms from participation in SMGs; (3) SMG composition, demographics, and dynamics; and (4) usefulness and use of data shared within the groups.

Conclusions: This mixed methods study shows the evolving landscape of SMG use in neurodevelopmental disorders, highlights its benefits and downsides, and is widely applicable to all parent SMGs for specific niche medical conditions. Using the strength of these groups in a more collaborative approach in the future could prove useful to clinicians, families, and researchers alike.

KEYWORDS

genetics; rare disease; social media; genetic neurodevelopmental disorders; parental support; mixed methods research; online health communities

Introduction

Social media groups (SMGs) have dramatically changed the way individuals seek and share information online, particularly in the context of health care and are used by parents both as a support mechanism but also as a way of finding out information to help them look after their child [1,2]. Genetic neurodevelopmental disorders (NDDs) are rare with wide geographic spread, heightening the need for connection and increasing the information drought. Our recent literature review

XSL•FO
RenderX

(Bogaert et al, unpublished data,December 2024) showed that SMGs empower parents by providing key information and a support role. Most parents use social media to help them manage their child's NDD, and the majority use Facebook groups that are gene- or NDD-specific and are "closed" requiring authorized access by a group "admin" based on group-specific set criteria [3].

Regardless of the underlying disorder, parents use social media to acquire health-related information about specific medical concerns both before and after their child receives a medical diagnosis, and to seek out information based on other parents' lived experience. This also provides a sense of support and community. Parents increasingly use this acquired information to discuss and sometimes challenge health care providers regarding the treatment options that are being offered for their child [4].

Medical health care was named as one of the key information needs identified in a study of parents of individuals with rare genetic disorders in a Facebook community group [5,6]. Tozzi et al [7] undertook a survey of 516 Italian families with rare genetic disorders to describe their internet use and found that 99% searched on disease characteristics, with 93% looking for therapies and 63% for alternative therapies, indicating high levels of need around treatments and therapy [7].

The number of diagnosed individuals with NDDs has changed substantially over the last decade largely due to changes in technology and access to genomic testing [8]. This means that the number of SMGs and number of individual members within each SMG have rapidly increased since 2010 and continue to climb [3,9].

However, the data about how SMGs help parents is limited, and with increasing numbers of diagnoses, the landscape of social media use is shifting. Our study aimed to answer the research question, "How do parents of children with NDDs use SMGs for support, and what is the perceived impact of these groups on their emotional well-being and access to clinical information?"

We aimed to describe this landscape and lived experience shared in SMGs by parents of children with NDDs in order to inform improved digital collaboration for the benefit of patients and families, clinical care, and scientific advancement.

Methods

Overview

We used a convergent mixed methods design for the surveys of parents and for the interviews with parents. This approach allowed for the simultaneous collection and analysis of qualitative and quantitative data, which were integrated during interpretation to provide a comprehensive understanding.

Parent Surveys

This study is nested within the Genetic Rare Disease: Observational Cohort Study (GenROC) study, a UK-based cohort study of children aged 6 months to 16 years old with rare monogenic neurodevelopmental conditions (GenROC REC22/EM/0274) [10]. Parents were asked to complete 2 online separate patient questionnaires (PQs), PQ1 and PQ2 (completed between 2023 and 2025). Study data were collected and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) electronic data capture tools hosted at the University of Bristol. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources [11,12]. The parent questionnaires were developed with stakeholders (3 genetics researchers, 2 genetics charity representatives, 2 neurodisability pediatricians, 2 digital health academics, and 1 qualitative researcher) and patient participant involvement (PPI) input (6 parents of children with genetic NDDs and 1 adult with genetic NDD) and tested with 3 parents of children with NDDs using a think-aloud approach [13].

PQ1 and PQ2 both included social media questions (see Sections S5 and S6 in Multimedia Appendix 1) for the relevant sections of each survey, respectively, and development of PQ2 was informed by the results of the qualitative study described below.

Survey results were analyzed using descriptive statistics (in REDCap) for proportions and frequencies related to SMG use and parent attitudes.

Parent Interviews

A total of 17 parents (5 fathers and 12 mothers) of 13 children were purposively sampled (Low et al [10], submitted) and interviewed using a topic guide which was informed by the literature, clinical expertise, and PPI input. Most parents were interviewed one-to-one but 4 couples chose to be interviewed together. In one case, a mother was interviewed with her child present throughout. Interviews took place between October 2023 and March 2024.

Interviews took place on Zoom (Zoom Communications) and were recorded, transcribed, and anonymized, then imported into NVIVO qualitative data management software (release 1.71; Lumivero) for coding and data management. All interviews were undertaken by the first author.

Data were analyzed following the principles of inductive thematic analysis [14-16]. An iterative approach was used to develop an initial codebook (deductive component) [17]. After 8 parents were interviewed, the process was paused to review the data and to develop and refine the coding matrix. This was then used for the remaining transcripts. We determined that we would continue with interviews until no new code categories were being generated and no new themes were created [15,16]. No repeat interviews were undertaken. The first 8 transcripts were coded by the first author, and additional codes that were not covered by the initial codebook were then added (inductive component). In addition, 20% of the transcripts were double coded by an experienced qualitative researcher who was not a clinician and had no previous experience of pediatric genetic disorders. All discrepancies were reconciled through consensus. Data are reported according to the Consolidated criteria for Reporting Qualitative studies (COREQ) guidelines [18].

XSL•FO
RenderX

Data Integration

We integrated qualitative and quantitative findings during the interpretation phase using a side-by-side comparison approach [19].

Ethical Considerations

The GenROC study received Research Ethics Committee approval on December 15, 2022, and Health Research Authority approval on February 9, 2023. All participants provided informed consent for the interview as per the GenROC study protocol. All information is deidentified to protect confidentiality and anonymity.

Results

Parent Surveys

A total of 474 parents completed the GenROC parent questionnaire. Of these, 97 (20.5%) said that they were not a member of an SMG for whom no further responses were collated. In addition, 359/474 parents (75.7%) stated that they were a member of an SMG. Multimedia Appendix 2 shows that 352/359 (98.5%) of the SMGs were on Facebook. Multimedia Appendix 2 shows the categories of genetic group, geographical distribution, numbers of SMGs used, and size of groups, respectively. The 4/359 (1.1%) participants who stated that the SMG was not on Facebook did not provide information regarding the location of the group. Only 1 parent answered that their child was a member of an SMG. Those who participated in more than 1 SMG did not consider the information to be conflicting.

Almost half (n=126, 44.8%) remembered being asked when joining to keep information within the SMG confidential, but almost as many parents (n=113, 40.2%) weren't sure. Most parents (n=191, 61.2%) did not recall providing consent for their data from the SMG to be used elsewhere, with 30% (n=84) not being able to remember whether they had been asked. Of the 29 parents (10.3%) that recalled giving consent, 3 quarters remember giving consent to information being shared outside the SMG; 7 (24.1%) for any purpose; 15 (51.7%) to be shared with doctors and researchers working on the condition; and 7 (24.1%) could remember giving consent but could not remember any further details. A total of 65 (18%) respondents did not take part in any SMG with respect to their child's NDD.

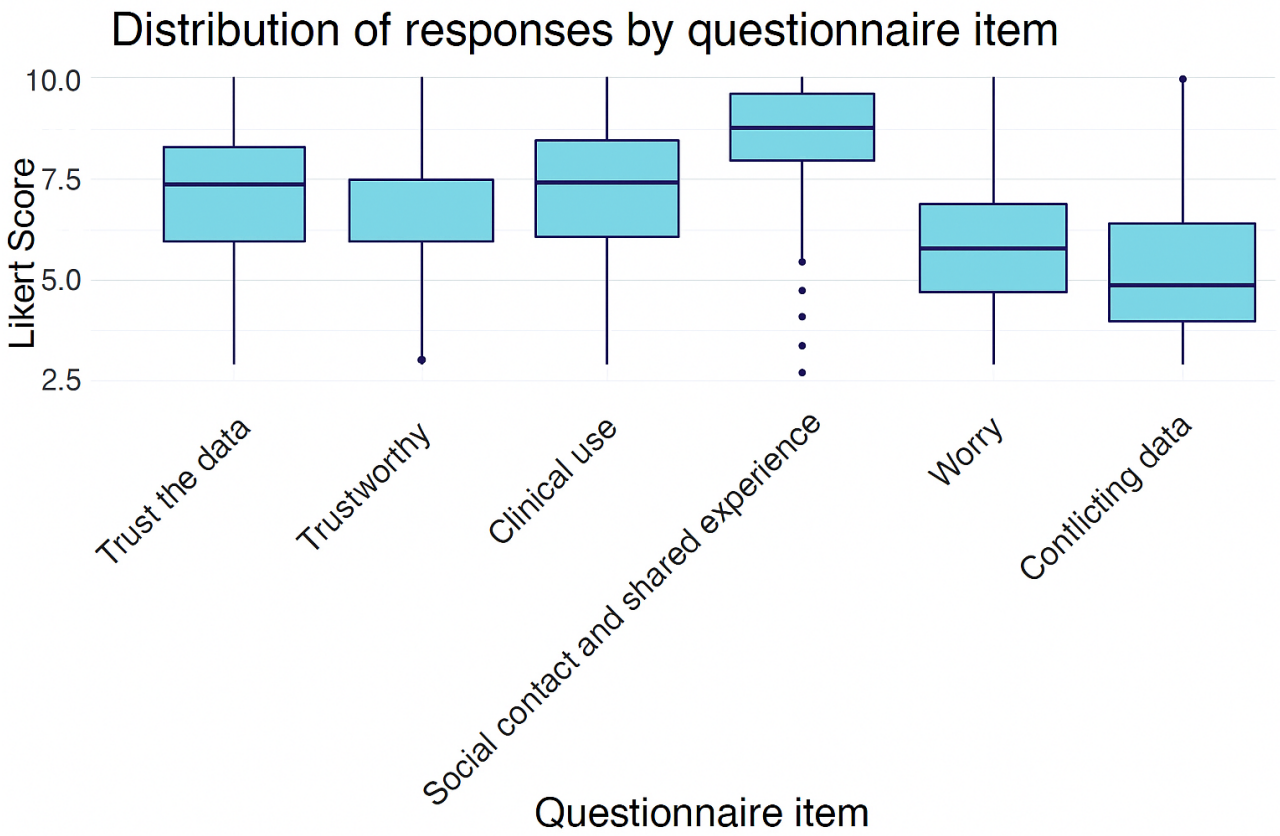
The results of the statements about attitudes toward the information held in the SMG are summarized in Table 1 (1 representing the lowest agreement and 10 the highest) with the distribution depicted in Figure 1.

XSL•FO
RenderX

Table . Responses by Likert scale to attitudinal statements.

Statement	Response rate[a] (N=359), n (%)	Mean (SD)	Minimum[b]	Median (IQR)	Maximum[c]
Item 1: "I completely trust the information provided in the group."	271 (74)	7.03 (1.98)	1	7 (5-8)	10
Item 2: "To what extent do you agree with the statement 'the information provided in the group is completely biased (for example a feature might look more common because people only respond to a poll if their child has the feature)."	263 (72)	5.77 (2.02)	1	5 (5-7)	10
Item 3: "To what extent do you believe that doctors or healthcare professions should be using the information from these groups when making clinical decisions?"	272 (75)	6.79 (2.03)	1	7 (5-8)	10
Item 4: "To what extent do you agree with the statement: The social media group helps by giving me contact with other people who have similar experiences."	277 (77)	8.52 (1.85)	1	9 (8-10)	10
Item 5: "To what extent do you agree with the statement: I find that the information from the group can make me worried or anxious."	269 (75)	4.69 (2.11)	1	5 (3-6)	10
Item 6: "I find that there is conflicting information in the different groups."	145 (92)[d]	3.51 (2.2)	1	3 (2-5)	10

[a]Response rates were calculated as a percentage of parents who responded to the question out of a total count of 361, the number of parents who replied "yes" to being a member of a social media group (SMG) in the question already discussed.



[b]Lowest agreement.

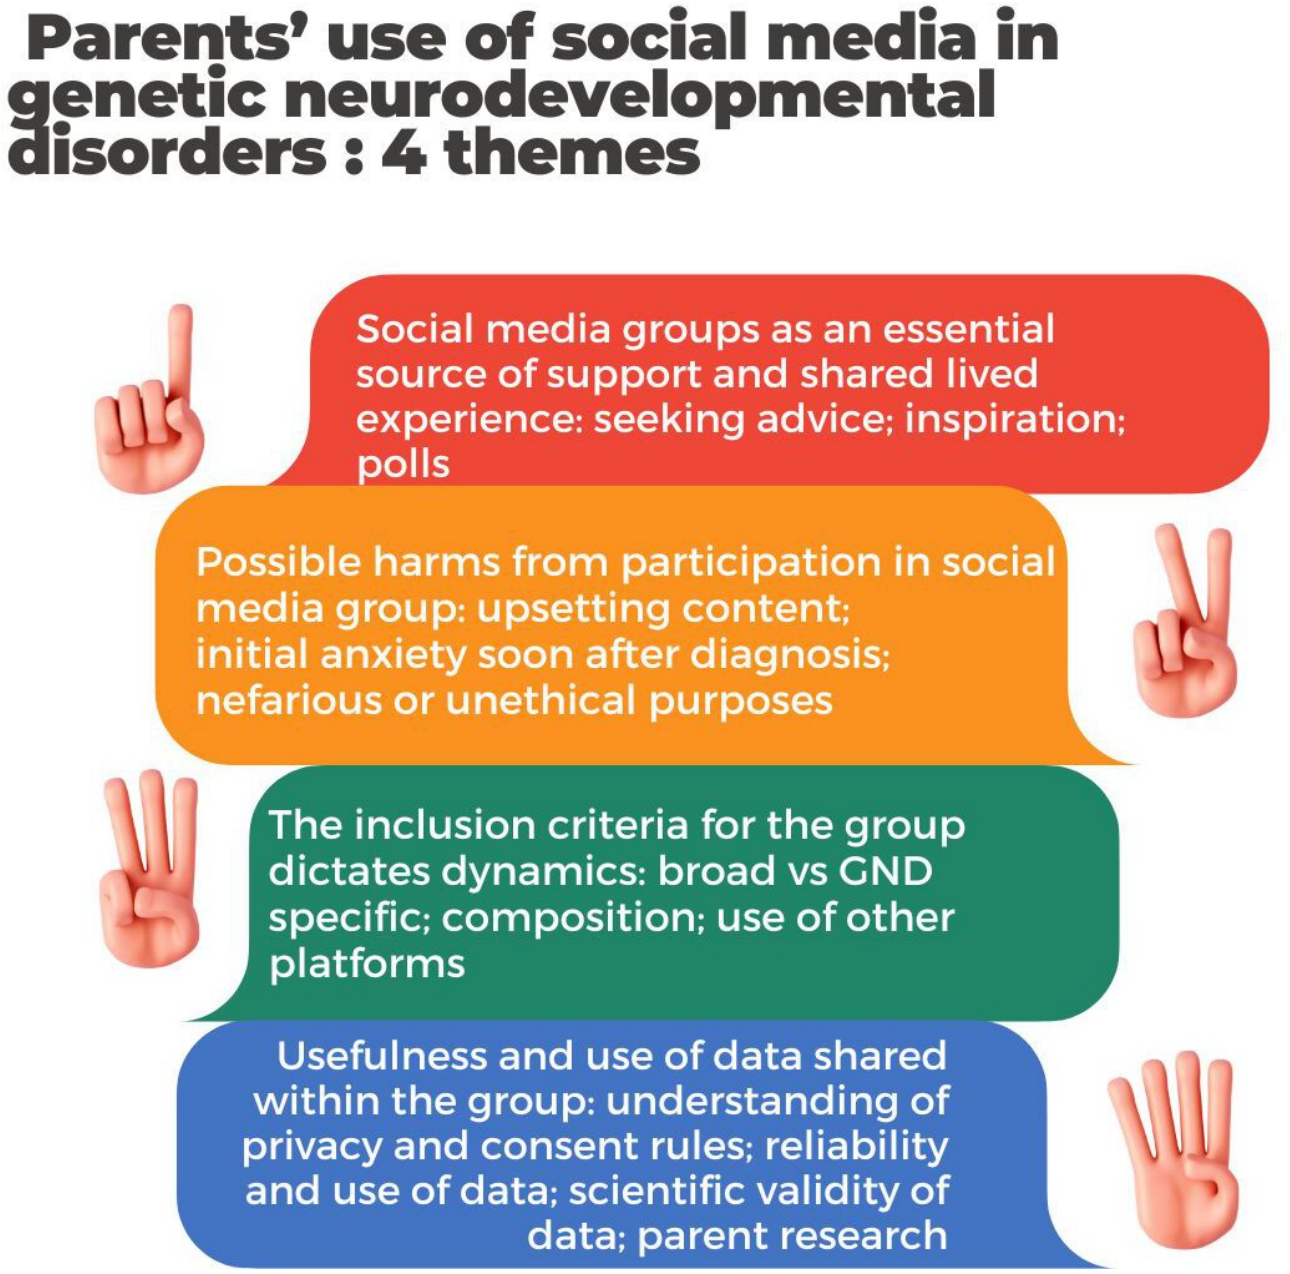
[c]Highest agreement.

[d]n=158, as this question was only asked of people who had responded that they were part of more than one SMG with respect to their child's genetic condition.

XSL•FO
RenderX

Figure 1. Distribution of responses by questionnaire item.

Most activity occurs in Facebook; 18 (8.3%) reported using a gene-specific WhatsApp group, with 5 (2.3%) using LinkedIn and 14 (6.4%) using Instagram. In addition, 10 (4.6%) follow an influencer on social media relevant to their child's diagnosis: 8 followed a parent of a child with the same condition, 4 followed a parent of a child with another genetic condition, and 1 was a person with a genetic condition. Only 7 (3.2%) reported listening to relevant podcasts.



Parent Interviews

A total of 4 main themes (see Figure 2) were created from the parent interviews.

Quotes and participants are numbered in the tables and identified as mother or father.

XSL•FO
RenderX

Figure 2. Summary of themes from parent interviews regarding parent use of social media groups (SMGs) with respect to their child's neurodevelopmental disorder (NDD). GND: genetic neurodevelopmental disorder.

Social Media Groups (SMGs) for Support and Shared Lived Experience

Table S1 in Multimedia Appendix 1 shows that some parents reported that clinicians signposted them to the gene-specific Facebook group after diagnosis as a possible avenue of support (Quote 1).

All parents described the SMG as providing them with a feeling of shared lived experience, which is vital for them as a coping mechanism (Quote 2).

The lack of natural history data in NDDs makes it hard for parents to know what the future might look like for their family, which they find very difficult. SMGs allow them to get more insight (Quote 3) and show how parents rely on the SMG as an easy way of accessing information about their child's NDD and as a way of staying up to date and well informed (Quote 4).

Parents described some of the reasons for searching or posting. These included:

1. To help find information before attending an appointment with a health care professional for their child (Quote 5).
2. To get ideas for specific aids, interventions, days out, or toys that might be particularly appropriate or enjoyable for their child (Quote 6).
3. For medical advice about their child from other parents in the group (Quote 7).
4. For polls to find out about the prevalence of symptoms, features, and interventions, as well as to help researchers (Quote 8).

Potential Harms From Participation in SMGs

Table S2 in Multimedia Appendix 1 shows that parents described 3 subthemes of potential harms through participation in SMGs.

XSL•FO
RenderX

First, parents become upset by the content that they read or see in the groups.

Reading the posts in the SMGs can cause anxiety, and this can lead to reduced use (Quote 9) or have an impact on mental health (Quote 10).

Parents talked about how they are particularly distressed when they read posts about children in the group dying. A parent explained that it is not simply the subject matter itself but also the reflex anxiety it generates about one's own child and a tendency to heightened anxiety and emotion within the group that can be difficult to deal with (Quote 11).

For some, the distressing content was about their own child. A parent explained that another member of the SMG was the first person to suggest the diagnosis for her child (Quote 12).

Second, joining a SMG soon after a child's diagnosis can result in a spike in anxiety.

Participation in the SMGs can cause considerable anxiety in parents when joining soon after their child's diagnosis (Quote 13). This was highlighted by a foster carer with her viewpoint on this initial spike of anxiety in biological parents (Quote 14).

The process of participating in the SMG, experiencing anxiety, and learning to manage that may be helpful in enabling parents to come to terms with their child's NDD (Quote 15). Another parent described this phenomenon of initial anxiety and tried to highlight positive stories for newly joined families but recognizes that even she can get anxious in the groups (Quote 16).

Third, SMGs can be used for harmful purposes, but this is infrequent.

Parents described use of data in SMGs for unintended or unacceptable purposes, including a description of members of the group whose children had variants of uncertain significance that "didn't look likely" and how they were trying to use information acquired in the group to try and obtain a diagnosis or "proof" for their child. A more extreme example of this misuse of data is where a parent describes a safeguarding case arising from a feeding tube Facebook group (Quote 17).

Parents reported that occasionally groups can be targeted for commercial purposes such as unsolicited marketing of equipment. While unwelcome, most of these instances are genuine; however, occasionally they can be preying on vulnerable families as part of a scam (Quote 18).

The Inclusion Criteria for the Group Dictates Dynamics

Table S3 in Multimedia Appendix 1 shows the inclusion criteria.

First, parent experience differs in groups that have broad inclusion versus specific criteria.

While most parents were members of NDD SMGs, some were members of broader SMGs as well. A foster parent reported preferring a broader fostering SMG to the NDD SMG as members were less likely to be offended by posts (Quote 19). In contrast, another parent explained that the mixed SMGs can result in a competitive dynamic between members who wish to be seen as the one having the most difficult time (Quote 20).

Second, group dynamics are impacted by geographical spread, size, and composition.

For some NDDs, the number of children being diagnosed has increased significantly, which has resulted in a much bigger SMG. This has resulted in some SMGs being split by composition (parents, grandparents, and researchers) and has impacted the content within the SMG (Quote 21). Some NDDs will have an international SMG as well as country-specific SMGs (such as UK families only). Parents explained the pros and cons of being part of one of the big international SMGs (Quote 22). Another problem with the international SMGs is that non-English speakers tend to receive fewer responses to their posts (Quote 23). As the SMGs get bigger and more children are diagnosed, more specific charities are set up, which can result in competition between charities within the groups. The same mother, who has set up an NDD charity, described some of the competing politics arising in a big SMG (Quote 24).

Third, group composition and dynamic may prompt the use of other platforms.

A parent explained that for the NDD, there is a UK-only Facebook group and then a bigger international one, hosted by a US charity. She reported that the UK SMG is very "quiet" and suspects that people think they have a higher chance of getting relevant information in the bigger SMG. However, there is still a desire for local or UK-specific support. For this reason, the UK-based charity is trialing a WhatsApp group just for UK families (Quote 25).

Another parent advocate who had set up a UK charity explained that she also uses LinkedIn for her charity work but in a professional capacity and in a different way from how she would use the Facebook group (Quote 26).

Usefulness and Use of Data Shared Within Groups

Table S4 in Multimedia Appendix 1 shows the usefulness and use of data shared within groups.

First, parent understanding about their data in the groups, privacy, and consent:

Parents varied in their recall of what they had been asked or what rules they agreed to when they signed up for the SMG (Quote 27). However, a parent was certain the only question they had been asked was whether their child had the specific genetic diagnosis.

Some parents considered the need to decide about sharing information in terms of their child's best interests (Quote 28). Parents reported they have noticed that many parents in the SMGs appear to trust it implicitly and will share highly confidential data (Quote 29). However, some parents stated that they had little confidence in anything they shared being kept private (Quote 30) and that there are no guarantees that the people who join are genuine (Quote 31).

Foster carers described a nuanced aspect regarding the privacy of data and the need to protect a looked-after child's identity, particularly within a small SMG in which a birth parent may be a member if they have the same genetic condition as the child

XSL•FO
RenderX

(Quote 32). This need for heightened privacy limits their ability to access the same amount of support from the SMG as others.

Second, parent views on the reliability and use for the data in the groups:

Parents discussed how they assess digital content for scientific validity. All report using search engines, mostly Google, as a starting point. Many reported that they would trust information that was in a scientific journal or if it was affiliated with a university in some way (Quote 33).

Third, parent views on the trustworthiness of the data in the groups:

Parents perceived a bias in the frequency of posters, but there were differing views. A parent commented that "you do tend to hear more from the people that are having the worst time"(#15, father), whereas another parent reported that the parents who post most have the "mildest" children (Quote 34).

Nonetheless, parents feel they are objective about the information being presented and consider it useful but anecdotal (Quote 35). Another parent talked about the need to verify and fact-check information from within the SMGs (Quote 36).

Fourth, parent-independent research and participation in research:

Although a lot of data are being collected in SMGs, most parents doubted that useful information could be extracted, or that it would be legal to do so, but felt that it was helpful to be able to search old threads such as regarding treatment options (Quote 37). Parents suggested that the data could be used to identify themes that could guide researchers toward avenues for future studies (Quote 38).

A parent reported that a large language model application is being used within their group that she found out about recently at the family conference (Quote 39).

Most parents described researching their child's specific genetic variant themselves. For some, this would be through the SMG, and some parents would develop expertise and answer other members' questions about the variants within the group. To gain understanding and expertise, they use online data sources with a search engine as a starting point (Quote 40).

Many parents reported taking part in online registries and in rare disease portals where they are asked to complete questionnaires at intervals. Parents considered this as being very different from their posting in Facebook groups, thinking of the former as scientific research and the latter as anecdotal and social.

Integration

Table 2 shows the side-by-side comparison approach of the qualitative and quantitative results. Mapping of the themes to the survey findings confirmed that parents highly valued SMGs for emotional support and shared experiences, though some reported moderate concerns about anxiety. Group composition influenced perceived support. While parents generally trusted SMG data, they acknowledged potential bias and privacy concerns.

Table . Joint display table mapping qualitative themes to quantitative results.

Qualitative theme	Subthemes	Mapped quantitative findings	Interpretation
Support and shared experience	Signposting by professionals, emotional connection, and practical advice.	High agreement (8.52/10) on SMGs[a] providing contact with similar experiences.	SMGs are a vital support system for parents.
Potential harms	Anxiety, distressing content, and misuse of data.	Moderate agreement (4.69/10) on SMGs causing anxiety.	Harms are present but not dominant; qualitative data adds nuance.
Group composition and dynamics	Inclusion criteria, international versus local, and platform choice.	A total of 98% (354/359) of SMGs on Facebook; some use WhatsApp or LinkedIn.	Group structure affects experience; larger groups may dilute support.
Usefulness and data trust	Privacy concerns, trust, bias, and research use.	Mixed scores: trust (7.03), bias (5.77), and doctor use (6.79).	Parents value SMG data but recognize limitations and risks.
Independent research and advocacy	Self-directed learning, registry participation, and data mining.	Not directly surveyed.	Parents are proactive in research; SMGs serve as informal knowledge hubs.

[a]SMG: social media group.

Discussion

Principal Findings

Use of SMGs is highly prevalent in this cohort and provides support and information to fill an existing gap. However, the information in these SMGs is largely anecdotal, requires a degree of critical assessment, and can cause anxiety. Understanding SMG use and activity is important to ensure optimal support for parents, to address information needs adequately, and to improve collaboration between parents, clinicians, and researchers.

Some parents told us in interviews that they were directed to the SMG by their child's health care professional who suggested it to them as an avenue of support and information. Unfortunately, this was not specifically quantified within our parent survey but is consistent with a previous study in which a quarter of parents were directed to the group by their child's health care professional [4].

XSL•FO
RenderX

Parents value these SMGs very highly as shown by their high Likert response and qualitative analysis that is consistent with the literature [5-7,9,20,21]. Most parents view the SMGs as an opportunity to connect with other families who are in the same situation and develop real connections with them and friendships. Parents particularly valued the chance to understand the spectrum of the NDD by looking at other members' posts about their children. Having members with older or adult children allowed them to get some understanding about the long-term outlook for their child, which is consistent with previous literature [5,21-23].

Some parents also use the SMG to obtain quasi-medical advice from other members and would trust it implicitly. We cited an example where a parent chose not to be present for an acute review of her child based on medical advice provided within the group. An important factor here may be responsiveness—Facebook groups provide rapid responses and ongoing support and feedback [24], which may empower a parent to make a decision to "watch and wait." However, some parents in our study reported concerns about using the group in this way and expressed concerns that the level of trust placed in the reliability of such advice might be unfounded or too high. This is echoed in a previous analysis of Hirschsprung disease in which the Facebook group was shown to have reach and responsiveness but lacked consistent evidence-based guidance in the posts [24]. A particular use detected in our study was to prepare a parent before a child's health appointment to ensure they knew what to discuss and request from the provider. While this behavior is cited as common among parents of all children [1], it is more nuanced in NDDs where parents may feel that they need to undertake this preparatory research to negate their clinician's lack of expertise. If clinicians recognize this phenomenon is occurring, they can use this as a route to provide better collaborative support for parents. An example of this might be suggesting to parents that they may read information in SMGs that they might want to note down and come prepared with some questions or even inviting parents to send questions in advance, which might allow the clinician adequate time to do their own research. A real-world scenario could involve a clinician opening with the question, "Have you read anything on the Facebook group that you want to discuss with me today?"

Most parents indicated high levels of trust in the SMG (by the Likert scale responses) and are not worried about their data or put off posting for this reason, although a small proportion did discuss their concerns around this. A study in 2022 of 231 parents indicated that parents do express concern about privacy issues and that the SMG's privacy setting can be a critical factor influencing active support group participation [4]. However, almost half of our respondents could not recall whether they had been asked to agree to any statements regarding consent or privacy when joining, but continued to participate in the SMGs. The analysis of parent interviews suggests that parents with the highest levels of concerns around privacy would be most cautious about what they post in the SMGs. It is also noteworthy that an SMG appears to be using some form of natural language processing model to mine the data for themes. This raises questions regarding consent within the groups and use of data.

Looked-after children represent a particularly vulnerable group within social media, and foster or adoptive parents are required to hide their identities to protect them. This can be difficult with a rare NDD where patient numbers may be very small. Genetic variants can be unique to a family or individual and could theoretically be identifiable, and so this may limit the foster or adoptive parents' options for interactions and questions within an SMG, limiting their support opportunities compared to other families.

SMG participation is not without its downsides. A spike in anxiety can occur initially after joining, particularly when this occurs soon after receiving a diagnosis (which is the most common time that parents join). Nonetheless, most of the survey respondents did not agree that the SMG made them worry more. The potential negative impact is sparsely discussed in the literature to date [6].

There was recognition of posting bias within the SMGs, but some of the parents who talked about this felt that they were able to assess the posts and come to conclusions about bias themselves. However, parents trust the data that are shared, as evidenced by the high levels of trust reported by the Likert scale, and parents report making health care decisions about a child presenting with new symptoms based on the SMG responses.

Our results show that there are many NDDs that have more than 1 SMG, which families can join, consistent with a previous estimate that 33% of monogenic disorders had more than 1 SMG [9]. It is likely that this percentage will have increased based on the rapid acceleration of diagnosis in these conditions. The same study found that SMGs with large numbers of members were more likely to be active and have the most posts [4]. This is in keeping with our findings that parents are likely to go to larger SMGs where they feel they have the highest chance of getting data that they seek. However, these larger SMGs appear to have downsides, as does the presence of more than 1 group per NDD. Our results suggest that there are increasing politics and tensions within groups, particularly where there is a suggestion of increasing competition for members within NDD charities and foundations, and that the SMGs may be being used to steer members toward particular organizations. These changing dynamics are scarcely explored in the literature to date, which may be because this is a newly evolving phenomenon with time and rapidly increasing numbers of diagnosed conditions.

The changing dynamics within groups have resulted in some groups trying options that are not Facebook. This has included WhatsApp as an option for 1 UK-based group who has fewer than 50 families. The decision was made to try and create a more UK-specific option for families. However, functionality may become a barrier as the group increases in size, as might its lack of interactive options and easy search tools. Our results otherwise suggest that parents are not using other platforms very much for this specific purpose. A smaller number of parents use LinkedIn, but particularly for professional advocacy purposes.

Facebook groups are closed, and it appears this is vital for ensuring families feel able to participate in a way that protects their privacy needs [8]. Nonetheless, our findings suggest that

XSL•FO
RenderX

SMGs could increasingly be used by researchers to engage with patient groups better. In addition, we report several examples within groups to determine appetite for a topic of research or assess the availability of data before embarking on a research proposal. Using poll results could also identify important topics that matter to families. Researchers need to establish positive connections with group administrators to do this successfully. Very little exists in the literature to date on this theme, again reflecting this rapidly advancing field and area.

Strengths and Limitations

This study uses a large cohort of parents of children with a mix of genetic conditions from across the United Kingdom. The majority of survey respondents and interviewees were mothers, but some fathers were included. Our methods were able to capture responses from parents who do not use SMGs or who have stopped doing so, as well as regular users. The lead investigator is a clinical geneticist, but the second coder for the interviews is a nonclinical experienced behavioral and psychological qualitative researcher. Parents described negative experiences with health care professionals suggesting that they felt able to express their views despite the researcher's clinical background. The PQ2 survey had questions that had hoped to capture parental behavior change regarding SMG with time but were limited in the short interval between survey administrations for some families who were recruited later.

Conclusions and Implications for Practice

Data poverty in rare diseases drives parents to do their own research and propels them into SMGs for connection. Parent-reported data in groups reflect lived experience data. SMGs are essential for parents as a space to connect and compare experiences and may represent an opportunity as an avenue to drive forward research connections and priorities and allow for opportunities for advocates and peer mentoring to flourish. Parents use SMGs as a quasi-clinical advisor in some situations and for preparation before attending health care appointments—this could represent a way in for enhanced collaboration with parents in the clinic. The rapidly changing landscape of NDDs may shift the dynamics within groups that could result in an evolution in the number of groups and platforms used. Limited reports exist on the negative aspects, and these appear to be a minority, but some parents reported reducing or stopping their use of the group altogether, which may be associated with these problems. Further research should ascertain if this is an increasing trend, as this could result in a support gap for parents in the future. Changing behavior over time and evolving information needs represent an avenue for future research.

Acknowledgments

We thank all the parents in the Genetic Rare Disease: Observational Cohort (GenROC) study for contributing their views and the GenROC study patient participant involvement (PPI) panel for their invaluable thoughts and guidance. The GenROC consortium comprises multiple contributors from National Health Service (NHS) sites across the United Kingdom, including individuals who have either acted as a local site principal investigator (PI) or associate PI, completed clinical proformas for GenROC, or contributed in other ways. The full list is shown in Section S7 in Multimedia Appendix 1. Tables S1-S4 in Multimedia Appendix 1 show quotes from parents for themes 1-4, and Section S5 shows the list of GenROC consortium members. Abstract

Background: Widely accessible, cost-effective early language development interventions for caregivers of young children are needed to promote optimal outcomes in children in the United States. Social media short-form videos, such as those on TikTok, may be a natural fit for delivering this type of intervention.

Objective: This study aims to examine the feasibility and acceptability of a low-intensity, short-term social media intervention for caregivers of young toddlers.

Methods: In total, 25 caregivers of children aged between 12 and 18 months participated in this study. We shared 32 short-form videos via TikTok over an 8-week period to help increase caregivers' knowledge about early childhood communication. We examined metrics to characterize participant engagement, explored measures of changes in caregivers' knowledge, and conducted a qualitative analysis of caregiver interviews after the intervention.

Results: Results indicated that most caregivers were able to consistently view the videos, with approximately 75% (16/21) viewership per video (mean 15.75 likes out of 21 possible likes), and caregivers reported positive effects of the intervention on their knowledge of how to support their child's communication. The results of the exploratory measure of change in caregiver knowledge were positive but not statistically significant (t_{21}=–1.357; P=.09). Caregivers offered suggestions for content and enhancements to videos for future investigations.

Conclusions: Low-cost, short-term social media interventions could be an effective means to equip caregivers with the information they need to advance their children's language abilities, particularly for families from lower-income backgrounds whose access to health information about their young children may be limited.

Introduction

Background

Infants undergo multiple developmental transitions that change the way they engage with the world around twelve months of age. Most infants take their first steps to become new walkers, become more consistent and advanced gesture users, and make the transition to symbolic language as they say their first words [1]. In the months that follow, variability in children's expressive vocabulary appears as some children learn words quickly, while others learn words more slowly [2]. Because children's language

XSL•FO
RenderX

outcomes are directly linked to their academic, social-emotional success, and mental health, promoting optimal language learning is a critical public health issue [3]. Efforts to bolster early language learning by supporting caregiver-child interactions, especially in lower-income communities, are key to promoting school readiness, social and emotional learning, and optimal language outcomes in all children [4].

However, more research is needed on effective interventions for caregivers and children at the population level to promote optimal child language outcomes while providing targeted support for children in greater need of intervention [3]. Investments in population-wide, universal interventions may bolster child outcomes by increasing caregiver knowledge and confidence in supporting their infant's early learning. Unlike more intensive coaching approaches that are often geared toward lower-income families, widely accessible interventions may also avoid stigmatizing families who are often the recipients of preventive interventions [5]. In this feasibility and acceptability study, we describe the development and the use of a cost-effective, media-supported approach to sharing information and strategies with caregivers to support language learning in toddlers aged between 12 and 18 months, a critical developmental inflection point. The BabyTok Project is designed as a light touch social media–supported intervention to increase caregivers' knowledge about early language learning and how they may promote it with the use of specific strategies.

Factors That Support Early Language Development

Caregiver-child interactions in the first few years of life are influenced by a family's culture [6] and what caregivers know and believe about children's language and cognitive development [7]. Caregivers who believe that children's language learning begins early and is dependent on the input from adults around them are more likely to engage their children in back-and-forth exchanges [7]. For their part, children also influence caregiver-child interactions through their own initiations and contributions during exchanges through vocalizations, gestures, gaze, and early word use [8].

While it is well established that sufficient language input is related to infants' early language learning [9], other characteristics of caregiver-child interactions contribute to meaningful moments of early word learning. For instance, the degree to which caregivers and children engage as conversational partners during back-and-forth turn-taking exchanges relates to children's later language outcomes as well as their neuroanatomy and physiology [10,11]. Caregiver input that is timely, contingent, and functional within the immediate contexts of everyday life also helps to facilitate early language learning [12]. During infancy and the early toddler years, linguistic features such as caregivers' use of parentese (marked by more exaggerated intonational patterns and repetition of words and phrases), gestural input [13], and touch cues also support early language learning in the first 2 years of life [14]. While some caregivers may know that these strategies support their child's ability to talk, others may not, particularly if they are first-time caregivers who do not have extensive experience interacting with infants and toddlers or if they do not have access to information about how children learn [7,15].

Interventions to Increase Caregivers' Knowledge About Early Language Learning

Several interventions that center on infants, toddlers, and caregivers demonstrate promise in supporting child language learning, particularly in communities experiencing poverty. For example, the "3Ts" home visiting curriculum [7] and another model named Duet [16] use home visiting models to enhance caregivers' knowledge and responsive interactions with toddlers. However, limitations of such approaches relate to scalability and cost. Training and employing home visitors for more time-intensive models limit the ability of programs to offer support for every child and family who qualifies. This does not mean that more intensive programs are not worth the investments they require; rather, additional approaches are needed at the population level to support widespread access to developmental information that may influence caregiver-child interactions.

Several mobile health interventions aimed at caregivers of very young children have shown evidence of effectiveness in increasing caregiver knowledge [17,18]. For example, an intervention called Sharing Stories used WhatsApp as a platform to promote responsive caregiving and parent well-being within a 6-week intervention in Tanzania. Caregivers in the intervention condition, which consisted of 6 content webinars on early learning, reported higher developmental outcomes for their children than the control group [19]. Fully asynchronous app-based interventions such as Háblame Bebé are also being tested in the United States to examine whether low-intensity interventions have a direct impact on caregiver-child interactions by sharing information about "language nutrition" in the early years of life [20]. While data from a randomized controlled trial are mixed related to the ability of Háblame Bebé alone to impact caregiver-child interactions, caregivers report positive outcomes related to increased knowledge about children's language learning and cultural pride regarding their use of Spanish with their child [21]. Compared to other areas, such as maternal and child health, developmental interventions that focus on early language development using social media are rare [17].

Although research evaluations to support early language development on social media are scarce, they could be a natural fit for mobile health interventions because many caregivers in the United States use social media to seek information and connections with others as they transition to parenthood [22,23]. Approximately 89% of new caregivers report using social media apps to search for information and social support about caregiving-related topics, such as infant sleep, feeding, growth, and development [24]. Low-income communities in the United States report the use of social media and the internet to access parenting information and social support at high rates, making it a logical platform to share information that could be accessible for all caregivers [23,25]. Mothers with low incomes in the United States have described using their mobile phones as a primary source of access to the internet, and they report using search features to quickly gain access to information while multitasking with other responsibilities [25]. Creators on social media already generate publicly available content specific to supporting language learning in young children and have large followings of caregivers. However, few investigations explore

whether caregivers can consistently access and retain information and use strategies from social media to support language-rich interactions with their children.

BabyTok Project

We first developed and tested the BabyTok Project as a means to connect with teachers of infants and toddlers during the COVID-19 pandemic because it made use of mobile technology while social distancing [26]. In our initial study, we conducted an 8-week intervention with teachers serving infants and toddlers in low-income communities by giving an overview of early communication development in the first year of life, responsive strategies to support child communication in the classroom, and affirmations for teachers about their critical role as early educators during the pandemic. The BabyTok Project reinforced the infant toddler teachers' positive interactions with children as described by the teachers, encouraged them to implement new communication strategies with children in their classroom in some cases, and increased or reinforced feelings of pride in their role in children's learning. Results also indicated positive, though not statistically significant, gains in knowledge scores related to early language learning on a standardized measure. Most participants endorsed the use of social media as a platform for the BabyTok Project because of its convenience, engaging style, and short-form nature [26].

Purpose of This Study

The purpose of this investigation is to examine the feasibility and acceptability of the BabyTok Project as a means to support home-based caregivers' knowledge about early language development and intervention. Feasibility is characterized by caregiver retention and caregiver engagement with the project videos and procedures, and acceptability will be described through qualitative analysis of caregiver interviews after the intervention. We also use an exploratory measure to determine the potential of the tools to capture change from a light-touch intervention such as the BabyTok Project for future effectiveness studies.

Methods

Participants

Study recruitment occurred in the summer of 2022 through an informational video that was posted on TikTok (ByteDance) and the study flyer posted on relevant Facebook (Meta Platforms, Inc) groups. To be eligible, caregivers had to (1) have at least 1 child aged between 12 and 18 months and (2) receive at least 1 public benefit (Women Infants and Children, Medicaid, Temporary Assistance for Needy Families, and housing assistance), which served as a proxy for income. Interested individuals were directed to a survey link that included 2 screening questions to verify their eligibility status (ie, "How old is your child?" "Does your family receive any of the following assistance: commodities, food stamps, housing assistance, Medicaid, supplemental security income, and/or WIC?"). While the intervention was intended to be universal, we focused recruitment on caregivers who used social services to ensure that the intervention was accessible and acceptable to caregivers with fewer financial resources.

After duplicates and incomplete responses from the initial interest survey were removed, 42 eligible caregivers across the United States expressed interest and shared their information to join the study within the 7-day recruitment period. Of them, 27 (64%) caregivers completed pretest measures and began participation in the study, while the remaining 15 (36%) did not respond to pretest measures. We held an initial Zoom (Zoom Communications, Inc) meeting with each of the 27 participants, which ensured the participants were real and not bots. Moreover, 2 (7%) participants did not complete any posttest data and were considered lost to attrition, so demographic data for 25 participants were reported. The study participants included 24 (96%) mothers and 1 (4%) grandmother. In total, 11 (44%) participants were White, 8 (32%) were Black, 2 (8%) were multiracial (Black and White: n=1, 4%; Black, White, and Hispanic: n=1, 4%), 1 (4%) was Asian, and 1 (4%) was Hispanic. In addition, 1 (4%) participant did not self-report her race or ethnicity. All (n=25, 100%) participants spoke English, and 4 (16%) spoke an additional language (ie, Spanish or Vietnamese), and they were aged between 23 and 49 years. In total, 15 (60%) participants reported having a male child, 10 (40%) reported having a female child, and none (n=0, 0%) were identified with a developmental condition (Table 1 presents more demographic information about the participants).

[a]GED: General Educational Development.

BabyTok Project Videos

The BabyTok Project videos were developed by the research team using the video production capabilities within the TikTok platform. Most videos featured the first author as a narrator in a conversational style that is common on the platform. All videos were recorded by the first author on her handheld iPhone (Apple Inc). The first video was an introduction by the first author explaining her credentials as a speech therapist and researcher and providing more details about the project. She served as the "narrator" for the videos and is a White female researcher who is also a parent. As 56% (14/25) of our sample was not White, we asked for feedback on her narration and relatability to gain participant input to guide future investigations. While we did not use caregiver feedback to guide the development of this set of videos, we built in feedback opportunities in the postintervention interviews to gather caregivers' ideas and preferences for content. A total of 33 videos (1 introduction video and 32 content videos) were shared with participants across 4 overarching topics: *using words*, *shared book reading*, *learning in everyday routines*, and *affirmations*. Videos were developed using the best available research on strategies to support early caregiver-child interactions and early development as described in the study by Romano et al [26].

At the midpoint, the first author also offered participants an opportunity to choose between topics to give them a role in content development, and most participants chose to gain more information about routines (Table 2 presents more detailed descriptions of the videos).

Table 2. BabyTok content video descriptions (n=32).

Topic	Videos, n (%)	Purpose
Using words	9 (28)	Children learn so much in their first few years of life, and their caregivers have a lasting impact on their development. These videos introduced expectations of milestones at various ages and strategies for supporting children's language development, such as expanding on their words and providing choices.
Shared book reading	6 (19)	Shared book reading with toddlers is shown to support their language learning and academic success. These videos shared information about the benefits of reading to toddlers, strategies to use during book reading, and choosing appropriate books for toddlers.
Learning in everyday routines	12 (38)	Learning opportunities are plentiful throughout daily routines. These videos shared foundational information about routines and examples of strategies to use during common daily activities, such as getting dressed or mealtime, to facilitate language development.
Affirmations	4 (12)	These videos were shared throughout the intervention as messages of encouragement for caregivers about their role as parents.
Participant Input	1 (3)	In this video the narrator asked participants for input about which topics they would like to learn more about in future videos.

Study Design

We used a convergent parallel design with an intervention mixed methods framework with a primary focus on qualitative data [27] to investigate the feasibility, usability, and acceptance of the BabyTok intervention for caregivers of young children. We collected qualitative data to support the continued development of the BabyTok intervention and quantitative data to investigate engagement and use of the intervention and its short-term effects and explore the utility of the measures used to describe intervention effects. The data were merged after individual analysis to present results on the holistic effects of the BabyTok intervention.

Measures

TikTok Engagement Metrics

TikTok engagement metrics were gathered to examine the feasibility of the intervention to shed light on how many videos participants viewed and how often they liked and commented on the videos. Public TikTok account owners have access to TikTok Analytics, which tracks metrics, including the number of likes, the number of shares, the number of views, and the average time viewers spent watching videos. However, to maintain a level of confidentiality for participants, we used a private TikTok account, and this precluded us from having access to all TikTok Analytics data. However, we were able to manually see total views for each video, the number of likes, and comments by each participant. To collect data regarding the participants' use of the BabyTok video series, participants

XSL•FO
RenderX

were asked to "like" the videos posted to indicate that they viewed them. To collect additional data about participants' engagement with videos, caregivers were invited to comment on the videos. Individual responses were tracked for each video by clicking each post and reviewing who liked or commented. After the study was completed, the TikTok metrics were analyzed by recording the total sums of likes and comments per video and the total sum of likes and comments per participant across the 8 weeks of the intervention and calculating the mean, SD, and range for each. The feedback was analyzed by reviewing individual comments made for each video.

Caregiver Interviews

Postintervention interviews were used to evaluate the feasibility and acceptability of the intervention from the vantage point of the caregivers. Participants were interviewed in English by a trained graduate research assistant or second author through web-based meetings on Zoom using a semistructured interview protocol. The semistructured interview protocol was adapted from a previous study that investigated a similar intervention with childcare providers [26]. The protocol contained 7 questions about what participants recalled from the BabyTok videos, their feelings about their role as caregivers because of the BabyTok intervention, and the impact of the BabyTok intervention on their interactions with their child. Questions also focused on the suggestions and feedback participants had about the BabyTok videos and if they would like to see content about different topics (Multimedia Appendix 1). Each interview lasted approximately 10 to 15 minutes, was screen recorded, and was transcribed using the Otter.ai platform. Two graduate research assistants reviewed the transcriptions and corrected any errors.

Exploratory Measure (Survey of Parent/Provider Expectations and Knowledge-Research)

For this study's purposes, the Survey of Parent/Provider Expectations and Knowledge-Research (SPEAK-R) was used as an exploratory tool to quantify changes in parents' perceptions of their understanding of the early childhood cognitive and language learning. The SPEAK-R is a 22-item, self-administered questionnaire designed to assess knowledge of and beliefs about early childhood cognitive and language development [28]. The questionnaire consists of 4 multiple-choice items, 14 Likert scale items scored as *definitely true (0)* to *definitely not true (4)*, and 4 Likert scale items reverse scored as *definitely not true (0)* to *definitely true (4)*. The questions focused on six topics: (1) bilingualism, (2) early exposure, (3) media use for child learning, (4) nature versus nurture, (5) sensitivity and responsiveness, and (6) talking and reading [28]. The SPEAK-R survey was developed and tested on multiple population samples that included caregivers with low incomes [15]. The second version (SPEAK-2) showed significant, positive correlations between scores and level of education, receptive language skills, and the quality of language in the home environment. The mean SPEAK-R score reported by its developers was 47.27 in a sample with low-income caregivers [15]. The SPEAK-R indices were proven reliable during field testing with Cronbach α scores of 0.92 [28]. The SPEAK-R was conducted at entry and after the 8-week intervention. The measure was gathered and scored using REDCap (Research Electronic Data Capture; Vanderbilt University), and the data were imported into SPSS (IBM Corp) for analysis.

Procedures

After the consent process was completed, the research team sent out a step-by-step handout via email and SMS text message with information for completing the pretest measures and accessing the BabyTok study channel. Participants completed a demographic survey and the SPEAK-R online. They also scheduled an observation with a member of the research team, hosted via a teleconferencing platform, to verify that they were not bots and to use it to pilot other potential observational measures. Caregivers were asked to interact with their child as they normally would during a typical routine or activity they would be engaging in during that time, such as playing with toys, book sharing, or caregiving activities, such as snacks and diaper changes.

After all participants completed the pretest measures, the research team began sharing videos with all participants on the social media platform 3 to 5 times per week. The videos were posted on the channel, and they were sent to the participants via direct messages. Participants were encouraged to watch each video, like, and comment to verify that they viewed the videos. At the end of this 8-week period, participants completed the posttest measures, which included the SPEAK-R and another recorded caregiver-child observation as well as an independent web-based interview regarding participants' perceptions of the BabyTok intervention.

Data Analysis

TikTok Engagement Metrics

We used a descriptive quantitative analysis to show means and ranges of the TikTok engagement metrics. We obtained simple counts of likes and comments per video and the number of likes and comments per participant.

Caregiver Interviews

The transcripts were analyzed based on the template analysis method as described in the study by Brooks et al [29]. The qualitative coding team included a doctoral student, a graduate-level research assistant, and an undergraduate research assistant. To become familiar with the data, each team member read and reread the transcripts and took general notes on thoughts about overall themes in the data. Next, the team met, discussed the data, took more notes, and began developing preliminary codes based on the interview questions, responses to the questions, and themes from a previous BabyTok Project [26]. The 3 main codes developed at this meeting were *takeaways from BabyTok*, *effects of BabyTok*, and *attitudes or perspectives or feelings about BabyTok*, and each code was assigned a different color. Next, the team split the transcripts among individuals and separately coded quotes within the transcripts by highlighting them in the color assigned to the corresponding code. The team met several more times to ensure the codes effectively described the data the data. Codes that were no longer applicable were removed, codes were reorganized and redefined, and a more accurate template was

XSL•FO
RenderX

developed. Specifically, we recognized that the code *takeaways from BabyTok* overlapped with the code *effects of BabyTok.* Because of this overlap, the codes were reclassified, with the code *takeaways from BabyTok* becoming a subcode of the code *effects of BabyTok.* In addition, the code *attitudes or perspectives or feelings about BabyTok* was split into the subcodes *supportive feedback* and *recommendations*. The team also identified several pieces of data that did not fit into the codebook framework but were important because they described the usefulness of the BabyTok content for different caregivers and in different contexts. Thus, the new subcode of *supportive feedback: content is useful for all caregivers* was established. Next, the team looked for disconfirming evidence or null effects. Because very few examples were discovered, instead of a separate code, we decided to include *negative or null effects* as a subcode of *takeaways from BabyTok*. Finally, the team cross-checked each other's coding by pulling a sample of 50 significant quotes from the transcripts and independently coding each quote to ensure consistency of coding. The final coding template included codes, subcodes, definitions of subcodes, and an example of a quote for each subcode (Table 3 presents the codebook).

To ensure the trustworthiness of the data, the data analysis team took several steps, such as those described by Nowell et al [30]. Our approach included data familiarization, debriefing with the first author, checking for coding reliability to support the credibility of our findings, providing thick descriptions coupled with several examples of direct quotes to increase transferability, and keeping an audit trail of our decision-making process to achieve dependability. By taking these steps, the confirmability of the data was established [30,31].

XSL•FO
RenderX

Table 3. Codebook for posttest caregiver interviews.

Theme	Definition	Sample quote
Effects of BabyTok		
Changes in how they interacted with their child	Differences in how the caregiver approached communicating, engaging, playing, and building a relationship with their child or children after participating in the BabyTok intervention	"I feel like I'm a lot more mindful of what I'm doing when I'm interacting with her...I try to repeat phrases more often and kind of pause and let her try to do it as well."
Changes in how they viewed their role as parents	Differences in how caregivers viewed and felt about their impact on their children (eg, how they develop, communicate, and learn) and/or differences in how they felt about their own parenting style or skills	"I was very critical about her not speaking yet and...really worried about it. But then she just...made me feel better...it's okay if they're not as far with their language as they're supposed to be...it helps me,...feel more grounded and not,...stressed out about it as much."
Changes they noticed in their child	Differences in the child's behavior and communication after trying BabyTok techniques, strategies, and tools.	"We're introducing 'POW'...the point, wait, and the wait for them to repeat type thing,...I noticed that my daughter was catching on to things a lot quicker when I was using like some of those resources."
Takeaways from BabyTok[a]	Information that caregivers described as remembering, learning, trying, or as being useful after participating in the BabyTok intervention	"...what I remember most is just labeling everything for them to help them build their vocabulary. So just labeling and giving them wait time to just kind of let it sink in and process."
Supportive feedback		
Use of social media platforms	Comments about the convenience and accessibility of hosting the videos on TikTok (eg, did not take a lot of time, could do from anywhere, and familiarity with TikTok)	"...I enjoyed all the content, it was super accessible to have it on TikTok, because it was there, and I could watch it once it was posted when it was convenient to me."
Engagement with other caregivers	Comments about interacting with and relating to other caregivers through the BabyTok platform to feel affirmed and build camaraderie	"...just to hear other people's opinions,...I'm dealing with the same thing as a mom' and it was just very enlightening. Sometimes you think like you're the only one in this situation, but come to find out you're not..."
Content delivery expert	Comments about the narrator in the videos and as the facilitator	"She is very enjoyable to watch. She's really cute. And she's really engaging....I enjoyed watching her videos...if you're wondering whether she's an appropriate candidate to continue doing videos, she's great. I loved her."
Trustworthiness	Comments about the credibility of the information shared and/or the participants' confidence in the source	"...I get a lot of parenting videos...but I don't know, for a research project,...I definitely felt like I was getting the right information versus you never know exactly what you're getting..."
Content is useful for all caregivers	Comments that the content was useful for new and experienced parents as well as other caregivers like grandparents.	"I think it's a great resource for all parents,...new and parents that are already experienced in parenthood just to open your mind and broaden your horizon and other ways to help implement teaching resources for your child."
Recommendations		
Content suggestions	Suggestions regarding the topics covered throughout the BabyTok project (eg, behavior management, potty training, routines, sign language, and bedtime)	"I guess one thing that I wish was covered a little bit more was routines...Routines and...how we can build in little learning...incorporate learning opportunities into our daily routines..."
Delivery suggestions	Suggestions regarding how the BabyTok project is shared, including what social media platforms are used, the format of the video, and how the participants were notified	"If maybe, throughout the project, there was like a email that went out at the end of the week, like, 'Hey, make sure you watch these five videos.' So, I knew if I missed one, to go back and find that rather than having to scroll through the whole account,..."
Suggestions for the engagement of users	Suggestions regarding how to increase interactions with BabyTok users, including how to facilitate discussion among users and how users could share videos of their children	"If it was more interactive with those that were participating...maybe if there was some type of participation through the process, outside of maybe commenting."

[a]Null and negative effects are included here and not as a separate subcode because they were uncommon but still relevant.

Ethical Considerations

All participants provided implied consent for the institutional review board–approved study (Florida State University 10003010) through an online interest form with a waiver of documentation of consent. Participants received up to US $100 in gift cards for compensation. Compensation was distributed via mail after pretest data collection (US $50) and the social

XSL•FO
RenderX

media intervention and posttest data collection (US $50). All participants were issued an alphanumeric code for all data files. One single excel file linked personal information to the code. The linking file and deidentified files are kept on an encrypted Microsoft Teams folder hosted by the university.

Results

TikTok Engagement Metrics

In total, 32 videos were shared across the 8-week intervention period. The data were gathered on 21 participants. We excluded 4% (1/25) of the participants who were lost to attrition (ie, did not complete any follow-up data) and 12% (3/25) of the participants who unfollowed the BabyTok page after the project ended. We were unable to gather their data from TikTok after they exited the group. Participants were asked to like a video as confirmation that they viewed it; 24% (5/21) of the participants liked all 32 videos, and most (16/21, 76%) of the participants liked more than half of the videos (mean 23.95, SD 8.99; range 3-32).

To understand which videos garnered the most engagement and discussion from caregivers, we examined the number of likes per video and the number of comments per video. The videos with the most likes (n=18) were videos about milestones for children aged 1 year and those aged 18 months and a video about modeling and waiting when labeling objects. In total, 2 (6%) of the 32 videos received the least number of likes (n=13); one was a video that asked participants' opinions about which video topics they would like to see posted during the week, and the other was about activities to engage in during a morning routine. Overall, viewership of each video was 76% (16/21); the mean was 15.75 (SD 1.39; range 13-18) likes per video. The number of comments per video ranged from 2 to 14 (mean 6.44, SD 2.68). The video with the greatest number of comments (n=14) was posted on the first day of the intervention and asked caregivers to share the words their babies understand. The video with the second-highest number of comments (n=12) asked caregivers to answer the question, "What's your baby up to?" The videos with the least number of comments, 2 each, were about coviewing with screens and constructive play.

We also gathered the number of comments per participant to understand more about engagement per participant. The number of comments was unevenly spread among the participants, with 4 (19%) of the 21 participants commenting >20 times and 13 (62%) participants commenting ≤5 times (mean 8.81, SD 8.9; range 1-28). When commenting on videos, participants typically shared their positive feelings toward the strategies suggested. Participants shared their excitement to try the strategies. For instance, about a video called *Three Tips for Book Time*, a participant stated, "I'll have to try this! Especially the waiting strategy." About a video describing a strategy of pointing, using 1 word, and then waiting a few seconds for a response, a participant shared, "I'm going to try it tonight when I read to him." Participants also shared how they were trying the strategies and how their children were responding. When commenting on a video about modeling words instead of pressuring children to say words with several prompts, a participant shared, "I did this with [my] son with 'banana' [his favorite food], and he tried to say it!" One participant shared how a motivational video helped her after a challenging time with her child. After viewing the video, *They Come to You*, she commented the following:

> *I needed to hear this today. After a long night with the babe, sometimes it's so easy to question my motherhood journey.*

Other common responses in the comments included sharing about their babies' milestones and how they felt affirmed and emoticons of smiles, laughs, and hearts.

Caregiver Interviews

Participants' perspectives of the BabyTok intervention were organized into 3 main themes: effects of BabyTok, supportive feedback of BabyTok, and recommendations for BabyTok. Each theme included 3 to 5 subthemes, as displayed in Table 3. In total, 23 (92%) of the 25 participants completed individual interviews following the 8-week BabyTok intervention.

Effects of BabyTok

Changes in How They Interacted With Their Child

In response to how the BabyTok videos impacted their interactions with their children, many (21/23, 91%) participants reported becoming more purposeful, more mindful, more positive, paying closer attention to their child, having more face-to-face interactions, and using strategies to promote communication more often. One participant stated the following:

> *I feel like I'm a lot more mindful of what I'm doing when I'm interacting with her on trying to do things that she might copy so that she can implement that and understand what I'm doing. I try to repeat phrases more often and kind of pause and let her try to do it as well.*

Another participant discussed the change in her phone use when interacting with her child:

> *I think it made me sit down and do more face to face with her. Get off the phone a little bit...and make sure that we are doing things to help promote her speech and just spend more time with them.*

Changes in How They Viewed Their Role as Parents

Participants reported changes in how they viewed and felt about their impact on their children's language development. They also expressed how they felt about their own parenting style or skills. For example, one participant described a change in her confidence and in the importance of her role:

> *I feel a lot more confident in my role and helping to develop her language development. And her development in general, like, the videos and description of the one-on-one time and the eye-to-eye contact, all of that being kind of brain food or setting them up for success...It made me feel like I had a more important role than I was giving myself previously.*

Another participant described how her understanding of the parent's role in a child's language development changed:

XSL•FO
RenderX

> *It kind of...put that into perspective and how I actually need to do that [consistently label] to help him develop, like how critical parents are to developing the language. It doesn't just come naturally to them from listening.*

Other (9/23, 39%) participants expressed their thoughts on their role with statements such as, "What I learned is that basically, we play a huge part in, you know, teaching our kids," and "...it made me feel more confident in things that I was doing," and "I feel like I have to remember to do a little bit more teaching than I did, than I have in the past."

Changes Noticed in Their Child

Participants described noticing that their children paid more attention, learned more quickly, and began to copy words. For example, after using a specific strategy from the videos, a participant stated the following:

> *It seems like still, he pays attention more when I do it. And it's nice, because it shows that he's trying to listen, and figure out what I'm saying.*

Another caregiver noticed that her child was beginning to say words because of trying a strategy suggested in a BabyTok video. She stated the following:

> *But she is picking things up like—she did say "cat" while we were doing that after I pointed out cat several times on several pages to her. I wasn't getting that kind of a reaction or that kind of an interest or response before I did that, because I wasn't waiting for any kind of a response from her.*

Another caregiver described a similar change in her child:

> *We're introducing "POW," I believe it was. Like the point, wait, and the wait for them to repeat type thing, which I thought was really cool, because I noticed that my daughter was catching on to things a lot quicker when I was using like some of those resources.*

Participant Takeaways

When asked what they remembered most about the BabyTok videos, participants described what they remembered, what they learned, or strategies they tried. Many (19/23, 83%) caregivers listed specific strategies that were shared in the videos. One participant said the following:

> *What I remember most is just labeling everything for them to help them build their vocabulary. So just labeling and giving them wait time to just kind of let it sink in and process.*

Another described learning from the demonstrations of implementing strategies:

> *I think what I remember the most about the BabyTok videos, were just some of the demonstrations, or I guess...suggestions on what you could do with the baby. So, I've blown bubbles, but I thought it was really intimate and kind of cool just to blow the bubbles while the kid was sitting. So, we tried that.*

A few (5/23, 22%) caregivers also described retaining content related to the emphasis on daily routines. One caregiver recalled how to talk to her baby during daily activities. She stated the following:

> *So, I think I definitely learned a lot of routines and when to talk and how to during throughout the day. That was really important for me to try to remember I could fit in throughout the day.*

Another remembered learning that routines were specific to each child and their family. She stated the following:

> *I think probably about setting a routine and how it doesn't have to be like a normal routine. It just has to be, because most people, they brush their teeth immediately before going to bed. But we have to kind of settle her down after that, because it's always a fight. And that's okay. It doesn't have to be [a] normal routine, it just has to be, this is what you do from day to day.*

Disconfirming and Null Effects

When asked what they remembered most about BabyTok videos, two participants described some of the strategies in the videos as not being useful. For example, one participant recounted the following about the point, one word, and wait strategy:

> *The one about the POW, the point, and then, say the word and then wait, I found that I like that a lot. It didn't really work for me. But I think I'm gonna keep trying.*

The other participant stated the following about trying the book reading and screen time strategies:

> *He doesn't really like books that much or TV. He just doesn't, you know, so I guess it's individualized for child. So, a lot of the book things, like I read him books, but usually he doesn't pay attention to them. So and then, like the screen time things, again, he doesn't pay attention to the screen at all.*

One caregiver was unable to try the strategies or implement new routines with her child because of her busy work schedule. She said the following:

> *My schedule has been off. So, most of the days he's at daycare or he's been with his dad the past three weeks...So I haven't really got a chance to spend time with him as much.*

Supportive Feedback

Use of Social Media Platform

Participants discussed the convenience and accessibility of being able to watch and learn while scrolling on TikTok. One participant described the following:

> *You're on TikTok anyway. So, if you follow them, and they'll come up on your following page, and, you know, it makes it like, not so stressful, like, you're not researching it, you know, intently, you're just scrolling, and I learned a million things. Since I've started watching videos, I cooked a meal off it last night. And so like, at the same time, when I'm*

XSL•FO
RenderX

> *scrolling, I'm like, "Oh, I just learned something I can do with my baby."*

Others liked the ease of use and the short length of the videos. One participant stated the following:

> *It's user friendly. You don't have to worry about, I don't know, she would just message us videos, and I just click on them, and it pops right up so fast.*

Another stated, "I liked that they were smaller, bite sized pieces, bite sized segments." However, one caregiver requested longer videos to be interspersed with the shorter videos.

Engagement With Other Caregivers

Another element of the social media intervention that participants enjoyed was engaging with other caregivers. For example, a participant stated the following:

> *So just to hear other people's opinions, like, "Hey, I'm dealing with the same thing as a mom," and it was just very enlightening. Sometimes you think like you're the only one in this situation but come to find out you're not and plenty of other parents are dealing with the same thing.*

Content Delivery Expert

Participants also shared their approval of the host and speaker in the videos with comments such as the following:

> *It's Mollie, right, that was doing the videos? She is very enjoyable to watch. She's really cute, and she's really engaging.*
>
> *She was very interactive and very responsive, like when we would make comments or have questions. So yes, I really enjoyed that part.*

Trustworthiness

Participants viewed the content of BabyTok as more trustworthy than information they received from other sources, such as family, friends, and content creators on TikTok. One caregiver commented the following:

> *I get a lot of parenting videos, but I don't know, this was specifically for a research project, so I definitely felt like I was getting the right information versus you never know exactly what you're getting on TikTok.*

Another described getting a "better perspective" from the content on BabyTok. She said the following:

> *Basically I really get my advice from like, parents and people, you know, who already have kids. Um, so it was just different to like, you know, actually, like, get a better perspective and learn more about how to teach babies and toddlers, you know how to speak.*

Content Is Useful for All Caregivers

Participants described the content as useful for a wide range of caregivers in multiple contexts. One participant commented that BabyTok would help introduce strategies for language development to the other caregivers in her child's life:

> *But then watching the videos gave me more ideas and how to help other people in our life, introduce things to her as well. So it's not just my responsibility, Dad can help and grandma can help and things like that.*

Some (9/23, 39%) caregivers described BabyTok as useful for all parents. One caregiver commented the following:

> *I think it's a great resource for all parents, like new and parents that are already experienced in parenthood just to open your mind and broaden your horizon and other ways to help implement teaching resources for your child.*

Another said the following:

> *So I think different generational gaps have different styles of parenting. So I think it's very beneficial for different generations. So, for example, a lot of the things that she was teaching I wasn't familiar with only because I'm not used to doing it that way. So I think different generations would find this beneficial to view those videos as well.*

Recommendations

Content Suggestions

To close out the interviews, the interviewers asked the participants if there was anything they wished was improved or included in the video. Many (16/23, 70%) participants responded with varying ideas for content additions, including more content about routines, baby signing, speech delays, help with bedtime, how to handle challenging toddler behaviors, and pretend play with toddlers. For example, a participant stated the following:

> *I guess one thing that I wish was covered a little bit more was routines...Routines and how you can build more—how we can build in little learning, like, incorporate learning opportunities into our daily routines is what I'm trying to say.*

Delivery Suggestions

In addition to recommending changes to content, some (10/23, 43%) participants recommended changes to video formats, how participants were notified of videos to view, and using other social media platforms, such as Instagram. Other suggestions included adding more to the videos to make them grab and hold attention. For instance, one caregiver said, "I think it would have been more interesting if there was more captions, or pictures and stuff on there," and another said, "Eye-catching, so instead just like someone talking, there were different varieties." One participant discussed the use of actual babies in videos to see the activities and strategies demonstrated. Finally, there were recommendations for how participants were notified of videos to view. A participant suggested a method of notification via email. She stated the following:

> *I think there were a few times where like, I missed a notification...If maybe, throughout the project, there was like an email that went out at the end of the week, like, "Hey, make sure you watch these five videos." So, I knew if I missed one, to go back and find that*

XSL•FO
RenderX

> *rather than having to scroll through the whole account to see if there was one I hadn't reacted to or liked or whatever.*

Suggestions for the Engagement of Users

Two (9%) participants wanted more interaction with other caregivers. The following quote from a participant demonstrated this:

> *I think, yeah, if it was more interactive with those that were participating. It is nice to watch the videos, you can do it on your own time, but maybe if there was some type of participation through the process, outside of maybe commenting.*

Another participant suggested the use of Facebook groups for added interaction among participants:

> *Facebook has groups, so y'all could make a BabyTok group. And then when y'all have videos, maybe you could put like a post that's like a discussion post about the video from October 11. And then maybe people could comment.*

Exploratory Measure (SPEAK-R)

We used a pre-post, paired samples 1-tailed *t* test to assess whether there were changes in caregiver knowledge on the SPEAK-R. A total of 22 caregivers completed the SPEAK-R at posttest measurement. Pretest data on the SPEAK-R had a mean of 48.62 (SD 7.70; range 30-63), and posttest data had a mean of 51.52 (SD 12.94; range 30-69). The 1-tailed *t* test was not statistically significant (t_{21}=–1.357; *P*=.09). Some SPEAK-R data were missing at posttest measurement (n=4), indicating a need for additional support for participants to complete it after the intervention. One participant had a notably low posttest score that might have indicated that they completed the measure without responding to all the items.

Integrated Results

We merged results across the qualitative and quantitative data to understand the feasibility and acceptability of the BabyTok intervention. As was expected with a distal measure there was incomplete alignment between the SPEAK-R items and the content of the BabyTok intervention. Some items on the SPEAK-R (ie, supporting dual language learning, when children begin learning Science, Technology Engineering and Mathskills) were not covered within the project videos, so we would not expect to see participant comments or gains in these areas. However, there was some overlap, specifically across 3 content areas: screen time, caregiver responsiveness, and shared book reading. Our integrated analysis focused on SPEAK-R items, TikTok metrics, and qualitative themes that were related to those 3 content areas (Multimedia Appendix 2 provides a joint display of merged results).

Overall, we found evidence of positive changes related to participants' knowledge about caregiver responsiveness and shared book reading across all 3 sources of data. Changes in pretest to posttest raw scores on the SPEAK-R items related to caregiver responsiveness (ie, items 26, 34, and 36) indicated that participants gained new knowledge within this content area, as evidenced by increases in the raw scores. A total of 3 (9%) of the 32 BabyTok videos included content related to caregiver responsiveness, and 5 (16%) videos included content related to book reading. Each of these videos, except one (ie, "Myths about Reading"), received at least 17 likes, which was more than the average number of likes across all videos. These videos also received various comments from participants, ranging from 3 to 9 comments. We collected various quotes from participants related to responding to their children and reading with their children across 4 subthemes, indicating that participants learned new strategies, saw changes in their child, and viewed their roles as parents differently in relation to book reading and caregiver responsiveness.

However, changes on the SPEAK-R items related to screen time for young children (ie, 14, 56, 57, and 58) were mixed from before the test to after the test. A total of 2 of the 32 BabyTok videos included content related to screen time; 1 (3%) had 16 likes and 2 comments; 1 (3%) received 17 likes and 9 comments. No (0/21, 0%) participants discussed this content in their interview, indicating that this content may not have been as important to their experience in the BabyTok intervention.

Discussion

Principal Findings

This study examined the feasibility and acceptability of the BabyTok Project with caregivers of toddlers while exploring potential outcome measures for future investigations. We wanted to understand how and to what degree caregivers engaged with the BabyTok Project, what they retained from the content, and what caregivers liked or did not like about their experiences with the videos and the platform. Overall, participants expressed positive feedback about the BabyTok content and the short-form, video-based nature of the intervention. Although the distal knowledge measure (SPEAK-R) showed raw score gains but not statistical significance, most (22/23, 96%) participants listed specific strategies that they recalled from the videos and gave examples of using the strategies with their child.

Caregiver Engagement With the BabyTok Content

In general, we found consistent engagement through likes from most caregivers throughout the project (mean 15.75, SD 1.39 likes/video; viewership: 16/21, 75%). This could suggest that the intervention is well aligned with caregivers who use their mobile devices to access content on social media with regularity and that the content might fit in easily with their use patterns [25]. Two caregivers reported watching the videos when they were sent a direct message, two other caregivers watched them in a batch and "caught up" on the videos when prompted. Still more caregivers viewed the videos from their "For You" screen on the app, suggesting that the multiple points of contact may have helped increase the ability of caregivers to access the videos. The overall viewership and engagement data among caregivers were similar to that of the infant toddler teachers in our earlier investigation (16/21, 75% and 73%, respectively). While it is not possible to directly compare to other app-based studies such as Háblame Bebé that can track time in the app [21], we note similar patterns of engagement in that most (16/21, 76%) caregivers participated at intended levels, with a few low responders, indicating the need for individualized support. One

XSL•FO
RenderX

caregiver in our investigation had notably low viewership, suggesting the need for additional strategies to increase engagement for some caregivers. Such individualization could include tailoring when the direct messages are sent (to align with their time on social media or their off time from work) and when, how, and how often reminders are sent.

Caregivers Gave Specific Details From the Content

Caregivers described the convenience of the short, "bite-sized" content units, that they were on the app anyway for other purposes, such as looking for dinner recipes or entertainment, and that they were able to learn useful information to support their child's learning. Caregivers noted they may not have had time to watch long videos, but the short content units kept them in touch with the ideas presented in the videos more often and made it enjoyable. This feedback was also consistent with that of the infant toddler teachers in the earlier investigation. Although this study did not experimentally evaluate whether caregivers made changes in their interactions, caregivers did indicate that they believed the approach supported them in engaging their child in language-rich interactions and equipped them with strategies to use every day. Among the strategies, caregivers found the content related to the point, one word, and wait strategy to be salient, along with expansions and book-sharing strategies for their toddlers. The specificity of caregivers' responses around these strategies was encouraging because it reflected ideas shared in the videos that caregivers were not likely to have learned elsewhere.

Caregivers Described the Trustworthiness of the Content

The first author, who is also the main video narrator, provided her credentials in an introductory video at the beginning of this study. This may be one reason that caregivers described the content viewed on the BabyTok page as "the right information" and that it gave them a "better perspective" about toddler language development than information they received from family, friends, and other TikTok creators. These statements relating to trustworthiness are encouraging and may indicate caregiver acceptability of the content and overall intervention.

Suggestions for Additional Content

Caregivers gave suggestions for future videos, which can be implemented into future studies, such as including the use of different methods of delivery (ie, Instagram or Facebook groups); use of text on screen, including more eye-catching images; and videos with real babies and caregivers to show examples of the strategies. They also suggested content that extends from communication content directly into everyday concerns, such as sleep and challenging toddler behavior. This is important because caregivers seem to not only want information about how to help their children talk but also ways to navigate everyday challenges that caregivers of children in this age range face, which may then impact their interactions with their child. Tackling these parenting issues may also give caregivers a means to engage with one another as they share what has worked and what has not for their child, which could serve to build their own confidence in sharing their experience with one another.

Implications for Media-Based Universal Interventions

While we cannot extend these findings to other types of interventions, there are potential implications for video-based interventions with caregivers of young children. Similar to our experience with teachers [26], home-based caregivers did not have a 100% watch rate, but they did view most videos, on average. Because few caregivers will be able to watch every video, it is important to build in redundancy by reinforcing similar messages and delivering the same message more than once. Furthermore, our attempts at reaching caregivers through multiple modes, such as sending videos via direct messaging, SMS text message reminders, and the "For You" page. seemed to help increase the number of videos viewed by each caregiver. While publicly available content may have similar messages as the BabyTok videos, there are no mechanisms yet to support caregivers to consistently engage with the content beyond what appears based on the algorithm or to ensure that enough video content reaches users to create changes in knowledge and caregiver-child interactions.

Limitations and Future Directions

While the findings in this investigation suggest the promise of social media–based interventions to support caregiver knowledge about early language learning, the study does face several limitations. First, the small sample size of participants may be a limiting factor in evaluating and drawing conclusions from the data. Next, because of the nature of the TikTok platform, we had limited metrics available to us as a private TikTok page. With this lack of metrics, we were not able to gather data on the watch time of each video by the participants. It is possible that participants may have pressed "like" on the video without fully viewing it, and it is also possible that participants did view the video but neglected to press "like," leading to an underrepresentation of their viewing. We also did not collect data to understand how our participants typically engaged with and used social media to compare with how they engaged with and used the BabyTok content relative to other social media content. We made assumptions that participants engaged with content if they liked and commented on the videos, but they may have engaged in other ways, such as showing the video to a friend or partner.

In future studies, we could ask caregivers to report on their overall social media use patterns to compare their engagement with the content relative to their overall social media use. Although our sample of participants was similar in age and gender to the average US TikTok user, there were some differences in parenting status, education level, income level, and race or ethnicity [32,33]. These differences may have made it more difficult to evaluate engagement data of some participants, as they may not have been typical TikTok users. Our participants were more educated (bachelor's degree: 9/25, 36%) compared to the average US adult aged >25 years (23.5% with a bachelor's degree) [34], and fewer of our participants had their toddlers in childcare outside the home (6/25, 24%) than the average US family (55%) [35]. This may indicate that caregivers who are in the home and more educated may be more likely to access and engage in this type of social media intervention.

XSL•FO
RenderX

Although some caregivers reported gains in their child's communication, we did not directly measure child language skills as an outcome in this feasibility and acceptability study. It is important to note that children should acquire new words during this developmental period, so randomized controlled trials are needed to determine whether there are child-level effects above and beyond the communication gains that would take place through the child's maturation alone.

The SPEAK-R provided a related outcome representing caregiver knowledge, although there were items on the measure that did not align with the video content (ie, early mathematics and cognitive concepts). Those domains would not have been likely to change because of the BabyTok intervention. SPEAK-R has been used as an outcome in a few studies that offer video-based educational content [36], but it is difficult to compare relative changes between studies because our intervention focuses only on communication rather than communication and cognition. In addition to measuring caregiver knowledge, it would also be useful to measure long-term impacts on children's vocabulary development by using caregiver-reported tools about their child's communication in a larger, randomized study. Additional future directions also include creating and testing Spanish-language videos for caregivers in the United States who speak Spanish as a primary language, with a focus on supporting children in both languages.

Conclusions

The findings of this study add evidence to the feasibility and acceptability of the BabyTok Project as a means to increase caregiver knowledge of how to support children's language learning. This research is important because, to date, there have been few social media–based interventions targeting children's early communication. While there is a sizeable body of evidence related to intensive coaching models to help caregivers engage with their children, low-cost, light-touch interventions could be a scalable and accessible means to equip caregivers with information they need to advance their children's language abilities [21], with downstream effects on academic and social outcomes if future efficacy testing indicates positive effects. This approach to intervention may be particularly important for families from low-income backgrounds whose access to health information about their young children may be limited.

Abstract

Background: Anemia remains a significant public health concern with adverse effects among children. Noninvasive screening assessments enable the early detection and prompt treatment of anemia. However, there is limited literature on the use of such screening assessments.

Objective: The study aimed to assess the prevalence of and factors associated with being at risk of anemia among Malaysian children aged ≥6 months to ≤36 months by using a noninvasive hemoglobin assessment.

Methods: This was a cross-sectional study (from July to December 2022) of outpatient Malaysian children, aged ≥6 months to ≤36 months, who were selected from five maternal-and-child health clinics by convenience sampling. At risk of anemia was defined as a total hemoglobin level of <12 g/dL, measured using the Masimo Rad-67, a noninvasive screening device for total hemoglobin levels. The χ^2 and multiple logistic regression analyses were used to assess the prevalence and factors associated with being at risk of anemia, using R-Studio (version 4.0.0).

Results: The study included 1201 participants, of whom 30% (95% CI 28 - 33) were at risk of anemia. Children aged 6 - 12 months (210/364, 57.7%, *P*<.001), those of Asian Malay race (238/364, 65.4%, *P*<.05), those residing in the Klang district (123/371, 33.9%, *P*<.05), those born via a normal vaginal delivery (275/364, 75.5%, *P*<.05), those without a family history of thalassemia (284/364, 78.0%, *P*<.05), and those with lower weight-for-age Z scores (*P*<.05) were associated with being at risk of anemia. Children aged 6 - 12 months (adjusted odds ratio=1.73; 95% CI 1.34 - 2.24) had higher odds of being at risk of anemia compared to children aged >12 - 36 months. However, weight-for-age (adjusted odds ratio=0.88; 95% CI 0.80 - 0.98) was associated with lower odds of being at risk of anemia.

Conclusions: The current study revealed a substantial prevalence of Malaysian children being at risk of developing anemia. The study results therefore imply a need for more community education and awareness on anemia, including nutrition education, as well as targeted community screening to enable the early detection and prompt treatment of anemia cases. Anemia reduction strategies in Malaysia should consider the highlighted factors indicative of higher risk of anemia.

Introduction

Anemia is a specific condition where the body does not have enough normal or healthy red blood cells or hemoglobin (Hb) to provide adequate oxygen to the body tissues. It is usually caused by iron deficiency, which is the most common micronutrient deficiency in both low-income and high-income countries [1,2]. Generally, it takes at least several weeks after the depletion of iron stores before anemia develops. When iron deficiency occurs, Hb concentrations are reduced to below-optimal levels, a condition known as iron deficiency anemia (IDA) [2], which is the most common type of anemia found in children. Among children, the most common causes of IDA include insufficient iron intake along with rapid growth, low birth weight, and gastrointestinal losses, among others [3,4].

Generally, the prevalence of anemia and IDA in low-income countries is three to four times higher than that in high-income countries [1]. The global prevalence of anemia in 2019 was 39.8% in children aged 6 - 59 months, with 269 million children having anemia, while in Malaysia, the prevalence of anemia was 24.6% in children of the same age [5]. In Malaysia, the current prevalence of anemia is approximately 46.5% among children, and 1 in 3 children (<5 years of age) has iron deficiency [6,7].

Iron deficiency can occur without anemia; this occurs when the iron store is depleted while the individual is still having normal Hb levels. IDA is a situation where the iron store and Hb levels are both below normal levels. Iron deficiency and IDA are typically diagnosed through an invasive blood test, with one of the diagnostic criteria for anemia being a Hb level below 11 g/dL [2]. The American Academy of Pediatrics recommends that all infants be tested for anemia starting between ages 9 months and 12 months [8], and that for those who have risk factors for iron deficiency, additional screenings will be required at later ages between 1 and 5 years [9].

Iron deficiency in childhood is associated with adverse outcomes such as impaired neurocognitive function and brain development, as well as compromised immune function [10,11]. In Malaysia, recent evidence shows that anemia is associated with cognitive and motor delays among infants aged 6 - 12 months [12]. This implies that prompt diagnosis and anemia prevention are essential through early screening during infancy and early childhood.

The conventional diagnosis of anemia and IDA in infants is difficult, as blood sampling and obtaining sufficient blood volume are often difficult for typical laboratory detection. Moreover, these tests can be painful for the participant, expose the staff to human blood, and require training and quality control to ensure appropriate utilization and adherence to standards [3,11]. In this regard, an alternative device can be preferable, such as noninvasive Hb screening using a sensor that shines multiwavelengths of light through the finger of the patient [13]. Such noninvasive device options include the Masimo Pronto (Masimo Corporation) and Masimo Rad-67™ Pulse CO-Oximeters (Masimo Corporation). These devices were cleared by the US Food and Drug Authority for use in clinical and nonclinical settings to measure oxygen saturation [14] and have been used as a noninvasive measurement method for determining the Hb levels in children [15]. The Masimo Pronto and Masimo Rad-67™ Pulse CO-Oximeters have good accuracy and validity compared to Hemocue (HemoCue); however, the Hb levels were underreported for the devices compared to the levels determined in venous blood samples [16-18]. This study used the Masimo Rad-67™ Pulse CO-Oximeter for anemia screening.

This study aimed to assess the prevalence and factors associated with being at risk of anemia (defined as total Hb levels <12 g/dL) among Malaysian children aged ≥6 to ≤36 months by using noninvasive Hb assessment (the Masimo Rad-67 Pulse CO-Oximeter). We used a noninvasive approach for anemia screening and compared the prevalence rates with those obtained in previous studies. Using a noninvasive screening approach offers the potential for the early detection and prompt treatment before worsening of the child's condition to severe anemia-related complications.

Materials and Methods

Study Design

This was a cross-sectional study among children aged ≥6 months to ≤36 months conducted in five maternal-and-child health clinics and Ministry of Health primary care clinic settings in urban and rural areas of Malaysia from July to December 2022. The clinics were chosen and the study participants were enrolled based on the need to include major ethnic groups in Malaysia in the study via convenience sampling.

Participants and Sample Size Planning

The study participants were outpatient children aged ≥6 months to ≤36 months at maternal-and-child health clinics accompanied by their primary caretakers (ie, parents, grandparents, or relatives) who were aged ≥18 years and could speak English, Bahasa Malaysia, or Chinese (Mandarin). Children who came to the clinics for routine vaccinations or routine health examinations were enrolled if the study requirements were met. The plan was to have 50% of participants aged 6 - 12 months and 50% aged >12 - 36 months, with the following ethnicity distribution: 69.8% Malay and Bumiputera, 22.4% Chinese, 6.8% Indian, and 1% others to ensure good representation of data from each site.

The study excluded children with any medical conditions for which interventions to increase nutritional intake might not be effective, per the investigator, in improving weight gain and the nutritional status. In addition, children participating in other studies involving iron-fortified foods or supplementation and those whose caretakers were not able to communicate effectively with the interviewers were excluded. The enrolment at the clinic was stopped when the participant number for specific sexes, age groups, and ethnicities, determined at the start of the study, was achieved. The World Health Organization and World Bank estimated the prevalence of anemia (ie, Hb level <11 g/dL) at 25% in 2019 among Malaysian children under 5 years of age [19]. In this study, we estimated that 30% of children aged ≥6 to ≤36 months will be at risk of anemia (ie, Hb level <12 g/dL), and considering a precision of ±3% and 95% confidence level,

XSL•FO
RenderX

a sample size of 1200 subjects was required after accounting for 10% each of screen failures and dropouts. Any withdrawn subjects and screen failures were replaced until the sample size was obtained.

Data Collection

The study was conducted in five maternal-and-child health clinics that were conveniently selected based on the research need: three from urban areas and two from rural areas of Malaysia. From each of the clinics, approximately 240 participants were selected. Interviewers were trained on the protocol. The trained interviewers identified and approached potential participants and asked the parents or guardians to participate in the survey. Those who were willing to participate were screened for eligibility, and written consent was obtained after they were briefed about the study objectives, procedures, and other details. Respondents were reminded of their right to quit the study at any time without any consequences, and anonymity was guaranteed.

During the assessment, a clip with a sensor attached to the Masimo Rad-67 Pulse CO-Oximeter was placed on the child's finger or toe, and the reading took approximately 30 seconds. Children found to be at risk of anemia were referred to healthcare professionals for further clinical assessment. In addition, the child's weight (kg) and length or height (cm) were measured and input into the Iron Strong app (Groupe Danone).

Data were collected via the Iron Strong app device, a data collection tool with an optical character recognition model that allows the user (by taking a picture) to accurately predict all units and digits on the Masimo Rad-67 Pulse CO-Oximeter and stores the data within the app or server during face-to-face interviews in English, Bahasa Malaysia, or Chinese (Mandarin). The interview and data collection took about 30 - 40 minutes to complete.

Measurements

Development of the Questionnaire

The questionnaire was developed by a panel of three public health researchers. Bilingual researchers translated the English version of the questionnaire into Bahasa Malaysia and Chinese (Mandarin). The agreed versions were back-translated into English by independent bilingual researchers to ensure linguistic equivalence. The questionnaire was not pretested because it mainly asked about respondents' sociodemographic characteristics, anthropometric measurements, and 24-hour dietary recall.

Sociodemographic Characteristics

Participants reported their sociodemographic characteristics, such as the child's sex, age, race, residence location, physical activity, as well as caregiver's education level and household income. Birth history key indicators were asked, including mode of delivery, gestational age at birth, birth order, and the number of siblings. In addition, key indicators of family history such as thalassemia diagnosis and family history of anemia were asked.

Hb Level and Other Rad-67 Measurements

Anemia was assessed on the basis of the continuous total Hb level, with a cutoff value determined at <12 g/dL; this value was indicative of at risk of anemia, after considering the underestimation of the Hb concentration reported for Masimo devices [16-18]. This was measured using the Masimo Rad-67 Pulse CO-Oximeter, which is a noninvasive device for screening the total Hb levels. The reliability of the Masimo Rad-67 Pulse CO-Oximeter was reported to be ±1 g/dL versus the laboratory reference device in adults who had no motion, children, and infants. These findings have been validated by a group of researchers from Thailand [20].

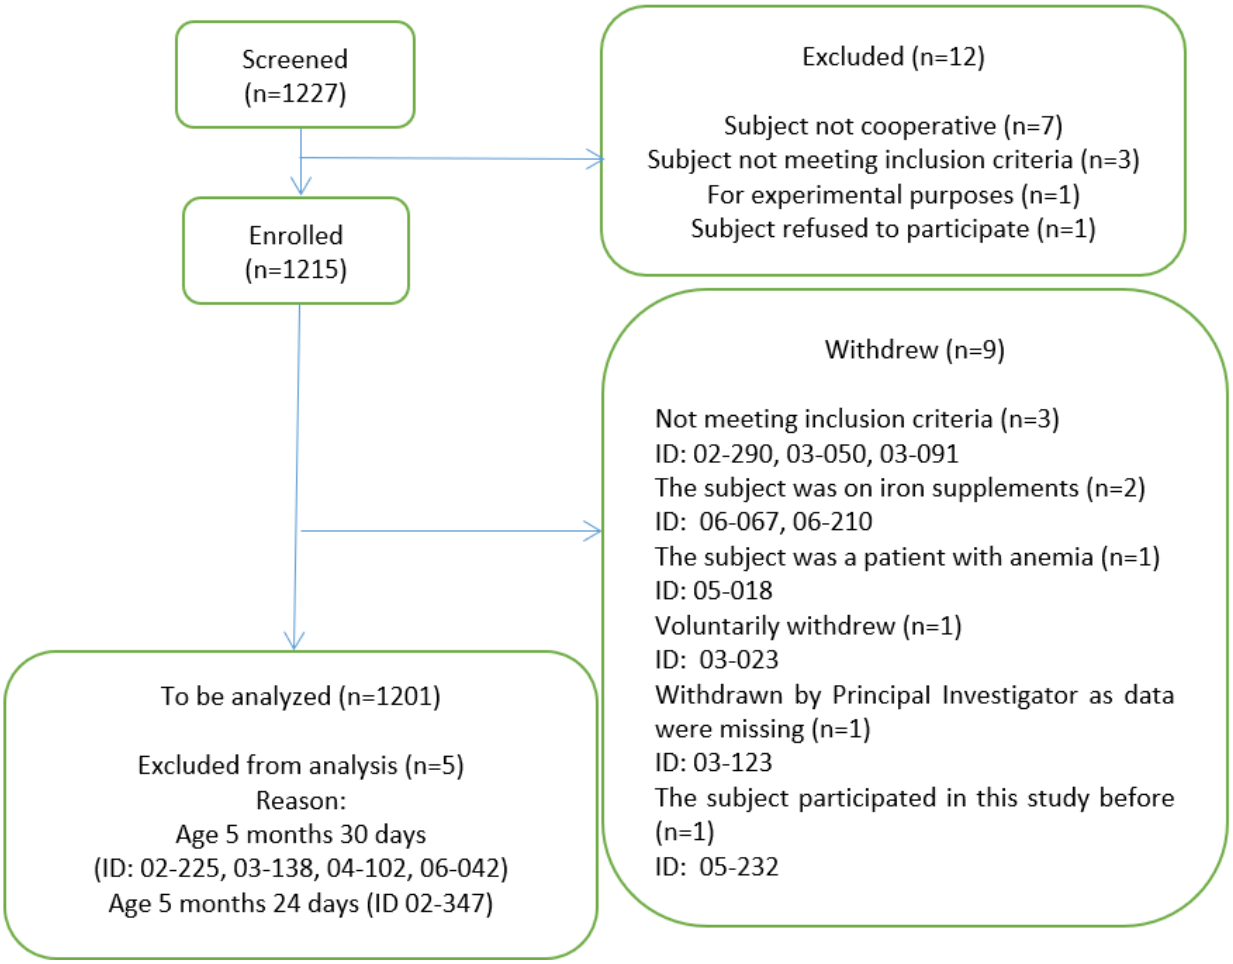
Growth Parameters

Growth parameters were taken from the documentation available in the infant and child health record book. These parameters were taken by trained clinic nurses using standard methods.

Statistical Analysis

Categorical variables were summarized as the frequency and percentages, while continuous variables were summarized as the mean and standard deviation. Being at risk of anemia was the dependent variable. The χ^2 test was used to test for the differences in background and predictor variables between children at risk of anemia and those not at risk. Bivariable and multivariable logistic regression models were fitted to explore the association between independent variables and the dependent variable (at risk of anemia). The multivariable regression models included significant factors on bivariable analysis as well as other factors known to be associated with being at risk of anemia from previous studies, regardless of their significance on bivariable analysis. We presented the respective crude odds ratios, adjusted odds ratios, 95% CI, and *P* values. All the analyses were performed using R-Studio (Posit, PBC), version 4.0.0, with a *P* value <.05 being the level of statistical significance.

Ethical Considerations



The study was approved by the Medical Research and Ethics Committee, Ministry of Health Malaysia (Ref: 21 - 02114-PV7(2)) and the Medical Research Ethics Committee, University of Malaya Medical Centre (Ref: 20211014 - 10694). Study data were anonymized to ensure the privacy of all participants and were accessed only by authorized personnel. Informed consent was obtained from all participants prior to their involvement in the study. Participants were provided with detailed information about the study and were informed that participation was voluntary and that they could withdraw at any time without penalty. For secondary analyses of previously collected data, the original informed consent covered subsequent research uses, as confirmed by the ethics committee. Participants in the study received RM 20 (US $4.50) as monetary payment that was approved by the ethics board for their time and effort involved in participation.

XSL•FO
RenderX

Results

A total of 1227 potential respondents were reached, of whom 27 declined to participate due to various reasons, yielding a response rate of 97.9% (Figure 1).

Figure 1. Flowchart depicting the selection of study participants for a cross-sectional study on the prevalence and risk factors of anemia among Malaysian children aged 6 - 36 months. The study was conducted across five maternal-and-child health clinics in Malaysia between July and December 2022.

Characteristics of Participants

A total of 1,201 participants were included in this study (Table 1). Slightly more than half were male (631/1201, 52.5%) and aged >12 - 36 months (610/1201, 51%); the majority were Asian Malay (727/1201, 60.5%) and from urban areas (687/1201, 57.2%). The majority had mothers with no university degree (898/1201, 74.8%), were born full-term (916/1201, 76%), via normal vaginal delivery (860/1201, 72%), and were of second or higher birth order (767/1201, 63.9%). Moreover, a very small number reported a family history of thalassemia (6/1201, 0.5%) with a quarter not knowing their thalassemia status (316/1201, 26.3%), while a majority had no family history of anemia (1078/1201, 89.8%) and reported moderate or vigorous physical activity (862/1201, 71.8%).

Population at Risk of Anemia and Other Masimo Rad-67 Pulse CO-OximeterParameters

Of the 1,201 participants, 364 (30%, 95% CI 28 - 33) were identified as being at risk of anemia on the Masimo Rad-67 Pulse CO-Oximeter (Table 2). Additionally, participants had a mean (SD) weight-for-age Z score of −0.67 (1.29), length-for-age Z score of −0.65 (1.72), and weight-for-length Z score of −0.41 (1.29).

Table . Population at risk of anemia and other Rad-67 measurements (N=1201).

Study site	Frequency of subjects at risk of anemia, n/N (%)

Distribution of Being at Risk of Anemia by Study Variables

The distribution of being at risk of anemia across the study variables is shown in Table 3. Children aged 6 - 12 months (n= 210, 57.7%), those of Asian Malay race (n=238, 65.4%), those from Klang district (n=123, 33.9%), those birthed via normal vaginal delivery (n=275, 75.5%), and those without a history of thalassemia (n=284, 78.0%) were associated with being at risk of anemia. Additionally, children at risk of anemia had significantly lower weight-for-age Z scores (ie, a greater negative deviation from the normal weight) than those at no risk.

Factors Associated With Being at Risk of Anemia Among Malaysian Children Aged ≥6 Months to ≤36 Months

The results of bivariable and multivariable logistic regression are detailed in Table 4. In our logistic regression analysis examining being at risk of anemia in children, the primary independent variable, weight-for-age Z score, showed a statistically significant inverse association with being at risk of anemia both in univariable (crude odds ratio=0.91, 95% CI 0.82 - 1.00; *P*=.046) and multivariable models (adjusted odds ratio=0.88, 95% CI 0.80 - 0.98; *P*=.020), indicating that higher Z scores were associated with reduced odds of being at risk of anemia. Among the covariates, only age showed a significant association; specifically, children aged 6 - 12 months had 1.73 times higher odds of being at risk of anemia compared to those aged 12 - 36 months (adjusted odds ratio=1.73, 95% CI 1.34 - 2.24; *P*<.001). Other demographic and medical factors, such as sex, race, residence location, and socioeconomic status, did not significantly impact being at risk of anemia (Table 4). This study underscores the importance of weight monitoring and age-specific interventions in mitigating anemia risk in children.

Discussion

Principal Findings and Comparison with Previous Works

The study assessed the prevalence and profiles of Malaysian children aged ≥6 to ≤36 months being at risk of anemia using a noninvasive Hb approach (the Masimo Rad-67 Pulse CO-Oximeter). Unlike the conventional methods of assessing anemia, this noninvasive screening approach offers rapid, accurate, and reproducible results, favoring the implementation in maternal child health clinics for early detection and prompt treatment before the condition worsens to severe anemia-related complications. This study had a response rate of 97.9% and only 7 out of 1227 patients were not cooperative to be included in the study. A high response rate among participants to be part of the study indicates their receptiveness to a noninvasive approach. The lack of parental consent due to invasive approaches has been observed and highlighted as a limitation in a similar study [21]. Caregivers of children highly favor noninvasive disease screening methods that lead to better testing compliance compared to invasive techniques that can cause discomfort and pain [22]. Noninvasive methods also reduce the risk of infection and could potentially be more cost-effective due to less usage of consumables and reagents [23].

This study found that 30% of Malaysian children aged ≥6 to ≤36 months were at risk of anemia. The observed prevalence was slightly higher than the 25% national prevalence of anemia among children below 5 years [19]. Moreover, the observation was also higher than that observed in two previous studies, which reported prevalence rates of 21.2% [23] and 22.3% [24], respectively. However, the observed prevalence was lower than the prevalence rate of 42.4% reported by Sabri et al [12] and 46.5% reported by the 2022 National Health and Morbidity survey [7]. As a screening tool for anemia, the Masimo Rad-67 Pulse CO-Oximeter is less stringent, which may account for the slightly higher prevalence observed in this sample population. As this is as a screening tool, confirmatory laboratory tests will be required for a diagnosis after screening.

This study focused on looking at contributing factors of anemia, although it did not measure iron content to evaluate the prevalence of IDA. A retrospective study in Pulau Pinang showed that the rate of IDA was 24% among children [24]. However, the 24-hour dietary recall that was performed may give an idea of the children's iron intake. It will be interesting to see if the children's intake of iron and other nutrients has any association with anemia development in this study. In this study, parental interpretation was used to measure physical activity. No specific children's physical activity measurement tool was used.

Although several measures have been undertaken, the observed prevalence of being at risk of anemia in Malaysia is substantially high, implying a need for more focused interventions aimed at prevention, early screening, and detection as well as treatment. In this regard, the extensive use and adoption of noninvasive screening tools at maternal and health clinics, which are points of child vaccination and regular health checks, would be essential for the early detection and providing prompt treatment, thus curbing the adverse complications of anemia in children [25-27].

The study explored factors associated with anemia among Malaysian children, of which age and weight-for-age were significant. The study results indicate that a higher risk of anemia is more common among children aged 6 - 12 months and lower weight-for-age. As expected, our results partly agree with the existing literature that has also reported children 6 - 12 months to have a higher risk of anemia compared to older children, due to increased iron needs that, if not provided by weaning foods, put this age group at a higher risk of serious anemia [3,4,28]. This aligns with previous studies that have reported a similar trend in India [29], Ethiopia [30], Brazil [31], and Peru [32].

Notably, although nonsignificant on adjusted regression analysis, children of the Asian-Malay race showed higher proportions of being at risk of anemia (65%) than other races, a finding that aligns with previous studies that have reported racial disparities in the risk of anemia [33,34]. Khalil et al showed a vast difference in the prevalence of anemia between the Orang Asli tribes in Malaysia, which was attributed to differences in socioeconomic background and other risk factors of anemia [35]. Similar to another study, anemia prevalence differences observed among racial and ethnic groups in this study can also be due to different food practices and low dietary intake of iron [21].

We expected thalassemia, a genetic predisposing factor affecting one's Hb concentration, to be positively associated with the risk of anemia, which is in contrast to this study's finding. In our study, Thalassemia status is based on parental and carer's reporting and could be subjected to reporting error, since as high as 26.3% of the subjects were unaware of their thalassemia status. Similarly, cesarean section as a mode of delivery is reported to have a negative impact on child feeding practices compared to normal vaginal delivery [21]; thus, we expected a positive association with anemia risk, which also deviates from our finding. Nonetheless, the difference in sample size and composition in our study could explain the observed mismatch. Additionally, mothers with children born of cesarean section and with thalassemia may be more aware of the increased risk of anemia from clinical counseling and education [36]. Therefore, they may be more likely to take extra measures to

XSL•FO
RenderX

prevent anemia in their children, unlike mothers with no such known risk, which may explain our finding of surprisingly increased risk of anemia among children born via normal vaginal delivery and with no family history of thalassemia.

Malnutrition has been previously recognized as a factor for anemia among underweight children [28,37]. Additionally, micronutrient deficiency, food insecurity, and poverty have been established as factors leading to underweight children [28,38]. A study in China found that malnutrition resulted from the caregiver's lack of knowledge of child feeding practices [37], which may also be a contributing factor to anemia among children in this study. In addition, although the current data revealed that children from lower-income families had a higher proportion of being at risk of anemia, the household income surprisingly showed no statistically significant association with being at risk of anemia in the previous study [37].

It is worth noting that the observed high prevalence of anemia risk among children, including Malaysian children, is driven by complex interlinked factors including socioeconomic status, access to healthcare, dietary patterns, and cultural practices, amongst others [21,28,37,38]. A few such factors have been re-echoed in this study. The socioeconomic status, for example, affects food access and dietary quality, which are primary causes of anemia [28,38]. The socioeconomic status also affects healthcare access, without which the impact of anemia among children may be worsened. This calls for a comprehensive and inclusive approach to designing anemia prevention programs, considering the interaction of various key drivers.

Implications of Study Findings

Our study findings have some practical implications for addressing the observed high risk of anemia among Malaysian children. There is a need for more efforts in strengthening prompt community screening of anemia nationwide to enable the early detection and, thus, appropriate intervention or treatment, and this could be achieved by the adoption and use of noninvasive screening tools like the Masimo Rad-67 Pulse CO-Oximeter. The study results also imply that the Masimo Rad-67 Pulse CO-Oximeter could be a useful tool in the clinical assessment of Malaysian children for anemia, which could be incorporated into regular child immunization and monitoring visits. These efforts and other anemia prevention strategies should focus on children aged 6 - 12 months of Asian Malay heritage or race, and underweight children because they have a higher risk of anemia. Moreover, more efforts are needed in community education and sensitization about anemia risk, its consequences and prevention, and this should focus on the mothers and caregivers of children under 5 years. Additionally, nutritional education should be incorporated in the discussions with parents and caregivers after the examination of infants and young children to reduce the incidence of being underweight among children and to ensure anemia prevention and reduction.

Limitations

The study has some limitations. Some of the data, especially background predictor variables, were based on self-reporting, risk recall, and misclassification biases. Moreover, given the cross-sectional design of the study, no causal inference can be drawn between anemia and the other factors considered, beyond mere associations. Despite the limitations, the study provides valuable information on the prevalence of the risk of anemia and associated factors among Malaysian children using a noninvasive assessment tool.

Conclusions

Using a noninvasive screening tool, the study found that 30% of Malaysian children aged ≥6 to ≤36 months are at risk of anemia. Moreover, children aged 6 - 12 months and of Asian-Malay heritage or race had high odds of anemia. Weight-for-age was also negatively associated with the risk of anemia. Therefore, there is a need for more efforts in targeted community screening to enable the early detection and prompt treatment of anemia. More community education and awareness about anemia, including nutrition education, is also needed to address the high levels of anemia in the country.

Acknowledgments

We would like to acknowledge all health clinics staffs for the support given to undertake this study. We also would like to thank Dr Nouran Hamza for her contribution in the study's statistical analysis. Our special thanks and appreciation also goes to all children and their mothers who voluntarily participated. This project was funded by Danone Specialized Nutrition (Malaysia) Sdn Bhd.

Abstract

Background: Managing preoperative anxiety in pediatric anesthesia is challenging, as it impacts patient cooperation and postoperative outcomes. Both pharmacological and nonpharmacological interventions are used to reduce children's anxiety levels. However, the optimal approach remains debated, with evidence-based guidelines still lacking. Health care professionals using social media as a source of medical expertise may offer insights into their management approaches.

Objective: A public survey targeting health care professionals was disseminated via social media platforms to evaluate current practices in anxiety management in children. The same questions were posed during an annual meeting of pediatric anesthesiologists with their responses serving as reference. The primary objective was to compare pediatric anesthesia expertise between the groups, while secondary objectives focused on identifying similarities and differences in preoperative anxiety management strategies hypothesizing expertise differences between the groups.

Methods: Two surveys were conducted. The first survey targeted 100 attendees of the German Scientific Working Group on Pediatric Anesthesia in June 2023 forming the "Expert Group" (EG). The second open survey was disseminated on social media using a snowball sampling approach, targeting followers of a pediatric anesthesia platform to form the "Social Media Group" (SG). The answers to the 24 questions were compared and statistically analyzed. Questions were grouped into 5 categories (pediatric anesthesia expertise, representativity, structural conditions, practices of pharmacological management, and practices in nonpharmacological management).

Results: A total of 194 responses were analyzed (82 in EG and 112 in SG). The EG cohort exhibited significantly greater professional experience in pediatric anesthesia than the SG cohort (median 19 vs 10 y, $P<.001$), higher specialist status (97.6% vs 64.6%, $P<.001$), and a greater pediatric anesthesia volume (43.9% vs 12% with more than 500 cases per year, $P<.001$). Regarding the representativity, 2 items out of 4 were statistically significant (level of care of institution, annual caseload of institution). Regarding the overall anxiety management practices used, there is a heterogeneous response pattern within both groups.

Conclusions: Despite heterogeneous approaches, health care professionals using social media demonstrated less expertise in pediatric anesthesia but showed minimal differences in the daily management of preoperative anxiety compared with pediatric anesthesia experts. Our study highlights the potential for meaningful use of social media but future studies should explore the impact of social media health care professionals' knowledge in other specific topics. Additionally, regarding preoperative anxiety, further recommendations are needed that could help to standardize and improve anxiety levels in children.

Introduction

Although “no fear” is the first of the “10-N quality criteria” in pediatric anesthesia, preoperative anxiety remains prevalent [1,2]. It is evident that high levels of anxiety are associated with decreased cooperativeness during induction of anesthesia, increased postoperative analgesic requirements, increased rates of postoperative delirium, and maladaptive behavioral problems [3,4]. Therefore, it is crucial to keep anxiety levels low.

Established options for preoperative anxiolysis in children include pharmacological and nonpharmacological interventions. Midazolam, clonidine, and dexmedetomidine as well as (s-)ketamine are frequently used for pharmacological premedication [5,6]. However, the general use of these drugs is subject to controversial debate [6,7]. Nonpharmacological interventions include parental presence at induction of anesthesia, educational approaches (eg, informational mediation and prior inspection of the operating room), complementary medical procedures (such as acupuncture, music therapy, hypnosis), and cognitive-behavioral therapeutic measures (such as strengthening coping strategies, distraction, breathing exercises, model learning) [8-14]. Nonpharmacological interventions have been shown to be at least as effective as the administration of midazolam [15]. Although many different options are available, there are currently no evidence-based recommendations and guidelines on which intervention is best for which situation. Recently, we conducted a survey on the current practice of preoperative anxiety management in pediatric anesthesia among German-speaking participants [16]. It was conducted during an expert meeting of the Scientific Working Group for Pediatric Anesthesia of the German Society of Anesthesiology and Intensive Care Medicine and revealed relevant differences in the structural conditions, management of pharmacologic premedication, and the use of nonpharmacologic measures [16].

However, participants in expert meetings may not accurately reflect the realities of daily anxiety management practices. Social media, defined as “any form of electronic communication [...] to share information” [17], offers the potential to enhance these insights by leveraging swarm intelligence and engaging a broader and more diverse group of health care professionals involved in preoperative anxiety management. Web-based surveys disseminated through social media targeting pediatric anesthesia health care professionals could thus capture a larger, geographically diverse sample, enhancing overall insight. While web-based surveys are efficient and cost-effective, they have limitations, such as open participation, low response rates (≈10%), and uncertain respondent identity [18]. In contrast, closed-group surveys, such as those conducted among expert meeting participants, provide more defined and reliable profiles, potentially serving as a reference for comparison.

Thus, a web-based survey on preoperative anxiety was sent to social media users involved in pediatric anesthesia, and their responses were compared with those from a pediatric anesthesia Expert Group (EG). The study aimed to test the hypothesis that expertise and preoperative anxiety management practice differ between a broad, randomly selected social media population and a dedicated EG.

Methods

Overview

The web-based survey was aimed at anesthesiologists who are active on social media. Currently, there are approximately 27,000 anesthesiologists in Germany, around 3300 in Austria, and 1600 in Switzerland [19-21]. It is estimated that approximately 70% - 90% of all physicians actively use social media, meaning that around 25,000 anesthesiologists were eligible to participate in the web-based questionnaire [22,23]. As this was an open survey, the participation of nonanesthesiologists could not be excluded. The survey related to the scientific conference was directed at the scientific working group on pediatric anesthesia in German-speaking countries. It consists of physicians with predominantly high expertise in the field of pediatric anesthesia, with approximately 100 participants attending the conference each year.

Ethical Considerations

This analysis did not require approval by an institutional review board or entry into a clinical trial register since it did not include data from patients or medical records according to the Helsinki Declaration. Participation was voluntary, and privacy was ensured through the anonymous collection of study data. No personal information, cookies, or IP addresses that could enable identification were stored. Participants did not receive any compensation.

Survey Development

We adhered to the items of the “Good practice in the conduct and reporting of survey research” and the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [24,25]. Technical tests were carried out before the surveys were conducted to enhance comprehensibility and rule out possible errors. The completion rate (ratio of users who finished the survey/users who answered the first question) was calculated for both groups and the participant rate (ratio of unique visitors who agreed to participate/unique first survey page visitors) for EG. For completeness checking, incomplete data were marked as “not applicable” to indicate the extent of survey completion. The processed data consisted of 2 surveys, each conducted independently. There were no follow-up validation attempts to verify if the respondents were truly qualified.

Data Sources

The first survey was conducted among participants of the annual meeting of the Scientific Working Group on Pediatric Anesthesia of the German Society for Anesthesiology and Intensive Care medicine (DGAI), which took place in Hamburg, Germany, on June 16 - 17, 2023. During the event, access to a web-based survey, using Microsoft Forms (Office 365), was given via a QR code. The survey contained 25 questions targeting the daily practice of preoperative anxiety management in children (Multimedia Appendix 1). Those respondents formed the EG, serving as a reference to the second survey. The results of this survey were formerly published [16].

XSL•FO
RenderX

The second open survey was announced among followers of a German-language podcast on pediatric anesthesia [26]. This podcast is broadcast on platforms such as Spotify and Apple Podcast (in total 44 platforms) and has achieved approximately 130k downloads and streams with its 34 episodes (data retrieved on July 01, 2024). Users were given access to this survey from October 01 to 31, 2023. The first call for participation was made on October 01, 2023, via short posts on the social media platforms X, Bluesky, and Instagram, as well as posts on the corresponding social media accounts in the field of anesthesiology following the random snowball sampling method. The invitation included an image with a QR code and a link to the web-based survey (Multimedia Appendix 2) along with a request for reposts. Several reposts were made and a short podcast episode on October 19, 2023, was broadcast to recall for participation (1117 downloads in the survey period). The episode was available on major podcast platforms, including Podigee, Spotify, Apple Podcasts, Amazon Podcasts, and Google Podcasts [27]. In comparison to the first survey, this one was expanded to cover the broad spectrum of social media users with 4 more questions (marked with asterisk (*) in Multimedia Appendix 1). Respondents formed the "Social Media Group" (SG).

All items were displayed on a website and were only interrupted by adaptive questions. Completeness checks before submission were not integrated, and respondents were able to modify their answers before submission. For both surveys, multiple participation could not be technically excluded but respondents of the second survey were asked to refuse participation in case of prior participation to the first survey. Multiple selections were possible for some questions.

Data Processing

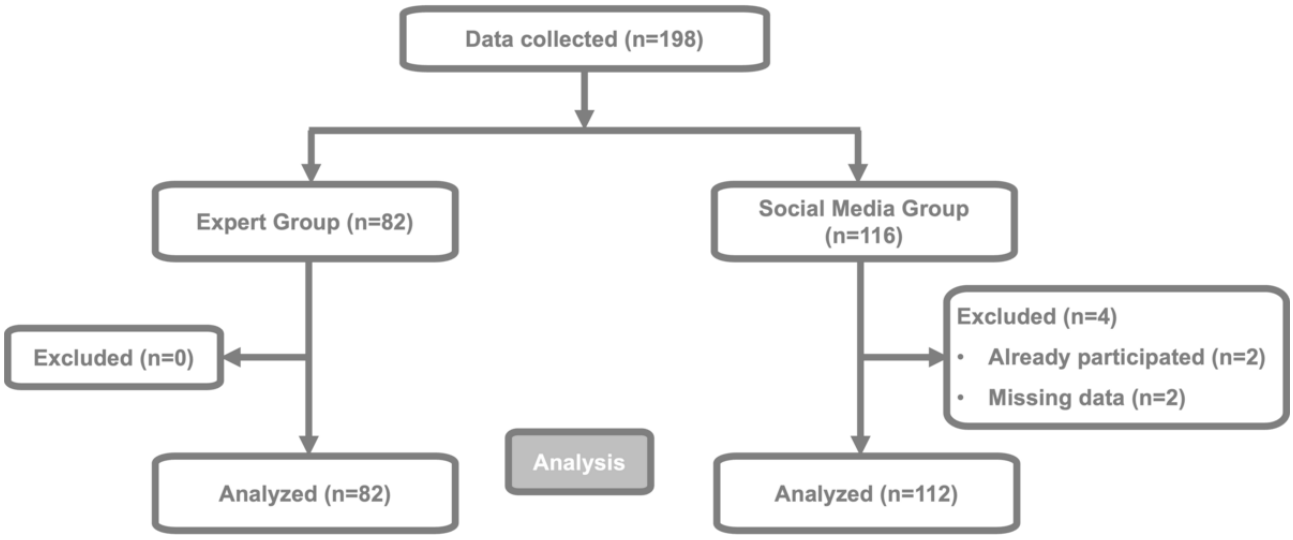
Both survey data were checked for incomplete data and then matched using Microsoft Excel (Office 2019, Microsoft). The questions were clustered into five categories: (1) pediatric anesthesia expertise (3 items), (2) representativity (5 items for both surveys and 4 additional items in SG), (3) structural conditions (9 items), (4) practices of pharmacological routine (6 items), and (5) practices of nonpharmacological routine (2 items). The item "zip codes" and the 4 additional questions were excluded from the comparison between the 2 groups, resulting in a total of 24 items being compared.

Objectives

The primary objective was to assess the pediatric anesthesia expertise of the SG compared with the EG, given by significant differences in professional expertise (defined by years of professional experience), expert status (defined as being a board-certified anesthesiologist with passed professional examination), and a number of personal annual pediatric anesthesia case volume. The secondary objectives were the differences in the clustered categories of general characteristics and practices in managing preoperative anxiety, capturing structural conditions and practices in both pharmacological and nonpharmacological interventions.

Statistical Analysis

In the descriptive analysis, we presented the absolute and relative frequencies for the respective groups for categorical variables and the medians, IQRs, and total ranges for the respective groups for continuous variables. We applied a significance level of 0.05 for all statistical tests. The Kolmogorov-Smirnov test was used to assess the normality of the distribution. *P* values for the comparison of both groups were calculated using Fisher exact test or chi-square test for categorical variables, and the Wilcoxon rank sum test for continuous variables. Analysis and illustrations were performed using GraphPad Prism (GraphPad Software) and Microsoft Excel (Office 2019, Microsoft).



Results

Overview

A total of 198 respondents participated in both surveys, 82 respondents in the EG and 116 respondents in the SG, respectively. Two responses from the SG were excluded due to prior participation in the EG survey, and another 2 responses were excluded due to missing data, leaving 194 responses for the final analysis in both groups (Figure 1). Unless stated otherwise, the full analysis set consisted of 82 respondents in the EG and 112 in the SG, with nonrespondents excluded from all calculations.

XSL•FO
RenderX

Figure 1. Flow chart of data collection and analysis.

The participation rate in EG was 82% as 82 participants out of 100 joined the survey during the annual meeting. Since no IP addresses were recorded, the participation rate for the SG could not be calculated. The completion rate of analyzed data was 100% in both groups.

In the 5 clustered categories, we found 10 out of 24 items to be significantly different in the response behavior between the 2 groups (see Table 1, corresponding questions in Multimedia Appendix 1).

[a]Not applicable (only 4 responses in the EG and only 1 response in the SG, no statistical analysis was carried out).

Pediatric Anesthesia Expertise

The level of pediatric anesthesia expertise demonstrated by the SG was significantly lower than that reported in the EG. This was given by a lower number of professional experience in the SG with a median of 10 years (IQR 6 - 18; total range 1 - 45) compared with a median of 19 years (14-25; 5-35) in the EG (*P*<.001), a lower share of respondents in the SG group of specialists, with 64.6% (64/99, with 13 nonrespondents), compared to 97.6% (80/82) in the EG group (*P*<.001), a lower share of respondents in the SG group reported performing more than 500 pediatric anesthesia cases per year, with 12% (13/108, with 4 nonrespondents), compared to 43.9% (36/82) in the EG group (*P*<0.001; details in Table 2).

[a]EG: Expert Group.

[b]SG: Social Media Group.

[c]4 nonrespondents; total n=112.

Representativity

Both groups showed a similar gender distribution, with 56.6% (45/81, 1 nonrespondent) female respondents in EG compared to 50% (56/112) in SG (*P*=.51) and the same percentage of respondents from Germany (93.8% each; 76/81, with 1 nonrespondent, in EG and 105/112 in SG). In the EG, respondents originated from 3 more countries (Switzerland, Austria, and Italy), whereas in the SG, respondents came from 5 more countries (Switzerland, Austria, Serbia, United Kingdom, and Hungary).

Differences in the level of care across respondents' workplaces were statistically significant (*P*<.001, Table 3). Most respondents came from university hospitals (28/81, 1 nonrespondent, 34.6% in EG vs 33/112, 29.5% in SG) while more respondents came from standard care hospitals in the SG (27/112, 24.1%) than in the EG (6/81, 1 nonrespondent, 7.4%).

Table . Level of care across respondents' workplaces.

	EG[a] (n=81)[b], n (%)	SG[c] (n=112), n (%)
Ambulatory	6 (7.4)	10 (8.9)
Standard care hospital	6 (7.4)	27 (24.1)
Children's hospital	18 (22.2)	11 (9.8)
High care hospital	17 (21)	27 (24.1)
University hospital	28 (34.6)	33 (29.5)
Others	6 (7.4)	4 (3.6)

[a]EG: Expert Group.

[b]1 nonrespondent; total n=82.

[c]SG: Social Media Group.

The annual pediatric anesthesia caseloads varied between groups. In the EG group, most 71.3% (n=57) reported over 1000 cases annually, with smaller proportions handling 500-999 (n=11, 13.8%), 250-499 (n=10, 12.5%), or fewer than 250 cases (n=2, 2.5%). In the SG group, 34.6% (n=36) managed over 1000 cases, 22.1% (n=23) reported 500-999, 18.3% (n=19) had 250-499, and 25% (n=26) handled fewer than 250 cases. Some respondents in both groups did not answer (n=2 in EG and n=8 in SG).

Structural Conditions

In EG, 36 (43.9%) respondents reported having a written standard operating procedure for managing preoperative anxiety, compared with 43 (38.4%) respondents in SG (*P*=.46). A preoperative preparation for children and their caregivers was included as part of anesthesia information by 28 (34.1%) respondents in EG and by 35 (31.3%) respondents in SG (*P*=.76). Among those who reported using specific material, there was no difference in the choice of measures (*P*=.90). The most frequently used materials were "pediatric-specific informed consent", information flyers, and comics (Table 4).

XSL•FO
RenderX

Table . Materials used to help prepare children and their caregivers preoperatively.

	EG[a] (n=28), n (%)	SG[b] (n=35), n (%)
Pediatric-specific informed consent	19 (25.5)	23 (20.5)
Information flyer	16 (21.5)	15 (13.4)
Comics	8 (10.7)	10 (8.9)
A designed mascot	7 (9.4)	8 (7.1)
Videos	4 (5.4)	2 (1.8)
Other[c]	2 (2.7)	3 (2.7)
Hypnosis	1 (1.3)	0 (0)
Guidance through the operating room	2 (2.7)	1 (0.9)

[a]EG: Expert Group.

[b]SG: Social Media Group.

[c]Other used materials mentioned: instruction on how to use topical anesthesia patches, offering website information, the use of soap bubbles, and a virtual operating theater tour.

When asked whether the local structural conditions would generally allow the parents to be present until the children are anesthetized, 52 (63.4%) respondents in the EG and 50 (45%) respondents in the SG answered in the affirmative (*P*=.01). Among those, 38 (46.3%) respondents in the EG and 57 (50.9%) respondents in the SG reported not offering parents to be present during the induction of anesthesia. In EG, 26 (31.7%) respondents reported enabling parental presence while 29 in SG (25,9%). Another 18 (22%) respondents in the EG stated that parental presence depends on the individual workplace within their institution, while 26 (23.2%) respondents in the SG reported the same. The place where the children were separated from their parents or parental substitutes did not differ significantly between the groups.

Separation locations for children from parents did not significantly differ between groups (*P*=.84). Most commonly, separation occurred during transfer to the operating room (EG: 44 out of 80 respondents, 55%; SG: 67 out of 109 respondents, 61.5%). Separation in the induction room was less frequent (EG: 13 out of 80 respondents, 16.3%; SG: 13 out of 109 respondents, 11.9%) and in the holding area similarly rare (EG: 12 out of 80 respondents, 15%; SG: 13 out of 109 respondents, 11.9%). Separation in the operating room itself was reported even less often (EG: 9 out of 80 respondents, 11.3%; SG: 12 out of 109 respondents, 11%), while on the ward it was rarest of all (EG: 2 out of 80 respondents, 2.5%; SG: 4 out of 109 respondents, 3.7%). A small number of respondents did not provide an answer (EG: 2 respondents; SG: 3 respondents).

A total of 95.1% (78/82) of respondents in EG and 99.1% (111/112) in SG reported that children's anxiety is not routinely measured. Regarding anxiety scales, 31.7% (n=33) of EG respondents and 55.8% (n=67) of SG respondents stated that they were not familiar with any. The Yale Preoperative Anxiety Scale was the most recognized scale in the EG, with 25% (n=26) of respondents indicating familiarity with it. In contrast, only 8.3% (n=10) of respondents in the SG reported familiarity with the Yale Preoperative Anxiety Scale. The visual analog scale (VAS) was the most recognized scale in the SG, with 30% (n=36) of respondents indicating familiarity with it. In contrast, only 24% (n=25) of respondents in the EG reported familiarity with the VAS.

Practices of Pharmacological Interventions

The use of pharmacological premedication in daily practice was reported by 80.5% of respondents (66/82) in EG and 79.5% (89/112) in SG, with no statistically significant difference between the 2 groups (*P*>.99), indicating that both groups have a similarly high rate of routine use of premedication.

When it comes to actively avoiding premedication, there was a significant difference between the 2 groups (*P*=.04). In EG, 50% (41/82) tried to avoid premedication, whereas only 34.4% (39/112) in the SG did so.

Both groups showed similar responses (*P*=.24) regarding their decision-making process for administering pharmacologic premedication (refer to Table 5). Individual responses included consulting children or their parents about the need for premedication, with some also specifying the placement of an intravenous line before anesthesia induction.

XSL•FO
RenderX

Table . Criteria for deciding on premedication use. Multiple answers were possible.

	EG[a] (n=82), n (%)	SG[b] (n=112), n (%)
The children are generally premedicated with medication	28 (34.1)	55 (49.1)
According to the child's anxiety	52 (63.4)	52 (46.4)
According to the parents' anxiety	18 (22)	18 (16.1)
According to the child's wishes	38 (46.3	35 (31.3)
According to the parents' wishes	22 (26.8)	25 (22.3)
According to medical history	46 (56.1)	52 (46.4
According to experience/gut feeling	31 (37.8)	46 (41.1)
Individual answer	12 (14.6)	10 (8.9)

[a]EG: Expert Group.

[b]SG: Social Media Group.

In both groups, midazolam was reported as the most frequently used premedication drug (EG: 81/82, 98.8% and SG: 112/112, 100%). In EG, (es-)ketamine (41/82, 50%), clonidine (18/82, 22%), and dexmedetomidine (6/82, 7.3%) were used as well as in SG (42/112, 37.5%; 19/112, 17%; and 11/112, 9.8%, respectively) without significant difference (P=.23). Overall, midazolam was the drug of first choice in both groups (76/80, 2 nonrespondents, 95% in EG vs 105/111, 1 nonrespondent, 94.6% in SG).

The median minimum age for administering premedication was 6 months (6-8; 0-48) in EG and 9.5 months (6-12; 0-36) in SG (P<.001).

Practices of Nonpharmacological Interventions

Nonpharmacological interventions were routinely used by 60 (73.2%) respondents in EG and by 78 (69.6%) respondents in SG (P=.63). There was a significant difference (P<.001) in the selection of which nonpharmacological interventions were used (Table 6). While in the EG parental presence was the most reported intervention (43/60, 71.7%), it was the use of videos in the SG (62/78, 79.5%).

Table . Practices of nonpharmacological interventions. Multiple answers were possible.

	EG[a] (n=60), n (%)	SG[b] (n=78), n (%)
Parental presence	43 (71.7)	38 (48.7)
Videos (tablet, smartphone, etc)	42 (70)	62 (79.5)
Reading or showing books	21 (35)	29 (37.2)
Games	17 (28.3)	14 (17.9)
Other activities[c]	12 (20)	12 (15.4)
Audio books	8 (13.3)	5 (6.4)
Music distraction	7 (11.7)	14 (17.9)
Hypnosis	7 (11.7)	2 (2.6)
Behavioral exercises	7 (11.7)	0 (0)
Clowns	5 (8.3)	4 (5.1)
Virtual reality glasses	2 (3.3)	4 (5.1)

[a]EG: Expert Group.

[b]SG: Social Media Group.

[c]Other activities mentioned in both groups were the use of a floating bird, the integration of cuddly toys, the use of a glitter wand, interactive storytelling, a starry sky projection, and the use of soap bubbles.

Discussion

Principal Results

The respondents to the publicly announced survey on social media demonstrated significantly less pediatric anesthesia expertise than the respondents to the survey among experts. This was evidenced by fewer years of professional experience, fewer board-certified specialists, and a lower pediatric anesthesia caseload. However, when looking at the items related to the practice of pediatric anxiety management, significant differences were found in less than a third. Regardless of the survey group,

XSL•FO
RenderX

our results showed very heterogeneous approaches to the management of preoperative anxiety in pediatric patients.

Our study presents 2 principal findings. First, it remains debatable whether web-based surveys are an effective method for reaching the target group of pediatric anesthesia providers. On the one hand, the respondents to the web-based survey rated their level of expertise lower than those who were involved in a scientific meeting survey. However, specific parameters that best identify an expert in the field of pediatric anesthesia remain undefined. It seems clear that increased experience in this field correlates with a lower rate of complications in children [28]. A high volume of pediatric anesthesia cases likely contributes to a higher level of expertise. Being classified as a specialist (board-certified anesthesiologist) further indicates that a minimum standard of experience in pediatric anesthesia has been met [29]. However having many years of professional experience does not necessarily equate to extensive pediatric anesthesia practice, as hospital structure, hospital focus, and patient demographics may limit exposure to pediatric cases [30,31]. In addition, the higher share of institutions with a higher level of care and a higher number of children's hospitals among experts might indicate pediatric anesthesia expertise due to a higher pediatric caseload. But there may be also anesthesia providers with a high individual pediatric caseload in standard care hospitals. On the other hand, when responses from an EG exhibit significant heterogeneity [16], it is not unexpected that similar heterogeneity would persist when querying a larger (or another) sample. This leads to the conclusion that it is not that obvious as our results may indicate which of the 2 groups can more accurately reflect the actual reality of pediatric anesthesia care.

Further, the dissemination of a web-based survey through social media is debatable. The methodology of web-based surveys offers significant advantages, particularly due to their rapid deployment and extensive reach, which facilitate the swift collection and distribution of data. Similarly, social media, which has become increasingly popular in the medical field, enables the rapid dissemination of insightful opinions and information and underscores the value of web-based surveys [23,32]. Drawbacks of web-based surveys are the inadequate representation of the sample population due to insufficient coverage, the absence of a sampling frame to guide sample selection, nonselection bias, and a low participation rate, which is estimated at approximately 11% [33-35]. Of course, it is difficult to verify data quality with anonymous questions, and there is ongoing research into how to implement attention checks or other means of detecting poor-quality data in web-based surveys [36]. The presence of selection bias within the SG is also possible. This could skew the data, as operating within a "bubble" may predominantly reach individuals already familiar with the topic, potentially also limiting a full representation of reality. An interesting direction for future research could involve comparing groups with similar characteristics to examine whether the survey access method (social media vs conference or "classic") introduces a selection effect related to expertise. With a participation rate of more than 80%, the EG directly addressed at the conference meeting demonstrated a high willingness to participate. Overall, slightly more responses were collected in the SG, even though access was open for an extended period and potentially a higher amount of respondents, indicating a low response rate in this "digital" SG. This suggests that if a survey on a specific topic, such as anxiety in pediatric anesthesia, is announced via social media, it is likely that only a specific subset of individuals, those with a particular interest or relevance to the topic, will actively engage and participate.

The second point, apart from the discussion about whom to ask for pediatric anesthesia surveys, is what both groups have in common: There is a large heterogeneity in applied anxiety management practices. This includes the debated issue of parental presence during anesthesia induction. Although it does not reduce children's anxiety, children have the right to be accompanied by their parents or substitutes. Surprisingly, parental presence during induction remains uncommon [37,38]. Local conditions appear to inhibit parental presence, and even if it was possible in principle, it is often not implemented. Potential reasons for this could include the need for additional staff or carefully coordinated arrangements to manage the logistics of parental involvement, as well as considerations pertaining to hygiene.

The same heterogeneity exists in the question of when which child should receive premedication. This is shown by the many varying approaches regardless of the 2 survey groups. Medication is currently made in a highly inconsistent manner, largely based on individual clinical judgment. When it comes to the application of medication, midazolam holds a high relevance in both groups. However, it has been proven to significantly reduce preoperative anxiety, it also has evident disadvantages including a long recovery time, respiratory adverse effects, and amnestic effects [6,7]. That may explain why all respondents reported using alternative premedication agents such as (es-)ketamine, clonidine, and dexmedetomidine frequently [5]. In addition, the application of nonpharmacological interventions is heterogeneous [15]. But if applied, one of the most favored options is video distraction. This does not seem surprising since video distraction is easy to implement, widely available, and requires no training or infrastructure (unlike, for example, clowns).

With regard to anxiety scales, it is noteworthy that 30% of the experts were unfamiliar with any scales for measuring anxiety. Awareness of specialized scales, such as the modified Yale Preoperative Anxiety Score, was higher among the EG, likely due to its frequent use in studies and the fact that many experts are affiliated with university settings [39]. In contrast, participants in the SG reported slightly greater familiarity with the VAS, a tool widely recognized for its application in pain management [40]. Despite the availability of these tools, their limited use remains puzzling. Broader implementation could enhance the identification of preoperative anxiety and increase awareness of its importance in clinical practice.

Limitations

The study faced several limitations. First, it is prone to bias as there likely was a potential overrepresentation of more tech-savvy individuals in the SG, leading to a demographic discrepancy compared with the EG with a potential risk for self-selection bias. Second, the reach of the web-based survey

XSL•FO
RenderX

could not be sufficiently quantified, and attention checks were omitted, compromising information about the response rate and its quality. The survey was disseminated through a variety of social media platforms, but without considering social media use statistics, which may have biased the sample. Additionally, the anonymity of the survey precluded verification of respondent accuracy.

Conclusion

The respondents from a scientific working group on pediatric anesthesia had more professional experience in this medical subspecialty and also more specific knowledge than survey participants from social media. However, when it comes to the use of strategies that reflect daily practice, the groups differed little and only in general terms. A diverse range of pharmacological and nonpharmacological interventions are used in daily practice and their use seems to be based more on individual preferences. Consequently, there is a need for evidence-based recommendations regarding the appropriate use of these interventions, including indications for their use. Web-based surveys via social media can have the potential to gain insights into daily practice on specific topics like managing preoperative anxiety in pediatric patients. Further studies should investigate whether surveys disseminated through social media yield similar results in other specific subject areas.

Acknowledgments

We acknowledge financial support by Land Schleswig-Holstein within the funding programme Open Access Publikationsfonds. We would like to thank all participants of these surveys. AS would also like to thank his friend and podcast partner Dr Gordon Fink.

Authors' Contributions

AS contributed to the conceptualization, methodology, validation, formal analysis, investigation, resources, data curation, visualization, and writing the original draft. CE was responsible for reviewing and editing the draft and validation. MN contributed to conceptualization, methodology, validation, data curation, writing the original draft, and reviewing and editing the draft. CM was involved in conceptualization; methodology; validation; data curation; and writing, reviewing, and editing the draft.

Conflicts of Interest

AS is the host of a German-language podcast on pediatric anesthesia (“Kinderanästhesie-Talk”). The other authors do not have any conflicts of interest to declare.

Abstract

Background: The cause-effect of stunting is known as a complex factor, including family, environmental, social, and cultural factors, in stunting among children. Yet, the latest updated associated factors emphasizing on social and environmental factors are still limited.

Objective: This study aimed to analyze the latest evidence on the factors associated with stunting, with a particular focus on various factors.

Methods: A secondary data analysis using the 2023 Indonesia Health Survey (Survei Kesehatan Indonesia [SKI] 2023) was conducted. This study analyzed a total of 78,049 (or 81,068 if weighted) children aged 5 years and younger who had a complete response to all interest variables. Bivariate analysis using the Pearson χ^2 test with a *P* value of <.05 for determining a significant association and a multivariate analysis for further analysis of the association between the outcome and each predictor were implemented.

Results: The prevalence of stunting in this study was 15,958/78,049 children (19.69%). In the adjusted analysis, immunization status (adjusted odds ratio [aOR] 1.34, 95% CI 1.22 - 1.48; *P*<.001) and KPS (Kartu Perlindungan Sosial; Social Protection Card) ownership (aOR 1.13, 95% CI 1.05 - 1.21; *P*<.001) were significantly associated with higher odds of stunting. Conversely, children in the wealthiest quintile were significantly less likely to experience stunting compared to those from the poorest families (aOR 0.47, 95% CI 0.42 - 0.52; *P*<.001). Other variables, such as household water sources (aOR 1.18, 95% CI 1.00 - 1.37; *P*=.04), and geographical location, particularly in Sulawesi (aOR 1.23, 95% CI 1.14 - 1.33; *P*<.001) and Papua and Maluku (aOR 1.20, 95% CI 1.08 - 1.33; *P*<.001), were also significantly associated with increased odds of stunting.

Conclusion: Not receiving immunization, consuming water from unimproved sources, ownership of a Social Protection Card, and living in regions such as eastern Indonesia were significantly associated with childhood stunting. These findings emphasize that social and environmental factors remain critical determinants of stunting. Improving multifaceted and holistic interventions, with a focus on immunization coverage, good water access, social protection, and reducing regional disparities, is essential to accelerate progress toward stunting reduction targets.

(JMIR Pediatr Parent 2025;8:e68918) doi:10.2196/68918

KEYWORDS

associated factors; stunting; children under five years; social determinants of health; children

Introduction

Stunting, defined as poor linear growth with a height-for-age z-score less than –2 SDs of the median determined in the World Health Organization's (WHO) Child Growth Standards [1], is still a global public health issue, especially in low- and middle-income countries [2-4]. The condition has been known as a significant indicator of chronic malnutrition and leaves irreversible impediments throughout life [5,6]. Approximately,

XSL•FO
RenderX

148.1 million (22.3%) of children aged 5 years and younger were diagnosed as stunted worldwide in 2022 [4], with an estimated 98% children with stunting residing in low- and middle-income countries [7] and about 52% living in Asia [4]. The consequences of stunting can reflect on further child development, including in terms of health, physical and cognitive, leading to a higher risk of morbidity and mortality [8-10].

According to the Indonesia Health Survey (Survei Kesehatan Indonesia, SKI) in 2023, the prevalence of stunting in Indonesia remains substantial at 21.5%, indicating that about 1 in 5 children ages 5 years and younger is affected, with the highest incidence observed among children aged 24 to 35 months [11]. Digging deeper to the geographical location, huge geographical disparities of children with stunting exist in which eastern regions of Indonesia, namely Papua, Nusa Tenggara, and Sulawesi, indicated a significantly higher prevalence [12]. This percentage of children showed a steady decrease in the past decade [13], yet the number is still far from Indonesia's national target in reducing child stunting to 14% by 2024 [14]. Furthermore, the Joint Malnutrition Estimates (JME) released in 2023 recorded that only one-third of all countries worldwide are on track to cut across half the percentage of children affected by stunting [4]. Reflecting on this evidence, a comprehensive evaluation of existing stunting reduction programs and a more in-depth analysis of the associated factors is needed.

The etiology of stunting is multifactorial. The WHO developed the conceptual framework on childhood stunting [15], explaining the cause-effect of complex factors, including family, environmental, social, and cultural factors, in stunting among children aged 5 years and younger. Previous studies have also justified that maternal factors, such as mother's height, mother's BMI, antenatal care history, mother's education, are considered as another direct factor of stunting among children after the child's factors [2,5,16-18]. While the children-related factors that have been discovered include the child's age, sex, low birth weight, feeding practice, exclusive breastfeeding, lack of food intake, and infection or disease history [5,16,19,20]. Beyond biological and behavioral factors, a growing body of research highlights the importance of socioeconomic [2,18] and environmental conditions, including household wealth, access to clean water, sanitation, hygiene practices, and geographic disparities, as indirect but critical determinants of stunting [17,21-23].

Despite these known pathways, there remains limited large-scale national evidence from Indonesia that focuses specifically on how social and environmental (or exposome) factors influence stunting outcomes. Given Indonesia's vast geographic diversity and persistent regional inequalities, it is essential to examine how broader contextual factors interact with stunting risks. This study aims to fill this gap by analyzing nationally representative data to identify key social and environmental determinants of stunting among Indonesian children ages 5 years and younger. The findings will provide actionable insights for designing more context-specific, equity-oriented interventions and contribute to accelerating national progress toward the 2024 target and Sustainable Development Goals (SDGs).

Methods

Study Design and Data Collection

A secondary data analysis was conducted by extracting data from the 2023 Indonesia Health Survey (Survey Kesehatan Indonesia) for which the survey is the integration of 3 researches: the Basic Health Research (Riset Kesehatan Dasar, RISKESDAS), the Indonesia Nutritional Status Monitoring Survey (Survei Status Gizi Indonesia, SSGI), and Biomedical and dental-and-oral examinations. The survey had included a nationally representative sample of households, households with children aged 5 years and younger, and individuals' characteristics with a total sample of 877,531 household respondents and 314,161 households with children aged 5 years and younger, from 38 provinces and 514 administrative cities or districts across Indonesia.

Sampling Technique and Study Population

In the SKI 2023, stratified sampling technique was used at the block level census and household level of chosen block level census, to get a representative sample for all provinces. A total of 34,065 blocks census was stratified using explicit stratification; meanwhile, implicit stratification was applied for the household level. The response rate of SKI 2023 was 98.74% with 1,191,692 respondents, consisting of interviewing 877,531 respondents of member of households and anthropometry examination of 84,267 respondents of children aged 5 years and younger (see Multimedia Appendix 1). Before collecting data, informed consent was obtained from every respondent. This study analyzed a total of 78,049 children (or 81,068 if weighted) aged 5 years and younger who had a complete response to all interest variables (sex, immunization status, last months' history of diarrhea, place of residence, social protection card ownership, household water sources, water quality, and geographical location). Weight and sampling design were used for adjustments in this analysis.

Data Collection and Procedure

The SKI 2023 took place from August 2023 to early October 2023. There were 3 questionnaires used in this survey, namely: household questionnaire, children aged 5 years and younger questionnaire, and individual questionnaire, all of which reflect the population and health-related issues relevant to Indonesia. This study used the children's data for analysis. Data were requested legally to the Ministry of Health website [24]

Measurement of Stunting and Covariates

The stunting among children aged 5 years and younger was the dependent variable of interest, while several independent variables like socioeconomics and environments were included in the analysis depending on the availability in SKI 2023. Stunting was defined using HAZ (height-for-age z-score), considering the sex, height, weight, and age of individuals. Individuals with a z-score< –2 were categorized as stunted. Our definition matched with the standard defined by the WHO [25].

Water quality was categorized as poor and good, meanwhile household water source was categorized as improved, unimproved, and surface water. Water quality was defined by

XSL•FO
RenderX

the physical parameters of the water. If a household responded "No" to all these physical quality issues (turbidity, color, taste, foam, and odor), their drinking water was categorized as good quality [26]. Improved water sources consisted of packaged water, refilled water, piped water, boreholes or wells with pumps, protected dug wells, protected springs, rainwater collection, water hydrants, water bought from vendors, and water terminals. Unimproved water sources included unprotected dug wells and unprotected springs. Surface water, such as water from rivers, lakes, or irrigation canals, was classified separately. This classification was derived from the Demographic and Health Surveys (DHS) categorization [27].

Last months' history of diarrhea was categorized as yes, no, and don't know. This 3-category classification was used because recall of diarrheal episodes over the previous month can be subjective and uncertain. Respondents may not clearly remember or recognize whether symptoms met the criteria for diarrhea, so the "don't know" option captures this uncertainty. For immunization status, the categorization was divided as yes and no or unsure. Immunization records tend to be more definitive, as caregivers often have vaccination books (KIA [Kesehatan Ibu dan Anak], the Mother Child Health Book, or the pink book) to clearly recall vaccination history. Thus, grouping answers to "no" and "unsure" simplifies analysis by treating any lack of confirmed vaccination as absence of immunization. Female and male were a categorization used for sex. Place of residence was categorized as rural and urban. Social Protection Card (Kartu Perlindungan Sosial, KPS) ownership was categorized as yes and no. Geographical location of children was categorized as Java, Sumatera, Bali and Nusa Tenggara, Kalimantan, Sulawesi, and Papua and Maluku. In this study, the wealthy index was grouped into 5 quintiles as poorest, poor, middle class, wealthier, and wealthiest. Prevalence of stunting was calculated for each category of the covariates to assess distribution patterns.

Statistical Analysis

Initial analysis started with frequency distribution analysis of the sociodemographic characteristics and relevant external factors associated with stunting among children. To assess the frequency distribution, bivariate analysis using Pearson χ^2 test was implemented with a P value of <.05 for determining a significant association. The association between outcomes and predictor variables was analyzed using binary logistic regression as presented in a crude or unadjusted analysis and to examine the association between predictors and stunting. Odds ratios (OR) with 95% CI were reported.

The selection of reference categories was selected based on findings from previous research, which indicate that the risk of stunting tends to increase among children with incomplete immunization, recent episodes of diarrhea, lower wealth quintile status, and those residing in rural areas [28-31]. In line with these findings, the reference groups were chosen to allow meaningful comparison. Finally, a multivariate analysis has been done to assess further association between the outcome and each predictor. All statistical analysis was implemented using SPSS (version 26.0 for Windows; IBM Corp).

Ethical Considerations

This study used secondary, deidentified data from the 2023 Indonesian Health Survey (SKI 2023), which was conducted by the Indonesian Ministry of Health with previous approval from the National Ethics Committee. As this study used publicly available, anonymized data, it was classified as exempt from additional ethics review. The National Ethics Commission classified this study as "exempted" and the Indonesian Ministry of Health collected the data with informed consent, ensuring participants signed a consent form, emphasizing that participation was voluntary and confidential. The Indonesian Ministry of Health has made the data available to the academic community through its website [24].

Results

Prevalence of Stunting Among Covariates

The prevalence of stunting in this study was 15,958/78,049 (19.69%). Among the water and sanitation factors, the prevalence of stunting was dominant in households with poor water quality 665 (21.9%). In addition, households with surface water sources had higher prevalence of stunting 96 (29%) compared to unimproved 636 (25.2%) and improved water sources 15,226 (19.5%).

Among individual factors, we found that the prevalence of stunting was high among children who had diarrhea last month 968 (24.7%) and also male children 8601 (20.8%). Children with no status of vaccination were also seen with higher prevalence of stunting 1593 (25%). In terms of community factors, we found that children who lived in rural areas had a higher prevalence of stunting 7266 (21.7%). In addition, households who had KPS had a higher prevalence of stunting 3439 (23.4%) and also households in the poorest, poorer, and middle class had higher prevalence of stunting 2800 (27.6%), 3395 (23.5%), and 3488 (20.5%), respectively. The prevalence of stunting was also higher in Papua and Maluku 601 (26.2%), Sulawesi 1538 (24.7%), and Kalimantan 1039 (20.5%; see Table 1).

Poorest	2800/10,147 (27.6)
Poorer	3395/14,459 (23.5)
Middle class	3488/16,994 (20.5)
Wealthier	3432/19,296 (17.8)
Wealthiest	2843/20,172 (14.1)

[a]KPS : Kartu Perlindungan Sosial (Social Protection Card).

Factors Associated With Stunting

In the bivariate analysis with the unadjusted model (see Table 2), we found that water quality, household water sources, immunization status, KPS ownership, and also wealth quintile were associated with stunting (*P* values<.05). Both geographical and history of diarrhea were partially associated with stunting, as only some categories were significant with stunting (*P* values<.05). However, some independent associations in bivariate analysis were not strong enough to be significant after adjusting with other variables.

In the adjusted models (see Table 2), the variables that remained significant were immunization status, KPS ownership, and wealth quintile. We found that children with no immunization status had higher odds of developing stunting (aOR 1.34, 95% CI 1.22-1.48). In addition, children whose households owned KPS also had higher odds of developing stunting (aOR 1.13, 95% CI 1.05-1.21). We also noticed a gradient of decreasing risk along with the increasing status of wealth quintile. Children in the wealthiest (aOR 0.47, 95% CI 0.42-0.52), wealthier (aOR 0.61, 95% CI 0.55-0.67), middle (aOR 0.71, 95% CI 0.65-0.78), and poorer (aOR 0.83, 95% CI 0.76-0.91) classes had lower odds of developing stunting compared to children in the poorest class.

Partial associations in the adjusted model were found in the variables such as household water sources and geographical location (see Table 2). Children whose household water was unimproved had higher odds of developing stunting (aOR 1.18, 95% CI 1.00-1.37), but such association was not found in the surface water categories. Finally, children who lived in Sulawesi (aOR 1.23, 95% CI 1.14-1.33), and Papua and Maluku (aOR 1.20, 95% CI 1.08-1.33) had higher odds of developing stunting compared to children who lived in Java, but the odds of stunting were lower for children in Sumatera (aOR 0.84, 95% CI 0.79-0.91). Such an association was not found in Bali, Nusa Tenggara, and Kalimantan.

Discussion

Principal Findings

In this study, the prevalence of stunting among children aged 5 years and younger was 19.69% (15,958/78,049). Although this figure appears lower than the national estimate reported by SKI 2023, which recorded a prevalence of 21.5% [11], it is important to note that our analysis used a different subset of the same dataset. Specifically, the discrepancy may be due to the application of distinct inclusion criteria in our study that focused on children with complete data for selected socioeconomic and environmental variables. In which, we may have excluded some high-risk groups or regions. Therefore, this finding should not be interpreted as a trend or decline in stunting prevalence over time, but rather as a context-specific estimate based on an analytical sample tailored to explore social and environmental determinants.

A downward trend in stunting prevalence has highlighted an updated figure in this study. Comparing to the overall report of SKI 2023, the existence of variation in the prevalence of stunting, even though using the same dataset, might be attributable to differences in the inclusion criteria for the variable use. As this study includes the set of data on influential factors, more of which are social and environmental factors. This finding is lower than the findings from India (31.7%) [32], Afghanistan (44.7%) [33], Bangladesh (26.7%) [34], Pakistan (40%) [35], and Timor Leste (45.1%) [4]. The difference in findings might rely on the efforts in public health intervention, such as nutritional programs, economic and social development conditions, accessible community-based health services, environmental focus, and the disparities of investment in nutritional-sensitive strategies. Previous studies [36,37] revealed that inadequate investment in nutrition could hinder the progress of reducing stunting to reach the global goals of 40% by 2030. Hence, the positive result of Indonesia's integrated efforts should be in scaling up existing programs and investing more in nutrition-sensitive programs.

This study revealed that children who did not receive immunization are 1.34 times higher odds of being stunted compared to children who received immunization. Some studies are in line with findings across the literature [19,38-42]. This association could be due to interrelated factors, particularly infection rates and nutritional status. Inadequate immunization is linked to the high risk of infectious diseases, which can negatively affect a child's growth and development [43,44]. In addition to direct impact on nutritional status, a study has proven the significant improvement of anthropometric outcomes among children who have received immunization [45]. At this point, addressing stunting requires a comprehensive programmatic approach, integrating immunization programs with maternal and child health, rather than relying solely on nutritional intervention programs.

Our study found that children from households receiving KPS were significantly more likely to be stunted compared to those not receiving the benefit. This is in line with a previous study that mentioned that the Conditional Cash Transfer program does not result in reducing stunting in poor children aged 5 years and younger [46]. On the other side, children of household-owned KPS are significantly associated with stunting, which is an unexpected result, as KPS are originally designed to alleviate poverty and improve access to basic needs, including food, health care, and education. Several potential mechanisms may explain this association. First, the presence of KPS itself is an indicator of household vulnerability. The families receiving it are among the poorest, and the underlying socioeconomic disadvantages may outweigh the benefits received from KPS. Second, while the KPS provides rice subsidies, school allowances, and limited health support, it may not directly address dietary diversity, child feeding practices, or access to quality health care, which are critical determinants of nutritional status. Third, there may be issues related to implementation or adequacy. A study in Palembang, Indonesia, mentions that families with more than 4 members or more, the children have the risk of stunting even if they already get subsidized [47]. The value of support provided may be insufficient to meet a household's nutritional needs. Finally, some households may not use the benefits effectively due to lack of nutrition literacy or limited access to supporting services.

The study found that as the wealth quintile increases, the risk of stunting among children aged 5 years and younger decreases, with children from the wealthiest families being less likely to be stunted than those from the poorest families. Previous studies have proven the same result, that is, children from the poorest families are prone to develop stunting [2,3,16,18]. The relationship might be attributable to economic inequality between quintile groups, where children from wealthiest families often have food security, accessibility to consume a high quality of foods, health care services, improved sanitation, and water resources [48,49]. On the other hand, all these facilities are being a limit for children from the poorest families [18].

RenderX

Nutrition intervention [50-52], such as providing supplementary foods for children with stunting, has been implemented by the Indonesian Government and showed a significant result in intervening undernutrition issues [51]. Expanding these interventions across Indonesia, with an emphasis on equal access in all regions, is essential for addressing stunting on a larger scale.

In this study, children exposed to unimproved water sources had 1.18 times higher odds of being stunted compared to children who were exposed to improved water sources. A study in Ethiopia, India, Peru, and Vietnam is correspondent with this finding, which showed the consumption of improved water source decreasing the risk of stunting among children [19,53]. Consuming from an unimproved water source increases the infection rate and the incidence of diarrhea among children that indirectly affects nutritional status of children [54]. Unimproved water sources might contain pathogenic microorganisms and other chemical substances that cause diarrhea or other infectious diseases [22]. Some studies justified that intervention on hygiene and sanitation is significantly improving children's growth [55-57], indicating sanitation and hygiene improved water sources intervention must be included in the national program for achieving the stunting reduction target.

In terms of geographical location, the odds of being stunted among children who reside in Sulawesi and Papua and Maluku are 1.23 times and 1.20 times, respectively, compared to those who reside in Java. Meanwhile, children living in Sumatera are less likely to be stunted compared to children living in Java. Common findings also have been proven by studies that tried to map the stunting prevalence in and across Indonesia [12,18]. The rationale is exacerbated by inequality conditions across Eastern Indonesia, of which many regions have limited access to decent health facilities and resources [58,59], particularly the proportion of health care personnel and services as they are centralized in Java and Sumatera. These findings suggest the government should enhance the infrastructure developments, especially in health, and distribute more health personnel outside Java and Sumatera Island.

The findings from this study offer several implications for policy and program planning. First, the identification of social and environmental determinants, such as low household wealth, regional disparities, poor access to clean water, and incomplete immunization. This highlights the need for multisectoral approaches that extend beyond direct nutrition interventions. Nutrition programs should be designed with a broader lens, integrating improvements in public health infrastructure, social protection targeting, sanitation, and health education. For example, linking immunization programs with nutritional screening and counseling may enhance early identification of at-risk children. Second, the geographic disparities observed support the prioritization of region-specific interventions, particularly in Papua, Maluku, and Sulawesi, where stunting remains persistently high. Tailoring intervention packages based on local infrastructure, culture, and needs can increase effectiveness. Finally, the unexpected finding regarding KPS beneficiaries emphasizes the importance of monitoring and evaluating the impact of social programs on nutrition outcomes and modifying them to include behavior change communication, food diversification support, or conditional nutrition services. In this way, evidence from large-scale secondary datasets can directly inform data-driven, equity-focused strategies to reduce stunting nationally.

Strengths and Limitations of the Study

A large dataset as representative of the national population of Indonesia has been used in this study. However, the researcher has limited control over the selection variables, data quality, and indicators for measurements due to the use of secondary dataset. Social desirability bias might exist since the survey used self-reports for gathering the information. Some potentially important determinants of stunting, such as detailed dietary intake, feeding practices, or maternal nutritional status, were not available, and therefore could not be included. Second, the use of self-reported data introduces the possibility of social desirability and recall bias, which may affect the accuracy of responses, particularly in sensitive areas such as household wealth or immunization history. Another limitation is the cross-sectional design of this study, which allows for the identification of correlations between exposures and outcomes but does not permit determination of the temporal sequence of events. As a result, causal inferences about the relationship between the identified risk factors and stunting cannot be made.

Conclusion

This study reinforces the idea that childhood stunting remains a significant public health concern requiring multifaceted interventions. Key social and environmental factors, including incomplete immunization, KPS ownership, low household wealth, use of unimproved water sources, and residence in Sulawesi, Papua, and Maluku were all significantly associated with the increased odds of stunting. These findings offer updated national evidence on the contextual determinants of stunting in Indonesia.

To accelerate progress in stunting reduction, increasing immunization coverage should be prioritized, supported by community-based health education targeting mothers and caregivers. The association between KPS recipients and higher stunting risk suggests that existing welfare programs may need to be strengthened or better integrated with nutrition-sensitive interventions. Furthermore, sanitation factors, particularly access to improved water sources, should receive greater policy attention. Finally, improving access to quality health care across all regions, especially underserved areas, is essential for effective and equitable stunting prevention efforts nationwide.

Data Availability

The datasets analyzed during this study are available from the Indonesia Ministry of Health through the 2023 Indonesia Health Survey (Survei Kesehatan Indonesia [SKI] 2023) data request portal [24].

Abstract

Background: The United Nations considers children a crucial national asset and makes their welfare a top priority. However, infant mortality remains a persistent challenge, notably in Arab nations. Bahrain, Kuwait, and Oman, despite sharing similar income brackets and health care systems, differ in health policies, demographics, and maternal-child resource allocation. These countries also faced sharp fiscal deficits during the 2020 COVID-19 crisis. Compared to wealthier nearby nations like the United Arab Emirates, their lower gross domestic product further complicates efforts to reduce the Infant Mortality Rate (IMR) and sustain effective, equitable child health strategies.

Objective: This study aimed to identify factors contributing to the IMR in Bahrain, Kuwait, and Oman by establishing an interpretative framework to examine the influence of sociodemographic, macroeconomic, health status and resource, and environmental factors.

Methods: A longitudinal study collected annual time-series data (1990 - 2022) for Bahrain, Kuwait, and Oman from international open sources. To counterbalance the time-series effects on both IMR and explanatory factors, a generalized least squares model based on the Cochrane-Orcutt procedure with a first-order autoregressive model was used.

Results: Generalized least squares shows that the total fertility rate has a strong effect on IMR among the 3 countries (Oman: β=1.138, *P*<.001; Kuwait: β=.429, *P*=.006; Bahrain: β=.610, *P*=.03). Health status and resources, such as female life expectancy at birth, had an inconsistent impact on the IMR, with a positive effect (β=.103, *P*=.002) for Oman and a negative effect (β=−4.0697, *P*<.001) for Kuwait. Macroeconomic factors, such as female unemployment, were significant in decreasing the IMR only for Kuwait (β=−.076, *P*=.008). Gross domestic product per capita is significant only for Bahrain (β=−.398, *P*<.001). Environmental factors included CO_2 emissions, which negatively impacted Oman's IMR (β=−.077, *P*=.03), and N_2O had a positive effect on Bahrain's IMR (β=.420, *P*=.04).

Conclusions: This study indicated the substantial effects of sociodemographics, health status and resources, macroeconomics, and environment on the IMR in 3 Arab countries. Sociodemographic and health-related factors like female life expectancy, fertility regulation, and female unemployment level were identified as key determinants of infant mortality.

Introduction

Background

Infancy is a crucial period in human life, the time of equal or greater dramatic developmental changes than any other in the human lifespan [1]. The most notable ones include capabilities, the complexity of the nervous system, the emergence of sensory and perceptual abilities, the development of communication skills, and many other factors. Therefore, most societies view children as a national asset and allocate a significant portion of their resources to their care and support. However, despite the improvements in health care, the Infant Mortality Rate (IMR) is still a problem in many regions of the world, especially in Arab countries [2]. The World Health Organization (WHO) defines IMR as "the probability of a child born in a specific

XSL•FO
RenderX

year or period dying before reaching the age of one, if subject to age-specific mortality rates of that period" [3]. IMR provides an overview of the background conditions that the child lives in, and it is calculated using the annual number of infant deaths during a year in the numerator, divided by the total annual number of live births in the same year, multiplied by 1000, for the same geographic area and time [4]. According to data from the World Bank, Oman's IMR in 1963 was drastically high, with 219 infant deaths per 1000 live births. The IMR, however, dropped to 9 infant deaths per 1000 live births in 2021 [5]. The same pattern applies to Bahrain; the IMR in 2021 was 5.9 deaths per 1000 live births, compared to 104 deaths in 1963. The declining trend in the IMR for Kuwait is evident, from 99 infant deaths per 1000 live births in 1963 to 8 deaths per 1000 live births in 2021. These 3 Gulf Cooperation Council (GCC) countries exhibit comparable IMR patterns and follow the anticipated worldwide historical decline.

A previous study determined the impact of various health resource determinants on IMR in Oman, considering that total health expenditure has a detrimental and statistically significant effect on IMR [2]. Another important aspect is ensuring that the mother has optimal health during the peripartum period, which substantially impacts the IMR. Mothers with multiple pregnancies, a history of infant mortality, or previous preterm births are associated with higher rates of infant death [6,7]. The leading cause of infant mortality in developing countries is infections, particularly infectious diseases that result in high neonatal mortality [8]. Infant health status also seems to have a significant impact on death rates. Preterm delivery and a low birth weight baby appear to be some of the most prominent causes of increased mortality [7].

Multiple studies have affirmed the relationship of some sociodemographic factors with the likelihood of infant deaths. For instance, a study showed that consanguinity indirectly increases the likelihood of congenital abnormalities, which may increase the risk of death from complications in infants born with these congenital malformations [9]. In addition, a study emphasized the need for implementing a national neonatal screening program to assess the exact burden of high rates of inborn errors of metabolism in Bahrain, aiming to reduce mortality and morbidity through early management [10].

Macroeconomic factors are significant predictors of IMR [2,11]. The countries in the Arabian Gulf displayed a special interest in regional child mortality indicators under the guidance of the Gulf Health Council. Studies reported that the Gulf countries have significantly improved the general health of their communities and significantly decreased IMR compared to the past as a result of the significant expansion of their economies and their performance as measured by their gross domestic product (GDP), both overall and per capita [11] and the same idea presented by another study [2].

The relationship between environment and national per capita income is clear [12]. Moreover, in some nations, there is a correlation between health and income, as they heavily rely on oil and gas exports. Oman, Kuwait, and Bahrain are known for having similar per capita income levels in the GCC countries. However, the widespread burning of fossil fuels over time has a detrimental effect on environmental quality. The primary greenhouse gases responsible for climate change are carbon dioxide (CO_2), nitrous oxide (N_2O), and methane. GCC states are major sources of CO_2 emissions, a significant GHG component. Energy production, particularly the burning of fossil fuels (eg, coal, oil, and gas), and the region's high energy consumption are factors in the increase in CO_2.

Bahrain, Kuwait, and Oman are Arab countries that have the lowest GDP among other GCC members [13]. This suggests that fluctuations in economic productivity could be shaping infant mortality trends. Both Oman and Bahrain reflect comparatively fragile economic conditions for their populations, as evidenced by lower per capita foreign investment and modest central bank reserves [14]. Such indicators suggest a decline in financial resilience, which may limit the ability of expectant mothers to afford essential health care services, thereby affecting both fertility patterns and infant survival rates. Compounding this issue, women in many developing nations often shoulder substantial fiscal hardship, and the resulting gaps in perinatal care access are strongly linked to elevated infant mortality risks [8,15]. This means that their government spending exceeded their revenues, which could lead to debt and inflation problems that affect health care expenditure. Their total fertility rates have declined similarly, from an average of 7.2 in 1960 to 2.8 in 2020, comparable to those of other non-oil Arab countries following the Arab Spring [16]. This indicates that their population growth and structure have undergone significant changes over time, which could impact their social and economic development. In addition, the 3 Arab countries have had almost identical declining rates of infant deaths in the past 30 years. Furthermore, their research performance is the lowest in the GCC region, with a similar number of research articles per million population over the past 25 years [17]. While these countries exhibit similarities in income levels and health care infrastructure, they differ in specific health policies, population demographics, and resource allocations, particularly in relation to maternal and child health. For example, Oman and Bahrain emphasize preventive health care through vaccination programs and public health campaigns in allocating health resources. Kuwait has historically prioritized curative services in its health care strategy [12,14]. In terms of policy structure and vision, Bahrain's health care strategy is increasingly aligned with its economic vision to enhance public health outcomes and support sustainable development, often leveraging international collaborations [15]. Oman's policies focus on expanding access to rural health care, aligning with its commitment to decentralization [2,18]. In contrast, Kuwait's policies focus on advanced medical facilities and specialist care, reflecting a more urban-centered approach [11,19]. In terms of population growth, Kuwait has experienced steady growth, driven primarily by expatriate labor demands. Oman, on the other hand, has a slower, more balanced growth between locals and expatriates, while Bahrain's growth is urban-centric due to its smaller size [20]. By conducting this comparative analysis, this study aims to uncover unique insights into how these factors influence IMR among the 3 countries, and further research is needed to fill the existing gap in the literature.

XSL•FO

Purpose of the Study

This study aimed to identify factors contributing to the IMR in Bahrain, Kuwait, and Oman by establishing an interpretative framework to examine the influence of sociodemographic, health status and resources, macroeconomic, and environmental factors.

Methods

Study Design

For 33 years, from 1990 to 2022, this retrospective time-series study gathered data for Bahrain, Kuwait, and Oman. The time frame for the study was selected after the 1990s because these countries did not have access to accurate, official yearly data before that time.

Data Resources

This study gathers yearly secondary data for Oman, Kuwait, and Bahrain. The data and descriptions were collected from the World Bank [5] and the Organization of Islamic Cooperation Statistics Database, which is maintained by the Statistical, Economic, and Social Research and Training Center for Islamic Countries [21].

Ethical Considerations

Ethical approval was obtained from Sultan Qaboos University Medical Research Ethics Committee (#2666). This study used secondary data that did not involve any interaction with individual human participants and presented no reidentification risk due to the aggregated nature.

Sample Size

This study's sample size (number of years) was specified according to GLS with a first-order autoregressive model and using R software ("nlme" and "MASS" library) by the R Foundation. Suppose we expect the slope of the fertility rate on IMR to be 0.6 and the rho to be 0.5 in a first-order autoregressive model. At least, this study required a sample size of 30 years for each country, with approximately 71% power at a 5% type I error.

Data Collection

We follow the evaluation criteria to ensure the degree of relevance and viability of these data [2]. A data cleaning process was also carried out, which was considered one of the key actions taken to ensure the quality of the data. Initially, the team collected data on health status and resources, sociodemographics, macroeconomics, and environment for each country based on available databases from the World Bank [5] and the Statistical, Economic, and Social Research and Training Center for Islamic Countries [21]. For sociodemographic, Bahrain and Kuwait included 10 variables: maternal or paternal educational level, maternal age, parental occupation, consanguinity, total fertility rate (births per woman), infant gender, birth rate, population density, and monthly income. For environmental, all 3 countries had data on 3 variables: CO_2 (metric tons per capita), methane, and N_2O emissions. In macroeconomics, Oman included 3 variables: GDP, GDP per capita, and female unemployment, while Bahrain and Kuwait included 6 variables: GDP, GDP per capita, gross national income, gross national income per capita, female unemployment, and inflation. For health status and resources, Oman and Bahrain included 13 variables: total health care expenditure, prematurity, birth weight, fetal growth, congenital abnormalities, neonatal sepsis, multiple pregnancies, history of preterm birth, history of infant death, delivery room resuscitation, mode of delivery, female life expectancy at birth, and immunization. Kuwait included the same 13 variables plus 5 additional variables: skilled health staff, access to safe water, hospital beds, and the number of doctors and nurses. Furthermore, any variable in this study that did not have data for one of the 3 countries was excluded because it cannot be used to compare across the 3 countries. Those independent variables with high multicollinearity with other variables will also be removed. In addition, variables with 20% or more missing data were eliminated and cannot be included in the analytical process. These variables require imputation, which is only imputed for 2 to 3 years, especially for CO_2 and N_2O in the environmental data for all 3 countries. Multiple regression imputation was used to fill in the missing data gaps for further analysis.

A recent systematic review and meta-analysis in GCC countries [19] provided the foundation for selecting relevant health status and resource, sociodemographic, and macroeconomic variables that affect IMR in the target countries. In addition, variables related to environmental factors were included based on other related studies [12]. Our investigation encompasses diverse independent variables spanning four key categories: macroeconomic, sociodemographic, health status and resources, and environmental. These variables collectively influence IMR, which serves as our research's dependent variable and primary outcome. For further details, refer to Multimedia Appendix 1, which lists the relevant variables.

Statistical Analysis

Descriptive statistics (eg, mean, SD, maximum, and minimum) were used to explore the characteristics of both IMR and explanatory variables for each target country. First, the variables within each factor, as outlined in the Data collection section, were identified as statistically significant factors of IMR across all 3 countries through univariate analysis. These variables, at $P<.05$, were subsequently integrated into a multivariable analysis for each country. To counterbalance the time-series effects on both IMR and explanatory factors, this study used generalized least squares (GLS) regression analysis based on the Cochrane-Orcutt procedure, which controls for a first-order autoregressive model. Other researchers have recommended this approach for analyzing national panels with time-series features [22-24]. By using GLS analysis, we can address our research objectives. In addition, this study assessed correlation ($r\geq0.8$) and collinearity (variance inflation factor≥10) to identify any strong correlations among macroeconomic, sociodemographic, health status and resources, and environmental factors. Variables exhibiting strong correlations were excluded from the analysis [25]. All analyses were conducted using IBM SPSS and EViews 11, with a significance level set at 5%.

Results

Descriptive Characteristics of the Variables in Bahrain, Kuwait, and Oman

This study compiled 33 years of macroeconomic, sociodemographic, health status, and resource, environmental, and IMR data from 1990 to 2022 in three Arab countries (refer to Table 1). Oman significantly reduced IMR, dropping from 31.7 to 6.4 deaths per 1000 live births. Bahrain followed with a decrease from 19.6 to 5.3, and Kuwait experienced a reduction from 14.7 to 6.3 deaths per 1000 live births (refer to Figure 1). However, the average IMR was 10 deaths per 1000 live births in Kuwait and Bahrain, while Oman had a slightly higher average of nearly 14 deaths per 1000 live births. In terms of total fertility rate, Oman had the highest rate at 3.7 births per woman, while Bahrain had the lowest at 2.5 births per woman. When considering female life expectancy at birth, Kuwait had the highest at 79.7 years, and Bahrain had the lowest at 75.8 years. In terms of economics, Oman had the lowest GDP per capita at US $14,056.8, while Kuwait had the highest at US $28,678.9. Regarding CO_2 emissions, Kuwait had the highest level at 23.5 metric tons per capita, while Oman had the lowest at 12.8 metric tons per capita.

Figure 1. Infant mortality rate in Oman, Kuwait, and Bahrain (1990 - 2022).

Associated Factors on IMR for Each Country

In the univariable analysis, the total fertility rate and female life expectancy at birth were significant (P<.05) across all sociodemographic and health status and resource variables in all 3 countries. In macroeconomics, female unemployment and GDP per capita (in USD) were significant (P<.05) in all countries. In addition, CO_2 and N_2O emissions in environmental factors were also found to be significant (P<.05) across all countries. These 6 variables were included in the GLS regression model to explore which factors were associated with IMR in each country. Table 2 displays the explanatory factors associated with IMR for each country, showing significance in the model. The analysis reveals that the total fertility rate has a strong effect on IMR among the three countries: Oman (β=1.138, t=8.988, P<.001); Kuwait (β=.429, t=2.965, P=.006); Bahrain (β=610, t=2.310, P=.03). However, the study shows that female life expectancy at birth had an inconsistent impact on the IMR. It had a positive effect on IMR for Oman (β=.103, t=3.541, P=.002) but a negative effect on IMR for Kuwait (β=−4.069, t=5.588, P<.001), while having no significant effect (β=.137, t=0.998, P=.33) on IMR for Bahrain. In addition, the macroeconomic factors represented female unemployment and GDP per capita. Female unemployment was significantly associated with IMR only in Kuwait (β=−.076, t=2.868, P=.008), and GDP per capita was significant only for Bahrain, with a β coefficient of −.398 (t=−3.854, P<.001). Moreover, the model indicates a relationship between CO_2 and N_2O emissions and IMR; specifically, CO_2 emissions have a negative impact on Oman's IMR (β=−.077, t=2.370, P=.03). However, N_2O emissions have a positive and direct effect on the IMR in Bahrain (β=.420; t=2.118, P=.044).

Discussion

Principal Findings

This study used GLS with a first-order autoregressive model to investigate the determinants influencing the IMR in Oman, Bahrain, and Kuwait. These determinants, including fertility, female life expectancy, unemployment, GDP per capita, and environmental pollutants, intertwine uniquely across 3 Arab countries, shaping infant mortality patterns. These contextual determinants highlight how sociodemographic, health resources, macroeconomic, and environmental forces converge to influence newborn survival outcomes in complex, country-specific ways.

The Effects of Sociodemographic Factors on IMR

Among the 3 countries, the sociodemographic determinant, represented by the total fertility rate, has a direct and strong effect on IMR, consistent with the findings of other studies. Internationally, the impact of maternal education on infant mortality may be mediated by fertility [26,27]. Regionally, numerous studies conducted in Oman have examined the impact of various factors on the IMR. Their findings showed that the fertility rate significantly predicts IMR [2,18]. Our study showed that the total fertility rate in Oman is the highest (b=1.138, *P*<.001), followed by Bahrain (b=0.610, *P*=.029) and Kuwait (b=0.429, *P*=.006) in terms of IMR in their respective countries. The total fertility rate represents the number of children that would be born to a woman if she were to live to the end of her childbearing years. A greater probability of complications developing during pregnancy is associated with a higher fertility rate, which implies that the mother will give birth more frequently [19], and any pregnancy complications may increase the risk of mortality for both the infant and the mother [28].

The Effects of Health Status and Resource Factors on IMR

In Oman, the female life expectancy at birth has a direct impact on IMR (β=.103, *P*=.002). However, it has a negative impact on IMR in Kuwait (β=−4.069, *P*<.001), and it is not significant in Bahrain (b=0.137, *P*=.33). This indicates the number of years a female newborn would survive if the mortality patterns at the time of the birth continued to remain the same throughout her life [11]. Oman's first documented IMR was in 1963, which was drastically high. However, this rate dramatically declined across the years until it reached 9 baby deaths per 1000 live births in 2021. Indeed, it was a significant decline, but more needs to be done to maintain it. Since Oman's IMR is still the highest in the GCC despite similar economic conditions, indicating that if the health policies, medical facilities, cultural norms, and economic status, therefore, the mortality patterns that were in place at the time of the female's birth continued to remain the same or worse, the IMR will increase. However, Kuwait's IMR is slightly better, reaching 8 deaths per 1000 live births in 2021. If the mortality patterns and factors associated

XSL•FO
RenderX

with them that were in place at the time of the female's birth continued to remain the same or improved, this would further decrease the IMR. In contrast, the lack of a significant relationship between female life expectancy at birth and IMR in Bahrain may be due to a more direct impact on infant death rather than female life expectancy. Our findings suggest that the IMR in Bahrain is influenced by macroeconomic factors, specifically GDP per capita, as well as environmental factors, particularly N_2O emissions. This pattern differs from the other 2 countries analyzed, where these variables showed varying degrees of impact. These findings suggest that specific factors, such as economic structures and environmental conditions, play a critical role in infant death in Bahrain.

The Effects of Microeconomic Factors on IMR

This study found that female unemployment has a negative effect on the IMR in Kuwait (b=−0.076, *P*=.0008), while it is not significant in Oman (b=−0.122, *P*=.05) and Bahrain (b=0.489, *P*=.19). This finding was consistent with a study done for Macau [29]. However, numerous studies have emphasized the critical significance of a higher proportion of the employed population in lowering the IMR regionally [18] and internationally [30]. In addition, this result contrasts with the GCC region systematic review, which concluded that only paternal working status matters and that maternal employment had no impact on IMR [19]. Being a housewife is associated with providing better care, spending more quality time with the baby, and meeting the child's psychological and physical needs. As a possibility, society has left the child's responsibility and care to the mother alone, and the father has no connection to the matter. Therefore, if the mother pays little attention to her work, the child will remain without care, which leads to a high infant mortality rate. We recommend further research to investigate why female unemployment has a negative impact on the IMR in Kuwait. Additionally, our findings showed that GDP per capita significantly reduced the IMR only in Bahrain (b=−0.398, *P*<.001) but not in Oman (b=−0.057, *P*=.302) or Kuwait (b=−0.0011, *P*=.97). A study in Oman reported a contrasting negative impact of GDP per capita on IMR [2]. This difference may stem from our inclusion of a broader data range and environmental factors such as CO_2 emissions, which exert a more direct influence on IMR in Oman than GDP per capita. Furthermore, the lack of a significant relationship between GDP per capita and IMR in Kuwait could be attributed to the multifactorial nature of health care outcomes in the country. GDP per capita likely impacts healthcare quality and equity rather than directly determining IMR. Other determinants, such as the total fertility rate, female life expectancy at birth, and female unemployment, may dilute the direct effects of GDP per capita on IMR. These findings underscore the importance of context-specific analyses in understanding the intricate relationship between economic indicators and health outcomes.

The Effects of Environmental Factors on IMR

This study has indicated that environmental determinants represented by CO_2 emissions negatively impact Oman's IMR (β=−.077, *P*=.026). A study found that CO_2 emissions and nonrenewable energy are indirectly essential determinants of the IMR [31]. They have varying effects on the different income groups. This implies that nonrenewable energy indirectly increases the mortality rate for people in lower-middle and upper-middle-income countries but reduces it in high-income countries [31]. As indicated earlier, Oman lacks the high-income capacity that would enable it to be a country with higher CO_2 emissions control, so we recommend further studies based on this idea. High nonrenewable energy use can be related to the country's better economic and employment status, so it depends on its ability to control CO_2 emissions. However, previous studies have demonstrated that respiratory disorders and a high mortality rate are primarily caused by environmental pollution. Moreover, the model indicated that the environmental construct in Bahrain is best reflected by N_2O emissions (β=.420, *P*=.044). N_2O emissions contribute to the global accumulation of greenhouse gases, leading to adverse environmental and health effects. Numerous studies have documented the health risks associated with nitrate toxicity, including methemoglobinemia in newborns and its strong correlation with cancer [32].

Limitations and Future Directions

Many variables considered had potential significance according to the previous studies. However, with incomplete data, many variables were excluded from the analysis. Nevertheless, these variables may still affect the IMR in each country, so interpreting the results requires caution due to this issue. Furthermore, more studies using longer longitudinal data are recommended. Another limitation of this research is related to the analysis method. The GLS model does not account for the indirect effects of explanatory variables on IMR. More studies should be recommended to examine its impact on IMR among countries.

Conclusions

This analysis revealed the substantial impact of sociodemographic, health status, and resource factors, as well as macroeconomic and environmental factors, on the IMR in 3 Arab countries. Sociodemographic and health-related factors like female life expectancy, fertility regulation, and female unemployment level were identified as key determinants of infant mortality. Based on the empirical facts regarding the environment, promoting clean energy development to enhance human health is recommended. In other words, the IMRs of these countries are expected to decline even further due to the adoption of environmental quality policies. The results of this study suggest improvements and interventions that consider macroeconomic, environmental, sociodemographic, and health status-related issues.

Abstract

Background: Previous research suggested that parent-administered pediatric *tuina* could improve symptoms of attention-deficit/hyperactivity disorder (ADHD), such as sleep quality and appetite.

Objective: This study aimed to explore the experiences and perceptions of parents administering pediatric *tuina* to school-aged children with ADHD in Hong Kong.

Methods: This qualitative study was embedded in a pilot randomized controlled trial on parent-administered pediatric *tuina* for improving sleep and appetite in school-aged children diagnosed with ADHD. Purposive sampling was used to invite 12 parents who attended a pediatric *tuina* training program and delivered the intervention to their children at home for at least 8 weeks. Data were collected through semistructured focus group interviews and individual interviews, which were audio-recorded, transcribed verbatim, and analyzed using thematic analysis.

Results: Two main themes emerged: (1) effects of parent-administered pediatric *tuina* and (2) parents' experience of administering pediatric *tuina*. Parents reported significant improvements in children's sleep quality, appetite, behavior, mental state, and academic performance. Facilitators provided professional guidance and applied a user-friendly course design. Challenges included difficulties in mastering techniques, locating acupuncture points, and time management. Participants suggested the need for more traditional Chinese medicine pattern diagnostic sessions, real-time supervision methods, and extended follow-up to better observe long-term effects.

Conclusions: Parent-administered pediatric *tuina* was perceived to improve children's sleep quality and appetite significantly, along with other aspects of well-being. Professional guidance and a structured training program facilitated implementation, and challenges highlighted the need for more frequent diagnostic sessions, real-time supervision, and extended follow-up.

Trial Registration: ClinicalTrials.gov NCT06007742; https://clinicaltrials.gov/study/NCT06007742

Introduction

Attention-Deficit/Hyperactivity Disorder

Attention-deficit/hyperactivity disorder (ADHD) is a common neurodevelopmental disorder in children, affecting approximately 5% of the pediatric population [1]. It is characterized by 3 primary symptoms: inattention, hyperactivity, and impulsivity [2,3]. Children with ADHD often experience additional mental, emotional, or behavioral disorders, which can include learning disorders, sleep disorders, oppositional

XSL•FO
RenderX

defiant disorders, anxiety, and conduct disorders [4]. Among the comorbidities, sleep problems and appetite disturbances are particularly prevalent among school-aged children with ADHD [5,6]. Sleep problems can include difficulty falling asleep, restless sleep, frequent awakenings, and difficulty waking up in the morning [7]. These sleep issues may be caused by the hyperactive and impulsive nature of ADHD, the side effects of medications, or coexisting emotional and behavioral issues [8]. Eating problems are common in children with ADHD, ranging from poor appetite and picky eating to overeating and cravings for unhealthy foods [9]. The causes of these eating problems can include the side effects of ADHD medications, which often suppress appetite, and the impulsivity associated with ADHD [10]. Notably, stimulant medications, which are commonly prescribed for ADHD, can lead to sleep disturbance and eating problems [11]. Sleeping and eating issues can affect the child's physical health, growth, and development, which could complicate the management of ADHD symptoms [5,6]. Strategies such as establishing consistent bedtime routines, creating a calming sleep environment, and encouraging balanced diets are crucial to specifically address sleep and appetite issues [5,6]. Parents and caregivers play a vital role in implementing these coping interventions to help manage symptoms and improve the quality of life for the child and the family [12].

Parent-Administered Pediatric *Tuina*

Pediatric *tuina*, also known as pediatric *anmo* or traditional Chinese medicine (TCM) pediatric massage, is a specialized form of massage therapy tailored for infants and children [13]. It is grounded in TCM principles, which emphasize the harmonious functioning of the body's systems [13]. In ancient Chinese medicine, the term "double *yang* person" was used to describe individuals exhibiting symptoms of ADHD [14]. By targeting specific acupoints, pediatric *tuina* aims to restore the *yin-yang* balance, thereby enhancing overall health and well-being. As an external, noninvasive therapy, it offers a complementary approach to conventional medical treatments, providing a holistic option for pediatric care [13]. This therapeutic technique has been extensively studied for its potential benefits in addressing various clinical conditions and diseases [15] such as diarrhea [16], anorexia [17], torticollis [18], constipation [19], enuresis [20], and functional dyspepsia [21]. Pediatric *tuina* is used to promote the growth and development of healthy children in China [22]. The practice of pediatric *tuina* involves the stimulation of specific areas or acupoints on the body through various manipulation techniques, including pushing, kneading, pressing, rotating, nipping, circular movements, and pounding [13]. These techniques generate different types of stimuli on the skin, which are detected by surface sensory receptors and transmitted to the central nervous system [23]. This sensory input is believed to induce a series of protective and adaptive homeostatic activities within the body. Research has demonstrated that in young children, the skin can rapidly regulate basic and adaptive homeostatic responses [24]. This regulation may be facilitated by a low compensatory basal level of stress-responsive enzymes, allowing for a broad range of physiological responses [25]. The mechanisms behind these responses suggest that pediatric *tuina* may substantially affect the autonomic nervous system, potentially leading to improved clinical outcomes for various pediatric conditions [26].

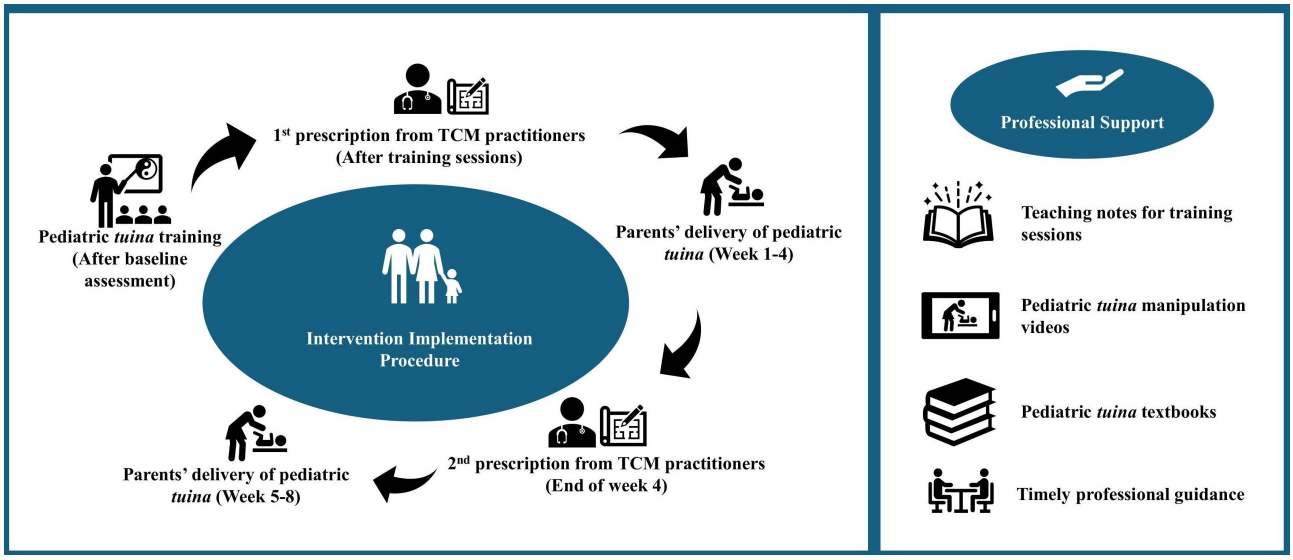
Research Gap

In recent years, several research studies have preliminarily demonstrated the effects of pediatric *tuina* in treating ADHD. For instance, a randomized controlled trial (RCT) on 120 children with ADHD comparing pediatric *tuina* with medication reported that the Conners scores in the pediatric *tuina* group were significantly lower than those in the control group (Cohen d=0.96, P<.05), as were the ADHD scores (Cohen d=.57, r=0.28, P<.05). The incidence of adverse events was lower in the pediatric *tuina* group (3.33%) than in the control group (16.67%, P=.015) [27]. A systematic review of 11 clinical trials suggested the potential benefits of pediatric *tuina* in improving concentration, mood, sleep, and social functioning in children and adolescents with ADHD [28]. However, the extant literature lacks robust qualitative insights into parents' understanding of using this intervention and the specific implementation as a complementary intervention. Therefore, limited information exists exploring the practicalities, challenges, and perceived benefits of parent-administered pediatric *tuina* for ADHD. The authors' team recently conducted a pilot RCT to further examine parent-administered pediatric *tuina* for improving sleep and appetite in school-aged children with ADHD in Hong Kong. This study is the qualitative part of the pilot RCT, aiming to further explore parents' experiences and perceptions of delivering pediatric *tuina* at home, particularly in parents' experiences on its effects on children's sleep and appetite and parents' experience of administering pediatric *tuina*. This project could provide valuable insights into the real-world application of pediatric *tuina* and offer guidance for parents and health care providers in optimizing this intervention's use in more contexts.

Methods

Ethical Considerations

Ethical approval for the study was granted by the Hong Kong Polytechnic University (HSEARS20230810005). A written informed consent to participate in this study was obtained from the participants. Each participant was assigned a randomly generated code to ensure confidentiality. Each participant received a cash incentive of HK $200 (approximately US $25.64 based on an exchange rate of HK $1=US $0.1282) to acknowledge their participation.



Study Design

This project was registered on ClinicalTrials.gov under the identifier NCT06007742. This study presents the qualitative findings from a pilot RCT investigating the effects of parent-administered pediatric *tuina* on sleep quality and appetite in school-aged children with ADHD in Hong Kong. In the RCT, parents received systematic training from TCM practitioners, including 2 face-to-face sessions (each lasting 2 hours). The first session focused on theoretical knowledge, and the second session covered TCM pattern identification and pediatric *tuina* techniques. Following the training sessions, parents administered pediatric *tuina* to their children at home over an 8-week period on the basis of individualized prescriptions formulated by TCM

XSL•FO
RenderX

practitioners. Each participant in the pediatric *tuina* group received parent-administered pediatric *tuina* sessions every other day, totaling 24 sessions over an 8-week period (at least 3 sessions each week). Each session lasted approximately 25 - 30 minutes. The *tuina* protocol was developed from a 2021 feasibility RCT for ADHD involving 64 parent-child pairs, where 128 individualized pediatric *tuina* prescriptions were analyzed to identify commonly used and safe acupoints [29]. The resulting standardized basic prescription allows TCM practitioners to make individualized modifications based on syndrome differentiation. This TCM diagnosis guided the selection of specific acupoints and manipulation techniques tailored to each child's condition. Details regarding the implementation of the intervention are illustrated in Figure 1. The interviews commenced 1 week after the completion of treatment for the first wave of participants in the RCT, which was conducted in 3 sequential waves. Interviews were strategically scheduled at 3 distinct timepoints, following the conclusion of each treatment wave. This timing ensured that participants had sufficient experiences and perceptions for in-depth exploration and allowed for the prompt collection of data while their experiences were still vivid, ensuring accurate and immediate reflections on the treatment effects. The study's reporting adhered to the Consolidated Criteria for Reporting Qualitative Research's checklists [30].

Figure 1. The implementation of the parent-administered pediatric *tuina* program. TCM: traditional Chinese medicine.

Setting

This study used a qualitative approach with the use of semistructured focus group interviews and individual interviews. The research methodology allows for a great flexibility of the participants to join. The focus group interviews were conducted face-to-face in the campus of the Hong Kong Polytechnic University.

Participants

Participants were parents with children with ADHD. The participants for the interviews were invited from the participants in the pilot RCT who received the parent-administered pediatric *tuina* intervention [31]. Recruitment information was sent to potential participants by WhatsApp message at the end of February 2024, and purposive sampling was applied for recruitment. The children included in the pilot RCT (1) were aged 6 - 8 years; (2) possessed internationally recognized diagnostic information or certification for ADHD; and (3) had a score equal to or higher than 39 (borderline cutoff) of the Sleep Disturbance Scale for Children, which indicated sleep problems of children. The parents included in this study (1) participated in the project on using parent-administered pediatric *tuina* for improving sleep quality and appetite in children with ADHD who completed the 2-month treatment and follow-up assessment of the intervention during the treatment period, (2) were able to communicate in Cantonese fluently, and (3) agreed to participate and were willing to share their experience in applying this intervention. This study focused on children aged 6 - 8 years, representing the early school-age period. This study focused on children aged 6 - 8 years, representing the early school-age period. This focus is driven by the significance of early intervention in ADHD's developmental trajectory and the specific responsiveness of this age group to pediatric *tuina*. Research suggests that early school years are critical for implementing interventions that could substantially alter the course of ADHD, making timely and targeted intervention essential [32]. Furthermore, tactile therapies such as pediatric *tuina* are shown to be highly effective in younger children, who are generally more receptive to such treatments [33].

Data Collection

A semistructured interview guide was created and refined on the basis of previous relevant studies and comments from experts, including 2 TCM practitioners (KCL and PMW) and 2 qualitative researchers (WFY and SCC). The guide comprised 5 open-ended questions detailed in Textbox 1. The focus group interviews were moderated by the first author (SCC), with an assistant moderator (LYP) responsible for note-taking and operating the recording equipment. Both moderators received training from the corresponding author (WFY), a TCM practitioner with extensive research experience in TCM interventions and qualitative methodologies. At the beginning of each interview session, the moderator introduced herself,

XSL•FO
RenderX

clarified the study's purpose and procedures, and emphasized the confidentiality rules. She also explained the questions and facilitated group interaction by providing prompts and pauses, ensuring that the discussion remained focused without imparting any value judgments. Participation in the study was voluntary, and no individuals other than the participants and researchers were present during the interviews. Participants were reassured that, although the sessions were audiotaped, their names would not be recorded.

Textbox 1. Questions for the semistructured interview.

Do you think pediatric *tuina* has changed or affected your child's eating habits?
Do you think pediatric *tuina* has changed or affected your child's sleep?
Besides diet and sleep, in what other aspects do you think pediatric *tuina* has changed or affected your child?
What difficulties did you encounter from learning to performing pediatric *tuina*?
How do you evaluate the content and process of the pediatric *tuina* treatment for attention-deficit/hyperactivity disorder? What are the advantages and areas for improvement?

Data Analysis

All interviews were audiotaped and transcribed verbatim in traditional Chinese before data analysis commenced. All study-related documents and transcripts were deidentified, and the audio files were destroyed once transcription was completed. The transcripts were analyzed using thematic analysis with hierarchical coding [34,35]. The template analysis applied the following steps: (1) an initial reading of the transcripts to identify a priori themes and perform preliminary coding; (2) development of an initial coding template; (3) systematic review of all datasets to refine the template by adding, removing, or merging codes as necessary; and (4) finalization of the template for application to the entire dataset [36]. The first author (SCC) conducted the transcription and initial coding, which were subsequently reviewed for accuracy and consistency by another researcher (HL). Any discrepancies in coding were resolved through consultation with the principal investigator (WFY). Microsoft Word software was used to manage the coding process [37,38]. Descriptive statistics were used to summarize the demographic characteristics of the sample. The Results section presented a summary of the main themes and subthemes, illustrated with participant quotes. For each quote, only the participant codes are provided.

Trustworthiness

This study adhered to the trustworthiness criteria for qualitative research as outlined by Lincoln and Guba [39,40]. For credibility, a semistructured interview guide was developed through 2 group discussions and subsequently pilot-tested during the initial interview session. Purposive sampling was used to select participants capable of providing diverse perspectives and experiences relevant to the intervention delivery. For transferability, the richness of the data was assessed using the saturation theory [41]. Data collection continued until the point of near exhaustion of new information, which was achieved by the third session [42]. Dependability was maintained through independent coding of the collected data by 2 researchers, complemented by regular debriefing sessions with WFY, an individual with substantial expertise in qualitative research. Finally, participants were provided with the findings, including the code tree and quotations, for their feedback and verification to ensure confirmability. This process aimed to minimize bias and ensure that the intervention reflected the true perspectives and experiences of the participants.

Results

General Characteristics of Data

In total, 4 group interviews and 3 individual interviews were conducted in Cantonese between February 2024 and April 2024. The group interviews averaged 86 minutes in duration, ranging from 77 to 96 minutes, and the individual interviews averaged 35.3 minutes, with durations ranging from 30 to 46 minutes. Of the 61 parents invited, 12 ultimately participated. Each interview session included between 1 and 3 participants, none of whom knew each other. Themes and subthemes were initially identified by the fourth interview session and further refined by the seventh session.

Sample Profile

Overall, 12 parents, comprising 10 females (83.3%) and 2 males (16.7%), whose children were diagnosed with ADHD participated in the interviews. The average age of the parents was 40.1 (SD 3.7) years, and the mean age of their children was 6.9 (SD 0.9) years. Detailed demographic information on the participants can be found in Table 1.

Current treatment for ADHD (child), n (%)		
	Medication	3 (25)
	Cognitive behavioral therapy	3 (25)
	Others	1 (8.3)

[a]All income values are presented in Hong Kong dollars. For the purpose of this study, the conversion rate used is HK $1=US $0.1282 (as of February 2024).

[b]ADHD: attention-deficit/hyperactivity disorder.

Major Themes

Two themes regarding the participants' experience in applying the parent-administered pediatric *tuina* intervention and participating in the study were identified: (1) effects of parents performing pediatric *tuina* and (2) parents' experience of performing pediatric *tuina*. The specific subthemes under each theme were described. Table 2 presents the code structure.

XSL•FO
RenderX

Table . Code structures.

Themes and subthemes		Code units
Effects of parent-administered pediatric *tuina*		
	Improvements in children's eating	• Increased appetite and food intake • Improved diet structure (less picky eating and trying new things) • Improved gastrointestinal function (indigestion, vomiting, and constipation)
	Improvements in children's sleep	• Improved sleep quality (restlessness, snoring, teeth grinding, sweating, and yelling) • Improved sleep habits (shorter time to fall asleep and able to sleep on their own)
	Improvements in other aspects of children	• Improved behavioral habits (milder behavior) • Improved mental state (relaxed and better emotions) • Improved attention (academic performance) • Improved interpersonal relationships (family and school) • Improved physical condition (bedwetting, rhinitis, weight, and height)
Parents' experience of performing pediatric *tuina*		
	Advantages of this intervention implementation	• User-friendly course design (appropriate difficulty and clear teaching materials) • Professional guidance from instructors • Noninvasive treatment method • Customized diagnosis and treatment • Satisfactory treatment effects (effective and quick results)
	Difficulties encountered during implementation	• Difficulty in operation (knowledge, locating acupuncture points, and techniques) • Difficulty in children's cooperation • Time management difficulties (parents and children)
	Parents' suggestions on improving the intervention	• Increasing guidance during practice and operation • Use of real-time supervision methods (such as electronic records or apps) • Increasing number of diagnostic sessions • Extending treatment and follow-up time

Effects of Parent-Administered Pediatric *Tuina*

This theme encompasses three subthemes: (1) improvements in children's eating, (2) improvements in children's sleep, and (3) improvements in other aspects of children.

Improvements in Children's Eating

Parents observed noticeable improvements in their children's eating habits following the administration of pediatric *tuina*. Many reported an increase in appetite and food intake, as illustrated by one parent who stated, "I think his appetite is better...at least he's willing to eat more, which is an achievement; the most important thing is that he's willing to eat" [Participant 12]. Another parent noted a reduction in the child's resistance to eating: "Normally, if we hurry him to eat, he immediately says he's full, but after doing *tuina*, he says he wants more, and his food intake has increased" [Participant 59]. Additionally, some parents observed an improvement in their children's diet structure, with children becoming less picky and more willing to try new foods. A parent shared, "After the pediatric *tuina*, I felt he started eating meat...he even ate fish that he previously didn't eat" [Participant 1]. Improvements in gastrointestinal function were reported, with one parent noting a remarkable change: "His stools have clearly improved, previously they were like small pellets, similar to Maltesers...during the massage period, his stools became much more normal" [Participant 50]. Another parent highlighted the benefits of stomach massages: "I think massaging his stomach helped with bowel movements...his stomach is more relaxed now, it used to be tight, and his belly was cold before, now it's warm" [Participant 40].

XSL•FO
RenderX

Improvements in Children's Sleep

Parents also reported enhancements in their children's sleep quality and habits after pediatric *tuina*. Improved sleep quality was a common theme, with one parent describing their child's more stable sleep: "Before doing *tuina*, he used to sleep like a whirlwind, rolling from the head to the foot of the bed and back all night long, but now he's more stable and it's less frequent" [Participant 59]. Another parent mentioned a reduction in excessive sweating and sleep disturbances: "He usually sweats a lot while sleeping, even at 4 AM he still sweats, but after the *tuina*, he sweats less...also, he used to yell in his sleep, I had to wake him, about two or three times a week, but this has noticeably reduced now" [Participant 50]. Improved sleep habits, such as shortened time to fall asleep and the ability to sleep independently, were noted. A participant shared, "He sleeps more soundly now; previously, he had no sense of security and needed me to accompany him to sleep, but now, for example, after I massage him and turn off the lights, he is willing to sleep by himself, at least it's the first step" [Participant 40]. Another mom observed, "It takes him less time to fall asleep now; it used to take him two hours to fall asleep, but now it might only take half an hour" [Participant 59].

Improvements in Other Aspects of Children

Beyond eating and sleep, parents observed various other benefits of pediatric *tuina* on their children's behavior and overall well-being. Improvements in behavioral habits were frequently mentioned, with one parent noting a decrease in aggressive behavior: "I think he has fewer outbursts, and so do I...he used to hit people, very bad temper like a volcano...now I feel like he has fewer explosive moments" [Participant 12]. Enhancements in the children's mental state were reported, with one mom describing their child as more relaxed: "I think he's more relaxed, when I massage him, I ask if he likes it, if it hurts...he says he likes it, it's very comfortable...I think his emotions are more relaxed" [Participant 43]. Another parent noticed improved emotional expression: "Previously, he would get very angry if he didn't like what I said, but now he just says, 'Mom, I don't like it, I don't want you to say that,' expressing himself more gently" [Participant 13]. Improvements in attention and academic performance were highlighted by some parents, with one noting, "The homeroom teacher says he's doing okay, although he still gets easily distracted sometimes, but compared to last semester, he has made progress" [Participant 40]. Another parent observed remarkable academic improvements: "My son scored over 70 in listening in the first semester, but after doing *tuina*, he scored 95 in both Chinese and English exams at the end of March; I'm not sure if it had an effect, but I can see his attention has improved" [Participant 52]. Enhanced interpersonal relationships were reported, with one parent stating, "During the *tuina* process, the parent-child relationship improved, he likes to discuss math with his dad, using many methods to calculate, which helps his academics, he feels a sense of achievement, more confident, and even teaches friends how to calculate, and his relationship with classmates has improved" [Participant 15]. Physical conditions, such as bedwetting, rhinitis, weight, and height, were noted to have improved. One parent shared, "After the *tuina*, his nose is no longer as sensitive, it used to be really bad, I even thought about taking him to see a doctor" [Participant 52]. Another parent observed, "Her physical condition has really improved, he eats more, sleeps better, and her weight has increased...she gained a few pounds compared to last semester" [Participant 52]. Bedwetting was reported to have decreased, with one parent stating, "He used to wet the bed, but recently it has decreased" [Participant 43].

Parents' Experience of Performing Pediatric *Tuina*

Parents' experiences of administering pediatric *tuina* include three subthemes: (1) advantages of this intervention implementation, (2) difficulties encountered during implementation, and (3) parents' suggestions on improving the intervention.

Advantages of This Intervention Implementation

Parents highlighted several advantages of implementing pediatric *tuina* for their children. One notable advantage was the user-friendly course design, which many found to be appropriately challenging yet accessible. As one parent explained, "The Chinese medicine doctor starts by explaining things, we initially didn't know much about acupuncture points, but I think the course depth is suitable for us parents" [Participant 31]. Additionally, parents appreciated the professional guidance from instructors, with another parent noting, "I think they did a good job. A Chinese medicine PhD analyzed the problem, and then a *tuina* therapist taught the techniques and let me record videos. After filming, they explained the whole process, answered my questions directly, and didn't make it difficult to grasp. Later, they sent me the technique videos, which was great" [Participant 13]. The noninvasive nature of pediatric *tuina* was valued, with one parent stating that "(Pediatric *tuina*) is more natural and noninvasive, which is already very good" [Participant 1]. Furthermore, parents appreciated the customized diagnosis and treatment plans tailored to their children's specific needs. One parent shared, "The first time I came back to see the doctor, I described my child's situation, and the doctor added two acupuncture points, explaining that it was because of my child's current condition, which I found acceptable" [Participant 43]. Lastly, the satisfactory treatment effects were highlighted, with parents observing quick improvements in their children's overall well-being. As one parent noted, "I think pediatric *tuina* is effective for my child. At least his emotions improved, as well as his appetite, diet, growth, and digestion" [Participant 1]. Another parent remarked, "After two weeks, I noticed he slept better" [Participant 59], and another one observed, "In the first week, I felt he became more obedient and focused" [Participant 4].

Difficulties Encountered During Implementation

Despite the advantages, parents also encountered several difficulties during the implementation of pediatric *tuina*. One common challenge was the difficulty in operation, particularly in terms of knowledge, locating acupuncture points, and mastering techniques. As one parent expressed, "When actually performing the *tuina*, we were guessing. I felt uncertain about the position and pressure, and we were trying to imitate, so some areas were unclear, like using several fingers..." [Participant 43]. Another difficulty was gaining children's

XSL•FO
RenderX

cooperation, with one parent noting, “He found repeating the same thing boring and asked if there was anything else to do” [Participant 40]. Time management posed a considerable challenge for parents and children. One parent mentioned: “I was very busy myself and didn’t have the determination to schedule a specific time for the *tuina*” [Participant 13]. Another parent added, “If I felt it was too late or he was tired that day, I would do one or two techniques and then sleep” [Participant 40].

Parents’ Suggestions on Improving the Intervention

Parents suggested several improvements to enhance the implementation of parent-administered pediatric *tuina*. Increased guidance during practice and operation was a common request. One parent suggested, “It would be better if the doctor could watch the whole process of how I execute it from start to finish. We are beginners and may not notice if we are making mistakes” [Participant 43]. Another parent proposed: “I hope the doctor can check our techniques after a few weeks” [Participant 24]. The use of real-time supervision methods, such as electronic records or applications, was suggested to facilitate the process. As one parent noted, “The paper (logbook) could be converted to phone input, as *tuina* requires using olive oil, and the paper gets oily after filling it out” [Participant 50]. Another parent mentioned, “Using an app would save parents some effort. Besides recording if the points were done, it could also record the time, duration, and timely track the child’s weight, eating, bowel movements, and sleep” [Participant 31]. Parents also expressed a desire for an increased number of diagnostic sessions. One parent stated, “More TCM pattern diagnostic sessions would give us more confidence. Now it’s once every four weeks; if it were every two weeks, we’d feel more assured. Sometimes we are just blindly following instructions” [Participant 59]. Lastly, extended treatment and follow-up time were deemed necessary by some parents to observe long-term effects. As one parent remarked, “I think it needs more follow-up, a few months would be best. I genuinely want to see the long-term effects” [Participant 52].

Discussion

Main Findings

This study explored the effects and parental experiences of administering pediatric *tuina* to improve sleep and appetite in school-aged children with ADHD. This study is the first qualitative investigation into parent-administered pediatric *tuina* for addressing specific issues in children in Hong Kong. Insights from 12 parents were gathered using semistructured focus group interviews and individual interviews. The findings revealed 2 key themes: the effects of pediatric *tuina* on children and parents’ experiences with the intervention. Parents reported significant improvements in their children’s eating habits, sleep quality, and other areas such as behavior, mental state, and academic performance. They also highlighted advantages such as the user-friendly course design and professional guidance but noted challenges in mastering techniques and managing time. Parents suggested more guidance, real-time supervision, frequent diagnostic sessions, and extended follow-up to improve the intervention.

Comparison With Previous Studies

The findings of this study align well with a previous RCT on the effects of pediatric *tuina* for improving children’s sleep quality and habits, eating habits, behavioral regulation, emotional well-being, and parent-child relationship [29]. Improvements on children’s sleep quality and habits are consistent with the results of several previous studies examining the effects of pediatric *tuina* on sleep disturbance [43,44] or sleep problems in populations with different conditions such as bronchitis [45] and pneumonia [46]. The enhancements in eating habits reported by parents are in line with findings from a systematic review of pediatric *tuina* for anorexia in children on 28 RCTs [17]. In this study, a meta-analysis based on 9 RCTs indicated that pediatric *tuina* was superior to Western medicine (mean difference: −0.88, 95% CI −1.27 to −0.5) and Chinese herbs (mean difference: −0.69, 95% CI −1 to −0.38) in terms of improving food intake, suggesting that pediatric *tuina* could be an effective intervention for children with eating difficulties. The improvements in behavioral regulation and emotional well-being noted in this study mirror those documented in research on other pediatric massage therapies. Previous studies have found that children receiving massage therapy exhibit lessened behavioral outbursts, improved self-regulation, enhanced emotional regulation, reduced anxiety, and improved mood [47,48]. Moreover, the findings regarding the enhancement of parent-child relationships resonate with previous research emphasizing the importance of parental involvement in therapeutic outcomes. Studies on parent-involved therapies, such as cognitive behavioral therapy for children with ADHD, have shown that active parental participation is crucial for achieving effective outcomes [49,50]. Parent-administered pediatric *tuina* increases quality time spent between parents and children, thus fostering closer bonds, enhanced communication, and a sense of security. This engagement is similar to the benefits seen in cognitive behavioral therapy, where parental involvement plays a critical role in the success of the intervention.

The findings reveal notable inconsistencies with previous research focused on the effects of parent-administered pediatric *tuina* on children’s attention. While a prior qualitative study on exploring the effects of parent-administered pediatric *tuina* on ADHD in preschool children conducted in Mainland China reported that almost all parents who participated reflected that pediatric *tuina* had minimal effect on improving attention in their children [51], this study reveals considerable improvements in children’s attention and academic performance based on the description from several parents. The possible explanation may be attributed to the context (eg, culture and intervention implementation) and population differences between the two studies. In this study, the participants are school-aged children who may be more responsive to physical touch due to their developmental stage [52] and the academic demands [53] they face, which could enhance the effect of improved attention on academic performance. Additionally, cultural factors in Hong Kong, such as parental involvement and parental warmth in education, may have contributed to the more pronounced effects observed in this study [54]. Besides, the face-to-face TCM pattern diagnosis and parent training of this study may be more

XSL•FO
RenderX

accurate than the web-based intervention implementation mode of the previous study, thereby generating more satisfactory effects on children's attention. These inconsistencies underscore the need for further research to explore the contextual factors that influence the implementation of pediatric *tuina* across different populations and developmental stages.

One unanticipated finding was that pediatric *tuina* produced remarkably fast-acting benefits across various health outcomes, as reported by parents. For instance, one parent observed that their child's sleep quality improved noticeably after just 2 weeks of treatment. Another parent noted that their child's weight, which had been stagnant at 16 or 17 kg for a year, increased rapidly to 18 kg after 4 weeks of pediatric *tuina* therapy. Additionally, another parent observed considerable behavioral changes within the first week, noting that their child became more obedient and focused. Possible explanations for the fast-onset of pediatric *tuina* relate to the young age of participants and the underlying effect theory of pediatric *tuina*. According to the TCM theory, children, particularly those under 6 years of age, are more responsive to sensory stimuli due to their more sensitive organs [23], making them more receptive to external manipulations. This heightened sensitivity potentially allows the effects of pediatric *tuina* to activate the body's self-healing mechanisms quickly [55]. The concentration of pediatric *tuina* acupoints in areas rich in sensory receptors, such as the palms and head, enables effective stimulation of these receptors, thereby initiating quick physiological responses [56]. Furthermore, the specific manipulations used in pediatric *tuina*, such as pressing and rubbing, provide varied sensory stimuli that are rapidly processed by the nervous system, leading to swift improvements in the body [26]. While previous research has primarily focused on the targeted outcomes of pediatric *tuina*, the findings of this study offer new insights into the onset speed of these benefits, challenging the common perception that TCM interventions are primarily suited for chronic conditions and work slowly.

Implications

The findings have remarkable implications for several key stakeholders. For pediatricians, the integration of pediatric *tuina* into conventional ADHD treatment protocols is recommended, particularly for managing common comorbidities such as sleep and eating disorders in young children. For TCM practitioners, developing systematic training programs for parents to administer pediatric *tuina* effectively at home is meaningful for extending the benefits of this therapy beyond clinical settings and addressing a broader range of pediatric conditions. For researchers focusing on parent-administered pediatric *tuina*, future clinical trials should aim to enhance the guidance provided during practice, which can be achieved by developing real-time supervision methods, increasing the frequency of diagnostic sessions, and extending the treatment and follow-up periods. Besides, future research should consider triangulating qualitative findings with quantitative data to enhance the robustness and applicability of the study results.

Limitations

The limitations of this qualitative study should be acknowledged. First, the mixed-method approach, incorporating individual interviews and focus group interviews, was necessitated by time management barriers faced by participants. While this approach allowed great flexibility and participation, it may have introduced variations in the depth and breadth of data collected, potentially affecting the consistency and comparability of the findings. Second, the study was geographically limited to Hong Kong, which may have restricted the generalizability of the results to other populations and cultural contexts. The unique cultural and health care practices in Hong Kong could have influenced parents' perceptions and experiences, potentially differing considerably from those in other regions. Third, only participants who were willing to attend and had completed the intervention period were included, which may have excluded the perspectives of those who declined to participate in the interviews and may have expressed more negative views.

Conclusion

The findings reveal that parent-administered pediatric *tuina* considerably improved children's sleep quality, appetite, behavioral habits, mental state, and academic performance. Parents appreciated the professional guidance and user-friendly course design, which facilitated the intervention's implementation. However, challenges included difficulties in mastering techniques, locating acupuncture points, and managing time. Parents expressed the need for more frequent diagnostic sessions, real-time supervision, and extended follow-up to observe the long-term effects. Future research should address these challenges and consider integrating qualitative findings with quantitative data to enhance the robustness and applicability of the results.

Acknowledgments

This research was supported by a grant from the Chinese Medicine Development Fund (22B2/023A_R1). We wish to thank all participants for their help with this study.

Abstract

Background: Digital parent training programs (DPTs) have emerged as a scalable solution for treating childhood oppositional defiant disorder (ODD), offering remote access and reduced barriers to care. However, there is limited data on their potential to reach untreated populations and their effectiveness during times of crisis, such as war.

Objective: This study aimed to evaluate the reach, usage patterns, human support needs, and clinical outcomes of a fully remote guided DPT for child ODD, comparing 2 cohorts treated before and during wartime in Israel.

Methods: Parents of children with ODD were enrolled in a human-supported DPT, with 25 families recruited before and 30 during wartime. Data included self-reported questionnaires (measured before-, postintervention, and 3 months after the end of the intervention), platform usage metrics, and clinician assessments.

Results: Most families (62%, 34/55) had not previously received any intervention for their child's behavior problems. Significant self-reported improvements in child behavior (Cohen $d \geq 0.79$) and parenting practices ($0.39 \leq$ Cohen $d \leq 0.87$) were found post intervention. On average, families engaged with the program for 138.6 minutes across 31.4 unique logins, supported by 38.8 minutes of human interaction, primarily via messaging. During wartime, parents completed onboarding significantly faster (15.70 days vs 31.36 days) and were more likely to complete the critical "overcoming disobedience" phase (27/30, 90% vs 17/25, 68%). However, while self-reported changes were similar, clinician-rated recovery from ODD was marginally lower during wartime (13/30, 43% vs 17/25, 68%).

Conclusions: DPTs present an acceptable avenue for care that could reach parents who have not sought treatment through traditional channels. However, this study's results suggest that their clinical effectiveness may be lower under extreme stress conditions such as wartime, underscoring the need for future studies in this area.

KEYWORDS

parent training; crisis; behavior problems; usage; oppositional defiant disorder; wartime; digital health

Introduction

Oppositional defiant disorder (ODD) is among the most prevalent types of mental disorders affecting young children, and it is crucial to treat it at an early onset [1]. However, the provision of child mental health services is limited [2]. In Israel, the wait times for publicly administered face-to-face mental health interventions are very long, with an ongoing gap between supply and demand that is not easily closed [3]. To address barriers related to service delivery in the treatment of behavior problems, digital parent training programs (DPTs) aimed at treating childhood disruptive behaviors have emerged over the last decade [4-6]. These interventions have demonstrated efficacy in meta-analyses [7-9], with trials reporting at least

XSL•FO
RenderX

moderate effect size improvements in child behaviors for guided DPTs (Cohen *d*>0.50) [7,9,10].

Although DPTs appear to offer a feasible way to increase access to care, it is unclear the extent to which these interventions reduce the mental health treatment gap by reaching parents who have not previously sought treatment for their child's condition. Furthermore, it is uncertain how much human support is needed as an adjunct to DPT usage, especially when the program's design incorporates automated features that potentially reduce the need for human support. Our own study of DPTs for child behavior problems showed that, compared to a standard format, an enhanced intervention in terms of its design increased user engagement (2.5 times higher completion rate) and program efficacy in reducing child behavior problems (Cohen *d*=0.43-0.54) in a self-guided condition [11]. However, the degree of human support required when deploying such interventions remains unclear.

In addition, this study began before the war in Israel (which began on October 7, 2023) and continued during wartime. This unexpected war resulted in a deterioration in mental health and a profound need for mental health support for the whole population [12]. For this reason, we sought to use our data to answer questions relating to the impact of a conflict setting on the acceptability and effectiveness of DPTs. There is a significant gap in the literature, with very limited evidence on whether the use of digital mental health interventions for child routine care differs under conditions of war. A notable study examined enrollment and completion rates of a nationwide guided DPT for children with disruptive behavior before and during the COVID-19 pandemic [13]. In the study, program enrollment did not change significantly under COVID-19 restrictions, while the completion rate actually increased. It remains unclear whether the usage of guided DPTs for child behavior problems increases during wartime, as observed during COVID-19, and what their effectiveness is in terms of clinical outcomes, an area that is yet to be explored.

The main aim of this study was to evaluate the potential deployment of a DPT for child behavior problems as a scalable form of care. In particular, our study (1) examined the extent to which a remote onboarding procedure, including reaching people through social media, could reach parents who had not previously sought treatment for the relevant condition; (2) evaluated the timeline of remotely administered onboarding process, which included contact with a clinician; (3) evaluated the DPT's usage patterns, human support, and effectiveness; and (4) assessed differences in reach, usage, and efficacy in the context of war, which began halfway through the study's deployment.

Methods

Participants and Recruitment Procedure

Eligibility

Parents were eligible to participate if they met the eligibility criteria (see Textbox 1).

Textbox 1. Eligibility criteria.

Inclusion criteria:

- Parents had a child between the ages of 3 and 7 years with an elevated level of behavior problems based on the Eyberg Child Behavior Inventory (ECBI; ECBI problem≥15 and ECBI intensity≥132) [14].
- The behavior problems described by the parents in an interview conducted by a licensed clinician met the criteria for oppositional defiant disorder.
- They had access to a smartphone device and a personal computer with an internet connection.

Exclusion criteria:

- Their child was taking medication or was in regular contact with a professional for behavioral or emotional problems.
- They were currently accessing parenting support elsewhere.
- Their child had been diagnosed with an intellectual disability or developmental delay.

Recruitment Procedure

Parents were recruited for the study from January 1, 2023, to January 10, 2024, through Facebook advertising, a method previously shown to reach broad and diverse populations across socioeconomic backgrounds in ways comparable to traditional recruitment approaches [15]. Because the program and all study materials were provided in Hebrew, the campaign specifically targeted Hebrew-speaking parents of children aged between 3 and 7 years, residing in Israel. There was a planned pause in recruitment between May 2023 and the beginning of October 2023 due to summer and holiday breaks in the education system. Recruitment was then delayed because the war began on October 7, 2023, which meant that the recruitment of the 2 cohorts (before and during wartime) took place during 2 consecutive school years.

Parents registered their interest in participation through the study home page, where they completed a brief eligibility screener as a first step. Screening, interest, and parents' understanding of the terms of the study were confirmed through a phone call with a research assistant, followed by a link to complete the informed consent online. Parents then participated in a remote assessment with an independent clinician (author OB). Eligible participants were then referred to complete the baseline assessment. Those who completed the assessment received login details to the intervention's platform, with complementary guidance from their assigned human supporter. Parents who were not eligible to participate were referred to

XSL•FO
RenderX

local services. No compensation was provided for participation, other than access to the intervention.

Benevolent Parenting Intervention

Multimedia Appendix 1 presents a comprehensive review of Benevolent Parenting DPT. The program is based on predefined decision rules that are either event- or time-based [16], meant to increase user engagement through effort optimization design [17] and therapeutic persuasiveness, which integrate behavior change techniques with persuasive design features specifically for digital delivery [18,19]. This framework complements the taxonomy of behavior change techniques [20] by emphasizing effective operationalization and delivery of techniques in-app (eg, prompts, self-monitoring, feedback, and adaptation), a distinction that is particularly important in digital interventions where technique presence without proper delivery yields limited impact. A self-directed version of the program has been shown in previous research to achieve a high therapeutic persuasiveness evaluation score (4.5/5) and high completion rates among parents [11].

The program incorporates common themes of evidence-based DPTs for childhood disruptive behaviors (eg, overcoming disobedience). Each theme in the program comprises a short 10-20 minute learning phase followed by a 1-2 week focusing phase. The focusing phase is designed to help the desired therapeutic activities become salient in the parents' minds and to help them acquire skills in a nonjudgmental manner, while avoiding the burden and potential failures that may be associated with the idea of "training." For that reason, the program incorporates the following features: (1) call to action: timely digital triggers related to the specific goals of the modules they have completed; (2) creation of salience through self-monitoring and ongoing feedback; and (3) adaptation to user state based on parents' reports, which are used to acknowledge their success and to suggest additional actions.

Human support followed a manual based on our previous work [21,22] and included: an initial message sent when parents first logged into the program, a message following the completion of each learning and focusing phase, contacting parents via the messaging platform if disengagement was identified, response to participant-initiated messages, and a phone conversation offered following the completion of the "overcoming disobedience" module to reinforce parental efforts during the subsequent focusing phase (see Multimedia Appendix 1 for a detailed review). The supporter used a dashboard that provided information on engagement markers and participants' progress.

Measures

Parents were assessed at 3 time points: before the intervention (baseline, T1), immediately after (postintervention, T2), and 3 months after the end of the intervention (follow-up, T3).

Self-Reported Measures

Child behavior problems were assessed using the Intensity and Problem subscales of the 36-item Eyberg Child Behavior Inventory (ECBI) [14,23,24] (α coefficients: ECBI Problems, α=.89 and ECBI Intensity, α=.91). Parental disciplinary behaviors in response to their child's misbehaviors were assessed using 2 Parenting Scale (PS) subscale scores—Overreactivity (11 items) and Laxness (10 items) [25] (α coefficient: Laxness, α=.90 and Overreactivity, α=.82). Task-specific self-efficacy was assessed using items taken from the Parenting Tasks Checklist (PTC) Setting Self-efficacy (six statements) and Behavioral Self-efficacy (six statements) subscales [26] (coefficient : PTC Setting, 0.85; PTC Behavioral, 0.96). Positive parenting practices were assessed using the Alabama Parenting Questionnaire (APQ) Positive Parenting Practices subscale (six items) [27] (coefficient =0.79).

Clinician Assessment of ODD

A structured interview was conducted with the parents, administered by a licensed clinician (clinical child psychologist) at T1 and T2 using a secure online video connection. The clinician was trained by the study's principal investigator (a licensed clinical psychologist with expertise in treating children and their parents) on the interview protocol. The clinician confirmed with the parents that no exclusion criteria were met (at T1) and examined whether the child met the criteria for ODD. To do so, the clinician addressed and documented the child's symptoms of ODD (according to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition) reported by the parents (at T1 and T2), following Pelham and colleagues' [28,29] paradigm that demonstrated sufficient internal reliability and validity. Any questions regarding the symptoms of ODD that arose in specific cases were discussed with the study's principal investigator before making a final decision.

Program Usage and Completion Rate

Measures of program usage included the number of login days, unique logins, and total time of use. We also recorded the percentage of people completing the "overcoming disobedience" module, which was deemed the main obligatory component in the intervention, and the percentage of program completion. The metrics of human support documented during the intervention delivery were message content, the occurrence of phone calls, and the time spent during each supportive contact (including the time to take notes).

Statistical Analyses

Demographic, usage, and clinical characteristics are reported as frequencies and percentages for categorical variables, and as mean (SD) for continuous variables. Differences between the 2 study cohorts were calculated using Mann-Whitney *U* tests for continuous variables and chi-square tests for categorical variables (due to sample size limitations). Pre-post differences in outcomes over time were calculated using dependent-sample 1-tailed *t* tests for the total sample and Wilcoxon signed-rank tests within each cohort (pre- and during-wartime) to reduce reliance on normality assumptions given the modest and unequal subgroup sizes. Effect size estimates included Cohen *d* for *t* tests, the Crammer *V* for chi-square tests, and *r* for Mann–Whitney *U* and Wilcoxon tests (calculated based on the *z* value from the test divided by the total number of observations).

We determined the study sample size based on the total participant population, as we had not planned to divide the sample into 2 groups according to wartime conditions. Data on

XSL•FO
RenderX

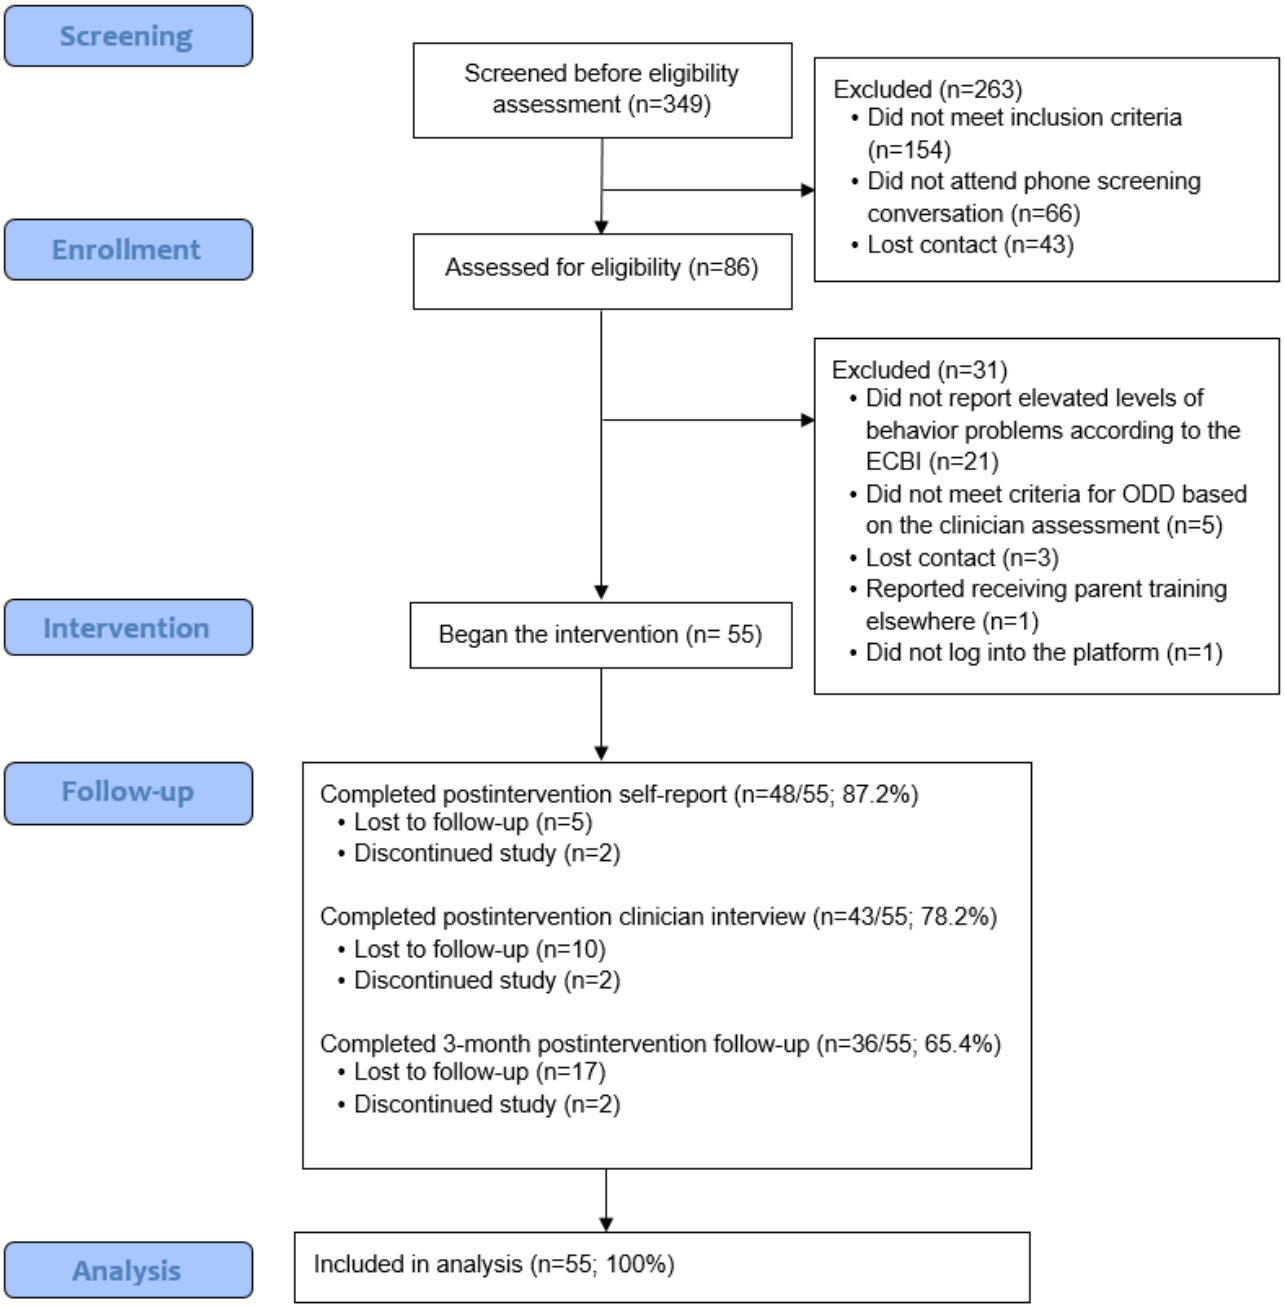
guided DPTs aimed at treating children at the *clinical* range of behavior problem symptoms point to at least moderate effect size improvement in child behavior problems (eg, child behavior problems: Cohen *d*>0.50, intent-to-treat analyses) [7,9,10]. Even when taking the lower end of this spectrum (an estimated effect size of 0.50), a sample size of 50 participants provides 0.96 power (1-tailed α=.05) to detect significant differences in the continuous variables.

We conducted intent-to-treat analyses for all reported clinical outcomes at postintervention time points. Multiple imputations (5 sets) were generated using predictive mean matching as the imputation. Sensitivity analysis was performed, showing that the statistical test results from complete case analyses were similar to the imputed analyses (completer analyses are presented in Multimedia Appendices 2 and 3). All analyses were performed using SPSS (version 27; IBM Corp).

Ethical Considerations

The study was approved by the institutional review board (ethics committee) of the University of Haifa (342/22). Screening, interest, and parents' understanding of the terms of the study were confirmed through a phone call with a research assistant, followed by a link to complete the informed consent online. Parents who were not eligible to participate were referred to local services. No compensation was provided for participation, other than access to the intervention.

Results



The participant flow diagram is presented in Figure 1, and participant demographics are presented in Table 1. Overall, parents from 55 families with children with ODD enrolled in the study and began the intervention. Among them, 25/55 (46%) families began the intervention and completed their postintervention assessment before wartime, while the remaining 30/55 (54%) began the intervention and completed their postintervention assessment during wartime. The mean age of the children at the beginning of the intervention was 5.33 (SD 1.14) years, and 32/55 (58%) children were boys. The leading parent in all families was the mother, whose mean age was 36.7 (SD 3.54) years. No differences in demographic variables were identified based on intervention cohorts.

Parents in 34/55 families (62%) reported that this was the first intervention they had received for their child's behavior problems. A chi-square test revealed a significant difference between those receiving the intervention for the first time and the rest of the sample in terms of religiosity (secular vs more religious; χ^2_1=4.34; *P*=.04). Among secular families, 14/27 (52%) reported that this was the first intervention they had received for their child's behavioral problems, whereas among traditional or religious families, 22/28 (79%) reported the same. No other differences in demographic or outcome variables were found between these two categories.

It took parents 22.82 (SD 15.80) days on average to complete their onboarding procedure and begin the intervention. There was a significant difference in the time it took parents to begin the intervention based on study cohorts (*P*≤.004; ie, *P*=.004, *P*=.002, and *P*<.001). Specifically, during wartime, it took parents half the time (15.70 days) to begin the intervention than it did before wartime (31.36 days).

[c]N/A: not applicable.

[d]This question was accidentally not presented to the first 18 participants in the first cohort, and for this reason, we did not statistically examine the differences between the 2 cohorts in terms of this variable.

[e]Refers to the parent leading the intervention.

[f]In Israeli shekels (1 shekel was approximately US $3.8 at the time of the study).

[g]This was the first intervention the parents had received with the target of treating their child's behavioral problems.

[h]Significant results.

Program Usage and Completion

Program usage and completion rates are presented in Table 2. The mean time to complete the program was 12.34 (SD 5.18) weeks and included an average usage time of 138.6 (SD 63.41) minutes. Altogether, parents from 44/55 families (80%) completed the "overcoming disobedience" theme, and parents from 35/55 families (64%) completed the whole intervention. The total human support time invested on average per family was 38.81 (SD 35.32) minutes, most of which was spent on text messaging (mean time 30.2, SD 29.9 minutes).

Parents who completed the interventions during wartime logged into the program on significantly more days (r=.28; P=.04), and significantly more of them completed the "overcoming disobedience" theme (Cramer V=.27; P=.04). Parents from this cohort also received more messages from the human supporter (Cramer V=.28; P=.04). It is important to note that, during wartime, parental usage was higher on all metrics (eg, 70%, 21/30 program completers compared to 56%, 14/25 in the cohort before the war), although the results did not reach the level of statistical significance.

[f]Includes the time it took the supporter to write messages, document notes, and discuss cases with the supervisor.

Intervention Outcomes

Descriptive statistics and statistical differences in self-reported changes in child behaviors and parenting variables at postintervention and follow-up time points are presented in Table 3. Statistical differences in self-reported changes between the 2 cohorts are presented in Table 4. Significant improvements were found among all outcome variables postintervention (compared to baseline), with large effect size improvements in child behavior problems (ECBI Cohen *d*=0.79-0.83), medium to large effect size improvements in parenting styles (PS Cohen *d*=0.52-0.87), and medium effect size improvements in task-specific sense of efficacy (PTC Cohen *d*=0.57-0.65) and positive parenting practices (APQ Cohen *d*=0.39). Effects remained significant at follow-up time points for all outcome variables, with descriptively larger effect sizes than postintervention (eg, ECBI *Cohend*=1.02-1.10). No differences were found between the 2 cohorts in terms of self-reported variables.

Changes in cases not meeting the ODD criteria postintervention based on the clinician interviews are presented in Table 5. The impact of wartime on not meeting the criteria for ODD postintervention was found to be marginally significant (*P*=.07). In the prewartime cohort, 17/25 children (68%) did not meet the criteria for ODD following the intervention; during wartime, 13/30 children (43%) did not meet the criteria for ODD following the intervention.

Discussion

Principal Findings

This study found that the DPT primarily reached parents who had not received care for the current condition. The demographic characteristics of our sample, particularly regarding education, income, and religiosity, were comparable to national data for parents in Israel, supporting the representativeness of the study population [30-32]. In addition, the DPT was found to be effective at reducing child behavior problems and improving parenting-related variables. Differences were identified between the study cohorts based on the context of war in the region.

This study found that the remote recruitment procedure was successful at reaching mostly parents who had never received an intervention for their child's ODD (34/55, 62%). This finding aligns with broader research showing that digital and remote mental health interventions can indeed increase access and reach new people in need, or earlier in the prodromal process [33,34]. It is important to note that this study also found that we were able to reach more families for the first time (22/28, 79%) if they were nonsecular. It could be that, in Israel, secular families are more likely to seek psychological services independently, but this needs to be further examined in future studies.

In terms of program usage, most parents (44/55, 80%) completed the "overcoming disobedience" theme, the most important skill area in the program. Parents also used the program for more than 2 hours (138.6 minutes) on average, scattered across multiple sessions (a total of 31.4 unique logins). This pattern of use differs completely from that of therapist-led parent training, which is based on a much smaller number of sessions, each lasting 40-50 minutes [35]. It could be that this pattern of use (ie, in small pockets of available time) is more relevant to parents who decide to use digital interventions to self-manage their child's state. The total human support time spent during this program was quite small (an average of 38.81 minutes), with parents preferring to message the supporter rather than engage in phone conversations. It is worth noting that studies in which support is primarily provided through phone calls have reported a higher level of human support (eg, [10,36]). It would be interesting to further investigate the extent to which parents

XSL•FO
RenderX

prefer phone calls when text messaging is available and how this choice influences the outcomes.

In terms of wartime impact, the results showed that, during wartime, parents completed their onboarding process in half the time it took before the war. Parents also used the program more extensively, with 90% (27/30) completing the "overcoming disobedience" skill acquisition phase and logging into the program 7 more days than the cohort participating before wartime. The greater volume of supporter messages observed during wartime is best interpreted as a protocol-triggered outreach message based on a higher share of parents reaching key phases in the program (eg, "overcoming disobedience"); notably, parent-initiated messages were similar across cohorts, and total support time did not differ. This usage pattern fits with the patterns described by Sakari et al [13] in comparing the use of a DPT before and during the COVID-19 pandemic. That report indicated that program completion rates actually increased during the COVID-19 epidemic. It is plausible that the growing need for support during times of crisis is manifested in increased use of the digital intervention. However, while our findings indicated comparable improvements based on parental self-reports, our study revealed a close to significant difference between the 2 cohorts in the percentage of children not meeting the criteria for ODD post intervention based on clinician assessment (13/30, 43% recovered during wartime vs 17/25, 68% before the war). Although this is only a marginally significant result, it suggests a potential trend toward an effect, mainly because of the descriptively large difference in percentages of children meeting the ODD criteria.

Research has indicated that environmental stressors, such as those present during wartime, can significantly affect the efficacy of mental health interventions. For instance, studies have shown that ongoing stress and trauma can complicate the treatment process (eg, [37]). Supporting this notion, during the war that began on October 7, 2023, a study examined the prevalence of mental illness and reported prevalence rates of generalized anxiety disorder and depression of over 42% in an Israeli representative sample [12]. In our study, it could be that the ability of parents to use coping strategies was strained, thereby impacting the overall effectiveness of the parent training intervention. It is also possible that parents' own mental health, particularly symptoms of anxiety and depression, played a role in both their engagement with and response to the intervention during wartime. Elevated distress may have limited parents' capacity to apply therapeutic strategies consistently, potentially contributing to the lower clinician-rated recovery rates observed in this period. However, we did not have any relevant data to assess whether parental mental health impacted both the increased usage and decreased effectiveness. Future studies could benefit from incorporating brief parent mental health screeners to examine how parental anxiety and depression relate to engagement patterns and intervention outcomes, as well as whether improvements in the parent–child relationship lead to secondary benefits in parental well-being.

While this paper was not designed as a cost-benefit analysis, cost and clinician time are relevant factors when considering the scalability of an intervention and are therefore worth noting. The direct cost per treatment in this study included 2 clinician assessments (30 minutes each, before and after the intervention) and an average of less than an hour of human support during the intervention. Regarding the latter, the supporter spent less than 40 minutes on average providing support, including note-taking. Assuming a cost of approximately Israeli Shekels (ILS) 200 per clinician assessment and ILS 100 per hour of human support (including overheads), the direct cost per family is estimated at ILS 500 (≈US $130; approximately ILS 1=US $3.8 at the time of the study). These estimates exclude costs related to upgrading and maintaining the platform, office needs, administrative tasks, and management. Overall, the time and cost required for this guided DPT are considerably lower than those reported for traditional behavior parent training programs, underscoring the model's scalability potential.

Limitations

This study implemented a 1-arm intervention condition without a control group. It was not feasible to deploy a no-treatment control condition while examining the real-world use of an intervention, as the recruitment and promotion of the intervention (and study) would have differed. An ethical consideration also arises during wartime, in that it would not be ethical to withhold a timely digital intervention when people may need it the most. The absence of a control condition means that the overall pre- to postintervention effects could be attributed to additional factors. However, the reported effects are similar to those reported in a randomized controlled pilot trial of the same DPT in its unguided format [11]. Another limitation concerns our operationalization of engagement, which focused on objective indicators of usage such as log data, completion rates, duration, and navigation patterns. While these measures are commonly used and provide valuable insights into user behavior, they do not capture the full spectrum of engagement [38,39]. Future studies should complement such objective measures with indicators of experience, including satisfaction, engagement in therapeutic activities, affective responses, and attention. Integrating both behavioral and experiential dimensions of engagement would allow a more comprehensive understanding of how parents interact with digital interventions and how engagement relates to outcomes.

Conclusions

DPTs present a form of care that could reach parents who have not sought treatment through traditional channels. These programs are acceptable, with preliminary evidence showing them to be highly used and effective. Examining the impact of DPTs during crisis times provides valuable insights into the potential use of these scalable interventions, which have a particular advantage in terms of deployment during crises. Stakeholders should have an articulated plan for the deployment of such interventions. Such strategic planning can not only address immediate needs during a crisis but also contribute to long-term public health strategies by integrating DPTs as a regular component of mental health care provision. Future research should explore ways to further optimize human support models, assess the role of parental mental health in engagement and outcomes, and evaluate the program's scalability across diverse real-world settings.

Abstract

Background: Managing a child undergoing growth hormone treatment (GHt) can be burdensome for the families, which can lead to psychological problems and poor treatment adherence. The Adhera Caring Digital Program (ACDP) is a mobile-based digital health intervention designed to support the physical and mental well-being of families of individuals with chronic conditions.

Objective: This study aimed to evaluate the clinical feasibility of a digital intervention to support families by focusing on caregivers of children undergoing GHt and its impact on treatment adherence.

Methods: This is a prospective observational study. A total of 51 caregivers of children undergoing GHt with low adherence (below 85%) to treatment were recruited at the Pediatric Endocrinology Unit at the Miguel Servet Children's University Hospital and enrolled into the ACDP for 3 months.

Results: A total of 51 parents participated in the digital intervention for 3 months. The use of ACDP was associated with a significant increase in adherence rate (P<.001). At baseline, all families had suboptimal adherence (below 85%), and after the intervention, 75% (n=38) of the families reached optimal levels of adherence. Also, the perceived pain of injection was reduced, as well as anxiety and stress. Initially, 21.56% (n=11) of caregivers reported depression symptoms, categorized as mild (11.76%, n=6), moderate (7.84%, n=4), and extremely severe (1.96%, n=1), while post intervention, only 1.96% (n=1) of caregivers reported depression as "severe." Anxiety levels at baseline were reported by a total of 23.53% (n=12) of caregivers (mild: 7.84%, n=4, moderate: 13.73%, n=7, and severe: 1.96%, n=1). After the intervention, only 11.76% (n=6) reported mild (5.88%, n=3) or moderate (5.88%, n=3) anxiety levels. Initially, 23.5% (n=12) of caregivers reported stress as mild (7.84%, n=4), moderate (13.72%, n=7), and severe (1.96%, n=1) stress, and following the intervention, these symptoms reduced to 7.84% (n=4) (mild: 5.88%, n=3, severe: 1.96%, n=1).

Conclusions: The ACDP is a promising tool, and it has been demonstrated to significantly increase the adherence rate, adding value to the patient and caregiver journey, and improving the management of growth hormone deficiency while promoting the overall well-being of family caregivers. Our results show that the digital support provided by the solution significantly increased the quality of life of the caregivers by increasing their psychological, emotional, and social well-being and decreasing their depression, anxiety, and stress symptoms.

Introduction

Background

Growth hormone (GH) deficiency (GHD) in the pediatric population causes short stature [1]. Children affected by GHD have also been reported to have worse quality of life, cognitive function, and fatigue than those with normal height [2,3]. Short stature in children is also associated with anxiety, depression, and social withdrawal [4-11]. Importantly, recent findings suggest that poor emotional well-being and health-related quality of life (HrQoL) of caregivers and/or parents are also negatively related to children's HrQoL, particularly in the context of pediatric health conditions.

These children's families are responsible for managing the disease. Within the family, family caregivers are the ones managing its treatment (daily injections of recombinant human GH) and the children's mental health. Caring might be burdensome and challenging [12,13], exposing the family caregiver to the risk of developing psychological problems [14]. Indeed, parental stress has been described as one of the consequences of managing GHD in children, leading to poorer adherence to GH therapy (GHt) and an impact on their environment and health [15,16]. Overall, family caregiver fatigue has been found to significantly impact the well-being of the caregiver and the patient living with a chronic condition [17]. However, the impact of the family caregiver specifically on GHDs remains unclear [18,19].

Digital health (DH) solutions are transforming the health care sector, as they can be a cost-effective option that allows accessible family-centered and personalized interventions. Indeed, mobile interventions have been proven effective in supporting caregivers in the management of chronic conditions [20]. One such innovation is the Easypod system, an electronic, fully automated device designed to streamline the GH treatment process. This system provides reliable real-time injection data, enabling health care providers to monitor patients' progress and make more informed treatment decisions. By identifying nonadherent patients earlier, the Easypod allows for more targeted support, enhancing both treatment adherence and outcomes [21].

The Adhera Caring Digital Program

The Adhera Caring Digital Program (ACDP) is a comprehensive, digitally delivered program designed to support the physical and mental well-being of family caregivers of individuals with chronic conditions. It aims to improve self-management and health outcomes for both the patient and their family caregiver [22]. The ACDP includes access to a mobile app for family caregivers, which is integrated into an artificial intelligence–powered platform that includes integrated data from injector devices, as well as tools for supporting clinicians to follow up on the health of the families.

This study aimed to evaluate the clinical feasibility of a digital intervention to support families by focusing on caregivers of children undergoing GHt and its impact on treatment adherence.

Previous Research

GHt for children is a critical yet challenging process that often demands significant effort from family caregivers. The burden of managing GHt can negatively impact the psychological well-being of caregivers and adherence to the treatment protocol, which, in turn, affects the health outcomes of the children undergoing treatment. This challenge necessitates the development of effective support systems for caregivers to ensure better adherence and overall health outcomes.

Recent advancements in digital health interventions have shown promising results in supporting caregivers of children with chronic conditions, including those undergoing GHt. Studies have demonstrated that digital tools can provide substantial benefits by improving treatment adherence and enhancing the mental health of caregivers. For instance, a recent study by Dimitri et al (2021) [23] found that digital interventions could significantly enhance treatment adherence in children with GHDs by providing real-time support and monitoring capabilities.

In another study, Savage et al [13] highlighted the transformative potential of DH platforms in pediatric endocrinology, emphasizing how patient-generated data and interactive support can lead to more integrated and personalized care models. This approach improves not only adherence but also the overall quality of care provided to patients.

The mental health and well-being of caregivers are crucial factors in ensuring successful GHt management. Zhai et al [24] reported the positive impact of DH interventions on reducing caregiver stress and anxiety, which, in turn, improved their ability to manage the treatment regimen effectively [24]. These findings underscore the importance of addressing the psychological needs of caregivers through innovative digital solutions.

Additionally, Lorca-Cabrera et al [25] explored the role of mobile health applications in supporting self-management and emotional well-being among caregivers. Their research showed that these applications could reduce the psychological burden on caregivers, thereby improving their overall quality of life and enhancing their capacity to support their children's treatment [25].

The ACDP builds upon these foundations by offering a comprehensive digital health intervention designed to support the physical and mental well-being of caregivers managing children undergoing GHt. This study aims to evaluate the clinical feasibility of ACDP and its impact on treatment adherence, contributing to the growing body of evidence supporting the integration of DH solutions in chronic disease management.

Methods

Overview

Family caregivers (ie, parents) of children with suboptimal adherence to GHt were recruited to the study at the Pediatric Endocrinology Unit at the Miguel Servet Children's University Hospital and were provided with access to the ACDP for 3

XSL•FO
RenderX

months. The protocol was prospectively registered in ClinicalTrials.gov (NCT04812665).

Participants were assessed twice (at recruitment and at 3 months' follow-up). The data collected were (1) demographic data (only at recruitment); (2) positive mood assessed with the Positive and Negative Affect Schedule (PANAS) [26]; (3) distress assessed using the Depression Anxiety and Stress Scale-21 (DASS-21) [27], general well-being assessed using the Mental Health Continuum Short Form (MHC-SF) [28], and self-efficacy assessed using the Generalized Self-Efficacy Scale (GSES) [29]; (4) HrQoL assessed using the KIDSCREEN-10 [30] and the Quality of Life in Short Stature Youth (QoLISSY) [31]; and (5) GHt adherence (%) by Easypod-Connect.

Recruitment

The inclusion criteria were as follows:

- Adherence to GHt monitored in the last month prior to enrollment indicates a ratio less than 85%.
- Family caregivers (and legal guardians) of children who receive GHt in accordance with approved indications in Spain.
- Explicit agreement on data sharing regarding adherence to GHt gathered through the Easypod-Connect.
- Participants must be able to interact with mobile phones and be willing to install the mobile-based solution of the study in their smartphone.
- Participants must sign the specific informed consent form for the study.

Only one legal guardian per child can participate in the study.

Procedure

The ACDP is a noninvasive, digitally delivered intervention designed to support family caregivers of children with chronic conditions. Specifically tailored for the context of GHt, the ACDP offers condition-specific educational content, evidence-based caregiving strategies, and self-management tools to help caregivers monitor progress and remain engaged with their child's treatment. To promote emotional well-being and adherence, the program delivers personalized motivational messages generated by an artificial intelligence–driven health recommender system. This system tailors its recommendations using both objective and patient-reported data: objective adherence data are collected via Easypod-Connect, an electronic auto-injector device that monitors and transmits GH administration data, while patient-reported outcomes are assessed at baseline and at 3-month follow-up using validated psychometric instruments (see Table 1). The ACDP is part of the Adhera Health Precision Digital Companion Platform [32], which has been developed using the best practices regarding data protection and quality management in accordance with the ISO (International Organization for Standardization) 27001 and ISO 13465 guidelines.

Table . SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) table.

Procedures	Visit 1 (baseline)	Visit 2 (3 mo)	Digital health intervention period	Follow-up (post intervention)
Screening for inclusion criteria	✓			
Informed consent	✓			
Baseline HrQoL[a] questionnaire (QoLISSY)[b]	✓			
Emotional well-being assessment (PANAS[c])	✓			
Self-efficacy (GSES[d])	✓			
Adherence monitoring		✓	✓ (throughout intervention)	✓
Digital support program usage			✓	
Child's growth monitoring	✓		✓	
Caregiver's QoL[e] follow-up (QoLISSY)		✓		✓

[a]HrQoL: health-related quality of life.

[b]QoLISSY: Quality of Life in Short Stature Youth.

[c]PANAS: Positive and Negative Affect Schedule.

[d]GSES: Generalized Self-Efficacy Scale.

[e]QoL: quality of life.

Statistical Analysis

Participants' questionnaire answers were digitally recorded through a Microsoft Forms form and extracted to a Microsoft Excel database. Descriptive analysis (means, SDs, and percentages) was used for demographic data. After checking the normality of each variable, pre-post *P* values of the psychometrics' parameters were checked using the Student *t* and Wilcoxon tests.

Ethical Considerations

This study protocol was reviewed and approved by the Spanish Ethics Committee C.P.-C.I. PI20/494. Written informed consent was obtained from participants (or their parent/legal guardian/next of kin) to participate in the study.

The privacy and confidentiality of all research participants were strictly maintained; all data were de-identified before analysis, and no personally identifiable information was collected or reported. Participants were not compensated for their participation in this study.

Results

Participants' Characteristics

A total of 65 parents provided informed consent. Of these, 14 were excluded from the analysis, as they did not access the digital intervention. The final sample's (n=51) characteristics are described in Table 2. Participants were 42.14 (SD 5.78) years old on average, and the sample mostly comprised women (n=35, 68.6%). The average age of the child taken care of was 7.9 (SD 2.9) years, receiving GHt for 36.51 (SD 28.43) months. Regarding the education level, 15 (29.4%) caregivers hold a university degree, 20 (39.2%) have professional training, 12 (23.5%) finished high school, and 4 (7.8%) finished primary school.

Table . Descriptive characteristics of the sample (N=51).

Characteristic	Value
Caregiver's gender, n (%)	
Male	16 (31.4)
Female	35 (68.6)
Caregiver's age (years), mean (SD)	41.45 (7.59)
Caregiver's marital status, n (%)	
Single	10 (19.6)
Married	33 (64.7)
Divorced	8 (15.7)
Education, n (%)	
Primary education	4 (7.8)
Secondary education/high school	12 (23.5)
Professional training	20 (39.2)
University degree	15 (29.4)
Child's gender, n (%)	
Male	25 (49.0)

Statistical Analysis

Quality of Life of Children

Almost all the psychometric questionnaires' results showed significant differences (ie, $P<.05$) after using the ACDP for 3 months (Table 3 and Figure 1). General health and quality of life were significantly improved based on KIDSCREEN-10 [30] and QoLISSY [31] psychometrics. General and Social well-being also improved significantly, while emotional well-being has improved as QoLISSY emotional scale scores increased, and the PANAS [26] indicated a statistically significant increase in positive affect (mood) as well as a decrease in negative affect. Social well-being also enhanced significantly according to both MHC-SF [28] and QoLISSY questionnaires. Self-efficacy, assessed using the GSES [29], increased, as did the QoLISSY coping score.

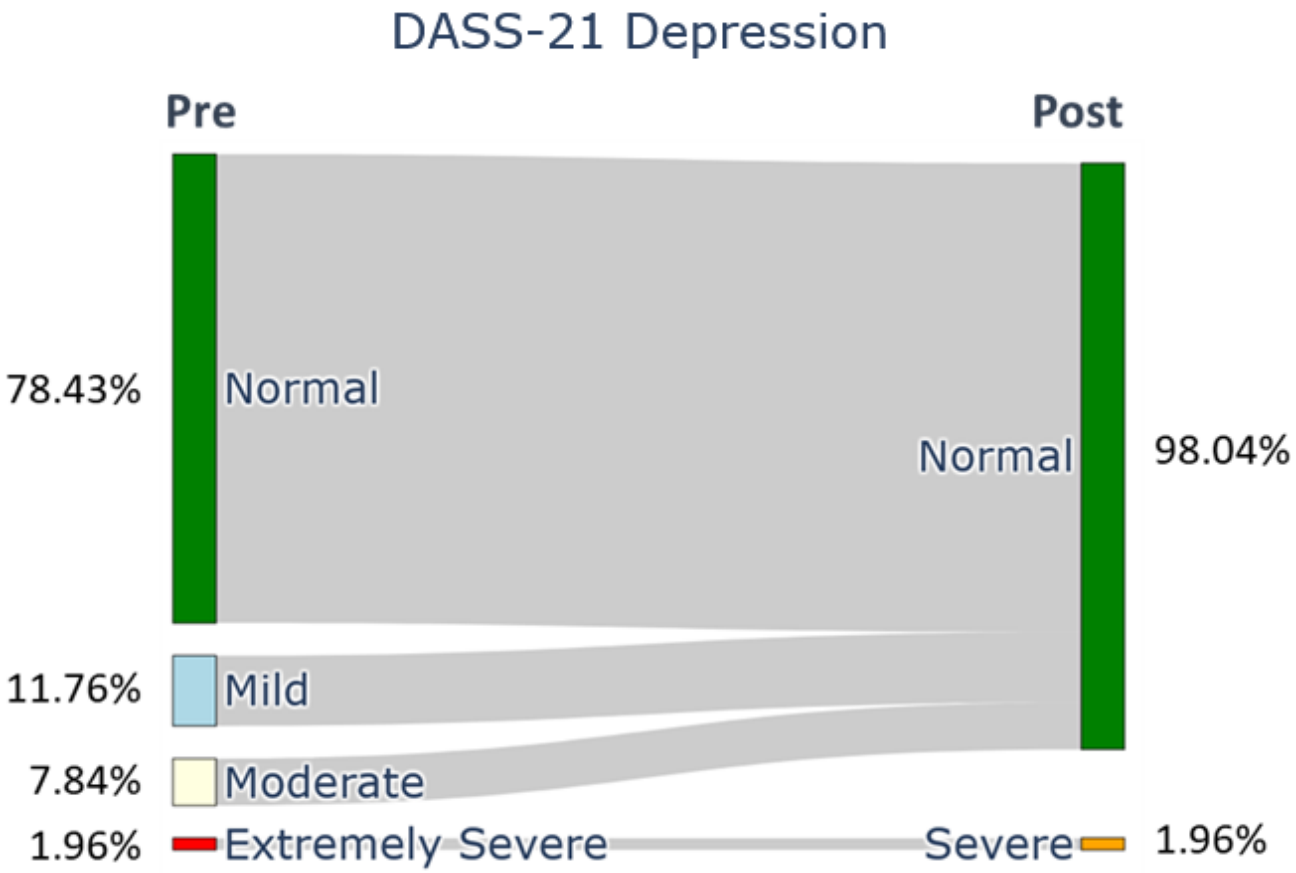
Figure 1. Changes in quality of life in youth with short stature (baseline and 12 wk).



Mental Well-Being of Parents

After the ACDP, the participants showed a significant difference in all the QoLISSY subscales except for the emotional (P=.28) scales. Meaningful results were found in the physical and social dimensions and in the child's future perception, coping, treatment, height-related beliefs, and effects of the child's short stature on the family scale. Concerning the mental health symptoms, the depression (Figure 2), anxiety (Figure 3), and stress (Figure 4) symptoms measured by the DASS-21 were reduced after the 3-month digital intervention.

Finally, the use of the ACDP was associated with a significant increase in the adherence rate (P<.001). At the baseline, all the families had suboptimal adherence (below 85%); after the intervention, 75% (n=38) of the families reached optimal levels of adherence. The QoLISSY item regarding perceived pain of injection was also reduced, which might explain that improved social well-being and reduced anxiety and stress were associated with reduced perceived pain from injection and overall contributed to improved adherence.

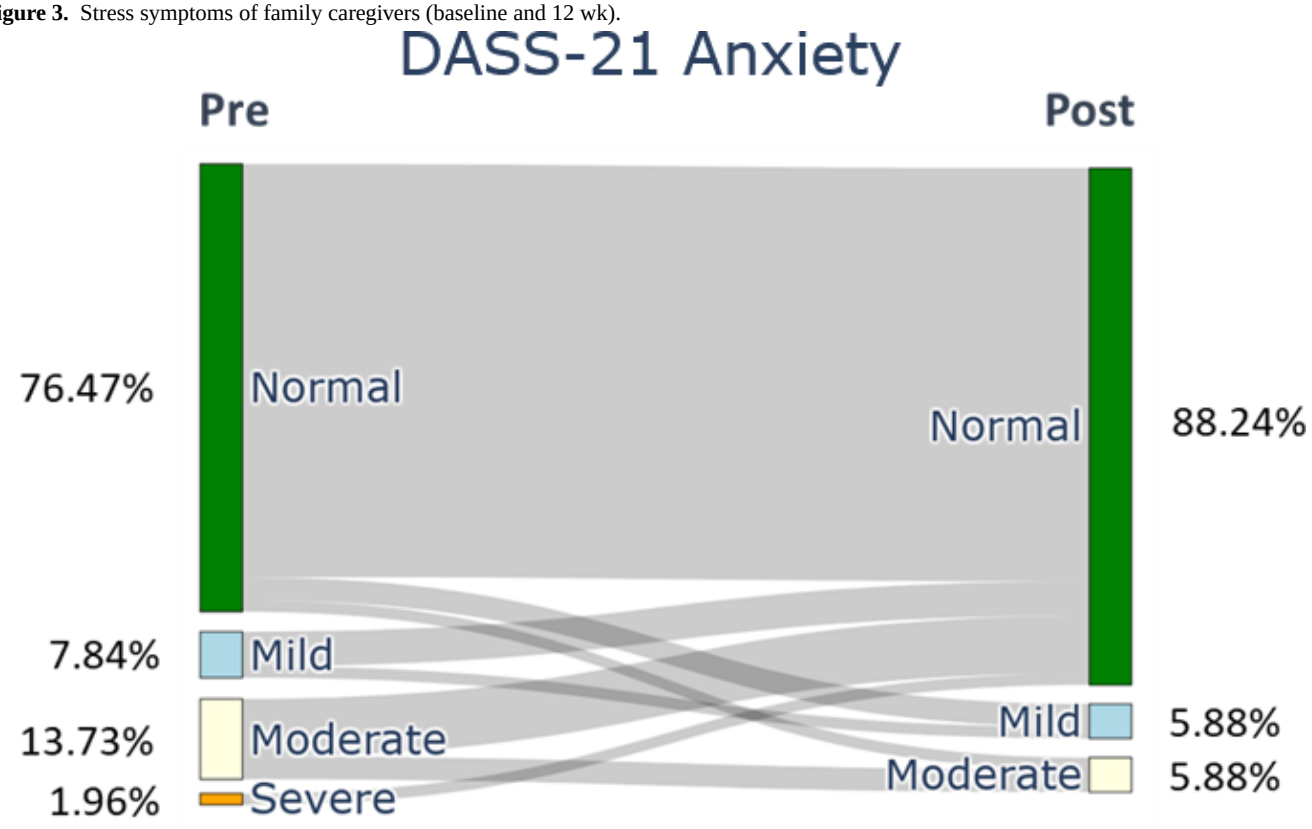
Figure 3. Stress symptoms of family caregivers (baseline and 12 wk).



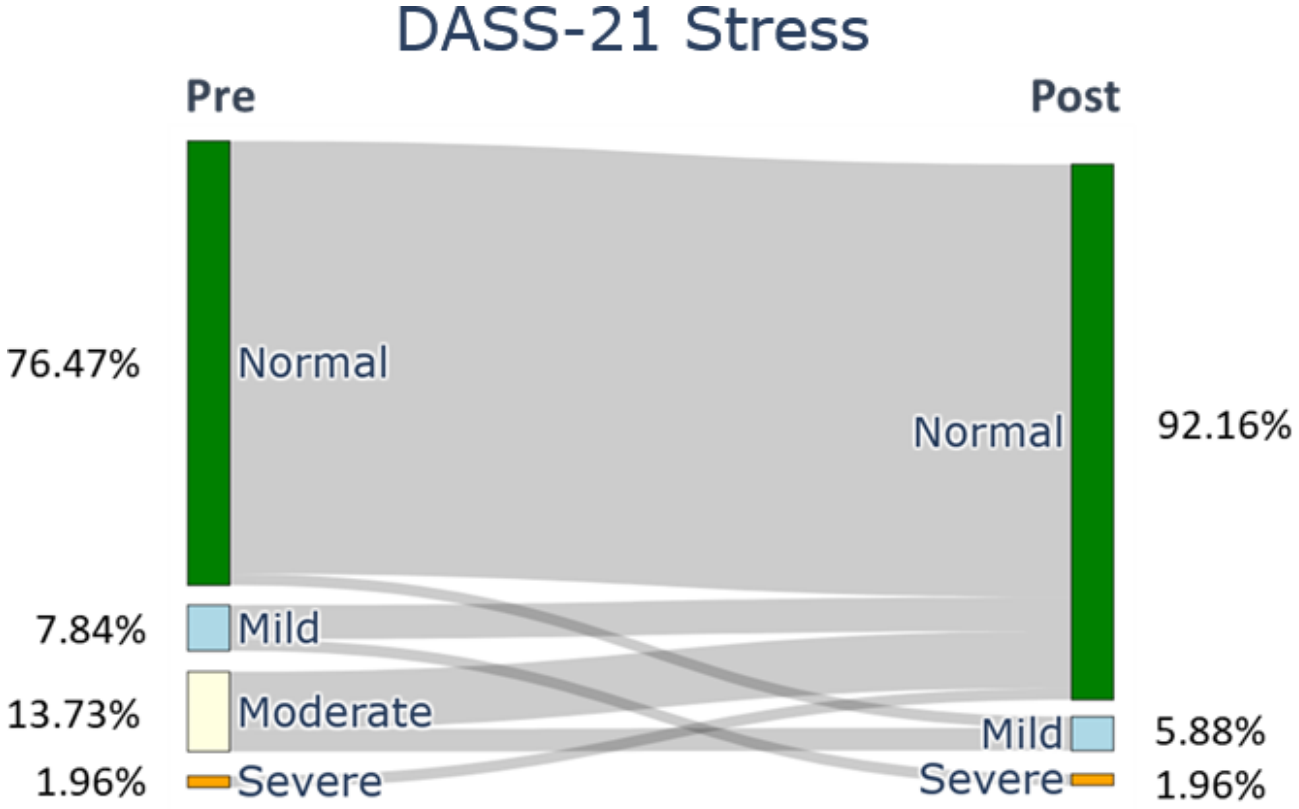


Figure 4. Stress symptoms of family caregivers (baseline and 12 wk).

Adult Growth Prediction

In this study, growth data (height) have been analyzed post hoc for studying the impact of the intervention on patients treated with GH in a post hoc explorative analysis phase. In this sense, patients' growth estimations are calculated by means of deviation from baseline children's growth charts, based on the participants' adherence levels to GHt. Specifically, measurements of patients' height were collected in four fixed

XSL•FO
RenderX

time points: (1) 6 months before treatment, (2) start of treatment, (3) start of the study, and (4) 6 months after the start of the study. Finally, another important variable ΔHSDS (change in height standard deviation score) that has been computed is the change in height deviation values between consecutive time points. The impact of the intervention in the growth status was analyzed by focusing on the patients who switched from medium to high adherence (~70% of the participants). Thus, assuming that without participation in the study, the patients' adherence levels would have been medium, and the overall effect on mean ΔHSDS was computed by comparing the 48-month estimations of medium-only (hypothetical) cases with the real situation (70% high and 30% medium adherence, based on data analysis).

The average estimated ΔHSDS value for patients with medium adherence was 0.9, while that of the real (70% high and 30% medium adherence) cases was 1.04. Hence, an increase of 0.14 was observed in terms of ΔHSDS, meaning that the average participant is going to grow more thanks to the intervention. In other words, the increase in ΔHSDS indicates a reduction in the height gap between the patient's actual growth and the expected growth based on baseline charts. This suggests improved growth outcomes due to better adherence to the treatment.

Discussion

Principal Results

The management of children undergoing GHt has been reported to be burdensome [14]; specifically, it can be a time-consuming and exhausting process as family caregivers need to (1) ensure that their children receive the injections at the right time and at the correct dosage while providing emotional support and (2) address any mental health issues that may arise. Family caregivers' fatigue and stress can negatively influence treatment adherence and the child's health [14,15]. This research contributes to the emerging work in supporting family caregivers of children undergoing GHt using digital tools [28] by showing that the ACDP can effectively empower family caregivers of children with GHD, including improvements in the well-being of both parents and children while promoting self-management of the condition.

Participants have reported a better quality of life and general health, as well as improvements in key points such as cognitive symptoms, mood, and emotional and social well-being. Most families involved in the study achieved optimal levels of adherence after the study. We found a statistically significant increase in positive affect (from 30.78, SD 7.27 at baseline to 36.53, SD 8.65 at the 3-month follow-up) with a statistically significant decrease in negative affect (from 18.98, SD 6.02 to 14.57, SD 4.18), which was measured using the PANAS. Also, the MHC-SF revealed a statistically significant increase in general well-being (from 0.62, SD 0.17 to 0.69, SD 0.21), social well-being (from 0.52, SD 0.19 to 0.65, SD 0.22) and general self-efficacy (from 31.31, SD 5.51 to 33.43, SD 5.31), with an increase in emotional (from 0.67, SD 0.20 to 0.71, SD 0.20), and psychological well-being (from 0.67, SD 0.18 to 0.72, SD 0.23). KIDSCREEN-10 revealed a statistically significant increase in HrQoL (from 49.19, SD 10.82 at baseline to 60.89, SD 16.86 at the 3-month follow-up) and a statistically significant increase in general health (3.43, SD 0.81 to 4.22, SD 0.81). Regarding the quality of life of youths with short stature, we found a statistically significant increase in scores on the physical scale (from 75.57, SD 19.51 to 81.94, SD 18.38), social scale (from 69.83, SD 20.35 to 77.72, SD 18.15), coping scale (from 40.98, SD 17.25 to 48.48, SD 21.32), height-related beliefs scale (from 8.31, SD 25.96 to 66.30, SD 28.20), treatment scale (from 53.54, SD 17.77 to 67.37, SD 21.93), and child's future scale (from 73.63, SD 25.57 to 82.65, SD 17.98), as well as an increase in HrQoL (from 74.94, SD 15.93 to 80.67, SD 14.46), and emotional scale (from 79.41, SD 15.07 to 82.35, SD 13.53). Lastly, we found statistically significant increases in growth rate on the child's short stature on the family's section of the QoLISSY (from 68.45, SD 18.94 to 77.72, SD 18.20) and treatment adherence (from 80.27, SD 4.77 to 88.98, SD 9.84).

Our findings show that at baseline, 21.56% (n=11) of caregivers reported depression symptoms, categorized as mild (11.76%, n=6), moderate (7.84%, n=4), and extremely severe (1.96%, n=1). Post intervention, depression was reduced to only severe (1.96%, n=1). Anxiety levels at baseline were mild (7.84%, n=4), moderate (13.73%, n=7), and severe (1.96%, n=1) for 23.53% (n=12) of caregivers. After the intervention, 11.76% (n=6) of caregivers reported mild (5.88%, n=3) or moderate (5.88%, n=3) anxiety levels. Stress symptoms also improved; initially, 23.5% (n=12) reported mild (7.84%, n=4), moderate (13.72%, n=7), and severe (1.96%, n=1) stress. Following the intervention, stress symptoms reduced to 7.84% (n=4), with only mild (5.88%, n=3) and severe (1.96%, n=1) symptoms remaining.

Limitations

This is a local study conducted in Zaragoza (Spain) with a small sample and no comparison arm. Because of inclusion/exclusion criteria, people with low digital literacy were not able to participate. Although the general prevalence of GHD is higher in boys, most caregivers participating in this study had daughters who have GHD; thus, parents of boys with GHD might have been underrepresented.

Comparison With Prior Work

The findings from this study align with and extend previous research on digital interventions aimed at supporting family caregivers of children undergoing GHt. Prior studies have highlighted the significant burden on family caregivers managing GHt, including the physical, emotional, and psychological stress that can negatively impact treatment adherence and the overall health of the child [13]. The ACDP demonstrates notable advancements in this area by providing a comprehensive digital health intervention that effectively supports both the physical and mental well-being of caregivers [33].

Previous research by Arriba et al [34] suggested that mobile solutions could potentially improve GHt adherence by addressing the emotional states of parents and caregivers. Our study, albeit observational, provides further evidence that digital tools appear to significantly enhance adherence rates by improving caregivers' psychological states. In particular, our study revealed a statistically significant increase in treatment

XSL•FO
RenderX

adherence from baseline (below 85%) to postintervention levels, with 75% of families reaching optimal adherence.

Furthermore, the mental well-being of caregivers showed substantial improvement, a finding consistent with earlier work by de Arriba et al [34], which highlighted the positive impact of the ACDP on caregivers' mental health. Our findings show that at baseline, 21.56% (n=11) of caregivers reported depression symptoms, categorized as mild (11.76%, n=6), moderate (7.84%, n=4), and extremely severe (1.96%, n=1). Anxiety and stress levels also showed marked reductions, aligning with the findings from the study by Cervera-Torres et al [22], which emphasized the importance of digital health support for emotional and self-management needs.

Moreover, our study's comprehensive assessment of quality of life and well-being metrics—using tools such as the PANAS, MHC-SF, and KIDSCREEN-10—demonstrated significant improvements in cognitive symptoms, mood, emotional and social well-being, and general health. These results further extend the insights from the study by Savage et al [13], which discussed the transformative potential of patient-generated data in integrated care models for GHt. The significant increases in positive affect, general well-being, social well-being, and self-efficacy among participants underscore the holistic benefits of digital health interventions.

Conclusions

In conclusion, the ACDP showed favorable acceptance for family caregivers of children undergoing GHt. It is a promising tool and has been demonstrated to add value to the patient and caregiver journey by improving GHD management while supporting the overall well-being of family caregivers. It has helped parents improve their mental well-being as well as treatment adherence. This study provides insights into how digital interventions can better support families of children undergoing GHt.

Acknowledgments

Abstract

Background: Health care chatbots can be used to support patients and their families with everyday decision-making. While there is some research on integrating artificial intelligence into pediatric care, no study has focused on the opportunity of implementing a generative artificial intelligence chatbot for pediatric rheumatology. Pediatric rheumatology conditions require intense family input, which can often leave families struggling to navigate disease flares, pain, fatigue, medication side effects and adherence, and support of their child, often when pediatric rheumatology departments are shut. Understanding how we can support families better, without the need for increased personnel, will have implications for the health care systems.

Objective: The study aimed to explore parental and children and young people's acceptance of chatbot use in a pediatric context, and understand how a chatbot could be specifically used for managing a child's chronic health condition.

Methods: This study was a mixed methods design, using both a family workshop and a subsequent questionnaire.

Results: In total, 22 participants contributed to the qualitative design using the world café methodology at a workshop, and 47 participants (36 parents and 11 children and young people) completed quantitative data via a questionnaire. Participants expressed their likelihood of using chatbot technology, including ChatGPT, due to its accessibility. However, participants had significantly greater intention (parents: $P<.001$; children and young people: $P=.006$) to use a specific chatbot over ChatGPT, due to increased trust, credibility, and specificity in design. Children and young people and parents should be distinguished as 2 user groups in chatbot design, reflecting their specific needs in chatbot features and personalization.

Conclusions: Overall, the study reinforced the need for a specialized and trusted chatbot designed with input from health professionals to assist families in managing complex chronic health conditions to support families in between appointments and complement existing face-to-face care. Future research should evaluate users' engagement with a functional prototype to investigate its usefulness and explore its implementation into families' everyday lives. Importantly, the current findings have broader implications for the field of pediatric health care, as similarly tailored chatbot interventions could benefit families who are managing other chronic health conditions.

(JMIR Pediatr Parent 2025;8:e70409) doi:10.2196/70409

KEYWORDS

pediatric health care chatbot; technology acceptance; parental attitudes; children and young people's involvement; chronic disease management; AI hesitancy; chronic health condition; artificial intelligence

Introduction

Background

Generative artificial intelligence (GenAI) tools, such as ChatGPT and health care chatbots, have become increasingly accessible. However, their adoption into health care is still in its infancy. Pediatric rheumatological chronic conditions are autoimmune disorders where the body wrongly attacks itself, as such they have no clear etiology and cure [1]. Juvenile idiopathic arthritis is the most common rheumatological condition affecting one in every thousand children and young

XSL•FO
RenderX

people, causing painful joint inflammation and damage often into adulthood [2,3]. Trial and error of treatments are often needed to manage symptoms and hopefully send children and young people into remission, where the disease becomes inactive. Parents need to take charge of managing their child's health, especially when health professionals are unavailable [4]. Thus, managing a chronic condition can cause a psychological burden to children and young people and their families.

Health professionals often use medical jargon, while parents favor more neutral and simpler terminology for their children [5]. This widens a gap in effective family-clinician communication, which could manifest in medical nonadherence and impact overall treatment efficiency [6]. As parents need to interpret complex information to an appropriate comprehension level for their children, their emotional burden also increases [7-10].

Emerging research on chatbots has demonstrated their opportunities and limitations in health care applications. ChatGPT is a general large language model (LLM) that has been found to be feasible in generating detailed and empathetic responses to patients' health inquiries [11]. Yet, it is prone to fabricate academic sources, a phenomenon known as "hallucination" [12]. ChatGPT also requires clear input from users to generate more accurate responses, than using ambiguous prompts [13].

Existing health care chatbots have shown promise in improving patient outcomes through integrated care [12,14]. Seeking health information web-based health information could be appealing due to its convenience, availability, and privacy when health professionals are unavailable [15]. Compared to general internet resources, chatbot use could reduce engagement with inaccurate and often overwhelming amounts of information on the internet [16]. However, maintaining clinician-patient communication remains important to prevent self-diagnosis [17]. Therefore, there is a need for a trusted and accessible resource to support families' decision-making, alongside health care providers.

It is crucial to understand users' adoption intention to ensure successful embedment of artificial intelligence (AI) intervention into their everyday lives [18,19]. Based on Ajzen's [20] theory of planned behavior, research on chatbot acceptance in health care [21,22] has identified key factors influencing adoption intention. The theory posits that an individual's behavior is determined by their behavioral intention, which is influenced by personal attitudes, subjective norms, and perceived behavioral control. Personal attitudes are suggested to be the most influential factor of behavioral intention as attitudes reflect individuals' own beliefs and schemata [20,23]. For example, Nadarzynski et al [21] found that perceived usefulness, perceived ease-to-use, and curiosity, predicted acceptance of chatbots, though lack of trust and humanness remain concerns. In pediatric care, parental attitudes toward general AI use reveal safety and ethical concerns [24,25].

A limitation of existing studies is that findings might not be generalizable to children with diverse medical backgrounds. For instance, only 24 out of 804 (3%) parents had experience with child hospitalization in Sisk et al [26]. Haley et al [27] found that parents of a child who had been hospitalized significantly prioritized AI accuracy, than those who had not. These families might have unique experiences with medical care, increasing barriers to adopting a novel intervention.

Existing research has also neglected children and young people's involvement as they often considered parental attitudes. Involving users in the development of AI health technology could increase transparency and trust while preventing dissatisfaction and disengagement [28,29].

Research Aims

The ongoing "IMPACT" (Interventions to Improve Mental Health Support in Families With Children and Young People With Chronic Rheumatological Conditions) project [30] aims to design, develop, and test a chatbot intervention to support families between appointments for pediatric rheumatological conditions. However, as part of this work, an opportunity arose to gain an understanding of parental and child thinking surrounding AI in general in health care. We, therefore, aimed to explore the attitudes and technology acceptance perspectives of parents and their children and young people. The overall aim is not for a chatbot to replace existing traditional care, but to enhance the support of families between appointments.

This study consists of 2 methodologies. The first piece of work presents data from a family co-design workshop, where families' opinions on using a chatbot in a pediatric health care context were gathered. Subsequently, a questionnaire was conducted to follow up on the findings identified at the workshop. This mixed methods design allows further probing of the data from the workshop and thus aids a richer insight into perspectives of AI in health care. This study presents both (1) the workshop and (2) the questionnaire, split into separate methods and results, with a combined discussion.

This study aims to address the following research questions (RQs): (RQ1) What are parental and children and young people's general attitudes and behavioral intentions toward chatbot use, such as ChatGPT? (RQ2) What are parental and children and young people's attitudes and behavioral intentions toward the potential use of a chatbot specifically designed for pediatric rheumatology and do they differ when considering ChatGPT? (RQ3) What are the opportunities and concerns parents and children and young people might have toward chatbot features and content?

Methods

Study Design

The methods section will first present information relevant to the workshop, followed by the questionnaire. This study used a mixed methods design. The main aim was to use qualitative data to understand the acceptance and use of a rheumatology-specific chatbot for parents. Quantitative data have been added to briefly outline the current use of GenAI or similar, with the main focus investigating the attitudes and intentions of using AI to inform health care management. The main target audience was parents, however, as their children also attended the family workshop, we felt it would be an opportunity to seek their perspectives.

XSL•FO
RenderX

Ethical Considerations

Ethical approval was granted by the Research Ethics Committee at National Health Service (NHS) Health Research Authority, Leeds West Research Ethics Committee, and HRA and Health and Care Research Wales (IRAS 329476). The research project has been reviewed and approved locally at Great Ormond Street Hospital for Children NHS Foundation Trust for capacity and capability. The "IMPACT" study officially opened at Great Ormond Street Hospital for Children on November 10, 2023 (study: 23IR07). Informed consent was sought from all participants. Secondary analysis utilising existing data from the IMPACT study was obtained with primary consent for participating in the project. Quantitative data was fully anonymised, whilst qualitative data was deidentified as outlined in the participant information sheets and consent forms. Participation was voluntary, and no compensation was received.

Family Workshop (May 2024, London)

Design

The workshop used the world café forum method, a qualitative participatory method used in health research [31-34]. In groups, participants rotate around tables to take part in different discussions. The host of each table remains to facilitate the cross-pollination of ideas from previous groups [33]. Participants are encouraged to express themselves creatively in texts or drawings [32].

The corresponding author acted as a table host to guide discussions. A young adult in remission from juvenile idiopathic arthritis and their parent acted as facilitators to maximize participant comfort and engagement, as they shared similar experiences. Another researcher acted as a notetaker. As part of the larger study, there were 7 other tables with different research focuses.

At our table, participants familiarized themselves with 3 sets of questions and ChatGPT responses regarding pediatric rheumatological conditions in a concept testing activity (Multimedia Appendix 1). These 2 conditions were used in relation to participants' personal experiences. ChatGPT was prompted to generate responses appropriate for either a 6-year-old child or a 13-year-old teenager. Participants were then asked to discuss their likes, critiques, and opportunities regarding these responses.

Participants

Families living with a pediatric rheumatological condition requested to attend the workshop after receiving a flyer from their local health care team across the United Kingdom as they attended clinical appointments or via social media advertisements from relevant charities. There were no restrictions on who could attend and whole families were encouraged to attend. To protect families' anonymity, limited demographic and identifiable information was collected. Inclusion criteria were that families needed to have experience with a pediatric rheumatology condition and be able to speak English. The participants had received rheumatology care from different parts of the United Kingdom. The main target group for this study was parents and carers, as the chatbot created as part of the IMPACT study is targeting parents and carers in the first instance. However, as children and young people also attended the workshop with their parents, their views were also explored to understand the differences and similarities between caregivers and children and young people.

Materials

As the world café method collects creative qualitative output, participants were provided with sticky notepads, colored pens, and paper to share their ideas. Printed handouts of ChatGPT responses were also provided. A computer was used to host a live interactive demonstration of ChatGPT.

Procedure

Participants were divided into 8 groups that rotated among 8 tables every 20 minutes, with 3 breaks provided to avoid fatigue. Prior to the main activity, the host, facilitators, and participants introduced themselves to one another.

To enable conversations to occur freely, audio recording was not conducted at any table at the workshop. However, detailed notes were taken by 2 notetakers, who then cross-compared their notes to ensure objectivity [35]. Hand-written notes by the participants were also collected. At our station, we conducted a live demonstration using ChatGPT to ease participants into the discussion. Then, participants were asked a set of structured questions and probes, 5 minutes after reading the ChatGPT responses. At the end, all participants and researchers gathered to have a debrief.

Other tables had similar setups. Detailed compiled notes were shared among the researchers electronically postworkshop to be used as secondary data if relevant. One of the other tables explored participants' consensus on chatbot features in a brainstorming activity, which generated relevant findings to answer RQ3. The findings from the brainstorming activity were summarized by notetakers and therefore no transcripts are available. This strategy helped enrich the dataset and allowed cross-comparisons between data compiled by different researchers, increasing interrater reliability.

Analytical Approach

A qualitative descriptive method was followed to stay close "to the surface of words and events" on a semantic level [36]. Trends were noted as the groups progressed leading to data saturation, but with specific attention to ensuring all participants were encouraged to share their perspectives, Since notes taken from the world café forums were already interpreted to some extent, this approach could mitigate further interpretative bias. The "IMPACT" Chief Investigator (PL), who is a senior pediatric rheumatology nurse with qualitative expertise, and Research Facilitator (KK) oversaw the data process and analysis.

For the concept testing activity, a deductive approach was appropriate as the questions were designed according to the predefined categories of "likes," "critiques," and "opportunities."

Questionnaire

Design

The questionnaire design was informed by our workshop findings and a pilot study (n=22) was conducted to test the

XSL•FO
RenderX

comprehensibility and relevance of questions. A nonstandardized questionnaire was devised for the purpose of this study to allow for bespoke questions to build upon workshop findings. The potential issues of language barrier, AI literacy, and children's comprehension level were considered. It was decided that the wording of questions should be kept simple and the number of question items on each construct should be reduced.

Using pilot feedback from the workshop, iterations were made. Initially, the term "ChatGPT" was used instead of "generative AI" or "chatbot" in the questions to provide clarity to those with less knowledge in GenAI. However, it might have measured attitudes specifically toward ChatGPT. For example, a parent said they would not use ChatGPT because "it doesn't give source references for its reply." While fabrication might be observed in ChatGPT, a specific chatbot could eliminate this issue. Therefore, questions were rephrased to measure and compare attitudes toward ChatGPT or similar GenAI and a rheumatological-specific chatbot. The final questionnaire was distributed electronically to ensure completion.

Participants

Participants were recruited separately from the workshop. Using a purposive sampling method, families who had already expressed interest in the "IMPACT" study were emailed the questionnaire link. Parents were the point of contact and were asked to share the child questionnaire link with their child if they were aged 8 years and older and wanted to take part. We asked that each family be represented by one parent only, but their children and young people may have also completed a questionnaire. This sample might have overlapped with the sample of the workshop and pilot study due to the anonymity provided through the questionnaire, the numbers of these are therefore unknown.

Materials

Two versions of the questionnaire were designed, one for parents and one for children and young people, consisting of 13 and 11 questions, respectively. Participants were asked for their age, current internet health information–seeking behavior, and their current use of ChatGPT or similar GenAI. Then, participants were introduced to ChatGPT. Next, they were asked about their behavioral intention of using ChatGPT for seeking health information. This was followed by a short answer question where participants were asked to explain their rating. Participants were then presented with a scenario of a health care chatbot specifically designed by health professionals for pediatric rheumatological conditions. They were asked to rate their intention toward using this specific chatbot and explain whether their attitudes differed regarding the general and specific chatbot. Additionally, parents were asked whether their behavioral intention to use a chatbot for health care differed when it was for their child's health or their own health.

Procedure

The questionnaire was reviewed by the "IMPACT" Chief Investigator and Research Facilitator for iterations. The questionnaire was distributed through REDCap (Research Electronic Data Capture; Vanderbilt University) and sent out via email on June 21, 2024, to 60 families. A reminder was sent on June 25, 2024, and access to the questionnaire was closed on July 1, 2024.

Analytical Approach

Using Likert rating and open-ended questions, the questionnaire generated both quantitative and qualitative data. To investigate whether there is a within-group attitudinal difference in using ChatGPT and a rheumatologically specific chatbot for health, a post hoc 2-tailed Wilcoxon signed rank test was conducted. As the data were not normally distributed, the nonparametric design was used to interpret the data. Reliability measures were not used due to the minimal questionnaire design, considering sample characteristics. SPSS Statistics (version 29; IBM Corp) was used for quantitative analysis.

Braun and Clarke's [37,38] and Bryne's [39] 6 phases of reflexive thematic analysis were used to interpret the qualitative data. The steps followed included (1) familiarization with the data where participants' responses were read through to understand the overall tone and content; (2) ascribing primary codes; (3) secondary inductive coding; (4) clustering codes together to identify common ideas, factors, and findings; (5) transforming clusters into relevant and understandable themes; and (6) creating the report [37-39]. The entire analytical process and any discrepancies were regularly discussed with the "IMPACT" team (PL and KK). An audit trail and reflective data were kept at every step. An inductive thematic approach was used to analyze open-text responses to avoid overlooking unexpected themes [37]. Data were analyzed at a semantic level, staying true to participants' perspectives, which is appropriate for understanding individual stories and contexts in health research [40].

Results

The results section will first present the family workshop findings, followed by findings from the questionnaire.

Workshop Findings

Two tables at the co-design workshop explored possible chatbot features and the opportunity of using a chatbot in pediatric rheumatological care, respectively. In total, there were 8 groups of mixed participants which included children and young people (n=9; age range 5 - 26 y; mean age 13.3, SD 6.3 y) and parents (n=13). Each group consisted of 2 - 5 participants.

Chatbot Features

Personalization

Participants felt that the chatbot needs to evolve with them. For instance, families felt that simple language should be used at the beginning of diagnosis. However, explanations should become more advanced in the subsequent years as families become more familiar and do not want to feel patronized. An opportunity proposed by one participant was the idea of a "science-ometer" slider for users to dictate how scientific they wish the explanation to be. Overall, participants thought that the chatbot should be tailored to the individual patient's age, personality, and neurodiversity.

XSL•FO
RenderX

Tone

Participants thought that the specific chatbot should have a friendly, reassuring, and trustworthy tone. However, they attributed most of the trustworthiness to the endorsement by the NHS behind the design of the chatbot. Children and young people thought that the chatbot should not feel medical at all but like a peer. However, parents wanted to talk to a mentor figure, whether that is a parent with more experience or a health professional.

Anthropomorphism

The younger participants wanted to pick an animal avatar that "felt right" for them, such as a dolphin. This feature was less important for older participants and parents, who prioritized the content. They also expressed that the chatbot name or avatar would not affect their intended use. However, they also proposed other symbols to represent the chatbot, such as a torch or volcano.

Concept Testing

Conducting concept testing is advantageous in the early development of an intervention to reduce the risk of users not liking the concept, leading to limited adoption [41]. Table 1 provides a summary of users' likes, critiques, and posed opportunities.

Table . Summary of concept testing findings.

Categories	Comments
Likes	• Visual Imagery aids explanation and understanding. • Storytelling narrative is relatable. • The more technical version actually explains how the illness works well.
Critiques	• Children of similar ages do not always think in the same way, since they are exposed to different things. • Unless age is put into the prompt, users are shown information that is too confusing. • The analogy used in the 13-year-old explanation attempted to sound more technical but still used the castle analogy that was used in the explanation for a 6-year-old. It was confusing and inappropriate.
Opportunities	• Doctors' and experts' input is required for the chatbot to be reliable. • Doctors should be able to see a record of questions asked by the families to aid communication. • The child should be considered as a user for autonomy.

Questionnaire Findings

Overview

A total of 47 participants were recruited, including 36 parents and 11 children and young people (see Table 2 for demographic information). Responses to closed questions are summarized in descriptive statistics first, followed by statistical analyses. Qualitative findings are supported by the use of participant quotes ("P" denotes parent and "CYP" denotes child or young person quotes). Subsequently, qualitative analysis of responses to open-ended questions is discussed.

XSL•FO

Castleman/mixed connective tissue/morphea/rare genetic disorder/scleroderma/SLE[g]	8 (22)	1 (9)

[a]Parents and children and young people may not be from the same families.

[b]JIA: juvenile idiopathic arthritis.

[c]JDM: juvenile dermatomyositis.

[d]CAPS: cryopyrin-associated periodic syndrome.

[e]CRMO: chronic recurrent multifocal osteomyelitis.

[f]PFAPA: periodic fever aphthous stomatitis.

[g]SLE: systemic lupus erythematosus.

Descriptive Statistics

A total of 26 (70%) parents stated that they had heard of ChatGPT or other GenAI before, but only 14 (39%) of these said they had used any AI platforms. Of those who had, they used it for work purposes (n=11), while others (n=3) used it for general questions or "only experimented" with it. On the other hand, all 11 children and young people (100%) had heard of the technology. Less than half (n=5, 45%) had used it before; for learning (n=3), research work (n=1), and asking general questions "like the Snapchat AI" (n=1). Participants rated their self-confidence in using ChatGPT or similar GenAI technology on a 5-point Likert scale (1=not at all confident, 5=extremely confident), which was found to be low for both parents (median 2, IQR 1-3) and children and young people (median 2, IQR 1-4).

Participants were also asked to rate their likelihood of using ChatGPT or similar GenAI technology on a 5-point Likert scale (1=not at all likely, 5=extremely likely). Children and young people gave a high rating for their likelihood to use a specific chatbot (median 4, IQR 3-4) compared to ChatGPT (median 2, IQR 1-4), with a larger discrepancy indicated in the latter. Parents also rated the intended use of a specific chatbot (median 4, IQR 4-5) higher than ChatGPT (median 3, IQR 2-4) in managing their child's condition. Additionally, parents' ratings for using ChatGPT for their child's health were slightly lower than using it for their own health (median 4, IQR 2-4).

Inferential Statistics

A Wilcoxon signed rank test confirmed that there was a statistically significant difference in parents' attitudes toward using either a general or specific chatbot to assist in managing their child's health (z score=3.8; P<.001; r=0.63). Children and young people's attitudes were consistent with those of their parents (z score=2.5; P=.006; r=0.75). A total of 21 parents and 8 children and young people self-reported to be more likely to use a specific health chatbot than a general chatbot like ChatGPT. The likelihood of use was tied among 13 parents and 2 children and young people. In addition, 2 parents were more inclined to use ChatGPT than a specific chatbot for their child.

Qualitative Analysis of Questionnaire

Two follow-up questions were asked to better understand the reasons behind their ratings. Three themes were identified: accessibility, trust, and credibility in a chatbot, and specificity of chatbot design. Each theme was divided into subthemes, with quotes from participants as supporting evidence. Two subthemes in accessibility and trust and credibility did not include any quotes from children and young people because their responses were not relevant to the particular subthemes.

Theme 1: Accessibility

Limited Accessibility to Health Care Professionals

None of the children and young people mentioned the role of health professionals, whilst one participant noted their dependence on their parents. Parents expressed how using a

XSL•FO
RenderX

chatbot can mitigate the issue of having limited accessibility to health care professionals when they have questions about their child's health. As a result, many noted that they seek advice anywhere and appreciate any help. For example:

> *Any help is better than no help.* [P2]
>
> *I know the doctors do not have the time to spend with us to answer all our questions.* [P22]

Efficient Tool for Information-Seeking

One child or young person mentioned that they did not think of using ChatGPT for seeking health information before but for academic purposes only. Parents perceived the chatbot to be an efficient tool in terms of time and accessibility for information seeking, even when they were specifically asked about ChatGPT.

> *I think it's the way forward to get immediate access to health information, I've just been hesitant to use it previously but can now see the benefits of using it.* [P9]

Comprehension Accessibility

Another aspect of accessibility was the level of comprehension of health information. Parents thought chatbot-generated information could be rational, tailored, and understandable for the child. A parent said they would value tailored chatbot answers due to challenges with accessing health professionals.

> *Because it would give rational and factual information rather than trying to get answers that would not be appropriate for my child.* [P14]

Theme 2: Trust and Credibility in a Chatbot

Concerns Regarding ChatGPT's Inaccuracy

Both parents and children and young people expressed a lack of trust and confidence regarding the inaccuracy of ChatGPT on 2 levels: its open-source nature and its processing ability of complex medical information. Participants thought that ChatGPT could learn from sources that are not verified, resulting in unreliable, fabricated, or biased output. Participants also expressed distrust toward ChatGPT specifically for health care purposes, due to how complex medical information could be.

> *[ChatGPT] It is open source so [it] may use unreliable or biased sources and it is dependent upon the prompts provided so in a medical context it could be easy to get it wrong and receive inaccurate responses.* [P34]
>
> *Mainly [I have not used it] because I hadn't thought of doing so. After some thought, I wouldn't trust the information to be accurate.* [CYP3]

Unfamiliarity With Using the Technology Limits Trust

Some parents voiced their unfamiliarity with chatbot technology which led them to not having tried ChatGPT before. Therefore, they were not certain about its usefulness. Yet, all parents seemed open-minded to give the technology a try.

> *I prefer to speak to a person who can understand nuance but would be open-minded to give AI a go ... the proof would be in the experience.* [P32]

Reliance on Other Credible Sources

Participants compared chatbot use for health care to other sources that are deemed more credible, such as NHS resources and published research papers. Some participants sounded hesitant as they said that they expressed uncertainty about ChatGPT's accuracy and reliability.

> *I tend to look for the NHS website or research papers that have been published on the topic rather than asking a chatbot type for answers more so because I then can cite the information and figure out where it's all come from. I am not sure if you can do that with ChatGPT.* [CPY4]

Theme 3: Specificity of Chatbot Design

Active Involvement of Health Care Professionals

Input by health professionals and experts in the design of a specific chronic health-focused chatbot was perceived to increase its accuracy and reliability, compared to ChatGPT. Participants expressed increased comfort with using a specifically designed chatbot. However, participants' perception was solely based on their expectations rather than experience as the chatbot has not been developed yet.

> *Due to it being more regulated and designed by health professionals who will hopefully monitor effectiveness and reliability of content.* [P25]
>
> *If the information is given by a specialist who deals in these illnesses day in [and] day out, I am way more inclined to trust the information given due to it being a reputable source. It's a confident way to ask information and receive in a familiar way with the added comfort of knowing it is from a reputable source. Which is why my opinion changed rather drastically in a positive way [compared to ChatGPT].* [CYP4]

Fit-for-Purpose

All participants expressed that they were more inclined to use a chatbot that is specialized in rheumatology compared to a general chatbot like ChatGPT, GenAI, or Google. The importance of specialization due to the rarity and complexity of conditions and symptoms was highlighted.

> *It's important to us to have a resource available for this chronic condition that is not the same as Google.* [P28]
>
> *If it's specific to JDM, I would be far more likely to use it [than ChatGPT]. JDM is so rare, that questions wouldn't be answered unless it was programmed specifically for JDM.* [P5]
>
> *Rheumatological conditions can have such a vast array of symptoms that a nonhealth backed system could become quite scaremongering in leading to false information. If using a platform that has already narrowed down the results to trusted rheumatology*

XSL•FO
RenderX

information, I would feel a lot more comfortable using it [than ChatGPT]. [CYP3]

Discussion

Principal Findings

Using a mixed methods approach, we were interested in exploring both parental and children and young people's attitudes and behavioral intentions toward using ChatGPT, a general chatbot that is commercially available in a health care context (RQ1), as well as their attitudes and behavioral intentions toward using a chatbot that would be specifically designed for pediatric rheumatology. The major difference between these 2 applications concerns the content returned to families, with a specifically created disease-specific chatbot only having access to a "closed system" of physician-endorsed data, rather than the ability to search the internet and bring back results with no safety netting from a health professional. We wanted to investigate whether the behavior intentions differed and if so, how (RQ2). Opportunities and concerns raised by children and young people and parents toward chatbot features and content were identified to indicate practical design implications (RQ3).

Children and Young People and Parental Attitudes and Behavioral Intentions Toward ChatGPT and a Specific Chatbot (RQ1, RQ2)

The themes that emerged from the qualitative data contribute to our understanding of participants' attitudes and behavioral intentions supported by the quantitative data. The accessibility of the chatbot to families was a key influencing factor in adoption intention. Parents explained that they would be likely to use the chatbot as they saw it as a time-efficient and easily accessible tool to turn to when health professionals are not available. Parents found chatbot technology, including ChatGPT, to be more direct and quicker in giving them the answers they need than other web-based resources. This may explain why parents were equally likely to use it for their own health and their child's health. While it was not measured whether parents have health conditions themselves, they seemed to hold some health behavior motivation and curiosity toward a new accessible intervention. The findings are in line with previous research, which identified curiosity, perceived ease-of-use, and convenience to be motivators of health care chatbot adoption [21,42]. Chatbots, whether generally or specifically designed, could bring convenience to parents when health information-seeking. The integration of GenAI into the health care system is believed to have a positive impact on supporting medical research and decision-making for patients, families, and health care workers [43].

Our results showed that there was a statistically significant difference between participants' likelihood of using ChatGPT and a specific chatbot for managing their child's chronic health condition. Both parents and children and young people were significantly more likely to use the specific chatbot than ChatGPT for this purpose.

Trust and credibility in a chatbot was another theme identified. It highlighted participants' concerns regarding ChatGPT's accuracy which limited trust. They questioned its reliability due to open-sourcing and fabrication tendencies. Existing studies have consistently identified trust as a crucial factor in converting new users to adopt a novel technology intervention like a chatbot across contexts [21-23]. Additionally, participants thought that ChatGPT might not understand complex medical information in pediatric rheumatology and provide accurate responses. Participants' unfamiliarity with ChatGPT might have also contributed to the overall low rate of current use. Despite finding ChatGPT accessible, participants would rather obtain internet resources from trusted sources, like the NHS website. Participants demonstrated careful evaluation of ChatGPT content, which is congruent with how patients processed and sought health information on the internet in Sillence et al [44]. While perceived ease-of-use and convenience could increase adoption intention to using a health care chatbot, users must first establish trust [23]. This is supported by Abbasian et al [45] who found that accuracy, trustworthiness, and empathy should be assessed when evaluating health care–specific chatbots.

What differentiated participants' attitudes toward ChatGPT and the specific chatbot was the addition of health professionals' input and the specific design focus in the latter. The theme of specificity of chatbot designs showed that users expected the specific chatbot to be specially trained to recognize information related to rheumatological conditions. A strong need for a resource specific to pediatric rheumatology was expressed due to the disease's complexity. The specialized tool was perceived to be more reliable than ChatGPT, increasing users' trust in its evidence-based input and monitored output. Participants displayed a high level of trust toward the specific chatbot and made comparisons to ChatGPT. Participants' trust toward the specific chatbot might be explained by the theory of planned behavior [20]. It posits that subjective norm influences behavioral intention, besides attitudes. Participants might have attributed their trust in health providers to trust in the chatbot [23,46]. Participants of this study have demonstrated great engagement with the wider research project, which is advocated by health professionals they trust. Hence, families might have relied on health professionals' opinions to form a strong subjective norm to follow, thereby increasing their adoption intention. This is further supported by findings from the review by Tangsrivimol et al [47] assessing the benefits and limitations of currently available chatbots such as ChatGPT and similar chatbots relying on GenAI. They have highlighted issues with existing chatbots by discussing ethical considerations and challenges with data governance and privacy concerns, as well as issues relating to inaccurate and misleading information provided by freely available chatbots based on erroneous algorithms and hallucination. Using an LLM for managing a child's illness raises ethical concerns around safety, accountability, and privacy. Incorrect advice could cause harm, and there is no clear responsibility if things go wrong. Sharing sensitive health information also risks breaching confidentiality. Additionally, reliance on LLMs might undermine trust in health care professionals and could introduce bias, leading to unequal care. The aim of health care–specific chatbots is to overcome these issues by providing secure platforms and providing content, and features tailored to the audiences they are targeting,

XSL•FO
RenderX

whilst still encouraging engagement with existing health care teams.

Besides trust, another concern raised in previous literature on health care chatbot adoption was the lack of humanness, compared to interactions with a health professional [21]. However, we argue that lack of humanness may not always be a concern. Reducing human-human interactions could be beneficial, such as creating a stigma-free safe space. Under the theme of accessibility, the subtheme of comprehension accessibility discussed the need for a tool that can provide understandable, tailored, and rational information. Indeed, stigmatizing health-related experiences could reduce patients' engagement in medical care, treatment adherence, and help-seeking behavior [48]. Therefore, chatbot use might reduce any perceived stigma in patient-clinician interactions and provide tailored answers that users can understand. As a result, it could promote positive patient-clinician relationships and treatment outcomes.

Through analyzing families' attitudes and behavioral intentions, it was identified that users need a tool that is highly accessible to compensate for limited contact with health professionals; that they can trust, such as being backed by credible experts; and that they can depend upon to provide accurate answers to questions specific to pediatric rheumatology. However, it is important to note that this tool is seen as an aide to support the family in everyday life situations, and should be a trusted source of information. Moreover, it should not be used as a replacement for existing care provided by health care teams but rather as a platform that should be used in conjunction with existing face-to-face care from health care providers.

Opportunity of a Pediatric Chatbot (RQ3)

Through concept testing, the visual imagery and storytelling narrative used by ChatGPT were well-liked and thought to be appropriate for children and young people. However, they noted that children of the same age could behave and think very differently. In line with Vygotsky's [49] sociocultural theory, children's cognitive development is influenced by their social interactions and environment, irrespective of biological age. Hence, it might not be effective to dictate the level of comprehension in chatbot-generated output solely by age.

Younger participants and adults expressed different preferences for chatbot features and tone. Currently, parents are identified as the main user who will primarily use the chatbot either by themselves or with their children. Participants in concept testing discussed that children and young people should be considered as its own user group. There is therefore an opportunity to create a separate user interface and persona to engage children.

A study examined the impact of personas in a health care chatbot on adult users' engagement [50]. It drew on the social response theory [51], which argues that users react to computers with human-like attributes similarly to human-human interactions. The study created the personas representing a hospital institution, expert, peer, and dialogical self to measure the effect of age and gender on affective bond and use. While the study concluded with mixed findings, future research could investigate the impact of different chatbot personas on intervention engagement in children, young people, and parents. However, the functionality and usefulness of a chatbot intervention should still be prioritized over social features [52]. This is particularly highlighted by a scoping review that reviewed health-related chatbots more closely. They found that mental health and well-being–promoting chatbots need to prioritize content and functionality above everything else. For example, they found that only 44% of chatbots successfully addressed suicidal thoughts. Thus, demonstrating the need to focus on safety to safeguard vulnerable populations [53].

Limitations

Since participants were recruited voluntarily, they may be subject to social desirability bias toward the research project and team, as well as the recruitment of families from social media who equally may be biased toward AI. Additionally, some participants may have completed both the workshop and questionnaire, potentially increasing bias compared to those who only completed the survey. However, by asking participants to explain their ratings on chatbot use, they were encouraged to engage more deeply with the topic which increased objectivity [52].

The forced-choice design limits interpretation, as participants had to select the preferred option even if they were dissatisfied with both. This approach captures relative preference but may obscure low overall acceptance. Participants' attitudes were also measured based on a hypothetical scenario of chatbot use, which may not be representative of a real-life situation. However, a study found that behavior is better predicted by actual experience, than attitudes that were formed based on the stimuli provided by the researcher [54]. It was not feasible in this study since the chatbot is yet to be developed. Future research could compare changes in participants' attitudes after the chatbot has been developed. This could generate insights into how well the chatbot is embedded in users' everyday lives, which is a common concern in AI health care technology [18].

While the use of a mixed methods approach has mitigated some limitations, it increased the complexity of the study. Questions from the questionnaire measure generated both quantitative and qualitative data. This was in addition to the qualitative data from the family workshop, which consisted of primary and secondary datasets. In addition, findings from one method slightly overlapped with findings from another. As a result, it increased the difficulty in data processing and interpretation. Findings from different methods had to be carefully evaluated to ensure a holistic understanding of the research problem and research questions and a clear audit trail and regular team meetings were essential to identify potential biases. Additionally, the sample size for children and young people was too small to allow for more in-depth interpretations of the findings. Children and young people were included in this study as they attended the workshop alongside their parents, and it provided an opportunity to collect preliminary data on their views. Further research could investigate their viewpoint in more detail to understand their views on GenAI and health-specific chatbots.

As health care chatbots can have a wide spectrum of applications and target audiences, a limitation in the research field is that it is hard to compare study results. To illustrate, a recent

XSL•FO
RenderX

systematic review on health care chatbots by Laymouna et al [55] found that only 10 out of 161 (6%) studies reviewed were designed for chronic health patients. Health care chatbots could also serve different functionalities, such as everyday management, education, and administrative support. Another review on chatbots for chronic patients [56] only discovered 10 published studies, confirming that the research field is still in its infancy. Moreover, 60% of studies looked at different chronic health conditions. It is important therefore to consider developing specialized chatbots for different conditions as they potentially vary in symptoms, causes, and management.

Conclusions

This study contributes to the body of literature on AI in pediatric health care, by exploring parental and children and young people's attitudes and acceptance toward a specialized GenAI chatbot for pediatric rheumatology. While this study focused on pediatric rheumatology, findings might be generalizable to other chronic pediatric health conditions. The study also adds to the existing studies on health care chatbots, as the preference for a specific chatbot is demonstrated over a general chatbot, like ChatGPT. Families wanted a chatbot that was accessible and able to "translate" medical information into language suitable for individuals' comprehension levels. Moreover, trust and credibility regarding the chatbot's input, design, and regulation promoted users' adoption intention. As the current "IMPACT" study is based on the concept of a specialized pediatric chatbot, future work should continue to involve users in chatbot development. A chatbot developed for specific pediatric conditions could drastically change the way patients and caregivers seek health information digitally. Not only will families receive the information they want when they need it but also they could be empowered in chronic health management, whilst maintaining a partnership with their child's health professionals.

Acknowledgments

The study is part of a wider research project led by Great Ormond Street Hospital for Children NHS Foundation Trust in London, United Kingdom. We would like to express gratitude to the IMPACT (Interventions to Improve Mental Health Support in Families With Children and Young People With Chronic Rheumatological Conditions) steering group for their support throughout this project and to all the children, young people, and parents who took part. The steering group comprises Eire Byrne, Natalia Kasaru, Morgan Pawlett, Cameron Papantoniou, Emily Earle, Nathanael Bourns, Rachel Pulfree-Blythe, Eunice Kasaru, Emma Piepenstock, Gemma Molyneux, and Heather Rostron [30]. This study is funded by a National Institute for Health and Care Research (NIHR) Advanced Clinical Academic Research Fellowship (ICA-ACAF-302864).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to them containing identifiable information regarding the participants but are available from the corresponding author upon reasonable request.

Authors' Contributions

CWYL conducted the research and wrote the manuscript with significant input and supervision from KK and PL in every process. KK also engaged in data collection for the questionnaire study. KK and PL were significantly involved in data processing and analysis. PL oversaw the whole study and the wider research project. All authors read and approved the final paper.

Conflicts of Interest

PL is currently receiving a personal fellowship award from the National Institute for Health and Care Research (NIHR) fellowship for nonmedical health care professionals (ACAF reference 302864), and as PPIE colead for the NIHR Great Ormond Street Hospital for Children (GOSH) BRC, she receives some salary support from the NIHR Biomedical Research Center at GOSH. PL is also a senior center affiliate at the Center for Adolescent Rheumatology Versus Arthritis at University College London (UCL) University College London Hospitals (UCLH), and GOSH, which is supported by Versus Arthritis (21593).

Abstract

Background: Caregivers of children with mental health challenges are at heightened risk for burnout and absenteeism. This strain affects both their well-being and work performance, contributing to widespread workplace issues. Digital mental health interventions (DMHIs) are increasingly used to support pediatric mental health, but their impact on caregiver outcomes remains underexplored.

Objective: This study aimed to explore the associations between caregiver burnout, absenteeism (ie, missing work), comorbid symptoms, and child mental health problems, and to assess whether caregiver burnout and absenteeism improved as their child participated in a pediatric DMHI.

Methods: This retrospective study included 6506 caregivers whose children (aged 1 - 17 years) received care from Bend Health, Inc, a pediatric DMHI providing digital-based therapy and coaching, digital content, and caregiver support. Caregiver burnout, absenteeism, comorbid symptoms, and child mental health symptoms were measured by monthly assessments. Cumulative link models were used to assess the associations of between child symptoms and caregiver outcomes and to assess changes in caregiver outcomes over the course of the DMHI. Analyses of baseline associations included the full sample (n=6506), while analyses of pre-post changes in caregiver outcomes were conducted in caregivers with elevated burnout (n=2121) and absenteeism (n=1327) who had an assessment after starting care.

Results: At baseline, 45.96% (2990/6506) of caregivers reported elevated burnout and 28.96% (1884/6506) reported elevated absenteeism. More severe burnout was associated with having a child with elevated symptoms of any type (all P<.01). More severe absenteeism was significantly associated with having a child with elevated symptoms of depression (z=3.33; P<.001), anxiety (z=3.96; P<.001), inattention (z=2.48; P=.013), and hyperactivity (z=2.12; P=.03). Burnout decreased for 68.64% (1456/2121) and absenteeism decreased for 87.26% (1158/ 1327). Greater months in care was associated with less severe caregiver burnout (z=−5.48; P<.001) and absenteeism (z=−6.74; P<.001).

Conclusions: DMHIs for children may reduce caregiver burnout and absenteeism. These findings emphasize the value of employers offering pediatric DMHIs as part of employee benefits, potentially enhancing workplace outcomes.

Introduction

Children and adolescents in the United States aged 3-17 years are experiencing record levels of mental and behavioral health issues such as anxiety, depression, and attention-deficit/hyperactivity disorder (ADHD), which can contribute to increased stress, fatigue, sleep disturbances, and overall strain on family well-being [1,2]. Alongside the decline of pediatric mental health in recent years, fewer caregivers have reported that they are coping with the demands of parenting,

XSL•FO
RenderX

citing increased emotional distress, worry, feelings of helplessness, and family strain [2-5]. As a response to the crisis in caregiver mental health and well-being, the US Surgeon General issued a 2024 advisory calling for greater support for parent and caregiver mental health to improve family well-being [4].

There is substantial evidence that caregivers of children with mental health challenges are particularly vulnerable to poor mental health outcomes, as they work to meet their children's complex needs [6,7]. Caregivers whose children experience emotional and behavioral problems are under additional strain, as they frequently experience elevated parental stress, fatigue, and poor sleep [6-11]. This degradation of caregiver well-being ultimately spills into different areas of life [12], including both family and professional responsibilities.

In a survey of parents who were concerned about their children's mental health, 48% said that their concerns impacted their performance at work in some way—including challenges such as frequent disruptions during the workday and difficulty concentrating on the job [13]. Caregivers may also have to miss work, given the need to take time off for their child's medical appointments, as well as to tend to their own recuperation and care [13,14]. For example, 46% of caregivers of a child with ADHD reported reducing their weekly work hours, and 11% stopped working altogether after their child's diagnosis [15]. Burnout and absenteeism impact both caregivers and employers, leading to reduced work performance, higher employee turnover, and significant productivity costs [16,17]. Thus, the issue of caregiver well-being is critical for society as a whole, including the health care system, individuals and families, and also businesses. Given evidence suggesting the deterioration of caregiver workplace outcomes associated with caring for a child with mental health challenges, there is a need for effective treatments for both child and caregiver well-being.

Digital mental health interventions (DMHIs) in academic and commercial settings have proven effective in treating common mental and behavioral health problems in children [18-22], offering accessible and cost-effective solutions compared with standard care [23,24]. Our previous research demonstrates that a commercially available DMHI can effectively improve mental health in children and adolescents [18,19]. Additionally, multiple systematic reviews highlight DMHIs as a highly promising solution for youth mental health [20,21]. More recently, a digital platform integrating both asynchronous and synchronous support successfully reduced anxiety and depression in a large sample of Australian youth [22]. Although these interventions primarily focus on the child, our previous findings suggest that caregivers may experience secondary benefits (eg, improvements in sleep and stress) when their children receive care through a pediatric DMHI [10]. However, the impact of pediatric DMHIs on caregiver burnout and absenteeism remains underexplored. This gap in knowledge is critical, as understanding caregiver well-being is essential to supporting their ability to manage both their child's treatment and their own work and personal responsibilities effectively.

Using retrospective analyses, the purpose of this study was to (1) explore associations between caregiver burnout, absenteeism, comorbid symptoms, and child mental health problems among caregivers seeking mental health treatment for their children, and (2) assess whether caregiver burnout and absenteeism improved while their child participates in a pediatric DMHI.

Methods

Design and Participants

This study is part of a broader research effort examining the impact of a pediatric DMHI on child and caregiver outcomes. While we have published other analyses among youth and caregivers who participate in care with Bend Health [10,18,19,25], this is the first study to specifically assess the relationship between child mental health challenges and caregiver workplace outcomes (absenteeism and burnout). Caregivers of children (aged 1-17 years) participating in care with Bend Health, Inc, a collaborative care pediatric DMHI, were eligible for inclusion in this study if (1) they completed the caregiver assessments (burnout, absenteeism, sleep problems, and parental stress) at baseline (before the start of care), and (2) their child attended at least 1 session with a Bend Health practitioner (behavioral care manager [BCM], behavioral health coach [coach], or therapist) between January 1, 2023, and September 16, 2024. A total of 6508 caregivers were eligible for inclusion.

Ethical Considerations

Caregivers provide informed consent during enrollment in care with Bend Health, Inc, for primary data collection required for regular participation in care and they also agree to the use of their data in further analyses. Caregivers agree to these terms on behalf of their children and themselves, and adolescents (aged 13-17 years) also assent on their own behalf. For the purposes of this study, only deidentified data were used. There was no compensation for participation in this study because the analysis was retrospective. Study procedures were approved by the Biomedical Research Alliance of New York (Study 23-12-034-1374; approved June 5, 2023). No portion of this manuscript used generative artificial intelligence for development or writing.

Treatment

Bend Health, Inc, is a collaborative care DMHI, which delivers comprehensive mental health care to members (aged 1-17 years) and their caregivers. Care with Bend Health is described elsewhere in more detail [18,19]. Briefly, members can enroll via referral from their primary care provider, via insurance or employer benefits, or through direct-to-consumer channels. After enrollment in the web-based platform, a BCM is assigned to each member to coordinate care and communicate with external providers (eg, primary care providers), per the collaborative care model. The BCM assembles the care team, assigning a coach, and sometimes a therapist, based on coverage and each member's unique needs, and then they continue to oversee each member's care. Module-based care programs are assigned to each member to directly address a particular symptom domain (eg, anxiety or depression) and in an age-appropriate manner. In synchronous video-based sessions, the practitioners on a member's care team deliver

XSL•FO
RenderX

evidence-based care as aligned with the care plan. Members may attend multiple sessions monthly with their care team, and they may also receive care from a psychiatric provider if medication management is referred. While care with the DMHI targets the pediatric member, caregivers are closely involved in care and may receive mental health and behavior change tools to implement personally or in their interactions with their child or adolescent. Caregivers are required to attend sessions for safety reasons if their child is younger than 13 years.

Measures

The member's (ie, the child's) demographic information, including the date of birth, sex at birth (male, female, or other), gender (male, female, transgender, nonbinary, or other), and race or ethnicity, is provided by caregivers at enrollment with Bend Health, Inc. The race or ethnicity options are specified in Textbox 1. Starting May 26, 2023, the options were expanded to be more inclusive of a diverse population, and multiple responses were allowed.

Textbox 1. Race or ethnicity response options during enrollment, including options added to the demographic questions partway through the study period.

Ethnicity response options

- American Indian or Alaska Native
- Asian
- Black or African American
- Hispanic or Latino
- Native Hawaiian or other Pacific Islander
- White
- Other (removed from the list of options starting May 26, 2023)
- Chinese (added to the list of options starting May 26, 2023)
- Vietnamese (added to the list of options starting May 26, 2023)
- Filipino (added to the list of options starting May 26, 2023)
- Korean (added to the list of options starting May 26, 2023)
- Japanese (added to the list of options starting May 26, 2023)
- Chamorro (added to the list of options starting May 26, 2023)
- Other Asian (added to the list of options starting May 26, 2023)
- Some other race or multi-racial (added to the list of options starting May 26, 2023)
- Mexican, Mexican Am, Chicano (added to the list of options starting May 26, 2023)
- Puerto Rican (added to the list of options starting May 26, 2023)
- Cuban (added to the list of options starting May 26, 2023)
- Another Hispanic, Latino, or Spanish origin (added to the list of options starting May 26, 2023)

As part of care at Bend, caregivers and adolescents (aged 13-17 years) complete mental health assessments during enrollment, and they also complete follow-up assessments every month during care to measure both caregiver and member symptoms. Caregivers complete assessments to measure caregiver burnout, absenteeism (missing work), sleep problems, and parental stress, as well as inattention, hyperactivity, and oppositional symptoms for their child or adolescent (caregiver report). Caregivers of children (aged 1-12 years) also complete assessments to measure their child's anxiety, depressive symptoms, and sleep problems (caregiver report). Adolescents (aged 13-17 years) complete their own assessments to measure anxiety, depression, and sleep problems (self-report).

For all assessments except burnout, screener items are used to flag symptoms requiring further assessment. When responses to the screener items are flagged (indicating probable symptoms), the caregiver or the adolescent screens-in and completes a full validated assessment. In 2024, Bend Health's method of screening-in to the validated assessments changed. From January 1, 2023, to January 22, 2023, caregivers and adolescents completed all screeners at each assessment, followed by validated assessments based on screener responses. From January 23, 2024, onward, if an assessment is screened-in, all following assessments for that symptom are automatically screened-in. From January 23, 2024, to August 9, 2024, screeners were not taken if past assessments were screened-in. From August 9, 2024, onward, screeners were taken in addition to validated assessments when past assessments were screened-in. Once all assessments are completed (after approximately 5-25 minutes), the caregiver and child or adolescent are shown a summary of their results, including an indication of whether any symptoms were mild to severe. The assessment results are also viewed by BCMs and the care team to monitor treatment progress and make adjustments to the care plan, as necessary.

XSL•FO
RenderX

Caregiver Symptoms

Caregiver symptoms were assessed using Bend Health's regular symptom assessments, which measure a caregiver's well-being while their child is in care. To assess caregivers' work burnout, caregivers respond to a single question [16,26]: "Overall, based on your definition of burnout, how would you rate your level of burnout?" Caregivers respond using the following options: (1) "I enjoy my work. I have no symptoms of burnout" (no burnout), (2) "Occasionally I am under stress, and I don't always have as much energy as I once did, but I don't feel burned out" (low burnout), (3) "I am definitely burning out and have one or more symptoms of burnout such as physical and emotional exhaustion" (mild burnout), (4) "The symptoms of burnout that I'm experiencing won't go away. I think about frustration at work a lot" (moderate burnout), and (5) "I feel completely burned out and often wonder if I can go on. I am at the point where I may need some changes or may need to seek some sort of help" (severe burnout). Studies have demonstrated that this single-time burnout measure is valid and reliable [26-28]. This item has demonstrated good concurrent validity with the emotional exhaustion subscale of the Maslach Burnout Inventory, supporting its reliability in assessing burnout [29].

To assess caregivers' work absenteeism, defined as missing full or partial days of work, caregivers are asked the screening question: "During the past four (4) weeks, have you missed part of or an entire day of work? Have you had to come in early, go home late or work on your day off?" Responses are "Yes" or "No," and caregivers are prompted to complete section B5 of the Health and Work Performance Questionnaire (HPQ) if they respond "Yes" [30]. B5 of the HPQ includes 5 items asking the number of days (range: 0-28) in the past 4 weeks that the caregiver (1) missed an entire day of work due to problems with their own physical or mental health, (2) missed an entire day of work for any other reason (including vacation), (3) missed part of a workday due to problems with their own physical or mental health, (4) missed part of a workday for any other reason (including vacation), and (5) came in early, went home late, or worked on a day off (extended workdays). The final item is not used to assess absenteeism and thus was not considered in this *study. Section* B5 of the HPQ has demonstrated good validity, showing strong correlations with objective measures of work performance and self-reported job performance [30].

To assess caregiver sleep problems, caregivers are asked to respond to the screener question: "During the past two (2) weeks, how much (or how often) have you had problems sleeping—that is, trouble falling asleep, staying asleep, or waking up too early?" Responses are on a 5-item Likert-type scale (0=Not at all, 4=Nearly every day). If the response is 2 or greater, the caregiver completes the Insomnia Severity Index (ISI), which includes 7 items about sleep difficulties [31]. Responses to each question are on a 5-item Likert-type scale (0=None, 5=Very severe). The ISI shows strong validity, correlating well with clinician-rated insomnia and sleep diary measures [31].

To assess parental stress, caregivers complete the Parental Stress Scale (PSS) [32], which queries a caregiver's feelings about their caregiving responsibilities and their relationship with their child or children. First, they respond to the following 2 items from the PSS: "The major source of stress in my life is my child" and "Having a child leaves little time and flexibility in my life." Best-fit responses are selected on a 5-item Likert-type scale (1=Strongly disagree, 5=Strongly agree). If the response to either question is 3 (undecided) or greater, the caregiver completes the remaining 16 items of the PSS. Some items on the PSS are framed as a negative caregiving experience (eg, "Having children has been a financial burden"), with greater responses indicating more severe parental stress. Other items are framed as a positive caregiving experience (eg, "I am happy in my role as a parent"), with greater responses indicating less severe parental stress (reverse items). The PSS shows good validity, correlating strongly with related measures of parental stress and well-being [32].

Child and Adolescent Mental Health Symptoms

All assessments of mental health for children (aged 1-12 years) are completed by the caregiver (caregiver report), including assessments of anxiety, depression, sleep problems, ADHD symptoms (inattention, hyperactivity, and opposition), and sleep problems. Adolescents (aged 13-17 years) complete their own assessments of anxiety, depression, and sleep problems (self-report), but their caregivers complete the assessment for ADHD, given the need for proxy report on these symptoms. For all assessments, the reporter (caregiver or self) responds to a few screening items to flag mental health symptoms. If mental health symptoms are flagged by these screeners, the reporter completes a full validated assessment to further quantify outcomes.

For child symptoms of anxiety, depression, and sleep problems, caregivers of children respond to screener items from the *Diagnostic and Statistical Manual of Mental Disorders* (Fifth Edition, Text Revision) (*DSM-V-TR*) Cross-Cutting Symptom Measure screeners [33]. If a response of 2 or greater is given to any screener, they complete the corresponding PROMIS (Patient-Reported Outcomes Measurement Information System) anxiety, depression, or sleep assessment [34]. Responses to the anxiety and depression PROMIS assessments are made using a 5-item Likert scale, with greater response values always indicating more severe or frequent symptoms (1=Never, 5=Almost always). Responses to the sleep PROMIS assessment are made using different 5-item Likert scales (depending on the question; eg, 1=Not at all, 5=Very much), with greater responses on some items indicating more severe or frequent symptoms and greater responses on other items indicating less severe or infrequent symptoms (reverse items).

For adolescent symptoms of anxiety, depression, and sleep problems, adolescents respond to items derived from the following respective screeners: Generalized Anxiety Disorder 2-item (anxiety) [35], Patient Health Questionnaire 2-item (depression) [36], and *DSM-V-TR* Cross-Cutting Symptom Measure screener for sleep (sleep problems) [33]. If there is an aggregate screener score of 2 or greater, they complete the corresponding validated assessment. For anxiety symptoms, adolescents complete the full Generalized Anxiety Disorder 7-item (GAD-7) [35]. For depressive symptoms, adolescents complete a version of the Patient Health Questionnaire 9-item

XSL•FO
RenderX

that is modified for adolescents (PHQ-9A), excluding the item about suicidal ideation [36]. For sleep problems, adolescents complete the self-report version of the PROMIS sleep assessment [37], which includes the same items as the caregiver report version used for children.

For child and adolescent symptoms of ADHD, caregivers respond to 2 *DSM-V-TR* Cross-Cutting Symptom Measure items to screen for symptoms of inattention and hyperactivity (1 question) and opposition (1 question) [33]. If symptoms are flagged given responses to these screeners, caregivers complete all of or some of the subsets of the Swanson Nolan and Pelham Rating Scale version 4 (SNAP-IV) assessment [35], which includes 3 groups of questions measuring symptoms of inattention (items 1 - 9), hyperactivity (items 10 - 18), and opposition (items 19 - 26). Responses to all items are on a Likert scale from 0 (Not at all) to 3 (Very much). From January 1, 2023, to March 31, 2024, a score of 1 or greater to the screener about inattention and hyperactivity prompted the completion of only the inattention and hyperactivity items, and a score of 1 or greater to the screener about opposition prompted the completion of only the opposition items [6]. Beginning April 1, 2024, caregivers complete all 26 questions of the SNAP-IV if their response to either screening question is 1 or greater. See the Multimedia Appendix 1 for further details on all measures used.

Outcome Calculations

Caregiver outcomes were calculated as follows. Using established criteria [27], elevated burnout was defined as a burnout score of 3 or more (mild to severe burnout). For absenteeism, reported partial days of work missed (items 3 and 4) were considered 0.5 days missed, so days of work missed was calculated as the sum of the number of full days missed (items 1 and 2) plus the sum of the number of partial days missed: item response 1 + item response 2+ (0.5 × (item response 3+ item response 4)). If the absenteeism assessment was screened-out, the number of days of work missed was 0. If the number of days of work missed exceeded 28, this value was replaced with 28. Given that the standard work week is five 8-hour days, severity of absenteeism was determined as follows: “No missed work” (screen-out or days of work missed is 0), “Missed less than one week of work” (days of work missed is 0.5-4.5), “Missed one to two weeks of work” (days of work missed is 5-9.5), “Missed two to three weeks of work” (days of work missed is 10-14.5), and “Missed three or greater weeks of work” (days of work missed is 15 or greater). Elevated absenteeism was considered missing work for 0.5 days or greater in the past 28 days. Caregiver sleep score was calculated by aggregating the responses to all 7 ISI items, for a total score of 0-28. Elevated sleep problems were considered moderate severity or severe insomnia symptoms, per the defined ranges of clinically significant sleep problems [31]. Parental stress was calculated by aggregating responses to the 18 items (with scores reversed for the reverse items), for a total score of 18-90. Elevated parental stress was considered a score of 42 or greater, given severity thresholds used by others [38,39].

Child and adolescent mental health outcomes were calculated as follows. Child anxiety and depressive symptom scores, as well as child and adolescent sleep scores, were calculated by aggregating the responses to the respective PROMIS assessments (with scores reversed for the reverse items) and then converting these total scores to *T*-scores using standardized conversion criteria [34,37,40]. Adolescent anxiety scores were calculated by aggregating responses to the GAD-7 [35]. Adolescent depression raw scores were calculated by aggregating responses to the PHQ-9A and then multiplied by 9, divided by 8, and rounded to the nearest whole number to account for the single omitted item. Inattention, hyperactivity, and oppositional symptom scores were calculated by aggregating the responses to the items in each of the symptom subsets of the SNAP-IV [41]. Symptom severity was determined for all child and adolescent symptoms using previously defined criteria [34,37,39,41-43].

For all analyses, caregiver burnout was reported based on response to the single item, and caregiver absenteeism was reported as severity of absenteeism and number of days of work missed. We chose this analytic approach to ensure that results are robust to minor changes to the screening and assessment methods (Multimedia Appendix 1). Therefore, for all outcomes except caregiver burnout and workplace absenteeism, symptom severity was analyzed as “elevated” or “not elevated.” For all symptoms except caregiver burnout, absenteeism, and parental stress, outcomes were classified as elevated if symptom severity was moderate to severe, and not elevated if the assessment was screened out or symptom severity was low to mild. A decrease in burnout or absenteeism from baseline (first assessment) was defined as a decrease in burnout score or a decrease in number of days of work missed, respectively.

Statistical Analysis

Caregiver Burnout and Workplace Absenteeism at Baseline

Caregiver outcomes at baseline (first assessment before beginning care with the DMHI) were analyzed for all caregivers with complete caregiver assessments (n=6508). Caregivers with duplicate baseline assessments (n=2) were removed for a sample size of 6506. The following characteristics were described for these caregivers: mean child age (at baseline), child sex, child race or ethnicity, type of participation with the DMHI (BCM intake only, coaching only, coaching and therapy, or therapy only), and duration of participation with the DMHI (first event to last event). Burnout and absenteeism scores were reported, as well as group trends for the number of days of work missed. Cumulative link models (CLMs) were used to assess whether workplace outcomes were associated with caregiver’s comorbid symptoms. For burnout, the predictors were elevated absenteeism, elevated sleep problems, and elevated parental stress. For absenteeism, the predictors were elevated burnout, elevated sleep problems, and elevated parental stress. Child (child and adolescent, grouped for analyses) characteristics and mental health symptoms were assessed to identify associations between predictors and caregiver burnout and workplace absenteeism. Only caregivers of children and adolescents aged 6 years or older (given age validation for pediatric assessments) and whose child had all mental health assessments complete were included in analyses (n=5628; Multimedia Appendix 1).

XSL•FO
RenderX

CLMs were used to determine whether the following child characteristics and mental health symptoms were associated with the severity of caregiver workplace outcomes (burnout and absenteeism): age (child vs teen), sex (female vs nonfemale), elevated depression, elevated anxiety, elevated inattention, elevated hyperactivity, elevated opposition, and elevated sleep problems.

Change in Caregiver Burnout and Workplace Absenteeism

Change in caregiver burnout and workplace absenteeism over their child's care with the DMHI was assessed for caregivers with elevated burnout and elevated workplace absenteeism at baseline who also met the following inclusion criteria: baseline assessment completed within 2 months of beginning care with the DMHI (ie, for an accurate assessment of mental health status at care start), and had at least 1 completed follow-up assessment after the start of care with the DMHI (see Multimedia Appendix 1 for details on exclusions). Ultimately, 2121 were included in the analyses for change in burnout and 1327 were included in the analyses for change in absenteeism. Percentages of caregivers with a decrease and increase in workplace symptoms— for both burnout and absenteeism (number of days of work missed)—were reported for the caregivers' first follow-up assessment during care as well as their last follow-up assessment during care. Percentages of caregivers with elevated workplace outcomes at these time points were also reported, and the percentages of caregivers with a decrease in workplace symptoms *reported at any time during care* were reported. Finally, percentages of caregivers with nonelevated workplace symptoms at baseline and elevated workplace symptoms at the last follow-up were reported. For absenteeism, reported decreases in the number of days worked were compared with zero using Wilcoxon signed rank tests.

For caregivers of a child with elevated mental health symptoms at baseline, the maximal percent decrease in child mental health symptom severity during care was calculated. The maximal decrease in child's mental health symptom severity was compared between groups using Wilcoxon signed rank sums tests for caregivers with a decrease in workplace symptoms versus those with no decrease in workplace symptoms at last follow-up. Only caregivers of a child with elevated symptoms at baseline and a follow-up assessment after the start of care were included in these analyses (Multimedia Appendix 1; n=1739 included in burnout and n=1041 included in absenteeism).

CLMs were used to determine whether months in care were associated with lower severity of burnout and absenteeism, and comorbid caregiver symptoms, child characteristics, and child mental health symptoms were assessed as potential covariates in these models. The basic model for each workplace symptom included months in care as a fixed effect. Likelihood ratio tests were used to compare this basic model with an identical model including a single potential covariate added as a fixed effect. The potential covariates assessed were elevated comorbid caregiver symptoms, child's age group (child vs teen), child's sex (female vs nonfemale), and child's mental health symptoms. Only predictors that significantly improved model fit were retained in the final model (see Multimedia Appendix 1 for comprehensive results from likelihood ratio tests). For burnout, all comorbid caregiver symptoms were retained, as well as child sex, and all child mental health symptoms. For absenteeism, all comorbid caregiver symptoms were retained, as well as the following child mental health symptoms: depression, anxiety, inattention, hyperactivity, and sleep. Only assessments taken after beginning care with the DMHI were considered in the CLMs.

For all CLMs, coefficient estimates were used to determine whether each predictor was associated with the severity of workplace symptoms. Throughout, the alpha-level was set to .05 for all analyses. Standard descriptive statistics (percentages; mean, SD; and median, IQR were used to describe data. Data were analyzed with RStudio (version 2023.03.0+386; Posit, PBC) [44].

Results

Overview

Overall, caregivers included in the analyses (N=6506) cared for children with a mean age of 10.58 (SD 3.81) years, and 49.86% (3244) of the children were female. In terms of reported race and ethnicity, 50.63% (3294) were white and 32.02% (2083) identified as "Other" or multiple race and ethnicity options. While all children had at least 1 session with a Bend Health practitioner, 16.25% (1057) completed only their BCM intake session, 59.67% (3882) were in coaching only, 22.69% (1476) were in coaching and therapy, and 1.40% (91) were in therapy only. The duration of participation in care with the DMHI was a median of 3.46 (1.7 - 5.9) months.

Caregiver Burnout and Workplace Absenteeism at Baseline

At baseline, 8.84% of caregivers (575) reported no symptoms of burnout, 45.20% (2941) reported low burnout, 33.60% (2186) reported mild burnout, 6.87% (447) reported moderate burnout, and 5.49% (357) reported severe burnout. In terms of absenteeism, 71.04% (4622) reported no missed work, 17.05% (1109) missed less than 1 week of work, 7.49% (487) missed 1-2 weeks of work, 2.29% (149) missed 2-3 weeks of work, and 2.14% (139) missed 3 or greater weeks of work. For those with any absenteeism (n=1884), they reported a median of 4 (2-7) days missed.

In terms of percentages of caregivers with elevated outcomes at baseline, 45.96% (2990) had elevated burnout, 28.96% (1884) had elevated absenteeism, 12.76% (830) had elevated sleep problems, and 17.57% (1143) had elevated parental stress. More severe levels of burnout were significantly associated with elevated absenteeism (z=15.30; P<.001), elevated sleep problems (z=20.41; P<.001), and elevated parental stress (z=15.30; P<.001). This same pattern was observed for severity of absenteeism; greater absenteeism was associated with elevated caregiver outcome severity of all types (all P<.001; Table 1).

More severe symptoms of burnout were significantly associated with having a younger child (child vs adolescent; z=3.20; P=.001), as well as having a child with elevated symptoms of

XSL•FO
RenderX

any type (all $P<.01$). Child sex was not associated with the severity of burnout symptoms. More severe absenteeism was associated with having a child with elevated symptoms of depression ($z=3.33$; $P<.001$), anxiety ($z=3.96$; $P<.001$), inattention ($z=2.48$; $P=.01$), and hyperactivity ($z=2.12$; $P=.03$). Child age and sex, as well as opposition and sleep problems, were not associated with the severity of absenteeism. Comprehensive results for all predictors in these analyses are reported in Table 2.

Table . Results from analyses assessing whether the severity of caregiver symptoms is associated with elevated comorbid caregiver symptoms.

Outcome (caregiver outcome severity)	Predictor (elevated comorbid caregiver symptom)	Estimate (SE)	*z* value	*P* value
Burnout	Absenteeism	0.81 (0.05)	15.30	<.001
	Sleep problems	1.49 (0.07)	20.41	<.001
	Parental stress	1.44 (0.06)	20.39	<.001

Change in Caregiver Burnout and Workplace Absenteeism

For 2121 caregivers with elevated burnout at baseline and a follow-up assessment after beginning care, the first-follow-up was completed after a median of 0.90 months (0.66 - 1.13) in care with the DMHI. At this time, 49.88% (1058/2121) of caregivers with elevated burnout at baseline had a decrease in burnout symptom severity, 7.97% (169/2121) had an increase in severity, and 62.47% (1325/2121) still had elevated burnout. At the last follow-up assessment during care with the DMHI, taken after a median of 2.80 months (1.27 - 5.40) in care, 56.58% (1200/2121) of caregivers with elevated burnout at baseline had a decrease in burnout symptom severity, 6.74% (143/2121) had an increase in severity, and 54.17% (1149/2121) still had elevated burnout. The percentages of burnout severity at baseline and last follow-up are reported in Figure 1. Overall, 68.64% (1456/2121) of caregivers reported a decrease in burnout at any point during care, with the first decrease reported after a median of 1.10 months (0.80 - 1.97). At the last follow-up, children of caregivers with a decrease in burnout (n=977) had larger improvements in their own mental health than children of caregivers with no decrease in burnout (n=762; median −65.63%, IQR −100.00 to −40.00 vs median −52.51%, IQR −95.81 to −28.57; $z=-5.22$; $P<.001$). For caregivers with nonelevated burnout at baseline, 9.61% (338/3178) met the criteria for elevated burnout at their last follow-up during care.

RenderX

Figure 1. Burnout symptom severity for caregivers with elevated burnout at baseline and a follow-up assessment (n=2121) reported for the baseline and last follow-up assessments.

XSL•FO
RenderX

In the analysis of burnout symptom severity during care with the DMHI, greater months in care was significantly associated with less severe symptoms of burnout (z=−5.76; P<.001). All elevated comorbid caregiver symptoms were associated with more severe burnout during care (all P<.001). The following child characteristics were associated with more severe symptoms of burnout: female sex (z=4.50; P<.001), elevated depression (z=2.01; P=.04), elevated hyperactivity (z=3.05; P=.002), and elevated sleep problems (z=4.18; P<.001). Child anxiety, inattention, and opposition were not associated with caregiver burnout during care (both P>.10).

At the first follow-up assessment during care with the DMHI, taken after a median of 0.93 months (0.70 - 1.20) in care, 73.25% (972/1327) of caregivers with elevated absenteeism at baseline had a decrease in number of days of work missed, 22.08% (293/1327) had an increase in days of work missed, and 60.14% (798/1327) still had elevated absenteeism. At the last follow-up assessment during care with the DMHI, taken after a median of 2.97 months (1.37 - 5.45) in care, 76.56% (1016/1327) of caregivers with elevated absenteeism at baseline had a decrease in absenteeism, 19.22% (255/1327) had an increase in absenteeism, and 52.75% (700/1327) still had elevated absenteeism. The percentages of amount of work missed at baseline and last follow-up are reported in Figure 2.

Overall, 87.26% (1158/1327) of caregivers reported a decrease in absenteeism at any point during care, with the first decrease reported after a median of 1.00 months (0.76 - 1.57). Caregivers with elevated absenteeism at baseline had a median decrease of 2 (4-0) days of work missed at first follow-up (z=−17.9; P<.001), and 2 (4.5-.5) fewer days of work at last follow-up (z=−19.2; P<.001). At the last follow-up, children of caregivers with a decrease in absenteeism (n=802) had larger improvements in their own mental health than children of caregivers with no decrease in absenteeism (n=239; median −64.29%, IQR −100.00 to −39.13 vs median −57.14%, IQR −91.75 to −28.57; z=−2.65; P=.008). For caregivers with nonelevated absenteeism at baseline, 10.95% (506/4622) reported missing any amount of work at their last follow-up during care.

In the analysis of change in absenteeism over time, greater months in care was significantly associated with lower levels of absenteeism (z=−6.72; P<.001). Elevated comorbid burnout significantly associated with higher levels of absenteeism during care (z=6.89; P<.001) and elevated child anxiety was marginally associated with higher levels of absenteeism (z=1.75; P=.08). Elevated comorbid sleep and elevated comorbid stress, as well as having a child with elevated depression, inattention, hyperactivity, and sleep, were not associated with absenteeism during care.

Discussion

Principal Results

Using retrospective analysis, the purpose of this study was to (1) explore associations between caregiver burnout, absenteeism, comorbid symptoms, and child mental health problems among caregivers seeking mental health treatment for their children, and (2) assess whether caregiver burnout and absenteeism improved while their child participates in a pediatric DMHI.

Before beginning care with the DMHI, 46% (2990/6506) of caregivers had elevated burnout and 29% (1884/5606) had elevated workplace absenteeism. Child characteristics and mental health symptom presentation were significantly associated with their caregiver's workplace symptoms. Furthermore, while their child participated in care, 69% (1456/2121) of caregivers reported a decrease in burnout and 87% (1158/1327) reported a decrease in absenteeism. These changes were notable after only 1 month in care, with 50% (1058/2121) of caregivers reporting reduced burnout, and nearly 3 in 4 (972/1327, 73%) reporting a reduction in the number of days of work missed. Greater time in the DMHI significantly associated with less severe workplace symptoms, and children of caregivers with improvement in workplace symptoms reported larger improvements in pediatric outcomes than those whose caregiver did have improvement in workplace symptoms.

We found that symptoms of elevated burnout and workplace absenteeism were prevalent in caregivers before starting care with the pediatric DMHI, as almost half and about one-third reported elevated burnout and absenteeism, respectively. It is well known that workplace burnout and absenteeism, which are at historic highs [45,46], are perpetuated by family-related stress, particularly a child's mental health difficulties [14,47-51]. Parents spend a significant amount of time managing their children's mental and behavioral health needs, which is exacerbated by lack of access to and knowledge of evidence-based mental health treatment options for their children [48,52]. Thus, it is unsurprising that percentages of burnout (2990/6506, 46%) and workplace absenteeism (1884/6506, 29%) were high among caregivers actively seeking treatment for their child's mental health challenges.

Burnout was higher among those caring for a child with any elevated mental health symptom severity, and absenteeism was higher among those caring for a child with elevated internalizing (ie, anxiety and depression), inattention, and hyperactivity symptoms. These findings align with previous literature suggesting a reciprocal relationship, where a child's mental health challenges exacerbate caregiver sleep problems and stress [53,54], which can contribute to caregiver burnout and absenteeism [55-57]. In turn, while some studies highlight the additional burden of parenting a child with mental health and behavioral challenges [6-9,11,58], caregiver burnout may exacerbate child mental health challenges by reducing the caregiver's capacity to provide emotional support and consistent care [59,60]. Given the complex bidirectional relationship between child-caregiver well-being [54], it is critical to highlight interventions that may produce benefit for both caregivers and their children. As the first study to examine both caregiver absenteeism and burnout across multiple child mental health challenges, this work builds on prior studies that have focused on single conditions (eg, ADHD and autism) or isolated workplace outcomes [15], contributing to a broader understanding of the link between caregiver and child well-being.

While children were in care with the DMHI, their caregivers exhibited significant improvements in workplace symptoms. Burnout decreased in 69% (1456/2121) of caregivers and absenteeism decreased in 87% (1158/1327) at any point during care, with caregivers reporting that they missed 2 fewer days of work at the end of their child's care than initially reported at baseline. Other studies have reported that caregivers whose children engage in traditional modes of mental and behavioral health care evince corresponding improvements, such as decreases in parental stress, sleep problems, anxiety, and depression [61,62]. In a study of caregivers and youth participating in a DMHI, Grodberg et al [48] found that increases in caregiver productivity throughout care were linked to increases in caregivers' feelings of connectedness to their children. Similarly, our recent evidence also suggests that caregivers whose children engage in a pediatric DMHI report decreased parental stress and sleep problems [10]. The present findings extend this work by demonstrating that these caregiver benefits also translate into occupational outcomes, with greater time in care associated with reductions in both burnout and absenteeism. Notably, improvements in caregiver workplace symptoms were associated with larger improvements in child mental health symptoms during care. These results are largely in-line with the broader literature that indicates a bidirectional relationship between caregiver and child well-being [53-57]. Our findings highlight the opportunity for employers to manage employees' burnout and absenteeism by providing mental health care not only for employees themselves but also for their children and families.

Strengths and Limitations

Our study has several strengths. This is the first study, to our knowledge, to address the potential downstream benefits of pediatric care with a DMHI on the workplace symptoms of their caregivers. The deterioration of parent and caregiver well-being has been increasing in prevalence and was called out in 2024 by the US Surgeon General as a critical problem [4]. We demonstrate that addressing child mental health may be an effective avenue to reduce caregiver strain and workplace problems. From an analytic standpoint, this study draws data from a large sample, with more than 6000 caregivers included in analyses of mental health symptoms at baseline, more than 2000 change in burnout analyses, and more than 1000 for change in absenteeism analyses. Additionally, this study assesses outcomes associated with an established, commercial, and successful DMHI, which has been shown to be effective in addressing child and adolescent mental health challenges [18,19,25]. Our findings overall contribute to a growing body of evidence supporting the use of DMHIs—which are typically more flexible and accessible than traditional care—to address both pediatric and caregiver well-being.

XSL•FO
RenderX

There are some limitations of this study. This was a retrospective study that prevented us from drawing any causal conclusions, and we relied on self-report measures to obtain information regarding all outcomes of interest. Further research using an experimental design and using objective measures where possible (eg, reports of caregiver absences from work) is necessary to determine whether involvement in a pediatric DMHI precipitates improvements in caregiver workplace symptoms. While some improvement may be expected due to regression to the mean following a child's referral to care, our findings suggest that greater time in care contributes to continued reductions in burnout and absenteeism. Controlled studies are needed to further clarify the extent to which these changes reflect treatment effects versus natural symptom resolution over time. We also did not collect demographic information on caregivers, which limits our ability to examine whether caregiver characteristics (eg, age and biological sex) influenced burnout and absenteeism.

Another limitation of this study is that we did not ask caregivers whether they were employed, their type of employment, or their hours worked per week. The burnout and absenteeism measures used in this study do not define "work," and caregivers responded based on their interpretation of what "work" was, full-time, part-time, paid, or unpaid. As a result, we were unable to differentiate between burnout and absenteeism among caregivers who were employed in different capacities or engaged in informal caregiving roles. Without these data, we cannot determine whether reductions in absenteeism reflect actual changes in workplace behavior, time away from caregiving responsibilities, or broader improvements in caregiver functioning. Future studies should consider frequency of occurrence and types of employment and inclusion of caregivers who engage in informal caregiving and other unpaid work when considering burnout and absenteeism [63]. We used a single-item burnout measure and a single section from the HPQ questionnaire to assess absenteeism, which prevented us from comprehensively assessing our workplace outcomes. These decisions were made to simplify the assessment process and limit burden. While we considered the possibility that improvements in child mental health could be linked to improvements in caregiver workplace symptoms, we did not examine the specific types of mental health symptoms or care targets, as these were beyond the scope of this study. Future studies should account for a variety of children's mental health symptoms and more comprehensively assess caregivers' burnout, absenteeism, and presenteeism to address these limitations.

Finally, the nature of administering assessments and screeners changed partway through the study. Given that the burnout assessment did not have a corresponding screener and the absenteeism screener was simply used to identify no absenteeism, we do not expect that these methodological changes had any substantive impact on our main findings. While the total scores for the other caregiver and child mental health outcomes may have been affected by the changes in the screening methods, we only assessed whether elevated versus nonelevated symptoms predicted caregiver workplace outcomes. Thus, we expect that our findings are robust to these small methodological changes.

Conclusions

Caregivers are growing increasingly concerned about their children's mental health, which in turn is impacting their well-being and performance in the workplace. This study provides promising preliminary evidence that caregivers show decreases in their burnout and absenteeism when their children participate in a pediatric DMHI. As such, employers should consider offering pediatric digital mental health care to employees with children experiencing mental health difficulties, which may mitigate burnout and absenteeism. While these findings highlight the potential benefits of digital mental health care for working caregivers, future research should compare DMHIs with traditional face-to-face mental health care to determine their relative effectiveness and accessibility.

Conflicts of Interest

DLS, MR, and DM are employed by Bend Health, and Bend Health delivered the treatment used in this retrospective study. JH is a paid consultant of Bend Health. KM is an employee of JH and Fit Minded. However, authors' employment status and/or salary are not dependent upon the results of their research.

Abstract

Background: Follow-up to eye care services for children, especially in the context of Nepal, is essential for ensuring a continuum of care. Hence, as a continued effort, we designed this study to explore the service users' experience of a community-based intervention to improve follow-up at Bharatpur Eye Hospital (BEH) in Nepal.

Objective: This study aimed to explore service users' experiences and perceptions of the community-based follow-up intervention for eye care services implemented by BEH in Nepal.

Methods: A qualitative study using an in-depth interview approach was used. Participants were purposively selected for this research study. Participants who were part of a quasi-experimental study conducted to improve follow-up services in BEH and their service catchment area were chosen. Participants who had not attended even a single follow-up visit and participants who attended at least one follow-up were recruited for this qualitative study. Based on the distance from the base hospital and the follow-up status, 65 participants were initially found eligible for the qualitative study. However, only 17 participants were available and consented. Topic guides were developed for the purpose of in-depth interviews specifically for participants who had not attended even the first follow-up visits and those who attended at least one follow-up visit. A total of 2 ophthalmic assistants, who were not a part of the main intervention study, conducted the interviews.

Results: In total, 17 service users whose children were receiving services from BEH participated in the qualitative study. We identified 4 key themes that provided invaluable information about the barriers and facilitators to follow-up as well as the experiences (positive or negative) of the participants that need to be considered in any future initiatives to improve follow-up in Nepal.

Conclusions: This study highlights the need for systematic development of interventions to address the unmet need for eye care services in the community through innovative, scalable solutions. As a next step, the BEH team will be working to develop such scalable solutions for Nepal. Such interventions will also need to be optimized for similar settings and countries to meet the goals of universal health coverage, vision 2030, and sustainable development goals worldwide.

Introduction

Background

Nepal's National Health Policy 2019 recommends the development and expansion of eye care services through public-private partnerships in all 3 tiers of primary care provided through the government health systems. It provides guidance on the integration of primary eye care with primary health care and the coordination of eye care programs by a dedicated eye unit at the federal ministry of health [1]. One such effort is the Retina Eye Care of Nepal (RECON) project, which was designed to strengthen retina eye care services in Nepal [2]. This initiative was a well-planned health education intervention targeting physicians' knowledge about diabetic retinopathy. Evidence from the evaluation of this initiative identified an increase in the number of referrals and attendance of patients for diabetic retinopathy screening with the change in knowledge and referral mechanism [3].

However, providing referrals does not mean the care is complete. Follow-up for eye care services for children, especially in the context of Nepal, is essential for ensuring a continuum of care [4]. Counseling and follow-up with patients are the key factors in improving the usage of health care services [5]. An exploratory analysis of data from one single hospital (Bharatpur Eye Hospital [BEH]), spanning from January 1, 2019, to January 7, 2019, revealed that only 22% of children aged 0-16 years attended at least one follow-up visit and the remaining 78% could not attend for various reasons. There are several studies conducted to find the impact of interventions, such as SMS text messaging, phone calls, and counseling to improve adherence to follow-up care in both adult and pediatric populations. One of the studies has shown that SMS text messaging reminders significantly improved follow-up adherence in pediatric cataract treatment compared to the control group [6].

A quasi-experimental study was carried out in Nepal by the BEH team to find the effectiveness of follow-up interventions, particularly counseling with the provision of information leaflets and reminders through phone calls and text messages to improve the follow-up rates in comparison to the existing standard care. The primary outcome of the study was measured by the number of children completing all 3 follow-up visits in different intervention groups. This research showed no statistically significant difference in the proportion of follow-up between the intervention groups. Only 3% (8/264) of children completed all 3 follow-ups, but the overall compliance with follow-up was only 0.76%, with more follow-ups in the reminder with SMS text messaging and phone call groups [7]. There may be several reasons for the poor adherence to follow-up visits, but it was hypothesized that COVID-19 was the major contributor since the study was conducted during the peak COVID-19 time. Hence, as a continued effort, we designed this study to explore the service users' experience of a community-based intervention to improve follow-up at BEH in Nepal. We believed that this study would provide invaluable information on the reasons for the poor follow-up outcomes from the quasi-experimental study and the potential drivers of developing a culturally relevant, context-specific intervention for improving follow-up to ensure a continuum of eye care in the communities of Nepal.

Primary Objective

The primary objective of this research study was to explore service users' experiences and perceptions of the community-based follow-up intervention for eye care services implemented by BEH in Nepal.

Methods

Study Design

The study design was a qualitative study using an in-depth interview approach.

Setting

The interview was conducted by visiting the participants' homes. The purpose of the study was to understand why the participants did not visit the hospital for follow-up. Hence, interviewing them at their residence was identified to be a feasible and effective option.

Study Duration

The study duration was 1 month, from January 15 to February 16, 2024.

Participants

Participants were purposively selected for this research study. Participants who were part of a quasi-experimental study conducted to improve follow-up services in BEH and their service catchment area were chosen. Participants who had not attended even a single follow-up visit and participants who attended at least one follow-up were recruited for this qualitative study. Participants were selected irrespective of the intervention groups they were enrolled in during the quasi-experimental study. The participants were residing within a 20-km radius of BEH, and the interviews were conducted in the participant's residence. Participants with relatively serious eye problems requiring multiple follow-ups were included. Based on the distance from the base hospital and the follow-up status, 65 participants were initially found eligible for the qualitative study. However, only 17 participants were available and consented. The interviews were conducted with these 17 participants.

Data Collection Process

Topic guides were developed by an expert in qualitative research, who was our research guide, for the purpose of conducting in-depth interviews specifically for participants who had not attended even the first follow-up visit and those who attended at least one follow-up visit. Overall, 2 ophthalmic assistants, who were not a part of the main intervention study, conducted the interviews. These interviewers had a brief orientation on the topic guide and interview process to ensure consistency in the conduct of the interviews. The topic guides were piloted with a few participants before interviewing the actual participants. After providing prior information and obtaining written consent from each participant, the interview was carried out in their own communities, as it was not feasible for the participants to attend the hospital for interview purposes. During the interview process, one of the ophthalmic assistants

XSL•FO
RenderX

conducted the interviews, and the other person was involved in observing and taking notes. Interviews were conducted with the parents or guardians of the children who received eye care services from BEH. The interview participants were the parents/service users who accompanied the child to the hospital during the initial checkup. All the interviews were audio-recorded using a smartphone with consent from participants. We chose to stop the interviews based on the principles of data saturation, that is, when no further information was provided by the participants interviewed.

Data Analysis

We used the framework approach to analyze the qualitative data from this study. Interviews were audio-recorded, and the recorded interviews were transcribed verbatim. The interviews were conducted in the local language (Nepali). Hence, the audio recordings were first transcribed verbatim, and subsequently, the transcribed interview transcripts were translated and back-translated to ensure consistency in English by the other members of the study team. The transcribed data were read a multiple number of times to ensure familiarity. Codes were then identified to understand the framework for analysis. The codes and categories identified from the transcripts were then applied to that framework. The charted data were then carefully interpreted. We carried out member checking to triangulate data and to ensure data confirmability.

Ethical Considerations

Ethics approval was obtained from the Ethical Review Board of the Nepal Health Research Council (ethical review board protocol registration number 761/2020 P and ClinicalTrials.gov number: NCT04837534). Written consent was obtained from the parents or guardians via a consent form before enrolling them in the study. All the information collected was secured and stored safely by the principal investigators. The data were completely anonymized for the purpose of privacy and confidentiality. The participants were not compensated for participating in the study.

Results

Overview

In total, 17 service users whose children were receiving services from BEH participated in the qualitative study. Details of the participants are provided in Table 1. Participants represented the actual communities in Nepal on important sociodemographics. We identified 4 key themes that provided invaluable information about the barriers and facilitators to follow-up as well as the experiences (positive or negative) of the participants that need to be considered in any future initiatives to improve follow-up in Nepal.

Table . Characteristics of study participants.

Interviewee	Relation with child	Age (years)	Education[a]	Profession	Child age (in years)	Approximate distance from hospital (in km)
1	Mother	25	Secondary	Housewife	2	5
2	Father	30	Secondary	Driver/business	6	5
3	Father	34	Secondary	Business	7	15
4	Mother	28	Primary	Housewife	2	7
5	Mother	35	Secondary	Business	9	18
6	Father	40	Secondary	Plumber	9	16
7	Mother	22	Illiterate	Housewife	1	54
8	Mother	40	Secondary	Housewife	10	34
9	Father	35	Secondary	Contractor	1	17
10	Father	30	Above secondary	Business	1	9
11	Mother	29	Secondary	Housewife	2	11
12	Mother	30	Secondary	Business	1	10
13	Mother	40	Illiterate	Housewife	4	12
14	Father	45	Secondary	Business	10	8
15	Father	40	Secondary	Unemployed	3	13
16	Mother	29	Secondary	Farming	4	6
17	Father	50	Primary	Retired/farming	10	8

[a]Illiterate: unable to read and write in Nepali; primary: up to grade 5; secondary: grades 6 to 10.

Barriers to Follow-Up

The main reasons for barriers to follow-up were (1) ignorance about the eye problem and the potential solutions, (2) the poor financial situation of the service users, and (3) lack of satisfactory experience from the service providers during follow-up. Service users lacked awareness about the importance

XSL•FO
RenderX

of regular follow-up for their children's eye condition. Some also found it very uncomfortable to go out and discuss this with others in the community for further support. This was particularly because they were financially poor and could not afford to spend time and seek this advice as well as the treatment charges in hospitals that may be imposed when they follow advice from the community. Hence, they did not attend the follow-up visit as advised by the BEH follow-up intervention.

Many expressed financial constraints as a barrier to follow-up. The costs incurred in the treatment and travel were not affordable for them. Also, they were skeptical about whether the medications, treatment, and investigation would fall under the insurance subsidy or not. Therefore, it was difficult for the service users to abide by the advice related to follow-up that was suggested.

> *People keep asking us to take our child to different places but its only us who know our situation – Not easy*

Many parents were busy and had to take off time from their routine schedules including their work commitments, which made it nonfeasible to comply with the advice for follow-up. As their children were studying and attending school, it was difficult to match their schedule to bring the child for follow-up as advised by the service providers. Lack of school attendance was considered by the service users as a huge loss. Also, the distance of the hospital from home was a barrier, as it cost time and money to travel to the hospital from their faraway residence.

> *My child needs to go to school, so difficult to come for follow-up during the school hours.*

The child was not compliant with the treatment given, like not wearing the glasses prescribed. Some parents were unsure if the child was asked to bring it for follow-up or not. There were a few service users whose children felt better with the initial treatment and so did not continue to follow up.

> *I do not recall being called for follow up.*

Experiences and Perceptions

During the interview, service users felt that their presence was not given any importance. Service users expressed that BEH was the main center for eye care in Chitwan and it was mostly overcrowded, implying a long waiting time, not just at one counter but in all the counters, rooms, and departments they visited. The system and pathway that service users were advised to follow were perceived to be outdated, and there was no fast-track or exclusive service for those referred by their own staff and their own catchment area, thus making the experience not very satisfactory. This was especially the case for those who could not afford the service and for those who required access to the service on an urgent basis. The service users suggested that it would have been better if there was a fast-track eye checkup system, especially for very small children and those who were invited for a follow-up appointment.

> *One whole day was wasted for eye checkup at BEH, no one valued our time, we are not sure why did they ask us to come for making us wait for so long*

The service users also felt that some hospital staff did not respond well. They expressed that the BEH support staff were busy on the phone and did not have a friendly approach. Some felt that there was miscommunication about the dates and time for follow-up and a lack of timely information provision and advice related to their felt needs. In addition, a few service users expressed that they were unable to recollect their experiences accurately as it has been a long time since they visited the hospital for follow-up.

> *I was there in the queue for 3 hours and when my turn came, I was handed out the paper and told to come the next day, that is unfair, they should have informed me on time, it is not possible for me to come here daily. I have a shop to run and so many errands at home!*

Service users also shared their positive experiences during the follow-up. They expressed that BEH was well known in our communities; therefore, whenever there was any eye care need, service users preferred visiting BEH rather than other centers (medical or optical shops). Some service users liked that the system was available to access eye care and felt that their experience was comfortable at BEH. One the key features liked by service users was proper signage, which guided them in identifying and accessing different departments. The token system for registration and access to respective departments without any waiting time and smaller queues and the presence of a separate department for children, which made the experience comfortable for the kids and their parents.

> *It has a homely environment and feels like a second home.*

Service users also felt that both clinical and nonclinical staff were well-behaved and had a friendly attitude. The doctors and other clinical staff used very simple and understandable advice. They expressed that the service providers had explained the procedures and treatment options clearly that made it very easy to understand and make decisions. Incidentally, some people experienced less crowd during their visit, so their experience was smooth and less time-consuming.

> *All staffs even the guard were very friendly to me.*

Service users felt that the doctors provided good treatment, provided patient education, and stressed the importance of follow-up visits. The counselor and other clinical staff were observed to have stressed the role of proper treatment options and a good healthy lifestyle to reduce eye problems (such as reducing screen time, having a good healthy diet, and importance of outdoor activities for children).

> *The eye check-up went easily, it was not at all complicated as anticipated.*

Drivers for the Follow-Up

One of the important facilitators for implementing any intervention at BEH was the trustworthiness and brand name of the service provider. Being the oldest and biggest eye care center in Chitwan, BEH has earned its reputation; people perceive it to be the key service provider for that the region.

XSL•FO
RenderX

This is the oldest and biggest centre for eyes in Chitwan, why would I go anywhere else?

Service providers expressed that the eye camps were regularly held by the BEH at schools and localities, which refer patients to the base hospital (BEH). They felt that the service providers helped with information regarding the importance of preschool vision screening. The hospital also provided a national health insurance scheme, so it was very economical to get treatment there. There was also a subsidy system for low-income patients, so no one was denied basic eye care at BEH. Related to the intervention, participants felt that the reminder phone call from the hospital was very useful and helped people to remind themselves of the upcoming follow-up date.

Discussion

Principal Findings

This qualitative study aimed to explore the reasons for poor follow-up for eye care services and the experiences of service users receiving pediatric eye care at BEH. The findings revealed a complex interplay of factors influencing adherence to follow-up appointments, encompassing barriers, negative experiences, positive experiences, and facilitators. Lack of information and awareness about the eye problem and the required care, poor experience in accessing follow-up care, opportunity cost, and financial constraints have been the key reasons for poor follow-up. In addition, the COVID-19 pandemic and the naturally recovered service users who may not need a follow-up may be the contributors to poor follow-up that must be considered.

These reasons for poor follow-up were the commonly identified barriers to accessing any health or rehabilitation, particularly in the context of low- and middle-income countries [8]. In a country like Nepal, the geographical access barriers could be an additional drawback, which was not evident from this study [9-11]. However, the experiences of those who attended the follow-up provided very useful insights about the important aspects to ensure during the development of any pathway for follow-up [12,13]. They stress the importance of systematically developing a specific pathway that is sensitive to the context and culture of the service users in the catchment area [14-16]. They also highlight the need for sensitizing the service providers to the fact that the delivery of health care services may not have the same process and pathways for all service users [17].

The positive experiences from this study reveal some of the important aspects that need to be considered while developing such follow-up pathways for improving the effectiveness and quality of service provision [18]. This is applicable not just to eye care but to all kinds of health care provision services [19,20]. Service providers, including field workers and ground staff; organization of care; and delivery of services must be carefully optimized for improving service efficiency [21]. Our study highlights these important drivers for improving eye care services [22].

The implications of this study highlight the need for more research into the interventions for follow-up, especially for eye care services in Nepal and similar contexts. Much of the care that are globally available is provided within an institution [3-7]. However, for eye care services, this approach needs to be different, and it should include community-based care connecting service users in the community to the service providers at the institutions [23,24]. Technology can be a huge advantage in developing such kinds of interventions. Hence, more research is required on the systematic development and evaluation of comprehensive interventions that can promote a continuum of care [25].

This study also has a few practice and policy implications. Increasing awareness about the problem and potential solutions at the first point of contact can promote the information required to identify choices of care and make appropriate decisions about it. Similarly, the optimization of insurance coverage for socially disadvantaged communities and economically deprived service users by ratifying existing policies or expanding and implementing coverage to provide financial relief for service users can add value and improve service users' experience positively [26].

Limitations and Strengths

This study also comes with a few limitations. Since the initial experimental study was conducted during the COVID-19 pandemic, it was difficult to locate the participants for recruitment. We collected data 2 years post COVID-19, but soon after, the experimental study to test the intervention effectiveness was completed. Although this might appear to contaminate the results, the authors did not identify any potential limitations or recall issues related to the objective of this study during the study. Also, the other stakeholders, such as service providers and administrators, were not interviewed. Doing so might provide their perspectives for understanding the actual context. The interview was recorded in Nepali and was later translated in English. This may have resulted in inadequate reporting of the emotional aspects of the interview. These aspects need to be carefully considered in future studies on this topic. The study also had a few strengths. This study was actually an extension of a quasi-experimental study to understand the lack of statistically significant differences in the findings of that quantitative study. This study enabled us to understand the reasons for systematically developing and evaluating interventions. The participants were those with a need to attend follow-ups but did not turn up. Hence, the data from interviews relate very closely to the purpose of the study. Data triangulation, through repeated verification of audio recordings and transcriptions, was completed. We also carried out member checking and added rigor to this study.

Conclusion

This study provides immensely valuable insights. It highlights the need for systematic development of interventions to address the unmet need for eye care services in the community through innovative, scalable solutions. As a next step, the BEH team will be working to develop such scalable solutions for Nepal. Such interventions will also need to be optimized for similar settings and countries to meet the goals of universal health coverage, vision 2030, and sustainable development goals worldwide.

Acknowledgments

We gratefully acknowledge the Seva Foundation (United States) and Seva Canada for funding this project. Additionally, we thank the Indian Institute of Public Health, Hyderabad, and the Pragyaan Sustainable Health Outcomes (PRASHO) Foundation for their valuable guidance and support throughout the project. We also extend our gratitude to the management and staff of Bharatpur Eye Hospital (BEH) for their contributions to various aspects of this study.

The Operational Research Capacity Building Study Group consisted of the following members: Indian Institute of Public Health, Hyderabad (Public Health Foundation of India): Prof Gudlavalleti Venkata Satyanarayana Murthy, Dr Sureshkumar Kamalakannan, Ms Ruchi Priya, Dr Rajan Shukla, Dr Shailaja Tetali, Dr Anirudh G Gudlavalleti, Dr Varun Agiwal, Mr Hira Pant, Dr Sirshendu Chaudhuri, Dr Nirupama AY and Dr Yashaswini Kumar. SEVA: Dr Suzanne Gilbert, Dr Ken Bassett, Ms Priya Adisesha Reddy, Ms Parami Dhakhwa, Mr Ram Prasad Kandel, Dr Binita Sharma, Mr Kuldeep Singh and Mr Prasanna Sharma.

Data Availability

The data collected have been presented in the manuscript. Any request for additional data will be reviewed by the advisory committee and will be shared upon request.

Authors' Contributions

MS, GB, SB, BP, SKK, RP, DSC, and PG conceptualized and designed the study. SKK finalized the topic guide for the interview. Deepak Kumar Yadav and Prakash Malla were responsible for conducting and recording the interview. Debaki Acharya conducted the data collection and data entry. MS, GB, SB, BP, SKK, and RP did the data analysis. MS, GB, SB, SKK, and RP drafted the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The transition from pediatric to adult health care marks a complex and pivotal process for adolescents and young adults with inflammatory bowel disease (IBD). This group requires support regarding disease self-management, skill development, and system navigation in preparation for transition. Evidence-based interventions are needed to promote optimal health and psychosocial outcomes for adolescents and young adults with IBD during this period.

XSL•FO
RenderX

Objective: A qualitative study embedded within a randomized controlled trial was conducted to evaluate the perceived impact of a biopsychosocial transition intervention on the transition experiences of adolescents and young adults, their views on the intervention, and recommendations for future care.

Methods: This patient-oriented research study used a qualitative descriptive design. Virtual semistructured interviews were held with 21 adolescents and young adults with IBD (16 - 18 y) enrolled in the randomized controlled trial (intervention arm n=11 and control arm n=10). Interviews were audio-recorded, transcribed, and analyzed using an inductive approach to reflexive thematic analysis. Five members of a Youth Advisory Panel with lived experience of IBD collaborated throughout data analysis, interpretation, and the presentation of findings.

Results: We constructed three themes through our analysis: (1) making meaning of transitions in care; (2) perceptions and impact of the biopsychosocial transition intervention; and (3) considerations for future transition care, including the importance of individualized support.

Conclusions: Our findings illustrate the importance of relationships and the impact of a biopsychosocial intervention on adolescents' and young adults' confidence, knowledge, and self-management skills during transition. The results, which indicate the criticality of tailoring transition supports according to adolescents' and young adults' preferences and characteristics, will be used to refine the biopsychosocial intervention before it can be scaled and spread.

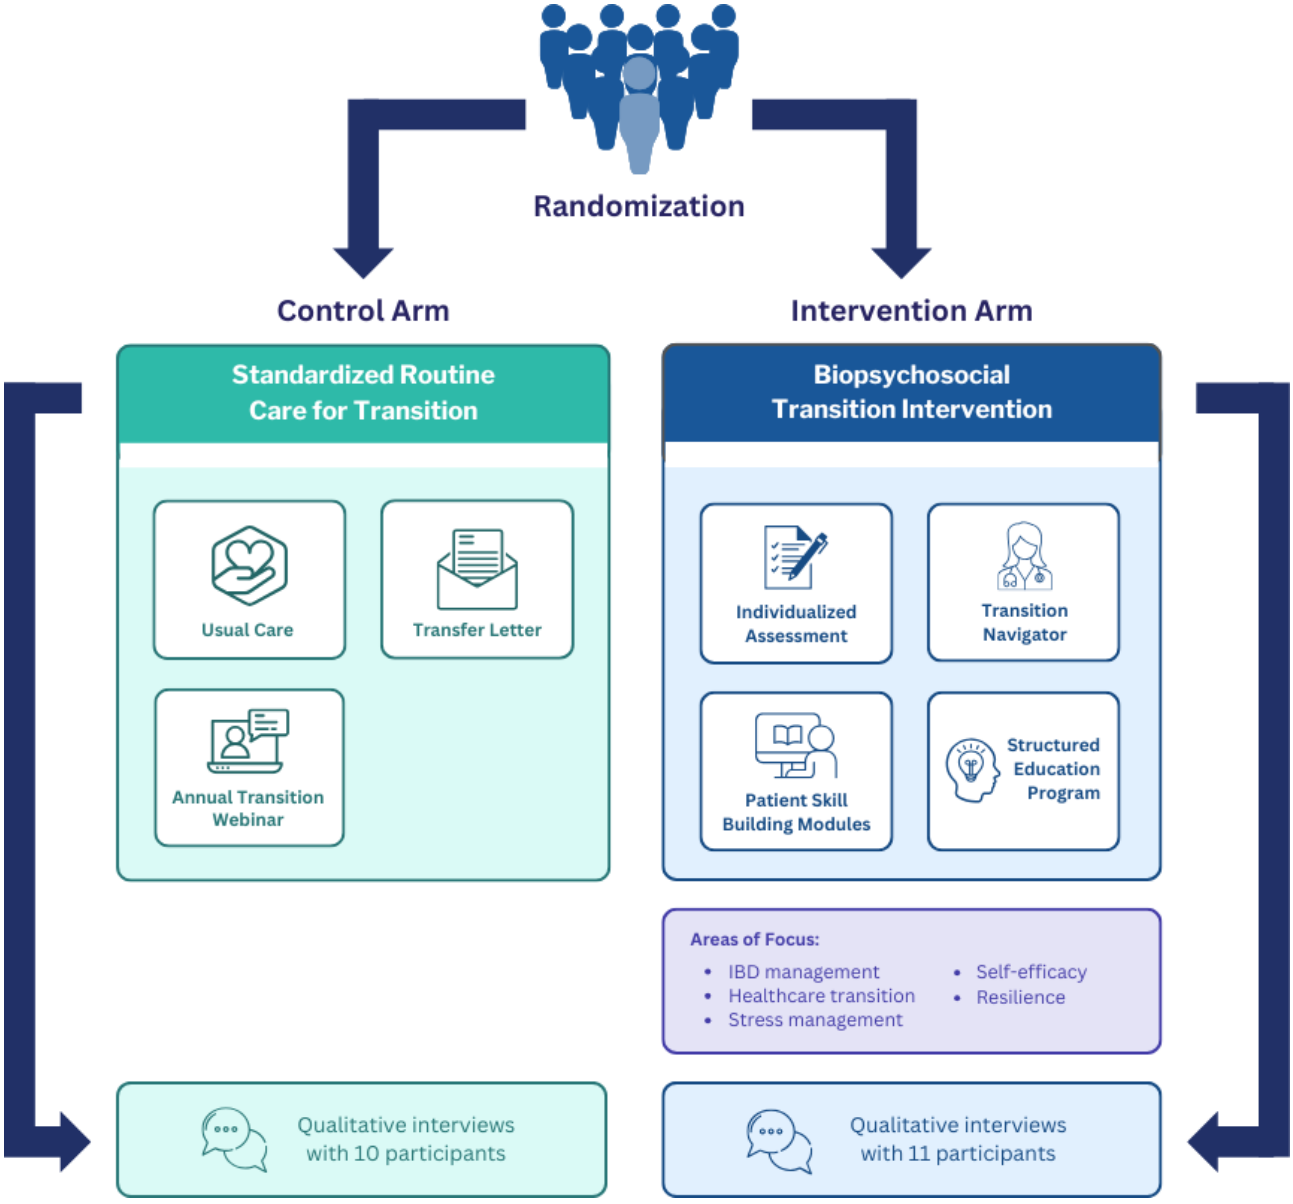
Introduction

The transition from the pediatric to the adult health care system can be a complex period for adolescents and young adults with inflammatory bowel disease (IBD) and their families [1]. In adult care, adolescents and young adults are expected to self-advocate, communicate with providers, understand their health history, and manage their health with greater independence [2,3]. However, service disruptions at the pediatric-adult juncture, shifts in parental involvement, a lack of readiness for transition, and differing treatment philosophies and models of care can complicate the transition process [1,4]. While the transition from pediatric to adult care for adolescents and young adults with IBD has been well studied and identified as a priority area for policy and program development [5-7], evidence-based transition interventions that account for the priorities of adolescents and young adults are needed.

Adolescents and young adults with IBD face a series of challenges around the transition from pediatric to adult care [1]. Psychosocial stressors are prominent at this stage of life, including the emergence or worsening of mental health conditions, changing roles within the family, and co-occurring transitions in the areas of employment, education, and living [8]. Termination of longstanding relationships with pediatric providers and expectations for autonomous management of one's health condition following a transfer out of pediatric care can exacerbate the challenges associated with this period [1,9]. Additionally, this group is susceptible to poor health outcomes and high health care costs should the transition from pediatric to adult care be disjointed [10-12]. Therefore, a purposeful, coordinated, and planned transition from the pediatric to the adult health care system is required to ensure adolescents and young adults with IBD can achieve the best possible health and psychosocial outcomes during a complex developmental period [13].

Transition interventions for adolescents and young adults with IBD to date have typically included joint pediatric-adult clinic visits, face-to-face education about disease processes and self-management, and meetings with allied health professionals focused on self-efficacy and goal setting [14]. However, transition intervention components are highly variable and limited research has focused on adolescents' and young adults' perspectives of the most valuable and well-received aspects of such interventions [14]. Further, there is no level-one evidence (eg, randomized controlled trials [RCTs]) for any intervention in transition in IBD [15]. To improve the standards for health care delivery and transition care across Canada for adolescents and young adults with IBD, a biopsychosocial transition intervention was developed and is currently being evaluated in a type 1 hybrid effectiveness-implementation trial (ClinicalTrials.gov NCT05221281) [16]. While various functional and implementation outcomes are being assessed within the RCT using standardized measures, qualitative research can elucidate adolescents' and young adults' needs and experiences of the intervention to support the translation of findings into practice [17]. Thus, the objectives of this study were to explore adolescents' and young adults' transition experiences, perceptions of the transition intervention, and recommendations for future transition care to inform the refinement of the intervention.

Methods



Study Design and Population

This patient-oriented research study [18] adopted a qualitative descriptive design [19] to understand the needs and experiences of adolescents and young adults with IBD during the transition while concurrently assessing the perceived impact and acceptability of the biopsychosocial transition intervention. It was embedded within an ongoing multicenter RCT evaluating the effectiveness of the transition intervention among

XSL•FO
RenderX

adolescents and young adults with IBD [16]. A qualitative descriptive design was used to explore the perspectives of adolescents and young adults in addition to the outcomes being assessed in the RCT [16,19]. The intervention consisted of (1) an individualized assessment, (2) a transition navigator, (3) patient skill-building delivered via online modules, and (4) a structured education program (see Figure 1 for an overview of the RCT design) [16]. Half of the RCT participants were randomized to the biopsychosocial intervention, and half received a standardized version of routine care for transition [16]. Adolescents and young adults in the intervention arm received support from a transition navigator. They had access to online skill-building activities and an online education program with topics focused on IBD management, resilience, health care transition, self-efficacy, and stress management for the duration of the study [16]. Though the RCT has 3 study sites at Canadian tertiary care centers, this study explored the perspectives of adolescents and young adults at the study site, which has the largest cohort of participants and has participants who had access to the intervention for the longest duration.

Figure 1. Overview of RCT design. IBD: inflammatory bowel disease; RCT: randomized controlled trial.

In embracing a patient-oriented research approach [18], the study investigators collaborated with a project-specific Youth Advisory Panel (YAP) consisting of 5 patient partners with diverse backgrounds, expertise, and lived experience with IBD. YAP members were recruited from an existing national IBD advisory council. The national IBD advisory council was involved in a previous qualitative study conducted by our team [20]. Subsequently, select advisory panel members expressed the desire to become involved in this study to further explore and contribute to the qualitative findings. The YAP consisted of 3 male and 2 female members aged 18 - 30 years from across Canada, thereby increasing the study's transferability with enhanced diversity of input and representation of health care experiences. The YAP members actively contributed to data analysis, interpretation, presentation of results, and preparing this article, helping align research findings with patient-identified priorities [18]. This collaborative partnership and bidirectional flow of knowledge helped cultivate a sense

XSL•FO
RenderX

of ownership in members while capturing nuanced insights often overlooked in traditional research paradigms. YAP members were supported and mentored by 2 study team members (BA and AM) throughout the process. Study investigators and YAP members frequently corresponded via email. They held virtual weekly or biweekly progress meetings over 3 months (March-May 2024) with flexible agendas to promote clarity of purpose, efficient use of time, and active participation during meetings.

Eligibility and Sampling

Study procedures are available in a prior publication [20]. Briefly, eligible qualitative participants were the following: (1) aged 16 - 20 years, (2) English-speaking, (3) diagnosed with IBD, (4) enrolled in the RCT at the SickKids study site for at least six months, and (5) capable of providing informed consent. Purposive sampling [21] was used to select a clinically and demographically diverse sample of adolescents and young adults in the intervention and control arms, with varying levels of engagement with the intervention. We discontinued recruitment once we gleaned a breadth and depth of relevant information from participants to answer our study questions [22].

Data Collection

A female qualitative researcher with a social work background conducted individual interviews with adolescents and young adults using an institutional account of Microsoft Teams (Microsoft Corp). A semistructured interview guide, developed with YAP members and an interdisciplinary team of IBD clinicians and researchers, was used. Interview questions focused on adolescents' and young adults' experiences preparing for or undergoing health care transitions, perceptions of the biopsychosocial intervention, and recommendations for future transition care in IBD. Consent was obtained, and interviews were digitally recorded, transcribed, verified, and anonymized before analysis. Reflective memos were used during data analysis to highlight striking patterns and impressions of the interview data [23]. Participants received a US $20 electronic gift card and 1 volunteer hour for completing an interview.

Data Analysis

An inductive approach to reflexive thematic analysis [23,24] was used to analyze the data. Interview transcripts were reviewed by 2 coders (BA and M Browne) who reflected on their positionality, assumptions, and social locations in reference to the data. The coders then engaged in line-by-line coding inductively, designating codes to portions of interview text to categorize shared ideas [23,24]. They met consistently during the coding process to consider their perceptions of the data, important codes, and emerging patterns and to begin collectively making sense of the data [23]. Codes were grouped into themes to capture the meaning and key concepts within the data, and relationships between codes and themes were examined using mind maps. YAP members independently reviewed the list of codes and preliminary mind maps. YAP members shared their opinions on organizing concepts, developing themes and figures, and determining which ideas were most important to convey synchronously at online team meetings using the Microsoft Teams platform and asynchronously using collaborative documents. The preliminary themes, codeveloped with the YAP, were presented to the larger team for input, refined, and final themes were named and consolidated through discussion. Analysis was conducted using NVivo (version 14; Lumivero).

Ethical Considerations

Institutional approval for this study was obtained from The Hospital for Sick Children (SickKids) Research Ethics Board (REB #1000078476). Informed consent was obtained for each participant in the RCT and prior to enrollment in this substudy.

Results

Overview

A total of 21 adolescents and young adults were interviewed between May and September 2023 (intervention arm=11 and control arm=10). Participants were aged between 16 and 18 years, primarily female, and at different stages of health care transition. The demographic and clinical characteristics of the participants are presented in Table 1. Participant identifiers beginning with "C" denote control arm participants, and those beginning with "I" indicate intervention arm participants in the results. We constructed three themes through our analysis: (1) making meaning of transitions in care; (2) perceptions and impact of the biopsychosocial transition intervention; and (3) considerations for future transition care, including the importance of tailored supports.

Theme #1: Making Meaning of Transitions in Care

Overview

Adolescents and young adults expressed a range of reflections on the meaning of the transition from pediatric to adult health care. Their conceptualizations of this transition ranged from "switching doctors" to more existential thoughts about the health care transition, marking the loss of childhood. The meanings ascribed to health care transitions appeared to influence adolescents' and young adults' feelings about entering adult care and their overall readiness to engage in self-care tasks with greater autonomy.

On one end of the spectrum, adolescents and young adults described the transition to adult care as "an inevitability and a necessity" [C-036] once they were aged 18 years. Participants with this view seemed to understand transition as moving from one specialist to the next, with expectations that care would be delivered similarly. Those who conceptualized this change as primarily related to switching providers without ascribing a deeper philosophical meaning to transition tended to express minimal concerns or worries about entering the adult system. Many of these participants had well-managed IBD or family members (eg, parents or siblings) with IBD who were already receiving treatment in the adult system. As described by 1 participant, "For me, it's not a big deal, you're just switching doctors. And it'll just be the same thing over there anyway, so I'm not really stressed out about it." [C-001]. Importantly, however, those with this mindset had not yet transferred or been exposed to the adult care environment.

Others reflected that the transition to adult health care aligned with the launch from adolescence to young adulthood. Many adolescents and young adults viewed the health care transition as a signal that they were now "grownups" [I-039] who would be required to assume new roles and responsibilities within and outside their IBD management. Some adolescents and young adults felt the transition allowed them to reflect on their growth and development. There was an overarching sense of hope for the future, while, at times, this was coupled with feelings of sadness about the loss of relationships with familiar pediatric providers: "I mean, it's a sign of maturity and that I'm growing. It's kind of sad in that way, but you know, it's a part of life." [C-031]. Most participants accepted the transition and described it as a period in which they would take greater initiative, advocate for themselves, learn more about their health history, and plan their appointments. One participant shared:

> *I look at [transition] as me having to know a lot about myself, especially where I am with my health. At the end of the day, my mother has to stop bringing me to*

XSL•FO
RenderX

> *the appointments, I can't bring her all the time, right? Because it's that independent thing that comes in. So I think it's just a learning experience about myself, learning about where I am with my health, knowing everything that I need to know for myself so I don't have to depend on anybody else to know it for me.* [I-021]

Most participants felt motivated, empowered to take ownership of their care, and even excited to enter a new environment, mainly due to the reputations of the adult IBD clinics or specialists and their confidence in their ability to self-advocate. However, a few adolescents and young adults expressed some hesitance about moving into adult care due to the perceived expectations of adult providers: "While new things are exciting, they're also unknown and unknown things are scary. [My adult team] will have expectations for grownups, but I don't really feel like a grownup" [I-039]. The following subtheme delves into the role of relationships between adolescents and young adults and their support networks.

Relationality and Transitions to Adult Care

Trusting relationships with health care providers, family members, and peers emerged as transition facilitators for adolescents and young adults. When participants had strong and supportive relationships with their pediatric health care providers, they expressed confidence in their adult IBD providers' ability to meet their needs: "I have lots of trust in my pediatric doctor, so if he recommended me to this one then this one must be pretty great." [C-014]. Adolescents and young adults outlined their hopes for developing trust with their new providers in adult care and shared examples of factors promoting engagement with clinicians. These included providers offering clear and detailed responses to adolescents' and young adults' questions, adopting a nonjudgmental stance, being transparent about treatment plans, offering adolescents and young adults choices, listening intently to their concerns, and asking for adolescents' and young adults' input on health-related decisions.

Adolescents and young adults receiving the biopsychosocial intervention described their relationship with the transition navigator as being one of the most beneficial aspects of this study. Many felt the navigator played a key role in preparing them for the transition by serving as a point of contact for any questions or concerns and "checking in" with adolescents and young adults, particularly between their final pediatric and first adult appointments. Adolescents and young adults described the transition navigator as demonstrating genuine care for their well-being, offering support with the transition to postsecondary education, encouraging the development of self-management skills, and providing anticipatory guidance about what to expect in adult care. "[My transition navigator] made that effort to make me feel like she's not just a transition navigator, she's a person that actually cares about me." [I-015]. The quality of their relationship with the transition navigator also prompted some adolescents and young adults to open up about their emotions and mental health. In one case, this led to a participant receiving a diagnosis for longstanding anxiety symptoms and subsequently accessing mental health supports:

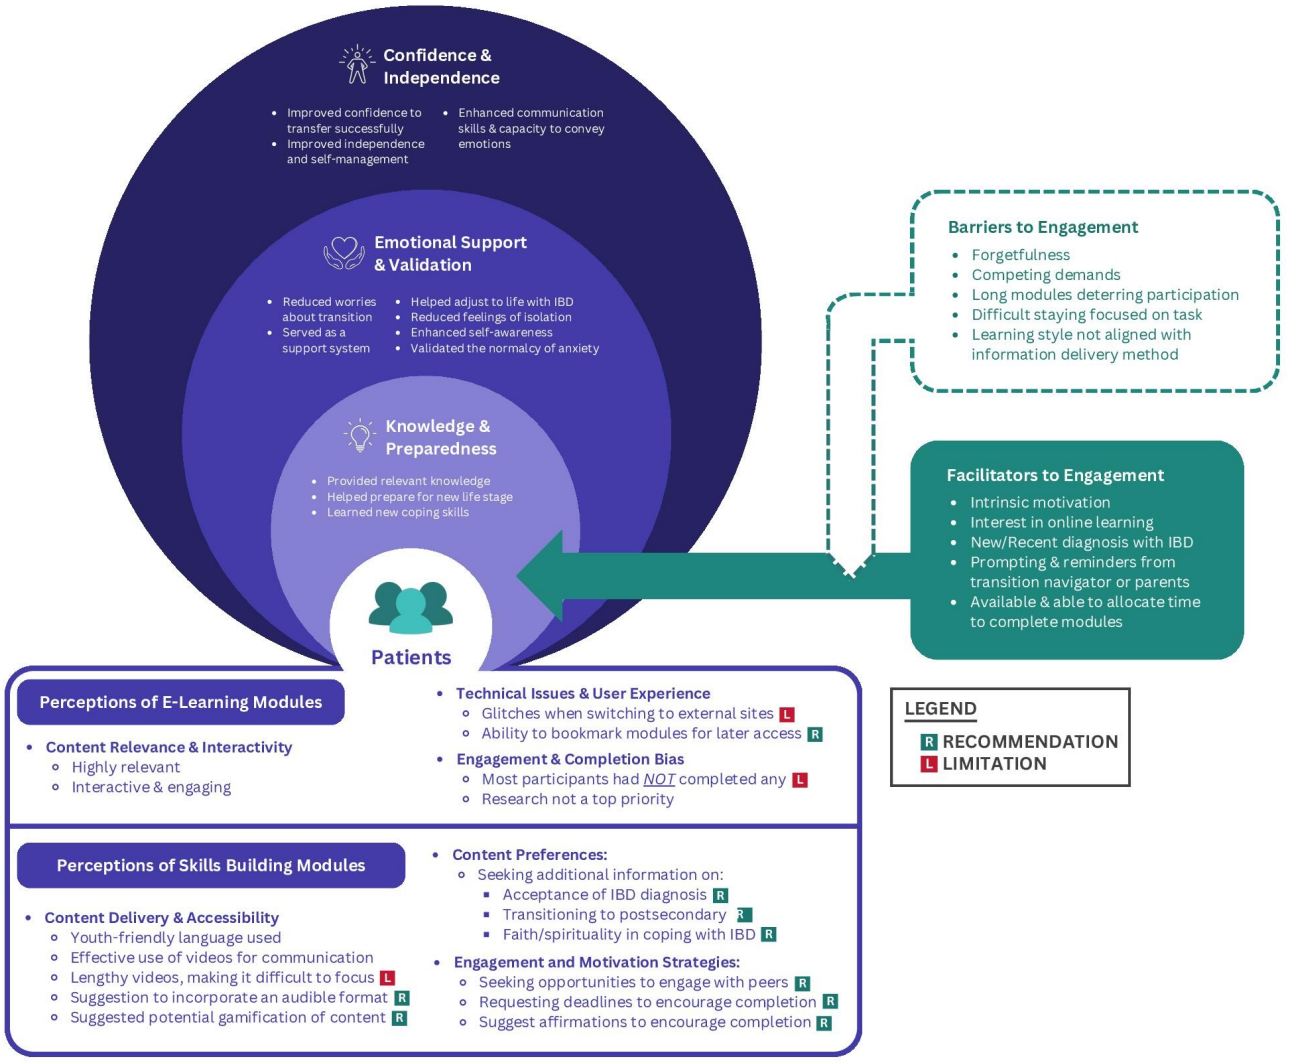
> *Before I got diagnosed with generalized anxiety, I talked to my transition navigator about how I was feeling and how I didn't really know how to cope. She helped me make the decision to go see a doctor about it to see if [I] could get prescribed medication or get some sort of diagnosis. Even though I was kind of on edge about going to a doctor for something that sounded so silly in my brain, she helped me calm myself about it.* [I-016]

Lastly, adolescents' and young adults' relationships with family members and peers facilitated the acquisition of self-management skills and enhanced confidence in preparation for transition. They described the pivotal roles their parents played in helping them cope with IBD and how they are taking more responsibility for specific tasks over time:

> *My parents have always been supportive and on top of it, maybe even a little more than I have. Because at first, I was in denial, I was like, "no, my IBD's not that bad". But they were keeping me on top of my medication and stuff, especially when I was younger, my mom helped me a lot with that. I've become a little more independent now and I'm able to take medication on my own.* [I-020]

Many outlined the value of having parents, siblings, and extended family members offering emotional support (eg, listening, reassuring, or encouraging), instrumental support (eg, teaching how to refill prescriptions), and advice as they approach the transition to adult care. Parents often served as mentors to adolescents and young adults, coaching them to assume greater responsibility for their care and IBD management incrementally. Most participants were aware their roles would change in adult care and were working with parents to practice skills and negotiate what these new roles would be like posttransfer.

The transition experience appeared to be constructed in relation to others. Trusting relationships with health care providers, family members, and peers were found to promote confidence and readiness to engage in the tasks required to manage IBD care during transition. Adolescents' and young adults' ability to communicate their needs openly to others (and feel validated by them) was a priority for participants, and supportive relationships helped facilitate this.



Theme #2: "It Gets Me Ready to Start Doing Things on My Own": Perceptions and Impact of the Biopsychosocial Transition Intervention

Overview

A combination of adolescents' and young adults' communication preferences, personality characteristics (eg, curiosity, motivation, or social), learning styles, and sources of support influenced their uptake of and perspectives on the intervention. Participants' perceptions of the intervention's impact fell into three categories: (1) knowledge and preparedness, (2) emotional support and validation, and (3) confidence and independence. Additionally, barriers and facilitators to engagement with the intervention were described by adolescents and young adults (Figure 2).

XSL•FO
RenderX

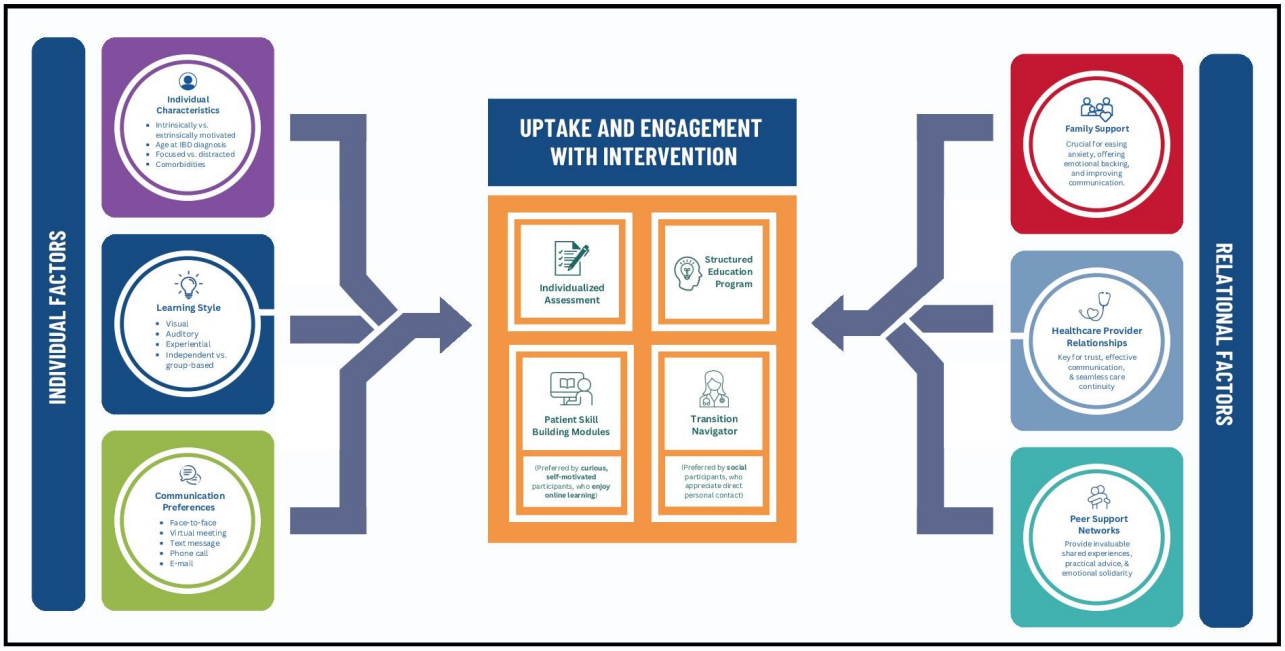
Figure 2. Impact and perceptions of the biopsychosocial transition intervention. IBD: inflammatory bowel disease.

Knowledge and Preparedness

Adolescents' and young adults' experiences of the intervention indicated that acquiring knowledge helped foster a sense of agency and supported their transition readiness. Core components of the transition intervention helped adolescents and young adults envision their transition journeys while arming them with the competencies required to succeed in adult care and life. Participants receiving the intervention expressed positive sentiments about their experiences in the trial, noting that it catalyzed personal growth and empowerment. Shifting from a mindset of passive acceptance to one of proactive engagement in navigating the complexities of transition, many participants, with curious mindsets, described applying newly acquired skills and knowledge in their daily lives to improve aspects of pain management, communication, and self-regulation:

> *The transition from pediatric care to adult healthcare is one that's not easy, [but] there are things that you can learn in order to be more successful during transition with respect to being an adult. I think it's really just using your skills, engaging in things like mindfulness, and building your confidence so that you can communicate with your healthcare team as best as you can.* [I-019]

A few participants even considered the newfound sense of agency to extend beyond health care transitions to encompass broader life transitions, such as education, career choices, and relationships:



> *Before I started this, I barely even knew what transition was! It was very foreign to me and it was almost scary because I didn't know what to expect. Especially in addition to going from high school to university, there was just a lot of stuff going on in relation to transition. So having these modules, having this information is something that has definitely helped me in that sense.* [I-007]

Emotional Support and Validation

Given the myriad of psychosocial stressors and challenges inherent in transitioning from pediatric to adult care, adolescents and young adults voiced that validation and emotional support were important. Participants in the intervention arm found these types of support in different intervention components based on their individual characteristics and relational factors (Figure 3).

XSL•FO
RenderX

Figure 3. Factors influencing engagement with the intervention. IBD: inflammatory bowel disease.

Most adolescents and young adults who were social found that having direct access to a transition navigator (eg, via text or email) offered reassurance and interpersonal connection; one such adolescent or young adult shared: "100% talking to [my transition navigator is the most helpful component of the intervention] because I'm a people person, so talking to somebody is very helpful, whereas I just get bored doing the modules and stuff." [I-016]. Other participants with similar personality characteristics felt that having a transition navigator helped foster a trusting relationship that extended beyond clinical interactions, providing them with an open outlet to voice their hopes, fears, and concerns regarding their transition to adult care. Many adolescents and young adults even felt immediately more prepared to transition, knowing that their transition navigators represented a dependable source of information that they could turn to and confide in during times of need: "I did get a person [transition navigator] who I can text about anything I'm struggling with. They've definitely helped me be open about how I'm feeling." [I-007]

Other adolescents and young adults voiced that the variety of concepts covered in the skills-building modules validated their concerns and helped them feel less alone in coping with the challenges of living with IBD: "if they're making modules like this, I'm not the only one that's feeling like this." [I-020]. Regardless of their personality traits, most adolescents and young adults described being well supported by their transition navigator in making informed decisions, whether that be related to accessing postsecondary accommodations or scholarships, obtaining referrals to relevant resources (eg, mental health services, volunteer opportunities, or support groups), or learning about the expectations of adult IBD providers.

Confidence and Independence

Adolescents and young adults outlined how the intervention promoted confidence in preparation for adult care. Some adolescents and young adults viewed the skills-building modules as the most relevant and beneficial aspect of the intervention because they gained independence through acquiring new strategies. Participants who were self-motivated and enjoyed online learning appreciated the wealth of information offered on a range of topics and the ability to access the modules at their own pace given their busy schedules at this stage of life (eg, planning for postsecondary education, participating in extracurricular activities, or working). Additionally, most adolescents and young adults felt that the skills and knowledge developed through the intervention could be applied to their illness and beyond: "I feel like the skills are the most applicable to your everyday life. You can use them with Crohn's or without Crohn's. They teach you how to deal with any obstacle you might have in that sense." [I-019]

Many adolescents and young adults outlined the impact of the intervention in its entirety on their feelings of confidence and preparedness for a new care environment:

> *To have a navigator or to have modules, I just feel more comfortable now and more confident. Because even before I was like, "what's going to happen when I turn 18? I don't want to leave [pediatric hospital] because I just feel like they know all about everything I've been going through and have helped me.*" [I-020]

While all participants receiving the intervention approved of its impact on their knowledge, skills, emotional well-being, confidence, and overall preparedness for transitioning to adult care, each adolescents' and young adults' preferences and personality traits impacted how and where they experienced the greatest benefit.

Barriers and Facilitators to Engagement

As outlined in Figure 3, a series of individual, intervention-specific, and familial characteristics supported or hindered adolescents' and young adults' engagement with the intervention and in their overall health care.

Individual characteristics that facilitated engagement included being newly diagnosed with IBD, having strong relationships

XSL•FO
RenderX

with health care providers, and feeling well supported by family members and peers. Adolescents and young adults with recent diagnoses were motivated to complete the skills-building modules because they were interested in developing a higher-level understanding of their illness, including symptom management, self-care, and peer support. Adolescents and young adults who were intrinsically motivated and had learning styles conducive to online learning with visual aids, audio, and text-based materials favorably viewed the presentation of the modules. Consequently, these individuals did not require much prompting as they were driven to learn and expand their skill sets of their own accord.

The support systems adolescents and young adults had in place were critical to the uptake of the intervention, particularly for those who described themselves as forgetful. Most participants benefited from the navigator prompting or reminding them to complete the modules and appreciated the navigator's persistence in communicating with them. Adolescents and young adults with comorbidities (eg, diabetes, arthritis, or anxiety) seemed to require more encouragement from the transition navigator or family members to support module completion, given they were managing multiple illnesses, appointments, and medication regimens. Some adolescents and young adults described completing the modules alongside parents who were interested in learning and supporting their adolescents or young adults, aiding participants who may otherwise have lacked interest in engaging with the content: "My mom was super on top of it [skills-building modules], and she's like, 'come do the modules with me'" [I-020]. When these supports were available, adolescents and young adults seemed better able to complete the materials and solidify their learnings through conversation and questions.

Regarding barriers to engaging with the intervention and completing the skills-building modules, most adolescents and young adults cited competing demands (eg, examinations, work, family, or romantic relationships) and forgetfulness as factors influencing their ability to commit time toward modules, despite their interest in the content. Some participants felt it challenging to initiate contact with the navigator or begin a new module without prompting because the research was admittedly not their top priority:

> *Sometimes, it's hard for me to open the tablet and go on there [to do the modules] because it's not the first thing that comes to my mind. Every day, I wake up, and I'm like, "Okay, I have to do this and that today. I also have to message this person [transition navigator]," and I don't get around to doing it.* [I-021]

The length of the modules was described by several participants as a deterrent, especially for those with difficulty staying on task. Some adolescents and young adults struggled to remain engaged and interested in the skills being discussed, inadvertently leading them to become distracted:

> *With the modules, I get distracted very easily, so it's been very hard for me to stay on task. I've been struggling to remember since the end of grade 11 to do these modules. It's not that they're boring per se, it's that I'm not focused enough, ever.* [I-016]

Finally, adolescents and young adults whose learning preferences were at odds with how information was conveyed in the modules and educational curriculum faced barriers to retaining knowledge. For instance, participants who were visual learners expressed difficulties taking in the information and solidifying their learning, given that most of the content was delivered via a speaker on camera without visuals to illustrate concepts. This led to feelings of frustration and a lack of motivation to stay engaged for some:

> *I don't know if it's because I'm a visual person, but sometimes it's really hard for me to sit down and watch somebody talk for 20 minutes. Something about it disengages me. My ears are open, but I'm not really taking in everything.* [I-021]

In summary, each adolescent's or young adult's learning styles, needs, and preferences were important factors to consider when using and evaluating the intervention.

Theme #3: Considerations for Future Transition Care

Overview

Adolescents and young adults in both arms of the trial highlighted a "gentle transition," defined as a period of overlap between pediatric and adult IBD providers or a joint visit with pediatric and adult providers, as an approach that would help reduce stress and illustrate that "the first team trusts the second team fully" [C-006]. Most participants also felt the topic of transition should be raised, and the process started early (around being aged 16 years) to allow ample time for gradual skill acquisition:

> *I'd say [introduce transition] at about 16 because 18 is when transition starts and throughout the journey, you don't really realize how little time you have until it's right there and it's knocking on your doorstep. But if you start teaching what they need to learn at around 16, I think they'll be able to develop skills and become more mature and be able to deal with those things as time goes on.* [I-019]

Adolescents and young adults approved of the value of a clinician (eg, transition navigator) responsible for "guiding [youth] through the transition process" [C-006], offering advice, addressing transition-related concerns, and providing service navigation. They felt having a trusted person they could go to (as opposed to a website or app) would allow them to practice the communication and advocacy skills needed for adult care in real time:

> *If you can have someone that people can reach out to and talk to, actually face-to-face whether it's Zoom, texting, calling, or emailing, I feel like that would be beneficial just so they know they're actually talking to someone. And that would help with socializing and getting them used to adult responsibilities and communicating on their own.* [C-013]

Others suggested providing adolescents and young adults with case scenarios that commonly arise for transition-age youth

XSL•FO
RenderX

with IBD to role play, followed by discussions about how to respond to different situations. They felt this approach would help them solidify experiential knowledge, build confidence, and prepare them for possible challenges:

> *I think it would be the most helpful to have [youth] actually do a fake phone call. Because if you're talking about something like a conversation, it's better to learn it in its application and learn to try to say things yourself rather than knowing that you have to do something like, "oh, I should say that, I should do this". Being forced to deal with some of the discomfort that might come along with the conversations and practicing that would be beneficial.* [C-036]

Finally, participants advocated for group-based education sessions (either in person or online) to support their learning. Those in the intervention arm felt that providing a method for adolescents and young adults with IBD to (optionally) interact with one another through the online platform would allow them to feel more connected and less alone.

Recommendations for Refinement of Biopsychosocial Intervention

Adolescents and young adults in the intervention arm highlighted the importance of keeping participants engaged in the intervention (and their care more broadly) around the time of transition when young people face competing priorities; thus, they suggested shortening the modules into "bite-sized" [I-007] pieces to improve their delivery. Several adolescents and young adults were interested in audio versions of the skills-building modules based on their learning styles and preferences. Many participants thought including games, knowledge tests, or offering awards for completion could help participants stay motivated and on task. Most participants were satisfied with the range of topics available regarding the module content. However, a few adolescents and young adults felt having materials focused on accepting IBD and adjusting to life with a chronic illness would be beneficial to them, especially for those newly diagnosed or experiencing challenges coping with IBD. Others suggested incorporating education focused on diversity within IBD, including the roles of faith, cultural traditions, and food customs in IBD management. Lastly, some adolescents and young adults felt the transition to postsecondary (education or employment) should be elaborated upon in the modules based on their experiences, especially advocating for themselves with teachers or employers and accessing accommodations.

Discussion

Principal Findings

Using qualitative methods, this study offered a detailed understanding of the experiences, priorities, and needs of adolescents and young adults with IBD during the pediatric-adult transition. Learning about the biopsychosocial intervention from adolescents' and young adults' perspectives contextualized the RCT results and provided insights about engagement, acceptability, and future directions. Our findings revealed the importance of making meaning during health care transition, the impact of the biopsychosocial transition intervention, and adolescents' and young adults' viewpoints on future transition care.

Regarding conceptualizations of the transition to adult care, adolescents and young adults with IBD expressed various ideas about its meaning. Hislop et al [25] outlined a similar range of views regarding the transition to adult care from youth with chronic conditions, from "laid back" to "anxious." Additionally, the youth in their study expressed the value of social interaction with family, peers, and professionals to assist with the transition from pediatric to adult care [25]; findings echoed in the present study. Of note, most participants in our study had not yet transferred to adult care at the time of data collection, possibly influencing their conceptualizations of transition. Understanding adolescents' and young adults' views on the meaning of transition and the quality of their interpersonal relationships could support the development of personalized transition plans in clinical settings that consider their readiness. It is also important to examine whether adolescents' and young adults' conceptualizations of transition before they enter adult care impact their capacity for self-management and experiences posttransfer.

This study validates the importance of relational support for adolescents and young adults with IBD, which helped facilitate engagement with the intervention and readiness for transition. Fostering positive relationships with health care providers, family members, peers, or community members may play an important role in promoting flourishing, a known predictor of physical and mental health [26,27]. Given adolescents and young adults are often experiencing multiple life transitions simultaneously, external support is critical [26]. Future research could explore the development and evaluation of companion modules or educational resources for family members supporting adolescents and young adults with IBD.

Tailoring educational resources and support to align with the needs of adolescents and young adults arose as a prominent concept in this study. This included considering adolescents' and young adults' communication preferences, learning styles, familial or community supports, and pre-existing traits, including age at IBD onset and personality characteristics, in designing and delivering patient education. Individualizing care according to genetic, social, and individual- and family-specific factors is a key tenet of precision child health, an emerging paradigm for pediatric quality and safety [28]. Precision child health focuses on the unique needs and characteristics of pediatric patients and their families to provide proactive, person-centered care [28]. Moreover, offering personalized support for adolescents and young adults with chronic conditions transitioning to adult care according to their level of preparedness has been endorsed in the literature. Charles et al [29] identified a typology of transition readiness for adolescents and young adults with congenital heart disease, suggesting that different groups require varying levels of support in preparation for the transition, from minimal intervention required to "follow-up needed" to "at-risk." A transition intervention that is customized based on the ethnocultural needs of adolescents and young adults with traumatic brain injury has also been described and reported [30]. Further, the IBD literature demonstrates the importance of

XSL•FO
RenderX

delivering culturally sensitive care that recognizes the impact of health inequities, cultural values and beliefs, and the roles of implicit or explicit biases on patients' experiences navigating the health care system [31]. Our results provide evidence of the criticality of attending to adolescents-, young adults-, family-, and system-level factors in providing transition care to promote optimal experience, uptake, engagement, and outcomes.

Patient navigators have been identified as a promising intervention for adolescents and young adults with chronic conditions transitioning to adult care [32,33]. Our results confirmed the value and acceptability of the relational support offered by a transition navigator, with participants detailing the navigator's impact on their experiences and outcomes during the transition. This was especially apparent for adolescents and young adults with challenging diagnostic journeys, mental health concerns, and co-occurring conditions. This speaks to the potential usefulness of a transition navigator intervention for adolescents and young adults with chronic health conditions or mental health conditions more broadly. Given the logistical challenges of holding joint pediatric-adult clinic appointments in North America, cross-appointed navigators could be a favorable option for promoting continuity of care [34,35]. Further exploration of individual characteristics, including personality traits and existing supports, and how these relate to engagement during transition is warranted. Adolescents and young adults in our study expressed their interest in gamified transition resources to enhance motivation to engage with educational materials. Indeed, a recent scoping review identified that gamification improves patient engagement and biopsychosocial outcomes and could represent a valid approach to cancer patient education [36]. Future research could explore gamification within IBD care and its impact on patient experience, knowledge, and outcomes. Finally, given the complexity of factors (eg, communication preferences, personality, or learning styles) influencing adolescents' and young adults' transition needs, future iterations of the biopsychosocial transition intervention could consider the integration of artificial intelligence to support adolescents and young adults. This would enable tailored guidance when navigator support is unavailable (eg evenings or weekends) or when adolescents and young adults prefer more self-directed approaches.

Limitations and Future Directions

This study's results should be considered in light of some limitations. Sampling bias could be a concern given that the qualitative study participants were enrolled in an RCT and consisted of mostly female participants. Regarding transferability, our findings may not apply to all adolescents and young adults with IBD or those in different health care systems or regions. Additionally, only 1 participant had completed any education modules at the time of the interview, so we could not assess participants' perceptions of this aspect of the intervention. To enhance trustworthiness, we used member checking with the YAP. YAP members reviewed and confirmed the data and interpretations, which helped ensure our findings' accuracy. Following initial coding and analysis based on their lived experiences, they provided their insights and perspectives. Finally, they co-authored, reviewed, and offered feedback on this paper.

Future research in this field could examine the experiences of adolescents and young adults with IBD in various cultural and socioeconomic contexts. This would allow for a more complete understanding of the transition process and different groups' unique challenges given research has shown that access to resources, cultural values, health literacy, family roles, faith, and stigma play important roles in the daily realities of individuals with IBD [31,37]. Qualitative research involving data collection with adolescents and young adults at multiple time points (eg, pretransfer, during the transition, or posttransfer) could offer unique insights into how their care needs and priorities evolve to support the development of tailored interventions. Finally, the development and evaluation of resources targeting caregivers and parents of adolescents and young adults with IBD could be considered, given their critical roles in mentoring and coaching adolescents and young adults during transition.

Conclusions

Incorporating qualitative data within the RCT enabled a multifaceted exploration of the acceptability of a biopsychosocial transition intervention through different sources of information to support the translation of findings into practice. Our findings provide important insights into the needs and experiences of adolescents and young adults with IBD during the transition, including the criticality of considering individual, family, and system-level factors when implementing clinical interventions for this population. These results will contribute to developing youth-friendly resources and possibly refining the biopsychosocial transition intervention before scale and spread.

Acknowledgments

The authors thank the adolescents and young adults who participated in this study and the Crohn's and Colitis Canada Youth Advisory Panel (including but not limited to Gary Gill, PM, Diana Marcovici, CP, and TS) for their valuable contributions to this research. The authors are grateful to the following people for help with the design and conceptualization of this study: Usha Chauhan, Sneha Dave, Marla Dubinsky, Johanna Escher, Thea Ewert, Karen Frost, Daniel Green, Jennifer Jones, Lydia Knorr, Dominique Levesque, Meranda Nakhla, Susan Samuel, and Alene Toulany. The authors also acknowledge the contribution of the External Advisory Committee for this project: Dan Turner, Marla Dubinsky, Johanna Escher, John Marshall, Meranda Nakhla, Geoffrey Nguyen, Susan Samuel, Alene Toulany, and Daniel Green. This study was supported by a grant from the Leona M. and Harry B. Helmsley Charitable Trust and Crohn's and Colitis Canada. This study was also supported by The Canadian Children IBD Network (with funding provided by the CH.I.L.D. Foundation). The funding sources did not support this study's design,

Abstract

Background: With the increasing implementation of patient online record access (ORA), various approaches to access to minors' electronic health records have been adopted globally. In Sweden, the current regulatory framework restricts ORA for minors and their guardians when the minor is aged between 13 and 15 years. Families of adolescents with complex health care needs often desire health information to manage their child's care and involve them in their care. However, the perspectives of adolescents with serious health issues and their parents have not been studied.

Objective: This study aims to qualitatively and quantitatively investigate the perceived benefits and risks of ORA and the awareness of and views on ORA regulations among adolescents with serious health issues and their parents in Sweden.

Methods: We used a convergent mixed methods (qualitative and quantitative) design, consisting of a survey and semistructured individual interviews with adolescents with serious health issues (aged 13-18 y) and their parents. Participants were recruited via social media and in clinics. Quantitative data were presented descriptively. Interviews were audio recorded, transcribed, and analyzed using inductive thematic content analysis.

Results: The survey population included 88 individuals (adolescents: n=31, 35%; parents: n=57, 65%). Interviews were completed by 8 (26%) of the 31 adolescents and 17 (30%) of the 57 parents. The mean age of the surveyed adolescents was 16 (SD 1.458) years, and most of the parents (29/57, 51%) were aged 45 to 54 years. The surveys indicated that most of the parents (51/56, 91%) were critical of the access gap, and most of the adolescents (20/31, 65%) were unaware of the age at which they could gain access. In the interviews, adolescents and parents identified benefits related to ORA that were categorized into 6 themes (*empowering adolescents*, *improved emotional state*, *enhanced documentation accuracy*, *improved partnership and communication*, *supported parental care management*, and *better prepared for appointments*) and risks related to ORA that were categorized into 4 themes (*emotional distress and confusion*, *threatened confidentiality*, *increased burden*, and *low usability*). Adolescents' and parents' views on ORA regulations were categorized into 3 themes (*challenges of the access gap*, *balancing respect for autonomy and support*, and *suggested regulatory change*).

XSL•FO
RenderX

Conclusions: In Sweden, ORA regulations and a lack of available information cause significant inconvenience for adolescents with serious health issues and their parents. Views on access age limits differed, with adolescents expressing their perceived need for independent access, while parents exhibited concerns about adolescents having ORA. The findings indicated the importance of increased education, dialogue, and flexibility to uphold confidential and consistent delivery of adolescent health care. Further exploration is needed to understand the experiences of adolescents and parents in diverse clinical and geographic contexts, as well as the perspectives of pediatric health care professionals on restrictive ORA regulations.

Introduction

Background

Worldwide, online record access (ORA) enables more patients and caregivers to read their health records via patient portals. Electronic health records (EHRs) often include clinical notes, laboratory test results, and medications. In the United States, the practice of sharing clinical notes with patients is referred to as "open notes" [1]. In the European Union, individuals have a right to access their health information in registries such as EHRs, under the General Data Protection Regulation. A proposed European Health Data Space will provide patients with access to their EHRs throughout Europe. A growing body of research [2] indicates that ORA benefits for adolescents and parents are similar to those for adults (eg, better recall, increased treatment adherence, and an increased sense of control [1,3,4]). Unique benefits for adolescents and parents may also include increased autonomy [5] and a supported transition from adolescent to adult health care [6,7].

Despite potential benefits, access to pediatric records is often restricted due to concerns about confidentiality, particularly during adolescence. While most young children benefit from parental proxy access, adolescents may be deterred from seeking help for sensitive health care issues if parental monitoring remains possible, leading to potential ethical concerns and a need to protect the developing autonomy of the young person [8]. As a result, 1 policy response has been to limit adolescents' and parents' access when the child becomes an adolescent. However, the implementation of patient-accessible EHRs (PAEHRs) for parents and adolescents differs globally [9-11]. A variety of access control practices attempting to balance parents' and adolescents' needs have been adopted, with approaches either based on set access limits or case-by-case assessment.

Sweden has an advanced ORA system, facilitated through the national PAEHR 1177 Journal. A regulatory framework implemented in 2017 grants parents default access to their child's PAEHR from birth until the child turns 13 years of age, after which the adolescent gains their own access at the age of 16 years. Parents' loss of access to their child's PAEHR when the child turns 13 years of age was due to concerns that teens may refrain from seeking care for sensitive issues, such as birth control, sexual health, or mental health, if they know that their parents have access to their records. In the first regulatory framework, adolescents themselves gained access to their records only at the age of 18 years, but this age limit was later lowered to 16 years, based on the argument that most teenagers are mature enough to make informed decisions about their health at this age. More than half (50.5%) of adolescents access their records from the age of 16 years [12]. The "access gap," when the child is aged between 13 and 15 years, a period during which neither the child nor the parent has access, has been criticized for hindering active participation and engagement in health care, especially by parents of children with serious illness [13,14]. There is an option for both guardians and minors to apply for extended access under special circumstances (such as chronic illness) when the child is aged between 13 and 15 years. The application process involves filling out and submitting a specific paper form to the health care provider, followed by a maturity assessment and approval by the health care provider's operations manager. To approve the application, health care professionals (HCPs) assess needs and risks, as well as the minor's level of maturity and wishes. The process must be repeated for each clinic where the minor is receiving care. However, few applications for extended access from either adolescents or parents have been observed [12]. Thus, although the restrictive policies are intended to ensure safety, their consequences for adolescents with serious health issues and their parent caregivers may be dire and have not been studied.

Several topic experts have noted the unique need for ORA among families where adolescents are undergoing treatment or have extensive contact with health care systems [15,16]. In previous research in Sweden, we found that adolescents with lower self-reported health may have less interest in being able to control who can access their records and to conceal information from relatives [17]. Indeed, many adolescents depend on their parents for health care management [6]. In addition, in an interview study, adolescents aged 13 to 17 years with cancer and blood disorders report that, after reading their records, they are better able to prepare for clinical consultations and are able to check accuracy; moreover, examining their test results makes it easier to talk to HCPs [7]. Parents of children who are critically ill report similar benefits: the ability to check accuracy [18], better understanding [18], improved recall of information [19,20], reduced anxiety [21], and an increased sense of control [21]. They also reported that ORA makes them better able to advocate for their child [18].

Parents offer complex home-based health care and provide emotional support in advocating for their child. Rather than communicating directly with HCPs, adolescents often prefer

XSL•FO
RenderX

asking questions via their parents [6,7]. Furthermore, a framework developed by Ford et al [22] described how partnerships between adolescents, parents, and HCPs can improve the adolescent's health, stating that, for example, adolescents are more likely to seek support from their parents if they are well informed.

Study Aim

Views on policies regarding adolescents' and parents' ORA access are underresearched. Increasing our knowledge about adolescents who are ill and parents in caregiving roles is vital to enable the design of informed policies and education for HCPs and patient portal users, with the long-term purpose of improving adolescent health. This study aimed to investigate, both qualitatively and quantitatively, adolescents' and parents' views on the perceived benefits and risks of using the PAEHR, as well as their perspectives on the national ORA regulatory framework in Sweden. Our research questions (RQs) were as follows:

- RQ1: What benefits and risks do adolescents and parents perceive regarding access to adolescents' health records for both adolescents and parents?
- RQ2: What are adolescents' and parents' views on and awareness of the ORA regulations governing access to adolescents' health records?

Methods

Ethical Considerations

This study received ethics approval from the Regional Ethical Review Board in Uppsala, Sweden (EPN 2022/02160). Survey participants provided consent digitally, while participants recruited in the clinic provided consent in paper format. No financial incentive was offered to survey participants; however, interview participants received a gift card worth 200 SEK (approximately US $18). Data were deidentified.

Study Design

Data collection occurred from March 2022 to November 2023, after ethics approval was received. A convergent mixed methods (qualitative and quantitative) approach was adopted [23,24]. Mixed methods can be defined as the "concurrent collection of both quantitative and qualitative data" where data are integrated in the analysis [23]. The purpose of combining methods was to provide a breadth of data on an understudied topic, with interviews designed to facilitate a deeper understanding of the reasons underlying the quantitative results. The qualitative component is reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) [25] guidelines (Multimedia Appendix 1).

Participants and Setting

We recruited adolescents aged 13 to 18 years with serious health issues and parents of adolescents aged ≥13 years with serious health issues with experience in accessing their child's EHR, either having lost access or gained extended access. In this context, serious health issues refer to physical or mental health conditions that significantly affect an adolescent's well-being and require ongoing care or intervention. Study participants were recruited via social media advertisements by patient organizations and through collaboration with Uppsala University Hospital and other clinical partners (eg, during appointments, by sending surveys via mail to former patients, and by posting study information in waiting rooms). Although citizens gain access to the 1177 Journal at the age of 16 years, adolescents aged ≥13 years were eligible to participate because they can apply for early access, and the study aimed to explore views on ORA regulations. Both parents of a child were able to participate.

The national regulatory framework for patients' ORA was designed by Inera AB, the company managing the 1177 patient portal that houses the PAEHR 1177 Journal, and approved by the Swedish Association of Local Authorities and Regions. The record typically includes clinical notes, test results, and diagnoses, but information availability differs across Sweden's 21 regions and affiliated HCPs (those who have agreed to provide access). No data are concealed from parental view unless an HCP actively chooses to block information access, which can occur in cases where, for example, child abuse is suspected.

Data Collection

Survey

Two survey instruments were designed: one for adolescents and one for parents (refer to Multimedia Appendix 2 for the full surveys and Swedish translations). For this study, 9 (69%) of 13 questions were included from the adolescent survey and 13 (93%) of 14 questions from the parent survey, based on the study aim (Textbox 1). Parents' awareness of ORA was not examined. The value of including patients in research has been noted previously [26,27]. Therefore, adolescents and parents were consulted for input, which was used to revise the surveys. Questions were not mandatory, except for those on inclusion criteria and contact information (in case the participant marked interest in participating in an interview). In Sweden, study participants aged <15 years must provide written parental consent, as mandated by the Swedish Act (2003:460) concerning the ethical review of research involving humans [28]. Therefore, age was a mandatory question for adolescents, along with the provision of written parental consent for those aged 13 or 14 years. In the web-based survey, adolescents could provide parental consent digitally. For participants aged ≥15 years, consent was provided by submitting the survey. The web-based survey was conducted using REDCap (Research Electronic Data Capture; Vanderbilt University) software.

Textbox 1. Survey questions for adolescents and parents.

ADOLESCENTS

Inclusion

1. How old are you?

a. How do you want to provide guardian consent? (if younger than 15 years old)

Experience with health care

2. What types of care have you received?

Views on and awareness of online record access (ORA)

3. At what age do you think you will have (or when you received) online access to your electronic health record (EHR)?

4. Do you want to be able to read your patient-accessible EHR?

5. To what extent do you agree with the following statements? (views on ORA age limits)

6. If you have thoughts or comments to add about the EHR, please write below.

Demographics

7. You identify as...? (gender)

8. Who do you live with? (select all that apply)

9. Would you participate in an interview about this?

a. E-mail

b. Phone number

c. How would you prefer to be contacted?

PARENTS

Inclusion

1. How old is the child for whom you base your answers?

2. Did you read your child's EHR online before your child turned 13?

Experience with health care

3. What types of care has your child received?

Views on ORA

4. To what extent do you agree with the following statements? (views on ORA age limits)

5. If you have thoughts or comments to add about the EHR, please write below.

Demographics

6. You identify as...? (gender)

7. How old are you?

8. Which region do you live in?

9. In what type of area do you live?

10. What is your level of knowledge in Swedish?

Interviews

The first author (JH, a PhD student in health informatics with past experience of qualitative research and training) conducted the interviews with participants who registered their interest in the survey. Verbal consent for audio recording was provided before the interview. Interviews were conducted between February 2022 and November 2023 via telephone or videoconferencing software. Interview guides were created based on prior work on ORA for adolescents, children, and parents (Multimedia Appendix 3) and included similar themes as the surveys. At the start of each interview, JH introduced herself and the reasons for conducting the research. JH had no prior relationship with any of the study participants.

Data Analysis

Descriptive statistics were used to present quantitative survey data. Of the 25 interviews, 18 (72%) were transcribed by a professional company and 7 (28%) by JH. Interview analysis was conducted by JH and MH using NVivo (release 1.7.2; Lumivero). MH is a researcher in health informatics with experience of leading and conducting qualitative research. As views on ORA regulations were previously unexplored, we analyzed the interview data using thematic content analysis [29] with an inductive approach. First, JH read all transcripts to develop an understanding of participants' responses. Next, the data were categorized into codes that were grouped into categories and themes. Definitions were refined further through discussions during meetings. Discussions of the findings among all authors improved credibility. Analysis of perceived benefits and risks was inspired by previous work [7,30].

Results

Participant Demographic Characteristics

In total, 31 (74%) of 42 adolescents and 57 (81%) of 70 parents completed the survey and were included in the study. While most of the participants identified as woman in both groups, the proportion was larger among parents (47/57, 83%) than among adolescents (15/31, 48%; Table 1). Regarding gender, of the 31 adolescents, 3 (10%) selected *other* or did not want to state their gender. Of the 31 adolescents, 1 (3%) had recently turned 19 years of age.

Table 1. Survey and interview participants' demographic characteristics (n=88).

Characteristics	Adolescents (n=31)		Parents (n=57)	
	Interviewed (n=8), n (%)	Not interviewed (n=23), n (%)	Interviewed (n=17), n (%)	Not interviewed (n=40), n (%)
Gender

Of the 31 adolescents and 57 parents who responded to the survey, 11 (36%) adolescents and 28 (49%) parents agreed to participate in an individual interview. Ultimately, of those agreeing to take part in an interview, 8 (73%) of the 11 adolescents and 17 (61%) of the 28 parents completed an interview, while 3 (27%) adolescents and 11 (39%) parents did not participate in an interview despite registering interest in the survey due to scheduling difficulties or a lack of response. Interviews lasted for a mean of 28 (range 13-40) minutes for adolescents and a mean of 42 (range 21-70) minutes for parents. Of the 17 parents, 5 (29%) reported having a medical profession. Notably, 2 (12%) of the 17 interviewees were parents of the same child, and none was a parent of a participating adolescent. All participants reported having moderate or higher levels of digital literacy.

As shown in Table 2, of the 8 adolescents, 2 (25%; aged 13 and 15 years) preferred parental ORA, whereas the remaining adolescents (n=6, 75%; aged 15 to 19 years) wanted their own access and either did not want or were indifferent to parental access, perceiving no need for it but expressing no privacy concerns. Almost all parents (16/17, 94%) desired longer access than current regulations allow (Table 3). The exception was a parent whose access was lost when their child was diagnosed with a serious health issue after the age of 13 years. Most of the parents (10/17, 59%) did not have access to their child's EHR; 2 (20%) of these 10 parents reported accessing it via the child logging in on their behalf. Additional demographic characteristics can be found in Multimedia Appendix 4.

Table 2. Adolescent participants' characteristics as reported in the interviews (n=8).

ID	Age (y)	Gender[a]	Interview setting	Child's diagnosis (age at diagnosis [y])	Current ORA[b] preference				Current ORA situation
					Adolescent	Start age (y)	Parent	End age (y)	
A27	19	Female	Telephone	Juvenile arthritis (14)	Yes, in favor	14[c]-15[c]	Okay but no need	13	Access by default
A14	18	Female	Telephone	Inflammatory bowel disease (17)	Yes, in favor	16-17[d]	No, opposed	16[c]-18[c]	Access by default

[b]ORA: online record access.

[c]Less restrictive than current regulations.

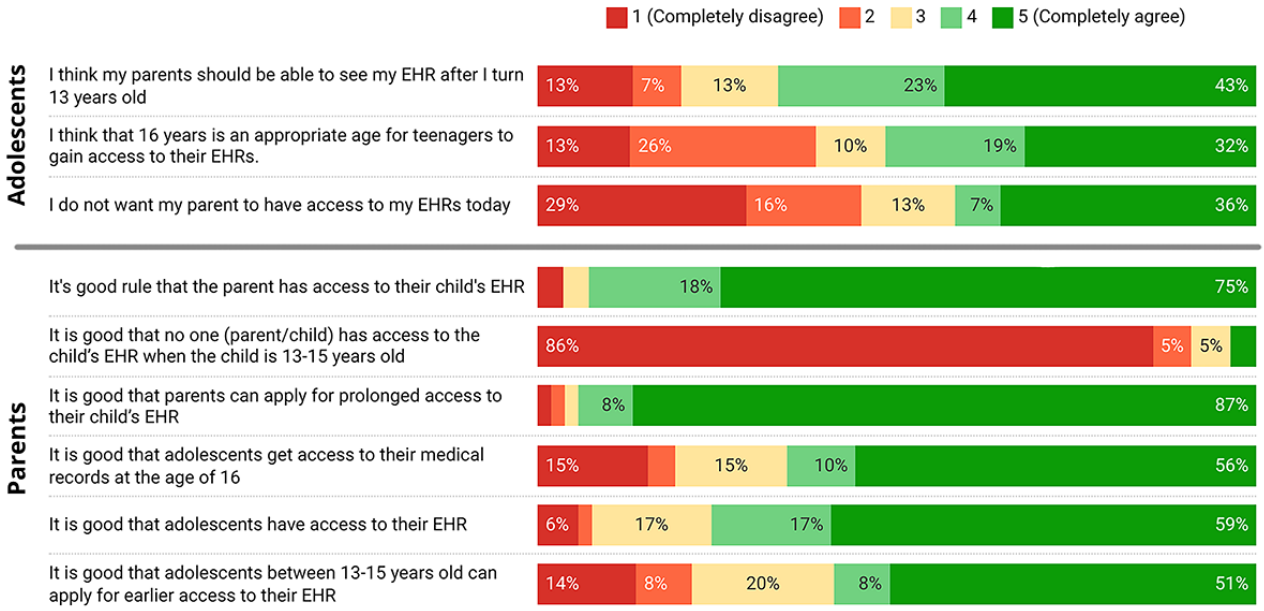
[d]Unable to specify.

[e]More restrictive than current regulations.

[f]EHR: electronic health record.



Quantitative Findings

Almost all adolescents (29/31, 94%) reported wanting access to their records. Low knowledge about the access age limit was observed: only a little more than a third (11/31, 36%) knew that the access age limit was 16 years of age, and almost as many (10/31, 32%) incorrectly guessed it to be 13 years of age. Of the respondents aged ≥16 years, 43% (10/23) claimed that they did not have current access to their records although this is the default.

Most of the adolescents (20/31, 65%) wanted their parents to be able to read their EHR after they had turned 13 years of age (Figure 1). A slight majority (16/31, 52%) agreed that 16 years of age is an appropriate age to gain access to one's health records. Most of the parents (51/55, 93%) were positive about parental ORA for children aged <13 years and negative about the gap in access from the ages of 13 to 15 years (51/56, 91%). Almost all parents (50/53, 94%) were positive about the option of applying for extended access for themselves, while more than half (30/51, 59%) were positive about adolescents applying for earlier access.

Most of the free-text comment data were reflected in the interviews. One parent responding to the survey noted that there should be a screening process for parents to access their children's records, while another referred to regulations regarding parents' rights to medication information as unclear, noting that the PAEHR is more restrictive than the information provided by pharmacies.

Figure 1. Adolescents' and parents' ratings for statements related to online record access and current regulations. EHR: electronic health record.

Qualitative Findings

Perceived Benefits of ORA

Adolescents and parents reported 6 perceived benefits of ORA: *empowering adolescents, improved emotional state, enhanced documentation accuracy, improved partnership and communication, supported parental care management,* and *better prepared for appointments* (Textbox 2).

Empowering adolescents referred to ORA helping adolescents to gradually become more involved in their care (eg, by helping them to remember appointments, track their illness, and understand their illness history). Adolescents shared that reading the notes from the beginning helped them gain a better understanding of what they had been through, providing information about events that they were too young to remember. Both adolescents and parents envisioned that this information would be helpful when meeting new HCPs. Parents were positive about their children being able to read the records "in the future," to understand their journey.

XSL•FO
RenderX

Textbox 2. Themes identified in the interviews of the perceived benefits of adolescent and parental online record access.

Empowering adolescents

- "It could be good to learn how to do things when you get older. When they might not be there." [A4, aged 13 years, diagnosed with cancer]
- "If you're 16, I believe you have the right to receive the same information that's actually written in the record." [P47, mother of child aged 15 years diagnosed with juvenile arthritis]

Improved emotional state

- "It's quite nice, well...if something happens, that I can go...I have security in that I can go back and read exactly everything, and even show that 'this is how it was.'" [A19, aged 18 years, diagnosed with juvenile arthritis]
- "As a mother I have felt that it is a security to be able to go back and read, 'what did they do now,' and it has felt good." [P15, mother of child aged 17 years diagnosed with cancer)

Enhanced documentation accuracy

- "We always have a discussion at health care meetings and such. But...they won't write down word for word what we have said...and sometimes there are misunderstandings, and then it's always good to be able to go back and check." [A26, aged 18 years, diagnosed with inflammatory bowel disease]
- "At several occasions, doctors have said, 'oh my god, how lucky you spotted that,' and such." [P22, mother of child aged 14 years diagnosed with cancer]

Improved partnership and communication

- "I have learned a lot through my parents sitting at home and reading, we have read the records together." [A23, aged 15 years, diagnosed with neurological disease]
- "[My boyfriend] has also been allowed to read a bit from the record...So that he can gain a better understanding." [A19, aged 18 years, diagnosed with juvenile arthritis]
- "You can sit together and reflect. Because otherwise it's somewhat difficult to just 'yeah, so now we're going to talk about this' and...then they want to go on some social media or something else like that. Maybe you can have a little focus on this." [P54, mother of child aged 17 years diagnosed with juvenile arthritis]
- "He clams up when doctors come to talk, then he won't speak, he won't say anything...It may be better if we talk together in advance, and he gets to ask us his questions, and we can ask the doctor." [P22, mother of child aged 14 years diagnosed with cancer]

Supported parental care management

- "You have to remember to schedule appointments and make sure to attend those appointments you've booked, so it's very, very much to manage logistically when you're sick, and it's quite nice to get help from parents when you're young." [A26, aged 18 years, diagnosed with inflammatory bowel disease)
- "It has been good to track it, because then you can also tell [the child] that 'you have to eat this vitamin because there is a deficit.' It's not as though I give her medication because it is fun." [P1, mother of child aged 14 years diagnosed with cancer]
- "Just last week, we had a situation where [my child] had got a specific medication and has been taking it, but then test results came and I saw that the levels regulated by this medication were sky high, so if we had continued taking the medication it might not have been so good. Then I could contact the physician to ask 'should we keep giving this medication or not?' And they say, 'no, don't do that.'" [P22, mother of child aged 14 years diagnosed with cancer]

Better prepared for appointments

- "I can tell [my child] that 'on Wednesday, we will see the physician, and we will talk about how to move forwards, and it might be that we will, blah blah blah,' whatever it is. And then he knows, so then when we meet the physician it won't be as dramatic." [P22, mother of child aged 14 years diagnosed with cancer]
- "We have a younger brother and live in the countryside, we have animals, and I may have to call my work and inform them I will be gone all week, so it facilitated a lot for everyone's well-being in the family that we could see for example test results on beforehand." [P52, mother of child aged 15 years diagnosed with skin disease]

Improved emotional state referred to an increased control and a sense of safety. Adolescents and parents reported that these feelings often related to having quick access to test results and being able to go back and read information. One adolescent (A26) described reading notes from childhood as fun and nostalgic. Parents reported feeling a sense of control due to increased knowledge about the illness and its terminology. Some parents stated that access to information reduced their anxiety and worry. One parent (P52) mentioned that because physicians did not always indicate that they had seen new test results, seeing that they had been active from checking the log list provided a sense of relief. Some adolescents described feeling safe when reading the EHR with their parents or merely knowing that their parents had access. One adolescent (A23) speculated that ORA provided parents with a feeling of safety, but parents

XSL•FO
RenderX

did not express this in relation to benefits of ORA for adolescents.

Enhanced documentation accuracy was reported as a benefit by both adolescents with ORA experience and parents; for example, it enabled them to ensure that HCPs had understood the information they shared during a consultation correctly and that there were no errors. Experiences of inaccuracies often involved HCPs misunderstanding details about symptoms, such as the degree of gravity or timing. One parent (P52) reported having once noted to an HCP that their child's records contained someone else's test results, apparent because the results were "too good." Another parent (P1) who had lost access to the EHR described a case involving their child where a referral had been sent for a sex change investigation because the HCP had misunderstood the adolescent's request to stop their period. The parent argued that if they had been able to review the EHR, they could have intervened earlier, preventing the adolescent's distress and avoiding unnecessary efforts.

Improved partnership and communication was reported as a benefit by both adolescents (with or without ORA experience) and parents. This referred to ORA enabling better communication among adolescents, parents, and HCPs in working together to manage the illness. Parents stated that ORA could help adolescents formulate questions beforehand, which the parents could then forward to HCPs. Many stated that parental ORA lessened the burden on the adolescent with health issues. The youngest adolescent (A4) expressed a substantial need for parental EHR access because they felt unable to manage everything alone. Older adolescents described that their perceived need for parental EHR access had decreased over time, partly because their ability to independently communicate with HCPs had increased. In addition, ORA facilitated reading the EHR together at home, allowing families to focus on the illness and providing an opportunity to ask questions in a safe environment, either in preparation for visits or as a way to debrief afterward.

Supported parental care management referred to ORA facilitating parents' provisioning of care in various ways; for example, both adolescents and parents reported that ORA facilitated parents' management of medications and appointments, improved recall of information, and enhanced parents' understanding of the child's health condition. Some parents stated that the EHRs contained more information than otherwise communicated, such as positive test results. Parents described that ORA facilitated dealing with insurance tasks and that access to test results enabled them to motivate the child to take their medications. Some parents noted that reading test results allowed them to anticipate being called to the hospital, enabling them to prepare their child mentally and emotionally in advance. Quick access to test results also enabled parents to speed up the care process and prevent unnecessary distress. One parent (P52) mentioned that test results revealed the child's actual condition, even when the adolescent claimed to feel well to avoid a hospital visit. The same parent stated that the only perceived benefit of their adolescent having ORA was that they could log in on their behalf.

Better prepared for appointments was reported as a benefit by both adolescents and parents, in that ORA facilitated the formulation of questions before appointments. Some parents described how ORA enabled preparations that were critical for their individual situation; for example, a parent (P52) living in the countryside could organize family life, animal care, and work in preparation for a hospital stay that might otherwise be sudden. Another parent (P22), whose adolescent had mild autism and struggled to process information during an appointment, described that ORA enabled her to use information from the EHR to prepare her child for what HCPs may bring up.

Perceived Risks of ORA

Participants identified 4 perceived risks of adolescent and parental ORA: *emotional distress and confusion*, *threatened confidentiality*, *increased burden*, and *low usability* (Textbox 3).

Emotional distress and confusion referred to the inability to understand information that was vague or written in clinical language, which could cause distress and lead to feelings of worry and frustration for both adolescents and parents. Confusion was also reported by an adolescent (A26) in relation to the unintuitive organization of information on the portal. Parents expressed concerns about adolescents reading concerning or negative test results while alone or learning about difficult medical events from their childhood, leading them to emphasize the importance (or necessity, for some) of having a parent present to answer questions and provide explanations. An adolescent aged 18 years diagnosed with juvenile arthritis (A26) recounted past experiences of feeling low after reading about traumatic experiences with health care in the EHR. Some adolescents and parents explained that their worry did not derive from accessing negative information in the record but from the progression of the illness itself. Two adolescents (A26 and A27) described that their close contact with HCPs reassured them that they would not receive bad news in the EHR without it being communicated in advance. Adolescents without experience of ORA did not anticipate emotional distress. While most desired an explanation from HCPs before receiving negative results, some reported prioritizing quick access to the information. Several parents recognized that other parents may worry; however, they themselves were not ones to worry.

XSL•FO
RenderX

Textbox 3. Themes identified in the interviews of the perceived risks of adolescent and parental online record access.

Emotional distress and confusion

- "It's those difficult words that one doesn't understand...And you don't really know what kind of test results you're getting back or what it means, so there's been quite a lot of Googling, consulting with mom all the time." [A10, aged 16 years, diagnosed with cancer]
- "One day it may pop up and boom, she has cancer everywhere and they can't do anything. And if you find out in her EHR. And the doctor hasn't called and explained anything. Then you get a little frustrated about it." [P2, mother of child aged 13 years diagnosed with cancer]
- "Some [parents] might say 'no, I won't read because it makes me more worried.' But in our case, I felt that nothing can... I'm already worried anyway, it's part of having a very sick child, so to speak." [P12, mother of child aged 17 years diagnosed with cancer]
- "If I read something and suddenly just feel like...oh my god, I got heart palpitations because I read something very negative or something. Then I think, for him to sit alone without anyone beside him and read this, no, I think that would just harm him, honestly. He's too young." [P22, mother of child aged 14 years diagnosed with cancer]
- "Even I, who work as a medical secretary, don't understand these terms either. I haven't worked in oncology. I don't understand everything either, so it's a bit poor of the doctors then perhaps also to dictate so that one doesn't...or the staff actually, to write and dictate so one doesn't understand." [P15, mother of child aged 17 years diagnosed with cancer]

Threatened confidentiality

- "If there's something I don't want them to know or something, they'll be able to see it or they'll be able to see all the notes that you might just...'They don't need to see this note.'" [A14, aged 18 years, diagnosed with inflammatory bowel disease]
- "If parents perhaps pressure one to log in, or something like that." [A29; aged 15 years; diagnosed with asthma, allergies, and mental health issues]
- "With honor-related violence, among other things, if you see that your child perhaps has a sexual activity and you don't believe it and so...yes, then it can get very bad...And also transgender care." [P54, mother of child aged 17 years diagnosed with juvenile arthritis]

Increased burden

- "[The teen] might have to bear too much responsibility." [P48, father of child aged 15 years diagnosed with juvenile arthritis]
- "I can understand that it could also lead to a greater workload for [HCPs], because I think that...Now, I might be a quite reasonable parent who also understands that one shouldn't reach out unnecessarily and so on. But I can imagine that there might be others who read things and maybe don't quite understand, and then they call." [P22, mother of child aged 14 years diagnosed with cancer]

Low usability

- "The website or app itself, or how one chooses to read the records, well...I can't say that it has a really great layout, and it's a bit difficult to know how everything is sorted and to find things." [A26, aged 18 years, diagnosed with inflammatory bowel disease]

Threatened confidentiality referred to the risk of sensitive information about the adolescent becoming visible to parents or others. While several adolescents mentioned that "the parent might see something one wants to hide," parents commonly specified potentially sensitive topics, such as mental or sexual health. One adolescent (A26) and many parents recognized that privacy may be a problem in families where parents seek to exercise control and may not focus on the child's best interest. Both adolescents and parents also recognized the risk that some parents might attempt to access their child's records via their account or pressure them to log in. Some adolescents and parents mentioned the risk of young adolescents sharing information with peers or on social media.

Increased burden referred to a burden placed on both adolescents and HCPs. Adolescents (only those who had not had access) and parents reported that granting adolescents access could lead to excessive responsibility for adolescents, who, especially when ill, wanted to be able to depend on their parents. Some parents imagined a burden on HCPs, such as adolescents sending numerous messages through the portal. Moreover, HCPs may feel compelled to omit sensitive information from the EHR, which would be detrimental to the child's future care. Some parents stated that patients' ORA is not a priority for HCPs, who understandably focus on providing care.

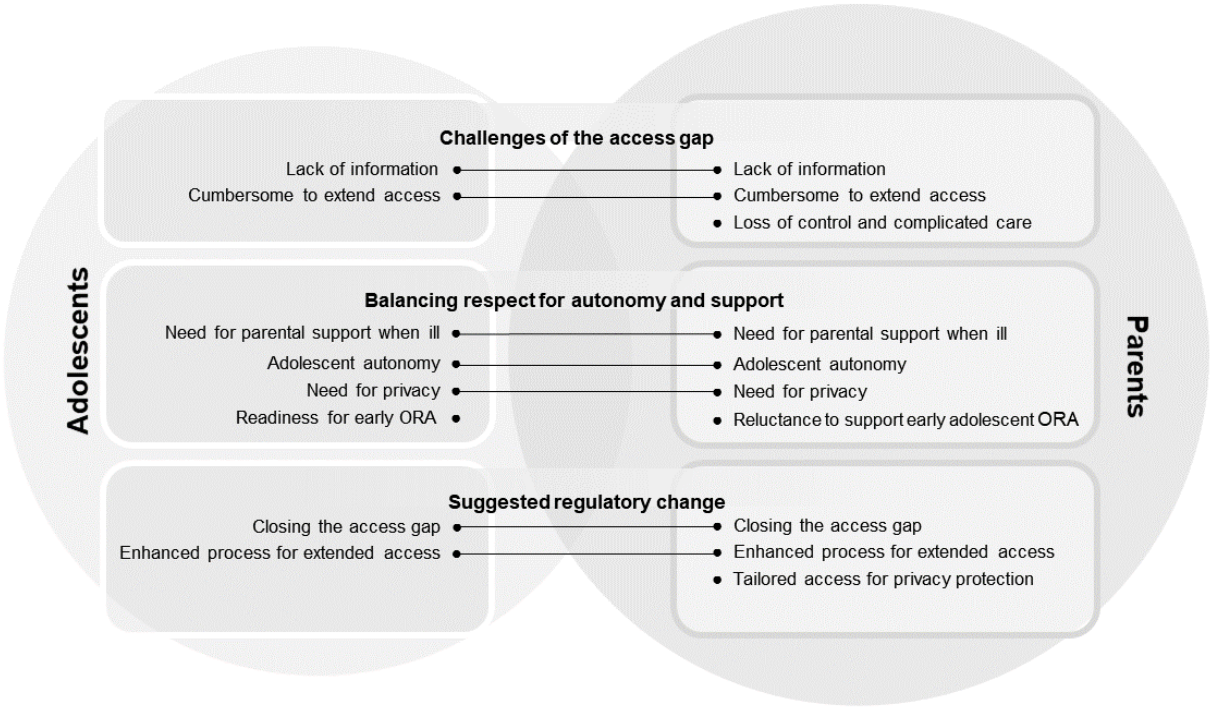
Low usability was reported as a downside or risk by an adolescent (A26), who found it challenging to locate and identify specific types of notes, such as diagnoses, clinical notes, or other documentation, due to unclear categorization and sorting. As a result, they spent more time searching for the desired information.

Views on ORA Regulations

Three themes were identified with regard to views on ORA regulations: *challenges of the access gap*, *balancing respect for autonomy and support*, and *suggested regulatory change* (Table 4). Similarities and differences between adolescents' and parents' report of themes and subthemes are visualized in Figure 2.

XSL•FO
RenderX

Table 4. Themes related to adolescents' and parents' views on online record access regulations.



Themes and subthemes	Representative quotes
Challenges of the access gap	
Lack of information	• "Being able to access it at all, I found out just a month ago from someone at a primary care clinic, that like, you have to order it and then you'll get it on paper...but, that you can get earlier access or so, I haven't heard anything about. And it's probably because even when you ask your physician at the clinic, they don't know either." [A29; aged 15 years; diagnosed with asthma, allergies, and mental health issues] • "We knew it would come, but we still thought that 'she is sick, maybe they understand that we should have access to the record anyways.' But it...it wasn't the case." [P2, mother of child aged 13 years diagnosed with cancer]
Losing access causes a loss of control and complicates care	• "I got really angry [when losing access], as I said, because it's my child that I'm responsible for. Then she shouldn't be able to do a bunch of things without my knowledge either." [P15, mother of child aged 17 years, diagnosed with cancer] • "I felt a confusion, not being able to read the test results, if she has inflammation in her body, where does she have it or does she not, how do the liver tests look? You couldn't follow her illness in the same way when you couldn't read the EHR [electronic health record]." [P38, mother of child aged 14 years diagnosed with juvenile arthritis] • "There is extra work, both for me and physicians...or the nurse I guess, because I have to call in. And I have to match their phone hours, and then I take their time and time from those who need it better." [P1, mother of child aged 14 years diagnosed with cancer]
Cumbersome to extend access	• "It feels like a very complicated process. Especially for 13- to 15-year-olds...like, we find it easy to do something on our mobile phones, fill it out there, but if we have to first find a paper, figure out how to print it, fill it out, send it in, get it signed, get it into the system...that probably takes a few months." (A29; aged 15 years; diagnosed with asthma, allergies, and mental health issues] • "You have a thousand other things that are higher priority when you have sick children...To then submit long paper forms, find the right nurse who also doesn't know what to do...and specifically write the exact clinic on them when you go to...they send referrals here and there, I barely know what all the clinics he has been to and is going to are called." [P52, mother of child aged 15 years diagnosed with a skin disease]
Balancing respect for autonomy and support	
Need for parental support	• "It can be good, because you're darn young, and maybe you don't know how to do everything yourself and might need help." [A4, aged 13 years, diagnosed with cancer] • "It's completely different from person to person. Some might develop faster than others. And if you haven't, it might be nice for parents to be able to help." [A27, aged 19 years, diagnosed with juvenile arthritis] • "I probably wouldn't have wanted [adolescents'] access that early. There is a conflict, I'm thinking, with the child's right to know and at the same time, whether a child is emotionally equipped to see serious illnesses or prognoses, and take in the information. I think that you're young when you are...below 16, you're still young to deal with these difficult things." [P48, father of child aged 15 years diagnosed with juvenile arthritis] • "Maybe they don't need access before they're 18...I feel at least that I'm glad he can access his EHR. Otherwise, we wouldn't have seen anything. Because it's mostly me who reads it." [P15, mother of child aged 17 years diagnosed with cancer]
Adolescent autonomy	• "I think maybe you can have access slightly earlier, so that you can like, understand a little bit." [A10, aged 16 years, diagnosed with cancer] • "I live in [region], where many live in rural areas and when you're 15-16, you can move away from home. Like, into the city, and then you become more or less an adult and a bit more, 'I can take care of my record myself.'" [A29; aged 15 years; diagnosed with asthma, allergies, and mental health issues] • "I would probably wish that [my daughter] had access to see her test results. It's still her life, you know." [P38, mother of child aged 14 years diagnosed with juvenile arthritis] • "This thing about medication and making your own decisions...it's something you have to phase in. For it to work, I think you need to phase it in over a few years. It's not something you just fix with a bang on your 18th birthday. So it's still good at 16 years old that they get access and...if they are mature and willing." [P54, mother of child aged 17 years diagnosed with juvenile arthritis] • "There are some children who are more mature than their parents, I think it provides an opportunity for the children who are interested and listen during their meetings like parents...I think the opportunity should be there for them to see the whole time." [P52, mother of child aged 15 years diagnosed with a skin disease]

Themes and subthemes	Representative quotes
Need for privacy	• "It really depends, like some might start...like, if we say that one goes to BUP [child and youth mental health services] or some other place...I would say it begins at around 12-13, that one seeks help but doesn't want to tell." [A29; aged 15 years; diagnosed with asthma, allergies, and mental health issues] • "I don't think it's really about age, but more about what happens in the child's life. Because I think that there might be a difference...I'm thinking in terms of privacy. Now we have an ongoing illness process where I believe he also benefits from us being involved in and being able to help follow up. And as long as he's in that loop...I think it's very important that we have access. But after that, maybe not as much." [P22, mother of child aged 14 years diagnosed with cancer] • "There are far too many controlling guardians out there who want to control their children and all that. But I think that it must be more prevalent within certain areas, such as counseling support and youth clinics and so on. And I think we should never have access to those." [P8, mother of child aged 14 years diagnosed with cancer]
Suggested regulatory change	
Closing the access gap	• "I think maybe parents should have access until you are 13-14, and then I think it should be brought up that you can gain your own access to it." [A26, aged 18 years, diagnosed with inflammatory bowel disease] • "I think one should be able to read always, or maybe until they're 16, and from 16 they can perhaps log in themselves." [P52, mother of child aged 15 years diagnosed with skin disease]
Enhanced information on extended access	• "Could one consider sending information to the health care center, to youth...I mean, to health care centers, that parents can apply [for access extension]? Or maybe conduct some webinar?" [P49, mother of child aged 15 years diagnosed with juvenile arthritis] • "I think it should be very clear on 1177, that 'if you want to see your child's medical record, fill in here' or something like that." [P54, mother of child aged 17 years diagnosed with juvenile arthritis] • "For anything that isn't transient, like a cancer diagnosis that doesn't go away on its own, there should be a dialogue at least 6 months before the child turns 13 with the treating physician, and it should pop up in the EHR when the doctor opens it. Explaining to both children and parents, 'this is what will happen if we don't do anything, and how do you view it and what would you like access to?' and so on...Perhaps even that there can be some standard procedure, 'this is how we usually do it when it comes to cancer diseases, that you have access to blah, blah, blah...this and this.' But this you won't see. So that the wheel doesn't need to be reinvented every time." [P8, mother of child aged 14 years diagnosed with cancer]
Tailored access for privacy protection	• "Can't you block certain parts [from parents], like youth psychiatry, counseling, youth health, or something like that? I'm thinking that you could be allowed to read all the time but maybe block certain parts." [P52, mother of child aged 15 years with skin disease] • "Maybe [the adolescent] can make an agreement with the person writing in the record that 'no, but this can be kept hidden, I don't want anyone else to see this.' That there's like a toggle switch, like, private or not. You know, like when booking [setting up appointments] in Outlook, you can just be like, this is private." [P22, mother of child aged 14 years diagnosed with cancer] • "I think that if a child seeks care independently, the health care professional could perhaps ask the question 'do you not want your parent to be able to read this?' That it can be customized." [P47, mother of child aged 15 years diagnosed with juvenile arthritis]

Figure 2. Themes related to adolescents' and parents' views on online record access (ORA) regulations.

Challenges of the access gap were mentioned by both adolescents and parents. Several parents expressed strong feelings of frustration and desperation over losing their access, citing the many benefits they had experienced. Despite receiving notifications, several parents had not fully understood that they would lose access when the child turned 13 years of age and were convinced that HCPs would ensure continued ORA due to their situation. Losing access made it difficult for parents to track their child's illness because they could no longer check test results, manage appointments, or monitor medications needing refills. Instead, they had to travel to the pharmacy for medications and contact HCPs to inquire about test results during designated hours, leading them to feel that they were burdening HCPs. Most adolescents and some parents were unaware of the option to apply for extended access, especially in the case of adolescents. Of those who had applied, a majority described the application process as cumbersome: identifying the right form; submitting separate applications for each desired unit; and parents needing to frequently raise the issue with HCPs, who often lacked the necessary knowledge or information. Difficulties with the application process were both anticipated and encountered. One adolescent (A26) and several parents had given up on their efforts to apply for access due to these challenges. A few parents who had applied for extended access immediately after losing access did not regain it until 6 months later, while 1 parent (P1) was still waiting for a signature, 2 years after applying.

Adolescents and parents were *balancing respect for autonomy and support* in their appraisal of appropriate access ages. Several participants perceived that the need for adolescent and parental ORA depended on factors other than age, such as the adolescents' maturity and interest, which may not correlate with age. Adolescents and parents who advocated access earlier than the age of 16 years focused on adolescents' rights to read their records, as well as the importance of involving interested adolescents with serious health issues in their care from an early age. By contrast, having a serious health issue was often perceived as a situation necessitating parental access beyond the age of 13 years, a view supported by 5 (62%) of the 8 adolescents and almost all parents (15/17, 88%). Parents stated that parental ORA should extend into adulthood for children with severe neurocognitive impairments. Some adolescents and most parents were positive about the idea of adolescents aged 16 years gaining access, citing that younger adolescents are often less capable of managing their care and require parental support. Still, most valued the opportunity for interested and mature adolescents to become involved in their own care before adulthood. Some parents were negative about early adolescent ORA, seeing it as a burden for the adolescent or perceiving illness-related information in the EHR as harmful. One parent (P48) stated that the age of 16 years is "too young to deal with such difficult matters," and several stated that adolescents should have a parent present when reading the records.

Another source of divergent opinion was adolescents' need for confidentiality. Privacy was a priority for adolescents and 1 parent (P55) who were positive about parents losing access when their child turned 13 years of age. Many referred to a difference in the timing of adolescents beginning to seek care for sensitive matters. While most parents were understanding of the need to conceal sensitive information, they still viewed their parental responsibility as critical. Most adolescents stated that they did not feel the need to conceal information from their parents, citing a relationship of openness and their parents' prior involvement in the treatment. Nevertheless, some expressed a desire to hide nontreatment information, such as alcohol use. The exception was an adolescent aged 15 years who had

XSL•FO
RenderX

experience with mental health care and was not open to parental access, stating that any information could be sensitive for an individual. Adolescents' view of sensitive information was generally broader than that of the parents, with parents primarily focusing on mental and reproductive health. Furthermore, several parents and 1 adolescent (A26) discussed the importance of considering adolescents who may experience harm from parental ORA, such as children with controlling parents or in honor-based contexts. However, a few parents argued that such cases are rare and that the majority of adolescents benefit from parental access.

Suggested regulatory change was mentioned by both adolescents and parents. A common suggestion was to remove the existing access gap between the ages of 13 and 15 years, perhaps by finding a middle ground. Furthermore, participants proposed increasing education for adolescents, parents, and HCPs about the option of access extension and the application procedure. Parents suggested facilitating the procedure by digitizing the application to the patient portal and enabling a combined application for all units involved in treatment. Both adolescents and parents cited the need for HCPs to have more knowledge of the process. Some parents also stated that parental access should be tailored based on adolescents' preferences or technological tagging of diagnoses, allowing for the concealment of sensitive information from parental view.

Mixed Methods Comparison

Overall, the qualitative accounts of adolescents and parents largely reflected and elaborated on their ratings and views observed in the quantitative measurements. Consistent with survey findings, both adolescents and parents criticized the access gap between the ages of 13 and 15 years and expressed a desire for this gap to be closed. The qualitative findings provided insights into the perceived benefits and risks of ORA, which aided an understanding of various findings, such as parents' preference for parental ORA over that of adolescents. Moreover, extensive challenges related to access extension were revealed.

Discussion

Summary of Findings

This study found that adolescents and parents were negative about the current access gap in Sweden for adolescents aged 13 to 15 years. While adolescents were largely positive about longer parental access, parents strongly advocated it. By contrast, adolescents also preferred earlier own access, which most parents opposed. The current option to extend access beyond the default was considered complicated due to a cumbersome application process and a lack of information and HCP knowledge. Perceived benefits and risks of ORA differ, revealing tensions in the respective views, particularly concerning parents' worries about adolescents' access.

Comparison With Prior Work

While in alignment on many aspects related to ORA regulations, adolescents and parents differed mainly in their views on adolescents' access. Our findings suggest a tension between adolescents and parents similar to that between patients and HCPs [31]—adolescents appreciate having access, while parents worry about adolescents' lack of health literacy and the potential for harmful consequences. While adolescents in this study acknowledged the risk of not understanding medical terminology with ORA, they expressed minimal concern and described coping strategies to manage this challenge. However, many parents perceived a lack of interest among adolescents in reading their records, in addition to a high risk of potential harm. This is in line with previously identified parental concerns, including the possibility of adolescents misunderstanding information or reading negative test results independently [7]. These concerns are understandable, particularly during times of illness and vulnerability when parents want to ensure the best possible care for their child [32]. Nevertheless, a recent case study comparing Swedish and Finnish adolescents' ORA use indicates that earlier access may lead to increased uptake at earlier ages [12].

The tension emerging from parents' hesitance to support adolescent ORA may in part be a result of the perceived serious risks in the face of a lack of significant benefits. Notably, while several adolescents reported improved emotional states and 1 adolescent speculated that parents may feel safer with ORA, no parent envisioned that adolescents may experience more control or increased safety. Furthermore, parents reported many benefits that adolescents did not perceive, such as being able to prepare the child for medical appointments and explain medication needs. This is important because noncompliance with treatment in adolescents has been documented [33], where access to information is essential [32]. The difference in adolescents' and parents' perceived benefits indicates the difficulty in understanding another person's perspective and experiences. Given the importance of partnerships between the adolescent patient, parent, and HCPs, noted in earlier work [22], there is potential for ORA to serve as a tool for improving such partnerships; for example, we identified that the opportunity to read EHRs together at home contributed positively to adolescents' and parents' experiences. A better understanding of each other's perspectives might help mitigate concerns about harm related to a lack of health literacy and confidentiality. Both adolescents and parents recognized the benefit of adolescent access in empowering adolescents and supporting the transition into adulthood, supporting previous work [6,7].

Most of the adolescents in this study were positive about allowing parental access after the age of 13 years, recognizing that parental support lessened the burden on the child, particularly in the case of serious health issues. However, adolescents advocated a need for privacy regarding some types of information unrelated to treatment. The need for privacy regarding sensitive information was reported to increase with age and also varied depending on the type of care received. Notably, an adolescent aged 15 years with experience of mental health issues such as depression (A29) preferred restricted parental access from the age of 12 or 13 years, which was earlier than the preference expressed by adolescents with diseases such as cancer, inflammatory bowel disease, or juvenile arthritis. The adolescent also reported having moved away from home for school, which likely increased their level of independence. While most of the parents reported that they would accept not having access to sensitive information, they often referred to

XSL•FO
RenderX

sensitive topics pertaining to sexual or mental health. Meanwhile, some adolescents cited allergies and experiences of bullying as potentially sensitive. Aligned with previous findings [17], adolescents stated that what is considered sensitive information can vary from person to person, indicating a need to allow adolescents to decide what should be visible to parents in the EHR. Parents suggested enabling customization of information availability, as has been recommended in earlier work [34]. An example of a system that allows customization is found in Finland, where HCPs assess each minor's decision-making capacity and then allow those found capable to decide whether parents should have access. While such case-by-case approaches lead to a risk of increased work burden for HCPs, more research is required to explore the feasibility of customized access.

Adolescents and parents reported low knowledge about access extension, the intended solution to aid families of children with serious illness during the access gap between the ages of 13 and 15 years. It was reported that HCPs often lacked knowledge about the application process and even the possibility of extending access. Our previous research shows that <1% of adolescents aged 13-15 and their parents access the Swedish patient portal [12]. Furthermore, adolescents lacked knowledge about regulations. Adolescents have reported receiving little encouragement from HCPs to access their records [35]. Possibly, the implementation of ORA in Sweden has failed to involve and educate HCPs about the new regulations. Furthermore, given that ORA and EHR documentation are known causes for HCP job dissatisfaction and burnout [36], some HCPs may be reluctant to encourage ORA use. To improve our understanding of HCPs' perspectives, the aim of a study conducted by the authors in parallel with this study was to examine the experiences and awareness of ORA regulations among oncology HCPs in Sweden.

Implications

On the basis of the findings, we have summarized a number of implications that concern adolescents with serious health issues and their parents (Textbox 4).

Textbox 4. Implications of the findings.

Implications

- Provide health care professionals (HCPs) with information on online record access (ORA) regulations related to extended access and guidance on how to facilitate the application procedure for adolescents and parents.
- Establish a plan for families with adolescents with serious illness to retain necessary ORA through a facilitated process of applying for extended access.
- Ensure clear communication to parents and adolescents about the management of sensitive information in records on the national patient portal.
- Provide comprehensive information to adolescents regarding the age limit for gaining access and the option to receive early access on the national patient portal.
- Provide comprehensive information to parents regarding ORA regulations, loss of access, and the option to extend access on the national patient portal.
- Foster dialogue between HCPs, adolescents, and parents regarding ORA and the concealment of sensitive information.
- Implement patient portal features that enable adolescents to customize the concealment of sensitive information according to their preferences.

Limitations

This study has a number of limitations. The sample size was relatively small due to persistent recruitment difficulties, particularly in engaging adolescent participants. Future research may explore alternative recruitment strategies, such as reaching adolescents through schools or other community channels. Moreover, half of the adolescents interviewed (4/8, 50%) were aged 18 or 19 years, which likely affected their views. Among the parent participants, the majority (47/56, 84%) were women, and approximately one-third of the interview participants (5/17, 29%) had a medical background or a partner working as an HCP. Notwithstanding this limitation, unequal sample sizes are a common occurrence in mixed methods research [23]. Furthermore, our sample included adolescents with a variety of conditions; however, the focus was not on comparing experiences across groups with specific illnesses but rather on exploring broader perspectives related to ORA use. While the parents varied in education, residential area, and income, most had Swedish as their primary language (53/56, 95%). Given the role of socioeconomic factors in driving disparities in pediatric ORA adoption [37,38], future work should include minors and parents from diverse language backgrounds to capture broader perspectives. Moreover, 1 survey item included a negation ("I do not want my parents to access..."), which could have been challenging for participants to interpret and therefore to accurately respond to on a scale ranging from 1 to 5. The surveys used were designed by the authors because there are no validated questionnaires available for examining views on ORA. Finally, both adolescents who had read their records and those who had not participated in the study. As a result, some shared their expectations rather than experiences. We strove to present the findings with due consideration to this limitation because there may be differences between expectations and experiences of ORA [2]. We did not provide a demonstration for adolescents without access, which may have impeded their ability to answer anticipatory questions. However, most of the interviews (5/8, 62%) with adolescents were conducted via telephone, precluding visual demonstrations. Regarding interviews conducted via videoconferencing software, it is possible that this format influenced participants due to the potential sensitivity of the topic. In addition, technical issues such as connectivity problems or the lack of a private and secure environment could have further impacted the conversation flow. However, video

XSL•FO
RenderX

interviews offer advantages over telephone interviews by allowing for the conveyance of nonverbal cues, such as facial expressions and body language, which can help foster a sense of connection and empathy between the interviewer and participant. An interview guide was followed to improve trustworthiness, and the study was reported in accordance with the COREQ guidelines.

Conclusions

In Sweden, the regulatory framework on ORA (characterized by a default lack of access for adolescents aged 13-15 y and their parents) and a lack of available information on access extensions creates challenges for parents of adolescents with serious health issues. Both adolescents and parents desire consistent access to the EHR that considers adolescents' growing need for privacy. While there is parental reluctance to support adolescent ORA due to concerns about potential harm and low perceived need, adolescents experience benefits from ORA that parents are not aware of, and vice versa. Informing adolescents, parents, and HCPs about experienced benefits and access regulations could improve partnerships, reduce distress, and facilitate adolescent care.

Acknowledgments

The authors are grateful to all participating adolescents and parents who shared their views and experiences, making this study possible, and feel privileged to have received their insights. Furthermore, the authors would like to acknowledge Lillemor Berntsson and Linn Ullberg Anderson at Uppsala University Hospital as well as the patient organizations that helped in recruiting participants. The authors would also like to thank the young experts panel at Uppsala University Hospital and the adolescents and parents who provided their input on the study material.

Abstract

Background: Caregivers of children with growth hormone deficiency often face emotional challenges (eg, stress) associated with their children's health conditions. This psychological burden might affect children's adherence to treatment and hinder their health-related quality of life (HrQoL). This assumption is leading to seriously considering multidimensional clinical approaches to pediatric health conditions where the emotional well-being of caregivers should be accounted for to optimize children's health outcomes. Novel mobile health (mHealth) solutions based on emotional and behavioral change techniques can play a promising role because they are increasingly used within different health areas to support adaptive psychological functioning. However, whether and how mHealth solutions of this type of emotional well-being support caregivers of children with growth-related problems is an issue that needs to be clarified.

Objective: This study aimed to gather qualitative information to better understand individualized experiences of caregiving of children undergoing growth hormone therapy (GHt) and perceived barriers or facilitators for the adoption of an mHealth solution called Adhera Caring Digital Program (ACDP).

Methods: A total of 10 family caregivers were recruited at Miguel Servet Children's Hospital, and they engaged with the ACDP for 1 month. The ACDP is a mobile-based digital intervention focused on promoting the overall well-being of family caregivers which provides access to personalized education, motivational mobile-based messages, and mental well-being exercises such as mindfulness or respiratory exercises. Subsequently, an individual semistructured interview was performed to gather qualitative user experience information.

XSL•FO
RenderX

Results: The digital intervention was well-received. The ACDP was found to be useful, easy to use, and understandable, addressing all the difficulties expressed by caregivers. It was also noted to be particularly helpful at the beginning of the treatment and, for some families, became a natural tool that strengthened the parent-child relationship.

Conclusions: The ACDP is a promising and well-accepted tool that enhances the experience of patients and caregivers. It improves the management of growth hormone deficiency and promotes the overall well-being of family caregivers.

Introduction

Growth hormone deficiency (GHD) in infants is a treatable disease that causes short stature [1]. The most used growth hormone therapy (GHt) for the pediatric population is a daily injection of a recombinant human growth hormone (rhGH) [2]. The daily administration is performed out of the clinic and requires patients and caregivers to be active and engaged in the self-management of this health condition. This active self-management is of paramount importance because poor adherence to rhGH treatments can lead to reduced efficacy and increased health care costs [3]. However, as the rhGH treatment can last many years, self-management is challenging for patients and caregivers [4], and suboptimal adherence to the treatment has been constantly reported in the literature [5]. Several factors such as missed injections, poorer level of treatment understanding, discomfort with the injections, and misperceptions about the consequences of missed doses have been reported as potential causes of poor adherence [5].

Children with GHD often have to address other issues related to their short stature that impact negatively on their quality of life. As exemplified, Stephen et al [6] found that children with GHD had significantly worse quality of life and cognitive functions than children with normal stature. Varni et al [7] found that children with short stature, including those with GHD, reported statistically significantly worse fatigue than healthy children. Social withdrawal, shyness, anxiousness, and depression have also been reported as a consequence of GHD [8-15].

Caregivers play a key role in the management of the GHD. They are responsible for the treatment management and administration of GHt to children who are not autonomous enough. Furthermore, they have the responsibility of managing their children's health condition, including all children's quality of life issues. This role is not premeditated nor chosen, so caring could turn out to be burdensome and affect the caregiver both psychologically and physically [16]. For instance, stress was one of the reported consequences of caring for children living with GHD, presenting higher levels of stress among parents whose children were receiving GHt, but still had short stature [17]. This higher stress level may impact their environment, their health, and treatment adherence [16]. Therefore, caregivers are at risk of developing psychosocial problems, such as anxiety and depression, that could seriously impact the child's health management. As an example, parental stress has been associated with poorer adherence of children to medical treatment [18]. Therefore, some authors have recommended assessing routinely caregivers' stress and conducting psychosocial interventions aimed at promoting caregivers' adaptation outcomes [17].

Currently, the health care sector is being transformed to benefit from the use of information and communication technologies. Digital health enables more accessible and potentially cost-effective alternatives to deliver family-centered interventions. Few studies have reported promising results on the efficacy of mobile health (mHealth)–based interventions for caregivers of children with chronic conditions [19]. Digital solutions, especially mobile apps, supporting patients and caregivers in the management of their disease have experienced significant and rapid growth. In GHD, Fernandez-Luque et al [20] found and analyzed 76 mHealth apps related to growth monitoring and growth hormone treatment available in the Android app store (Google). Most of these apps were intended for patients and caregivers. Some of the functionalities included in these self-management apps were education about GHD, education about growth tracking, and supporting and tracking adherence. However, the quality of digital health solutions is often not high enough and issues, such as trustworthiness or data privacy, are not appropriately addressed. This fact may lead to reduced adoption and engagement rates and, therefore, impact the effectiveness of the health interventions. In addition, the acceptability of digital health solutions by targeted users (patients or caregivers) is a key factor that also impacts the effectiveness of these interventions. Patients or caregivers will be reluctant to use digital health solutions that they do not find appropriate for them. There is still a need for conducting research on understanding the factors impacting caregivers' adoption and acceptance of the use of mHealth apps supporting them in the management of pediatric diseases.

Several technology acceptance models and theories such as the Technology Acceptance Model (TAM) [21] or the Unified Theory of Acceptance and Use of Technology (UTAUT) [22] have been proposed in the literature. The UTAUT and its versions have been widely used in digital health [23-25]. The UTAUT proposes that 4 constructs play a significant role as

XSL•FO
RenderX

direct determinants of user acceptance and usage behavior—performance expectancy, effort expectancy, social influence, and facilitating conditions. Performance expectancy is defined as "the degree to which an individual believes that using the system will help him or her to attain gains in job performance." This construct is related to concepts such as perceived usefulness, extrinsic motivation, and outcome expectations. Effort expectancy is defined as "the degree of ease associated with the use of the system." This construct is related to perceived ease of use. Social influence is defined as "the degree to which an individual perceives that important others believe he or she should use the new system." This construct is related to subjective norms. Finally, facilitating conditions are defined as "the degree to which an individual believes that an organizational and technical infrastructure exists to support the use of the system." In addition, the UTAUT defines 4 moderators (gender, age, voluntariness, and experience) that influence these determinants.

This research aims to gather qualitative information to better understand the psychological burdens experienced by caregivers of children undergoing growth hormone treatment, as well as the perceived barriers and facilitators related to accepting an mHealth solution that supports the self-management of GHD.

Methods

Recruitment

A total of 10 volunteer caregivers of children with GHD being treated by the physician AA from the Pediatric Endocrinology Unit at the Miguel Servet Children's University Hospital were invited to participate during face-to-face hospital visits. The sampling was selected by convenience from June to July 2021, and none of them refused to join the study. To be included in the study, all the described criteria had to be met (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Adherence to growth hormone therapy (GHt) monitored in the last month before enrollment indicates a ratio of less than 85% (since it has been considered as an index of relatively suboptimal adherence) [26,27].
- Legal guardian of children who receive GHt in accordance with approved indications in Spain.
- Explicit agreement on data sharing regarding adherence to GHt gathered through Easypod Connect (a digital platform that monitors GHt).
- Participants must not report any limitations in the use of smartphones and smartphone apps.
- Participants must accept the terms of use and agree to install the Adhera Caring Digital Program mobile-based intervention app.
- Participants must sign the specific informed consent form for the study.

Exclusion criteria

- Candidates without an Android or Apple smartphone because the solution only works through these 2 operating systems.
- Reporting any limitation in the use of smartphone apps.
- Only 1 legal guardian per child can participate in the study.

Procedures

At baseline, participants were requested to sign the informed consent and asked about demographic data and distress assessed by the Depression, Anxiety, and Stress Scale–21 (DASS-21) in its version in Spanish. After being introduced to the mHealth solution, they were guided to download, install, and configure the app on their own mobile phone. They were granted a free month of full access to the Adhera Caring Digital Program (ACDP).

After enrolling in the ACDP for 1 month, user experience was assessed with a semistructured interview. All the research was performed in Spanish.

Ethical Considerations

The current research was approved by the Ethical Committee CEICA (Comité de Ética de la Investigación de la Comunidad de Aragón; number CP-CI PI20/494). All procedures followed were in accordance with the Helsinki Declaration of 1975, as revised in 2000. Participation in the study was voluntary and anonymous; no compensation was given. All participants gave their informed consent. Audio recordings were deleted once transcribed. All personal information was deidentified.

Measures

DASS-21 Scale

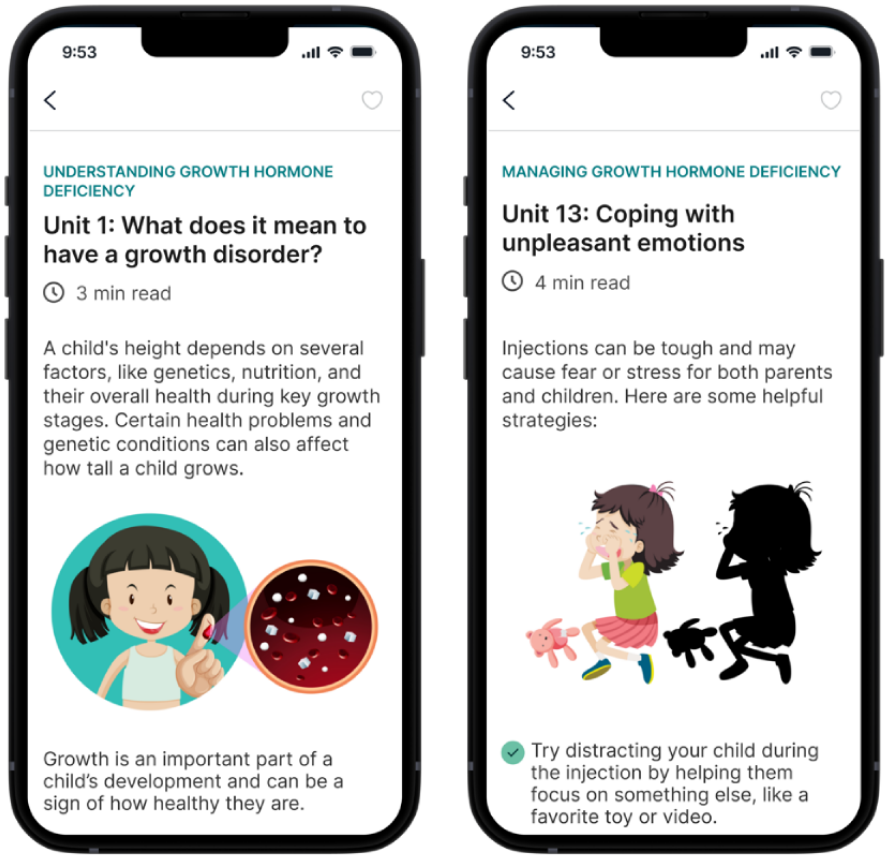
The DASS-21 is a self-reported questionnaire divided into 3 scales that measure the emotional states of depression, anxiety, and stress. Each scale has 7 items, which are graded on a Likert scale from 0 to 3 (0: did not apply to me at all, 1: applied to me to some degree or some of the time, 2: applied to me to a considerable degree or a good part of the time, and 3: applied to me very much or most of the time). The scores are calculated by measuring the result of each scale multiplied by 2. The final result is classified as normal, mild, moderate, severe, or extremely severe [26,27].

Qualitative Interview

A semistructured interview was designed in order to gather the user experience after joining the ACDP for one month.

XSL•FO
RenderX

Adhera Caring Digital Program



The ACDP is a mobile-based digital intervention focused on promoting the overall well-being of family caregivers which provides access to personalized education, motivational messages, and mental well-being exercises such as mindfulness or respiratory exercises. In this study, participants were invited to participate in the program for 4 weeks [28].

Psychoeducational modules provide educational content for parents or guardians of children with GHD (refer to Figure 1 for some examples). The contents include 39 units, classified into four sections: (1) managing GHD, (2) health habits to improve dealing with GHD, (3) adjusting to living with GHD, and (4) taking care of yourself to be able to take care of your child.

The program also includes a behavioral change module which complements and strengthens the knowledge of the psychoeducational module and provides lifestyle suggestions and action planning. It is done by delivering brief messages created by a multidisciplinary team of experts, including doctors and psychologists. The artificial intelligence–driven Adhera Precision Digital Companion Platform will select the tailored mobile-based messages to be sent (so the message selected will be personalized according to the patient profile, interests, and other peculiarities) [29]. This program incorporates the principles of personalized health education into a mobile platform, achieved by applying the Integrated Model of Behavioral Change [30] which is further expanded using recommender systems.

The ACDP is part of the Adhera Health Precision Digital Companion Platform, which has been developed using the best practices regarding data protection and quality management in accordance with the guidelines of ISO (International Organization for Standardization) 27001 and ISO 13465.

Figure 1. An Educational Unit within the app.

Interview Data Collection and Analysis

Participants were individually interviewed by 2 trained doctors (physicians) from the hospital. The training was provided by the sponsor's principal investigator through a workshop. The interviews were performed at the hospital or by secured video calls with caregivers or family and researchers being involved only. The mean duration of each interview was approximately 15 minutes. Individual interviews were anonymous, audio-recorded, manually transcribed, and anonymized by MP. MP and AJ-D managed and analyzed the transcripts using ATLAS.ti (Lumivero) Scientific Software Development GmbH (ATLAS.ti version 7.5.4 1993-2012 Windows). They performed an independent parallel analysis and arrived at the same conclusions regarding the themes that emerged during the interviews. Some translations of the interview can be consulted in Multimedia Appendix 1.

A data-driven inductive strategy was generally followed. However, some UTAUT model concepts [31] were considered regarding some aspects of technology acceptance, following a deductive-like approach in this specific case. The study followed the consensual qualitative research methodology [31,32]. In this approach, core ideas are identified and organized into

XSL•FO
RenderX

categories, which are embedded in broader domains. To do so, 2 reviewers (MP and AJ) independently extracted and organized the data. They then compared their findings in a series of feedback meetings to ensure objectivity and reach interrater consensus. A third reviewer (RH) was consulted in case of discrepancy.

Results

Overview

The characteristics of the sample (n=10) are described in Table 1. The majority of participants were female (80%) with a mean age of 44.9 (SD 4.41) years. Most of the caregivers were married (70%). In terms of education, the majority held a university degree (70%). The children were primarily female (70%) with a mean age of 10.6 (SD 2.5) years. The average age at the start of was 5.9 (SD 1.66) years and had been under treatment for a mean of 60.3 (SD 23.59) months. The mean adherence rate was 73.44% (SD 28.6).

Table 1. Descriptive characteristics of the sample.

Characteristic	Statistical value (N=10)
Caregiver's sex, n (%)	
Male	2 (20)
Female	8 (80)
Caregiver's age, mean (SD)	44.9 (4.41)
Caregiver's marital status, n (%)	
Married	7 (70)
Divorced	3 (30)
Education, n (%)	
High school	2 (20)
Professional training	1 (10)
University degree	7 (70)
Child's sex, n (%)	
Male	3 (30)
Female	7 (70)
Child's age, mean (SD)	10.6 (2.5)
Child's age at the start of the treatment, mean (SD)	5.9 (1.66)
Time under treatment (months), mean (SD)	60.3 (23.59)
Adherence rate to growth hormone therapy (%), mean (SD)	73.44 (28.6)

DASS-21 Scale

At baseline, DASS-21 showed that the majority of participants had no symptoms of depression (70%), anxiety (90%), or stress (70%). However, some of the participants had mild (20%) or moderate (10%) depression, severe anxiety (10%), and mild (20%) or severe (10%) stress, as described in Table 2.

XSL•FO

Stress	
Normal (0-7)	7 (70)
Mild (8-9)	2 (20)
Moderate (10-12)	0 (0)
Severe (13-16)	1 (10)
Extremely severe (17+)	0 (0)

Interview Results

A total of 3 domains were identified as shown in Figure 2, that are living with GHt, technology acceptance, and contents evaluation, containing a total of 8 categories. Furthermore, 1 category comprehended 4 subcategories.

Figure 2. Categories or themes identified in the interviews. GHD: growth hormone deficiency.

Living With Growth Hormone Therapy

This domain encompasses the perceived impact of dealing with this condition on caregivers' everyday lives. In total, 2 categories were highlighted, difficulties and perceived impact of caregiver support on child health.

Difficulties

This category was not included as a specific question of the semistructured interview. However, caregivers expressed concern about common issues. Beyond the diagnosis, participants reported children's behavioral issues and individual characteristics that hinder the treatment administration. For instance, the child's difficulties in understanding the disease promoted their refusal of hormone treatment.

XSL•FO
RenderX

> *She is a complicated child (…) that is my main problem. I do not know if it's something to do with my daughter's character or if I do not know how to deal with it.* [Caregiver 06]

> *The child said "why do I have to do this? I do not mind. I do not mind that people do not like it."* [Caregiver 09]

Daily injections were reported to be difficult for both, children and caregivers. Participants also expressed great concern about their children's lack of autonomy toward treatment. As children get older and socialize outside the nuclear family, the lack of autonomy in treatment becomes more evident, limiting children's independence and increasing caregivers' distress.

> *She will be thirteen this summer, fourteen next summer, and that has caused me a lot of problems. I can't let her sleep anywhere, if I let her, I have to go and perform the injection. Wherever she is. This means that I can't leave her with friends. She tells me, "I want to sleep over." Well, no. If you don't inject by yourself, you can't stay. It is impossible to go camping. It is a medication that has to be in a refrigerator... that she does not inject herself. How are you going to send her? My daughter has never been to camp.*" [Caregiver 02]

Caregivers' fear of hurting their children or mismanaging treatment was also raised.

> *I don't know if there are many children who inject themselves. Maybe there are a lot, but I haven't been able to. It's impossible for him; he has needle phobia.* [Caregiver 02]

> *My mouth went dry every time I had to inject her.* [Caregiver 02]

Perceived Impact of Caregiver Support on Child Health

Participants were asked whether they felt that being supported could influence their children's health. Many participants agreed that it was important to maintain a certain level of calmness and well-being as they could be perceived as role models by the children. Consequently, it is likely that if caregivers are angry or anxious these feelings would be transmitted to their children, increasing resistance to treatment.

> *If the parents feel bad, the children will feel awful (...). If I was stressed at the beginning, I transmitted the stress to the child, and it wasn't good. The children see us as... well, "if mom says that everything is going to be fine, then it will be fine." It is very important [to know] that if we are down, we transmit fear to the children. I think it is very important.* [Caregiver 04]

The importance of achieving personal well-being in order to effectively care for others was also emphasized.

> *It would be the main subject of the twenty-second century: taking care of yourself in order to take care of others.* [Caregiver 09]

Technology Acceptance

This domain highlights that, in general, caregivers expressed a positive attitude toward the use of technology as emotional and self-management support during the growth hormone treatment.

During the analysis, four categories concerning the usefulness of the digital solution were identified, of which the first 2 were directly related to the UTAUT model: (1) performance expectancy, (2) effort expectancy, (3) improvement opportunities, and (4) result of the ACDP usage.

Performance Expectancy

According to the authors, this construct refers to the user's perception of how effectively the technology will help them achieve improvement [31]. In this study, performance expectancy refers to the caregiver's perception of the ACDP's usefulness, regarding emotional support and management of the GHt. Overall, the participants agreed with the idea that digital solutions can be a useful and positive means of supporting the role of caregivers. They often mentioned that the wide variety of resources present in the ACDP allows very different types of families enjoy appropriate support for their specific needs. For instance, some caregivers stated how the ACDP helped them normalize the GHD and explain it openly to their children while paying attention to maintaining children's self-esteem.

> *Overall, I found it very useful, not only the theoretical part but the messages that appear on your cell phone. …. It is not that I see a part that is not useful and another that is more useful. I understand that for each person there may be a part that is more useful than others... But in general, I would give it a 9… (out of 10).* [Caregiver 01]

> *I really liked it because, of course, I didn't know how to encourage my girl and how to explain to her that this is something normal.* [Caregiver 04]

In addition, the ubiquity of the resources in the ACDP, available anywhere and anytime, was also appreciated. This, together with the fact that they perceived the contents of this digital solution to be highly reliable and clinically validated, made the caregivers feel reassured.

> *It is good to include explanations because sometimes in the consultation you feel overwhelmed and end up having doubts. Then the application reminds you everything again.* [Caregiver 03]

> *Well, what I have seen is that this is the information that should be there. ... In a consultation with the doctor, he will explain the medical issues. Then, on your own, you will go to Google and you will also search for medical issues. You will find good, bad, and irrelevant information. In addition, the information might be useful for you or not, and you might rely on information unrelated to your case. That is due to how Google works and how a low-skilled person might interpret the information. Regarding the emotional side, I do consider that it would be a very good path, a very good course or training, to have it at the beginning because it has*

XSL•FO
RenderX

> *the information that needs to be there. For me, this is the starting point. From there, you can find more, but there's the information you need to have.* [Caregiver 09]

Nonetheless, one parent expressed that they preferred receiving face-to-face support rather than having a mobile app for this purpose. Also, they shared that their child did not have some of the behavioral issues mentioned in the program. Thus, the caregiver stated that they could not apply all the information received within the digital program to make the child understand the need for treatment, but they saw it as useful to support parents.
