> *An application, no. A child psychologist, yes. A face-to-face, yes. I don't think the app would be useful [to make the child understand the need for treatment](...) Also, because of treatment insecurities, it would be useful for supporting parents, but through an app, I don't think it would work one hundred percent (...) I think that, apart from an application, a set [of activities] as well. A talk with parents...* [Caregiver 08]

Another person stated that one of the strategies proposed for managing the app was not suitable for their children because of their age. However, the caregiver expressed their will to continue trying other strategies suggested within the digital intervention.

> *And, in fact, I read it again and told her, "well, I'm going to try again and we're going to try to do it like this." Also, XXX is already 7 years old, so distracting her is complicated … no matter how much you form the habit: let's get her involved, let's play music, let's do it in some other way. She realizes it... You cannot fool her anymore. She knows that, in the end, [there is] an injection that she does not want. However, I will try these guidelines and ideas again.* [Caregiver 06]

Effort Expectancy

The effort expectancy concept refers to how easy the users perceive it will be to use a technology or system [31]. In this study, this construct is expressed in terms of the user experience and user interface, the structure of the information, and the degree of understandability.

The ACDP was described as easy to use by 8 participants. The adjectives "intuitive" and "beautiful" were also mentioned by some participants. It was stated that the user experience allows a peaceful state of mind which in turn facilitates the comprehension of its contents. The navigation flow was also appreciated.

> *I did not find it difficult. I found it, on the opposite side, very simple, very comfortable, very pleasant. Even the presentation of the application. Or I don't know what to call it, by folders and then more units. I find it very comfortable. I find it very nice. They are calm, it helps to make it more relaxed reading, which is what is needed for this type of information. It seems to me that you have taken great care of that.* [Caregiver 07]

However, 1 participant reported that she found the app neither pleasant nor unpleasant but contextualizing that was not important for her.

> *Neither particularly attractive nor obviously unpleasant [the application]. No, the design maybe... Because I pay little attention to those things and more to the information.* [Caregiver 01]

Most of the participants did not encounter technical issues while using the app. However, 3 users reported that they could not access a specific kind of notification related to motivational mobile-based messages. Another participant reported having issues accessing but it was smoothly solved through a password recovery process.

Regarding the understandability of the contents within the ACDP, most of the users described them as easily understandable, as the contents were described in a clear manner, using precise, direct, and natural language.

> *It seemed to me a very direct and very clear form of expression. It is very clear that anyone can understand it. That is very important. I found the information very clear. No difficult words or expressions that are difficult to understand. No, on the contrary, it seems to me that it is very well written. For easy understanding, yes. … They are like very short units that make you think. It doesn't make you read everything at once. It makes you think, and it is very good.* [Caregiver 07]

Nonetheless, a nonnative Spanish speaker reported that they would find some difficulties related to technical vocabulary related to the medical condition. These difficulties were solved by searching the words in a dictionary.

Finally, most of the users reported that the content was well-organized in diverse units, and provided brief pieces of information, with an interface similar to that of the social network platforms they are used to. This amount of information allowed for a better acquisition of knowledge and deeper reflections, compared with the relative overload of information that they felt during the diagnostic clinical visit.

> *The simplicity and clarity, the information come in very concise pills. It does not require a super long text that can make you feel tired, the information is very well dosed. … It is distributed in very chewable doses. In the open world we live in, we are more and more used to the Twitter context, with just a few characters. So, I think that this information and training is quite well dosed.* [Caregiver 01]

Improvement Opportunities

This category reflects that there is always room for improvement. The main limitation of the digital program was the moment in the patient journey when the digital program was introduced, which was mentioned by 7 participants. They declared that the digital intervention would have been especially useful right after the initial diagnosis, notwithstanding it still adds value to the GHD management at the present time.

XSL•FO
RenderX

> *I think I told you that at the beginning. I think it is a very positive, very good application. I think it will help families who are just starting out a lot, it will clarify things for them. And for families that have been using it for a long time, if it is shared with them, it will also strengthen what we have been doing for years. For those who are just starting out, it will really help them a lot more. As I was reading it I was saying "I wish I had had this when I started with this.*" [Caregiver 07]

The participants also commented on some desired additional content for the program. The parents mentioned that including techniques to involve the grandparents in the treatment (when possible) would be of interest. Also, a parent proposed including storytelling to reflect the reality of living with GHD. Thus, stories could be read before the treatment application, to help the child understand and normalize both the condition and its treatment.

> *I would look for more alternatives for the parents. It's very good to award prizes, it's very good to motivate them. But the motivation often also comes from the fact that there are alternatives for the children. I don't know [motivation] for them to start self-injecting. I don't know whether to look for other alternatives, other formulas, other... I don't know. Because I am looking for it, I told him, "be aware that if I inject you, you won't be able to stay anywhere. If I inject you, you won't be able to go camping." I don't know, look for some... some story motivating to [complete] a process, as ... the stories for children in the autism spectrum regarding how to go to a birthday, how to behave or socialize. I don't know if there is something uncomfortable like an injection, and there is some story or something that can be read to the children during nights that they can motivate themselves with. I don't know if there are any stories on the market. There surely will be.* [Caregiver 02]

Furthermore, some parents suggested that they would appreciate having a section with testimonials of other families living with GHD so that they could learn from others' experiences, or even get in touch with other families. Finally, a participant stressed the task of having a larger number of mindfulness and breathing exercises.

> *I don't think anything should be removed. Add what I was telling you, apart from those two small meditation and breathing practices. If there were any more, it would be good. I don't know if there could be some kind of sharing of experiences among people who are among parents, among children. Surely there are resources that we can use with each other... or situations how to handle them. I don't know if it is feasible in the application or not.* [Caregiver 06]

Result of the Adhera Caring Digital Program Usage

All the core ideas regarding the benefits of using the program fall within this category. Participants agreed with several benefits that the ACDP had provided them. On the one hand, it allows the normalization of their children's condition. This generates, for instance, increased self-esteem and decreased embarrassment in children. On the other hand, parents indicated that using the app leads to clarification of general concepts and knowledge about the disease, which empowers them. Finally, in the case of joint use with their children, the improvement in the relationship between caregivers and children was highlighted. The above-mentioned practical exercises have been described as "their moment together," which would be missed after the study was completed.

> *It's a perfectly normal thing, it's not like this happened to my daughter and she was born like this. It's normal. It's a disease like any other that can be cured. … she was a little embarrassed and [after] reading that with me... well, "look, I shouldn't be ashamed, that's the way it is. On the contrary, I have to say that I am brave, look. That I inject myself. And I'm going to grow up, and there's no problem." … I think I get along with her much better than before. It gives her more confidence, I don't know how to explain it. We accept it more.* [Caregiver 04]

Contents Evaluation

This domain encompasses the evaluation of the specific contents included in 2 components of the ACDP, personalized educational and mental well-being exercises.

Personalized Education

This category was organized in subcategories regarding the 4 sections of the personalized education section of the ACDP.

A. Managing GHD

In this section of the program, caregivers could obtain general information and advice on treatment management. Although it has been noted that this could be redundant as it is an explanation that the family receives when the patient is diagnosed, most participants agreed that receiving accurate and clear information resulted in a great benefit. Specifically, a sense of increased self-confidence and acceptance was highlighted in both patients and caregivers.

> *This information is missing at the beginning and creates uncertainty. Thinking about what we put in it and what effects it will have.* [Caregiver 08]

Among the most frequent core ideas were advice on how to mitigate the pain of the injection, or the reward system to promote treatment self-management.

> *(Talking about benefits of using the solution). Using ice or talking about something else... the typical advice given to mitigate the pain perception due to injections or the information given. For example, I read that sometimes it causes pain and other times it does not. It is something that we have experienced, and it is not known why. To me, it is something that catches my attention. I never knew if it was because the child was complaining because it really hurts, or because the needle is really very fine. So, I think having that knowledge regarding sometimes it hurts*

XSL•FO
RenderX

but you don't know why and sometimes it doesn't hurt is really important. [Caregiver 07]

B. Health Habits to Improve Dealing With GHD

Some units of the personalized education section were aimed at promoting healthy habits and, more specifically, enhancing healthier eating and sleeping habits. Overall, these contents were labeled as "interesting" and "important." However, 3 participants reported that they were already aware of that information since it had been provided by schools and pediatric health care providers. To them, this information was not that necessary.

Well, less useful, but not because they are not useful. Perhaps, for example, the component focused on healthy eating. It is very general information, but remembering it is important because not all families have the same opinion regarding diet or the importance of healthy eating. But maybe that's the less useful part if I have to say one. [Caregiver 07]

C. Adjusting to Living With a GHD

Considering the emotional impact of the diagnosis on the children's mental health, the program proposed the necessity of providing clear information about emotions and advice on how to strengthen the bond with the caregivers. Participants evaluated positively this content, being a topic that is rarely addressed by medical staff at diagnosis.

In my case, the first section related to the disorder. I can remember things that perhaps would have been forgotten. [Caregiver 06]

D. Taking Care of Yourself to Be Able to Take Care of Your Child

In line with the aforementioned, it is also important to consider the circular process of caring for oneself in order to care for others. Therefore, more content concerning the emotional management of caregivers was also suggested. They acknowledged the importance of their own emotional issues in the development of their children's treatment.

Mental Well-Being Exercises

These exercises included visually guided mindfulness and breathing exercises. This category gathers the users' opinions regarding mental well-being exercises. A caregiver described that practicing these exercises before applying the treatment had strengthened their relationship.

... I think I get along with her much better than before ... "mom, look what I can do." It gives her more confidence, I don't know how to explain it. ... It's our moment. She even told me the day before yesterday "when I don't do the sessions anymore it will seem strange to me, mom. That was our moment" I think it affects a lot, we talk about many things, and since we read it together (talking about the educational content) ... we commented on it. [Caregiver 04]

Some caregivers expressed their curiosity toward these practical exercises and found them appealing and enjoyable. Only 1 caregiver reported that they did not receive any benefit from these exercises, which might be related to their specific preferences as stated.

I especially liked the meditation practice. And I would tell you, I would include a little bit more. Regarding caregivers, I liked all contents focused on working as a support, as a caregiver. [Caregiver 03]

Discussion

Principal Findings

Caregivers of children undergoing GHt have reported several factors such as difficulties in understanding the disease or fear of hurting their children that may significantly impact the disease management. The role of caregivers is crucial in the management of GHD, and they have reported their well-being as a very important factor in being able to care for their children. Indeed, our results show that some caregivers have symptoms of depression, anxiety, or stress. In these circumstances, digital health enables the provision of digital services and tools supporting them in the care of their well-being and in the management of their children's disease. In this study, caregivers have expressed a positive attitude toward the use of mHealth solutions for health and well-being management. This finding is in line with those reported by other authors [32]. The results of this study support the ACDP as a feasible and potentially effective tool for caregivers of children undergoing treatment for GHD.

Caregivers' empowerment plays a key role in the effective management of GHD. Unfortunately, during routine consultations, it is not always feasible to cover all the aspects and doubts related to chronic diseases [32], especially the mental well-being of the caregiver. Digital health allows the provision of educational materials that are available just in time. Educational content must be designed not only to cover any lack of knowledge but also to encourage, empower, and optimize the caregivers' role as a manager of the GHD. In this study, caregivers realized and expressed the importance of emotional well-being as well as healthy habits and adequate control of unpleasant situations related to their child's condition. Considering that treatment adherence and the patient's health can be influenced by the caregiver's mental health [17], the ACDP can be a valuable part of the caregiver and patient journey. It is especially relevant once some participants expressed that the subcategory "family adjusting to living with a GHD" is not a common subject addressed during the diagnosis consultations. In this sense, participants in this study considered important not only the educational content but also the dispensing time of the digital health solution. Caregivers consider that the digital program is so useful that should be offered right after the diagnosis of the disease. To maximize their usefulness, digital health programs focused on helping caregivers manage their mental well-being and the day-to-day of their children's disease should be offered at the right time. Furthermore, it was suggested to include a testimonials section or a virtual space where families in the same situation can be in touch. These social features may impact user's motivation resulting in an increased adoption rate. This finding reinforces the fact that digital health can offer effective and motivational

XSL•FO
RenderX

services for caregivers' unmet needs that complement clinical practice [33,34].

Regarding the technology acceptance defined by the UTAUT theory [22-25], ACDP has been perceived positively by caregivers on performance expectancy and effort expectancy. The most important points of digital health solutions are that they can be used autonomously in the natural environment of the user, so usefulness, ease of use, and likeability are key [35,36]. The results indicate that the program seems to adjust to the core aspects of digital solutions as well as to cover all the needs and difficulties of participant caregivers of children and the user experience leads to a peaceful state of mind. Caregivers' stress levels can affect treatment adherence and the child's health [16], so giving them different tools to manage the disease seems to be a cardinal element in improving the quality of life of both. Therefore, understanding the factors that influence caregivers' adoption and acceptance of mHealth apps is essential for the development of effective digital health interventions [20]. Our study contributes to this understanding, addressing the barriers to acceptance, and adoption among caregivers managing pediatric diseases, including data security.

An interesting result is that the program has become a familiar intervention even though its target is caregivers. Some parents used mental well-being exercises together with their children, which has been reported as a great tool to improve the relationship between the caregiver and the child. Further research with higher samples will be conducted to explore deeply this promising result and analyze how this family intervention could impact caregivers' motivation, engagement, and well-being.

Limitations

This is a local study located in Zaragoza (Spain) with a small sample of 10 caregivers. Because of inclusion and exclusion criteria, people with low digital literacy were not able to participate. Interviewers were not experts but received training for the purpose of the study. Besides, although the general prevalence of GHD is higher in boys, most caregivers participating in this study were female with daughters affected with GHD, thus, parents with GHD sons might be underrepresented as well as male caregivers. Finally, the program needs further study to include recently diagnosed children.

Although there are quantitative questionnaires to measure the acceptability of digital solutions [37,38], we opted for a qualitative approach in order to get a more comprehensive understanding of the psychological burden experienced by caregivers of children undergoing growth hormone treatment, as well on the factors that influence the acceptability of the digital solution. Due to the post-positivist nature of the consensual qualitative research methodology, an interjudge reliability index is not calculated. However, trustworthiness in the qualitative analysis is guaranteed through iterative discussions between reviewers to share their independent interpretation of the qualitative data. Where consensus is not achieved, a deeper discussion is held until consensus is reached or a third independent reviewer is consulted.

Conclusions

In conclusion, the ACDP shows good acceptance results for family caregivers of children undergoing GHt. The interviews helped identify aspects for further refinement and improvement of the program, including a more intensive focus on the communication between parents and children. This study provides insights into how digital interventions can better support families of children undergoing growth hormone treatment.

Acknowledgments

Abstract

Background: Children with medical complexity represent a unique pediatric population requiring extensive health care needs and care coordination. Children with medical complexities have multiple significant chronic health problems that affect multiple organ systems and result in functional limitations and high health care needs or use. Often, there is a need for medical technology and total care for activities of daily living, much of which is provided at home by family and caregivers. Health IT (HIT) is a broad term that includes various technologies, such as patient portals, telemedicine, and mobile health apps. These tools can improve the care of children with medical complexity by enhancing communication, information exchange, medical safety, care coordination, and shared decision-making. In this study, we identified children with medical complexity as children aged <21 years who have >3 chronic health conditions. Community caregivers contribute to the care management of children with medical complexity, serving as advocates and coordinators, primary sources of information about children's needs, and facilitators of access to care. They are often the first point of contact for the families of children with medical complexity, particularly in vulnerable communities, including families in rural areas, low-income households, and non–English-speaking immigrant populations.

Objective: This study aims to introduce the HIT needs and preferences for children with medical complexity from the perspective of community caregivers. By including their perspective on HIT development, we can better appreciate the challenges they face, the insights they offer, and the ways in which they bridge gaps in care, support, and resources.

Methods: We conducted semistructured interviews (n=12) with formal community caregivers of children with medical complexity populations from a parent advocacy network on the US East Coast. Interviews were audio recorded via Zoom and then transcribed. An inductive thematic analysis was conducted to reveal HIT challenges and preferences for improving the care of children with medical complexity.

Results: We categorized the interview results into themes and subthemes. There are four main themes: (1) telehealth transforming care for children with medical complexity during the COVID-19 pandemic, (2) suggested tools and technologies for care for children with medical complexity, (3) HIT feature preferences, and (4) transition to adult care. Each theme had multiple subthemes capturing all details related to design features of needed technologies.

Conclusions: The study emphasizes the need to develop and enhance HIT for the care of children with medical complexity. The identified themes can serve as design guidelines for designers by establishing a foundation for user-centered HIT tools to effectively support children with medical complexity and their families. Telehealth and mobile health apps could improve care management and quality of life for children with medical complexity.

Introduction

Background

Children with medical complexity are a unique group within the pediatric population, characterized by diverse and significant medical needs. Though they represent <1% of children in the United States, children with medical complexities face chronic health conditions that are severe and enduring [1]. These children, all aged <21 years, often have congenital or acquired multisystem diseases or severe neurological conditions that lead to substantial functional impairments [2]. Although there is no universal definition, we used the most common criteria in our study for children with medical complexity as children aged <21 years who have >3 chronic health conditions [2].

Caring for children with medical complexity requires collaboration among stakeholders, including parents, health care providers in hospitals and clinics, school and home nurses, and community caregivers. Despite efforts, the challenges in coordinating care for these children persist, remaining largely unresolved [3]. These challenges include barriers to technology systems, inadequate access to health information, and a lack of partnership in care [4]. The burden of managing these complex medical needs falls heavily on parents, who often experience a significant caregiver burden [5].

Various technologies have been used in health care to improve the quality-of-care process. Health IT (HIT), including patient portals, telemedicine, and mobile health apps, has the potential to help with data management, sharing, and care coordination [6]. These HITs can positively impact medical outcomes, including physical, psychological, and continuity of care [7], minimize medication errors, and provide safer care [8]. For instance, telehealth emerged as a primary technology to provide safer care to children with medical complexity during the COVID-19 pandemic. Children with medical complexity is a vulnerable population that can benefit from technological interventions to improve care management, including information exchange, shared decision-making, and follow-up [9]. However, there is a need for studies to evaluate the effectiveness of HIT in caring for the children with medical complexity population and to identify the challenges and limitations associated with it. It is also critical to explore strategies for safely and effectively integrating HIT into the overall care management of children with medical complexity [10-12].

While parents are responsible for the day-to-day care of their children, community caregivers play a broader role by helping parents navigate complex health care systems. In addition, they ensure that children with medical complexities become fully participating and contributing members of their communities [13]. Community caregivers contribute to the care management of children with medical complexity, serving as advocates, coordinators, primary sources of information about children's needs, and facilitators of access to care [13]. In addition, they support families in vulnerable communities who have a child with a medical complexity, including families in rural areas, low-income households, and non–English-speaking immigrant populations [13,14]. Their experience navigating health care systems and HIT enables them to identify gaps in care and areas for improvement. Understanding their feedback and perspective on the use of technology in care for children with medical complexity is essential.

Objective

This study aimed to fill this gap by exploring how current tools and technologies are used and how they can be further optimized to meet the specific needs of children with medical complexity from the viewpoint of community caregivers. By gathering their insights, challenges, and recommendations, this study seeks to guide the development of technological solutions that enhance communication among stakeholders and improve the quality of life for children with medical complexity and their families. To our knowledge, this is the first study to specifically address technology suggestions from the perspective of formal community caregivers.

Methods

Study Design and Data Collection

We recruited formal community caregivers of children with medical complexity populations from the Parent Advocacy Network organization based in New Jersey in the United States, which was founded by the parents of children with special needs in 1987 to provide support to the families of patients with special needs [13]. The staff have supported >500 families of children with medical complexity in New Jersey for many years. We disseminated an informative recruitment email to all the staff members to participate in our study. Most of the staff are also parents of patients with special needs. We used a theoretical data saturation approach in recruitment. The saturation level was determined as the stage where adding more interviews would no longer enrich the conceptual depth of existing themes or reveal additional themes [15]. We ended up with 12 in-depth, semistructured interviews conducted from April 2023 to August 2023. Most (11/12, 92%) participants were female, and (1/12, 8%) participants were male. This study has an exploratory nature to identify various suggestions and needs in HIT design requirements for care for children with medical complexity. The exploratory nature of a qualitative approach generates very rich data and allows us to capture the caregivers' detailed experiences in the matter.

We conducted audio interviews over Zoom (Zoom Video Communications) and recorded all the interviews to be transcribed verbatim for the analysis. The interview guide included questions on the pros and cons of technologies used in care for children with medical complexity, user preferences and needs, suggestions for improving current technologies, telehealth experiences during the COVID-19 pandemic, and design recommendations for new technologies. We did ask probes when necessary to capture more details in unbiased ways. The audio interview was over Zoom per institutional review board requirement, so we did not record the video or observe any nonverbal cues. Each interview lasted from 45 to 60 minutes, and the participants' comfort level determined the duration in continuing to disclose their perceptions and share their experiences.

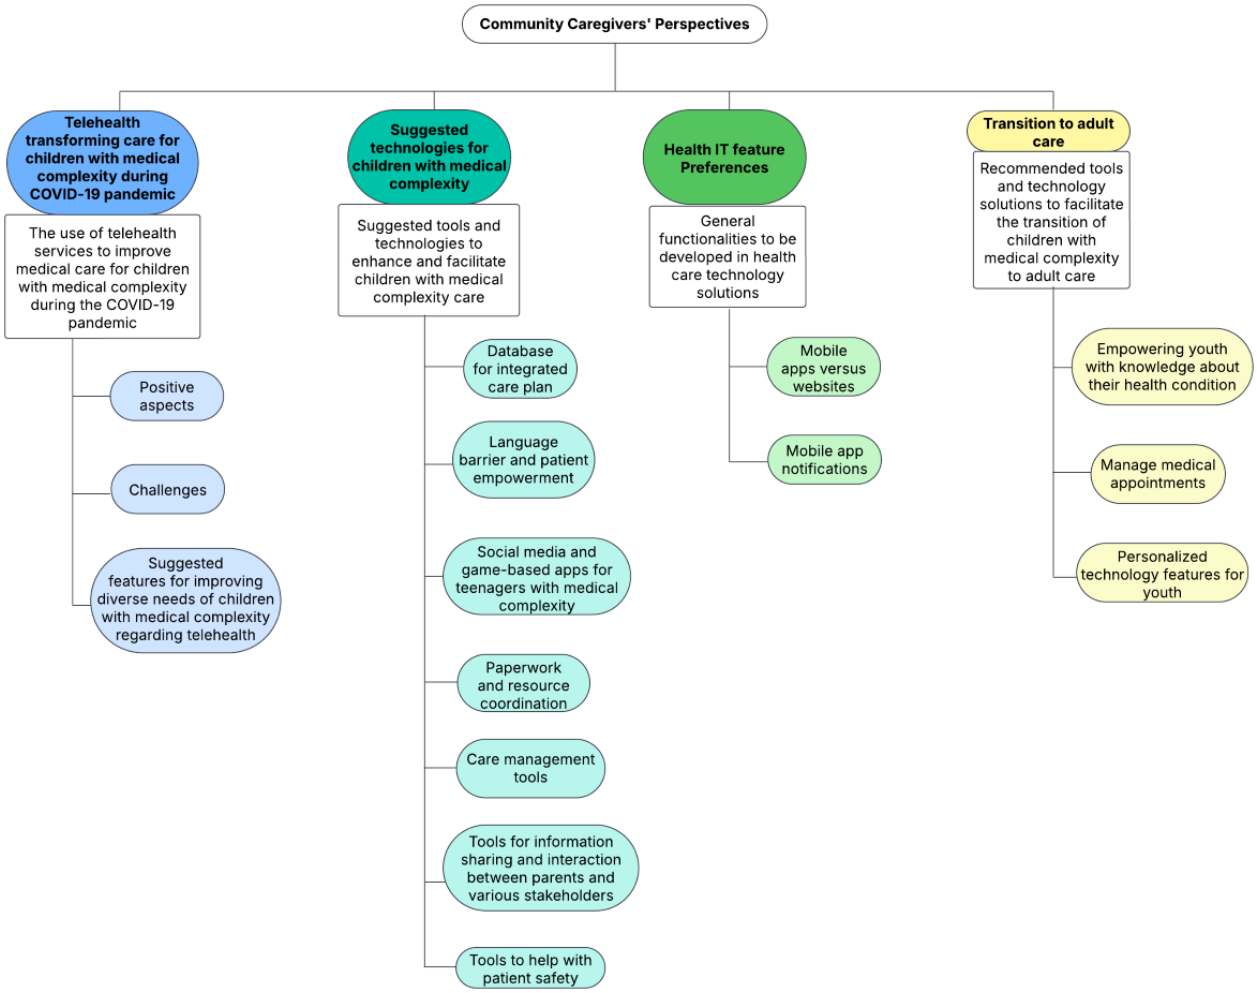
XSL•FO
RenderX

Data Analysis

The interviews were recorded, transcribed, and analyzed using inductive thematic analysis. The raw data were initially labeled into themes to capture essential data. The themes emerged upon comparing experiences views, situations, and contexts from the same and different participants, and we gradually refined the coding schema. We emerged themes by comparing experiences, views, situations, and contexts from the same and different participants and gradually refined the coding schema. The first author (FE) coded the data and created the themes and a codebook, which the second researcher (OA) validated and refined. Both authors performed the coding using Excel (Microsoft Corp).

During the data analysis process, the authors used an inductive approach to identify themes and understand technological needs, preferences, available options, challenges, and suggestions for improvements. The inductive approach is characterized by a search for patterns [16]. We identified 4 primary themes with their codes. After coding the data, both authors collaborated to categorize the data within each theme into subthemes. Subthemes define common dimensions within the main theme [17]. The objective was to explore the data beyond identifying common or dominant themes to uncover unique insights [18].

Ethical Considerations



This qualitative study used semi-structured interviews to collect data after obtaining ethics approval (ID 2023-006 (N)) from the Stevens Institute of Technology. The data was de-identified and does not include any identifier. Participants were paid 30 dollars compensation upon completion of the interviews.

Results

Overview

The inductive analysis resulted in four major themes: (1) telehealth transforming care for children with medical complexity during the COVID-19 pandemic, (2) suggested tools and technologies for care for children with medical complexity, (3) HIT feature preferences, and (4) transition to adult care. Figure 1 shows the 4 major themes and associated subthemes.

Figure 1. Identified major themes and subthemes.

XSL•FO
RenderX

Theme 1: Telehealth Transforming Care for Children With Medical Complexity During the COVID-19 Pandemic

The first primary theme identified from the thematic analysis was telehealth use, which is defined as using telehealth services to improve medical care for children with medical complexity health needs during the COVID-19 pandemic. We also developed several subthemes for positive and negative perceptions regarding telehealth use in care for children with medical complexity and suggestions to improve telehealth technologies for care for children with medical complexity from caregivers' perspectives.

The diverse needs of children with medical complexity result in varying health outcomes from telehealth services, depending on the child's medical condition during the COVID-19 pandemic. For example, participant 9 reported improvements in the child's health through telehealth visits, while participant 10 expressed dissatisfaction with the health outcomes achieved through telehealth therapy sessions:

> *They are all so different. I have one parent that I know when they went virtual, it worked beautifully with her daughter, who has limited speech. It helped so much because she was able to navigate everything. She had clear expectations. She is very visual. So it actually helped a lot.* [Participant 9]

> *Occupational therapy, or the physical therapy or speech therapy, even some of these therapy sessions cannot be offered for children who have very limited understanding or limited functional skills so having those virtual sessions were not beneficial for them, or meaningful for them. For example, if the child cannot follow a direction because of their cognitive ability, or because of that developmental status, then the virtual therapy is not meaningful for them. If the physical therapist is giving the child this direction but then the child cannot move, so the parent has to be right next to the child so that they can either assist the child or they can model that to the child. So then it is a barrier. If the parents are busy with their work, or if they have other commitments then the child is not getting the meaningful therapy sessions.* [Participant 10]

However, the participants who are the community caregivers shared common points regarding positive aspects, challenges they observed children with medical complexity parents experiencing, and ideas for improving telehealth services. Multimedia Appendix 1 presents subthemes of the positive aspects of telehealth as perceived by participants, alongside the challenges and limitations they experienced. It also includes suggestions for improving telehealth services to address the diverse needs of children with medical complexity. We reported at least 1 sample quote for each identified subtheme. Positive aspects include just-in-time access to care services (telehealth provides easier access to a variety of needed health care providers), facilitating physician-patient or parent interaction (telehealth facilitates interaction and communication between parents and providers during the COVID-19 pandemic), and overcoming geographical barriers (mitigating the barriers in health care services resulting from physical distance). However, participants also identified several challenges, including technical difficulties (the challenges and issues related to the technology used for telehealth appointments that impact the accessibility of services), a lack of communication while transitioning to telehealth during COVID-19 pandemic (the difficulties experienced due to unclear communication while shifting to telehealth services during the COVID-19 pandemic), and simplicity for non–tech-savvy parents (the need for technology that is easy to use and navigate, especially for parents who are not comfortable using various digital tools). In addition, participants suggested several features to improve telehealth for children with medical complexity, including visual graphics (using visual elements to enhance communication and engagement during the telehealth session), educational components (enhancing users' understanding of telehealth), video and audio support (the critical need for high-quality video and audio technology in telehealth to facilitate effective and accurate communication between health care providers and patients), questionnaire addition (the integration of questionnaires into telehealth services), and providing variety of ways to communicate (offering diverse methods to facilitate communication for patients who may find it challenging to express themselves).

Theme 2: Suggested Tools and Technologies for Care for Children With Medical Complexity

This theme covers suggestions for developing tools and technologies to enhance and facilitate care for children with medical complexity. Participants suggested developing various tools and technologies to support themselves or the parents of children with medical complexity, along with the features to be added to existing technology, as shown in Multimedia Appendix 2. One suggestion was the creation of a database for integrated care plans, a comprehensive system to help families manage and coordinate all aspects of their child's health care. This would serve as a centralized database to provide a clear and organized record of their child's information:

> *The parents need to keep records and, when anything changes, be ready and clear on what needs to happen. Even if a home nurse is coming to assist the parents, the parents are still, as I like to refer to them, the captain of the ship. They are the ones who need to know everything there is to know about their child's health.* [Participant 12]

Participants also recommended tools to address language barriers and empower patients, aiming to overcome communication challenges between parents and health care providers arising from differences in languages or communication styles:

> *It becomes even more complex for my underserved families. For example, if the nurse needs to talk to the child's doctors because the parent does not speak English, the parent should still be included in all of those conversations.* [Participant 5]

> *Some of the medical terminology is very difficult to translate into the parents' native language. Although we have the technology in place, certain medical*

XSL•FO
RenderX

> *terms cannot be translated or interpreted in a way that parents can understand.* [Participant 7]

To enhance social development for teenagers with medical complexity, suggestions included social media and game-based apps designed to improve social skills and provide relevant health care information in engaging formats:

> *When things are developed in a very controlled setting, they work fabulously. However, as they trickle down into real life and society, and real people use them, often the system itself does not work as it should. For example, a system that allows communication without speech by exchanging pictures might help children, but instead of encouraging language development, it may lead to them becoming too comfortable using pictures. When applied in real time, this is very challenging for them, and they are not motivated to become verbal. I have heard many parents complain about this. These should be considered social skill lessons. If a game or solution could be developed and applied to real life, that would be great.* [Participant 11]

Paperwork and resource coordination tools were also highlighted to help families organize and track paperwork and resources associated with their child's care:

> *Sometimes families are not always that organized. One of the things we always advise families is to write down information when they go to the doctor's office, whether in person or virtually. We encourage them to learn how to communicate effectively with doctors and schools and to centralize their paperwork in one place. Managing all the documents, doctor's notes, and medication records can be overwhelming, so it is important to teach families how to keep everything organized.* [Participant 3]

Regarding care management tools, participants suggested tools to assist parents with scheduling, tracking appointments, and managing medications:

> *Medications themselves can be particularly difficult to manage. Understanding and managing prescriptions, including knowing when to refill medications. There are complex instructions like "do not give this one with that one," "take this one with food," "this one needs to be refrigerated," and "this one is an intramuscular injection." With so many different medications and dosages, it can be overwhelming. For example, the same medication might require two pills in the morning and only one at night, which can change on the same day.* [Participant 3]

In addition, suggestions were made for tools to facilitate the exchange of information between parents, medical providers, and other care providers. Effective communication is essential for informed care coordination and comprehensive childcare:

> *Text-like feature that allows parents to choose who they want to include in a conversation. Parents do not necessarily want the school involved when it comes to medical matters. But it could have that option where the parent can choose to include people. It should have easy access to sharing and being able to pick and choose what you share and with whom. Making sure that the parent has control and is aware of who is getting what information.* [Participant 9]

Finally, the participants suggested tools to minimize risks and prevent errors in the care of children with medical complexity:

> *I think there is a need for tools and features that support children with medical complexity care to minimize risks. Unfortunately, families are sometimes the care managers. So, for example, if a child needs a diet for a gastrointestinal condition, yet also has kidney disease. They would need to consult with the medical team before they could give that diet and often that does not happen. The family has to say that this child has this medical condition and has to coordinate care between different teams, and it should not be that way, particularly with the availability of electronic health records. But unfortunately, they do not necessarily read the charts, or they are so siloed that they are only focused on their specific specialty.* [Participant 5]

Theme 3: HIT Feature Preferences

The analysis showed another major theme around general recommendations preferred in HIT. This theme may assist system and software engineers in developing effective platforms that meet the needs of parents and supporters of children with medical complexity. Understanding these shared preferences is essential for designing technology that provides meaningful support and enhances engagement. The participants expressed their preferences for mobile apps and websites. They valued the convenience of mobile apps for quick access. In addition, mobile apps are beneficial for caregivers or patients with disabilities. However, they recognized that older adults caring for grandchildren with medical complexity prefer websites for their ability to display information on larger screens, such as laptops. The participants also emphasized the importance of mobile app notifications in coordinating care by providing timely reminders for caregivers. Table 1 presents the participants' perspectives on mobile apps and websites.

XSL•FO
RenderX

Table 1. Perspectives on mobile apps and websites.

Subthemes and definitions	Quotes
Mobile apps versus websites (the comparison between mobile apps and websites in terms of preferences)	• "Mobile access provides much more freedom. You do not need to have your laptop with you; if you are outside, you can still access data through your mobile device. However, many grandparents who take care of their grandchildren might not be able to have or use mobile apps." [Participant 10] • "I think it is important to have something that is not so cumbersome, something they can pull out and use, which is a phone. The invention of the smartphone might have so many capabilities for individuals with disabilities." [Participant 12]
Mobile app notifications (the importance of mobile app notification feature for caregivers)	• "I would like an app to coordinate everything and also send reminders or share reminders of what is coming up next. For instance, in terms of care coordination, I am adding information to the app, perhaps that my child visited a specialist on this date, then maybe the app can add reminders in additional ways about an upcoming appointment. Or maybe, if I say in my notes that I met with this specialist and need to schedule a follow-up appointment with so and so. Maybe the app can understand the action items from those notes and say you mentioned this, and you need to schedule a follow-up appointment with this specialist." [Participant 1]

Theme 4: Transition to Adult Care

The last primary theme focuses on a sensitive period in the continuum of care of children with medical complexity. At the age of 21 years, children with medical complexity experience the transition or transfer of care from pediatric settings to an adult setting, findings showed suggestions for technologies specifically for this transition period. The community caregivers highlighted several features of these technologies, especially those related to enabling self-care and management for the patients. The theme emphasized the necessity of designing technology to empower the youth with the necessary knowledge during this transition to adulthood. In addition, given the shortage of resources and skillsets in adult settings compared to pediatric settings for the children with medical complexity population, they highlighted the various needs children with medical complexity teenagers or young adults with medical complexity might have during and after the transition; therefore, a personalized technology, specifically addressing their needs, would be beneficial. Table 2 presents the subthemes related to various suggestions for using technology to facilitate the transition to adult care.

Table 2. Suggested technology to support the transition to adult care.

Subthemes and definitions	Quotes
Empowering youth with knowledge about their health condition (providing youth with the necessary knowledge to understand and manage their own health issues)	"A youth app would be so important to support health care transition. It is supposed to start at 12 because our kids are going to grow up. Youth are going to go to college, and they are going to have a new provider who is a specialist. Mom is not going to be there with them. So, I believe it is important to provide them with resources about their disability, what it is, and their medications." [Participant 5]
Manage medical appointments (teaching youth with medical complexities how to schedule and organize their own health care visits)	"I think of an app that would help the child to make appointments such as a scheduler. As a mother of a child with medical complexity, we do everything. The truth is that they are going to grow up, and the first steps might even be just having your child sign their name when they come into a doctor's office or calling to make an appointment. The app should be integrated with text to talk for youth with medical complexity." [Participant 5]
Personalized technology features for youth (technology solutions that meet the unique needs and abilities of children with medical complexity)	"An app should be able to assess whether users can read well; based on this assessment, we would use either tenth or twelfth-grade English. If users have receptive issues or dyslexia, we will avoid using this font and instead use one without unusual markings. For example, consider a twelfth-grader who reads at a third-grade level but is transitioning to adulthood. Currently, there are no resources for this, so the child will often rely on information from his parents. This can be a real struggle because, although the content is intended for him, he does not have access to it." [Participant 10]

Discussion

Principal Findings

This qualitative study explores formal community caregivers' perspectives on integrating HIT in the care of children with medical complexity. Community caregivers are an essential part of the care model for children with medical complexity from underserved populations [13,14]. Our findings showed the critical benefits of telehealth for this population, especially during the COVID-19 pandemic, though some negative experiences and improvement suggestions are also noted. We also identified various specific needs that can promote future technology design to address the specific needs of children with medical complexity in care management as well as the interaction between the parents of children with medical complexity and care providers. Finally, our findings address the need for technologies that support the transition from pediatric to adult care for the children with medical complexity population. To our knowledge, this is the first study capturing children with medical complexity community caregivers' perception of the role and needs of HIT in an effective care for children with medical complexity model.

XSL•FO
RenderX

Shifting From In-Person Visits to Telehealth

The COVID-19 pandemic has accelerated the adoption of telehealth into the American health care systems, providing safe access to medical care [19,20]. The data reveal that telehealth provided alternatives and safer options to the children with medical complexity population during the peak time of the COVID-19 pandemic as a cost-effective solution that can potentially improve health outcomes for children with medical complexity, facilitate physician-caregiver interaction, and increase caregiver satisfaction, as reported in other studies [21-23]. Community caregivers emphasize that telehealth eases the burden on parents, especially those from underserved populations, by reducing the time they need to take off work and travel long distances, as discussed by other studies [24,25]. During the COVID-19 pandemic, telehealth was the safest method to maintain physical distance while ensuring timely and affordable care [26]. Telehealth facilitated follow-up care, reducing the burden on care teams and decreasing exposure risks for both patients and health care providers [27]. However, the findings also showed that there are certain tasks, especially in inpatient settings, which cannot be done using telehealth. Clear communication between parents and health care providers is needed to ensure timely and reliable care [28]. Our study also revealed that community caregivers advocate for the continuity of telehealth services after the COVID-19 pandemic, driven by the factors mentioned earlier. Despite its advantages, our analysis also showed several challenges related to telehealth use in the care of children with medical complexity. These challenges include technical difficulties, connection issues, a user-unfriendly interface, and a lack of clear instructions for parents to connect to the system [29-31]. These challenges should be addressed and enhanced for better use of telehealth in care for children with medical complexity.

A previous study focused on providing recommendations to enhance telehealth functionalities and support diverse communication needs from the perspective of children, which aligns with our findings [32]. Our participants reported that children with medical complexity often struggle to sit still, listen, and engage throughout a long telehealth session. They suggested that for children with medical complexity, particularly those with developmental disabilities, integrating fun graphics with timers into telehealth can transform their experience. This approach allows families to create a structured environment that actively engages children and leads to more productive telehealth sessions. Moreover, our participants suggest accommodating diverse communication preferences during telehealth sessions, as some children might feel more comfortable expressing themselves through text. Integrating features such as fill-in-the-blank sentences, text-to-voice options, and voice-to-text options can significantly enhance accessibility. In addition, allowing children to choose their voice gender and use emojis to convey their pain levels or express agreement and disagreement can facilitate more effective communication. These adaptations can help create a more inclusive and supportive telehealth experience.

In addition, health care providers must listen to parents' concerns and answer their questions, as it will assist them in coping with difficult situations [33]. Our participants recommend that preappointment questionnaires may enhance communication between parents and health care providers. This approach will help parents in addressing their concerns in advance, which will be discussed during the session. In addition, integrating an educational component into telehealth will enhance parents' understanding of the medical information presented during the session.

Technologies for Improving Outcomes of Care for Children With Medical Complexity

Community caregivers suggested tools to address various needs of this population, including parent or patient empowerment, information management, care coordination, communication, and patient safety. Visiting the physician's office can be stressful for this vulnerable group due to the unfamiliar environment [34,35]. Our study revealed that games and social media platforms could improve the social skills of children with medical complexity, such as interacting with the health care staff. Participants suggested gamified learning apps that focus on teaching what is socially appropriate and inappropriate. In addition, social media platforms, such as TikTok, Snapchat, and Instagram, provide short videos that capture children's attention. This feature can help children with medical complexities learn how to interact in a physician's office and encourage them to participate actively in their health management.

Several subthemes emerged from the analysis, showing various management tools to help the parents of children with medical complexity at different levels of care for children with medical complexity, not only in hospitals but mostly in home settings. The data clearly show the increasing interest among caregivers in integrating various HIT tools into the care for children with medical complexity journey to improve the quality of care. As this interest expands, concerns arise regarding validating these technologies, as many lack regulatory approval. In addition, improving patient safety in complex pediatric health care requires providing families with tools that help them with decision-making and communication. Successful communication requires timely information exchange between primary care, specialty care, and families to enhance medical outcomes for children with medical complexity [36]. Our participants indicated that parents often felt responsible for sharing information, as they are the primary drivers of their children's care. Miscommunication and the use of multiple medications in complex medical conditions increase opportunities for error, particularly as children transition between health care settings and practitioners [37]. Communication barriers often prevent parents from properly filling prescriptions or adjusting dosages, resulting in frequent errors and increased risks to patient safety [38]. In addition, parents need to find the right channels and have a road map to assist in understanding and managing the complicated situations or challenges they will encounter in the future [39]. Therefore, community caregivers ask for effective technologies and tools to be developed to address these critical needs of the parents of children with medical complexity.

Another subtheme highlighted the need to address language barriers and empower parents and patients, especially those from underserved populations with low education levels. Parents

XSL•FO
RenderX

with limited English proficiency encounter communication challenges that negatively affect access to and quality of health services for children with medical complexity [40]. Language barriers and health literacy limitations could be associated with parents' less understanding of diagnoses, treatment options, care plans, and follow-up recommendations [41]. In addition, language barriers include a limited understanding of medical terminology while explaining the child's diagnosis and treatment plan [42]. The parents want clear instructions, simplified medical terms, and concrete medication directions [43]. A well-designed tool can help these parents mitigate these barriers and become empowered in the care of their own children with medical complexity.

Preferences and Specifications for User-Centric Design

The data showed some discussions on preferences on the type of technology platforms discussed by community caregivers. The participants discussed their preferences for mobile apps and websites, focusing on how these platforms can meet diverse needs. Smartphones allow users to access information and services anytime and anywhere [44]. However, older adults caring for children or grandchildren with medical complexity might prefer using desktops and laptops, as larger screens provide a more accessible information display.

The participants also emphasized the importance of reminders and notifications in managing their caregiving responsibilities effectively. Reminders are an important feature in mobile apps, helping users manage medication, appointments, and adherence to medical conditions [45]. For instance, the participants in our study mentioned that writing notes is a common practice to keep track of important tasks and appointments; however, this can often lead to information overload and disorganization. It was suggested that an app could analyze these notes and identify action items. Then, the mobile app could send reminders on upcoming appointments and other important tasks. This could be achieved using an artificial intelligence (AI)–powered mobile app that uses natural language processing to analyze the text notes. AI-assisted mobile apps could be designed to provide personalized experiences for parents and offer insights that drive better decision-making [46]. In addition, AI-assisted apps could be extended to assist parents in enhancing medication adherence by recognizing medications and verifying their ingestion [47].

The Role of Technology in Supporting Transitions to Adult Health Care

Our data revealed an interesting theme focusing on the care transition or transfer of this vulnerable population from pediatrics to adult care and how to make this transition better by using various technologies and tools. These tools should educate youth about their complex medical conditions, medications, and overall health management [48]. Children with medical complexity will inevitably grow up, and they will need to navigate independent adult life and responsibilities. Managing multiple medical appointments and follow-ups becomes a significant skill while transitioning to adult care. Our participants suggested an app that includes features such as appointment scheduling and text-to-speech integration, which could help youth with medical complexity learn to navigate this aspect of their care independently. Furthermore, personalized technology solutions that adapt to individual reading levels and cognitive abilities are essential [49]. As suggested by Statewide Parent Advocacy Network participants, an app that provides content accommodating varying reading skills can ensure that children with medical complexity with different learning needs can equally engage with and access adult transition resources.

As shown in the literature, this transition period is risky, and adult settings are significantly less prepared compared to pediatric settings to care for this vulnerable population [50]. Transitioning from pediatric to adult health care is unique to each child and ideally occurs between the ages of 18 and 21 [51]. The negative impact of poorly managed care transition contributes to family burden and distress [52,53]. Families face significant challenges in motivating their children and often lack clarity about the steps needed for the adult care transition phase [53]. There is growing interest in leveraging HIT to facilitate the transition from pediatric to adult care [54,55]. Health care providers and parents support youth in developing autonomy, decision-making skills, and self-management by creating tailored plans that address their abilities and complexities [49]. This process can be further empowered by leveraging HIT, which can provide tools and resources to enhance personalized care and support this transitioning phase, as highlighted by the participants in our study.

Limitations

A limitation of this study is that the interviews were conducted with members of only one organization. In addition, we only collected gender as demographic information about participants. Our participants were predominantly female, so future studies could balance the insights by adding more male community caregivers.

Conclusions

This study explored and analyzed the needs of children with medical complexities and their caregivers throughout their care journey from community caregivers' perspectives. We identified several areas where HIT could enhance care for children with medical complexity conditions. There is a need for improvement in telehealth and the development of mobile health apps across various areas of care for children with medical complexity, such as data management, educational resources, care coordination, and transition to adult care. By addressing these areas, technology designers can contribute to more effective, coordinated, and personalized care for children with medical complexity. This improvement will potentially lead to better health outcomes and a higher quality of life for children with medical complexity.

Abstract

Background: Theory-informed strategies for engaging parents in children's physical activity (PA) promotion show promise. However, behavior-change interventions must become more rigorous in both their application of theory and the reporting of its use to continue to advance the field.

Objective: This study aims to elucidate how 2 behavior change theories were used to develop parent communication materials in a 20-week communications campaign, nested within a multilevel (school-home) intervention to promote children's PA. The innovation described in this study is derived from the Supporting Physical Literacy at School and Home (SPLASH) feasibility study (2021 - 2022).

Methods: A team of 7 experts, including graduate students, researchers, faculty, and child PA specialists, collaboratively designed the process used to develop the intervention content. With experience in theory-informed interventions and health-related communication campaigns, they held recurring meetings to refine the approach.

Results: A four-step process was used to develop the theory-informed parent communication materials: (1) establish a theoretical foundation for communication materials (ie, social cognitive theory and self-determination theory) and conduct focus groups with the priority population; (2) identify and select PA parenting behaviors aligned with evidence and behavioral theories to form PA parenting objectives that advance children's PA; (3) identify theoretical determinants of parent behavior change and outline methods for applying determinants to address PA parenting objectives; (4) operationalize theory-informed strategy and draft, review, and finalize materials. Parent communications were delivered through print materials and electronic channels, including email, text messages, Facebook (Meta Platforms, Inc), and activity videos.

Conclusions: This descriptive study advances progress in the development of school-based PA promotion efforts seeking to incorporate parent engagement strategies by detailing how behavior-change theories can be operationalized to improve PA parenting behaviors. This methodology is valuable for others seeking to translate theoretical constructs into behavior-change communication messages.

KEYWORDS

school-based physical activity; multilevel intervention; behavior change theory; physical activity parenting; communication material design; theory-informed design

Introduction

Participating in regular and sufficient physical activity (PA) is an essential contributor to optimal growth and development in childhood and favorable physical and mental health throughout the life course [1,2]. In the United States, changes in lifestyle factors, the built environment, and opportunities for PA have resulted in declines in children's PA, with disparities by gender, race, ethnicity, and family income becoming increasingly

XSL•FO
RenderX

pervasive [3-6]. The development of strategies that can improve and maintain children's PA is therefore a growing priority.

Based on the substantial amount of time school-aged children spend at school, the availability and accessibility of PA opportunities at school can have a significant impact on promoting children's PA [7,8]. Reviews of school-based PA interventions have shown promise for improving children's PA levels [9,10], with multicomponent, comprehensive school PA programs (ie, integration of multiple strategies during and outside school hours) potentially having the greatest impact on daily activity levels [11,12]. In addition, there is widespread belief that parent or caregiver (herein referred to as "parents," which includes biological parents, other biological relatives who may act as caretakers, and nonbiological parents such as adoptive, foster, or stepparents) engagement in school-based PA promotion efforts is essential for providing the consistent opportunities and support children need to be physically active [10,13-17]. As such, developing school-based PA interventions that involve parents has become an area of growing attention.

Some commonly used parent engagement strategies in school-based interventions include establishing clear communication channels between school and home, providing opportunities for parents to build their knowledge, skills, and confidence for supporting their children's behaviors, and engaging parents in activities at home to reinforce messages and practices taught at school [18]. However, the independent contribution that parent engagement strategies have on school-based intervention effectiveness, including child PA outcomes, is inconclusive [14,15,19,20]. A review by O'Connor et al [21] of school-based PA interventions with parental components found that inadequate and inconsistent reporting has made it difficult to interpret outcomes and draw conclusions on the most effective parent engagement strategies. Theory-based, empirically verified procedures are warranted to allow for a more systematic evaluation of such interventions' impact on both parent and child behaviors and for their eventual widespread dissemination.

There has been progress in the broader behavior-change science field to develop systematic methods such as ontologies [22-24], taxonomies [25-27], methods for mapping interventions [28-30], and a theory coding scheme [31] that can be widely applied across the design, implementation, and evaluation phases of theory-based health behavior interventions [32,33]. However, continued inconsistencies in theory application and poor reporting of theory use make it difficult to ascertain and disseminate effective methods, limiting both the advancement and practical application of behavior-change strategies [34,35]. Furthermore, these systematic methods provide frameworks for intervention planning and design broadly, with none focusing on the operationalization of theory into intervention content, such as communication materials. This may help explain why studies of communication interventions seldom provide descriptions of how theory was applied to messaging and materials design, making it difficult to interpret study results, draw broader conclusions about whether given theories are useful and replicate methods.

This descriptive study aims to address these gaps in school-based intervention design by detailing the development of theory-informed communication materials intended to engage parents in children's PA promotion efforts. More specifically, our work recounts how two behavior change theories were used to inform a 20-week multichannel communications campaign seeking to engage parents, nested within a school-based PA intervention (herein referred to as the "multilevel intervention"). This innovative descriptive study provides an example for operationalizing theory in communication messages for multilevel behavior change. These methods are of value to others seeking to be more rigorous in the application and reporting of theory use when designing parent engagement strategies to promote children's PA.

Methods

The Supporting Physical Literacy at School and Home Study

This work was conducted in partnership with New York Road Runners (NYRR). NYRR is the world's premier community running organization with a mission to help and inspire people through running. They have disseminated youth running and PA programming since 1999. In 2017, NYRR released a new running-based youth program, Rising New York Road Runners (RNYRR), that can be incorporated into before-, during-, and after-school PA opportunities. RNYRR programming focuses on enjoyable, inclusive, developmentally appropriate games and activities that sequentially build motor skills in one or more domains (eg, locomotion, balance, and object control) to improve children's physical literacy (PL), defined as their confidence, competence, and motivation to be physically active for life [36,37].

The innovation described in this descriptive study is derived from the multilevel intervention, the Supporting Physical Literacy at School and Home (SPLASH) feasibility study (NCT05887583). Implemented during the 2021 - 2022 school year, SPLASH was designed to support RNYRR's existing school-based PA program by developing and delivering strategies to engage families in children's PA beyond school as well.

The aims of the SPLASH study included: (1) the development of a theory-informed home-based communications component, and (2) an assessment of implementation feasibility and acceptability in the target population. Aim 1 is the focus of this descriptive study, and results from aim 2 are forthcoming.

Key Programmatic Elements

A 4-step process was used to develop the theory-informed parent communications. Each step in the process included several activities that were informed by theory and existing evidence. The outputs generated from the activities were then integrated into the subsequent step. The entire 4-step process serves as an example of designing theory-informed communication materials intended to engage parents in children's PA. Table 1 outlines the steps, activities, and outputs.

XSL•FO

Table . Development process of theory-informed communication materials.

Step	Activity	Output
Step 1: formative research		
Theoretical foundations	Aligned theoretical foundations for communication materials with overall multilevel intervention aims.	Theoretical basis established for communication materials.
Focus groups	Conducted focus groups with the priority population.	Summarized findings to tailor communication content.
Step 2: behavior change objectives	Conducted a literature review to identify and select PA parenting behaviors aligned with existing evidence and theoretical basis.	Parenting objectives are formed to advance children's PA[a].
Step 3: theory-informed strategy	Identified theoretical determinants of parental behavior change and outlined the application of determinants.	A strategy created to address PA parenting objectives.
Step 4: operationalization	Selected communication channels and drafted, reviewed, and edited materials to operationalize the theory-informed strategy.	Communication materials finalized.

[a]PA: physical activity.

Step 1 (formative research) took place during the grant proposal design phase in 2018 - 2019. Steps 2 - 4 took place from fall 2019 to spring 2021, with implementation of the multilevel intervention beginning in fall 2021.

The process included a planning and design team of 7 members, consisting of graduate students, research managers, research scientists, and faculty members from leading universities in nutrition, PA, and behavior change, and child PA specialists from RNYRR. The process was collaborative and iterative, consisting of recurring team meetings to review and discuss progress. Many team members had previously worked together on similar school- and community-based projects, including studies testing theory-informed approaches to promote child PA and improve health-related parenting practices [16,38-41]. Collectively, our team consisted of PA experts with experience in applying behavior change theories to intervention design and in developing and implementing communication campaigns to improve children's health behaviors.

Ethical Considerations

This study was reviewed and approved by the Social, Behavioral, and Educational Research Institutional Review Board at Tufts University (approval no 1812027; January 2019). All procedures were conducted following the ethical standards of the institutional research committee and the Declaration of Helsinki and later amendments. Informed consent was obtained from all participants before data collection. All data was deidentified and participants recieved a $50 Visa prepaid debit card for their time.

Results

Step 1: Formative Research

Theoretical Foundations

The theoretical basis for the communications campaign was selected during the grant proposal design phase in 2018. The National Institutes of Health Funding Opportunity Announcement (PAR-14 - 321) encouraged applications for "Phased Innovation (R21/R33) grant awards to support highly innovative research aimed at developing multilevel interventions that will increase health-enhancing PA: (1) in persons or groups who can benefit from such activity, and (2) that can be made scalable and sustainable for broad use across the nation." In response to this funding announcement, the authors partnered with NYRR to expand upon RNYRR's school-based PA program. We proposed developing strategies that would engage families in children's PA learning outside of school time to complement and reinforce the in-school programming. As the RNYRR school curriculum was developed with a focus on increasing children's PL, we sought to draw upon theoretical frameworks that would complement PL tenets when designing the family communication materials.

The concept of PL has been defined in several ways; for the multilevel intervention, we adopted the definition from the Aspen Institute's landmark 2015 report: "physical literacy is the ability (competence), confidence, and desire (motivation) to be physically active for life [42]." According to that report, ability or competence includes fundamental movement skills, which provide the foundation for a range of PA; confidence is one's belief in their ability to participate in sports or other physical activities; and desire or motivation includes intrinsic enthusiasm for PA.

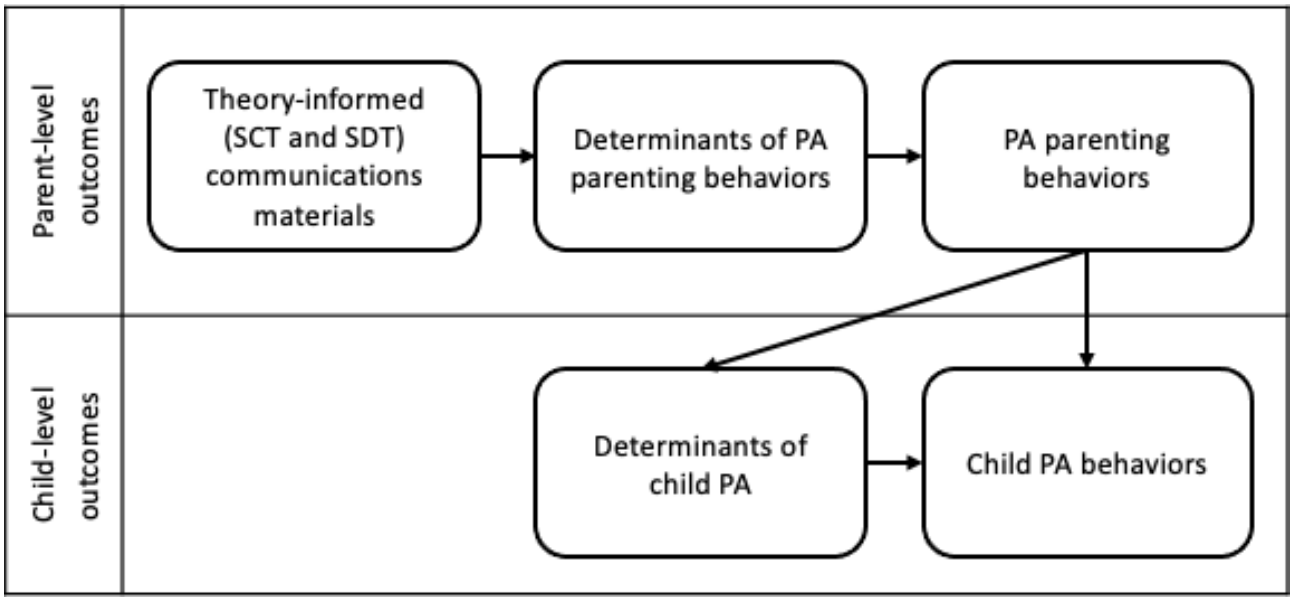
Social cognitive theory (SCT) and self-determination theory (SDT) are two theoretical frameworks that complement PL concepts. For example, SCT constructs of self-efficacy and behavioral skills are similar to the confidence and competence components of PL [43], and SDT centers on motivational states and therefore aligns with the motivational dimension of PL [44]. Furthermore, SCT and SDT are commonly used in the design of interventions to target the determinants of children's PA, aiming to improve the promotion and maintenance of PA across the lifecycle [43,45-47]; PL-based approaches focus on not just eliciting near-term PA but also enabling children to be "active for life [42]." Given the theoretical and empirical evidence for SCT- and SDT-based strategies in promoting children's PA, the alignment between these theories and PL concepts, and the

XSL•FO
RenderX

study team members' prior experience with the application of both theories, we selected SCT and SDT as the theoretical basis for our communication materials. Table 2 summarizes the relevant literature for SCT and SDT in children's PA behavior change.

Table . Summary of social cognitive theory and self-determination theory supporting evidence for children's physical activity (PA) behavior change.

Overview of theory	Behavior change mechanisms	Evidence for children's PA	Long-term maintenance of behavior changes	Application to intervention design
Social cognitive theory (SCT)				
Learning occurs in a social context through dynamic, reciprocal interactions between cognitive, behavioral, and environmental factors [48].	Behavior change is bidirectional and shaped by interactions between individuals and their environment, including others [49].	Observational learning, goal setting, and reinforcement are key to effective family-based interventions for increasing children's PA [50].	For long-term maintenance of behavior, SCT emphasizes the importance of a supportive environment [45].	SCT effectively supports school-based interventions by engaging parents and extending children's PA support across school and home environments.
Self-determination theory (SDT)				
Three innate and universal human needs underlie growth: autonomy, competence, and relatedness [51].	Behavior change relies on motivation and occurs when an individual's psychological and physiological needs are met [51].	A motivational climate that fosters effort, personal growth, and decision-making opportunities significantly improves children's PA outcomes [47].	For long-term maintenance of behavior, SDT emphasizes the importance of sustained intrinsic motivation for the behavior [45].	SDT is ideal for PA interventions that enhance children's intrinsic motivation by fostering enjoyment and interest [52].



Though both theories help to explain the determinants of and conditions necessary for promotion and maintenance of a behavior, integrating components of the two may provide a more comprehensive understanding and improve the overall effectiveness of an intervention [9]. The integration of SCT and SDT has been a promising area of interest in designing and implementing school-based PA interventions [53,54]. Underlying these studies is the concept that the three basic human needs outlined in SDT (ie, autonomy, competence, and relatedness) can be satisfied or inhibited by the cognitive, behavioral, and environmental factors outlined in the SCT [55]. For example, social environmental factors, such as support for PA (ie, encouraging children's choices, options, and opportunities to participate in PA) from multiple sources, may positively influence students' motivation for and long-term engagement in PA [56,57]. Conversely, autonomous motivation for PA can positively influence factors such as attitudes toward PA, thereby influencing PA intention [58].

While the overall behavioral objective of the multilevel intervention was to promote children's PA, the intention of our theory-informed communication materials was to engage parents and improve their PA parenting behaviors. By operationalizing theoretical constructs into the materials, we hoped to target the SCT and SDT determinants of PA parenting behaviors, thereby influencing the PA parenting behaviors. The improvement in PA parenting behaviors could then enhance the SCT and SDT determinants of their children's PA and promote their children's PA behaviors.

Figure 1 depicts the relationship between the theory-informed (ie, SCT and SDT) communication materials and parental- and child-level behavioral outcomes. By operationalizing theoretical constructs into the materials, we aimed to target the SCT and SDT determinants of PA parenting behaviors, thereby influencing the PA parenting behaviors. Improvement in PA parenting behaviors could then enhance the SCT and SDT determinants of children's PA and promote their PA behaviors.

Focus Groups

Focus groups were conducted with parents from the priority population to inform the overall development of the theory-informed parent communications. These focus groups explored parental knowledge and attitudes around child PA, parental perceptions of their children's PA engagement, perceived barriers and facilitators to supporting their children's PA, and current or preferred school-family communication channels.

Eight focus groups were conducted with parents of children in grades 3 - 5 in both the NYC and Boston areas between April and June 2019. Of the parents who participated in a focus group (n=69), 30% and 48% identified as non-Hispanic Black and Hispanic, respectively, and 89% identified as mothers. Results were coded by 3 study team members and organized by major themes. Primary results used in developing the materials include the following: (1) parents saw their children as lacking sufficient PA and viewed themselves as primary motivators, facilitators, and role models. Ensuring adequate PA for their children was a priority for them, (2) parents valued PE for teaching their children PA skills but wanted more school communication and involvement in PA opportunities. They preferred diverse communication methods with no single preferred frequency, and (3) parents wanted to engage in family PA but faced barriers such as time, energy, motivation, and space. They sought activity ideas aligned with PE lessons, adaptable for the whole family, and feasible in a limited space.

These findings contributed to a clearer understanding of the challenges faced by parents in our priority population to support or engage in PA with their children and highlighted potential opportunities to better connect families with schools. These findings were incorporated throughout the communication design process to ensure the final materials were responsive to the needs and preferences of the priority population.

Step 2: Behavior Change Objectives

To engage parents to promote children's PA, we needed to first identify priority PA parenting behaviors and the determinants of those PA parenting behaviors within the context of our theoretical basis. Reviewing the literature through the lens of SCT and SDT allowed us to understand how parents could both serve as an important socioenvironmental influence in the context of SCT and help satisfy needs in the context of SDT [59-61]. Our goal in step 2 was to (1) categorize the most influential parenting behaviors for promoting children's PA based on our literature review of existing evidence and (2) ensure the PA parenting behaviors aligned with the formative research conducted in Steps 1a and 1b. Collectively, step 2 details how our PA parenting objectives relate to the theoretical determinants of children's PA.

Our review of the parenting literature was conducted in the summer of 2019 by 3 study team members and supported by a Tufts University librarian. Web of Science, PubMed, and Ovid databases were used with a broad search strategy across all years of publication. Example search terms, informed by similar reviews, included terms related to parents (parent* OR famil* OR caregiver* OR family carer*), children (pediatric* OR child* OR kid* OR adolescen*), parent engagement (involv* OR participat* OR engage* OR outreach OR recruit* OR retain* OR retention*), intervention type (community-linked OR community-based OR school* OR teacher* OR student* OR classroom*), and child behavioral outcomes (exercis* OR recreation* OR fitness* OR physical activit*).

After reviewing 423 abstracts and 27 full-text papers, 3 categories of parental behaviors emerged as being supportive of children's PA behavior change: modeling of PA, parental support of child PA, and parental encouragement for child PA [50,62-64]. Termed collectively as "PA parenting practices," these behaviors are influenced by parents' own PA attributes and perceptions. For example, parents with a positive perception of PA, who engage in, value, and enjoy PA, tend to have a high self-efficacy to promote their child's PA. In addition, parents

XSL•FO
RenderX

who perceive that their child enjoys and is competent in PA are more likely to adopt responsive and structured PA parenting practices [65,66]. Responsive and structured PA parenting practices can, in turn, indirectly influence children's PA by enhancing children's modifiable PA attributes, such as their perceived competence, self-efficacy, and motivation for PA [66-68]. Some PA parenting practices, such as supportive behaviors, are associated with a direct increase in children's PA levels [50,64]. Therefore, by aiming to improve PA parenting practices through our materials, our intervention aimed to target parents as potential mediators of their child's PA behaviors [16,17].

The final parental behavior change objectives, with a brief description of specific behaviors, for our communications campaign were as follows. First, parents will serve as role models for their children's PA. Parents will model enjoyable and relevant PA behaviors individually and with their children. Second, parents will provide instrumental and informational support, including the provision of choices, for their children's PA. Specifically, (2a) parents will provide choices and descriptions of activities for their children to select from, and (2b) parents will promote a sense of familial connection around PA. Third, parents will provide praise and encouragement for their children's PA. This includes (3a) giving frequent, direct, specific, and positive feedback and encouragement regarding some aspect of their children's performance, and (3b) encouraging the use of process goals that allow for success and are achievable.

Table 3 exemplifies the relationships between the 3 parental behavior change objectives and the previously established theoretical basis for children's PA behavior change.

Table . Relationships between physical activity (PA) parenting objectives and theoretical constructs of children's PA.

PA parenting behavioral objective	• Theoretical basis for children's behavior change (related theory)
Parents serve as role models for their children's PA	• Observing parents (as influential role models) successfully performing the behavior can improve children's self-efficacy (SCT[a]) and promote feelings of relatedness (SDT[b]) and competence (SDT), while shifting outcome expectations (SCT).
Parents will provide instrumental and informational support, including provision of choices, for their children's PA	• Providing activity choices and a rationale for all prescribed activities supports the development of autonomy (SDT) and knowledge (SCT) of engaging in PA for the children. • Development of familial support (SCT) for the children can encourage feelings of relatedness (SDT).
Parents will provide praise and encouragement for their children's PA	• Positive feedback from parents supports the development of self-efficacy (SCT) and perceptions of competence (SDT) in the children. • Process goals that are moderate and focus attention on the task (rather than performance relative to others) support autonomy (SDT), perceived competence (SDT), and self-efficacy (SCT).

[a]SCT: social cognitive theory.

[b]SDT: self-determination theory.

Step 3: Theory-Informed Strategy

To target the parental objectives in our communication materials, we needed to (1) identify the theoretical determinants of the PA parenting behaviors we wished to change and (2) outline the methods for addressing the determinants in a communication campaign. Collectively, step 3 can be thought of as the theory-informed strategy for advancing our PA parenting objectives. Here, our definition of "theory-informed" is that the strategy for operationalization is informed by behavioral and social science theories [28]. Our theoretical basis provides evidence for why we anticipate our strategy will result in the desired parental behavior change.

Within the theoretical basis, we identified the determinants of the PA parenting behaviors we aimed to influence in our communications campaign. This process included a combination of literature and expert review from our team. After identifying the SCT or SDT constructs indicative of the parenting behavior, we then described the role of the theoretical determinant in advancing the behavioral objective. All constructs were contextualized based on their reciprocal relationships with one another. After determining the constructs predictive of the desired behavior change, we sought to outline the application of the constructs, or the methods for operationalizing the determinants into the communication messages. Outlining the methods for operationalizing the theoretical constructs required careful consideration for how to address the determinants through communication messages.

Table 4 shows how the PA parenting objectives were linked to methods via the behavioral determinants. The methods were applied by operationalizing the theoretical constructs into the communication materials in step 4.

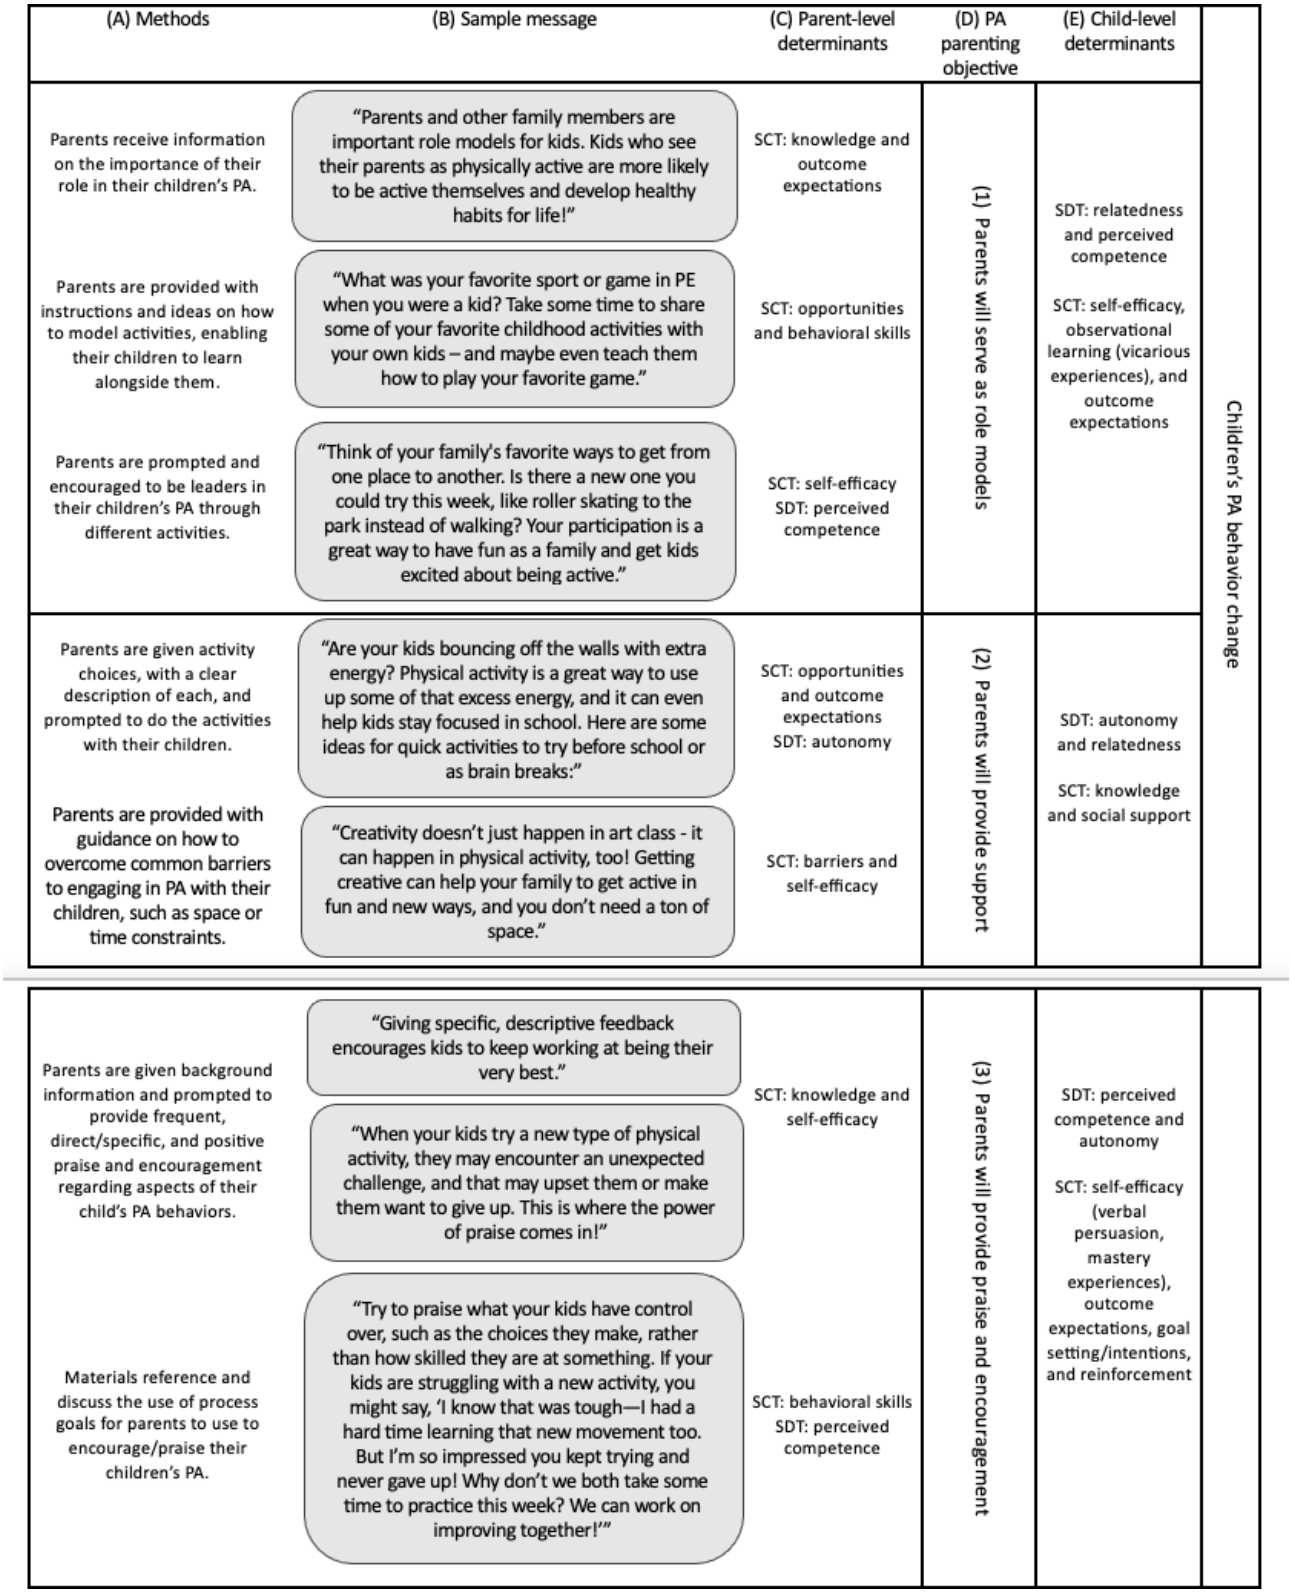
XSL•FO
RenderX

Table . Theory-informed strategy for achieving physical activity (PA) parenting behavioral objectives.

Objective	Theoretical determinants of parent behavior change	Methods for addressing determinants
Parents will serve as role models for their children's PA	1. Improving knowledge (SCT[a]) about the role parents play in children's PA can influence realistic outcome expectations (SCT) for parents and encourage them to be role models.2. Giving families opportunities (SCT) for observational learning (SCT) can enhance parents' behavioral skills (SCT) for role modeling behaviors.3. Providing enactive mastery experiences can enhance parents' self-efficacy (SCT) and perceived competence (SDT[b]) for role modeling behaviors.	1. Parents receive information on the importance of their role in their children's PA.2. Parents are given instructions and ideas for how to model activities with their children.3. Parents are encouraged to lead their children's PA by modeling activities with supportive and accessible prompts.
Support for their children's PA	1. Sharing new and enjoyable opportunities (SCT) for family activities can enhance parents' autonomy (SDT) for providing instrumental support for their children's PA.2. Giving parents suggestions for how to reduce barriers (SCT) to PA can enhance parents' self-efficacy (SCT) for providing informational support and provision of choices for their children's PA.	1. Parents are given activity choices, with a clear description of each, and prompted to do the activities with their children.2. Parents are provided with guidance on how to overcome common barriers to engaging in PA with their children, such as space or time constraints.
Parents will provide praise and encouragement for their children's PA	1. Providing information and examples about the role of encouragement and praise in their children's PA can improve parents' knowledge (SCT) and self-efficacy (SCT) for encouraging and praising their children's PA.2. The act of self-monitoring and setting goals (SCT) or intentions (SCT) as a family and reinforcing (SCT) them every week throughout the program can improve parents' perceived competence (SDT) for encouraging and praising their children's PA.	1. Parents receive background information and user-friendly prompts to give frequent, specific, and positive praise for their children's PA behaviors.2. Materials reference and discuss the use of process goals for parents to use to encourage their children's PA.

[a]SCT: social cognitive theory.

[b]SDT: self-determination theory.



Step 4: Operationalization

In the final design step, the theory-informed messages were written and fully integrated into communication materials. Communication channels included emails, text messages, Facebook posts, and newsletters. The process for drafting and editing the messages was iterative and involved the entire research team.

Figure 2 includes sample messages exemplifying how we operationalized our strategy to achieve our PA parenting behavioral objectives. Each sample message is a manifestation of one or more methods (Figure 2A). In operationalizing our strategy, we can target key parent-level determinants (Figure 2C) that influence our PA parenting behaviors (Figure 2D). The PA parenting objectives are linked to changes in children's PA behavior via the child-level determinants (Figure 2E).

XSL•FO
RenderX

Figure 2. Operationalization of theory-informed strategy for achieving physical activity (PA) parenting behavioral objectives. SCT: social cognitive theory; SDT: self-determination theory; PA: physical activity.

Two study team members worked together to write the first draft of the family communication messages. One Tufts team member served as the behavior change expert, ensuring the theoretical constructs, methods, and parameters identified in step 3 were incorporated into the content; the other RNYRR team member served as the curriculum expert, ensuring the school-based curriculum was aligned with the family content. Both team members carefully deconstructed each message and mapped theoretical constructs to the messages. A grid was created to keep track of construct operationalization, ensuring intentionality. Input was obtained from other team members over multiple rounds and edits. Careful consideration was taken to ensure the content was appropriate for the target audience's sociodemographic, cultural, and educational backgrounds.

XSL•FO
RenderX

Messages were refined and final edits were presented to and agreed upon by all team members. Final materials were translated into Spanish for the study's target audience.

Email served as the primary communication channel, with the other modes of communication written to reinforce that channel. All materials were aligned with the program theme, Rising Together, emphasizing the importance of being active as a family. Final material design was overseen by RNYRR to ensure consistency in appearance. When families signed up to receive the materials, they had the option to sign up for emails only, text messages only, or both emails and texts. To achieve equity in access to materials, all email communications were printed and delivered to participating schools to be placed into children's backpacks on a weekly basis. Print-based emails contained QR codes that could be scanned to access the electronic content. The 20-week communications campaign and multilevel program were pilot tested in 6 NYC elementary schools during the 2021 - 2022 school year.

Discussion

Principal Findings

This descriptive study details a 4-step process used to operationalize behavior change theory in a multichannel communications campaign, nested within a multilevel PA intervention. We describe systematic procedures that can be used in designing behavior change communication messages seeking to improve PA parenting behaviors and promote children's PA.

The ability of parent engagement strategies to effectively engage parents and promote children's PA in school-based interventions remains inconclusive [18]. We provide a practical 4-step process using commonly cited strategies that can be applied and empirically evaluated for their independent impact on school-based intervention effectiveness [14,50]. As Bandura [69] noted, public health campaigns are important for getting people to adopt health behaviors. However, health communications foster adoption of health behaviors to the extent that they raise individuals' self-efficacy. Health communications must therefore be designed to enable people to build the necessary skills and self-beliefs needed to change their behaviors. Given the intentionality and feasibility of our communications to engage parents and impact parental-level determinants and behaviors, future applications of our methods can begin to advance understanding of the isolated impact of parent engagement strategies on child-level outcomes.

Comparison With Prior Work

To our knowledge, this 4-step design process is innovative within multilevel behavior change interventions. Similar strategies have been used in designing interventions for various behaviors, including medication adherence [70], hand hygiene compliance [71], and occupational sedentary behavior [33], and in various contexts, including tailored feedback during a weight loss intervention [72] and a garden-enhanced nutrition curriculum [73]. However, only one of these interventions [74] addresses the complexity of promoting behavior change through an additional level of influence, as we aim to do in influencing PA parenting practices to promote children's PA. This additional level of behavior change makes our approach valuable for others seeking translatable methods for applying theory-informed strategies to multilevel behavior change, such as in efforts to promote children's PA.

Current frameworks for theory application do not include specific methods for designing health communications as part of intervention design [29,30,75]. While the theoretical evidence includes guides for translating theory-based methods into practical applications, these frameworks fall short of providing advice for operationalizing theoretical determinants into behavior change communication messages. Furthermore, while the empirical evidence provides examples of how theoretical constructs were translated into behavior change methods [70] or intervention activities and components [33,73,74], none have been specific to the translation of theory for the content of communications. This descriptive study addresses gaps in current intervention design frameworks and studies and complements their use by providing practical advice and examples for operationalizing theory into communication messages. The methods used in this descriptive study may, therefore, be used by interventionists in congruence with current frameworks to create communications that can be incorporated into multilevel behavior change interventions, which have been recommended for increasing children's PA [13].

While there are many functions and benefits of theory application during the design, implementation, and evaluation stages of interventions [49,75-77], increased effectiveness is often cited as the primary reason for the use of theory in behavior change intervention design [78]. This argument may hold for theory-informed approaches to promote children's PA [46,49,50], despite inconsistent conclusions on whether the use of theory improves intervention effectiveness [15]. Prior studies have noted that the variable findings on the effectiveness of behavior change interventions, including those for children's PA, could be explained by "methodological and reporting issues at study and review level," including issues with how theory is applied during the intervention design process [78]. Michie and Prestwich [31], for example, point out that "where a theoretical base for an intervention is stated, there is seldom reference to a method describing how the theory informed the design of the intervention." By providing a detailed example and replicable methods for applying theory to communication materials, one of the crucial steps in the intervention life cycle, we believe our study to be of benefit to others attempting to be more rigorous in both their application of theory and reporting of its use in PA interventions.

This descriptive study's description of the operationalization of theory in our communication materials will provide important contextual information for interpreting future results of the communications campaign. The feasibility of implementing the communications campaign and the acceptability of the materials for the target population will also be considered in a pilot study, and adjustments to the materials will be made. The adapted communications will be implemented in a randomized controlled trial. Findings from the trial will be used to understand if our theory-informed communications effectively engage parents, thereby influencing their determinants of PA and PA parenting

XSL•FO
RenderX

behaviors, while examining the overall impact of the intervention on children's PA determinants and PA behaviors. After a second phase of adjustment, including any adjustments to the methods outlined in this study, the communications may be considered for dissemination across the NYRR network of schools. Given the diversity and reach of the schools and the continuous feedback solicited by the program, the materials may continue to be adapted to fit local contexts and populations. The present descriptive study, together with future research plans, will therefore jointly advance the broader field of childhood PA research and practice.

Limitations

Given the lack of examples in the literature, our descriptive study is not without constraints. For example, when operationalizing the theory-informed strategy from step 3 into communication messages in step 4, we lacked explicit guidance on any methodological parameters that should be considered. As previously discussed by Kok et al [30], the effectiveness of a behavior change method will depend on whether the parameters for the method are satisfied. In other words, a theory-informed strategy requires more than outlining what constructs to target and what methods to use to operationalize the constructs; it requires a consideration for the "theoretical parameters under which the theoretical process is effective or not" [30,79]. An example in the context of our descriptive study would be that improving parental self-efficacy requires a series of reinforcing messages, as opposed to a single message [49]. Parameters for operationalizing theory are not clearly defined for the application of parenting behavior change. Empirical evidence of what conditions were used when operationalizing theory for parenting behaviors will be required to determine the relevant parameters for effectiveness.

Participation of the target population is important for establishing the most relevant theoretical determinants of a behavior or for understanding how theory-informed strategies should be applied in the design process [29]. Our formative research with the priority population, including focus groups with parents, focused on topics such as communication channel preference and the feasibility of engaging parents through communication materials but did not include an explicit theoretical focus. Additional formative research informed by SCT and SDT may have enabled further tailoring in how we operationalized theory in our communication messages.

Conclusions

This descriptive study advances progress in the development of school-based PA promotion efforts seeking to incorporate parent engagement strategies by detailing the operationalization of theory into communication messages. Future application of our 4-step process can be used to develop theory-informed communication materials that aim to target PA parenting behaviors.

The methodology detailed in this descriptive study is valuable for others seeking to translate theoretical constructs into behavior-change communication messages. This work provides an example and draws attention to the role of rigorous theory application and reporting in developing communications that support children's PA behavior change as part of overall behavior-change intervention design.

Abstract

Background: An adaptive text messaging intervention to promote adolescent physical activity has demonstrated feasibility, acceptability, and preliminary efficacy in a recent proof-of-concept study. To inform future intervention development, a secondary analysis of the data examined how physical activity is influenced by mood, environment, and physical feelings of energy and fatigue.

Objective: This study aims to understand how both macro- and microtemporal variables (eg, psychological and environmental variables at both levels) influence the efficacy of a brief mobile health intervention (ie, NUDGE) for physical activity.

Methods: Using a matched control design, we evaluated the effect of daily positive and negative affect, perceptions of the weather, energy, and fatigue as moderators of the effect of the intervention on 21 intervention participants and 21 matched controls.

Results: Consistent with study hypotheses, macrotemporal (levels of the variable on a 3-week timescale) moderators of intervention effectiveness were observed for positive affect (P<.001), negative affect (P=.03), energy (P<.001), fatigue (P<.001), and perceived weather barriers (P<.001) for moderate-to-vigorous physical activity. These effects were observed more consistently for moderate-to-vigorous physical activity than for sedentary behavior, which was only significant for energy (P<.001). No effects for microtemporal variables (at the day level) were observed.

Conclusions: There appears to be an optimization opportunity for mobile health physical activity interventions that can be achieved by personalizing intervention features and content based on approximately monthly assessments of affect, physical feeling states, and perceived weather barriers.

Introduction

Physical inactivity is a significant public health concern, with recent data showing less than 25% of youth meet the recommended 60 minutes of moderate-to-vigorous physical activity (MVPA) per day [1,2]. Consequences of low MVPA and high sedentary time over the lifespan have significant well-established links to cardiovascular disease, diabetes, poor respiratory health, and cancer [2]. Levels of MVPA decrease as children transition into adolescence, with the majority of individuals failing to meet physical activity guidelines by the age of 13 years [3]. Therefore, interventions targeting increases in MVPA and decreases in sedentary time are critical for

XSL•FO
RenderX

adolescents, with long-term benefits that may accrue through adulthood.

Effect sizes for pediatric physical activity interventions are small, producing an increase in objectively measured MVPA that is less than 5 minutes per day on average [4,5]. To improve the efficacy of physical activity interventions, behavioral scientists are leveraging digital technologies to gain insight into key determinants of adolescent physical activity. An innovative perspective involves examining how macrotemporal factors (ie, slow-changing variables over weeks or months) interact with dynamic, microtemporal factors (ie, fast-changing variables over minutes, hours, or days) to influence adolescent physical activity behaviors [6]. Studying physical activity behavior in this manner may increase the understanding of how fast-changing, microtemporal (eg, daily, within-day) and slow-changing, macrotemporal (eg, long-term) variables affect physical activity engagement and could subsequently inform adaptive intervention technologies that are individually tailored to accommodate these microtemporal and macrotemporal variables.

Studies demonstrate that contextual factors, such as the availability of sidewalks and playgrounds, are related to engagement in physical activity [7]. Other macrotemporal variables related to physical activity include person-specific motivational factors, such as self-efficacy for exercise and perceived behavioral control [8-10]. In addition, Cushing et al [11], as well as Dunton et al [12], demonstrated that microtemporal variability in affect (ie, positive and negative affect), physical feeling states (ie, energy and fatigue), and external context (eg, being at home, rainy weather conditions, or time of day) [13] is related to MVPA and sedentary time, and these findings have been extended to adults as well [14]. The field has successfully established broadly that MVPA interventions work; therefore, the critical next phase of intervention optimization is understanding for whom these interventions work and in what context [15].

Framed within the ORBIT (Obesity Relation Behavioral Intervention Trials) model of intervention development [16], we [17] developed and evaluated the NUDGE (Network Underwritten Dynamic Goals Engine) as an unrandomized proof-of-concept study. NUDGE is a mobile health (mHealth) intervention that uses an automated text-message platform to promote adolescent physical activity by prompting users to self-monitor and set daily goals for minutes of MVPA, which was informed by Carver and Scheier's [18] Cybernetic Control Theory. NUDGE demonstrated feasibility and preliminary efficacy for improving adolescent MVPA (Cohen d=0.83) and sedentary time (d=0.40). Evaluating macro- and microtemporal variables and their influence on NUDGE could be especially informative and provide insight into individual determinants of physical activity engagement for intervention development.

This study is a secondary analysis of NUDGE to guide future intervention development within the "refine phase" of the ORBIT model. Briefly, this phase uses available data or literature to iteratively make changes to a program before conducting a fully powered randomized controlled trial. The goal is to understand how both macro- and microtemporal variables (eg., psychological and environmental variables at both levels) influence the efficacy of a brief mHealth intervention (ie, NUDGE) for physical activity. We expected that both macro- and microtemporal positive affect and energy would be related to larger intervention effects (ie, more MVPA and less sedentary time), whereas negative affect, fatigue, and perception of poor weather would be related to a diminished intervention effect.

Methods

Participants and Procedures

We combined participants from 2 separate studies with identical procedures, ecological momentary assessment (EMA) protocols, and objective monitoring of physical activity. The primary difference between study protocols was that one study involved the delivery of the NUDGE program to the intervention group (detailed below), whereas the other study involved an attention control group. The research team recruited participants in the NUDGE group in 2017 and the attention-control group from 2015 to 2016. Recruitment occurred across all 4 seasons of the year. Recruitment methods included flyers, information letters, and social media postings. We excluded adolescents from participating if they had vision loss or low vision, could not read English, or had a medical condition that would limit their physical activity.

We conducted phone screenings with adolescents 13 - 18 years of age and their caregivers to determine their eligibility for the study and scheduled eligible adolescents for a baseline visit. At that visit, we obtained informed consent and assent for caregivers and adolescents, respectively. We provided participants with an accelerometer to wear on their nondominant wrist for the 20-day study period and trained them on how to respond to the EMA surveys via a study smartphone. To maximize adherence to the protocol [19], we allowed participants to select 4 times per day (2 morning and 2 afternoon and evening) to receive EMA surveys, with each survey delivered at least 2 hours apart. Participants in the NUDGE intervention chose an additional time in the evening to receive text messages to set physical activity goals and a time in the morning to receive a goal reminder text message. Participants received up to US $40 for completing study procedures.

NUDGE Intervention

As described elsewhere [17], the NUDGE intervention is an automated chatbot. Users are asked to set a daily physical activity goal in minutes of MVPA, which is stored by the system. Next, users are prompted to self-monitor their MVPA at the end of the day and are provided with feedback based on their goal attainment. This process repeats daily for the 20-day study period. A goal is set based on a user's self-reported exercise from the prior day. Users are allowed to set slightly more or less ambitious goals depending on their preference, but overall, the system encourages increasingly strenuous goals until users achieve 60 minutes of MVPA in a single day.

Matched Attention Control Condition

We drew a matched sample of 21 participants from a 100-person dataset of individuals who did not complete the intervention to

XSL•FO
RenderX

create the matched attention control. Attention control participants were matched to NUDGE participants on sex, age, and race and ethnicity, with priority given in the order the variables are listed. Participants who did not receive the NUDGE intervention were given the same study experience. They wore an accelerometer on their nondominant wrist, answered EMA surveys at 4 self-selected times per day for 20 days, and completed the same baseline and exit questionnaires. Research staff explained that the study was an assessment of physical activity and psychological variables, and the reimbursement structure was the same as the NUDGE group.

Measures

Demographics

Adolescents completed self-reported measures of demographic variables (eg, sex as a biological variable and race and ethnicity) during the baseline visit.

Physical Activity and Sedentary Time

We used wrist-worn ActiGraph GT3X-BT accelerometers (ActiGraph LLC) to measure physical activity across 20 consecutive intervention days. We initialized accelerometers to detect movements at 30 Hz. We processed the accelerometer data in Actigraph Actilife software v6.10.2 and converted raw measurements into 60-second epochs. We removed sleep and nonwear periods using the Sadeh et al [20] and Troiano et al [21] algorithms, respectively. We used the Chandler algorithm [22], a validated algorithm for measuring MVPA in youth using wrist-worn accelerometers, to define cut points for sedentary behavior, light physical activity, and MVPA.

Positive and Negative Affect

We measured positive and negative affect 4 times per day via EMA using the Positive and Negative Affect Schedule for Children (PANAS-C; [23,24]). The PANAS-C has strong psychometric properties for describing positive and negative affect and also demonstrates good test-retest reliability and convergent and discriminant validity [24,25]. Previous studies show delivering the PANAS-C on a mobile phone is feasible, reliable, and successful in gathering EMA responses to measure affect in real time [11,12,26,27]. The positive affective domain included the following mood states: joyful, cheerful, happy, lively, and proud. The negative affective domain included the following mood states: miserable, mad, afraid, scared, and sad. Participants rated the extent to which they experienced each mood state on a 5-point Likert scale from 1, “not at all,” to 5, “extremely.” We summed item responses for the positive and negative affective domains for each survey completion. We then mean-centered these values so that all regression weights were relative to no positive or negative affect. Finally, we averaged these values across the day to produce estimates of positive and negative affect for each study day.

Energy and Fatigue

Energy and fatigue were measured using questions from the Profile of Mood States (POMS; [28]) 4 times a day via EMA survey. For energy, 3 items with the highest factor loading from the vigor-activity subscale were used (ie, energetic, full of pep, and vigorous). For fatigue, 3 items with the highest factor loading from the fatigue-inertia subscale were used (ie, fatigued, exhausted, and worn out). Participants rated the extent to which they experienced each mood state on a 5-point Likert scale from 1, “not at all,” to 5, “extremely.” We summed item responses for the energy and fatigue scales for each survey completion. We also mean-centered these values so that all regression weights were relative to no energy or fatigue. We then averaged these values across the day to produce daily estimates of energy and fatigue.

Perceived Weather Barriers

We additionally measured participants’ perception of weather during EMA surveys with one item 4 times per day: “What is the weather like outside?” In this variable, the intent is to capture high or low perceptions of weather as a barrier and not actual weather conditions. Participants rated their perception of weather as 1, “too hot,” 2, “too cold,” 3, “just right,” 4, “too rainy,” or 5, “too windy.” Our app was limited and only allowed a single response to this prompt (eg, participants could not say it was both too hot and too windy). For this reason, we recoded responses to indicate endorsements of perceived optimal weather and perceived weather barriers (eg, 0=“just right” and 1=all other responses, respectively). Finally, a daily weather barrier score was generated to capture each of the 4 EMA responses by summing these responses across the day, where lower scores represented fewer perceived weather barriers to MVPA. The final daily weather barrier variable ranged from 0 to 4, where 0 represents a response of just right at each EMA survey and 4 represents an endorsement of a perceived weather barrier at each EMA survey. Higher scores indicate more cumulative perceived weather barriers within a day.

Data Analysis Plan

We first divided each hypothesized moderator (eg, positive and negative affect, energy, fatigue, and perceived weather) into between-person and within-person components. The 4 daily assessments were averaged into day-level variables, and then person-mean centering was used to calculate the within-person value [29]. For example, each participant received a personal between-person value of their positive affect, indicating their average level of positive affect during the study, as well as a within-person value of positive affect for each of the 20 days, indicating their daily positive affect relative to their average. Because within-day scores are aggregated at the day level, the within-person effects can be interpreted as day-to-day fluctuations.

Using SAS (SAS Institute) PROC MIXED, we used first-order autoregressive (AR1) multilevel models for the day-level physical activity and sedentary behavior dependent variables. Hypothesized moderators were specified as interactions with group participation (ie, NUDGE intervention vs attention control) on MVPA and sedentary time. All models were estimated using the full information maximum likelihood estimation [29], and separate models were run for each hypothesized moderator. Based on our prior work, we used a random linear model for time at the day level (with the first day of the study coded 0) in the current analyses [17]. For models with significant interactions, we conducted post hoc probing at the mean, as well as ±1 SD above or below the mean of the

XSL•FO
RenderX

moderator to determine simple slopes and regions of significance. Each model is conditioned such that regression coefficients can be interpreted as minutes of MVPA or sedentary time per day.

Ethical Considerations

All study procedures were approved by the local institutional review board at the University of Kansas (STUDY00140405). Informed consent and assent were obtained for data collected in this project and the study team has followed institutional policies for maintaining privacy and confidentiality. Data in the current manuscript are deidentified.

Results

Descriptive Statistics

The final sample consists of 42 adolescents aged 13 - 18 years (mean 15.14, SD 1.72) in a matched comparison design (ie, NUDGE vs attention control), based on age and sex (n=21 per group). Participants were predominantly female and Caucasian (32/42, 76.2% female and 28/42, 66.7% Caucasian). Detailed sample demographics are shown in Table 1. Over the course of the assessment period, participants in the intervention group engaged in an average of 46 (SD 42) minutes of MVPA and 649 (SD 174) minutes of sedentary time per day. The attention control group obtained an average of 24 (SD 27) minutes of MVPA and 733 (SD 220) minutes of sedentary time per day.

Table . Adolescent and caregiver demographic characteristics.

Characteristics	Both groups (N=42)	NUDGE group (n=21)	Attention control group (n=21)
Adolescent age, mean (SD)	15.24 (2)	15.14 (2)	15.14 (2)

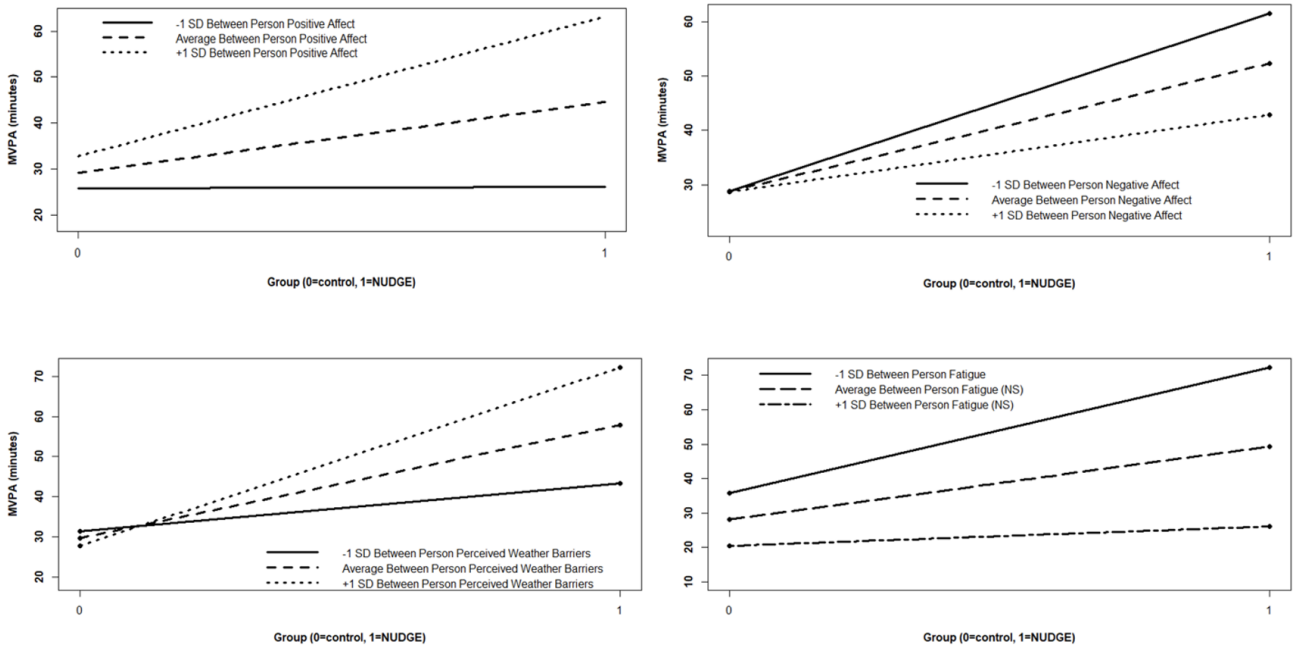
Model Building

MVPA Models

Overview

An empty model revealed that the intraclass correlation coefficient for MVPA was 0.43, indicating that 43% of the variance was day-level within-person (level 1) variability plus error and 57% was between-person (level 2). As noted above, all final models included a random intercept for the dependent variable and a random linear slope for time coded as day in the study starting at day 0. All models had a significant main effect for group (P=.03), and that parameter was included in all final models. All model effects are relations to MVPA at the day level, and β-weights are unstandardized beta coefficients and represent more or less daily activity relative to the control.



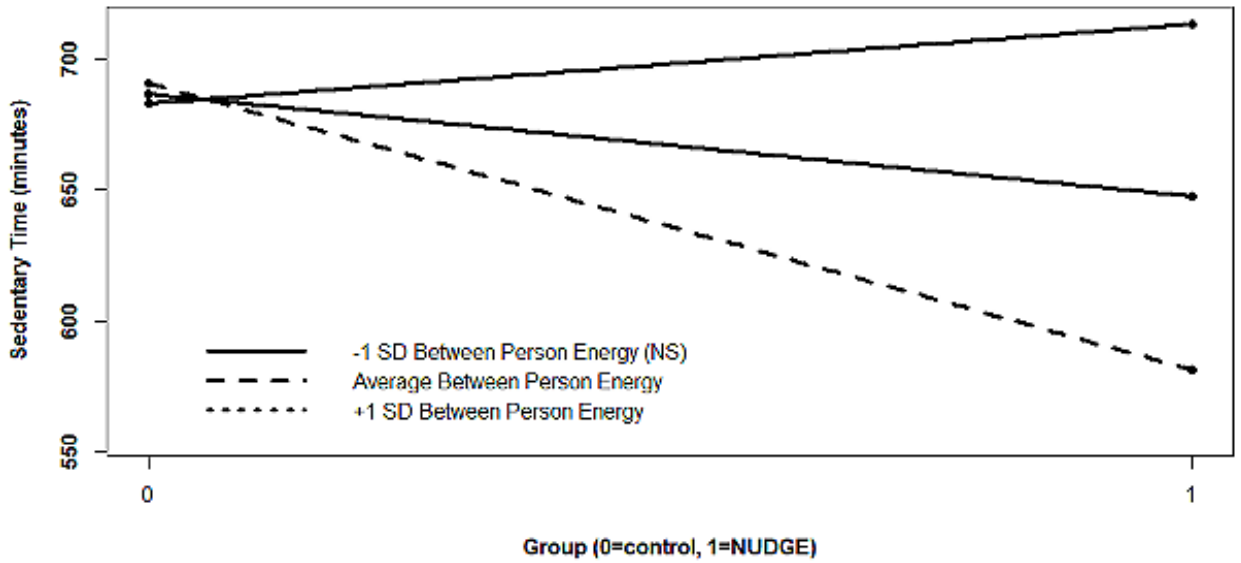
Positive Affect

There was a significant interaction of between-person positive affect and group (P<.001), such that being in the NUDGE intervention (vs control) was related to 30.42 additional minutes/day of MVPA (P<.001 from post hoc probing) among

XSL•FO
RenderX

individuals with levels of between-person positive affect +1 SD above the mean, but with a nonsignificant simple slope at −1 SD below the mean (See Figure 1A). The interaction between within-person positive affect and group was nonsignificant.

Figure 1. Interaction effects for affect and environmental moderators of the intervention effect. Note: Significant simple slopes, based on post hoc probing, are graphed for interactions where 2 or more levels of the moderator are significant. Nonsignificant slopes are not displayed. The model for fatigue moderating the intervention effect on MVPA did have 1 significant simple slope, but the single line is not displayed. MVPA: moderate-to-vigorous physical activity; NS: nonsignificant; NUDGE: Network Underwritten Dynamic Goals Engine.



Negative Affect

The final model for negative affect indicated a significant interaction between group and between-person negative affect (P=.03). Simple slopes indicated that individuals with between-person negative affect +1 SD above the mean obtained 14.08 more minutes/day of MVPA than the control, with those −1 SD below the mean obtaining 32.71 more minutes/day. Generally, participants with less negative affect experienced a greater beneficial effect of the NUDGE on MVPA. The interaction of group and within-person negative affect was nonsignificant.

Energy

The final model for energy predicting MVPA had a significant main effect of group (P<.001) and included a significant interaction between group and between-person energy (P<.001; Figure 2). However, post hoc probing indicated no significant slopes or regions of significance for this moderator. Within-person energy did not moderate the effect of NUDGE on MVPA.

Figure 2. Energy moderating the effect of Network Underwritten Dynamic Goals Engine on sedentary time. Note: Simple slopes, based on post-hoc probing, are graphed for with significant omnibus interactions; NS: nonsignificant; NUDGE: Network Underwritten Dynamic Goals Engine.

XSL•FO
RenderX

Fatigue

Individuals with lower levels of between-person fatigue (eg, −1 SD below the mean) in the NUDGE condition obtained more MVPA each day relative to their counterparts in the control condition (β=36.54; *P*<.001). Simple slopes were not significant for those with +1 SD above the mean levels of between-person fatigue. The interaction between within-person fatigue and group was not statistically significant.

Perceived Weather Barriers

The interaction term was again significant for perceived weather barriers, with those who perceived +1 SD more barriers than the mean obtaining 44.53 more minutes of MVPA each day in the NUDGE group than the control, and those with −1 SD below the mean obtaining only 11.99 additional minutes per day. Interestingly, those with higher levels of between-person who perceived weather barriers in the NUDGE condition obtained more MVPA compared to those with lower perceived weather barriers. Within-person–perceived weather barriers did not moderate the effect of NUDGE on MVPA.

Sedentary Time Models

Overview

An empty model revealed that the Intraclass Correlation Coefficient for sedentary time was 0.37, indicating that 37% of the variance was day-level within-person (level 1) variability plus error and 63% was between-person (level 2). As noted above, all final models included a random intercept for the dependent variable and a random linear slope for time coded as day in the study starting at day 0. All model effects are relations to sedentary time at the day level, and β-weights represent more or less daily activity relative to the control.

Positive Affect

The final model for positive affect predicting sedentary time included a significant main effect of group (β=−39.56, *P*=.02) and between-person positive affect (β=−6.39, *P*<.001). Neither between-person nor within-person positive affect moderated the effect of NUDGE on sedentary time.

Negative Affect

The final model for negative affect predicting sedentary time included a significant main effect of group (β=−58.05; *P*=.001) and between-person negative affect (B=10.00; *P*=.049). Neither between-person nor within-person negative affect moderated the effect of NUDGE on sedentary time.

Energy

The final model for energy predicting sedentary time had a significant main effect of group (*P*<.001) and included a significant interaction between group and between-person energy (*P*<.001). Individuals with +1 SD between-person energy above the mean (β=−109.21, *P*<.001) in the NUDGE group accumulated less sedentary time each day relative to their counterparts in the control condition. The simple slope was not significant at −1 SD below the mean. Within-person energy did not moderate the effect of NUDGE on sedentary time.

Fatigue

The final model for fatigue predicting sedentary time had a significant main effect of group (*P*<.001) and included a significant main effect of group (β=−50.33; *P*=.003) and between-person fatigue (β=16.29, *P*<.001). Interactions of between-person and within-person fatigue and the group were not statistically significant.

Perceived Weather Barriers

There were no significant main effects of group, between-person or within-person perceived weather barriers, or interactions between these variables predicting sedentary time.

Discussion

Principal Findings

This study aimed to determine how macro- and microtemporal variables influence the effects of our mHealth intervention targeting adolescent physical activity. All of the macrotemporal study variables moderated the effect of NUDGE on MVPA, but only macrotemporal energy moderated the effect of NUDGE on sedentary time. With the exception of macrotemporal perceived weather barriers on MVPA, all of our significant interactions were in the hypothesized direction. In other words, adolescents with higher levels of macrotemporal positive affect and energy experienced larger intervention effects (ie, more MVPA and less sedentary time). Similarly, those with lower levels of negative affect and fatigue experienced larger intervention effects. Microtemporal associations with MVPA identified in other studies were not as important in this study as might have been indicated by other associational work [10,12,30]. This study indicates that while microtemporal findings do likely hold potential for personalization, the most immediate opportunity may be at the macrotemporal level. Momentary affect is difficult to capture using passive monitoring; therefore, fortunately, macrotemporal assessment is both easier and more suitable [31,32].

The literature indicates that mHealth interventions produce significant positive health outcomes in youth. The majority of these interventions have used standardized protocols to deliver the same intervention content to users, usually in the form of text messages [33,34]. However, recent developments in mHealth technologies show that mHealth interventions can leverage personalization to promote behavior change [10,35]. In the next iteration of the NUDGE protocol, it may be possible to use baseline information on macrotemporal factors to optimize the intervention for each participant. For instance, participants with low levels of positive affect or high levels of fatigue at baseline may need a preliminary intervention that is more complex than simple text message prompts to set and keep track of their physical activity goals. In both instances, a brief behavioral activation intervention might be warranted to help adolescents acknowledge the importance of setting and meeting goals, even when mood or fatigue are barriers [36].

There are other tailoring opportunities based on how NUDGE interacts with macrotemporal variables assessed at baseline. For example, NUDGE produced a desirable effect for all participants regardless of macrotemporal negative affect or perceived

XSL•FO
RenderX

weather. However, it was more effective for those with lower negative affect. For individuals experiencing high negative affect, it may make sense to address this barrier first before enrolling participants in the NUDGE intervention or to use MVPA promotion strategies that are unlikely to be affected by affect (eg, scheduled family exercise). Similarly, the intervention was particularly effective for participants who demonstrated higher than average positive affect. For this group, additional prompts might be wasted contacts that could decrease engagement or lead to habituation [37]. Our results on fatigue suggest that those with higher-than-average fatigue may need a sequencing approach to improve their fatigue before starting on the activity intervention. Finally, the relationship with weather demonstrates that those who perceive more weather barriers derive more benefit from NUDGE, which may indicate the importance of goal-setting and review even in the face of environmental barriers. All of the intervention strategies discussed above fit nicely in phase 2 of the ORBIT model for refining behavioral interventions before proceeding to fully randomized control trials [16].

Within the ORBIT model, NUDGE was tested in a nonrandomized, proof-of-concept study. Initial findings were promising and indicate randomized pilot testing is warranted. However, the ORBIT model encourages behavioral scientists to consider how an intervention can be optimized and refined to deliver more efficient interventions. Rather than making clinical judgments or relying on anecdotal evidence to guide intervention refinement, we can use data from this study to inform the development of future versions of NUDGE. One iteration might use responsive, context-dependent intervention support while another might test tailored decision points for goal setting based on trait-level characteristics (eg, high negative affect and fatigue). This process of using empirical evidence for optimization represents a step forward in the development and refinement of technology-based behavioral interventions [38].

Limitations and Future Directions

Results from this study should be considered in light of several limitations. Most importantly, participants were not randomized. In addition, the sample was relatively small, participants were predominantly female and Caucasian, and only adolescents from a specific geographic location were included. Future studies should recruit a larger sample of youth to test the generalizability of effects found in this study and provide opportunities for fully powered analyses. In addition, a larger study may be able to identify microtemporal moderators that were not present in this study. While not a major contributor in this study, there is a growing body of literature establishing that microtemporal relationships do affect the health behavior of children and adolescents [30]. Another limitation of this study was our methodology for measuring psychological feeling states. While EMA allowed us to measure daily fluctuations in these states, our protocol instructed adolescents to answer several survey questions 4 times throughout the day for almost 3 weeks. Future studies may benefit from using smart devices (eg, smartwatches) to reduce participant burden by making survey prompts easier to complete and to capture physiological data related to energy and mood (eg, heart rate and skin conductance; [39]).

Findings from this study add further support for the effects of psychological variables and perceived weather barriers on adolescent MVPA and sedentary time. Results highlight the importance of assessing macrotemporal factors (eg, positive and negative affect, energy, fatigue, and perceived weather barriers) in the context of a physical activity intervention for adolescents. While our initial examination of NUDGE showed an overall increase in MVPA, the results from this study indicate that adolescents may respond differently to the NUDGE intervention based on their macrotemporal characteristics, such as positive and negative affect, energy, fatigue, and perceived weather barriers. Future mHealth intervention trials should test the impact of tailored content on adolescents' MVPA and sedentary time to further refine adaptive physical activity interventions.

Conclusion

Our secondary data analysis of the NUDGE intervention suggests that patterns of variables, such as affect, energy, fatigue, and weather may moderate the effectiveness of text-message interventions for physical activity. Future iterations of NUDGE may benefit from using tailoring variables to modify the intervention experience of each participant depending on their level of the variables explored in this paper.

Abstract

Background: The increasing prevalence of physical inactivity and insufficient sleep in adolescents likely contribute to worsening cardiometabolic and mental health. However, obtaining accurate behavioral measures is a challenge. Consumer wearable devices offer a user-friendly method to assess physical activity and sleep.

Objective: This study aimed to describe the process and the preliminary results of physical activity and sleep collected using a consumer wearable Fitbit device in an adolescent cohort.

Methods: We provided Fitbit Charge 2 or Charge 3 wrist-worn activity monitors to adolescent participants in Project Viva, a Boston, Massachusetts area cohort, from 2017 to 2022. We invited participants to wear the devices for ≥7 days for 24 hours a day to measure their physical activity, heart rate, and sleep, and allowed them to keep the device as a participation incentive.

Results: We collected over 7 million minutes of physical activity, heart rate, and sleep data from 677 participants, 53% (356/677) of whom were female. The mean (SD) age of participants was 17.7 (0.7) years. Among the 677 participants, 65% (n=439) were non-Hispanic White, 14% (n=947) were non-Hispanic Black, 10% (n=69) were Hispanic, 3.2% (n=22) were non-Hispanic Asian, and 7.8% (n=53) belonged to other races. Participants demonstrated a high adherence to the research protocol, with the mean (SD) wear duration of 7.5 (1.1) days, and 90% of participants (612/677) had 5 or more days wearing the device for >600 minutes/day. The mean (SD) number of steps was 8883 (3455) steps/day and the mean (SD) awake sedentary time was 564 (138) minutes/day. Male participants were more often engaged in very active (27 minutes/day) and moderately active physical activity (29 minutes/day) compared with female participants (15 and 17 minutes/day, respectively). Over 87% (588/677) of participants had sleep data available for 5 or more days, among whom the average nightly sleep duration was 7.9 (SD 0.9) hours.

Conclusions: This study demonstrated the feasibility of using consumer wearable devices to measure physical activity and sleep in a cohort of US adolescents. The high compliance rates provide valuable insights into adolescent behavior patterns and their influence on chronic disease development and mental health outcomes.

KEYWORDS

wearable device; Fitbit; physical activity; sleep; adolescents; behavior risk; mobile phone

Introduction

The prevalence of physical inactivity and insufficient sleep in adolescents has become a major health concern worldwide. In the United States, approximately 76% of children aged 6 - 17 years engage in less than the recommended 60 minutes of moderate-to-vigorous physical activity per day [1]. Similarly, almost a quarter of US children aged 6 - 17 years have less than the recommended 8 hours of sleep per day [2]. Adolescence is a vulnerable period for the development of both psychiatric and chronic medical illnesses [3]. A lack of moderate-to-vigorous physical activity is linked to a higher risk of excessive calorie

XSL•FO
RenderX

intake, obesity [4,5], and cardiometabolic diseases [6-8]; higher risk of depression and anxiety [9-11]; and lower cognitive and school performance [12,13]. In addition, insufficient sleep has been associated with unhealthy dietary behavior [14,15], being overweight [14,16,17], poor school performance, and depression [18-20]. Given the health concerns related to physical inactivity and insufficient sleep among adolescents, a better understanding of these health behaviors through accurate, large-scale data among representative populations is crucial.

Consumer-based wearable devices such as Fitbit (Google) have become popular for objectively measuring physical activity and sleep due to the advancements in microtechnology, wireless communication, battery capacity, and multidimension measurements. In addition, Fitbit devices use Bluetooth for easy data transfer to Fitbit servers through a smartphone or tablet, allowing for synchronization of real-time data. This helps avoid the burden of mailing devices back to researchers and potential data loss that may occur with actigraphs meant solely for research. Fitbits have been validated for collecting real-time behavior data on free-living subjects [21-25]. Although Fitbits have been used to collect real-time behavior data, researchers have not described real-world methods to operationalize consumer-based wearable devices to collect health behavior data in adolescent cohorts. Detailing the operational methods for these devices in real-world setting can enable researchers to examine this novel approach in depth and understand the measurement values.

In this study, we used commercially available Fitbit devices to gather physical activity and sleep data in adolescents. We describe our data collection and cleaning process, and present participants' wear-time results. The collected data will be used to study associations of physical activity and sleep with many aspects of adolescent and young adult health, including cardiometabolic, experiential, and mental health, in future research.

Methods

Project Viva Cohort

Project Viva is an ongoing prospective cohort focused on maternal and child health. We recruited pregnant women between 1999 and 2002 in eastern Massachusetts who received prenatal care at Atrius Harvard Vanguard Medical Associates. Detailed recruitment, eligibility, and cohort information have been previously reported [26]. We collected comprehensive information from mothers and their children at various life stages, and attempted to follow all willing participants after birth. Of the 2128 mother-child pairs enrolled at birth, 1576 pairs had not previously disenrolled and thus were eligible for the Mid-Teen visit.

Data Collection

We contacted participants from July 1, 2017, to August 30, 2021. We invited participants as mother-child pairs by mail or email to participate in the Mid-Teen visit when the child turned 16.5 years old. If the child had sibling(s) who were also enrolled in Project Viva, the sibling(s) also attended the visit regardless of the age.

We collected data on the demographic variables at several life stages. At recruitment, we collected data about the maternal education. We obtained the child sex at birth and birth date from hospital medical records. During the Mid-Teen visit, trained research assistants measured weight using a calibrated Tanita scale (model TBF-300A; Tanita Corporation of America) and weight using a calibrated stadiometer (Shorr Productions). We calculated the BMI using weight (kg)/ square of height (m^2). Race, ethnicity, and household income were collected through a questionnaire.

Wearable Device

We invited all adolescent participants to provide data on physical activity, heart rate, and sleep for 1 week to align with traditional actigraphy study and avoid over burdening participants. Participants had to consent to wear a Fitbit Charge 2 (before 2018) or Fitbit Charge 3 (after 2018) wearable device, depending on the year of the research visit. Both devices have the same core measurement technique, MEMS 3-axis accelerometer and optical heart-rate tracker and are able to track physical activity, heart rate, and sleep on free-living subjects [27,28]. Trained study staff instructed participants to download the Fitbit app on their smartphone and to register a Fitbit account. Study staff then linked their account ID to Fitabase [29], a data management platform to support research projects using Fitbit devices. Participants were asked to wear the device on the nondominant wrist and to synchronize their Fitbit with the app at least once daily. Once synced, study staff were able to access participant data through Fitabase. During the data collection period, research staff checked the platform 2 times a week. For those who did not provide the requested 5 days of data, we sent up to 10 reminders to participants to initiate or continue wearing the device and to sync their data on the app.

The Fitbit device measures physical activity, heart rate, and sleep stages. Physical activity is measured through miniaturized accelerometers. Fitbit uses a proprietary algorithm to calculate steps and categorizes activity intensity into 4 levels—very active, moderately active, lightly active, and sedentary, at the minute level [30,31]. The heart rate is measured through photoplethysmography, an optical technique that uses a light sensor to detect blood volume changes in the capillaries above the wrist [32]. Fitbit uses this measurement to run through a proprietary algorithm to get the beats per minute (bpm). Then, Fitbit combines the accelerometers and heart-rate pattern under a proprietary sleep algorithm to estimate sleep stages. Although some studies have implied that Fitbit may overestimate or underestimate the physical activity and sleep in certain situations, the algorithm has been validated in the contexts of measuring steps and 2-stage wake and sleep classification, with the accuracy mostly being between 80% and 90% when compared with research-grade devices [21-25,33-35].

Data Cleaning and Analysis

We downloaded minute-level Fitbit data on August 29, 2022. The data contained information on activity intensities, steps, heart rate, and sleep every minute. We used heart rate as a proxy to determine wear time. If participants did not have heart rate observed in a given minute, we considered it as nonwear time. We used 2 cutoffs to define participants' valid data, (1)

XSL•FO
RenderX

participants with heart rate data for at least 600 minutes (10 h)/day for 5-9 days and (2) participants with heart rate data for at least 1200 minutes (20 h)/day for 5-9 days. The first cutoff is commonly used in actigraphy studies [36], while the second cutoff allows us to evaluate participants who had high compliance in a full 24-hour period [37].

We used the minute-level data to calculate the results at the daily and participant levels for valid participants. For the daily value of physical activity, we calculated the average steps/hour (during wear time), total steps per day, awake sedentary minutes, lightly active minutes, moderately active minutes, and very active minutes. The awake sedentary time was defined based on the Fitbit algorithm and excluded sleep. We then used the daily value to calculate the physical activity at the participant level.

For sleep data, we selected participants who had sleep data for 5-9 days from the 600 minutes/day cutoff described above. Fitbit assigns 3 values to indicate sleep stages for each minute during sleep periods, “1” indicates being asleep; “2” indicates being in a restless state, which may indicate restlessness during sleep or wakefulness; and “3” indicates being awake during the sleep period. Otherwise, sleep is categorized as “NA,” which indicates being fully awake (ie, not part of a sleep period) [38]. We defined a series of sleep metrics based on previous studies [39-41]. We defined sleep cycle as a series of distinct stages of sleep that a person can go through from being asleep to being awake. We defined sleep period as a specific time interval between sleep onset and the end of sleep, where multiple sleep cycles can occur in 1 sleep period. To determine the main sleep period, we manually examined participants’ sleep cycles and merged sleep cycles if multiple cycles occurred between 6 PM and 6 AM. If no sleep was found between 6 PM and 6 AM, we then examined the post 6 AM sleep onset time and manually identified the sleep period based on all available Fitbit sleep records for the participant. For the calculation of sleep duration, we focused on the main sleep period, excluding any nap times that occurred after the main sleep period.

Next, we classified the total time spent awake between the sleep onset time and sleep wake up time as wakefulness after sleep onset (WASO). We used the total asleep time between the sleep onset and wake up time divided by the total sleep duration to calculate sleep efficiency. We also calculated the sleep midpoint, which is the middle time between the sleep onset time and final wake up time. We then used the sleep midpoint to determine social jet lag, which measures the difference in sleep midpoint time between week nights (Sunday-Thursday) and weekend nights (Friday and Saturday).

We obtained the demographic characteristics for all participants who had Fitbit data available and for the subset of participants with adequate wear time based on 600 minutes/day and 1200 minutes/day cutoffs. We determined the mean (SD) for average wear days, daily wear time, total steps/hour, and total steps/day using each minimal cutoff. We then compared the wear time by sex into 4 physical activity categories: very active, moderately active, lightly active, and awake sedentary in participants who met our 600 minutes/day cutoff. Finally, we showed sleep results for all valid participants and classified participants who had average sleep onset times before and after midnight, respectively. All the data preparation and analyses were conducted using R (R Foundation for Statistical Computing).

Ethical Considerations

The Institutional Review Board at Harvard Pilgrim Health Care approved this study protocol (235301). All participants provided written informed consent (if aged over 18 years) and assent in combination with parent or guardian informed consent (if under the age of 18 years).

Results

Overall

Out of the 901 invited participants, 809 consented to the Mid-Teen visit and 702 agreed to participate in the Fitbit substudy (Figure 1 shows the participant eligibility flow chart). We ultimately obtained Fitbit data from 677/702 participants (96% of those who consented to the Fitbit substudy). We found similar demographic characteristics between participants who consented to the Mid-Teen visit but did not consent to the Fitbit substudy and those who consented to the Fitbit substudy (Table 1). The raw dataset comprised over 7 million minutes of physical activity and 6 million minutes of sleep data from 677 participants. After data cleaning, the percentage of valid participants remained high (612/677, 90%, using the 600 minutes/day for 5-9 days as the cutoff, and 538/677, 79%, using 1200 minutes/day for 5-9 days as the cutoff).

Participant Compliance

Among all participants with valid data considering the cutoff of at least 600 minutes/day (on every day worn), participants tended to wear the device for more than 10 hours per day and for more days than requested (Figure S1 in Multimedia Appendix 1). Furthermore, the pattern of wearing the device for more than 10 hours per day persisted when comparing the first recording day with the last recording day (Table S1 in Multimedia Appendix 1). When comparing the wear time between the two cutoffs, the average number of wear days and daily wear time were similar between the 600 minutes/day cutoff group and the 1200 minutes/day cutoff group (wear days: 7.5 days, SD 1.1 days vs 7.7 days, SD 0.9 days; wear time: 1323 minutes, SD 100 minutes vs 1350 minutes, SD 61 minutes). Similarly, the average values for steps/hour were similar between the groups defined by the two different cutoffs (Table 2).

XSL•FO
RenderX

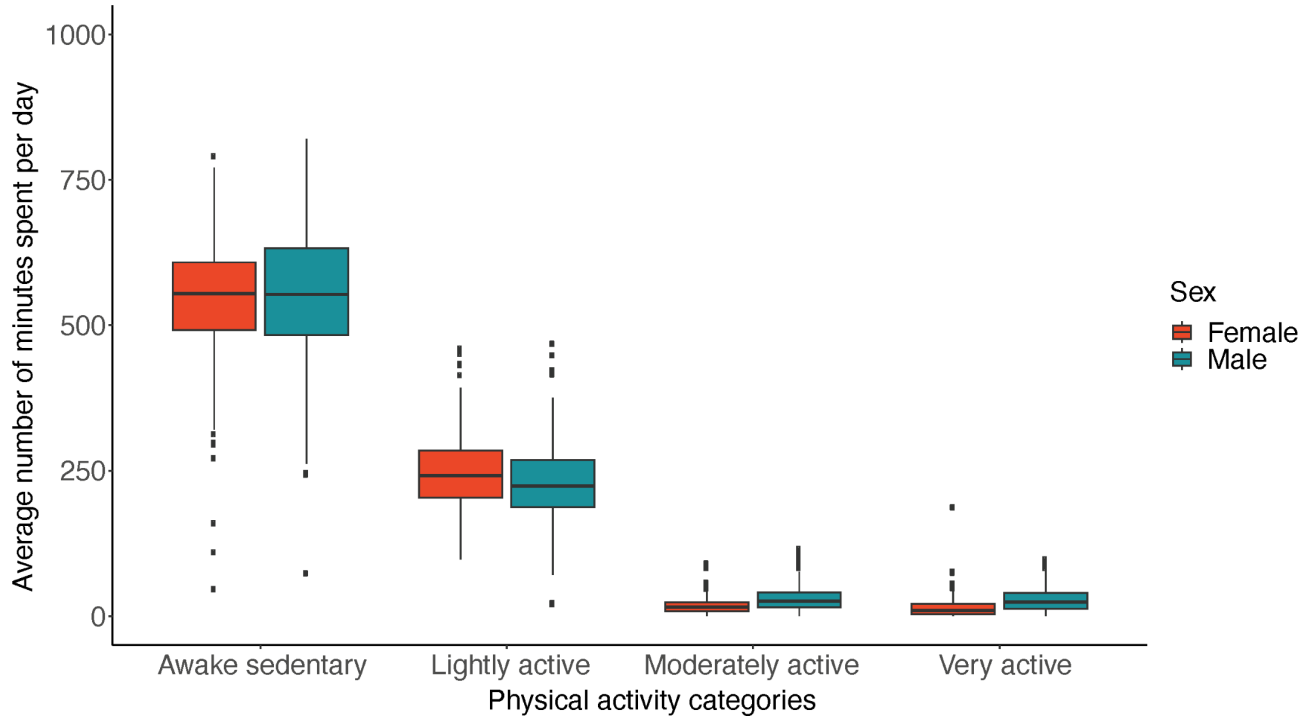

Table . Participants' physical activity results based on 600 minutes/day and 1200 minutes/day cutoffs.

Variable	Participants with valid data considering the cutoff of 600 min/d wear time for 5 - 9 days (n=612), mean (SD)	Participants with valid data considering the cutoff of 1200 min/d wear time for 5 - 9 days (n=538), mean (SD)
Total wear time (d)	7.5 (1.1)	7.7 (0.9)
Daily wear time (min)	1323 (100)	1350 (61)
Total steps per hour (steps/h)	399 (157)	400 (150)
Total steps per day (steps)	8883 (3455)	9041 (3414)
Physical activity level		
Very active (min/d)	20 (20)	21 (20)
Moderately active (min/d)	23 (18)	23 (18)
Lightly active (min/d)	235 (70)	239 (67)
Awake sedentary (min/d)	564 (138)	568 (121)

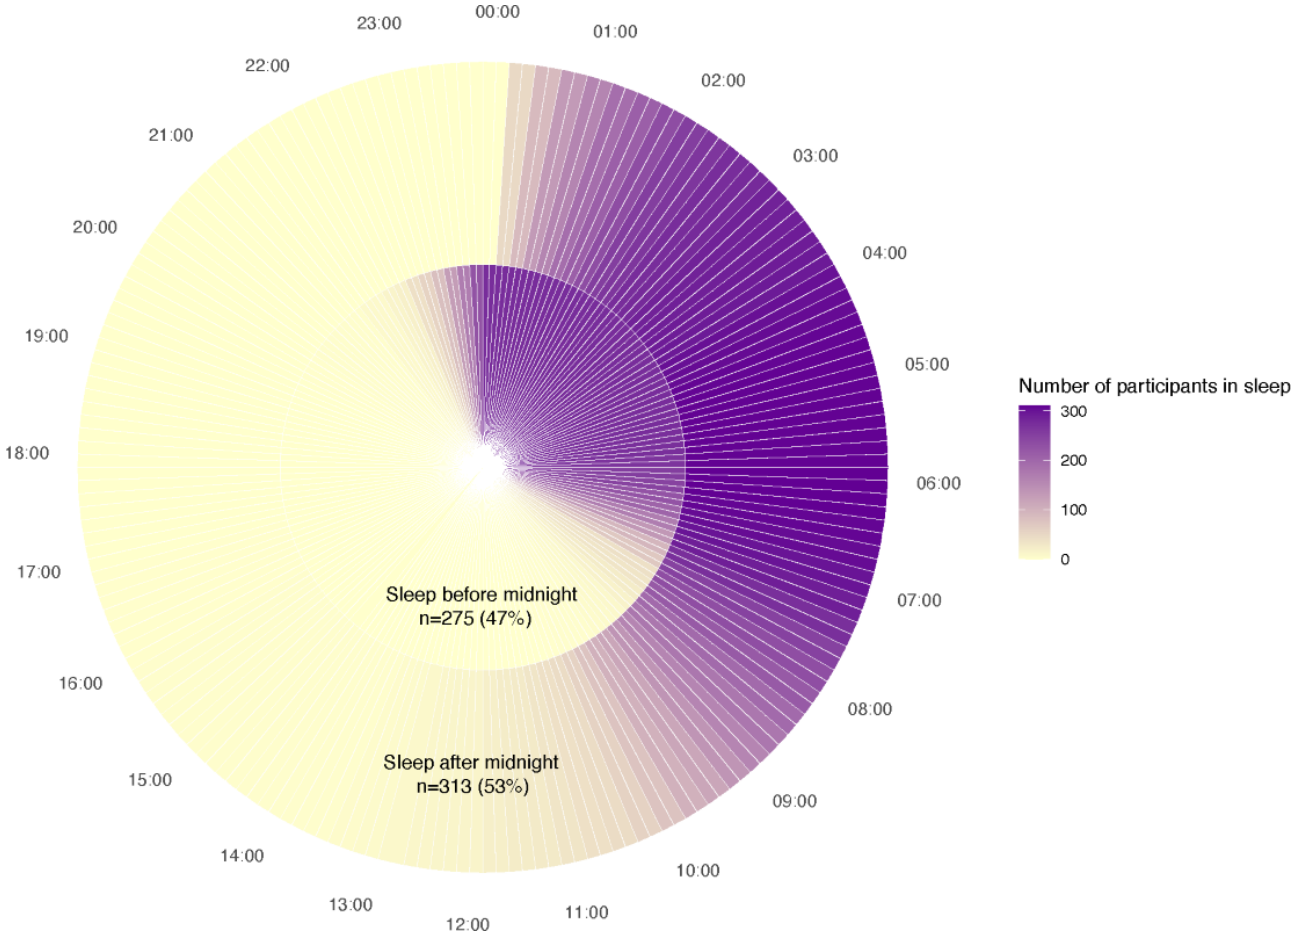
Physical Activity Results

Among the 4 physical activity categories (awake sedentary, lightly active, moderately active, and very active), we found that of the total awake wear time, the longest duration was spent in sedentary activity for both the 600 minutes/day cutoff group (mean 564 min/d, SD 138 min/d) and the 1200 min/d cutoff group (mean 568 min/d, SD 121 min/d; Table 2). The average wear time spent in the physical activity categories of very active and moderately active was less than 25 minutes per day for both cutoffs. Male participants spent a slightly higher wear time in the physical activity categories of very active and moderately active compared with female participants (very active: 27 min/d vs 15 min/d, moderately active: 29 min/d vs 17 min/d; Figure 2). On the other hand, female participants spent slightly more time in light activity compared with male participants (245 min/d vs 222 min/d).

Figure 2. Average time spent per day in each of the 4 activity levels: awake sedentary, lightly active, moderately active, and very active. Orange represents female participants and teal represents male participants. The vertical axis indicates the wearing time spent in each activity. Participants were selected using the minimal cutoff for wear time of at least 600 minutes/day for 5 - 9 days.

Sleep Results

Out of the 612 participants who wore the Fitbit for at least 600 minutes/day, 588 participants had sleep data available (Table 3). In these participants, the average number of days with sleep data available was 6.9 (SD 1.2) days with a mean sleep duration of 7.9 (SD 0.9) hours and average sleep onset time of 00:16 AM (SD 1.5 h). When stratified by weekends and weekdays, participants exhibited longer sleep duration during weekends compared with weekdays (mean 8.4 hours, SD 1.4 hours vs 7.8



XSL•FO
RenderX

hours, SD 1.1 hours), while the sleep efficiency and WASO stayed consistent (Table S2 in Multimedia Appendix 1). In addition, we classified participants into 2 groups (average sleep onset time before midnight vs average sleep onset time after midnight). The sleep efficiency and WASO were minimally different between the two groups. However, the group with the average sleep onset time before midnight had a longer sleep duration, more social jet lag, and earlier wake up time compared with the second group (sleep duration: 8.1 hours, SD 0.8 hours vs 7.8 hours, SD 0.95 hours; social jet lag: 1.0 hour, SD 1.2 hours vs 0.6 hours, SD 1.9 hours; and wakeup time: 07:16 AM, SD 0.9 h vs 09:09 AM, SD 1.6 h). Furthermore, Figure 3 shows that participants with sleep onset after midnight have a wider wake window (a larger SD) compared with participants with sleep onset before midnight.

Table . Sleep results for participants who have valid data for 5 - 9 days of sleep considering 600 minutes/day, and separated by sleep onset before midnight and sleep onset after midnight.

Sleep measure	Overall participants (n=588), mean (SD)	Participants with average sleep onset before midnight (n=275), mean (SD)	Participants with average sleep onset after midnight (n=313), mean (SD)
Number of days with available data	6.9 (1.2)	6.9 (1.3)	6.9 (1.2)
Sleep duration (h)	7.9 (0.9)	8.1 (0.8)	7.8 (0.95)
Sleep efficiency (%)	93 (5)	93 (6)	93 (5)
Wakefulness after sleep onset (h)	0.6 (0.4)	0.6 (0.5)	0.6 (0.4)
Social jet lag (h)	0.8 (1.6)	1.0 (1.2)	0.6 (1.9)
Sleep onset time	00:16 AM (1.5 h)	23:11 PM (0.6 h)	01:17 AM (1.2 h)
Wake-up time	08:17 AM (1.6 h)	07:17 AM (0.9 h)	09:09 AM (1.6 h)

Figure 3. Sleep patterns for participants with average sleep onset before or after midnight (N=588). The inner circle includes participants whose average sleep onset time occurred before midnight (275/588, 47%) and the outer circle includes participants whose average sleep onset time occurred after midnight (313/588, 53%). The clock is based on 24-hour clock with 15 minute intervals. The gradient represents the number of participants in sleep in that given interval, where more purple color indicates more participants in sleep.

Discussion

Principal Findings

Physical activity and sleep are major behavioral factors associated with various domains of health in adolescents. Consumer-based accelerometry devices, such as Fitbit, have enabled researchers to examine these behaviors efficiently at scale. For our Mid-Teen visit (aged ~17 years old), we invited Project Viva participants to use a Fitbit wearable device to collect physical activity and sleep data. We found participants were likely to consent and to wear the devices for the requested time. We observed that adolescents were spending the majority of their awake time in sedentary activities, with very little time participating in the physical activity categories of very active and moderately active. In the sleep data, we noticed that sleep onset time minimally impacted average sleep duration, sleep efficiency, and WASO; however, participants with a sleep onset after midnight tended to have much wider wakeup time window and less social jet lag.

The rising popularity of wearable devices has introduced a new method of data collection for assessing physical activity and sleep for epidemiology research [42]. This study illustrated the feasibility of using consumer-based wearable devices to collect human-behavior data, such as physical activity, sleep duration, and other sleep metrics, in free-living conditions. In addition, the high granularity of this data enabled us to examine physical activity and sleep at multiple levels: minute level, daily level, and the participant level. The objective data collection method avoided measurement errors resulting from recall or social desirability bias [43,44]. The device being used, unlike many research-based devices, does not need to be mailed back by participants, which avoided additional communication and shipping costs for the researchers, and participant burden of shipping back devices. We additionally avoided the potential of device and data loss during shipping. Furthermore, in the initial communications for the Mid-Teen visit, study staff informed participants that they could keep the device after the study period, and many participants felt it was a nice incentive to participate.

Project Viva has collected sleep and cardiometabolic health information across multiple visits in childhood and adolescence, and plans to continue health assessments in many domains in young adulthood. Our physical activity findings align with existing research, emphasizing the prevalence of sedentary lifestyle among adolescents [45,46]. Notably, we observed a delayed sleep onsite time and longer sleep duration on weekends, similar to previous studies [47,48]. For our future studies, we plan to examine associations of sleep and physical activity behaviors with cardiometabolic health data already collected at the midadolescence visit, such as weight, body composition, blood pressure, and blood biomarkers of cardiovascular health. Furthermore, we plan to use the Fitbit results as a calibration tool to enhance the accuracy and reliability of the self-reported physical activity and sleep data for participants who did not participate in the Fitbit substudy. These Fitbit data offer a unique way to examine health behavior and provide valuable insights into the relationship between behavioral factors and chronic disease development with opportunities for potential interventions. In addition, we have minute level and daily level dataset on objective health behaviors available for more detailed analyses.

Limitations and Challenges

While this study provides insights in using wearable devices to collect adolescent behavior data, there are some limitations to the inferences we can make. First, unlike other actigraphy studies that require participants to complete sleep diaries to self-report sleep onset and wake up times while wearing the device, our study did not request participants to fill out sleep diaries. This made it more difficult to clean the sleep data, especially for participants whose sleep period was less consistent, requiring us to make judgments based on their recorded sleep patterns and manually assign “sleep periods.” Second, despite instructing participants to wear the device on the nondominant wrist, we were unable to actively track the wearing status of the device. The wear habits might have influenced the accuracy of step counts and sleep stage recording [49-51]. The third limitation is the proprietary algorithm used by Fitbit. Although previous validation studies have shown 80% - 90% of accuracy for Fitbit devices in adolescents and adults when comparing both physical activity and sleep using research-grade accelerometry[21-25,50-52], the lack of accessibility to Fitbit’s underlying algorithms poses challenges in understanding the logic behind the algorithms for each device type and age populations. Finally, Project Viva is composed of adolescents from families with generally high median incomes and higher educational background, which could restrict the ability to generalize the findings to other populations. However, the high granularity data captures individual differences and can be used for comparative analyses as well as integrating with other cohort to extend the findings to a diverse population.

Conclusion

This study provided valuable insights into using consumer-based wearable devices to collect human behavior data. These data on physical activity and sleep characteristics are important for researchers seeking to understand their influence on chronic disease development and mental health outcomes. For future research, consumer wearable devices hold great potential for researchers to apply across different adolescent populations. Their use allows us to gain greater understanding of how lifestyle factors impact long-term health outcomes in diverse populations. These data may shed light on future policies or interventions aiming at increasing physical activity and improving sleep health, ultimately leading to improvements in physical and mental health.

Abstract

Background: Parents of preschool-aged children are a key focus for interventions to shape healthy lifestyle behaviors and support risk reduction for obesity from an early age. In light of limited existing evidence on the use of mobile technology to promote healthy lifestyle behaviors among young children, we sought to gather parental priorities regarding a mobile app focused on guided goal setting across the domains of diet, physical activity, media use, and sleep.

Objective: The purpose of this study was to explore the priorities and needs of parents of 2- to 5-year-old children to guide developing the content and features of a mobile app aimed at promoting healthy lifestyle behaviors using a novel convergent mixed methods approach.

Methods: From November to December 2021, we invited parents or guardians in Kentucky to complete a series of web-based concept mapping activities and semistructured interviews (total N=30). Using 2 lists of items focused on (1) parental priorities (content areas) and (2) application features, we asked participants to conduct concept mapping procedures for each list: a web-based sorting activity, where participants grouped items together into thematic piles that made sense to them, and a rating activity, where participants rated each item on a 5-point Likert-type scale. The qualitative interviews were transcribed verbatim, coded, and then analyzed by constant comparative analysis to identify themes. We used the quantitative findings from the concept mapping process to triangulate the resulting themes from the qualitative interviews and generate possible app content areas and features.

Results: The concept mapping results resulted in two 3-cluster concept maps. For parental priorities, participants identified the clusters Creating Healthy Eating Habits, Forming Boundaries, and Building Good Relationships; for app features, participant clusters included Eating Healthy, Using the App, and Setting Goals. The interview themes also represented those 2 domains. Overall, the participants indicated that the top priorities were general health and wellbeing, routine and setting boundaries, and food and healthy eating when it comes to building healthy behaviors among their preschool-aged children. Parents indicated that quick, easy, and child-friendly recipes, goal tracking, and the use of tips and notifications were the features they valued most.

Conclusions: This study contributes to the understanding of what parents or caregivers of young children want from mobile apps, in both content and features, to support building healthy behaviors and routines. The findings can inform future research

XSL•FO
RenderX

on the development and evaluation of existing or new mobile apps. Specific app features identified to meet family needs should be designed closely with a diverse set of families and tested using rigorous designs to identify the mechanisms of action that mobile apps may use for efficacious healthy parenting outcomes.

Introduction

Healthy lifestyle behaviors remain an essential focus for health care efforts in the United States. As of 2017-2020, the US obesity prevalence rate was 41.9%, with obesity being the leading cause of preventable death across major outcomes, such as heart disease, stroke, type II diabetes, and several forms of cancer [1]. Likewise, childhood obesity rates continue to be a concern in the United States, including a prevalence rate of 12.7% among 2- to 5-year-old children in 2017-2020, resulting in conditions such as high blood pressure, high cholesterol, asthma, sleep apnea, and joint problems at an early age [2]. Additionally, childhood obesity disproportionately affects children of lower socioeconomic status and minority groups [3-5], exacerbating and contributing to this vast array of secondary consequences [6,7]. The state of Kentucky currently ranks second in the nation for both adult and childhood obesity rates, with significantly high rates of obesity among rural Appalachian and urban minority residents [1,2,8]. Parents of preschool-aged children remain a key focus for interventions supporting communities with disproportionately high obesity rates in an attempt to curtail these rates from an early age [9].

Recent research on healthy lifestyle behaviors among preschool-aged children has identified relevant determinants and behaviors. For example, Townsend et al [10,11] describe 12 dietary and behavioral determinants for childhood obesity risk reduction: fat, dietary fiber, fruit or vegetables, calcium or dairy, sweetened beverages, restaurant-prepared food, breakfast, energy density of eaten foods, physical activity, TV-viewing, sleep duration, and parenting. A recent systematic review of family-based childhood obesity prevention interventions indicates that interventions tend to focus on the domains of diet, physical activity, media use, and sleep; however, less than half of the included studies targeted a behavioral domain beyond diet and physical activity, and only 16% targeted all 4 behavioral domains [12]. Likewise, few studies exist that focus on goal-setting interventions among children and adolescents [13], even though guided goal setting represents a feasible strategy for parents to improve health behaviors for obesity risk reduction among children [14]. Additionally, a recent meta-analysis indicated that obesity prevention interventions in youth with low socioeconomic status are more successful when several behavior change strategies are integrated, rather than relying solely on one strategy [15].

Thousands of mobile apps exist that focus on nutrition and physical exercise but are primarily geared toward adults [16]. In our recent review, we found only 3 preexisting reviews of multiple mobile health (mHealth) apps designed for children and parents between 2015 and 2022 [17]. Of the 3 reviews, only one provided a list of specific app names, focusing on nutrition as a behavioral intervention for child obesity [18]. The authors of this review concluded that most apps, although free or relatively inexpensive (making them highly attractive to parents), contained content of low quality, were poorly designed, or were not grounded in credible dietary guidelines due to a lack of involvement of nutrition or scientific professionals in the design process [18]. In this review, the most common nutrition features in such apps included promotion of energy balance and guidance on appropriate portion size, and the most common behavioral change feature involved goal setting. Our review identified only 9 apps that use goal setting to change the health behaviors of children.

In light of limited existing evidence, we sought to design a mobile app geared toward parents of preschool-aged (2- to 5-year-old) children, integrating guided goal setting across the domains of diet, physical activity, media use, and sleep. During the formative stage of app development, we sought to integrate feedback from parents with children in our target age range in order to assess major areas of interest and ways the app could best meet their needs. Using a novel mixed methods approach, we combined concept mapping activities and qualitative interviews to capture the perceptions of parents on app content and features. Concept mapping is a useful formative design research tool that uses a structured process to create a visual representation or cognitive map of ideas and concepts [19]. This method has been widely used in a range of formative research topics including mHealth app evaluation [20] and in the development of apps focused on reducing school absences [21]. To our knowledge, this is the first application of concept mapping combined with interviews in the formative design and development of a health-focused app for parents of preschool-aged children. Specifically, the purpose of this study was to use this novel convergent mixed methods approach to explore the needs and desires of parents of 2- to 5-year-old children for the content and features of a health-based mobile app designed to promote healthy behaviors to reduce future obesity risk.

Methods

Recruitment

Study inclusion criteria include the following: primary caregiver of a 2- to 5-year-old child, 18 years or older, and use a smartphone or mobile phone and smartphone apps. Participants were recruited via printed flyers placed at various community-based organizations and distributed via community outreach activities as well as email listservs and social media

XSL•FO
RenderX

channels managed by the university. Recruitment advertisements invited parents to participate in a study to help design a smartphone app for families. Those interested in the study could connect with the study team via an internet link, email, or telephone. The study team employed eligibility prescreening via a REDCap (Research Electronic Data Capture; Vanderbilt University) survey [22]. Participants had the option to complete the eligibility survey online or over the phone.

Ethical Considerations

A waiver of documentation of consent was granted by the University of Kentucky Medical Institutional Review Board (61563). The survey included a web-based process with consent indicated by selecting the "submit" button. If administered by phone, the staff read the consent information and asked participants to consent verbally. Eligible participants were contacted by study staff to schedule an interview and sent a link and log-in information for concept mapping activities.

Study Procedures

From November to December 2021, we conducted 60-minute qualitative interviews (N=30). Interviews were facilitated by staff with a background in public health nutrition and qualitative methodology and conducted via Zoom (Zoom Video Communications) [23]. Interviews were recorded with participant permission. The interview protocol was developed based on a multilevel model of behavioral factors related to pediatric overweight (eg, dietary intake, physical activity, sedentary behavior, sleep, family meals, parenting styles, and feeding practices) [10,11] and research on the importance of goal setting in behavior change [24,25]. In addition, questions were informed by our formative research that demonstrated interest in health-focused apps designed among parents with preschool aged children [26,27] and a review of the content and features of existing apps for parents related to goal setting and tracking [17]. Based on this literature, we developed a semistructured discussion guide (Table S1 in Multimedia Appendix 1) in which we intentionally grouped questions in three logically progressing areas: (1) overall parenting routines and challenges, (2) health and wellness for their preschool-aged child with probes in specific domains from the literature (eg, mealtime, sleep, and active play), and (3) current mobile app use and desired features.

Using a convergent mixed methods design [28], interview participants were simultaneously asked to join in web-based concept mapping activities. Concept mapping is a participatory mixed method that incorporates quantitative elements with qualitative data collection to build consensus around a topic of interest [19,29]. To begin, the study team developed 2 sets of items based on formative research [26,27], which responded to two focal questions: (1) What are health and wellness priorities of your 2- to 5-year-old child? (23 items) and (2) What are the features you would like to have on an app on your phone that could help you set goals and work on goals for taking care of the health and wellness of your 2- to 5-year-old child (31 items)? The first question sought to gather perspectives on app content while the second served to capture desires for app features. We asked participants to complete 2 procedures: a virtual sorting activity, where participants grouped items into thematic piles that made sense to them, and a rating activity, where participants rated each item on a 5-point Likert-type scale. For the 23 health and wellness priority items, this rating question was as follows: How important is this item to you as a priority for your child's health (from not at all important [1] to extremely important [5])? For the 31 app feature items, we asked the following question: How often would you use this feature in an app on your phone (from never [1] to all the time [5])? In addition, we asked demographic questions, including race, ethnicity, marital status, number of children, employment status, education, income, and receipt of assistance programs. All concept mapping data were collected using Groupwisdom (Concept Systems, Inc), a web-based concept mapping software [30].

Analysis

The qualitative interviews were transcribed verbatim and analyzed through a combination of a deductive approach and grounded theory to identify themes [31,32] using the ATLAS.ti qualitative data analysis software (version 8.0) [33]. The initial identification of overarching thematic codes used a deductive strategy based on the interview questions, which was informed by previous research on behavioral determinants related to childhood obesity risk reduction, mealtime and child feeding practices, and guided goal setting among parents of preschool-aged children [10,11]. This initial deductive analysis also focused on overarching thematic codes related to potential app features and tools for families of preschool-aged children [17]. Additionally, we used a line-by-line analysis approach to generate a list of emergent, more granular subcodes within the larger coding schematic. In total, 3 coders with backgrounds in public health were trained to allocate codes to quotations. Interrater reliability was determined according to the procedures of Gough and Conner [34], which resulted in a high level of correspondence (93% agreement). The criteria of Lincoln and Guba [35] for trustworthiness of qualitative research were applied to ensure credibility of the findings.

We analyzed the sorting data from each set of concept mapping items in the Groupwisdom software. Specifically, we used similarity matrices and multi-dimensional scaling to generate 2-point maps, which reflect group consensus on the similarity of items. Next, we performed hierarchical cluster analysis for each set of sorting data to group the sets of items into common thematic clusters, resulting in 2 cluster maps. We combined the point and cluster maps for each focus area (parental priorities and app features) to depict items within their thematic areas. As a part of the recommended concept mapping methodology, we also analyzed average item ratings for the Likert-type rating scales to determine which items participants believed were the most important priorities for the health and wellness of their child and which app features were most likely to be used [19].

Finally, we used the interview themes to triangulate the concept mapping findings. Specifically, we synthesized the parental priorities and desired app features results to derive possible content and features of a novel mobile app to improve health behaviors among preschool-aged children.

Results

Participant Characteristics

Table 1 shows the characteristics of those who participated in at least one activity (N=30): qualitative interviews only (n=2), concept mapping only (n=4), or both (n=24). Overall, the majority of participants identified as non-Hispanic White (93.3%), married (70.0%), having 1 or 2 children (80.0%; range 1 to ≥4), and being employed either part- or full-time (63.4%). A significant portion of the sample (36.6%) had a monthly income of US $2999 or less and 40.0% had not obtained a Bachelor's degree. For families using public assistance, most participated in a combination of WIC (Special Supplemental Nutrition Program for Women, Infants, and Children), SNAP (Supplemental Nutrition Assistance Program), and Medicare or Medicaid.

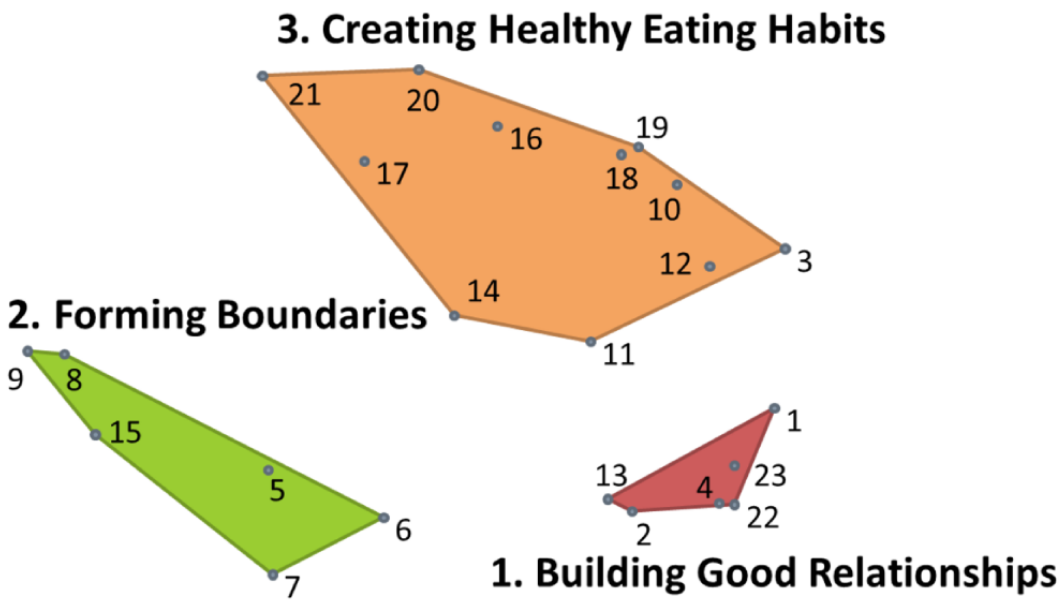
Medicare or Medicaid	6 (20.0)

Concept Mapping and Interview Results

The concept mapping results reflected both app content and features: parental priorities and app features. The in-depth interviews resulted in thematic areas containing 257 individual total codes which also fell into these areas. The parental priority themes included the following: desired areas for improvement, routine, mealtime or child feeding behaviors, active play or physical activity, and sleep. The app features' themes included recipes, goal tracking, grocery shopping or meal planning, and tips and notifications. Representative quotes from the identified themes are shared in Table 2.

XSL•FO
RenderX

Table 2. Representative quotes from the in-depth interviews by thematic areas.



Themes	Quotes
Desired areas of improvement	• I care about, of course, my children and their well-being. That they stay happy and healthy; mentally, physically, emotionally. (Mother of 2 boys ages 3 and 6 years old) • I'm always up for changes, improvements, anything that I can do that'll make anything easier or more efficient because a lot of times I'll do things the hard way instead of an easier way. I don't know why. My dad always said that I do everything the hard way. (Mother of a 4-year-old boy and a 1-year-old girl)
Routine	• We do try to follow [a routine] just because it tends to let our girls have a better, you know, day, especially when they're on their routine- and if they're not in routine, they tend to act out more. So, we do try to... but we don't always follow it, and sometimes it bites us in the [expletive] so on those days it's a little more difficult. (Mother of 2 girls 7 and 2 years old)
Mealtime and child feeding behaviors	• She's very picky. And I have a lot of issues with my weight and I'm afraid that she's going to too. So, I try to like- "Oh well here, I'm eating broccoli. Do you want to eat this? Because dinosaurs eat broccoli" because she likes dinosaurs so she's like, "No it's OK- I'm a dinosaur that doesn't like broccoli." (Mother of 2 girls ages 6 and 4 years old)
Planning grocery shopping	• I do better if I have a list. Sometimes we'll make a list on my phone before I go into the store, so I have something to make sure I get everything. And then a lot of times we'll use Click List, which makes it a lot easier because then everything that we need is all right there, like we have to order it that way, so that makes it a lot easier[…] Sometimes I'm still a pencil paper person too. I kind of do all of it. (Mother of a 4-year-old boy and a 1-year-old girl)
Active play or physical activity	• Then I know at school, right now they only get to go outside if it's warm enough so he hasn't been outside much, and I can tell on the days when he's been able to play outside at school versus when he hasn't. (Mother of a 3-year-old boy)
Sleep	• They report his behavior at school because sometimes he does not get good reports and his behavior at school- and I've told them it is directly related to sleep. […] That's one of the biggest factors like nights where I know that he's not slept as much, or if they've said he's took a nap or not. It's most directly related to his bad behavior, a lot of times at school, it'll be one the number one thing. So that is important. (Female caregiver to a 4-year-old boy)
App features	
Recipes	• The recipes that get more attention for me are ones I might actually use instead of just browsing would be the ones that's catered for the kids. Or to make it better for them or like a kid twist on something you know, that would be what I would want. (Caregiver to a 4-year-old boy)
Goal tracking	• I know at home sometimes we'll set goals for him. If there's an area that we see, an area of concern, then we'll do like a sticker chart like that I would use in school with a student to meet a certain goal, and we'll talk about that you have to do these three out of the five times. And so, I think if there was an app that would probably be easier than creating sticker charts all the time. (Mother of a 5-year-old boy)
Grocery shopping and meal planning	• I would be interested in it [a shopping list feature] if it was kid friendly and simple. Like if it would be probably like the simplest and quickest kind of interface. Some have gotten to cluttered and have to many things going on, to many things to edit, so, simple is best. (Caregiver to a 4-year-old boy)
Tips and notifications	• I would just say simple. As a parent with everything else on my plate, simplicity is the easiest way[…] if I'm looking for something in particular, I want to be able to find it as quickly as I can. (Mother of 2 boys ages 2 and 4 years old)

Parental Priorities

Figure 1 displays the combined point and cluster map for the parental priorities area, which shows each of the 23 items in relative positions based on similarity (ie, items close together were often sorted together by participants) and grouped into thematic clusters, providing understanding of perceived commonality. The resulting clusters were as follows: (1) Building Good Relationships, (2) Forming Boundaries, and (3) Creating Healthy Eating Habits. These cluster names were developed from pile names participants created in the sorting process and reflect the major desired areas for app content. Table 3 includes all of the concept mapping items grouped by cluster and sorted by the average rating for each item; the highest rated items for each cluster are shown in italics.

Figure 1. Parental priorities combined point and cluster concept map.

Table 3. Concept mapping items grouped by cluster with average item ratings (highest rated for each cluster in italics).

Cluster and item	Statement	Average rating (Importance: 1=not at all to 5=extremely)
Parental properties		
1. Building good relationships		
1	*Taking care of my child's health*	*4.96*
22	*Being a good parent*	*4.92*
2	Talking and listening to my child	4.88
23	Helping my child feel good about their body as they grow up	4.88
4	Spending quality time with my child	4.79
13	Playing with my child	4.67
2. Forming boundaries		
6	*Setting and sticking to boundaries that are clear*	*4.50*
5	*Establishing and sticking to a daily routine*	*4.17*
7	How to reward my child for good behavior	4.08
8	Limiting my child's time using a phone or tablet	4.00
15	Getting my child to bed on-time	4.00
9	Limiting my child's time watching TV	3.67
3. Creating healthy eating habits		
3	*Having a variety of healthy food choices at home*	*4.63*
12	*Being a good role model for my child by eating healthy*	*4.42*
19	Getting my child to eat vegetables	4.38
18	Getting my child to eat healthy food	4.29
11	Encouraging exercise or physical activity for my child	4.25
10	Making sure my child doesn't drink too much sugar	4.13
14	Being a good role model for my child by exercising	4.04
16	Preparing more meals at home	3.92
17	Cooking with my child	3.67
21	Ways to address my child's picky eating	3.58
20	Quick and easy recipes for my family	3.50
App features		
1. Eating healthy		
1	*Healthy recipes*	*4.42*
4	*Easy recipes*	*4.29*
5	*Quick recipes*	*4.29*
3	Recipes for kids	4.17
11	Add recipes to a meal plan	4.08
8	Recipe tips	4.04
6	Search and filter recipes	3.92
7	View recipe nutrition facts	3.88

XSL•FO
RenderX

Cluster and item	Statement	Average rating (Importance: 1=not at all to 5=extremely)
10	Make a meal plan	3.83
12	Tips about child health and nutrition	3.79
9	Make a grocery list	3.71
2	Recipes that can fit my family's dietary needs (eg, vegetarian, gluten free, no dairy, allergies, etc.)	3.50
2. Using the app		
13	*App alerts to view tips about child health and nutrition*	*3.50*
31	*Links to videos about child health and nutrition*	*3.50*
23	*Configure app preferences*	*3.25*
22	Setup my family profile—selecting a photo or avatar	2.88
28	Using the app with other family members	2.54
26	Sharing my goal progress with friends and family	2.08
25	Sharing my goal progress with other app users	2.04
27	Sharing my goal progress on social media	1.83
3. Setting goals		
20	*Set and track goals about making food more child friendly*	*3.88*
30	*Rewards or points for reaching my goals*	*3.79*
14	Quizzes to assess my child's health and well being	3.63
29	Getting feedback on how to improve on my goals	3.50
15	Set and track goals about my child's health and well being	3.42
24	Set and track goals about what my child eats and drinks	3.42
16	Set and track goals about my child's physical activity	3.33
18	Set and track goals about my child's mealtime routine	3.33
21	Reminder alerts to track goals for my child daily	3.29
19	Set and track goals about eating together as a family	3.21
17	Set and track goals about my child's bedtime	3.13

Building Good Relationships

Items in the Building Good Relationships cluster with the overall highest importance ratings included: "1. Taking care of my child's health" (4.96 out of 5) and "22. Being a good parent" (4.92 out of 5), which highlights the importance of overall child well-being. To begin the interviews, we asked about what is most important as a parent or caregiver of your 2- to 5-year-old child or children. Several parents mentioned child happiness or child emotional or mental health as a main priority. Parents also mentioned spending time with their child, active listening, and communication with their child as important aspects of their parenting style. Many parents stated their child's health in general was most important, while other parents mentioned specific areas of child health such as healthy eating and physical activity. Other areas of priority included building and sticking to a routine, school readiness, and participation in religion.

XSL•FO
RenderX

Forming Boundaries

The Forming Boundaries cluster spoke to the participant-identified need for routine and time management. Items "6. Setting and sticking to boundaries that are clear" (4.50 out of 5) and "5. Establishing a daily routine" (4.17 out of 5) had the highest importance ratings in the cluster. Caregivers described a routine or schedule to establish consistency and reliability for their children. The morning routine, although often the most stressful or hectic, was integral to several families, especially those with a strict morning schedule. Evening routines were often described as a way to establish togetherness and connection with their children, whether through mealtime, playtime, or screen time. Bedtime routines varied for families but were the most commonly described area of routine. Caregivers described that their schedules were highly dependent on a variety of factors such as non-autonomous work schedules, unemployment, appointments, busy lifestyles, child health, and their child's mood or behavior.

Many of those who said that their routine was important or somewhat important emphasized that "life is easier with routine, more difficult without," and that their children were motivated by or thrived on routine. However, not all caregivers identified as planners; ie, several caregivers explicitly mentioned they do not adhere to a routine or *play it mostly by ear.* Whether parents viewed routine as important or not, they were able to describe scenarios where lack of structure was linked to child behavior issues.

Appropriately, the screen time–related items fell in this cluster, including items "8. Limiting my child's time using a phone or tablet" and "9. Limiting my child's time watching TV." Interestingly, the phone or tablet item had a higher importance rating than watching TV (4.00 compared to 3.67 out of 6), suggesting phones and tablets may be a particular area of focus for screen time strategies. Tips for screen time reduction were desirable among interview participants. Barriers included: apartment living or not having a yard, child injuries, busy schedules, younger children (eg, infants) in the household, child health issues, and caregiver being unconcerned about screen time.

Similarly, the only sleep-related item, "15. Getting my child to bed on time," fell into this cluster. Most interview participants described a bedtime routine for their young children and stated that their child had a set bedtime. Participants who stuck to a routine described their child's sleep and sleep compliancy as easy, with good quality and quantity. Alternatively, some caregivers described children who had difficulty falling asleep, resisted sleep, or had issues with waking regularly in the night. Several sleep improvement strategies included having a light, night light, or red light in the room; reading to children before bed; use of supplemental melatonin; soft music; and limits on screen time. Participants also described barriers, such as the use of screens, continuation of breastfeeding, and co-sleeping.

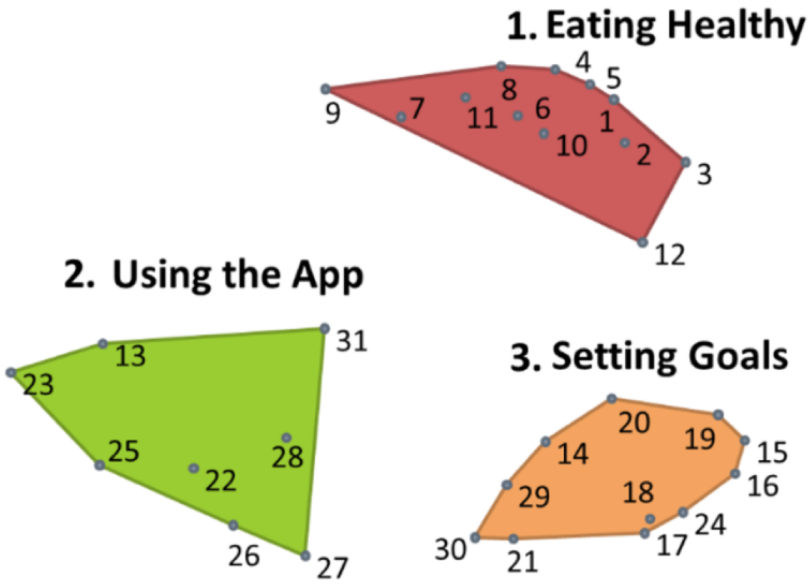
Creating Healthy Eating Habits

The food and nutrition items grouped together as its own cluster (Creating Healthy Eating Habits), including a variety of eating and meal planning or preparation items. The most highly rated were as follows: "3. Having a variety of healthy food choices at home" (4.63 out of 5), followed by "12. Being a good role model for my child by eating healthy" (4.42 out of 5) and "19. Getting my child to eat vegetables" (4.38 out of 5). Mealtime and child feeding were major themes of the interviews. Participant responses were mixed if planning healthy meals was easy, difficult, or somewhere in-between. Many participants stated they actively try to prepare and provide healthy meals for themselves and their children. However, barriers to planning healthy meals included busy schedules or time, finances, food allergies or intolerances in the household, caregivers identifying as poor cooks, and having to tend to more than one young child. Convenience food and eating out were mentioned by parents as a strategy to address busy schedules.

Barriers to desirable child feeding included the child wanting to eat different foods than those prepared, frequent snacking, and wanting to eat close to bedtime. Picky eating was the most frequently raised barrier; only 5 caregivers stated their child was not a picky eater. Successful strategies to combat picky eating included eating meals with children or modeling healthy eating, cooking or preparing food with children, making food child-friendly, and keeping foods separated or compartmentalized on the plate or during serving. Unsuccessful strategies included food coloring or telling the child that a favorite character or animal eats the food. Many parents also stated encouraging vegetable eating was an important part of child feeding. Notably, item "21. Ways to address picky eating" had the second-lowest importance rating in the cluster (3.50 out of 5); this rating may indicate participant preferences toward broadly increasing positive strategies and healthy choices rather than a focus on specific strategies geared toward picky eating.

Some parents practiced strict restriction of what they considered unhealthy or junk foods, while others allowed children to have unimpeded access to snacks high in sugar, fat, and excess calories. A few caregivers expressed concern over their own weight and how this extended to their concern about child overweight or obesity. Although located in the Building Good Relationships cluster, participants highly rated item "23. Helping my child feel good about their body as they grow up" (4.88 out of 5), further emphasizing participant concerns about weight and body image as it relates to food choices.

The diversity of thought around meal planning and grocery shopping may be reflected by the lack of highly rated items. For example, items such as "16. Preparing meals at home," "17. Cooking with my child," and "20. Quick and easy recipes for my child" that correspond to planning and preparing meals fell at the bottom of the ratings for the Creating Healthy Eating Habits cluster (3.92, 3.58, and 3.50 out of 5, respectively). The relatively lower ratings of these items may be due to the wide range of opinions and strategies used by study participants. Participants who identified as meal planners described their motivations and strategies, including budgeting, shopping for staples, or sticking to the list. Some parents found it easier to buy only a few items at a time, while others found it easier to shop in bulk—using storage capacities of their pantries and freezers. Key facilitators included proximity to the grocery store, sharing tasks with another parent or caregiver, and allowing children to choose items at the store. Barriers included busy



XSL•FO
RenderX

schedules, lack of time, finances, child misbehavior, and shopping with children present.

App Features

Figure 2 shows the combined point and cluster map for the App Features area. The App Features map included the following clusters: (1) Eating Healthy, (2) Using the App, and (3) Setting Goals; likewise, these cluster names were developed from participant pile names in the sorting activity. In the interviews, participants were asked about their current use of apps, especially those that helped with parenting. The type of apps most frequently used by participants to help with parenting were social media (eg, Facebook, Instagram, Snapchat), which caregivers used to follow nutrition-related content, such as recipes, and for parenting advice or finding childcare. Many parents said they used apps to search for and view recipes, including through social media pages, Pinterest, YouTube, and WIC apps. Other participants preferred to use general search engines to find recipes.

Figure 2. Application features combined point and cluster concept map.

Eating Healthy

The concept mapping results support a high interest level in recipes. Items “1. Healthy recipes” (4.42 out of 5), “4. Easy recipes” (4.29 out of 5), and “5. Quick recipes” (4.29 out of 5) had the highest ratings in the Eating Healthy cluster, indicating participants are likely to use these features often or all the time. Recipe viewing was among the most popular desired app features in the interviews; however, some participants did mention they either do not use recipes or are not interested in looking up recipes in an app feature. Participants expressed interest in recipes for the entire family, which could include kid-friendly options, rather than child-specific recipes. Caregivers’ desire for planning features like a grocery list maker and meal planning tools was also desired; however, in the concept mapping results, items around meal planning and grocery lists were not as highly rated as those related to recipes. When discussing this as an app feature, participants explained how meal or grocery shopping features may be more likely to be used if they are kept simple.

Setting Goals

The concept mapping findings also support the popularity of goal-tracking features. Item “20. Set and track goals about making food more child-friendly” (3.88 out of 5) had the highest rating for potential use among a variety of goal-tracking items in the Setting Goals cluster. Tracking features, especially goal tracking (eg, healthy eating, sticking to a routine, sleep, etc.) were also among the most desirable features among interview participants. Alternatively, some caregivers mentioned that, due to a lack of time or disinterest, they do not wish to log items or meticulously keep track of child-related goals on their phone. Some parents said this type of activity is already intuitive for them, so the feature would be unnecessary. Other participants said they already use a form of goal tracking that the app would allow them to simplify.

Using the App

Items “13. App alerts to view tips about child health and nutrition” (3.50 out of 5) and “31. Links to views about child health and nutrition” (3.50 out of 5) had the highest ratings among the Using the App cluster, supporting participants’ desire for helpful tips and notifications. The next highest rated item was “23. Configure app preferences,” suggesting that participants would like to tailor the app settings to their preferences. In the interviews, helpful tips and notifications were welcomed by caregivers; however, many wanted to be clear about the desired frequency at which they wished to be

XSL•FO
RenderX

notified on their phone. Developmental milestone tracking, general parenting tips, and the desire for everything to be in one place were desirable app features. Resoundingly, caregivers also voiced that simplicity and efficiency were important to them in an app.

Synthesis of Parental Priorities and App Features

Table 4 presents a list of possible content and features for a novel mobile app to improve health behaviors among preschool-aged children, based on the combined interview and concept mapping results. The first column depicts the topic areas of the overarching interview codes, the second column lists possible app content areas based on interview subcodes for parental priorities, and the third column lists possible app features based on interview subcodes along with the features rated as most desired in the concept mapping data, which are indicated in bold italics. By first understanding parental priorities, we ensured our resulting app content will be grounded in user-centered needs. In particular, parental feedback pointed to the need for a holistic app with a variety of health topics in one place, including a strong focus on food and nutrition, routines and time management, along with general parenting tips, each of which correspond to the clusters from the concept mapping process (Creating Healthy Eating Habits, Forming Boundaries, and Building Good Relationships). Informed by the concept mapping rating data, we gained information on ways to focus the development of our novel mobile app through the inclusion of quick, easy, and child-friendly recipes; grocery list or meal planning tools; goal tracking; helpful parenting tips; and the ability to control settings, such as notifications and recipe filters, to customize the experience for individual users. As a whole, exploring parental priorities and mobile app features in combination ensured our app development will be informed by both the desired content and functions that target users (parents with preschool children) would like to have.

Table 4. Summary of possible app content and features based on interview and concept mapping results (most desired features in italics).

Interview topic	Parental priorities: possible app content	Parental interests: possible app features

Food and nutrition	• Mealtime or eating behavior (eg, picky eating)
	• Making/planning healthy meals
		• *Quick, easy recipes*:
		  • Kid-friendly; cooking with kids
		  • Sort or filter ingredients; allergies
		• Grocery list or meal planning
		• Picky eating and child nutrition tips

Other health-related	• Limiting screen time • Dental health • Activities for children	• *Desire for multiple health topics in one place (holistic)* • Active play and activities for children tips • Features for parent and child
Routine and time management	• Time management/planning • Managing work responsibilities and parenting	• *Goal tracking* • *Ability to control settings* • Sleep (bedtime/nap) tracking • Ability to share success
Behavioral issues	• Discipline and rule setting • Sticking to boundaries • Reacting mindfully to behavior and patience • Influencing your child	• *General parenting tips* • Interaction with other parents or users • Account for other family members or parent
Developmental milestones	• Potty training • Improving speech • Socialization and interacting with others • Improving sensory development	• Developmental milestone tracking • Communication with health care provider

Discussion

Principal Results and Comparison With Prior Work

Concept mapping has been used on projects focused on childhood obesity prevention programs for adolescents [36] or for the development of culturally appropriate interventions [37], as well as for areas such as sugary drink consumption among children [38], food parenting practices [39], and overall childhood thriving [40]. To our knowledge, however, our study is the first application of the method to guide the development of a health behaviors app for parents of preschool-aged children. In this study, we used a novel, convergent mixed methods approach to identify parental child health priorities and mobile app features that parents or caregivers would prefer to use. Through the use of qualitative interviews, we were able to describe the breadth of parenting challenges and experiences the participants faced. With the addition of concept mapping activities, we were able to identify converging themes and assess priorities among the provided information.

Overall, the participants in this study indicated psychosocial health and general wellbeing, rather than specific behaviors, as their primary focus when expressing their interest in improving health among their preschool-aged children for mobile app content. Using previous research, 12 behavioral factors were identified related to childhood overweight and obesity that

XSL•FO
RenderX

parents identified when thinking about the health of their child [10,11]. Parent and caregiver responses in this study suggest the importance of establishing a routine and setting boundaries, particularly in areas such as screen time and sleep behaviors. Although healthy eating arose as the most desired topic for resources for young children, participants described a wide variety of preferences around meal planning, grocery shopping, and ways to improve food-related behaviors. Notably, our participants described the importance of all of the related areas identified in the previous literature as important app content to building healthy behaviors for preschool-aged children, including nutrition, physical activity, media use, and sleep.

For specific app features, parents indicated their top choices as (1) quick, easy, and child-friendly recipes; (2) goal-tracking features; and (3) the use of tips and notifications. Goal-setting has been a common behavior change feature used in mobile health applications for children in previous studies with techniques used such as rewards for making progress [18,41,42]. However, there has been a significant gap in that many of the mobile health applications do not feature the involvement of health professionals [18], and few apps exist with the intention of parents using them to modify their children's health behaviors [16,17,43]. In the recent review on goal-setting applications for parents and children, 9 applications were identified that allowed goal-tracking in the setting of health-related behaviors of children, with 6 focused on nutrition or mealtime, 5 focused on physical activity or screen time, 7 focused on sleep, and 6 focused on personal hygiene. None of the apps allowed a parent to specifically recommend goals for each child [17]. Furthermore, matching the divergent views about healthy eating strategies, our participants expressed diversity of thought on their potential use of meal planning or grocery shopping features, though many indicated they would use such features in an app. Additionally, participants expressed interest in tailoring the tips or notifications to a variety of use preferences. As with the health behaviors, our participants described a desire to have everything in one place, so they can find what they need quickly and easily depending on specific needs for their child.

Nutrition and facilitating family mealtimes and daily routines were clearly identified as priorities for this sample of parents and caregivers. The implications of the diverse needs, preferences, and priorities for child health described here may indicate that utility and engagement with mobile tools rest in the balance of simplicity with a choice of multiple features and content foci. Shopping, recipes, and cooking were central to the concerns expressed by these individuals. App features focused on recipes may be designed to incorporate multiple needs and priorities. For example, in order to support the "ease" of healthy meal preparation, provide a recipe feature that allows filtering by time to prepare, provide recipes that address different dietary requirements based on allergies or cultural preferences, or make a shopping list easy to create based on items needed for recipes. Given the preference for a one-stop mobile app, we anticipate that parents will be more engaged with apps that incorporate the whole child and provide behavioral, social, and psychological wellness resources as well.

Limitations

The study sample is representative of relatively lower income families who use public assistance programs; however, the sample included primarily non-Hispanic white and married participants whose perspectives may not represent those of other ethnicities or demographic groups. Future studies in this area should recruit and stratify participants of diverse backgrounds, including single parents and non-traditional family structures, to uncover differences in needs or desires. In addition, individuals choosing to participate in this type of study may be more engaged with parenting practices and improving their child's health than the general population, resulting in selection bias. The use of technology, such as Zoom, can also be a concern among this population; as such, we provided one-on-one assistance to ensure participants felt comfortable using the platform. Additionally, the study had a relatively small sample size, although appropriate for a qualitative approach. Likewise, the purpose of concept mapping is to identify consensus but is dependent upon the composition of the participant sample. Within the concept mapping data, high importance ratings with low variability are often seen, as items are included in the brainstorming list based on their potential importance; we experienced this issue in our data. However, by using multiple methods to triangulate our findings, we feel confident in the ability of our results to accurately capture the perceptions of parents of young children.

Conclusions

For our team, this formative research provided the groundwork for the development of a novel mobile app, including both content and features, for parents and caregivers of preschool-aged children focused on guided goal setting across the domains of diet, physical activity, media use, and sleep. A convergent mixed methods approach provided high-quality data on diverse parental perceptions and challenges and needs for families. Specific app features identified to meet family needs should be designed closely with a diverse set of families and tested using rigorous designs to identify the mechanisms of action that mobile apps may use for efficacious healthy parenting outcomes. This study makes important contributions to the mHealth field for understanding what parents or caregivers of young children want from mobile apps to support building healthy behaviors and routines. The findings can inform future research on the development and evaluation of existing or new mobile apps.

Acknowledgments

The authors would like to thank Caree McAfee and Jane Morgan for operational support of study implementation and thank Kentucky Cancer Program staff for distributing study advertisements in the community to promote the study (Angela Combs, Amy Oliver-Steinkhul, Wynona Padgett, Tonya Pauley, Mindy Rogers, Jeff Russell, Mary Jo Schneider, Ashley Teague, and

Abstract

Background: Digital mental health (dMH) interventions offer the ability to reach many more adolescents with anxiety than face-to-face therapy. While efficacious dMH interventions are available for adolescents, premature dropout and low engagement are common, especially if delivered on a self-help basis without any form of therapist guidance. This is concerning, given that higher engagement, in terms of the number of sessions completed, has been repeatedly associated with improved clinical outcomes. The reasons for poor adolescent engagement in dMH programs are unclear. A clear understanding of when and why disengagement occurs is important in order to seek to improve engagement rates. Contemporary models consider engagement as multifaceted, comprising both “use” (eg, amount of content completed, frequency of use, duration spent logged into the dMH program, and depth of use, such as word or character count) and “user experience” (eg, interest and satisfaction in the program and affect and attention whilst engaging in the program).

Objective: This study investigated the role of demographic and early engagement (EE) factors, specifically program use, in predicting overall program engagement and continued engagement, respectively, in a self-directed, internet-based cognitive behavioral therapy program for adolescent anxiety, namely, BRAVE Self-Help. It examined multiple measures of program use, including task completion, homework completion, and depth of response (character count of responses typed into program tasks). It also examined the moderating role of baseline anxiety severity.

Methods: Data collected between July 2014 and May 2020 from 2850 adolescents aged 12 to 18 years who participated in BRAVE Self-Help were analyzed via a series of moderated regressions.

Results: Results showed that EE (in terms of program use) was associated with continued engagement, demonstrated by early tasks (tasks completed in the first two sessions; R^2=0.035; P<.001) and early depth (characters written in the first two sessions; R^2=0.08; P<.001) predicting continued depth of program response (total character count of responses typed into all program tasks from sessions 3 to 10). Demographic factors and anxiety severity did not directly impact adolescents’ engagement in BRAVE Self-Help.

Conclusions: These findings highlight the need to investigate ways to (1) enhance EE and (2) better understand how to measure and capture all aspects of program engagement.

Introduction

Background

Approximately 6.5% of adolescents internationally experience anxiety [1]. Anxiety can become entrenched, lead to a lifelong struggle, and is linked to numerous other problems, such as reduced academic performance, poor self-esteem, social problems, substance abuse, depression, and attention and concentration difficulties [2,3]. Digital mental health (dMH) interventions are an effective treatment of choice for many adolescents with anxiety [4-6]. These digital interventions are highly accessible, flexible, affordable, require no waitlists, and reduce concerns about stigma [6].

While dMH interventions are highly accessible and efficacious, it is a concern that, when delivered on a self-directed basis without therapist support, many adolescents cease the program early or neglect to complete program activities [4]. For example, in a study on the dMH program, youthCOACH, which targets chronic medical conditions in youth aged 12 and 21 years using cognitive behavioral therapy (CBT), only 40% of adolescents adhered to the intervention (completed at least 80% of the seven modules) [7]. In another study on the BRAVE Self-Help program, an open-access CBT dMH program for child and adolescent anxiety, only 30% of the 4425 children and adolescents completed more than three sessions, with the greatest clinical improvements made by those users completing at least 6 of 10 sessions [4]. These findings are consistent with those of a recent systematic review and meta-analysis of 35 predominantly adult dMH interventions (both therapist-supported and self-help), which found that greater engagement was associated with stronger treatment gains [8]. Thus, those with lower engagement potentially fail to obtain the greatest clinical benefit.

Engagement in dMH Interventions

Gan et al [8] suggested that variability in the operationalization of engagement is a limitation of the dMH field, and defined engagement as any objective indicator of intervention use (eg, sessions completed, time spent, or number of logins). Indeed, a broader inspection of the literature reveals that dMH researchers have not applied a universal definition of the construct of engagement, and the term is frequently used interchangeably with “adherence,” “compliance,” and “use” [9,10]. To date, the majority of research has focused on the amount of the intervention completed, such as the number of completed treatment sessions or activities (eg, March et al [4], Calear et al [11], and Fleming et al [12]) to capture the use of dMH interventions. However, it is now widely acknowledged that engagement is multifaceted and incorporates more than just the number of sessions completed [4,13,14]. Two key reviews by Yardley et al [14] and Perski et al [15] suggest that engagement should be conceptualized as including both use and user experience. Use refers to the amount of intervention content completed (ie, completed sessions and activities), frequency of session completion, duration spent on intervention, and depth of responses (ie, character or word count). In contrast, user experience refers to subjective, self-reported experiences (ie, attention, interest, and satisfaction with the program), and affect experienced during the program [14,15]. The clinical validity and reliability of these constructs are not yet known; however, the frameworks proposed by Yardley et al [14] and Perski et al [15] provide a useful and comprehensive structure to guide research and advance our understanding and measurement of the numerous potential facets of engagement in dMH interventions.

Early Engagement

Given that higher program use (at least in terms of the number of sessions completed) has consistently been shown to be positively associated with treatment outcomes, but that many participants do not progress beyond a few sessions of dMH programs [8,16], it appears that understanding early engagement (EE) in the first few sessions could offer valuable insight and assist in identifying ways to enhance overall program completion. In a blended-care CBT intervention (combination of videoconference therapy sessions and personalized dMH activities), Wu et al [17] examined the predictors of program retention and found that engagement was poor if participants did not complete their assigned web-based activities early in treatment. Here, engagement was defined as the completion of both the first telehealth therapy session and assigned dMH activities after the session. In relation to self-help dMH programs, there is some research that has identified early “use” in dMH programs is related to program engagement, however, evidence is limited to engagement conceptualized as word count of activity responses [18]. For example, Wallert et al [18] found that writing more words in early dMH activities was related to higher rates of overall program adherence (completing three or more homework tasks). It is possible that greater effort or more in-depth use of content and tasks early in the program (better engagement) may facilitate interest, trigger symptom improvements, and sustained engagement over time. Given that more recent frameworks propose the conceptualization of engagement beyond the number of program sessions completed, there is a need to examine additional facets of engagement and determine whether different types of EE (eg, early completion of in-session and homework tasks, character count, subjective self-report measures, and affect experienced during the program) are important in facilitating program engagement in dMH interventions. This study focuses specifically on the program use component of engagement as it is typically routinely collected and operationalizes multiple measures of program use. It also focuses primarily on the role of EE as described above, and its relationship to overall engagement.

Factors Influencing dMH Engagement

Much of the existing literature has examined factors associated with dMH engagement in adult populations. In a review of 83 adult dMH programs, Liverpool et al [19] found that both intervention-specific influences (such as program suitability, usability, and acceptability) and person-specific influences (such as motivation, opportunity and time availability, family support, and capability) influenced user engagement. Borghouts et al [20] further highlighted that social connectedness, participants feeling “in control” of their health, and having insight into their concerns, were also facilitators of dMH program engagement. With respect to adolescent programs, a review of dMH programs

XSL•FO
RenderX

by Lehtimaki et al [21] found that female, those with lower baseline anxiety, and those with a longer history of mental health conditions were more likely to complete dMH interventions [21]. Similarly, March et al [4,16] found that male, those with higher baseline anxiety severity, and those living in nonmetropolitan regions showed lower levels of engagement (operationalized as the number of sessions completed) in a dMH program for anxiety. However, to date, there is very limited research specifically examining the individual facets of engagement (as suggested in the frameworks by Perski et al [15] and Yardley et al [14]) that predict program engagement with dMH interventions by adolescents.

Aims of This Research

This study examined the factors influencing program engagement, specifically, program use, in a dMH intervention for adolescent anxiety (BRAVE Self-Help). Extending on previous literature, engagement was conceptualized as being multifaceted. The first aim was to examine the effect of person-specific demographic factors (including gender, age, and residential location) on program engagement (sessions completed, in-session and homework tasks completed, depth (total character count), and average frequency (days) between sessions). The second aim was to examine the impact of EE on continued program engagement. EE was examined specifically in relation to program use, and conceptualized as the number of in-session tasks completed, homework tasks completed, and character count (depth of use), within the first two sessions of the program. In addition, previous research has found that participants completing a greater number of BRAVE sessions showed lower baseline anxiety severity [4] and were less likely to be classed in the high anxiety severity group when examining trajectories of change [16], suggesting that anxiety severity may be a relevant factor to consider. Therefore, this study further examined whether baseline anxiety severity moderated the relationship between demographic and EE factors and program engagement.

Methods

Participants and Procedure

Participants were 2850 adolescents aged between 12 and 17 years who had registered for the BRAVE Self-Help program between July 2014 and May 2020. In line with the intended audience of BRAVE Self-Help, only participants demonstrating baseline anxiety severity at an elevated or clinical level on the Children's Anxiety Scale 8-item (CAS-8; see below for details) [22] were included in this study. This study was restricted to adolescents who had completed at least 2 sessions of the program. This was in line with our conceptualization of EE in this study. To ensure adequate measurement of EE, data were required relating to in-session tasks completed (sessions 1 and 2), and between-session tasks (homework allocated in session 1 that was subsequently reported on in session 2). Thus, to provide a comprehensive indication of EE, we required data collected in sessions 1 and 2. Further, as per calls for research to more comprehensively examine engagement through multiple components (eg, Yardley et al [14] and Perski et al [15]), it was important to include 2 sessions in our definition of EE as many dMH programs focus only on introductory and education-based content in the first session (eg, March et al [16]) without the inclusion of many interactive activities. Therefore, examining only responses to session 1 would not allow sufficient examination of program use in the form of completed activities or use depth. Participants were excluded from the study if they were completing the program as part of a school curriculum or school-based intervention, in order to mitigate any other engagement strategies delivered to these participants (eg, mandatory attendance and homework completion and support or facilitation by a school professional).

Ethical Considerations

Participants were self-referred or referred by others (eg, general practitioners, school counselors, and other mental health practitioners) to the open-access BRAVE Self-Help program. No incentives were provided for participating in the program. Participants provided informed consent prior to commencing the program, and parental consent was also obtained if the adolescent was younger than 16 years of age. Informed consent was also provided for their data to be used in future research. All data analyzed were deidentified. During the registration process, participants provided demographic information (see below) and completed the CAS-8 [22]. This study was part of a larger, ongoing effectiveness study of BRAVE Self-Help (human research ethics approval: ETH2023-0832; University of Southern Queensland; 2020/581; Griffith University).

Intervention

This study used data extracted from BRAVE Self-Help for teenagers (aged 12 to 17 years), a dMH intervention for adolescents with anxiety [4]. BRAVE Self-Help is delivered in 10 web-based, interactive, weekly sessions of 30 to 60 minutes duration and includes cognitive-behavioral strategies such as psychoeducation, cognitive restructuring, physiological awareness, relaxation, graded exposure, problem-solving strategies, positive reinforcement, and guided imagery [23]. Homework tasks are allocated each week to consolidate and enhance learning from each session. Reminders to complete sessions are sent to participants via automated email. BRAVE Self-Help is completed without therapist support, and sessions can be completed at any time but must be completed in order. For a detailed description of the program, refer to March et al [4].

Measures

Demographics

Demographic information was measured at program registration and included age (years), gender, and location (postcode). Participants selected their gender from male, female, transgender, transsexual, transgender or transsexual, genderqueer, androgynous, or other. For analytic purposes, gender was recoded into male, female, and other. Those who identified their gender as "other" were excluded from analyses due to the small number of participants in this category (n=3). Location was coded according to the Australian Statistical Geography Standard [24] with participants categorized into: Major Cities, Inner Regional, Outer Regional, Remote, and Very Remote locations. For analytic purposes and due to the

XSL•FO
RenderX

small number of participants in Outer Regional, Remote, and Very Remote categories, the location was recoded into three categories: (1) Major Cities, (2) Inner Regional, and (3) Outer Regional and Remote.

Anxiety Severity

Anxiety symptom severity was measured at program registration through CAS-8 [22]. Respondents are required to rate on a 4-point scale from 0=Never to 3=Always, the frequency with which each item applies to them. Item responses are summed to produce a total anxiety symptom severity score between 0 and 24, with higher scores indicating greater anxiety symptom severity. CAS-8 scores above the 84th percentile (≥10 for male and ≥12 for female) were categorized as elevated, whilst scores above the 94th percentile (≥13 for male and ≥16 for female) were categorized as Clinical [22]. The CAS-8 has been shown to demonstrate high internal consistency (Cronbach α=0.89) [22]. The internal consistency of the CAS-8 in this study was good (Cronbach α=0.87).

Engagement

This study focused on engagement in terms of program use. A summary of all engagement measures and their operationalizations is provided in Table 1.

XSL•FO
RenderX

Table . Operationalizations of EE[a] and OE[b].

Variable	Definition	Method of measurement
EE		
Completed tasks in sessions 1 and 2 (early tasks)	Completed tasks were defined consistent with completed tasks for program engagement.	The total of the number of tasks completed in sessions 1 and 2, operationalized consistent with the program engagement definition for completed tasks, but for sessions 1 and 2 only.
Session 1 homework tasks completed (early homework)	Completed homework tasks were defined consistent with completed homework tasks for program engagement.	The number of session 1 homework tasks completed was measured, consistent with the definition for program engagement for homework tasks, but for sessions 1 and 2 only.
Depth of early responses (early depth)	Early depth was defined as the number of characters typed into free-text boxes in response to program activities.	The total number of characters included in free-text response boxes in sessions 1 and 2 was calculated. Homework tasks were not included.
OE		
Number of completed sessions (completed sessions)[c]	Adherence to prescribed program sessions.	The number of sessions completed.
Tasks completed (total tasks)[c]	Tasks were defined as an in-session activity or task embedded within the program, which required the participant to type in a textbox or respond to a question asked.	Total number of tasks completed throughout program. Each separate textbox or response activity was counted as one activity. Activities were defined as completed if the written response by the participant had a minimum of three characters. This was to reduce the probability of a participant filling in the textbox but not having engaged in the activity (ie, responding with an "x" or writing short answers). Each individual completed task was then computed to obtain the total number of tasks completed.
Overall homework tasks completed (total homework)[c]	Homework task completion was defined as a task embedded in the homework section of the session (as the start of the session), which required the participant to type in a textbox or respond to a question asked. Homework tasks were prescribed in the previous session and reported on in the following session.	The total number of homework tasks completed. Each separate textbox or response activity was counted as one activity. As with tasks completed, activities were defined as completed if the written response by the participant had a minimum of three characters.
Session frequency (frequency)[c]	Frequency was defined as how often a participant engages with the intervention.	The average number of days between each completed session.
Depth of responses (program depth)[c]	Program depth was defined as character count within program activities that required a written response. That is, the number of characters typed into free-text boxes.	Total number of characters typed into program activities. Homework tasks were not included. Character count was chosen (over word count) to minimize issues such as typing errors, and missing or additional spaces [25]. To compute the depth of responses, the total characters for each session was computed before averaging the total number of characters across completed sessions.

[a]EE: early engagement.

[b]OE: overall program engagement.

[c]These variables were measured across 10 sessions when demographic variables were the predictor of OE, but across sessions 3 to 10 when EE variables were the predictor of continued engagement.

Early Engagement

EE was defined as engagement within the first 2 sessions of the program. Similar to the operationalization of engagement by Wu et al [17] , EE in this study was defined as the number of tasks completed in sessions 1 and 2, the number of session 1 homework tasks completed (data collected in session 2), and depth of responses (character count) in sessions 1 and 2. Because homework tasks allocated in session 1 are completed between sessions and reported in session 2, it was essential that this study included session 2 in its conceptualization of EE.

Program Engagement

Program engagement was operationalized as both overall program engagement (OE) and continued engagement (CE). OE was measured through the total number of program sessions completed, total number of program tasks completed, total number of homework tasks completed, total engagement depth

XSL•FO
RenderX

(character count of responses typed into any program tasks), and average frequency of sessions (average days between sessions). CE was defined as engagement after session 2 (ie, the number of in-session and homework tasks, sessions completed, and depth of engagement from sessions 3 to 10 only). The number of prescribed tasks and homework tasks per session is detailed in Multimedia Appendix 1.

Analytic Strategy

Data were analyzed using SPSS Statistics (version 27; IBM Corp). EE and OE were computed from raw program output data and are described in Table 1 and reported in Table 2 for the total sample, elevated, and clinical subgroups. Differences between the elevated and clinical groups for overall and early program engagement were analyzed using Cohen *d*.

Table . Summary of participant demographic and clinical factors across baseline anxiety status.

Variable	Elevated anxiety (n=915, 32.11%)	Clinical anxiety (n=1935, 67.89%)	Total participants (n=2850)	*t* test (*df*)[a]	Cohen *d*[a]	Chi-square (*df*)[a]	*P* value[a]

[a]Ratio of difference, effect size (Cohen *d* and chi-square), degrees of freedom, and significance between the elevated and clinical group at baseline.

[b]Not applicable.

[c]332 participants did not disclose their residing location.

[d]Aboriginal and Torres Strait Islander data were not collected until August 27, 2018.

[e]Children's Anxiety Scale 8-item.

For the first research question, 15 separate moderated regression analyses were conducted to examine whether baseline demographic factors predicted OE (one moderated regression per predictor and dependent variable) and whether baseline anxiety severity moderated these relationships. Demographic factors (age, gender, and location) acted as the independent variables, whilst total completed sessions, total tasks completed, total homework tasks completed, depth of responses, and frequency of session completion acted as the (OE) dependent variables.

For the second research question, 15 separate moderated regression analyses were conducted to examine whether EE factors predicted CE (one moderated regression per predictor and dependent variable), and whether baseline anxiety severity moderated these relationships. Early tasks, early depth, and early homework acted as the independent variables. The dependent CE variables were completed sessions, total tasks completed, total homework tasks completed, depth of responses, and frequency of session completion.

Anxiety severity acted as the moderator variable, with participants categorized as either elevated or clinical. Regression

XSL•FO
RenderX

analyses were conducted separately for each predictor, given that previous research has shown certain demographic factors may contribute more to overall engagement than others [4,21] and models suggest that the multifaceted nature of engagement needs to be further understood [14,15]. As we were interested in understanding which EE factors had the strongest effects in predicting CE, we conducted separate rather than multivariate regression analyses. Given the large number of regression analyses conducted, a conservative Bonferroni correction of $P<.001$ was applied for all analyses.

Results

Demographic and Clinical Characteristics of Participants

A summary of participant baseline demographic and clinical characteristics across anxiety status is provided in Table 2.

EE, CE, and OE Characteristics

As seen in Table 3, adolescents in the elevated group demonstrated significantly greater OE than those in the clinical group, as measured by total homework, program depth, and early depth. Adolescents in the elevated group also had a significantly higher frequency (days between sessions) than those in the clinical group, which may suggest that these adolescents may be completing the program more in line with program frequency recommendations (sessions should be 5 to 7 days apart).

Table . Summary of OE[a], CE[b], and EE[c] characteristics.

Correlations Among Demographic Factors, OE, CE, and EE

Before completing moderated regressions, correlations were analyzed between all predictor and outcome variables, which are presented in Multimedia Appendix 2. Of the relationships of interest, greater age was significantly correlated with higher completed sessions, frequency, total homework, total tasks, and severity. Female gender was strongly associated with greater completed sessions and program depth. In relation to EE predictors, there was a significant correlation between higher early tasks and greater program depth, total homework, frequency, and total tasks. Greater early depth was also significantly positively associated with total homework, completed sessions, total tasks, and average frequency. Higher early homework was significantly and positively associated with program depth, total homework, total tasks, and frequency. Finally, lower anxiety severity was significantly correlated with greater program depth (CE), average frequency (CE), and program depth (OE).

Demographic Factors Associated With OE

Overview

The results of the moderated regression analyses examining whether demographic variables predicted OE, and if these relationships were moderated by anxiety severity, are presented in Tables S1-S5 in Multimedia Appendix 3.

Completed Sessions (OE)

The overall regression models were significant for gender (R^2=0.006; P<.001), but not for age (R^2=0.004; P=.01), and location (R^2=0.010; P=.01). Despite the overall model being significant, as shown in Table S1 in Multimedia Appendix 3, there were no significant unique effects for gender or interaction effects in predicting completed sessions (overall).

Total Tasks (OE)

The overall regression models were significant for age (R^2=0.007; P<.001), but not for gender (R^2=0.002; P=.*12*) or location (R^2=0.007; P=.05). There were no significant unique effects for age or interaction effects (Table S2 in Multimedia Appendix 3).

Program Depth (OE)

The overall regression models for age (R^2=0.003; P=.20), gender (R^2=0.000; P=.60), and location (R^2=0.004; P=.32) were not significant in predicting program depth (overall), nor were there any significant interactions (Table S3 in Multimedia Appendix 3).

Frequency (OE)

The overall regression models were significant for age (R^2=0.079; P<.001), but not for gender (R^2=0.003; P=.02) or location (R^2=0.005; P=.02). There was no significant unique effect for age and no significant interaction effects observed (Table S4 in Multimedia Appendix 3). Whilst not significant at the Bonferroni level, there was a trend observed for the effect of severity in the regression model testing gender as the independent variable. There was a negative relationship between severity and frequency (overall), r_{2188}=–0.082; P<.001, with higher levels of anxiety related to fewer days between sessions.

Total Homework (OE)

The overall models were not significant for age (R^2=0.004; P=.11), gender (R^2=0.002; P=.15), or location (R^2=0.004; P=.23), nor were there any significant interaction effects (Table S5 in Multimedia Appendix 3).

EE Factors Associated With CE

Outcomes from moderated regressions were conducted to determine whether EE variables predicted CE, and if these relationships were moderated by anxiety severity.

Completed Sessions (CE)

The overall regression models were significant for early depth (R^2=0.011; P<.001), but not for early tasks (R^2=0.004; P=.10) or early homework (R^2=0.004; P=.09). Despite the overall model being significant (Table S1 in Multimedia Appendix 4), there were no unique effects for early depth and no significant interaction effects across any of the regression models.

Total Tasks (CE)

The overall regression models were significant for early homework (R^2=0.236; P<.001), early tasks (R^2=0.310; P<.001), and early depth (R^2=0.166; P<.001) in predicting total tasks (CE). However, there were no significant unique effects or interactions at the conservative Bonferroni level, as shown in Table 4, though there were effects evident using a traditional P<.05 cut-off. Specifically, a trend was evident (P<.05) for a positive relationship between early homework and CE total tasks (r_{2850}=0.481; P<.001), with greater homework tasks completed in sessions 1 and 2 related to greater overall task completion. This was also the case for early tasks and CE total tasks (r_{2850}=0.555; P<.001), where greater tasks in the first 2 sessions were associated with greater CE tasks completed and between early depth and CE total tasks (r_{2850}=0.405; P<.001), with more characters written in the first two sessions being associated with more total CE tasks completed.

Early depth severity[c]	–.01	0.01	–0.60	.56	–0.04 to 02

[a]EE: early engagement.

[b]CE: continued engagement.

[c]Severity refers to baseline anxiety severity.

Program Depth (CE)

The overall regression models were significant for early tasks (R^2=0.035; P<.001), early homework (R^2=0.03; P<.001), and early depth (R^2=0.08; P<.001) in predicting program depth CE. As shown in Table 5, there was a significant unique positive effect for early tasks and early depth. CE program depth increased by 24.84 characters with each early task completed, explaining 3.5% of the variance in CE program depth. CE program depth also increased by 0.85 characters for each early depth increase of one character, accounting for 7.9% of the variance in CE program depth. Whilst not significant at the conservative Bonferroni significance level, there was a positive trend (P<.05) evident between early homework and CE program depth, r_{2850}=0.154; P<.001, with CE program depth increasing as early homework tasks increased. No significant interactions were found in any of the regression models predicting CE program depth.

Table . Linear model of EE[a] variables predicting program depth (CE[b]) as a function of anxiety severity.

EE predictors	β	Standard β coefficient	Individual regression coefficient (t)	*P* value	95% CI
Early tasks					
Constant	14.11	276.45	0.05	.96	–527.96 to 556.17
Early tasks	24.94	7.97	3.13	<.001	9.31 to 40.57
Severity	6.08	156.73	0.04	.97	–301.24 to 313.39
Early tasks severity[c]	–2.94	4.52	–0.65	.52	–11.80 to 5.92
Early homework					
Constant	264.36	216.70	1.22	.22	–160.53 to 689.25
Early homework	27.52	9.62	2.86	<.001	8.65 to 46.30
Severity	–11.54	123.25	–0.09	.93	–253.22 to 230.14
Early homework severity[c]	–3.85	5.47	–0.70	.48	–14.57 to 6.87
Early depth					
Constant	356.40	111.55	3.20	<.001	10.80 to 12.62
Early depth	.85	0.17	5.00	<.001	0.52 to 1.18
Severity	–28	63.80	–0.44	.66	–153.11 to 97.11
Early depth severity[c]	–.08	0.10	–0.87	.39	–0.277 to 0.108

[a]EE: early engagement.

[b]CE: continued engagement.

[c]Severity refers to baseline anxiety severity.

Frequency (CE)

The overall models were significant for early tasks (R^2=0.014; P<.001), early homework (R^2=0.013; P<.001), and early depth (R^2=0.015; P<.001) predicting CE frequency. However, no significant unique effects for early tasks, early homework, or early depth were found at the Bonferroni-adjusted level, nor were there any interaction effects (Table S2 in Multimedia Appendix 4). Although, in the regression model for early depth predicting CE frequency, there was a trend for a negative relationship between anxiety severity and CE frequency (r_{2188}=–0.082; P<.001), with days between sessions being fewer for those with higher baseline levels of anxiety.

Total Homework (CE)

The overall regression models were significant for early homework (R^2=0.215; P<.001), early tasks (R^2=0.244; P<.001), and early depth (R^2=0.094; P=.001) in predicting CE total homework. However, there were no significant unique or interaction effects in any of the models (Table S3 in Multimedia Appendix 4).

Discussion

Principal Findings

This study analyzed the relationship between demographic and EE factors, and OE and CE, respectively, and assessed whether such relationships were moderated by baseline anxiety severity in a dMH self-help intervention for adolescent anxiety, BRAVE Self-Help. Importantly, this study examined the utility of conceptualizing engagement, specifically, program use, in multiple ways to better understand engagement in dMH interventions. Overall, the results highlighted that a higher level of EE in the first two sessions was associated with greater CE (intervention-specific factor). This was evident specifically when predicting CE program depth (characters written), but a trend was also observed for CE tasks completed. That is, early depth of program use (characters written in the first two sessions) and early tasks completed in the first two sessions were associated with greater CE in terms of program tasks and depth of responses. In addition, there were bivariate associations between multiple EE and CE variables, suggesting a clear relationship.

Additionally, contrary to expectations, the study failed to demonstrate that anxiety severity impacts engagement either directly or indirectly for most indicators of engagement, although a higher baseline level of anxiety was associated with fewer average days between sessions (frequency). This may suggest that adolescents with more severe anxiety are eager to seek further assistance and see improvements in their anxiety. Although the impact of anxiety severity on engagement was inconsistent in this study, previous research has found that higher anxiety severity is related to poorer program engagement for adolescents in dMH programs [4,16,20,21]. Variations in the way in which engagement has been measured across studies may account for the difference in findings in this study.

XSL•FO
RenderX

Importantly, person-specific demographic factors (age, gender, and location) showed little relevance in predicting program engagement in this study. Previous studies have reported mixed findings with respect to the impact of demographic variables on engagement in dMH programs [4,16,21]. Further research in relation to the relevance of person-specific factors in predicting program engagement should be undertaken once engagement can be measured more holistically.

EE Appears Important

The intervention-specific finding that EE was generally associated with CE is not surprising, yet an important research finding. Whilst previous research has identified that program engagement is associated with positive clinical outcomes [4,8], this study shows that engaging well early in the program, specifically early program use, is specifically associated with greater CE. Although the effects were small, our findings highlight that there is a need to identify ways to meaningfully engage adolescents in both in-session and homework tasks in the first two sessions of the program, to increase program engagement, and ultimately, the benefits obtained from dMH interventions.

There are few studies that have identified that EE, in terms of use, is important in predicting program engagement, but these studies did not capture the full breadth of engagement (ie, as proposed by Perski et al [15]) and were blended-care or therapist-supported interventions, rather than self-help. In a blended-care CBT intervention for adults with anxiety and depression, where participants had both face-to-face video therapy and digital activities (eg, thought monitoring and mood diaries), participants were around 10 times more likely to withdraw from the intervention if they had not completed the assigned dMH activities after the first session [17]. However, unlike this study, Wu et al [17] defined engagement purely as the number of sessions and web-based activities completed. Another study by Wallert et al [18] demonstrated the importance of early use factors in a therapist-supported dMH program, however, that was limited to early word count and homework tasks only. The study by Wu et al [17] found that higher word count in the first homework tasks was associated with greater adherence (measured in terms of completed homework activities). Interestingly, EE factors included in this study were not associated with completed sessions, but rather, what adolescents did in the program (ie, the amount of in-session and homework activities and character count). This may reflect that participants get what they want or need, without having to complete the entire program (ie, symptom relief or education about anxiety). Alternatively, these findings may suggest that we have not adequately measured all aspects of engagement that relate to treatment outcomes. These results are consistent with findings by both Alberts et al [26] and Yardley et al [14] who found that program engagement may not necessarily predict clinical outcomes. Overall, this study's findings emphasize the importance of understanding more about EE, its relationship to program completion and outcomes, and the strategies to enhance it.

Defining Engagement

Contemporary models of engagement highlight the need to consider both user experience and use [14,15]. This study, whilst meaningful in highlighting the importance of EE (program use) in dMH programs for adolescents, did not capture all facets of engagement (eg, user experience), which may explain the small effect sizes found. There is a large variation in the way in which engagement is defined and measured across dMH programs [12], and engagement has not often been measured holistically. This study primarily focused on the use aspects of engagement rather than the experiential or affective elements. The assessment of user experience would allow the opportunity for a more nuanced understanding of engagement, where participants' own subjective experience of the program is measured [14,15]. For example, this could include self-report questionnaires or interviews on engagement and experience with the program, or examination of the content and quality of activity responses rather than just character count [15], which may allow a richer understanding of the factors predicting OE, reasons for disengagement, and inform the development or refinement of dMH programs to achieve higher levels of engagement.

Strengths and Limitations

This study holds several strengths. First, the study had a large sample size of adolescents taking part in a real-world effectiveness study. The study further explored novel predictive factors of engagement in dMH programs, filling a significant gap in the literature regarding our understanding of adolescent engagement, particularly adolescent use, in these programs. The results were also analyzed using both a conservative and traditional significance level, adding merit to our findings. Despite its strengths, there were some limitations inherent to the study. First, this study did not consider the predictors of people who fail to take up BRAVE Self-Help, for example, factors at registration, or in the first session, such as participant perceptions of the content being valuable and helpful, time available to complete the program, and beliefs about the need for treatment. These were not the focus of this study; however, they should be the focus of future research, with specific adaptations to collect data of this nature. Furthermore, while this study considered engagement as multifaceted, the components of engagement analyzed in this study were limited to the available data that has been routinely collected within the BRAVE Self-Help platform, and thus, not all components of engagement as suggested in the engagement models of Perski et al [15] and Yardley et al [14] could be examined. Specifically, this study focused on understanding multiple measures of program use, but did not address user experience, which should be analyzed in future research. Further, whilst this study did examine the role of anxiety severity in influencing engagement, it did not examine whether changes in anxiety experienced beyond EE and over the course of treatment, had additional influence on OE. It is possible that as anxiety symptoms reduce, participants would be more or less likely to continue to engage in the program, and this should be examined in future research. Finally, whilst not possible to include all potential psychosocial factors in this study and analysis, engagement may have been influenced by other factors, such as satisfaction with the

XSL•FO
RenderX

program, personality, socioeconomic status, and previous exposure to treatment.

Future Directions

This study highlights the need to better understand how to measure the construct of engagement and investigate the role of EE in supporting OE. It is recognized that facets of engagement may overlap and be interrelated (eg, completed tasks and completed sessions), and therefore, conducting a factor analysis may be useful in identifying whether these variables are discrete, and may assist in the empirical validation of proposed engagement models such as that of Perski et al [15] and Yardley et al [14]. Additionally, analysis of predictors of further potential facets of engagement, such as user experience as proposed by Perski et al [15] (including interest in the program and attention sustained within the program, affect, and satisfaction) will be useful in more broadly understanding the construct of engagement and its relationship to EE, anxiety severity, and outcome. Subsequent studies may also consider the use of digital linguistic tools, which may be useful in providing more information about whether sentiment and affect relate to engagement. Future research should also seek to understand how to enhance EE. This could be achieved through qualitative research with adolescents themselves, to better understand the unique needs of the user, and gain a detailed, nuanced account of how to enhance EE. Adding to our understanding will allow for dMH programs to be refined, tailored, and developed with such findings in mind. Taken together, the application of the findings of this study could improve engagement, and ultimately, potential clinical outcomes for adolescents with anxiety.

Conclusions

To date, there has been little research investigating the factors influencing engagement in dMH interventions for adolescents. The intervention-specific factor of poor EE, in terms of early program use, was found to be a barrier to CE in this study. Understanding how to better operationalize and measure engagement, along with identifying areas of focus to enhance EE, will help refine adolescent dMH interventions and aid in the design and development of future interventions. By doing so, user engagement can be enhanced and the benefit to the user of the program can be maximized.

Abstract

Background: Adolescence is a critical transitional period between childhood and adulthood, marked by dramatic changes in physical and psychosocial health. Adolescents are vulnerable to both depression and adiposity, but how these conditions evolve over time from adolescence to early adulthood and whether sex differences exist remains unclear.

Objective: This study aims to first identify the population heterogeneity in the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood and then explore the sex differences in the joint trajectories.

Methods: In this study, we adopt the latent class trajectory modeling to identify the combined trajectories of depressive symptoms and BMI from adolescence at baseline to early adulthood at follow-ups using a longitudinal study (2010-2020). We used the multinomial logistic regressions to examine the sex-specific associations with the trajectory classifications.

Results: Our results found that individuals' depressive symptoms and BMI might not always change parallelly from adolescence to early adulthood. Instead, some individuals appeared to be prone to depressive symptoms or elevated BMI, while others were multimorbid with both of them. Moreover, our study identified a clear sex-specific pattern in the joint trajectories of depressive symptoms and BMI: the females were at a higher risk of developing depressive symptoms but remained relatively stable weight status over time (odds ratio [OR] 0.68, 95% CI 0.52-0.89), while the males were at a lower risk of developing depressive symptoms but with an increasing risk of developing adiposity over time (OR 1.83, 95% CI 1.35-2.49).

Conclusions: Depressive symptoms and BMI might not always change in parallel from adolescence to early adulthood, and there is a clear sex-specific pattern in the joint trajectories of depressive symptoms and BMI. This will inform the design of future sex-specific interventions that match the distinguished profiles in male and female participants during the period of adolescence and early adulthood, respectively, thus maximizing the intervention effects in preventing both depression and adiposity in early life.

Introduction

Adolescence and early adulthood are critical periods transforming from childhood to adulthood with dramatic changes in physical and psychosocial health [1,2]. The health condition during adolescence and early adulthood not only lays a solid healthy foundation for the following life course but also sustains long-term health effects to the next life cycle (ie, intergenerational transmission). Indeed, many adult-prevalent, noncommunicable diseases, such as depression [3] and adiposity [4], start in adolescence or early adulthood. Globally, the prevalence of elevated depressive symptoms and obesity among adolescents has risen rapidly in recent decades [5,6] from 24% to 37% [7] and from 0.7% to 5.6% [8], respectively. Early adulthood is also crucial for both brain development and obesity prevention [9,10].

Multimorbidity refers to the coexistence of 2 or more long-term health conditions or diseases in an individual. Focusing on multimorbidity is critical, as targeting each health condition or disease in isolation can be ineffective and inefficient. To illustrate, if an intervention only focused on obesity by providing behavior change techniques to improve diet or physical activity behaviors, it would have neglected to provide emotional support for the vulnerable individuals, leaving them exposed to the potential adverse intervention effects such as body image dissatisfaction, low self-esteem, or even eating disorders [11]; by contrast, if an intervention targeted both depression and comorbid adiposity, it could combine elements of psychotherapy (eg, cognitive behavioral interventions) with healthy lifestyle enhancement, comprehensively covering both the physical and psychological health of intervention recipients [12].

To locate the time window when the multimorbidity interventions come in, it is important to clarify the longitudinal trends in depression and adiposity over time. For example, individuals with obesity at both age 13 and afterward had significantly higher risks of developing diabetes mellitus in adulthood, compared to those with obesity only at age 13 [13]. Another study pointed out that the trajectory of depressive symptoms over 10 years, rather than the one time point, had important health effects [14]. However, most existing studies typically assessed depression and adiposity cross-sectionally at one time point [15,16] but failed to capture their changes over time.

Researchers have called for breaking through the bottleneck of the “one-size-fits-all” intervention approach. One way to develop targeted interventions is to explore the sex-specific patterns of the coexistence of depression and adiposity [17]. Indeed, epidemiological studies have shown a higher risk of depression in females than males [18-21], while a higher risk of adiposity in males than females [22,23]. These findings might be attributable to the sex differences in individual- and family-level factors [17,24-27].

It is important to uncover the population heterogeneity in the longitudinal trends of depression and adiposity over time and to further explore whether the sex differences exist. Findings from such research could equip us to develop personalized, sex-specific interventions that consider the individual differences in the risk profile over time: depression alone, adiposity alone, or depression and adiposity simultaneously. For these reasons, we aimed to first identify the population heterogeneity in the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood and then explore the sex differences in the joint trajectories.

Methods

Data Source and Study Population

The data source of this study was the China Family Panel Studies (CFPS), a nationally representative survey conducted by Peking University [28]. CFPS was first launched in 2010 with 5 subsequent rounds of surveys conducted in 2012, 2014, 2016, 2018, and 2020. The target sample of CFPS represents 95% of the population in China. Specifically, CFPS used a multistage probability-proportional-to-size sampling method and randomly sampled 640 communities nested within 144 counties from 24 provinces and 32 townships in Shanghai. Survey participants included all economically connected household members. CFPS has collected rich data at the individual, family, and community levels [28]. In this study, we included adolescents aged 10 - 19 years without overweight 25 or depressive symptoms 26 at baseline, while some of them would enter the period of early adulthood during the 10-year follow-up surveys. To be eligible, participants should also have at least 2 measurements of BMI, BMI (kg/m^2)=weight (kg)/(height [m])^2 and at least 2 measurements of depressive symptoms available between 2010 and 2020.

Sex

The exposure variable of this study was the sex of the adolescents, referring to the differences in biological aspects between males and females.

Outcome Variables

Depressive Symptoms

Depressive symptoms were measured using the 20- or 8-item Center for Epidemiologic Studies Depression Scale (CES-D) during the 4 rounds (2012, 2016, 2018, and 2020) of surveys from 2012 to 2020. The CES-D has been validated and widely used to screen for depressive symptoms globally and in China [29-32]. To ensure comparability of outcomes measured by the 20- or 8-item CES-D, we converted the outcomes derived from the 8-item CES-D to the corresponding values measured by the 20-item CES-D based on the equipercentile equating method. We also calculated the *z* score of depressive symptoms: (score–mean score)/the SD of the scores.

BMI

Participants self-reported their height and weight in the CFPS questionnaires during the 6 rounds of surveys: 2010, 2012, 2014, 2016, 2018, and 2020. Studies have indicated that self-reporting data of height and weight are often highly correlated with the corresponding measurement data [33,34]. CFPS had very strict and standard criteria to control the quality of self-reporting data (Multimedia Appendix 1). Moreover, considering that the height and weight data of adolescents aged 10 to 15 were obtained

XSL•FO
RenderX

from both the adolescents and their parents, we have comprehensively considered these data as follows: (1) when adolescents' self-reported data and parents' proxy-reported data were both available, we prioritized the adolescents' self-reported responses as the primary data source. Meanwhile, we compared the data from those 2 sources and found that there was almost no difference. (2) For participants with only one available data source (either adolescents' self-report or parents' proxy report), the existing responses were retained for analysis. We then calculated the BMI *z* score to classify adolescents' weight status relative to their age and sex based on the World Health Organization standard [35]. That is, a BMI *z* score higher than zero means that adolescents' weight status was above the average weight status among those of the same age and sex. According to the World Health Organization standard [35], we defined adolescents with a BMI *z* score range of –2 to 1 as normal weight.

Covariates

We identified covariates based on our literature review and domain knowledge for the present topic [18,36-38]. We grouped the covariates into 2 classifications: the individual- and family-level covariates. The individual-level covariates included age (old or young), area (urban or rural), region (western or central or eastern), high birth weight (yes or no), preterm birth (yes or no), and the only child (yes or no) at baseline. The family-level covariates include parents' education level (college or above, or high school or below), whether the parents were obese or not, whether the parents were depressive or not, per capita household net income (high or low), left-behind children (yes or no), and primary caregiver (parents or other) at baseline.

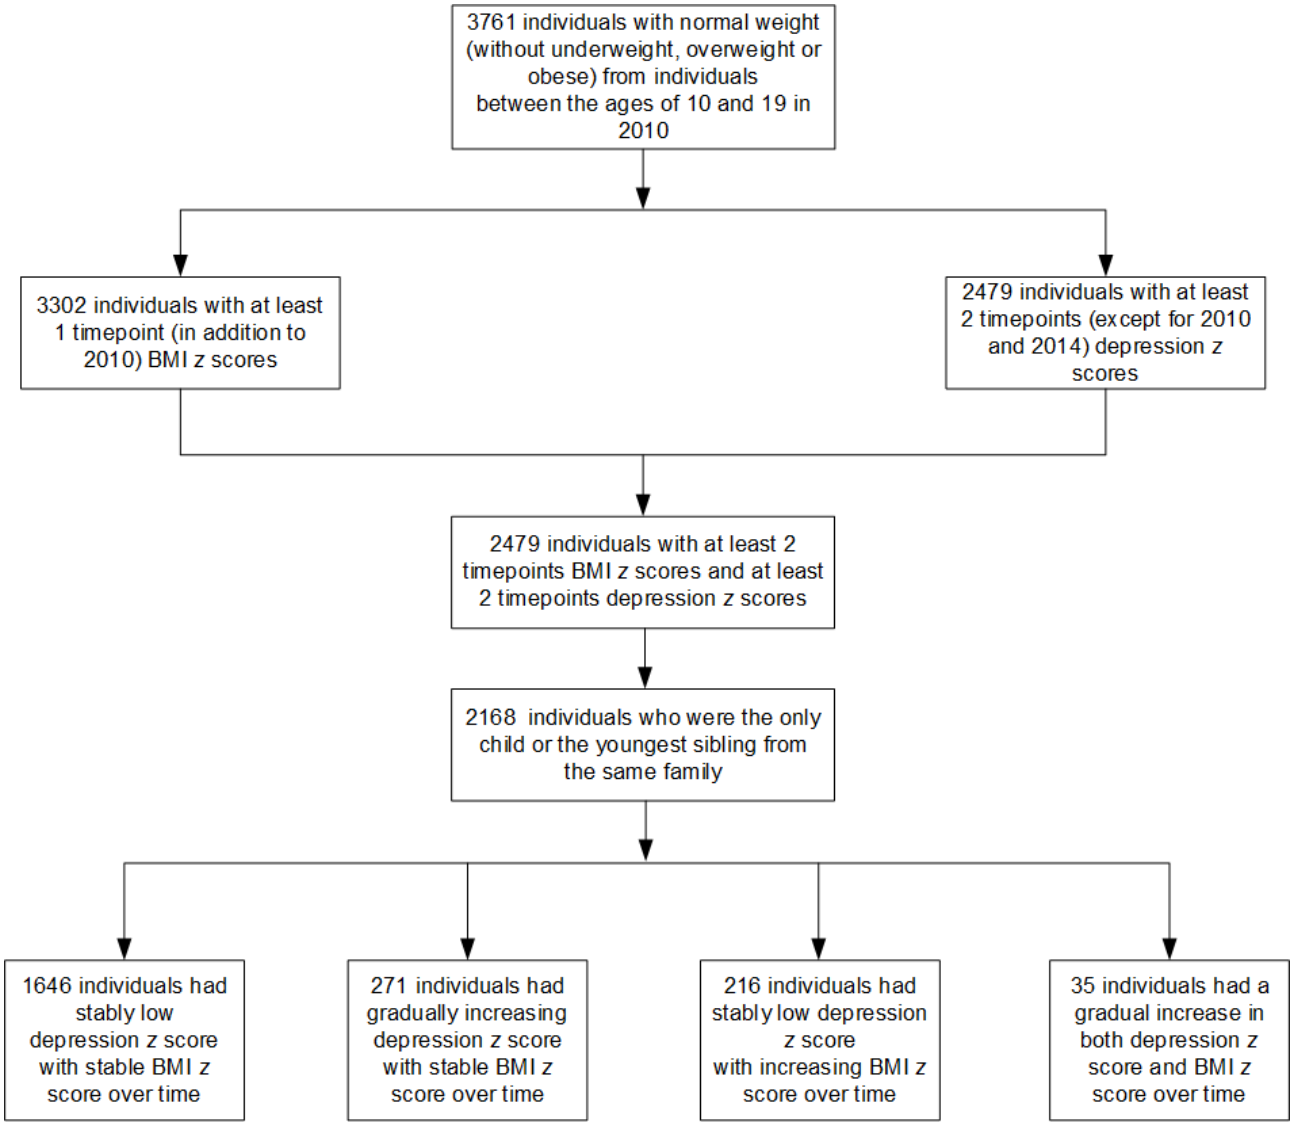
Statistical Analyses

First, we adopted the latent class trajectory modeling to identify the combined trajectories of depressive symptoms and BMI and classified the participants into heterogeneous groups [39,40]. To decide the suitable number of trajectories, we comprehensively considered multiple parameters such as the average of maximum probabilities, odds of correct classification, and so on (Tables S1 and S2 in Multimedia Appendix 2). We also validated the identified trajectories by analyzing their associations with subjective well-being and physical activity (Tables S3 and S4 in Multimedia Appendix 2).

Second, we used the multinomial logistic regression models to examine the association of sex with the participants' classifications. We used 3 models to ensure the robustness of the study findings. In Model 1, we analyzed the crude association without covariates; in Model 2, we analyzed the association with the individual-level covariates only, including age, area, region, high birth weight, prematurity, and being the only child; in Model 3, we analyzed the association with both the individual- and family-level covariates, including age, area, region, high birth weight, prematurity, being the only child, father's and mother's education, obese status of father and mother, depression status of father and mother, per capita household net income, left-behind children, and primary caregiver. We also conducted sensitivity analyses by (1) using multiple imputations by chained equations [41] to account for the missing values of covariates; (2) using the Chinese criteria to define wasting [42], overweight, or obesity [43] in adolescents; (3) using the data from the 5 rounds of surveys: 2010, 2012, 2014, 2016, and 2018, excluding the data from 2020 (during the COVID-19 pandemic); (4) identifying the combined trajectories of depressive symptoms and BMI among males and females, respectively. All statistical analyses were performed with R (version 4.4.2; R Core Team). "LCTMtools" [39] and "mice" packages were used for trajectory analyses and multiple imputations, respectively. Statistical significance was determined by a 2-sided $P<.05$.

Ethical Considerations

This cohort study was conducted based on the guidelines for reporting observational studies: the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement [44]. This study was ethically approved by the Peking University Institutional Review Board (IRB00001052-22091, IRB00001052-14010). The data used for this study were deidentified. For each completed individual questionnaire, respondents were compensated—either in cash or as phone credit—at an average value of approximately US $6, with the exact amount varying by region and survey mode.



Results

Study population

Figure 1 shows the flowchart of the selection process of the study population. Among 3761 adolescents (aged 10 - 19 years) with normal weight in 2010, 2479 individuals had at least 2 time points of measurement of depression as well as 2 time points of measurement of BMI from 2010 to 2020. Finally, we included 2168 individuals who were the only child or the youngest sibling from the same family to meet the requirement of statistical modeling for independence between individuals. The characteristics between the included 2168 individuals and the excluded 1593 individuals were broadly comparable (Table S5 in Multimedia Appendix 2).

RenderX

Figure 1. Selection of study population based on World Health Organization standards of BMI *z* score.

Description of the Joint Trajectories of Depressive Symptoms and BMI

Figures 2 and 3 show the trajectories of depressive symptoms and BMI *z* score over time, respectively. The study participants were classified into 4 types of joint trajectories of depressive symptoms and BMI: (1) “health-sustaining group” represented by stably low depression *z* score with stable BMI *z* score over time (1646/2168 individuals, 75.92%); (2) “depression-dominant group” characterized by gradually increasing depression *z* score with stable BMI *z* score over time (271/2168 individuals, 12.50%); (3) “adiposity-dominant group” marked with stably low depression *z* score with increasing BMI *z* score over time (216/2168 individuals, 9.96%); (4) “multimorbidity group” with gradual increase in both depression *z* score and BMI *z* score over time (35/2168 individuals, 1.61%).

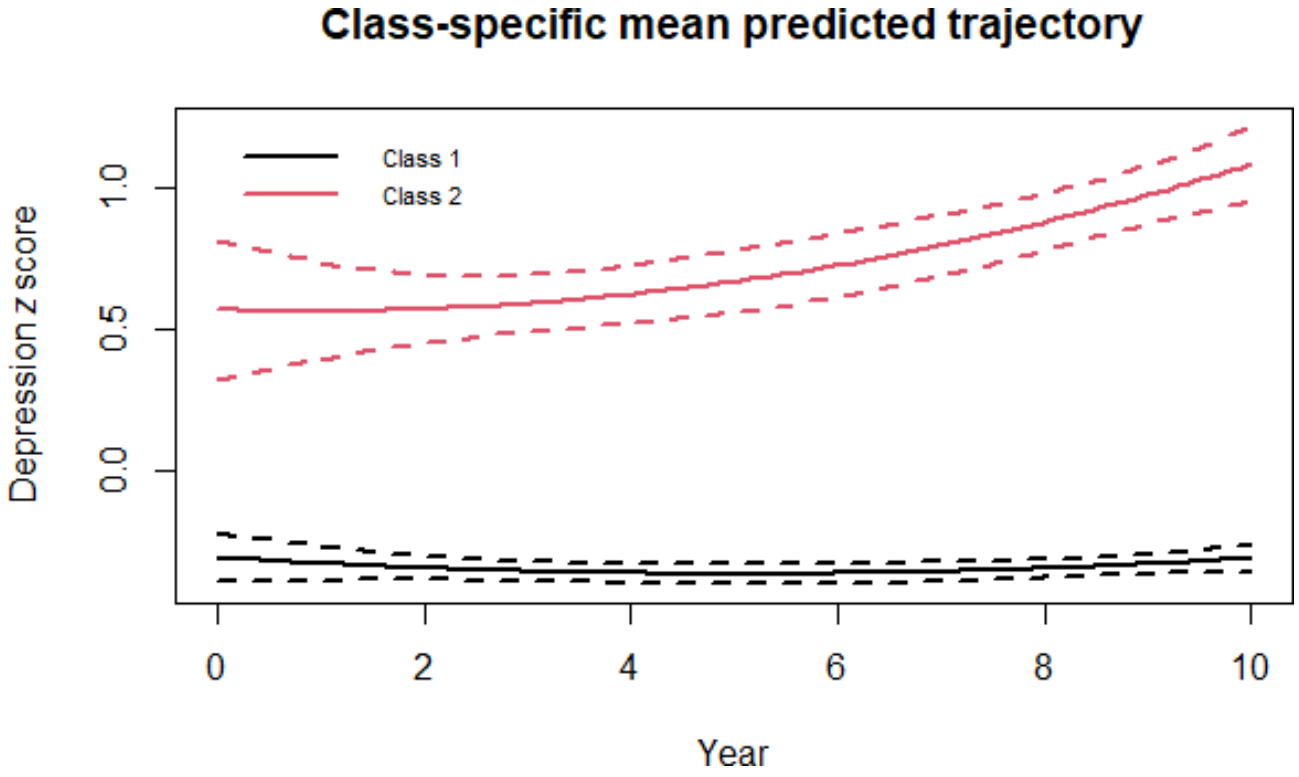
Figure 2. Classification of depression z score trajectory among individuals selected based on the World Health Organization standards Class 1: 1862 individuals; Class 2: 306 individuals.



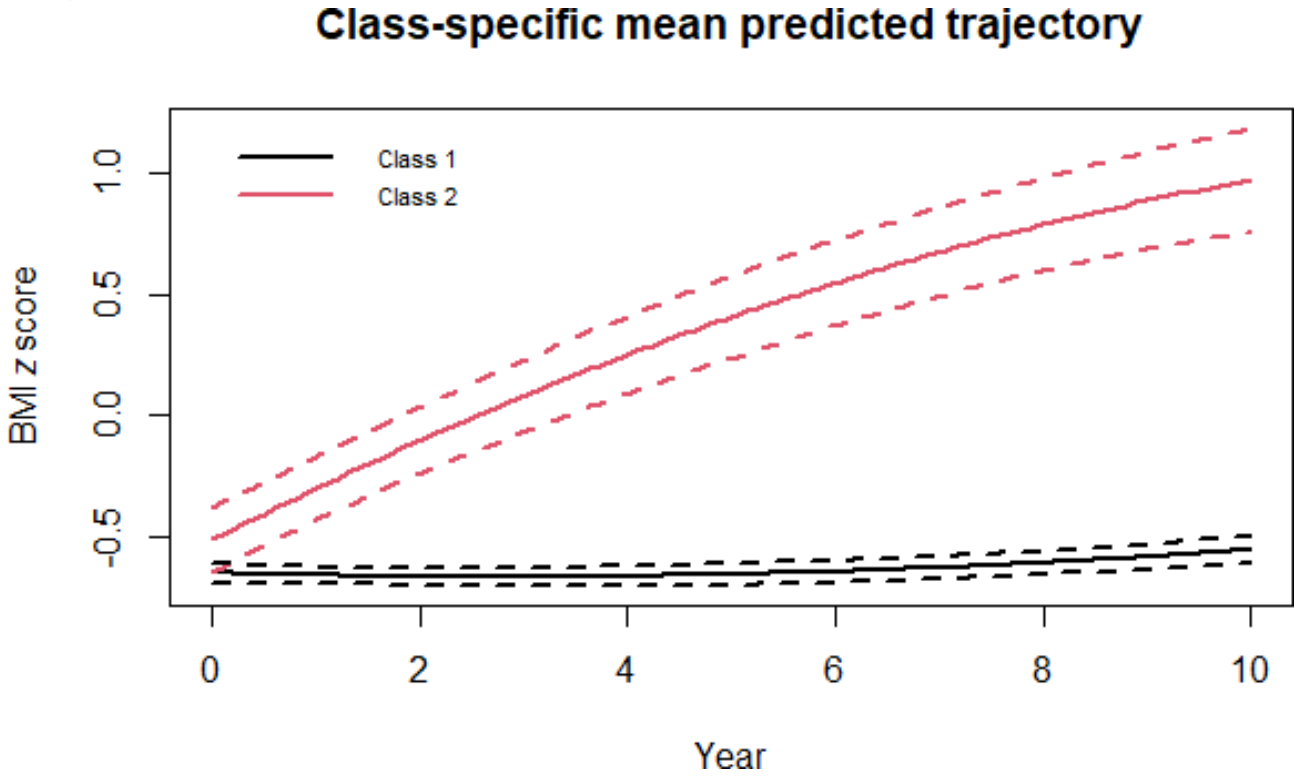


Figure 3. Classification of BMI z score trajectory among individuals selected based on the World Health Organization standards. Class 1: 1917 individuals; Class 2: 251 individuals.

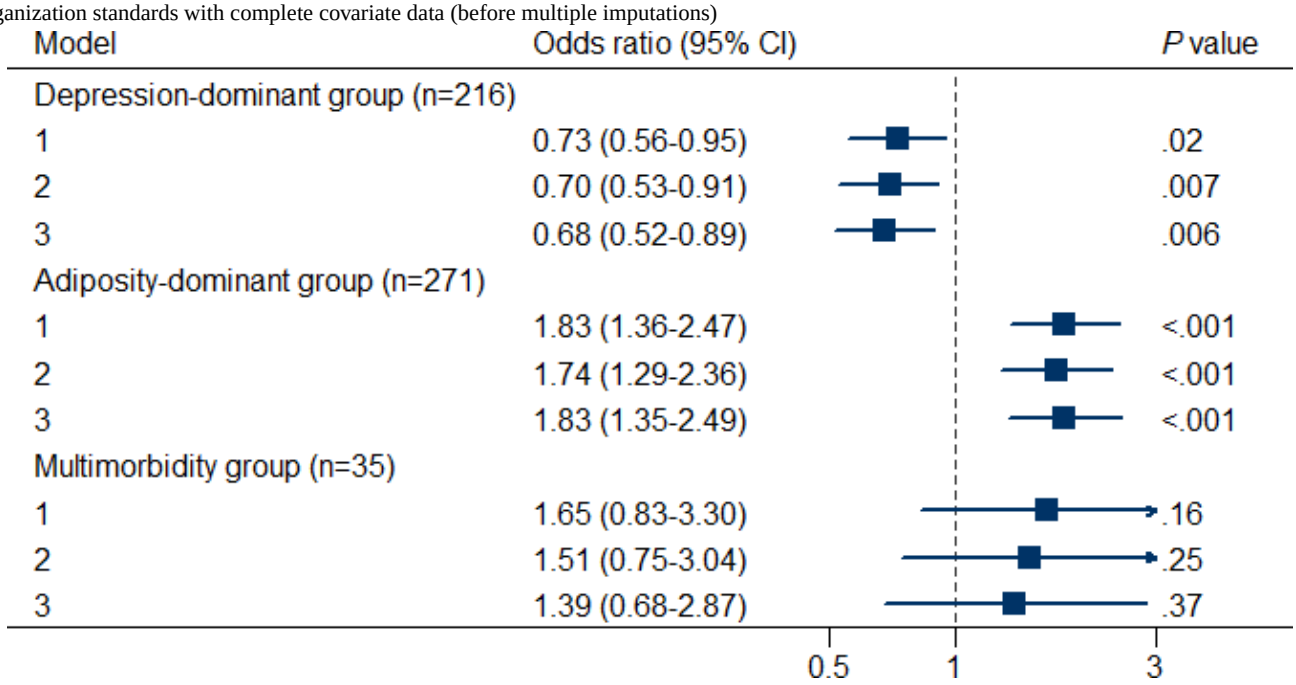

We further validated the classifications of joint trajectories of depressive symptoms and BMI by analyzing their associations with subjective well-being scores and physical activity levels. Concerning the subjective well-being scores, individuals with stable depressive symptoms had higher scores than their counterparts. Concerning physical activity levels, individuals with stable depressive symptoms or stable BMI *z* score over time tended to exercise more often than the remaining individuals (Tables S3 and S4 in Multimedia Appendix 2).

Association of Sex with the Joint Trajectories of Depressive Symptoms and BMI

From adolescence to early adulthood, the females occupied the majority (n=168/306, 54.9%) in the trajectory of gradually increasing depressive symptoms (N=306) over time; in comparison, the males occupied the majority (n=163/251, 64.9%) in the trajectory of gradually increasing BMI (N=251) over time. There were significant sex differences in the 4 types of joint trajectories of depressive symptoms and BMI. Specifically, the proportion of males in the depression-dominant group (116/271, 42.80%) was lower (*P*=.02) than that in the health group (833/1646, 50.61%). The proportion of males in the adiposity-dominant group (141/216, 64.98%) was higher (*P*<.001) than that in the health group. No difference was found in the proportion of males in the multimorbidity group (22/35, 62.86%) compared with the health group (*P*=.21). As shown in Figure 4, the results from Model 1 to Model 3 consistently showed that the females were more likely to be classified into the depression-dominant group (OR 0.68, 95% CI 0.52-0.89); in comparison, the males were more likely to be classified into the adiposity-dominant group (OR 1.83, 95% CI 1.35-2.49).

Figure 4. Sex differences in the joint trajectories of depression *z* score and BMI *z* score among individuals selected based on the World Health Organization standards with complete covariate data (before multiple imputations)

Sensitivity Analyses

The results from our sensitivity analyses were similar to those from the main analyses. Figure S1 in Multimedia Appendix 3 shows the results of using multiple imputations by chained equations. Figures S2-S5 in Multimedia Appendix 3 show the results of using the Chinese criteria to define wasting [42], overweight, or obesity [43] in adolescents. Figures S6-S8 in Multimedia Appendix 3 show the results of using the data of the 5 rounds of surveys: 2010, 2012, 2014, 2016, and 2018, excluding the data from 2020 (during the COVID-19 pandemic). Figures S9 and S10 in Multimedia Appendix 3 show the trajectories of depressive symptoms and BMI among males and female participants, respectively.

Discussion

Summary of Study Findings

This study used the population-based, nationally representative cohort study in China and showed that the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood varied greatly and were classified into 4 groups with distinct characteristics: health-sustaining, depression-dominant, adiposity-dominant, and multimorbidity groups. Moreover, the joint trajectories showed a clear sex-specific pattern: females were at a higher risk of developing depressive symptoms but maintained a relatively stable weight status over time, while males were at a lower risk of developing depressive symptoms but showed an increasing risk of developing adiposity over time.

Interpretation of Study Findings

Around a quarter of the participants were prone to depression or adiposity from before to during the COVID-19 pandemic, mirroring the health vulnerabilities during adolescence and early adulthood also shown in other studies [45,46]. Among these high-risk individuals, special attention should be given to those affected by both depression and adiposity, which could be interpreted by the shared genetic predisposition and brain circuitries that regulate both mood responses and homeostatic functions [47-49].

Interestingly, not all trajectories were parallel in the longitudinal changes in depressive symptoms and BMI. A possible interpretation is that the interaction between depression and BMI is a cumulative effect with some delays [50] rather than an instantaneous effect. This reminds us to continuously monitor and track the health status during adolescence and early adulthood with single depression or adiposity for a longer time and provide timely intervention to prevent the occurrence of multimorbidity.

XSL•FO
RenderX

Our findings, the female and male individuals showing a distinct pattern of the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood, could be interpreted by the sex differences in genetic backgrounds and inflammation process [24,47,51]. Our proposed interpretations of the genetic backgrounds and inflammation process are one of the common causes of depression and adiposity. Studies [47] have suggested that some genetic loci, such as NEGR1 (neuronal growth regulator 1 gene, enables protein binding) or neural growth regulators, were associated with depression on the one hand and BMI and severe early-onset obesity on the other hand. It remained to further explore sex-specific genes or genetic pathways that determine both depression and adiposity. Concerning the inflammation process, another pathway potentially connecting depression with adiposity [24], females were shown to produce more inflammatory cytokines than males within a similar immune response [51].

Other potential interpretations of our findings were related to body dissatisfaction [25], stress coping [52,53], and personality traits [27,54]. Body dissatisfaction, being more prevalent in females than males [55], might result in poorer trajectories of depressive symptoms and eating disorders [25]. Regarding stress coping, studies suggested that females tend to be more sensitive to social stress than males [53], thus posing females at a higher risk of depression than males [52]. In addition, the social stress on body image is more specific to females, making them more likely to maintain a normal weight than males. Regarding personality traits, studies have indicated that low agreeableness, more prevalent in males [27], was associated with a greater increase in BMI [54]. However, it remains to explore the specific mechanisms of personality traits underlying our findings.

The biological mechanisms underlying our findings are likely multifaceted. Beyond previously discussed factors such as stress coping, which may concurrently contribute to both depression and adiposity, the bidirectional vicious cycle between depression and adiposity [56] could also play a significant role. For instance, depression might promote adiposity (and subsequent multimorbidity development), and adiposity might also promote depression, resulting in a self-reinforcing loop. The strength of these bidirectional relationships may differ between males and females, potentially explaining the observed sex differences in the joint trajectories from normal state to comorbid depression and adiposity. More specific mechanisms should be further elucidated through targeted investigations in the future.

Comparison With Other Similar Studies

To the best of our knowledge, we have not found other studies that have explored the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood. The existing studies have only focused on the trajectories of depressive symptoms or adiposity separately.

Concerning studies examining the trajectories of depressive symptoms, Kwong et al [20] found similar findings to ours that females were associated with the childhood-persistent trajectory of depressive symptoms compared with the stable-low trajectory. Zhang et al [57] also found a poorer trajectory of depressive symptoms in Chinese females than in males. Concerning studies examining the trajectories of adiposity, Koning et al [58] found that the proportion of males in the group with increasing BMI *z* score tended to be higher than that in the group with a gradually decreasing BMI *z* score, which was also consistent with our findings.

Strengths and Limitations

Our study findings should be interpreted with caution. First, the height and weight data used for trajectory analyses were based on a self-report questionnaire. However, previous studies had found that self-reported height and weight data were often closely related to actual measured data [33,34], and the CFPS had strict criteria for controlling the quality of self-reported data (Multimedia Appendix 1), which could strengthen the reliability of our results. Second, a small proportion of study participants were classified into the multimorbidity group, limiting us to identifying potential sex differences compared to the reference group. Third, other potential confounding factors that could simultaneously influence depressive symptoms and BMI were not adjusted for due to unavailable data, such as individual dietary behaviors. Fourth, individuals' health problems that could be the source of depression and adiposity were not clear. However, we have analyzed whether there were differences in the distribution of malignant tumors or endocrine diseases among different sexes based on available data and found no statistically significant results (P>.05). Moreover, the probability of developing other chronic diseases is low in adolescents or early adults aged 10 to 24. Therefore, individuals' health problems will not have a significant impact on the results of our study.

Nevertheless, our study population was from a representative sample in China, which indicates great generalizability in the Chinese population. In addition, results from several sensitivity analyses were rather consistent, increasing the robustness of our study findings.

Research Implications

Adolescence and early adulthood are a critical "watershed" period when multiple risk behaviors might emerge, and in the meanwhile, these risk behaviors can be prevented and healthy behavior habits can also be established. Thus, this transitional period is also a critical "window" period when prevention-oriented interventions might come in. Multimorbidity of depression and adiposity has been widely recognized, and relevant pilot interventions are currently in the design or early implementation stage [59]. Our study is unique in taking a sex-specific view of the combined longitudinal trends of depressive symptoms and BMI from adolescence to early adulthood. Our findings indicated that multimorbidity intervention for both depression and adiposity may benefit more from designing sex-specific intervention measures compared with the "one-size-fits-all" approach, as females tend to be depression-prone but adiposity-resistant while males show the opposite pattern.

Conclusions

The findings of our study could pave the way for future multimorbidity interventions that aim to simultaneously prevent the 2 common health issues during adolescence and early adulthood: depression and adiposity. Data from the large,

XSL•FO
RenderX

representative sample in China showed that the depressive symptoms and BMI might not increase or decrease simultaneously from adolescence to early adulthood over 10 years; instead, there emerged 4 distinct groups of trajectories in the changes of depressive symptoms and BMI: health-sustaining, depression-dominant, adiposity-dominant, or multimorbidity group. We also identified sex differences in the joint trajectories of depressive symptoms and BMI from adolescence to early adulthood. This will guide the development of future sex-specific interventions tailored to the distinct profiles of males and females from adolescence to early adulthood, respectively, thereby optimizing intervention effectiveness for preventing both depression and adiposity in early life.

Abstract

Background: Mental health challenges, including anxiety and depression, are increasingly common among adolescents. Mobile health (mHealth) apps offer a promising way to deliver accessible cognitive behavioral therapy (CBT) interventions. However, research on the usability and effectiveness of apps explicitly tailored for adolescents is limited.

Objective: This study aimed to explore the usability, engagement, and perceived effectiveness of a mobile CBT app designed for adolescents, focusing on user experiences and mental health outcomes.

Methods: A qualitative study was conducted with 40 adolescents aged 13 - 19 years (mean age 15.8, SD 1.9 years; 18/40, 45% male; 22/40, 55% female) who engaged with a CBT app for 4 weeks. Mental health diagnoses included anxiety (20/40, 50%), depression (15/40, 38%), and both (5/40, 13%). Of these, 10 (25%) of the 40 participants had previous CBT experience. Feedback was gathered through focus groups and individual interviews, and thematic analysis identified key themes related to usability, engagement, and perceived effectiveness. Quantitative data on mood and anxiety scores were analyzed with paired *t* tests.

Results: The mean usability score was 3.8 (SD 0.6), and the mean effectiveness score was 3.9 (SD 0.7). Older participants (aged 16 - 19 years) reported significantly higher usability (mean 4.1, SD 0.4) and effectiveness scores (mean 4.3, SD 0.5) compared to younger participants (aged 13 - 15 years) (*P*=.03). Females had higher usability (mean 4, SD 0.6) and effectiveness scores (mean 4.2, SD 0.7) than males (mean 3.6, SD 0.7, and mean 3.5, SD 0.8, respectively; *P*=.03). Participants with prior CBT experience had 2.8 times higher odds of reporting high usability scores (95% CI 1.6 - 5; *P*=.002) and 3.1 times higher odds of reporting high effectiveness scores (95% CI 1.7 - 5.6; *P*=.001). Usability challenges included complex navigation (20/40, 50%), interface design issues (12/40, 30%), and content overload (8/40, 20%). Factors positively influencing engagement were motivation driven by personal relevance (20/40, 50%) and gamification features (10/40, 25%), while lack of personalization (14/40, 35%) and external distractions (18/40, 45%) were significant barriers. Mood improvement (15/40, 38%) and learning new coping skills (12/40, 30%) were the most reported outcomes.

Conclusions: The mobile CBT app shows potential for improving adolescent mental health, with initial improvements in mood and anxiety. Future app iterations should prioritize simplifying navigation, adding personalization features, and enhancing technical stability to support long-term engagement.

Introduction

Mental health challenges among adolescents have become increasingly prevalent, with issues like anxiety, depression, and stress-related disorders affecting a significant portion of this population [1-4]. Adolescence is a critical developmental period marked by emotional, cognitive, and social changes, which can increase vulnerability to mental health disorders [5-7]. The World Health Organization estimates that up to 20% of adolescents experience mental health conditions, highlighting the urgent need for effective and accessible interventions [8-10].

In response to this growing demand, mobile health (mHealth) apps have emerged as a promising solution for delivering mental health care [11-14]. These apps offer a flexible, cost-effective,

XSL•FO
RenderX

and private means for adolescents to access psychological interventions, which may otherwise be limited due to stigma, lack of resources, or geographical barriers [15-19]. Among the various therapeutic approaches, cognitive behavioral therapy (CBT) has proven to be particularly effective in addressing common adolescent mental health issues like anxiety and depression [20-24]. CBT focuses on helping individuals identify and modify negative thought patterns and behaviors, making it well suited for delivery via mobile platforms that offer interactive and self-guided modules [25-28].

Despite the promise of mobile CBT apps, there remains a significant research gap regarding their usability and effectiveness for adolescents [29,30]. Most existing studies focus on adult populations or general app evaluations without considering younger users' unique needs and preferences [31,32]. Adolescents may have different expectations for user experience, engagement, and motivation when interacting with digital health tools [33,34]. Additionally, this age group's developmental and emotional characteristics necessitate a design that fosters engagement and provides adequate support [35-39].

In Iraq, mental health services face significant barriers due to stigma, lack of resources, and geographical constraints, which limit adolescents' access to traditional therapy. Postconflict instability, socioeconomic challenges, and strained health care systems have compounded mental health issues among Iraqi youth, creating a need for innovative solutions tailored to this population. Adolescents in Iraq, particularly those in low-resource settings, may be unable to access face-to-face therapy due to the limited availability of mental health professionals and the high costs associated with treatment.

While the potential of mobile CBT apps is evident, there is a lack of research on their usability and effectiveness among adolescents, particularly in regions like Iraq. This study aims to address this gap by exploring the usability, engagement, and outcomes of a mobile CBT app tailored specifically for adolescents in Iraq. The findings will provide valuable insights into how digital mental health tools can be optimized to better serve this vulnerable population in low-resource settings.

This study aimed to evaluate the usability, engagement, and perceived effectiveness of a mobile CBT app for adolescents, with a focus on user experiences and its impact on mental health outcomes.

Methods

Participants

The study recruited adolescents aged 13 - 19 years who were experiencing mental health challenges, including anxiety and depression. A convenience sampling method was used to select participants from various sources, including local schools, mental health clinics, and online mental health communities. Participants were referred by counselors or health care providers and expressed interest in participating. Inclusion criteria required that participants had a self-reported diagnosis of anxiety or depression, regular access to a smartphone, and, for those aged <18 years, parental consent. A sample size of 40 adolescents was chosen for an in-depth qualitative analysis of diverse perspectives while maintaining manageability for detailed thematic analysis. The study was conducted in Mosul, Iraq, ensuring a regional context for the findings. Data confidentiality and participant anonymity were prioritized throughout the study. Each participant was assigned a unique identifier code used in place of personal information during data collection, transcription, and analysis. This ensured that no identifying details were linked to the responses. Informed consent was obtained from all participants, outlining their rights to privacy and the confidential handling of their data. Interview and focus group recordings were securely stored in encrypted files, accessible only to authorized research team members. All transcripts were deidentified prior to analysis to protect participant identities further, and findings were reported in aggregate to prevent any individual from being identified.

Intervention

Participants were introduced to a CBT mobile app designed specifically for adolescents. The app was commercially available and selected based on its adherence to established CBT principles, as well as its focus on common adolescent mental health issues such as anxiety, depressive thoughts, and stress management. The app featured interactive modules, journaling functions, mood tracking, and self-assessment tools, all aimed at guiding users through CBT-based interventions. The selection of the app was influenced by its popularity, user ratings, and evidence-based framework, ensuring that it met the study's requirements for delivering structured CBT exercises. Participants were asked to engage with the app for 4 weeks, with a recommendation to complete at least 3 CBT exercises per week, though they were free to use it at their discretion.

Study Design

The study adopted a qualitative approach to gather rich, in-depth insights into the participants' experiences with the mobile CBT app. Data were collected through focus groups and one-on-one semistructured interviews after the 4-week intervention period. This design allowed for exploring the app's usability, engagement, and perceived outcomes from the adolescent perspective. The qualitative approach was well suited in understanding users' subjective experiences and identifying themes related to app interaction and mental health improvement.

Data Collection

Data collection focused on both app interaction and user feedback. The following methods were used.

App Usage Metrics

In-app data were collected to track the frequency of app usage, time spent on activities, completion of CBT modules, and interaction with various app features (eg, journaling and mood tracking).

User Feedback

Participants provided feedback through focus groups and interviews, where they discussed their experiences with the app. Topics of discussion included usability (ease of navigation and design preferences), engagement (motivation to use the app and consistency of use), and perceived outcomes (changes in mood,

XSL•FO
RenderX

anxiety, or stress levels). Interviews were recorded and transcribed for analysis.

Outcome Measures

The study evaluated the following outcomes.

Usability

This included ease of navigation, design intuitiveness, and app aesthetics. Participants shared feedback on the app's user-friendliness and any barriers they encountered.

Effectiveness

Participants self-reported any changes in their mental health symptoms, particularly about anxiety and depression. Symptom reduction was assessed using qualitative descriptions of mood changes and mental health improvements throughout the study.

Overall Satisfaction

Participants reflected on their satisfaction with the app, including its features, content relevance, and overall impact on their mental health. Satisfaction was gauged through subjective feedback on whether they would recommend the app to peers or continue using it poststudy.

Ethical Considerations

This study was conducted in accordance with the ethical guidelines set in the Declaration of Helsinki and was approved by the institutional review board of the University of Ninevah (approval reference number: NURIRB/041/2023). All the processes involving human subjects were reviewed and deemed ethically acceptable by the institutional review board. As most participants were minors aged <18 years, extra ethical precautions were exercised. For participants aged <18 years, written informed consent was obtained from parents or their legal guardians and assent from the adolescents. The assent forms were read in age-specific terms so the minors would clearly understand the purpose of the study, procedures to be followed, risks and benefits, if any, and their rights, such as withdrawal from the study at any time without any penalty. Parents and guardians received full written and verbal explanations of the study, including confidentiality protocols and data privacy protections, so that participation would be based on fully informed decision-making. All data were anonymized and stored securely to protect participant privacy and confidentiality. Identifying information was stored separately from the main dataset and was accessible only to authorized research team members. No financial incentives or rewards were promised to the participants or their families for participating in this study, so as to avoid coercion or undue influence.

Results

Age, Usability, and Effectiveness

The study found that age was slightly correlated with app usability and effectiveness. Older adolescents (aged 17 - 19 years) generally reported higher usability scores and perceived greater effectiveness than younger participants (Table 1). This could be due to increased digital literacy and maturity in using therapeutic tools among older users, who may navigate the app more intuitively and apply CBT techniques more consistently.

Characteristic	Participants, n (%)	Usability score, mean (SD)	Effectiveness score, mean (SD)	Preferred features	Notable observations
Age (years)					
13 - 15	15 (38)	3.2 (0.5)	3.4 (0.6)	Gamification and mood tracking	Less consistent engagement but reported mood improvements
16 - 19	25 (62)	4.1 (0.4)	4.3 (0.5)	Journaling and thought reframing	Higher digital literacy correlated with better usability
Gender					
Male	18 (45)	3.6 (0.7)	3.5 (0.8)	Gamification and relaxation techniques	Gamification boosted engagement; preferred reward-based elements
Female	22 (55)	4.0 (0.6)	4.2 (0.7)	Journaling and mood tracking	Consistent journaling and tracking helped manage emotions
Mental health diagnosis					
Anxiety	20 (50)	4.0 (0.5)	4.1 (0.6)	Mood tracking and relaxation techniques	Frequent mood tracking to manage anxiety triggers
Depression	15 (38)	3.7 (0.6)	3.8 (0.5)	Journaling	Journaling as a primary emotional outlet
Both	5 (12)	3.5 (0.7)	3.6 (0.8)	Combination of all features	Mixed feature use, desire for more personalization
Previous CBT experience					
Yes	10 (25)	4.2 (0.4)	4.3 (0.6)	Thought reframing and relaxation	Higher familiarity led to easier app navigation
No	30 (75)	3.5 (0.6)	3.6 (0.7)	Mood tracking and gamification	Accessibility for beginners; tutorial recommended

[a]CBT: cognitive behavioral therapy.

Gender Differences

Gender differences were evident in feature engagement and overall satisfaction with the app. Female participants reported using journaling and mood tracking more frequently and found these features particularly beneficial for managing their emotions. Males, however, demonstrated a stronger preference for gamification elements, suggesting they might respond better to reward-based interactions within the app. This result indicates that gender-sensitive adaptations, like balancing gamified elements with reflective exercises, could optimize engagement.

Mental Health Diagnosis

Diagnosis type influenced how participants interacted with different app features. Adolescents diagnosed with anxiety frequently engaged with mood tracking to monitor their anxiety triggers and reported that it helped them feel more in control. In contrast, participants with depression found journaling more beneficial, as it provided an outlet for emotional expression. Those with both anxiety and depression reported mixed results, finding both features helpful but expressing a need for more personalized guidance. These findings suggest that tailoring app features based on specific mental health diagnoses may enhance effectiveness.

Previous CBT Experience

Prior CBT experience was associated with higher usability scores. Participants familiar with CBT concepts found the app easier to navigate and were able to engage more readily with tools like thought reframing and relaxation exercises. Those without prior CBT experience still reported short-term improvements, indicating that the app is accessible for beginners, though they noted that a brief tutorial on CBT basics could improve initial engagement.

Interaction Between Characteristics

When analyzing the interaction between age and diagnosis, older adolescents with anxiety showed a unique pattern of consistent engagement with mood tracking and relaxation exercises, possibly due to increased awareness of their symptoms and the therapeutic benefits of tracking. This contrasts with younger adolescents with depression, who were less consistent with engagement but reported substantial short-term mood

XSL•FO
RenderX

improvements when they did engage, highlighting age and symptom-specific usage patterns.

Usability Challenges

Overview

Several usability challenges were identified through participant feedback (Table 2). While the majority of adolescents found the app's interface visually appealing, many encountered issues related to its design and navigation. For example, one participant stated, "It was hard to find the tools I needed; sometimes I got lost in the app" [Participant 3, female, 16 years old].

Table . Themes identified in usability challenges (N=40).

Usability challenge	Description	Values, n (%)
Complex navigation	Difficulty in finding features or completing multistep tasks	20 (50)
Interface design	Issues with text size, button placement, or layout on mobile devices	12 (30)
Content overload	Feeling overwhelmed by the amount of content in some sections	8 (20)

Complex Navigation

Of the 40 participants, 20 (50%) reported difficulty navigating through the app, particularly when attempting to access multistep CBT modules. They expressed a desire for clearer instructions and a more simplified user interface.

Interface Design

Of the 40 participants, 12 (30%) mentioned that the app's text size and button placement were not user-friendly, especially when using smaller mobile devices. This affected their overall experience and led to frustration in some cases.

Content Overload

Of the 40 participants, 8 (20%) felt overwhelmed by the amount of information presented in certain sections of the app. They indicated that the extensive content occasionally discouraged further use.

Engagement

Participant engagement with the app varied and was influenced by several factors, including personal relevance and gamification features (Table 3).

Table . Factors influencing engagement with the CBT[a] app (N=40).

Factor	Description	Values, n (%)
Motivation (personal relevance)	Continued use linked to personal mental health needs and recognition of the app's benefits	20 (50)
Gamification and rewards	Positive response to interactive features and rewards	10 (25)
Personalization	Engagement hindered by lack of tailored content and goals	10 (25)

[a]CBT: cognitive behavioral therapy.

Motivation and Personal Relevance

Of the 40 participants, 20 (50%) who found the app's content personally relevant and aligned with their mental health needs reported higher levels of engagement. These participants were more likely to use the app consistently throughout the 4-week period. For example, one participant noted, "The rewards made it fun and kept me coming back" [Participant 5, male, 17 years old].

Gamification and Rewards

Of the 40 participants, 10 (25%) responded positively to the app's gamified elements, such as rewards for completing exercises and interactive features like mood tracking. They reported that these features enhanced their motivation to continue using the app.

Lack of Personalization

Of the 40 participants, 10 (25%) noted that the absence of personalization options, such as customized goals or tailored content, negatively impacted their long-term engagement with the app.

Perceived Effectiveness

The majority of participants reported experiencing positive mental health outcomes, although the duration of the benefits varied (Table 4). For example, one participant stated, "The app gave me exercises that helped calm me down before an exam" [Participant 2, male, 14 years old].

XSL•FO
RenderX

Table . Perceived effectiveness of the app (N=40).

Effectiveness outcome	Description	Values, n (%)
Mood improvement	Participants reported a reduction in anxiety or improved mood after using the app	15 (38)
Learning coping skills	Users noted acquiring new coping mechanisms for managing stress and negative thoughts	12 (30)
Short-term benefits	Short-term improvements, but benefits were not sustained without continuous app use	13 (32)

Mood Improvement

Of the 40 participants, 15 (38%) reported a noticeable reduction in anxiety levels and an improvement in their mood after completing CBT exercises, particularly those focused on breathing techniques and cognitive restructuring.

Learning Coping Skills

Of the 40 participants, 12 (30%) highlighted that they learned new coping mechanisms, such as identifying and challenging negative thought patterns, which helped them manage day-to-day stress.

Short-Term Benefits

Despite these positive outcomes, 13 (32%) out of 40 participants mentioned that the improvements were short-term and did not last without regular app usage. This suggests that sustained engagement is necessary for long-term benefits.

Barriers to App Usage

Several barriers were identified that limited participants' consistent use of the app or reduced its perceived effectiveness (Table 5).

Table . Barriers to app usage (N=40).

Barrier	Description	Values, n (%)
App functionality issues	Technical problems like slow loading times or app crashes	8 (20)
Lack of personalization	Limited customization options for individual needs	14 (35)
External distractions	Schoolwork, social media, or lack of time impacting regular usage	18 (45)

App Functionality Issues

Of the 40 participants, 8 (20%) experienced technical problems, such as slow load times or occasional crashes, which discouraged them from using the app regularly.

Lack of Personalization

As previously mentioned, 14 (35%) out of the 40 participants felt that the lack of individualized content limited their overall engagement and the app's relevance to their specific mental health needs. One participant shared, "I felt like the app understood what I was going through, and that kept me using it" [Participant 7, male, 15 years old].

External Distractions

Of the 40 participants, 18 (45%) cited external distractions, such as schoolwork, social media, and general time constraints, as reasons for inconsistent app usage. They suggested that push notifications or reminders could help them stay on track with their CBT exercises. A participant commented, "Knowing others were going through the same thing made me feel less alone" [Participant 4, female, 16 years old].

Data Analysis Process

A thematic analysis was used to systematically explore the data gathered from focus groups and individual interviews. This qualitative approach is particularly suited to understanding the nuanced experiences of participants, as it allows for the identification of patterns and themes within textual data [40]. The analysis followed an inductive approach, where themes were derived directly from the data without imposing pre-existing frameworks, ensuring that the findings reflect participants' perspectives authentically [41].

Steps of Thematic Analysis

The steps of thematic analysis were as follows:

1. Data Familiarization: all interview transcripts were thoroughly reviewed to immerse the research team in the data and gain an initial understanding of the content.
2. Coding: initial codes were generated to highlight recurring patterns, unique responses, and significant statements related to usability, engagement, and perceived effectiveness.
3. Theme Development: codes were then grouped into broader themes that encapsulated the key insights, such as barriers to engagement, facilitators of usability, and outcomes of perceived effectiveness.
4. Review and Refinement: themes were refined iteratively to ensure they were distinct, relevant, and reflective of the dataset as a whole.

This method is appropriate for the study as thematic analysis provides flexibility in analyzing diverse qualitative data and is well suited for understanding user experiences with interventions

XSL•FO
RenderX

such as mobile CBT apps [42]. It enables researchers to capture both explicit content and latent meanings in the data.

Adequacy of Sample Size

The sample size for this study is adequate based on qualitative research standards. Data saturation—a point where no new themes or insights emerge—can often be achieved with 6 - 12 interviews, depending on the study's scope and participant homogeneity [43]. In this study, combining focus groups and individual interviews ensured a rich dataset that captured a range of perspectives while adhering to the principle of saturation.

Discussion

Principal Findings and Interpretation

This study explored the usability, engagement, and perceived effectiveness of a mobile CBT app designed for adolescents facing mental health challenges, such as anxiety and depression. The findings provide valuable insights into the potential of mobile CBT apps while highlighting areas for improvement, especially for adolescents in low-resource settings like Iraq.

Usability and Personalization

One key finding was the usability challenges reported by participants, including complex navigation and nonintuitive design. Participants frequently mentioned difficulties in locating tools or navigating through the app's interface. This underscores the need for developers to prioritize user-centered design that is simple, clear, and adaptable to different devices and screen sizes.

Features such as guided tutorials and step-by-step walkthroughs can facilitate easier navigation for adolescents with varying levels of digital literacy. Additionally, the app should be rigorously tested across multiple devices to ensure smooth performance and minimize technical barriers that deter consistent use.

A significant recommendation based on the feedback is the incorporation of personalization features, which could enhance the app's effectiveness and user engagement. Developers could implement adaptive algorithms that adjust content based on user input and progress, allowing the app to deliver more targeted interventions. For example, users could set personal mental health goals, such as reducing anxiety before exams, and the app could tailor CBT exercises accordingly to align with these objectives. Additionally, personalized content delivery based on self-assessment responses could ensure that users receive modules or exercises most relevant to their emotional state or specific stressors. Regular mood check-ins could further refine these recommendations, offering targeted suggestions that align with the user's evolving needs and experiences.

Consistent with earlier studies, such as Zhang et al [44], the app demonstrated potential in improving adolescents' mental health outcomes by providing accessible and flexible therapeutic tools. Previous work has highlighted the importance of user-friendly interfaces in promoting app adherence [45], and this study reinforces those conclusions. Participants' feedback about challenges in navigating the app echoes findings from Cheng et al [46], where adolescents reported that complex interfaces reduced their motivation to engage consistently.

Furthermore, the study aligns with the conclusions of Miller et al [47], which emphasized the critical role of personalization in enhancing the efficacy of digital interventions. Like Milleret al [47], our results suggest that tailoring app content to users' unique needs and progress is key to maintaining engagement and achieving desired outcomes.

The study revealed that engagement was strongly influenced by participants' perceptions of the app's relevance to their specific mental health needs. Participants who felt that the app effectively addressed their challenges were more likely to use it consistently, a finding supported by Banneyer et al [48], who demonstrated that content alignment with user needs significantly improves adherence to digital mental health interventions. Gamification features, such as badges, levels, and progress tracking, were identified as key motivators that sustained interest and encouraged continued use. These findings align with Ng and Wong [49], who reported that gamification elements enhance user engagement by creating a sense of achievement and progress.

Additionally, social features like anonymous peer support or community forums emerged as promising strategies for fostering connection and reducing feelings of isolation. This observation resonates with Silberg et al's [50] findings, who highlighted the role of social support mechanisms in increasing the acceptability and usage of mental health apps. In collectivist cultures like Iraq, where community and social bonds are deeply valued, enabling adolescents to share their progress or experiences anonymously could enhance engagement by leveraging these cultural strengths. This aligns with Patel et al [51], who noted the importance of culturally sensitive features in ensuring the success of digital health interventions. Future research should investigate the impact of such social features in different cultural contexts to determine their broader applicability and effectiveness.

Perceived Effectiveness

The perceived effectiveness of the app was influenced by its ability to address specific mental health challenges faced by participants. Such feedback highlights the importance of targeted interventions that address adolescents' real-world stressors. Participants also emphasized the need for evidence-based tools that provide tangible benefits. Incorporating features that explain the rationale behind each exercise and how it aligns with CBT principles could enhance perceived effectiveness and build user trust.

The findings align with prior research on adolescent mHealth engagement, such as those of Ghosh et al [52] features like personalization, gamification, and caregiver endorsement are critical for adolescent engagement in mHealth apps. Similarly, Oakley-Girvan et al [53] emphasized the importance of adaptive content and user-centered design in sustaining engagement. These studies underscore the importance of tailoring mHealth interventions to meet the unique needs of adolescent users while addressing cultural and contextual factors.

XSL•FO
RenderX

Long-Term Benefits and Sustainability

While most participants reported short-term improvements in mood and anxiety, the benefits were not sustained without regular app usage. This finding highlights the need for future mobile CBT apps to incorporate features that foster long-term engagement and sustained mental health improvements. Features such as regular reminders, progress tracking, and reinforcement of positive behaviors over time could play a crucial role in maintaining user involvement. For instance, push notifications reminding users to complete CBT exercises, celebrate milestones, or provide motivational messages have been shown to improve engagement and adherence in similar interventions [51].

Additionally, there is significant potential to integrate digital and human support in future app iterations. Adolescents could benefit from a hybrid model that combines the self-guided app with access to mental health professionals or peer mentors when needed. This approach aligns with findings from Gentry et al [54], which demonstrated that blending digital tools with human interaction significantly enhances mental health outcomes. Similarly, Patel et al [51] emphasized that hybrid models are particularly effective in resource-limited settings, where direct access to therapists is scarce. In regions like Iraq, where mental health resources are constrained, a blended approach could address both accessibility and sustainability challenges. By combining the strengths of digital and human support, mobile CBT apps could ensure broader and more enduring benefits, providing an effective solution for sustaining mental health improvements over time.

Implications for Future Development

The findings of this study highlight several key recommendations for the future development of mobile CBT apps for adolescents, particularly in low-resource settings like Iraq:

- Simplify navigation to enhance usability, ensuring the app is easy to use across different devices and levels of digital literacy.
- Incorporate adaptive personalization that tailors content based on individual user needs, goals, and progress.
- Gamify engagement to sustain motivation and encourage regular use, with a focus on rewards that resonate with the adolescent user base.
- Address external barriers such as distractions and time constraints by providing flexible features like push notifications and offline accessibility.
- Consider cultural and regional factors when designing apps, ensuring that features such as peer support align with the social values of the target audience.

Recommendations

Enhance Personalization

Adaptive Content Delivery

Integrate artificial intelligence–based algorithms to tailor content to the user's progress, mood, and engagement level. For example, adaptive modules can adjust the difficulty of activities based on the user's performance or offer reminders tailored to individual schedules.

User-Centered Goal Setting

Allow users to set personal goals within the app, such as managing daily stress or improving sleep. Personalized progress tracking and feedback can enhance motivation and sustain engagement over time.

Localized and Culturally Relevant Content

Incorporate content that resonates with the cultural background and life experiences of adolescents in Iraq, such as language options and culturally sensitive scenarios that foster user connection and comfort.

Incorporate Gamification Elements

Reward Systems and Badges

Introduce badges, points, or achievements for completing exercises, engaging regularly, or reaching personal milestones. A reward system can make engagement feel more rewarding and less clinical.

Interactive Challenges and Quests

Design challenges that encourage users to engage with the app routinely, such as completing daily mindfulness exercises or participating in weekly reflections. This can add a playful dimension to the app while reinforcing positive habits.

Social Sharing Features

Users can share their achievements with peers or within safe, moderated groups. Social elements can increase accountability, foster community, and provide an additional layer of engagement.

Streamline Navigation and Interface Design

Simplified User Flows

Minimize the steps required to reach core functionalities like exercises or mood tracking. Intuitive navigation should allow users to quickly locate and engage with tools, even if they only have a few minutes available.

Onboarding Tutorials

A brief, interactive onboarding process can familiarize new users with app functions, making it easier to navigate from the start. Offering short tutorials on new features introduced in updates can also enhance usability.

Improve Technical Stability

Offline Functionality

Given connectivity challenges, especially in rural areas, consider building offline capabilities for essential features, allowing users to complete exercises or track their mood without internet access.

Regular Testing and Updates

Frequent testing for bugs, usability issues, and prompt updates will improve overall stability and user satisfaction.

XSL•FO
RenderX

Conclusions

Overall, this study demonstrates that mobile CBT apps hold great promise for improving adolescent mental health, particularly in low-resource settings like Iraq. By addressing usability challenges, enhancing engagement through personalization and gamification, and overcoming barriers to usage, mobile CBT interventions can become more effective and accessible tools for young people. As digital health solutions continue to evolve, developers should prioritize user-centered, flexible designs that cater to the unique needs of adolescents in diverse cultural contexts. Future research should explore how to extend the long-term impact of these interventions, potentially through hybrid models that combine self-guided app use with professional support.

Acknowledgments

The authors thank the district health office and health facility staff for supporting and facilitating the data collection.

Authors' Contributions

RHI, MHY, MQH, SHAM, MFA and OAM conceived the study. RHI analyzed the data and wrote the first draft. All the authors have read and approved the final manuscript.

Abstract

Background: Mental health problems among adolescents are increasing, and internet-delivered acceptance and commitment therapy (iACT) constitutes a possible way to improve access to care while reducing costs. Nevertheless, few studies have investigated iACT for adolescents in regular primary care nor the role of parental support.

Objective: This is an exploratory evaluation investigating iACT, with or without parental support, for adolescents. The aims were to examine treatment adherence, symptoms of anxiety and depression, psychological flexibility, and overall functioning.

Methods: Adolescents with anxiety were recruited within the regular primary care patient flow during the implementation phase of therapist-assisted iACT for adolescents. Assessment and inclusion were executed face-to-face. Due to organizational reasons, the assignment of treatment methods could not be randomized. Adherence was investigated by measuring the number of completed modules. Outcome measures were collected by self-assessment questionnaires including the Revised Children's Anxiety and Depression Scale and Avoidance and Fusion Questionnaire for Youth, as well as interviews using the Children's Global Assessment Scale. The analysis was performed as an exploratory evaluation using descriptive data for treatment adherence and nonparametric within-group analysis with the Wilcoxon signed rank test for related samples and treatment outcomes. This evaluation is naturalistic, and the results are preliminary and of a hypothesis-generating character and should be handled with caution.

Results: The iACT group without parental support (n=9) exhibited a gradual dropout throughout the treatment period (n=5), whereas the iACT group with parental support (n=15) exhibited the lowest number of dropouts from treatment before completion (n=2), of which all occurred during the second half of treatment. The within-group, per-protocol analyses for the Revised Children's Anxiety and Depression Scale indicated reduced symptoms of anxiety and depression at the 12-month follow-up (z score: –2.94; P=.003; r=–0.6). The within-group, per-protocol analyses for the Avoidance and Fusion Questionnaire for Youth indicated

XSL•FO
RenderX

increased psychological flexibility at the 12-month follow-up (*z* score: –2.54; *P*=.01; *r*=0.55). Nevertheless, no differences in overall functioning measured by the Children's Global Assessment Scale were found.

Conclusions: The results indicate that parental support might play a role in treatment adherence in iACT for adolescents with anxiety. Moreover, the outcome measures suggest that iACT for adolescents in primary care could constitute an effective treatment for both anxiety and depression, as indicated by the symptom reduction and increased psychological flexibility, maintained at the 12-month follow-up. Nevertheless, due to a small and gender-biased sample size with a large proportion of dropouts and missing data, a nonrandomized assignment of intervention, and an analysis limited to within group, this study should be considered an explorative evaluation rather than an outcome study.

Introduction

According to the National Board of Health and Welfare in Sweden, mental health among children and young people has deteriorated, both based on self-reported psychological symptoms and on diagnosed mental disorders [1]. Anxiety and depression have been identified as significant factors, of which anxiety is the most common [2]. Furthermore, both anxiety and depression are associated with social withdrawal, adverse effects on academic performance, functional impairment, and ultimately, risk factors for suicide [3,4]. For adolescents with generalized anxiety disorder (GAD), separation anxiety disorder, and social phobia, the selective serotonin reuptake inhibitor Sertraline, as well as cognitive behavioral therapy (CBT), are the recommended treatment methods [1]. According to the Swedish National Board of Health and Welfare, CBT is well documented, recommended as a first intervention [5], and considered an effective treatment for anxiety disorders in children and adolescents [6].

In Sweden, primary care services include performing an initial assessment on children and adolescents regarding symptoms, symptom severity, and eventual need for treatment. If an anxiety disorder is assessed to be mild, an intervention shall be offered, and if moderate to severe, the patient shall be triaged to psychiatric care [5]. Furthermore, early intervention is crucial in preventing chronic mental illness [7], but many adolescents do not seek help from mental health care. O'Dea et al [8] have identified a lack of awareness among the population of signs of mental ill health, limited access to health care, and costs as possible obstacles. The authors suggest internet-based CBT (iCBT) as a way of increasing accessibility to treatment while reducing costs and that iCBT exhibits similar effect sizes as face-to-face treatment.

In a systematic review and meta-analysis, Vigerland et al [9] evaluated 25 studies on iCBT, including only studies in which the mean participant age was younger than 18 years. Of the studies, 7 studies were based on a Swedish population and 6 studies were on anxiety. The authors concluded that iCBT has positive outcomes, may be feasible, and exhibited moderate effect sizes compared to the waitlist. In a Danish randomized controlled trial (RCT), 70 adolescents with anxiety disorders were randomized into either iCBT or waitlist, and the iCBT group exhibited significant improvement based on both adolescent and parent ratings and that iCBT exhibited moderate to large effect sizes between groups [10]. Moreover, in an Australian RCT, 115 adolescents with anxiety from a community sample were randomized to either iCBT, face-to-face CBT, or waitlist conditions. At the 12-month follow-up, the authors found no significant differences regarding treatment outcomes between the groups and concluded that iCBT offers reduced therapist time and hence increased accessibility [11]. In a Swedish study, 120 adolescents were randomized to either standard iCBT, iCBT with learning support, iCBT with chat, or iCBT with learning support and chat. The group with learning support initially exhibited better outcomes but the difference was not sustained at the 6-month follow-up, and the authors determined iCBT to be an effective treatment method for adolescents with anxiety and depression. The authors found small effect sized on secondary outcomes related to anxiety and that the effect sized indicated the benefits of memory support during iCBT [12]. Nevertheless, in all the abovementioned studies, the participants were recruited either via advertisements or referral to secondary care. Thus, none of the studies were conducted in regular primary care.

Acceptance and commitment therapy (ACT) is a third-wave behavioral therapy oriented at acceptance and mindfulness and aimed at increasing psychological flexibility, defined as the ability to be present and act accordingly in line with one's values [13]. Face-to-face ACT is considered an effective treatment for children and adolescents with anxiety disorders [14,15] and exhibits small to medium effect sizes regarding anxiety and depression [16]. In a Swedish study, Nissling et al [17] investigated the effectiveness of internet-delivered ACT (iACT) on adolescents with anxiety by randomizing 52 participants aged 15-19 years from all over Sweden into either iACT or waitlist. Both groups improved but the participants in the intervention group exhibited significantly higher improvements regarding anxiety and exhibited moderate effect sizes between groups. The authors concluded that iACT is effective in improving quality of life and psychological flexibility, which in turn was associated with reduced anxiety symptoms. Another study randomized 348 adolescents to either (1) iACT student coach and a digital coach group, (2) only iACT digital coach group, or (3) no intervention. The authors found significant improvements in the iACT groups compared to the control

XSL•FO
RenderX

group regarding reduced anxiety and increased valued action and self-compassion [18].

Few studies have examined iACT for adolescents in a routine primary care setting. To broaden the understanding of iACT in primary care for adolescents with anxiety, the Internet Mediated Psychological Treatment-Acceptance and Commitment Therapy (IMPACT) project was conducted as an ongoing evaluation during the implementation of iACT for adolescents in the region Västra Götaland in southwestern Sweden. The intervention in focus is the same as that in the study by Nissling et al [17] and contains ACT features [19].

In the first IMPACT paper, the authors highlighted the importance of parental involvement in iACT for adolescents, suggesting it might compensate for low treatment motivation [20]. In the second IMPACT paper, the authors concluded that the role of the parents needs clarification [21]. Attention to parental engagement in mental health treatments of adolescents has increased in recent years, and in 2015, a review of 23 papers was conducted by Haine-Schlagel and Walsh [22]. The results indicated potential links between parental participation and positive outcomes. The authors concluded that further research is needed to determine treatment factors, as well as organizational factors, regarding parental engagement in mental health treatment for both children and families. Moreover, Lundkvist-Houndoumadi et al [23] performed a phenomenological analysis of 24 semistructured interviews with Danish families in which the youth received CBT for anxiety with parental involvement. The authors concluded that the therapists' expectations of the parents to be cotherapists were difficult to implement in some cases due to the family dynamics and the expectations and resources among the parents. Overall, there seems to be a need for further information regarding the parental role in iCBT and iACT for adolescents and how the parents can support the adolescent's treatment. Haine-Schagel and Walsh [22] have concluded that research regarding parental engagement would benefit from more studies on specific parent-supportive behaviors in clinical interactions [22].

In summary, few studies have investigated iACT for adolescents in a routine primary care setting nor the role of the parents. Therefore, the IMPACT project aimed to conduct an ongoing evaluation of introducing iACT for adolescents with anxiety in primary care. This is the third part of the IMPACT project and is aimed at conducting a follow-up 12 months after receiving iACT with or without parental support. The primary outcomes consist of treatment adherence and symptoms of anxiety and depression, and the secondary outcomes consist of psychological flexibility and overall functioning in adolescents. Thus, the aims of this evaluation can be concretized as follows:

1. Is there a connection between parental support and adherence to iACT for adolescents with anxiety?
2. Does iACT for adolescents with anxiety result in decreased symptoms of anxiety and depression between pretreatment and 12 months after terminating treatment?
3. Does iACT for adolescents with anxiety result in increased psychological flexibility between pretreatment and 12 months after terminating treatment?
4. Does iACT for adolescents with anxiety result in improved overall functioning between pretreatment and 12 months after terminating treatment?

Methods

In this section, the study design, participants, procedure, intervention, measures, data analysis, and ethical considerations are presented.

Study Design

Initially, the intention was to perform a follow-up of iACT during the implementation phase in primary care and to conduct between-group analyses. However, due to organizational limitations, the authors instead opted for a pragmatic approach to the data. Consequently, the analysis was converted into an exploratory evaluation of iACT for adolescents with anxiety in primary care.

The IMPACT project was conducted within the regular patient flow during the implementation phase and due to organizational reasons, randomization of the participants could not be made. Using a non-RCT, the therapists assigned the participants to either iACT with or without parental support or treatment as usual (TAU), consisting of face-to-face treatment for anxiety individually or in a group format. Therefore, the authors had limited insight into the assignment process. Therefore, this study is naturalistic and the results are preliminary and of a hypothesis-generating character.

Quantitative data were collected before, during, and after treatment, and follow-ups were performed 6 and 12 months after terminating treatment. In this evaluation, pretreatment and the 12-month follow-up are being compared. Due to difficulties in recruiting therapists, the sample size is relatively small, which further decreases the quality of the data, furthermore, the amount of missing data is relatively large.

No a priori power analysis was conducted, so between-group analyses could not be made. Therefore, the TAU group is not included in this evaluation, adherence measures are analyzed using descriptive data, and outcome measures are analyzed using within-group analyses. Therefore, the results are treated as an explorative evaluation of iACT in practice rather than a scientific study.

Participants

The participants were recruited from adolescents seeking help in primary care for anxiety symptoms at 3 different health care centers located in southwestern Sweden and specialized in treating adolescents with mental health issues. Previously, there was no iACT program for young people in Sweden, and the treatment program was developed and adapted for the 13-18 years age group, hence the age group that was studied. The inclusion criteria consisted of being aged 13-18 years; having access to a computer, iPad, or smartphone with internet access; being able to read and write in Swedish; and having been diagnosed with mild to moderate anxiety such as GAD, social phobia, panic disorder, or unspecified anxiety disorder. The exclusion criteria consisted of having a neuropsychiatric diagnosis, intellectual disability, bipolar disease, suicidality, or

XSL•FO
RenderX

ongoing psychotherapeutic treatment or daily consumption of benzodiazepines.

This evaluation originally included 35 participants aged 13-18 years. Of these participants, 9 participants received iACT without parental support; 15 participants received iACT with parental support; and 11 participants received TAU, of which, 8 participants received group therapy and 3 participants received individual therapy. Besides providing iACT, 2 of the health care centers involved in the study only provided group therapy, whereas the third only provided individual therapy. Since no power analysis was performed before the data collection, comparisons between groups could not be made, hence the TAU group was excluded from this evaluation. Table 1 demonstrates the distribution of age and gender among the participants.

Table 1. The distribution of age and gender among the participants.

Variable	Frequencies		
	iACT[a] without parental support (n=9)	iACT with parental support (n=15)	TAU[b] (n=11)

13-15	8 (89)	10 (67)	9 (82)
16-18	1 (11)	5 (33)	2 (18)
Sex, n (%)			
Female	8 (89)	15 (100)	10 (91)
Male	1 (11)	0 (0)	1 (9)
Other	0 (0)	0 (0)	0 (0)

[a]iACT: internet-delivered acceptance and commitment therapy.

[b]TAU: treatment as usual.

Procedure

Patients aged 13-18 years, accompanied by a parent, seeking help in primary care for anxiety problems were informed about the study and were offered participation by the therapist. All the adolescents included provided verbal consent and the parents provided written consent prior to participation. The patient and the parent participated in an assessment and inclusion meeting conducted by a participating therapist. The parent was subsequently led to another room to fill in a questionnaire whereas the adolescent was interviewed further.

After the assessment, all the participants who met the inclusion criteria were assigned by the therapist to either iACT, with or without parental support, or TAU. The assignment of groups was not randomized, and the authors have no information on how many patients were excluded from the study by the therapists nor how the therapists assigned the patients into groups.

Furthermore, the participating adolescents completed questionnaires before, during, and after treatment, as well as 6 and 12 months after treatment termination, and participated in diagnostic clinical interviews before and after treatment, as well as 12 months after treatment. To ensure the integrity of the adolescents and data security, the forms were distributed via the survey platform Esmaker [24], if possible, and otherwise in paper format. The paper forms and interview protocols were also added to a research journal to collect additional data such as other ongoing treatments.

The recruitment process took place from 2018 to 2020, hence parts of the data collection coincided with the COVID-19 pandemic, during which some upper secondary schools in Sweden introduced distance learning for periods of time while other schools did not [25]. It is possible that the pandemic affected the number of participants in the study. Furthermore, due to the difficulty of recruiting therapists, the number of participants in the study is relatively low. Despite the low number of participants, the recruitment was terminated due to financial reasons.

Intervention

In this study, the participants were recruited from 3 health care centers that were specialized in adolescent mental health and located in southwestern Sweden: Gothenburg, Borås, and Uddevalla. These centers form a part of primary care and are specialized in helping patients aged 6-18 years. The therapists in this study were either licensed psychologists or intern psychologists, and as a part of implementing iACT at these centers, they participated in a 2-day course and received specific training in iACT for adolescents.

iACT Without Parental Support

These participants received a guided, internet-based, self-help program called Anxiety Help for Adolescents (in Swedish: Ångesthjälpen Ung) developed by Psykologpartners W&W AB. The program is adapted for patients aged 13-19 years with mild to moderate anxiety, for example, social phobia, GAD, panic disorder, obsessive-compulsive disorder, or unspecified anxiety disorder [19].

The iACT intervention consists of 8 modules and the recommended treatment duration is 10 weeks with weekly feedback from the therapist. The program is adapted to the target group of adolescents regarding formulations, concretizations of theoretical concepts, and clinical examples, as well as the overall structure, and presents different strategies through text, videos, exercises, and forms. There is a messaging function in which the therapist and the patient can communicate asynchronously, and the therapist can initiate conversations

XSL•FO
RenderX

through telephone, video calls, or physical meetings at the clinic. The therapist supports the patient through motivation, giving feedback, answering questions, and prompting upcoming parts of the program [19]. For a detailed list of contents of the iACT intervention, see Multimedia Appendix 1.

iACT With Parental Support

These participants were assigned to the iACT program described above, with the addition of receiving parental support on how to support their adolescent's anxiety regulation. Both the participants and parents were initially given information about the content and structure of the iACT program [19]. Subsequently, the parents took part in 3 physical meetings during their adolescent's treatment period, either individually or in groups, and were conducted with the help of a manual (Multimedia Appendix 2). The content included psychoeducation about anxiety and different reactions, examples of different anxiety disorders, and behavioral strategies to handle anxiety such as exposure, relaxation, breathing, balance activity, and rest. All the information was condensed into a pamphlet called More Than Afraid (in Swedish: Mer än rädd) [26].

TAU Group

The participants in the TAU group received the treatment they would normally be offered at the clinics, consisting of face-to-face treatment for anxiety individually or in a group format, both 8 weeks long, as conventional in clinical settings. The TAU group is not included in this evaluation since the groups could not be compared.

Measures

The adolescent filled in the following forms before, during, and after treatment, as well as 6 and 12 months after treatment:

- Revised Children's Anxiety and Depression Scale (RCADS-Children, 47 items), consisting of the 2 main scales, anxiety and depression, and the 6 subscales, social phobia, panic disorder, GAD, compulsive disorder, separation anxiety, and depression, on which higher scores indicate a higher number of symptoms. The subscales exhibit a high internal consistency (α=.78-.88) in a sample of 513 children in the United States [27,28].
- Avoidance and Fusion Questionnaire Youth (AFQ-Y8), designed to measure the level of psychological flexibility in youth aged 12-20 years: higher scores indicate higher levels of psychological inflexibility. In a Swedish sample of 62 children undergoing cancer treatment, AFQ-Y8 exhibited acceptable internal consistency (α=.76), good test-retest reliability (ICC=0.64), and convergent validity (r=0.42) [29].

Furthermore, the adolescent was interviewed before and after treatment and 12 months after completion. The assessments were performed by a psychologist or intern psychologist using the following measures:

- The Mini International Neuropsychiatric Interview for Children and Adolescents was used for diagnostics [30] and exhibits validity and test-retest reliability comparable to other standardized screening tools [31,32].
- The Children's Global Assessment Scale (CGAS) was used to assess overall functioning. The interviewer performs an assessment of the adolescent's level of functioning on a scale from 1 to 100, of which a higher score indicates a higher level of functioning [33]. CGAS exhibits high interrater and test-retest reliability, as well as high discriminant and concurrent validity [34-36].

Data Analysis

This study aimed to investigate whether there is a connection between parental support and adherence to iACT for adolescents with anxiety and whether the treatment results in differences in symptoms of anxiety and depression, psychological flexibility, and overall functioning at 12 months after terminating treatment.

Due to a nonrandomized design, a small sample, a large dropout, and the fact that no a priori power analysis was made, the data are nonparametric, which makes between-group comparisons less meaningful. Therefore, the TAU group (n=11) is not included in this evaluation. Adherence was analyzed using descriptive data and Meier-Kaplan survival analysis, a statistical method used for measuring the distribution of time of occurrences in cohort groups [37]. In this study, dropout is defined as terminating the iACT program before the last module. Participants with missing time-to-event data were excluded from the Kaplan-Meier analysis. Meanwhile, the outcome measures were analyzed using within-group comparisons.

Adherence was analyzed for all participants receiving iACT without parental support (n=9) and with parental support (n=15), presented in separate groups. In contrast, for the outcome measures, all participants receiving iACT are presented as 1 group, including both with and without parental support due to small groups. In the outcome measures, the pretreatment measurement and the 12-month follow-up were compared and only included participants completing both the premeasurement and the 12-month follow-up.

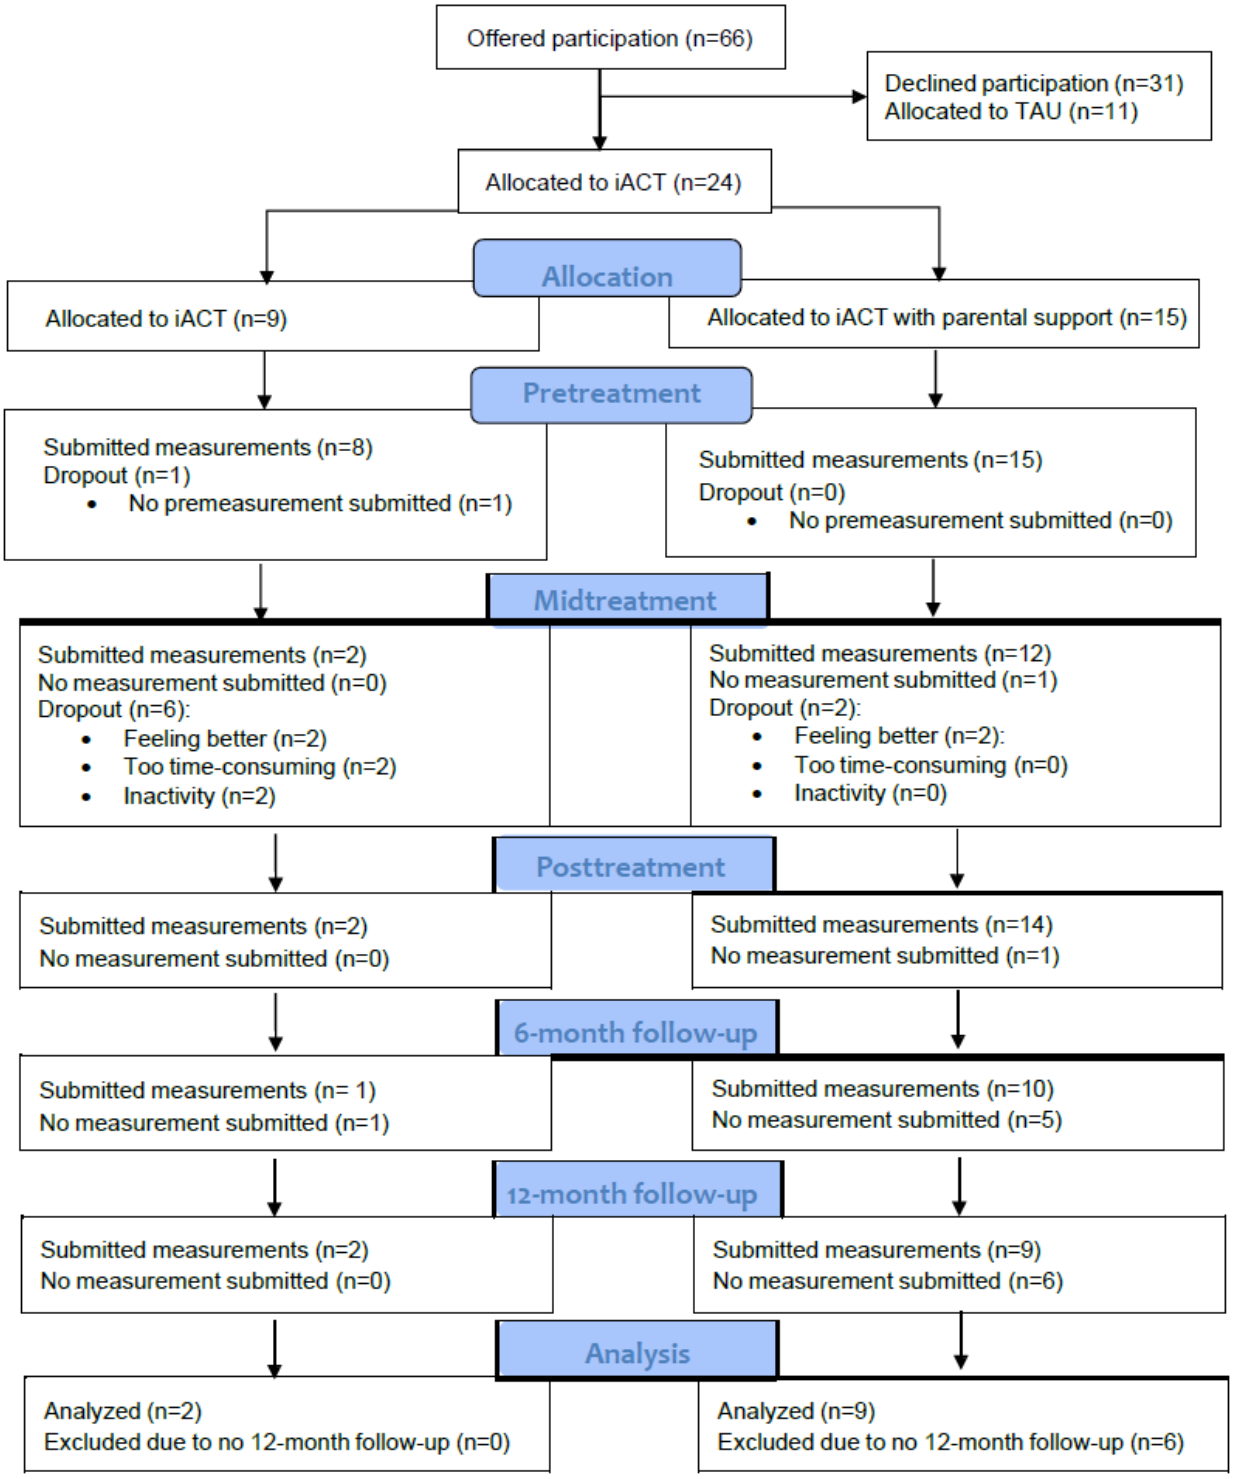
For the outcome measures, patient-rated scores using RCADS and AFQ-Y8, as well as therapist-rated scores using CGAS and within-group analyses were performed using the nonparametric statistical method Wilcoxon signed rank test for related samples. Effect sizes were calculated based on the formula described by Field [38] and were interpreted as 0.10-<0.3 (small effect), 0.30-<0.5 (moderate effect), and ≥0.5 (large effect). The within-group analyses were performed in SPSS Statistics (version 29; IBM Corp).

Ethical Considerations

This evaluation constitutes a part of the research project IMPACT in 2017-2021 (Swedish National Research Register; ID: 240221), approved by the Regional Ethics Committee in Gothenburg (Dnr: 703-17). The IMPACT project was designed to conduct an ongoing evaluation of introducing iACT for adolescents with anxiety in primary care during the implementation phase, and this evaluation is a 12-month follow-up. The participants have been informed that their participation is voluntary and that they have the right to cancel without further explanation. Moreover, the participants have been informed that participation in the study will not in any way affect their future opportunities for care and treatment at

XSL•FO
RenderX

the health center and that participation in the study will not be mentioned in medical records. Both accessing care and participating in the study were free. Furthermore, the participants have been informed about how the data will be managed, including confidentiality aspects, as well as analysis and presentation. The confidentiality of all participants is thus guaranteed, and consent from all participants has been obtained including both adolescents and parents. Digital forms were collected using the survey platform Esmaker [24], and data were analyzed using SPSS Statistics.



Results

Overview

In this section, the results are presented regarding treatment adherence and outcome measures based on the questions of the aims. Adherence is presented for all participants (n=35), and the participants receiving iACT are presented in 2 separate groups: iACT without parental support and iACT with parental support. The outcome measures are presented for the participants who completed the assessments for both the pretreatment and the 12-month follow-up (n=11). Moreover, the iACT participants are presented as 1 group, regardless of whether they have received parental support or not. Below, the primary outcomes are presented. Figure 1 demonstrates a CONSORT (Consolidated Standards of Reporting Trials) flow diagram of the study.

Is There a Connection Between Parental Support and Adherence to iACT for Adolescents With Anxiety?

For the analyses regarding adherence to treatment, the participants were presented in 2 groups: iACT without parental support (n=9) and iACT with parental support (n=15). Table 2 demonstrates descriptive statistics for the number of completed modules or sessions at the time of terminating the program.

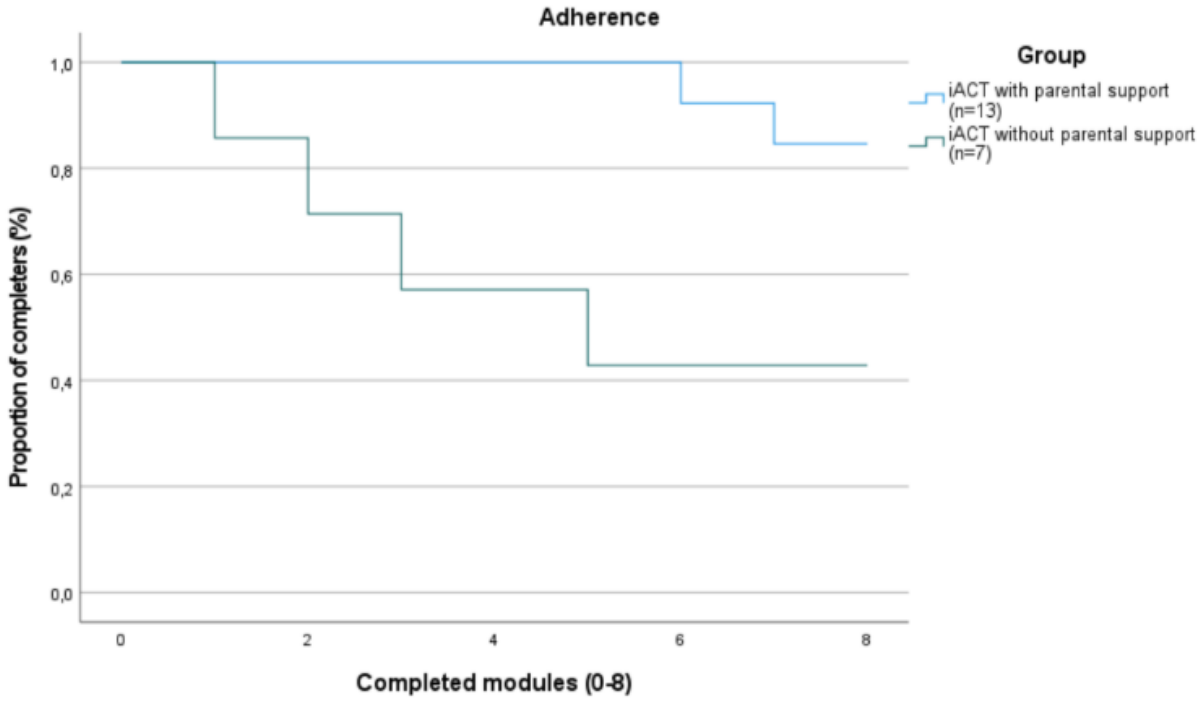
Table 2. Descriptive statistics for the number of completed modules.



Completed modules or sessions(%)	iACT[a] without parental support (n=9), n (%)	iACT with parental support (n=15), n (%)
<25	1 (11)	0 (0)
25-50	2 (22)	0 (0)
50-75	1 (11)	1 (7)
75-100	3 (33)	12 (80)
Missing	2 (22)	2 (13)

[a]iACT: internet-delivered acceptance and commitment therapy.

The participants receiving iACT without parental support (n=9) exhibited a gradual dropout rate throughout treatment, of which 5 participants dropped out before treatment completion. In contrast, the participants receiving iACT with parental support (n=15) exhibited the least number of dropouts (n=2), of which all occurred during the second half of the treatment.

Figure 2 demonstrates a Meier-Kaplan graph illustrating the dropouts. The x-axis represents at which module the dropout occurred, with 0 indicating dropout before initiating treatment and 8 representing complete treatment. The y-axis represents the percentage of participants remaining in treatment.

Figure 2. Proportion of dropouts between groups of internet-delivered Acceptance and Commitment Therapy (iACT) with or without parental support.

Does iACT for Adolescents With Anxiety Result in Decreased Symptoms of Anxiety and Depression Between Pretreatment and 12 Months After Terminating Treatment?

In this section, the results of the patient-rated RCADS scores are analyzed for all participants completing both the premeasurement and the 12-month follow-up (n=11). In this section, the participants receiving iACT are in the same group, regardless of whether they have received parental support or not. Table 3 demonstrates descriptive statistics for the therapist-rated measurement points on RCADS.

[a]RCADS: Revised Children's Anxiety and Depression Scale.

[b]iACT: internet-delivered acceptance and commitment therapy.

The results from the Wilcoxon signed rank test for related samples for the RCADS total scores demonstrated a decrease in symptoms of anxiety and depression and a large effect size for the RCADS total scores from preassessment to the 12-month follow-up (*z* score: –2.81; *P*=.005; *r*=0.60). When analyzing anxiety and depression scores separately by subscales, reductions between the pretreatment assessment to the 12-month follow-up assessment for both anxiety (*z* score: –2.81; *P*=.005; *r*=0.60) and depression (*z* score: –2.67; *P*=.008; *r*=0.57) and large effect sizes were obtained. Below, the secondary outcomes are presented.

Does iACT for Adolescents With Anxiety Result in Increased Psychological Flexibility Between Pretreatment and 12 Months After Terminating Treatment?

In this section, the results of the patient-rated AFQ-Y8 scores are analyzed, indicating the adolescent's self-rated levels of psychological flexibility. In this section, the participants receiving iACT are presented in the same group, regardless of whether they have received parental support or not. Table 4 demonstrates descriptive statistics for the therapist-rated measurement points on AFQ-Y8 and CGAS.

Table 4. Descriptive statistics for the measurement points on AFQ-Y8[a] and CGAS[b].

iACT[c] (n=11)	Score, mean (SD)	Score, median (IQR)	Score, range
AFQ-Y8			
Pretreatment	18.8 (5.8)	21 (12-22)	11-30
Posttreatment	14.9 (7.7)	13 (10-20)	3-30
6-month follow-up	12.3 (7.6)	11 (7-17)	3-27
12-month follow-up	12.7 (6.7)	11 (8-17)	5-29

The results from the Wilcoxon signed rank test for related samples for the AFQ-Y8 demonstrated increased psychological flexibility from preassessment to the 12-month follow-up (*z* score: –2.54; *P*=.01; *r*=0.55).

Does iACT for Adolescents With Anxiety Result in Improved Overall Functioning Between Pretreatment and 12 Months After Terminating Treatment?

In this section, the results of the therapist-rated CGAS scores are presented. The results from the Wilcoxon signed rank test on the CGAS total scores indicated no difference between measurement points from pretreatment to the 12-month follow-up for the iACT group (*z* score: –0.51; *P*=.96; *r*=0.146).

Discussion

Overview

This evaluation aimed to investigate whether there is a connection between parental support and adherence to iACT for adolescents with anxiety and whether iACT for adolescents with anxiety results in a difference in symptoms of anxiety and depression, psychological flexibility, and overall functioning, between the pretreatment measurement and 12 months after terminating treatment. In this section, the principal findings, limitations, and implications will be discussed in contrast to other studies. Overall, the results must be handled with caution due to the nonrandomized design, small sample size, and large amount of missing data.

Principal Findings

Overview

The IMPACT project was conducted as an ongoing evaluation to broaden the understanding of iACT for adolescents with anxiety in a routine primary care setting during the implementation phase. In the first IMPACT paper, Weineland et al [20] concluded that the interviewed therapists were positive to iACT for adolescents but also identified challenges such as motivating patients. In the second paper, Lilja et al [21] found that the interviewed parents expressed uncertainty about their role in the treatment and clearer parental treatment support was suggested. This is the third part of the IMPACT project, consisting of a follow-up on adolescents with anxiety 12 months after receiving iACT, with or without parental support regarding treatment adherence, symptoms of anxiety and depression, and psychological flexibility, as well as overall functioning. The primary outcomes are discussed below.

Is There a Connection Between Parental Support and Adherence to iACT for Adolescents With Anxiety?

Regarding treatment adherence, the participants receiving iACT with parental support exhibited later and fewer dropouts than the participants receiving iACT without parental support. These findings might be due to the idea suggested by Weineland et al [20] that parental support could compensate for low treatment motivation among adolescents. However, due to the nonrandomized design and small sample size in this, further research is needed to test this hypothesis in RCTs and with larger samples. Other potential mediating effects could be giving the parents a deeper understanding of anxiety in both themselves and the adolescent, as well as how to support their adolescent and function as a cotherapist alongside the therapist. In addition, in each group, 2 participants discontinued treatment due to feeling better, indicating that dropouts from treatment are not necessarily negative.

In previous research, the authors have pointed to potential connections between parental support and positive treatment outcomes in children and families [22], including that some parents need support in their role as cotherapists in treatment [23]. The current research on the role of motivation in iACT for adolescents with anxiety is currently limited. Nevertheless, in a Norwegian study, Fjermestad et al [39] concluded that motivation predicts early alliance in CBT for youth with anxiety. Furthermore, in a Danish study by Stjerneklar et al [10], both the parents and the therapists were encouraged to help motivate the adolescent in their iCBT, in which iCBT exhibited moderate to large effect sizes between groups on anxiety compared to the waitlist.

Furthermore, iACT with parental support can be considered a complex intervention, which can be defined as an intervention consisting of multiple components. Complex interventions cause challenges in the development and identification [40] and Hasson and von Thiele Schwartz [41] claim that complex interventions tend to be at a disadvantage in research due to the difficulty in isolating them from the context. The authors argue that this applies to a large amount of psychological treatment methods, compared to medical treatments.

Does iACT for Adolescents With Anxiety Result in Decreased Symptoms of Anxiety and Depression Between Pretreatment and 12 Months After Terminating Treatment?

Outcome measures were investigated using a within-group analysis, in which the iACT-group demonstrated reduced symptoms of anxiety and depression between the preassessment and 12-month follow-up. Multiple previous studies have indicated positive treatment outcomes for iACT for adolescents with anxiety [9-12], but few have performed follow-ups at 12 months after treatment or longer. In the meta-analysis by Vigerland et al [9], of the papers on iACT for children and adolescents with anxiety, 2 papers had a 1-year follow-up: Spence et al [11] concluded that the improvements in both CBT and iACT were maintained at the 12-month follow-up and Tillfors et al [42] discovered significant improvements in iACT for high school students with anxiety disorder, maintained at the 12-month follow-up. Nevertheless, none of the studies included follow-ups more than 1 year after treatment, hence the long-term effects of iACT for adolescents with anxiety should be investigated further.

In this evaluation, in 2 of the cases, the results of Mini International Neuropsychiatric Interview for Children and Adolescents and CGAS exhibited an increase in symptoms and a decrease in functioning between the post and 12-month follow-up. Therefore, the interviewer had the impression that the COVID-19 pandemic influenced the results. In both cases, of which 1 participant from the iACT group and 1 from the

XSL•FO
RenderX

TAU group, the participant was diagnosed with social phobia at the 12-month follow-up and described that at least some of the symptoms were due to returning from distance to classroom learning. In addition, the authors suspect that the pandemic itself could have affected the anxiety levels and functioning of the participants, for example, fear of the disease itself or uncertainty about the future.

In a Swedish study, the authors surveyed 1818 adolescents, of which approximately 80% transferred to distance learning during the pandemic. The authors concluded that most of the participants experienced decreased mental health, especially female participants and those in distance learning. The authors also discovered that distance learning could result in less victimization and poorer mental health overall [43]. In another Swedish study, 3068 participants aged 16-17 years filled in a questionnaire about the impact of the COVID-19 pandemic from December 2020 to March 2021. The author concluded that female participants reported more worry than male participants and that participants with a lower socioeconomic background reported higher levels of worry in general, except for climate anxiety [44].

In an international systematic review and meta-analysis of 74 papers on anxiety among children and adolescents during the pandemic, the authors concluded that anxiety levels were more prevalent among female participants than male participants in North America and Europe than South America and Asia, during the second wave of COVID-19 and school closures [45]. A Finnish study surveyed 450,000 participants aged 13-20 years about the pandemic. The authors discovered that social anxiety increased from 2013 to 2021, especially among the female participants, and that unmet needs for schoolwork support, and fear of getting infected by COVID-19 or transmitting it to others were associated with high levels of social anxiety. Nevertheless, the authors observed no clear connection between time spent in distance learning and levels of social anxiety [46].

Furthermore, in an American study, 280 high schoolers were surveyed on social anxiety and the use of technology. The author discovered a positive relationship between social anxiety and a preference for using technological communication instead of face-to-face communication [47]. In an international study, 2665 participants aged 18-25 years from 121 countries, of which the majority from Australia, the United States, and the United Kingdom, were surveyed on social restrictions related to COVID-19 and its effect on loneliness, social anxiety, and depression. The authors concluded that reductions in social restrictions resulted in an increase in social anxiety due to having to readjust to the social environment [48]. In other words, the relationship between the COVID-19 pandemic and anxiety among youth is a complex matter with a diversity of outcomes, of which multiple possible scenarios might have affected the results of this study.

In this study, COVID-19 can be considered a confounding factor, which Jager et al [49] defined as a risk factor, unequally distributed among the participants, and not included in the causal pathway. Pourhoseingholi et al [50] define confounding factors as a variable affecting the variables studied but not their relationship. To prevent or reduce the confounding factors, Jager et al [49] suggest using exclusion criteria, for example, participant age, randomizing the assignment to groups, matching participants for example in pairs with or without exposure, or stratifying the participants into subgroups. Pourhoseingholi et al [50] mention that stratification is suitable with a low number of strata, whereas multivariate models, such as analysis of covariance, as well as logistic and linear regression, can be used with a larger number of covariates and confounders. The secondary outcomes are discussed below.

Does iACT for Adolescents With Anxiety Result in Increased Psychological Flexibility Between Pretreatment and 12 Months After Terminating Treatment?

In this evaluation, the analyses of AFQ-Y8 demonstrated an increase in psychological flexibility between the pretreatment measurement and the 12-month follow-up. These results are in line with previous research, concluding iACT to be effective in reducing symptoms of anxiety and increasing psychological flexibility, as well as suggesting a possible link between anxiety levels and psychological flexibility [17].

Does iACT for Adolescents With Anxiety Result in Improved Overall Functioning Between Pretreatment and 12 Months After Terminating Treatment?

In this evaluation, the analyses of overall functioning using CGAS did not indicate differences between the pretreatment measurement and the 12-month follow-up. However, in a meta-analysis of 9 RCTs on iACT for pediatric anxiety disorders, of which 7 included CGAS as a measure of functioning, the authors concluded that their confidence in the effect of iACT on functioning is low [51].

In summary, the results of this evaluation support a possible connection between parental support and adherence to iACT for adolescents with anxiety. Further research is needed to investigate the nature of the connection. Furthermore, the analyses of the outcome measures indicate reduced symptoms of anxiety and depression and increased psychological flexibility between the pretreatment measurement and the 12-month follow-up but no difference regarding overall functioning. However, due to a nonrandomized design, a small sample size, and a large amount of missing data, the results are uncertain, and the generalizability is severely limited.

Limitations

In this evaluation, the participants were recruited within the regular patient flow in primary care, which on one hand increases the ecological validity of the study but on the other hand decreases the control of several third variables influencing the groups. Performing pragmatic evaluations on how the treatment method works under regular conditions is a concrete way to achieve local evidence. Evaluating iACT the way it is provided in clinical practice, without adding resources or excluding patients for the sake of the evaluation, can provide a closer input on the actual effect, which in turn can increase the external validity.

Due to organizational problems in conducting the study, the participants could not be randomized and were instead assigned

XSL•FO
RenderX

to iACT or TAU following a nonrandomized design. Since the authors could not control the assignment of treatment method, no conclusions on eventual differences in treatment outcomes between groups could be made. Therefore, the TAU group was omitted from this evaluation and the internal validity is reduced.

This evaluation took place during the implementation phase of iACT in primary care, which poses its own unique challenges. Hasson and von Thiele Schwarz [41] suggest that performing follow-ups and giving feedback are ways to increase the motivation to implement a new method. In other words, the evaluation itself can influence the object of evaluation. During the IMPACT project, one of the staff members at one of the clinics involved mentioned that the project helped them initiate the implementation.

For the therapists involved in this study, the implementation phase included a learning phase in assessing and assigning iACT to patients. In the first IMPACT paper, the interviewed therapists discussed which patients iACT can be helpful for. The therapists concluded that iACT is more suitable for patients with self-discipline, acceptance of personal responsibility, capability of introspection, and appreciation of working independently with the program. Furthermore, the therapists concluded that iACT is better suited for patients with anxiety rather than depression and that the symptoms should not be too severe, wide-ranging, or long-standing, and that the patient preferably should be in the upper teens. Furthermore, several therapists expressed that iACT is less suitable for patients with learning disabilities, neuropsychiatric illness, or dyslexia [20].

The participant recruitment took place between 2018 and 2020, hence parts of the data collection took place during the COVID-19 pandemic. The authors suspect that the pandemic influenced the anxiety and functioning of the participants both directly, such as fear of infection, and indirectly such as transferring between distance and classroom learning in some cases. Ideally, the authors could have addressed this during the study, for example, by specifically asking about the effect of the pandemic. Thus, the results should be handled with caution.

The sample size in this study is relatively small, especially in the subgroup analyses, which severely limits the generalizability of the results. Furthermore, this evaluation contained a relatively large amount of missing data in proportion to the sample size. In a review paper, Kang [52] reviews techniques for managing missing data and argues that the best method is prevention, for example, by minimizing the number of follow-ups. The data collection for the IMPACT project consisted of surveys before, during, and after treatment and at 6- and 12-month follow-ups, as well as interviews before, during, after, and 12 months after treatment. It is possible that the number of measurements might have had an impact on the participation, for example, by reducing the motivation to participate. On the other hand, a larger number of measurement points, as well as both written and spoken, results in more opportunities to collect data.

In this evaluation, missing data were handled by complete case analysis, which Kang [52] does not recommend with small sample sizes. Applying the last-observation-carried-forward method would have increased the amount of data included in the analyses. However, since the previous measurements occur closer to the treatment phase, this could also create a bias in the data. Furthermore, due to a large number of missing data, the authors determined that the last-observation-carried-forward method would risk being too misleading; therefore, only participants with complete data were included in the analysis.

Regarding dropouts, Kang [52] recommends documenting the reason and thus enabling further analysis. In this evaluation, treatment adherence was investigated by analyzing the timing and reason behind the dropouts. Nevertheless, more actions could have been taken in preventing and investigating the dropouts. In a Swedish RCT, 162 adults were investigated regarding their participation in iACT to explore variables predicting dropout, adherence, and outcomes. The authors concluded that the level of treatment credibility predicted dropouts whereas attrition was associated with higher levels of impulsivity and low levels of intrinsic treatment motivation [53].

The generalizability of the results in this evaluation is limited due to the small and gender-based sample of young people that were included. To achieve a better understanding of mental health in male adolescents and to enhance primary care services, it is important to address gender bias in future research and clinical work. Furthermore, the amount of missing data was relatively high, which further reduced the possibility of drawing conclusions based on the data.

Due to limitations in the study design regarding a small and gender-biased sample size with a large proportion of dropouts and missing data, a nonrandomized assignment of intervention, and analysis limited to within-group, this investigation should be considered an explorative evaluation of a new method rather than a scientific outcome study. Further research on iACT in the regular patient flow in primary care is needed.

Conclusions

This evaluation consists of a follow-up on adolescents, 12 months after receiving iACT, with or without parental support. Due to a large amount of missing data, the results should be viewed as an evaluation rather than a scientific study. Adherence to treatment was investigated, indicating that parental support could increase adherence to iACT, which in turn might improve the conditions for young patients undertaking iACT treatment. The results also underscore the importance of parental involvement in the treatment of adolescents with mental illness. More research is needed to explore the relationship between parental support and treatment outcomes and how clinicians can facilitate the process.

Future research should investigate internet-based treatments for adolescents in primary care with additional, possibly digital, parental support programs in RCTs. After the IMPACT project was conducted, an internet-delivered parental support program was developed, in which information about how to support the adolescent during treatment was added [19]. Further research is needed on parental support in this format as well. Moreover, further research is needed on involving next of kin in health care in general.

Furthermore, the analyses of the outcome measures suggest that iACT might be an effective treatment for both anxiety and

XSL•FO
RenderX

depression and has the potential to be an effective treatment of comorbidity and a broader spectrum of anxiety problems.

Acknowledgments

First and foremost, the authors would like to acknowledge Närhälsan and Omtanken, as well as Research and Development Primary Health Care, Region Västra Götaland, Gothenburg, Sweden, for making the Internet Mediated Psychological Treatment-Acceptance and Commitment Therapy (IMPACT) project possible. Furthermore, we would like to thank all health care staff and participants for their time and contributions. Finally, we would like to thank the project managers in Region Västra Götaland. Regional R&D, DNR: 834181 and DNR: 758551 funded the study, received by the second author as the main applicant.

Conflicts of Interest

None declared.

Abstract

Background: As adolescents increasingly engage with digital experiences, the internet serves as a platform for social interaction, entertainment, and learning. The COVID-19 pandemic accelerated this trend, with remote learning and restricted physical interactions driving changes in internet behavior. Adolescents spent more time on gaming and social media, reflecting a notable shift in use patterns.

Objective: We hypothesized that the COVID-19 pandemic changed internet use patterns among Korean adolescents, including content types, time spent on web-based activities, and pathological use prevalence. Additionally, we anticipated that these changes would correlate with shifts in adolescents' psychological status during the pandemic.

Methods: Data from 827 adolescents aged 12 to 15 years (n=144 in 2018, n=142 in 2019, n=126 in 2020, n=130 in 2021, n=143 in 2022, and n=142 in 2023) were gathered over 6 years from 43 middle schools across 16 regions and 1 hospital in South Korea. The demographic data collected included age, sex, and school year. Participants also provided information on their internet use patterns and levels of internet addiction. Additionally, psychological status, including mood, anxiety, attention, and self-esteem, was assessed.

Results: There were significant differences in the depression scale (Patient Health Questionnaire 9). The Patient Health Questionnaire 9 scores for 2018, 2019, and 2023 decreased compared to those in 2020, 2021, and 2022 (F_5=3.07; P=.007). Regarding changes in internet use behavior, game playing among adolescents decreased after the pandemic compared to before, while watching videos increased. Additionally, the rate of problematic internet use was highest for games before COVID-19, but after COVID-19, it was highest for videos, and this trend continued until 2023 (χ^2_3=8.16, P=.04). Furthermore, this study showed that the Young's Internet Addiction Scale (YIAS) score was highest in the game group in 2018 compared to other groups before COVID-19 (F_5=14.63; P<.001). In 2019, both the game and video groups had higher YIAS scores than other groups (F_5=9.37; P<.001), and by 2022, the YIAS scores among the game, video, and Social Network Service groups did not differ significantly. The degree of influence on the severity of internet addiction was also greatest for games before COVID-19, but after COVID-19, the effect was greater for videos than for games.

Conclusions: During the COVID-19 pandemic, internet use for academic and commercial purposes, including remote classes and videoconferences, increased rapidly worldwide, leading to a significant rise in overall internet use time. The demand for and dependence on digital platforms is expected to grow even further in the coming era. Until now, concerns have primarily focused on the use of games, but it is now necessary to consider what types of internet behaviors cause problems and how to address them.

Introduction

Background

Since its first appearance in a psychiatric context in 1998 [1], the maladaptive and addictive use of the internet, often referred to as internet addiction or internet use disorder, has been increasingly addressed over the past two decades. The internet use rate of Korean adolescents was around 50% in 1999, rising to 99.5% in 2023 [2,3].

Among adolescents, internet applications have shifted from being a supportive function to dominating their daily lives, sometimes leading to addictive use. Both the American Psychiatric Association and the World Health Organization have acknowledged this behavioral phenomenon in their classification manuals, the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5; since 2013 as a condition for further study) and the forthcoming *International Classification of Diseases, 11th Revision* (in the chapter on "Disorders due to behavioral addictions"). However, several authors have criticized this decision, citing a lack of conceptual and empirical foundations [4-9]. Moreover, Griffiths [10] insisted that the context (activities) of internet use is far more important than the amount of time spent on web-based activities.

In almost all studies, adolescents and young adults are consistently identified as the group with the highest prevalence of internet use. As adolescents increasingly engage in digital experiences, the internet serves as a versatile platform for social interaction, entertainment, and information acquisition [11]. Empirical studies have explored the intricate relationships between different types of internet activities and their associated risks. For instance, the problematic use of video games, social media, and the internet has been linked to various mental health issues, such as emotional distress, self-esteem problems, and attention problems, among adolescents [12]. A systematic review of the literature by Coutelle et al [13] suggested that psychological status including inattention, anxiety, and depression significantly impact internet addiction. Additionally, the heterogeneity in internet behavior patterns during the pandemic underscores the importance of considering individual differences when addressing problematic internet use [14].

The COVID-19 pandemic's impact on internet use highlights the need to understand the complexities of adolescent web-based activities and their mental health. In a review of longitudinal or repeated cross-sectional, follow-up studies, Wolf and Schmitz [15] declared that the COVID-19 pandemic and related stressors could impact the mental health of children and adolescents. Moreover, latent profile analyses reveal distinct patterns of internet and gaming use, suggesting that adolescents' engagement with digital platforms can be categorized into different profiles based on the intensity and type of use [16-18].

The COVID-19 pandemic further accentuated the use of digital platforms, as social restrictions necessitated remote learning and limited physical interactions. This shift resulted in altered internet behavior patterns among adolescents, with a notable increase in the time spent on internet gaming and social media [11,16].

Hypothesis

We hypothesized that the COVID-19 pandemic changed psychological status, as well as internet use patterns regarding internet content, use time, and pathological use, in Korean adolescents. Additionally, the severity of pathological internet use was influenced by psychological factors, including mood and attention, during the COVID-19 pandemic.

Methods

This study is a repeated cross-sectional study that tracked data from 827 students over 6 years.

Participants

Over 6 years, data from 827 adolescents (n=144 in 2018, n=142 in 2019, n=126 in 2020, n=130 in 2021, n=143 in 2022, and n=142 in 2023) aged 12 to 15 years were gathered from 43 middle schools across 16 regions and 1 hospital in South Korea.

Through a web-based advertisement on the Korean Game Culture Foundation website from January 1, 2018, to December 30, 2023, a total of 69 middle schools from 32 regions and 2 hospitals from 2 regions in South Korea applied to the Visiting Game Class program for game literacy education. Of these, 43 middle schools from 16 regions and 1 hospital were selected through the multistage sampling method. First, the selection was divided by region and hospital; 16 (50%) out of 32 regions were randomly selected, and 1 (50%) of the 2 hospitals in each selected region was chosen at random. Then, among the 52 schools within these 32 regions, 44 (85%) schools were selected. However, 1 school deferred its participation to 2024 due to its academic schedule, so it did not contribute to the research data. Trained agents from the Korean Game Culture Foundation visited schools and hospitals to conduct an investigation.

Ethical Considerations

All data collected by the agents were anonymized, and participants were rewarded with school supplies worth approximately US $10. Approval for the current study was granted by the Institutional Review Board at Chung-Ang University (1041078-202201-HR-052). We obtained informed consent for research participation from both the students and their parents.

XSL•FO
RenderX

Demographics and Internet Use Patterns

The demographic data collected included age, sex, and school year. Participants also provided information on their internet use patterns and levels of internet addiction. We defined "problematic internet use" as answering "yes" to the following questions: "Did you hear that people important or close to you consider your internet use to be a problem or suggest you meet a doctor or specialist for it?" [19].

The Young's Internet Addiction Scale (YIAS), a commonly used instrument for assessing internet addiction and web-based activities such as gaming, was used. This scale comprises 20 items, each rated on a 5-point Likert scale. The internal consistency of the Korean version of the scale has been reported to range from 0.90 to 0.93.

Psychological Assessment Scales

The Patient Health Questionnaire 9 (PHQ-9) was used to assess depression, with each item rated on a Likert scale from 0 to 3. A cutoff score of 10 (out of 27) was used to indicate depression. Park et al [20] validated the Korean version of the PHQ-9, which demonstrated an internal consistency of α=.81.

The DuPaul Attention-Deficit/Hyperactivity Disorder (ADHD) scale, particularly the ADHD symptom severity scale (ADHD Rating Scale [ARS]), includes 18 items, with 9 items dedicated to inattention and 9 to hyperactivity [21]. So et al [22] validated the Korean version of the ARS (K-ARS) and reported an internal consistency ranging from 0.77 to 0.89.

The Social Phobia Inventory (SPIN) is a self-report questionnaire consisting of 17 items designed to measure three dimensions of social anxiety. Cho et al [23] developed a Korean version of the SPIN (K-SPIN) and reported a high internal consistency with a Cronbach α of 0.91.

The Two-Factor Self-Esteem Scale (SE) is based on a modified version of the Rosenberg Self-Esteem Scale. It conceptualizes self-esteem as an individual's perception of their worth, incorporating elements of self-respect and self-confidence [24]. This scale contains 10 statements that assess overall feelings toward oneself. Participants indicate their level of agreement on a 4-point Likert scale, ranging from 1 (disagree completely) to 4 (agree completely). The internal consistency of the Korean version of the scale, referred to as the Self-Esteem Scale-Korean, has been reported with a Cronbach α of 0.79 [25].

Data Analysis

Demographic characteristics, including age, school year, and internet use time across years, were analyzed using ANOVA tests. Sex and internet activity across years were analyzed using chi-square tests. The YIAS scores and psychological scale scores, including PHQ-9, K-ARS, K-SPIN, and SE were also analyzed using ANOVA tests. The correlations between age, SE, PHQ-9, K-SPIN, K-ARS, IT use time, and YIAS were assessed using Pearson correlation analyses. The correlations between sex (IT activity) and age, SE, PHQ-9, K-SPIN, K-ARS, IT use time, and YIAS were assessed using Spearman correlation analyses. The correlation between sex and IT activity was assessed using Kendall tau-b correlation analysis.

We conducted hierarchical linear regression analyses using YIAS scores as the dependent variable to identify factors influencing the severity of problematic internet use. In Model 1, we tested the associations of demographic factors with the severity of problematic internet use. In Model 2, psychological factors were added to test their associations beyond the effects of demographic factors. In Model 3, internet use time was added to test its association beyond the effects of demographic and psychological factors. Finally, in Model 4, internet activities were added to test their associations beyond the effects of demographic factors, psychological factors, and internet use time. Statistical significance was set a priori at α=.05 (two-sided) to limit type-I error. All analyses were conducted using the *Complex Samples* module of the *PASW* statistics software package (version 19; IBM Corp).

Results

Demographic and Clinical Characteristics

There were no differences in sex ratio and age across the 6 years. Similarly, there were no differences in the scores of the self-esteem, social anxiety, and attention scales over the same period. However, significant differences were observed in the PHQ-9 scores (F_5=3.07; P=.007). The PHQ-9 scores for 2018, 2019, and 2023 were lower compared to those in 2020, 2021, and 2022. Additionally, there was a significant difference in internet use time (F_5=6.30; P<.001). Internet use time was highest in 2020 and 2021, followed by 2022 and 2023, and lowest in 2018 and 2019 (Table 1).

Changes in Internet Activities of Korean Adolescents Over 6 Years

Over the past 6 years, the population engaged in gameplay had decreased, while the population watching videos had increased. In 2018, a total of 51.4% (74/144) of the population engaged in gameplay, and 29.9% (43/144) watched videos. By 2022, these figures had shifted to 32.9% (47/143) for gameplay and 35.7% (51/143) for video watching, and in 2023, to 35% (50/142) for gameplay and 37.8% (54/142) for video watching (2022: χ^2_3=11.20, *P*=.01; 2023: χ^2_3=12.32, *P*=.006). Similarly, in 2019, a total of 46.2% (66/142) engaged in gameplay and 35% (50/142) watched videos. By 2022, these figures had changed to 32.9% (47/143) for gameplay and 35.7% (51/143) for video watching, and in 2023, to 35% (50/142) for gameplay and 37.8% (54/142) for video watching (2022: χ^2_3=8.68, *P*=.03; 2023: χ^2_3=8.16, *P*=.04; Figure 1).

SNS: Social Network Service.

Differences in Problematic Internet Use for 4 Activities in Korean Adolescents Over 6 Years

Until 2019, the proportion of problematic internet use was highest in the gaming group among the 4 types of internet use. However, the proportion of problematic internet use in watching videos abruptly increased in 2020 and has maintained its top position until 2023. The proportion of problematic internet use in Social Network Service (SNS) use continuously increased until 2021 but decreased in 2022 and 2023 (Figure 2).

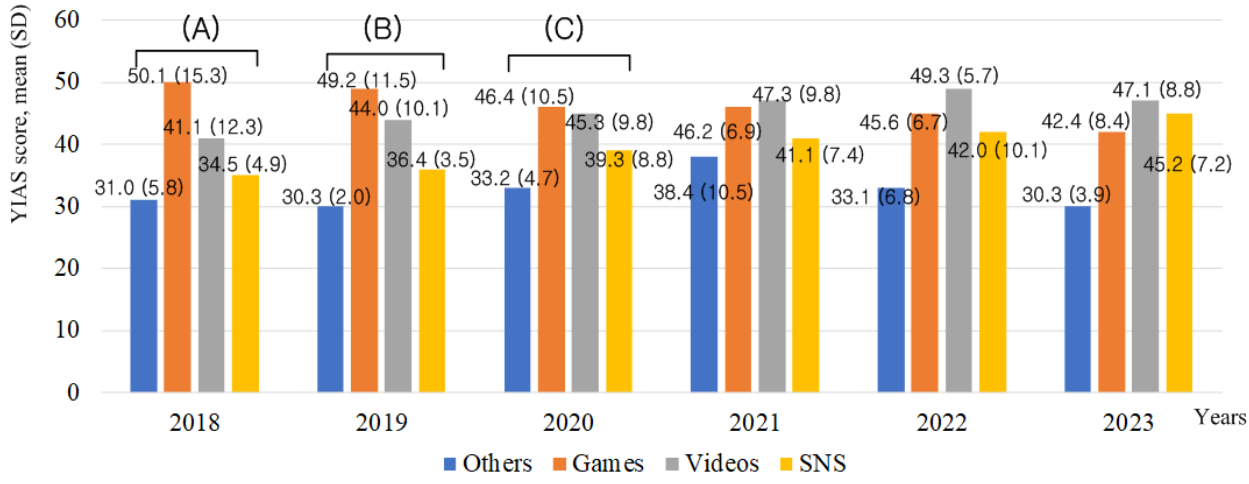

Figure 2. Changes in problematic internet use for 4 activities in Korean adolescents over 6 years. SNS: Social Network Service.

Differences in YIAS Scores for 4 Activities in Korean Adolescents Over 6 Years

In 2018, the YIAS scores for gameplay (mean 50.1, SD 15.3) were the highest compared to other activities. The YIAS scores for watching videos (mean 41.1, SD 12.3) were higher than those for SNS use (mean 34.5, SD 4.9) and other activities (mean 31.0, SD 5.8; F_3=14.63; P<.001). In 2019, the YIAS scores for gameplay (mean 49.2, SD 11.5) and watching videos (mean 44.0, SD 10.1) were higher than those for SNS use (mean 36.4, SD 3.5) and other activities (mean 30.3, SD 2.0; F_3=9.37; P<.001). In 2020, the YIAS scores for gameplay (mean 46.4, SD 10.5) and watching videos (mean 45.3, SD 9.8) were higher than those for SNS use (mean 39.3, SD 8.8) and other activities (mean 33.2, SD 4.7; F_3=4.98; P=.003). In 2021, there was no significant difference between the scores of the four activities (F_3=2.33; P=.08). In 2022, the YIAS scores for other activities (mean 33.1, SD 6.8) were significantly lower than those for gameplay (mean 45.6, SD 6.7), watching videos (mean 49.3, SD 5.7), and SNS use (mean 42.0, SD 10.1; F_3=6.83; P<.001). However, there was no significant difference between the scores for gameplay, watching videos, and SNS use. In 2023, the YIAS scores for other activities (mean 30.3, SD 3.9) were significantly lower, than those for gameplay (mean 42.4, SD 8.4), watching videos (mean 47.1, SD 8.8), and SNS use (mean 45.2, SD 7.2; F_3=4.73; P=.004). However, there was no significant difference between the scores for gameplay, watching videos, and SNS use (Figure 3).

Figure 3. The changes in YIAS scores for 4 activities in Korean adolescents over 6 years. (A) Game>Videos>SNS=Others (F_3=14.63; P<.001). (B) Game=Videos>SNS=Others (F_3=9.37; P<.001). (C): Game=Videos>SNS=Others (F_3=4.98; P=.003). SNS: Social Network Service; YIAS: Young's Internet Addiction Scale.

Differences in Influencing Factors for YIAS Scores

Considering the beta values of Model 4, the order of statistically significant influences on the severity of internet addiction in 2018 was as follows: game playing, PHQ-9 scores, watching videos, K-ARS scores, and IT use time (Table 3 and Table S1 in Multimedia Appendix 1). In 2019, the order was game playing, watching videos, PHQ-9 scores, K-ARS scores, and IT use time (Table 3 and Table S2 in Multimedia Appendix 1). In 2020, the order was K-ARS scores, game playing, and watching videos (Table 3 and Table S3 in Multimedia Appendix 1). In 2021, the order was PHQ-9 scores and watching videos (Table 3 and Table S4 in Multimedia Appendix 1). In 2022, the order was watching videos, game playing, PHQ-9 scores, K-ARS scores, and SNS use (Table 3 and Table S5 in Multimedia Appendix 1). In 2023, the order was PHQ-9 scores, K-ARS scores, watching videos, SNS use, and game playing (Table 3 and Table S6 in Multimedia Appendix 1).

Discussion

Principal Findings

The goal of this study was to examine changes in internet use patterns among adolescents, from before to after the outbreak of the COVID-19 pandemic. Our findings revealed several changes in internet use time and patterns, as well as shifts in problematic use behavior before, during, and after COVID-19.

The results showed that PHQ-9 scores were low before and after the COVID-19 pandemic, but high from 2020 to 2022, when the pandemic was at its peak. This aligns with previous studies indicating a high proportion of adolescents experiencing depression and anxiety during the pandemic [26,27]. The COVID-19 pandemic brought significant changes to adolescents' lives, potentially acting as environmental stressors [28]. To avoid exposure to the virus, young people actively avoided social activities, and many children and adolescents were confined to their homes for extended periods due to lockdowns. This social isolation has been associated with an increased risk of depression and anxiety in children and adolescents [29]. Additionally, the fear of infection itself was linked to anxiety and depression [30]. With the lifting of lockdowns, most people have resumed their lives, and depression and anxiety likely diminished since the peak of the pandemic due to the development of coping mechanisms and hopeful news about vaccines during the "honeymoon phase" of the disaster [31-33].

Similar results regarding the relationship between mental health and internet addiction during the COVID-19 pandemic were reported in several studies [34,35]. Ye et al [34] reported that depression is positively correlated with internet addiction during the COVID-19 pandemic. Moreover, adolescents with depressive disorders could have a higher risk of internet addiction. In a meta-analysis, Tang et al [35] reported that the association between problematic smartphone use and depressive symptoms became stronger after the COVID-19 outbreak.

To our knowledge, there is evidence of changes in internet use patterns during the pandemic, including increased dependence on the internet [36]. In a large, national youth sample, cross-sectional study conducted in the United States during the early period of the COVID-19 pandemic, the absolute time of internet use among teenagers more than doubled compared to prepandemic times [37]. Additionally, a systematic review and meta-analysis of screen time among children and youth aged 0 to 21 years before and after the pandemic showed a 1.6-fold increase in screen time during the pandemic [38]. Similarly, in this study, from 2020 to 2021, during the COVID-19 outbreak, adolescents used the internet more than before, and their internet use time decreased as the COVID-19 peak passed. Previous studies have shown that internet use time increased as physical activity decreased due to the lockdowns caused by COVID-19 [39,40]. These results may reflect decreased screen time as physical and offline activity increased when daily life recovered after COVID-19 [41].

XSL•FO
RenderX

During the pandemic, teenagers increased their internet use for various purposes, such as interacting with friends, doing homework, enjoying games, and attending remote classes [42]. Generally, internet addiction is suspected when an individual devotes excessive time to internet use [43]. Excessive internet use is known to likely lead to internet addiction, especially in children and adolescents [44]. Similarly, as adolescents spend more time on web-based activities during the pandemic, many studies have shown an increased risk of internet addiction. For instance, a study examining internet addiction in Taiwanese high school students during COVID-19 found a 24.4% rate of addiction, indicating an increase compared to prepandemic levels [45]. In a longitudinal study on the developmental qualities of children and adolescents during the COVID-19 pandemic, Wang et al [46] suggested that the pandemic may lead to a decline in positive youth development, making them more vulnerable to internet addiction. Additionally, a study conducted in India investigated the effect of the COVID-19 lockdown on internet addiction in late teenagers, showing a 14.84% increase in internet gaming disorder (IGD) frequency compared to previous studies in the same region [47]. However, most studies focused only on excessive internet use and did not differentiate specific internet activities. Therefore, to address problematic internet use among adolescents, it is necessary to examine in more detail which specific internet activities are problematic.

Looking at the changes in internet use behavior that this study focused on, game playing decreased in adolescents after the pandemic compared to before the pandemic, and watching videos increased further. In addition, in this paper, the problematic internet use rate of games was the highest before COVID-19. Still, after COVID-19, the problematic internet use rate was the highest in the video group, and this trend continued until 2023. In addition, as our study showed, the YIAS score was the highest in the game group in 2018 compared to other groups before COVID-19. Still, in 2019, the YIAS scores in the game and video groups were higher than other groups, and the YIAS scores between the game, video, and SNS groups did not differ significantly as we went into 2022. The degree of influence on the severity of internet addiction was also the largest in the game group before COVID-19, but the effect on the video group was greater than in the game group after COVID-19.

Similar to these findings, several studies have reported significant changes in how individuals allocate time across different activities during the COVID-19 pandemic, noting increased SNS use, watching videos, and more, not just gaming [36,48,49]. According to a probability-based tracking survey of tweens and teens in the United States, there was no significant difference in teen gaming time between 2019 and 2021. Still, the time spent watching videos increased significantly, up to 23 minutes daily [50]. As several reports suggest, overall, the global gaming market has shrunk since the COVID-19 pandemic [51], and gaming users' gaming hours have declined since the peak [52]. On the other hand, the video-related industry has grown significantly as lockdowns have made it one of the major recreational activities [53]. According to Morse et al [54], TV or streams or movies have emerged as a new leisure activity, with activities experiencing the greatest increase during COVID-19. Another study suggests that Netflix, Hulu, and Amazon Prime Video are now recognized as some of the most important TV networks and video sources for the younger adult generation, further highlighting the popularity of streaming services [55]. Similarly, other studies point to the problematic use of SNS platforms, including video consumption by adolescents [36,56,57].

In the paper by Nawaz et al [36] on technology utilization in the new post–COVID-19 era, social networking platform engagement has increased markedly as study participants have been given more time for web-based social interaction. Meanwhile, in one study conducted in Italy, video consumption through certain platforms, like TikTok, during the COVID-19 pandemic strongly predicted social media addiction [56]. In addition, similar to previous studies that revealed that adolescents' social anxiety can lead to problematic social media use [57]; the increasing web-based social interaction trend, rather than internet gaming, reflects the growing dependence on digital connections as a coping mechanism during physical distancing and quarantines, with web-based streaming services, including videos, also experiencing notable use increases [36]. Taken together, even before COVID-19, video-sharing platforms such as YouTube [58] and social media platforms such as Instagram or Snapchat were already gaining popularity [59]. However, short video consumption worldwide saw the fastest and largest increase in the early stages of the pandemic, especially among those aged 15-29 years [60], where teenagers would have sought self-expression and social rewards by recording and communicating their daily lives [61]. Furthermore, the rise in the use of SNS and video apps during COVID-19 suggests a shift in overall trends during physical distancing, searching for information, and using platforms to help maintain social relationships [62].

As mentioned in the previous results, the COVID-19 pandemic has significantly changed people's lives worldwide, with internet use at the center of this change. Although internet use has alleviated mental health symptoms for many and helped them cope with new trends [63,64], adolescents have been able to devote more time to web-based activities, especially during emotionally demanding times, which can lead to problematic use [65]. It is essential to provide guidance to reduce the risk of such addiction. Adults should observe how much time adolescents spend on web-based activities (eg, playing games and watching videos) and help them manage these activities [48].

However, problematic internet use has not yet been sufficiently discussed. The American Psychiatric Association included IGD in *DSM-5* [66], and the World Health Organization included gaming disorder in the *International Classification of Diseases, 11th Revision* [67], but current societies present only diagnostic criteria for games. This study shows that games no longer account for a high percentage of adolescents' problematic internet use time. In addition, the *DSM-5* acknowledges the limitations of the absence of well-studied subtypes for IGD and acknowledges that there are limitations to the diagnosis, such as the fact that it is not clear which game type is specifically included in IGD diagnosis [66]. Furthermore, a survey of

XSL•FO
RenderX

adolescents in China on IGD, problematic smartphone use, and problematic SNS use found that each has a different core symptom, with problematic SNS use requiring a different therapeutic approach as it shows a different core symptom [68]. Similarly, as Griffiths [10] argued in his study on the concept of internet addiction and IGD, it should be understood that people addicted to web-based activities, such as web-based games, web-based gambling, web-based sex, and web-based shopping, should not be defined as people with internet addictions, but rather as people with game addictions, sex addictions, or shopping addictions, who are engaged in addictive behavior using the internet as a tool. Chen et al [69] reported that problematic smartphone use was associated with the COVID-19 pandemic outbreak, whereas problematic internet gaming was not. Previous studies suggest that the focus should be on how the internet is used, rather than seeing the excessive internet use itself as the problem. It is not just gameplay time that is a problem—as individual internet behavior patterns have changed during the COVID-19 pandemic, these points should be considered when solving problematic internet use.

Limitations

There are some limitations to this study. First, there may be sampling errors in representing the overall internet use patterns of teenagers, as the survey only included teenagers aged 13 to 15 years. Second, because this study did not track the same population over 6 years, it was unable to fully capture the trends in internet addiction and patterns of internet use among adolescents. Third, this study could not fully capture changes in internet addiction and mental health because it was not a longitudinal study within a single group.

Although literature on the pandemic has surged with the global spread of COVID-19, little has been studied about the changes in media and content use caused by the pandemic [70]. To the best of our knowledge, this is the first study to focus on changes in internet use patterns due to the pandemic. The strength of our study lies in surveying the same teenage group over 6 years before, during, and after COVID-19 and further investigating which types of internet use were identified as problematic. Based on these changes in internet use patterns and problems among teenagers, this study contributes to the literature on understanding the trends in internet use behavior caused by COVID-19 and helps predict future changes in internet use.

Conclusions

During the COVID-19 pandemic, academic and commercial internet use through remote classes and videoconferences increased rapidly worldwide, leading to a rise in overall internet use time. The demand for digital platforms will continue to grow in the coming era. Until now, discussions have primarily focused on the use of games, but it is now necessary to consider what types of internet behavior cause problems and how to address them.

Abstract

Background: Anxiety disorders are the most common mental health conditions worldwide, yet 65% of those affected do not access services. The high prevalence of anxiety and the low rate of intervention uptake highlight the urgent need to develop timely, scalable, and effective interventions suitable for adolescents. This study adapted existing single-session interventions (SSIs) to further develop an SSI focused on a growth mindset regarding negative emotions for adolescent mental health.

Objective: The study aims to compare the effectiveness of 4 SSIs, SSI of a growth mindset for anxiety (SIGMA), SIGMA with boosters (SIGMA-Booster), SSI of a growth mindset of personality (SSIGP), and an active control group (support therapy [ST]), in reducing adolescent anxiety.

Methods: Classes from each secondary school were randomized to 1 of 4 intervention conditions: SIGMA, SIGMA-Booster, SSIGP, or ST. Each intervention took approximately 45 minutes online. Participants reported on anxiety symptoms (primary outcome), depressive symptoms, suicidal/self-harming thoughts, perceived control, hopelessness, attitude toward help-seeking, and psychological well-being (secondary outcomes) at preintervention, 2-week follow-up, and 8-week follow-up. Participants also completed a feedback scale postintervention. Generalized estimating equations were used to examine the effectiveness of the SSIs.

Results: A total of 731 adolescents from 7 secondary schools were randomized. The intent-to-treat analysis found a significant decrease in anxiety symptoms. The mean and 95% CI at baseline were 6.8 (6.0-7.6) for SIGMA-Booster, 6.5 (5.8-7.3) for SIGMA, 7.0 (6.2-7.7) for SSIGP, and 6.9 (6.1-7.7) for ST. At the 2-week follow-up, the mean and 95% CI were 5.9 (5.1-6.7) for SIGMA-Booster, 5.7 (4.9-6.5) for SIGMA, 5.4 (4.6-6.2) for SSIGP, and 5.7 (4.9-6.4) for ST. At the 8-week follow-up, the mean and 95% CI were 5.9 (5.1-6.7) for SIGMA-Booster, 5.3 (4.5-6.0) for SIGMA, 5.6 (4.8-6.4) for SSIGP, and 5.8 (5.1-6.6) for ST. These reductions were observed across all 4 groups. Moderation analysis found that participants with higher motivation for change, higher baseline anxiety scores, and fixed mindsets showed greater improvements in anxiety symptoms. Most participants (459/731, 62.8%) viewed the feasibility and acceptability of the SSIs positively.

Conclusions: The SSI for all 4 groups was effective in reducing anxiety and depression among adolescents over 8 weeks. Our data suggest the potential benefits of brief web-based interventions for adolescents, which could serve as scalable, destigmatized, and cost-effective alternatives to school-based programs. The intervention effects may have been underestimated, as this study did not exclude adolescents with minimal or no anxiety symptoms. Future studies should focus on the specific effects of interventions for adolescents with varying levels of anxiety symptoms.

Introduction

Background

Anxiety is one of the leading causes of illness and disability among adolescents aged 10-19 years [1]. Approximately 6.5% of adolescents worldwide and 6.9% in Hong Kong have been diagnosed with anxiety disorders [2,3]. In Hong Kong, for example, 1 in 4 secondary school students experienced high subclinical anxiety symptoms over a 3-month period, requiring clinical intervention [4]. Based on prevalence rates and local youth population data [5], it is estimated that approximately 85,000 secondary school students in Hong Kong require help and intervention for anxiety symptoms.

However, an estimated 65% of individuals with generalized anxiety disorder in Hong Kong did not access mental health services [6]. Among those who sought help, the median waiting time from symptom onset to receiving public child and adolescent psychiatric services was 58 weeks. Meanwhile, the cost of private treatment was reported to be HK $3000 (US $386) per monthly consultation, making it unaffordable for many families, who were left with no choice but to wait for public services [7]. Existing approaches, such as clinic-based treatments provided by highly trained mental health professionals, face significant limitations, including lengthy waitlists, high costs, and challenges in large-scale dissemination. This traditional setting further restricts access to services in special circumstances, such as during the COVID-19 pandemic [8]. Moreover, adolescents with mental health symptoms are particularly vulnerable to stigma and discrimination and may be reluctant to seek school-based interventions [9]. Even among youth who access care, most drop out prematurely, completing only 3-4 therapy sessions on average [10]. While natural remission without treatment may occur, it is uncommon [11]. Given these challenges, there is a clear need to develop briefer, scalable, nonstigmatizing, and youth-friendly interventions for adolescents with general anxiety symptoms. A brief intervention that fosters insight or reduces anxiety about mental health symptoms may help alleviate mental health problems and support remission.

Single-session interventions (SSIs) are structured programs designed to involve only 1 visit or encounter with a clinic, provider, or program [12]. These interventions can function as stand-alone treatments or as adjuncts to clinical services. Notably, research has shown that the number of sessions is not related to the magnitude of the treatment effect [13]. As a very brief intervention consisting of just 1 session, SSIs have demonstrated a relatively substantial effect on youth psychiatric problems. A previous meta-analysis [14] reported a mean postintervention effect size of 0.32 (Hedges *g*), with the largest effect size observed for anxiety (0.56). Although the effects of SSIs were moderated by follow-up length, with smaller effect sizes observed in follow-ups exceeding 13 weeks [14], Schleider and Weisz [15] still found significant improvements in youth depression and perceived behavioral control following growth mindset SSIs, with effects lasting up to 9 months compared with an active control. They also found that enhancing belief in personality change improved treatment access for adolescent depression [16], although no significant changes were recorded for general anxiety, social anxiety, or conduct problems [17]. Walton and Wilson [18,19] emphasized the importance of precise interventions that target the underlying psychological processes contributing to social or psychological problems, as well as the need for an adaptive context to maximize the potency of brief interventions. Thus, the effectiveness of SSIs is closely tied to their content (what to intervene) and implementation strategies (how to intervene).

Given the substantial evidence linking fixed mindsets to youth mental health problems [20] and the positive effects of growth mindset SSIs on anxiety-related outcomes [21], this study developed and examined the efficacy of growth mindset SSIs for adolescent anxiety in the Chinese context. Although some cultural adaptations of growth mindset SSIs have been made for non-Western populations, such as Indian adolescents [22], few studies have examined growth mindset SSIs in the Chinese context, particularly for anxiety-related outcomes [23]. We aimed to advance the existing literature by implementing and comparing different domains of growth mindset and developing implementation strategies for SSIs among Chinese adolescents. First, this study developed the SSI of a growth mindset for anxiety (SIGMA). As fixed mindsets about negative emotions (beliefs that one's negative emotions cannot change) have been closely associated with adolescent depression and anxiety [24,25], interventions that promote growth mindsets about negative emotions (beliefs in the changeability of one's negative emotions) may help alleviate worry and anxiety in adolescents. Second, to examine the effectiveness of SIGMA, we adapted the existing SSIs into Chinese and compared them with SSI of a growth mindset of personality (SSIGP) and support therapy (ST) [15,26]. Third, we collected feedback from social workers and counselors based on the principle of patient and public involvement, and they suggested that boosters could help strengthen the effectiveness of brief interventions. Thus, we designed booster reminders for SIGMA and examined whether reinforcing the core messages of the intervention with boosters would strengthen its effectiveness. A deviation from the 3-arm intervention protocol is that we increased the sample size of participants receiving SIGMA with booster (SIGMA-Booster) messages, establishing it as an independent group. As a result, the SIGMA-Booster group and the SIGMA group now have sample sizes equivalent to the other 2 groups (SSIGP and ST), rather than selecting only half of the original SIGMA group to receive booster messages. We proposed this 4-arm randomized controlled trial to provide evidence on the effectiveness of

XSL•FO
RenderX

SIGMA (including SIGMA and SIGMA-Booster) and compare it against the existing growth mindset intervention (SSIGP) and support theory as an active control. Beyond its research significance, the study's findings could have broad implications for mental health care practice and policy. If the SSIs in this study are found to be effective, they could be scaled up in schools and community settings, offering a cost-effective and accessible solution to address youth mental health needs. This could reduce the burden on overstretched traditional mental health services and inform public health policies, such as integrating SSIs into school mental health programs or national strategies.

Objectives

The primary objective of the study was to evaluate the effectiveness of a single-session growth mindset intervention for negative emotions (abbreviated as SIGMA) in reducing general anxiety symptoms among secondary school students.

The secondary objective was to compare the effectiveness of the aforementioned programs on secondary outcomes, including reductions in depressive symptoms, suicidal/self-harming thoughts, and hopelessness, as well as increases in perceived control over emotions, attitudes toward help-seeking, and psychological well-being.

Study Hypothesis

- Hypothesis 1: SIGMA (including SIGMA and SIGMA-Booster) and SSIGP are more effective than the active control, ST, in the primary outcome of (1) reducing general anxiety symptoms, and in the secondary outcomes of (2) reducing depressive symptoms, (3) reducing suicidal/self-harming thoughts, (4) reducing hopelessness, (5) enhancing perceived control, (6) increasing positive attitudes toward help-seeking, and (7) enhancing psychological well-being.
- Hypothesis 2: SIGMA (including SIGMA and SIGMA-Booster) is more effective than SSIGP in the outcomes listed from (1) to (7).
- Hypothesis 3: The effectiveness of SIGMA-Booster is greater than that of SIGMA in the outcomes listed from (1) to (7).
- Hypothesis 4: The effectiveness of SIGMA is greater in participants with higher motivation for change than in those with low or no motivation.
- Hypothesis 5: The effectiveness of SIGMA is greater in participants with higher baseline anxiety levels than in those with lower baseline anxiety levels.
- Hypothesis 6: The effectiveness of SIGMA is greater in participants with a more fixed mindset at baseline than in those with a more growth-oriented mindset at baseline.

Methods

Ethical Considerations

This study received ethical approval from the Hong Kong Polytechnic University Institutional Review Board (reference number HSEARS20201004001-01) and complied with institutional guidelines and the Declaration of Helsinki. Parental consent and student assent were obtained for all participants. Participants were informed of their right to withdraw at any time without penalty. Data were anonymized (eg, school names removed, unique codes assigned) and stored securely. Participants who completed the entire study received HK $100 (US $13) worth of supermarket coupons as compensation, while participating schools were provided with aggregate mental health reports for institutional support purposes.

Study Design

The study design was described in the published protocol [27]. The trial was prospectively registered at ClinicalTrials.gov (NCT05027880) under the trial ID NCT05027880.

Unlike the published protocol, we made SIGMA-Booster a separate arm to examine whether booster reminders would help promote the long-term effects of the SSI. Based on the principle of patient and public involvement, we consulted the targeted participant population as well as their teachers and counselors. They suggested that boosters, as reminders, should be helpful for long-term changes. Thus, we designed 5 boosters and printed them into folders to be used as weekly reminders between the 2- and 8-week follow-ups (from week 3 to week 7). Only the SIGMA-Booster group received these boosters.

Thus, 4 classes from the same grade of the participating school were randomized (using computer-generated random numbers) into the (1) SIGMA group, (2) SIGMA-Booster group, (3) SSIGP group, and (4) ST group (active control condition group), all of which received the ST intervention at the same time (Figures 1 and 2). Participants in the SIGMA-Booster arm received the SIGMA intervention along with weekly reminders of key intervention messages as boosters from weeks 3 to 7. Two schools did not have enough classes in 1 grade, so classes from other grades at those schools were invited to join the study. All participants received regular interventions at school. Three repeated assessments were conducted for the 4 groups simultaneously at (1) baseline, (2) 2 weeks postintervention, and (3) 8 weeks postintervention. The cluster randomization at the classroom level helped balance the risk of contamination between the experimental and active control groups, as well as account for school heterogeneity due to factors such as school culture, schedule, and management.

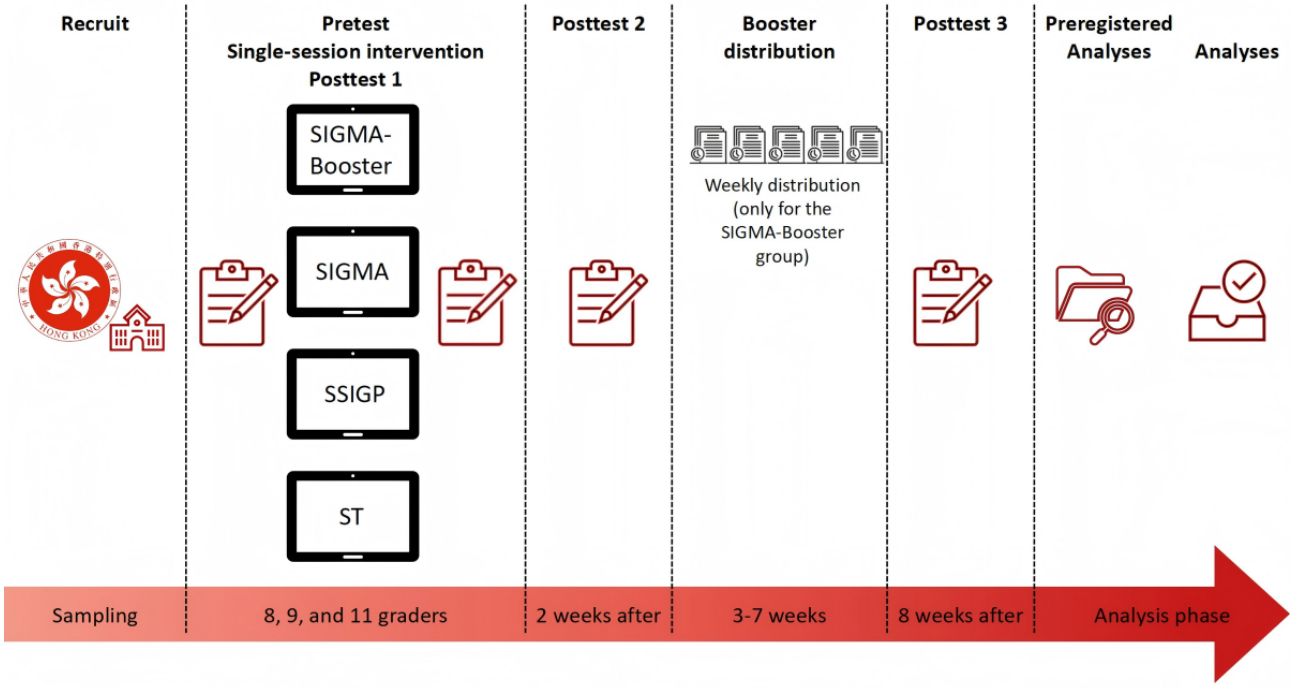

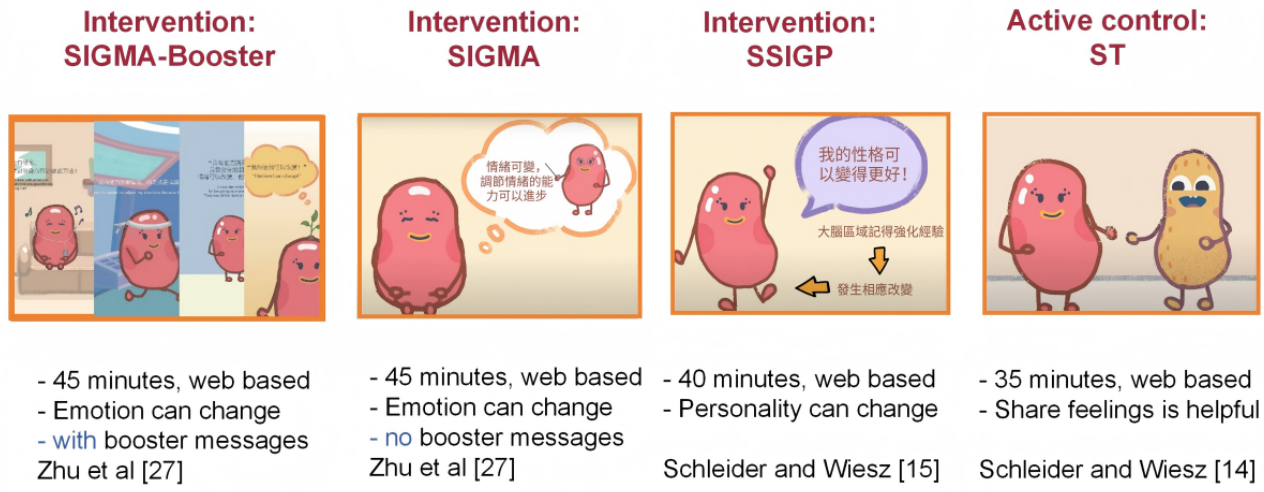

Figure 2. Intervention designs. SIGMA: single-session intervention of a growth mindset for anxiety; SSIGP: single-session intervention of a growth mindset of personality; ST: support therapy.

Participants

Seven schools from Hong Kong Island, Kowloon, and the New Territories participated in the study. These included schools that used English, Chinese, and mixed English and Chinese as the teaching medium. We targeted participants from form 2 to form 3 (grades 8-9). If a school did not have 4 classes in 1 grade, or if the number of eligible participants in a class was too few, we invited additional classes from other grades to participate.

Inclusion Criteria

Eligible participants were recruited from the 7 secondary schools through cluster randomized sampling. We included participants who (1) were Chinese youth able to read and write Chinese, (2) had sufficient visual and auditory abilities to complete the intervention and assessment, and (3) were able to give assent to participate in the study. As 2 schools did not have enough classes in 1 grade and invited classes from other grades to participate, a few participants above the age of 16 years were included, which did not follow the inclusion criteria outlined in the protocol (12-16 years old).

Exclusion Criteria

Exclusion criteria included (1) lack of parental consent; (2) inability to stay focused for the duration of the intervention, which is approximately 45 minutes; and (3) intellectual disability or severe illness or pain that could introduce significant bias in the students' health and mental health conditions. Eligible participants were not screened for anxiety symptoms, so this study comprehensively examined the efficacy of the interventions among students with absent, mild, moderate, and severe levels of anxiety.

XSL•FO
RenderX

Procedure

The school and student recruitment process included the following steps: First, we sent research invitations to schools randomly selected from the school list. Invitations ceased when 7 schools agreed to participate. To ensure sufficient participant recruitment, we recruited 1 additional school beyond the protocol's plan. Four classes from the same selected grade(s) at each school were randomly chosen to join the study. The 4 selected classes were then randomized to the SIGMA condition, SIGMA-Booster condition, SSIGP condition, and the active control condition using random numbers. All students in those classes were invited to participate, with final participation contingent upon parental consent and students' assent.

After providing consent, students scanned a QR code to access the baseline questionnaire and the intervention program via the Qualtrics survey system (SAP SE). Students within the same class were assigned to the same intervention conditions. The interventions were conducted separately for each group in the school activity rooms, which were equipped with sufficient computers or tablets and headphones (Figure 3). All intervention activities were self-administered and delivered in a web-based format. The principal investigator (SZ) and well-trained research assistants remained in the intervention rooms to provide guidance and assistance if needed. All groups in the same school received interventions concurrently to minimize the influence of the time factor.

Figure 3. Intervention in a classroom.

Trial Power and Sample Size

To ensure the sample size was sufficient to test the hypotheses, a small to medium effect size (Cohen *d*=0.33) was used based on prior research [15]. Power was set at 0.80, and α was set at .05. A final sample size of 584 (146 per arm) was required. Considering the attrition rate from our previous studies in school settings (<20%), the baseline recruitment target was set at 732 participants (183 per arm). We ultimately recruited 731 participants. As the number of participants in each class varied, the final number of participants in each of the 4 arms differed.

Measures

Primary Outcome

Anxiety symptoms, measured using the 7-item Generalized Anxiety Disorder (GAD-7) scale [28,29], were the primary outcome. The 7 items assessed whether anxiety symptoms had bothered the individual during the previous 2 weeks, with frequency ranging from 0 (not at all) to 3 (nearly every day). Example items included: "Feeling nervous, anxious, or on edge" and "Not being able to stop or control worrying." The GAD-7 is a self-rating scale that effectively reflects symptom severity in adolescents and is highly correlated with clinician-administered ratings of anxiety symptoms. It is brief and suitable for self-report studies [30]. The Cronbach α for the scale was 0.93 [31]. By summing the scores of the 7 items, the following classifications were used: 0-4 indicated the absence of anxiety symptoms, 5-9 indicated mild anxiety, 10-14 indicated moderate anxiety, and 15-21 indicated severe anxiety. Based on the severity of anxiety, participants were categorized into 2 groups: the high anxiety group (scores of 10-21) and the nonhigh anxiety group (scores of 0-9) in this study.

Secondary Outcomes

The 9-Item Patient Health Questionnaire

The 9-item Patient Health Questionnaire (PHQ-9) [32,33] was used to assess participants' depression levels and suicidal/self-hurting thoughts over the previous 2 weeks, with frequency ranging from 0 (not at all) to 3 (nearly every day). The first 8 items (PHQ-8) were used to measure depression severity (sum of the 8 items), while the last item assessed suicidal/self-hurting thoughts. Responses of 1-3 on the last item were coded as "yes," and a response of 0 was coded as "no." Example items from the PHQ-9 included "Little interest or pleasure in doing things" and "Feeling down, depressed, or hopeless." The item assessing suicidal/self-hurting thoughts was "Thoughts that you would be better off dead or of hurting yourself in some way."

Perceived Control

The Anxiety Control Questionnaire [34] is a 15-item tool that measures participants' perceived control over their anxiety. The Emotion Control subscale, 1 of the 3 validated subscales, consists of 5 items (eg, "I am able to control my level of anxiety"), including 1 reverse-scored item (When I am anxious, I find it hard to focus on anything other than my anxiety). Responses are rated from 0 (strongly disagree) to 5 (strongly agree). The sum of the 5 items indicates the level of perceived control. The Cronbach α was 0.73.

Hopelessness

The 4-item Helplessness subscale of the Demoralization Scale [35] was used to measure participants' outlook on the future. Each item was rated on a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree). The sum of the 4 items

XSL•FO
RenderX

was used to assess hopelessness, with a higher score indicating a correspondingly higher level of hopelessness. An example item was "I feel hopeless." The Cronbach α for the Chinese version of this Helplessness subscale was 0.72 [36].

Attitude Toward Seeking Help

We used 3 items from the Attitude Toward Seeking Counselling Help Assessment [37] to measure participants' understanding of counseling and attitudes toward seeking counseling help. Example items included "If I believed I was having a mental breakdown, my first inclination would be to get professional attention" and "Professional counseling and treatments can help people improve mental health." The Cronbach α was 0.72 [37]. Additionally, 2 items were used to assess participants' intention to seek help. The 2 items were "When I encounter difficulties, I will not ask for help from teachers" and "When I encounter difficulties, I will not ask for help from social workers/counselors." These 5 items were rated on a 7-point Likert scale, ranging from 1 (strongly disagree) to 7 (strongly agree). After reverse-scoring the 2 help-seeking intention items, the sum score of the 5 items represented participants' attitudes toward seeking help, with a higher score indicating more positive attitudes toward seeking help.

Psychological Well-Being

The short version of the 14-item Warwick-Edinburgh Mental Well-Being Scale (WEMWBS-14) [38,39] was used to measure the extent to which participants generally experienced well-being states. The WEMWBS-14 consists of 14 items, each rated on a 5-point Likert scale ranging from 1 (none of the time) to 5 (all of the time). The sum score of the 14 items indicated the participants' overall well-being level. An example item was "I have been feeling optimistic about the future." The scale's Cronbach α was 0.93.

Fidelity Checking and Intervention Feedback

Mindsets of Negative Emotions

The validated Chinese version of the 12-item Mindset of Depression, Anxiety, and Stress Scale (MDASS) was used to assess participants' beliefs regarding the changeability of negative emotional states, such as depression, anxiety, and stress [24]. Sample items included: "When you have a certain level of depression, you really cannot do much to change it," "To be honest, people cannot really change how anxious they are," and "No matter how hard people try, they cannot really change the level of stress that they have." Each item was scored on a 6-point Likert scale ranging from 1 (strongly disagree) to 6 (strongly agree); a higher score indicated a more fixed mindset toward negative emotions (Cronbach α=0.94). It included 3 subscales: depression mindset, anxiety mindset, and stress mindset, with 4 items in each subscale. The Cronbach α values for the 3 subscales were 0.91, 0.89, and 0.90, respectively [24]. By summing the total score, we defined fixed and growth mindsets using a cutoff score of 42, which was calculated by adding the midpoint (ie, 3.5) of the 6-point scale for the 12 items. Individuals scoring equal to or greater than 42 were considered to have more fixed mindsets, while those scoring below this cutoff were considered more inclined to have growth mindsets.

Mindset of Personality

Three items from implicit theories of personality [40,41] were used to measure the belief in the changeability of personality on a 6-point Likert scale, ranging from 1 (strongly disagree) to 6 (strongly agree). A higher score indicated a more fixed mindset of personality. A sample item was "People can do things differently, but the important parts of who they are can't really be changed." The Cronbach α was 0.85.

Motivation to Apply What Was Learned From the Program

In addition to the baseline assessment, immediately after the intervention, participants were asked to rate the extent to which they would like to apply the intervention content and improve their emotion regulation on a 6-point Likert scale (1-6), with a higher score indicating higher motivation. We defined high and low motivation groups based on the median cutoff after summing the 2 motivation items.

The Intervention Feedback Scale

This scale was developed based on the Theoretical Framework of Acceptability, which includes 7 component constructs: affective attitude, burden, intervention coherence, perceived effectiveness, opportunity costs, self-efficacy, and ethicality [42]. A general acceptability item, 6 items corresponding to the 6 components of the Theoretical Framework of Acceptability (excluding ethicality), and 4 items—including an open-ended written feedback item—were integrated to comprehensively assess the acceptability of the intervention. These items were drawn from the well-validated Program Feedback Scale [43]. For the Feedback Scale, except for the open-ended item, the other 10 items were assessed on a 5-point scale (eg, "How acceptable was the intervention to you?" with responses ranging from "1=completely unacceptable" to "5=completely acceptable"). The Feedback Scale was administered immediately after the intervention.

Attention-Checking Items

To ensure data quality and assess participant attention, 2 attention-checking items were included at all assessment points (baseline and follow-up surveys). These items directly instructed participants to select a specific option based on the given instructions. A sample question was "Please select 'strongly agree' for this item."

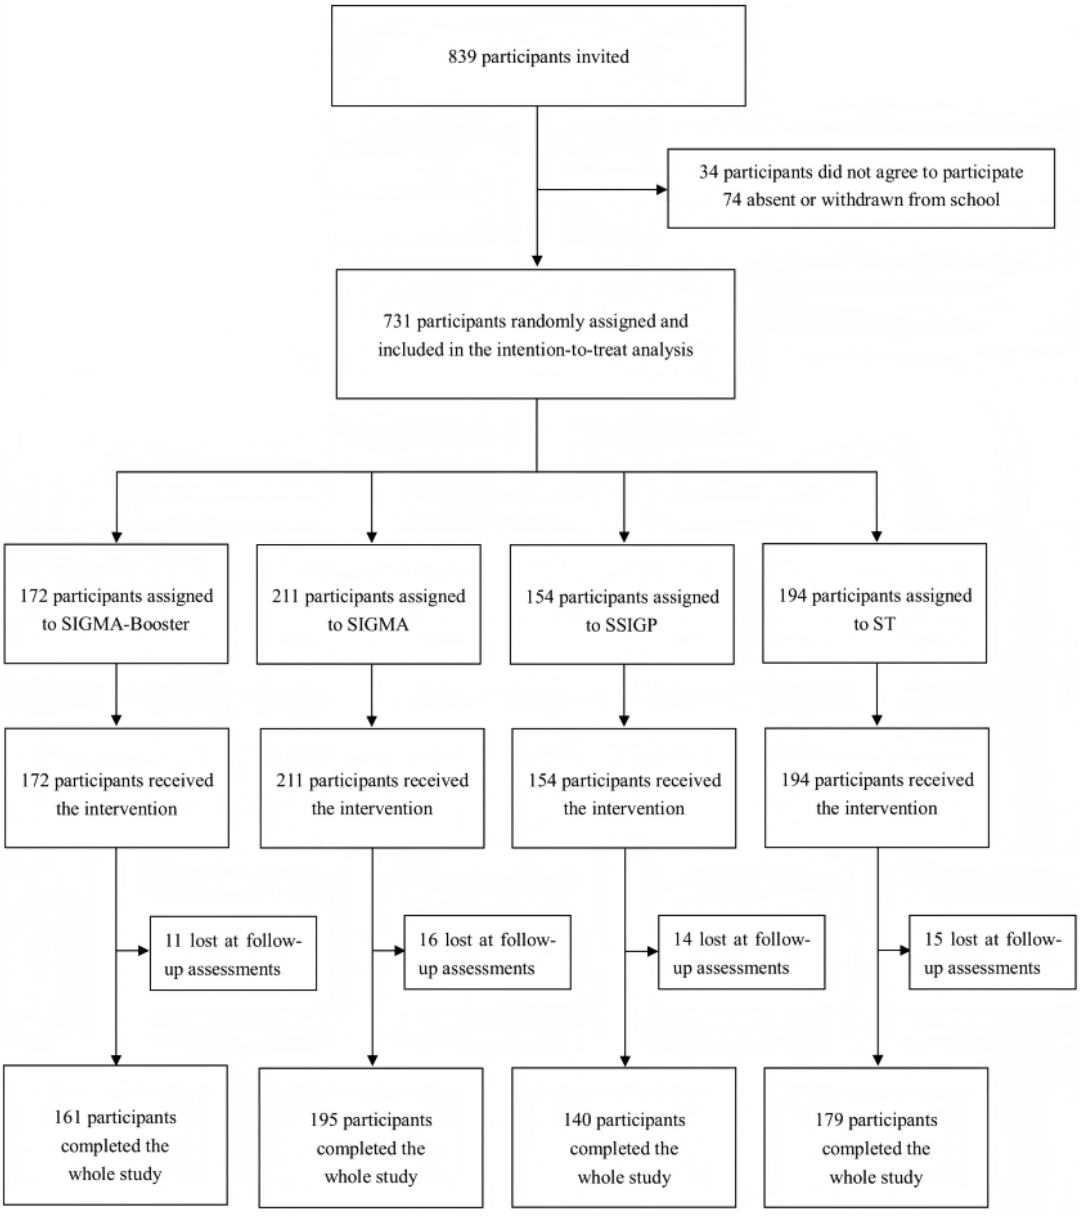
Sociodemographic Information

Sociodemographic information of participants was collected at baseline to examine group variability in factors such as gender, age, grade, ethnicity, and socioeconomic status (SES).

Data Analysis

We used an intention-to-treat approach in our primary analysis, where all participants who consented to participate were included. Participants who completed all assessments and passed both attention-checking items at each assessment point were classified in the per-protocol population. A per-protocol analysis was conducted as a sensitivity analysis. Multilevel modeling was used to account for the cluster randomization of classes within the same school [44]. All percentages and scores were presented with 1 decimal place. To examine the effects of the interventions, generalized estimating equations were used to

XSL•FO
RenderX



test the group effect, time effect, and their interaction effect on outcome measures. A statistically significant interaction effect indicated the effectiveness of the treatments. Additionally, we calculated effect sizes using estimated marginal means. These effect sizes, expressed as Cohen *d*, compared mean gain scores reflecting changes in each outcome from baseline to the 2 follow-ups for youth receiving the mindset versus active control interventions. The effect sizes were also compared between participants in the intervention group who received booster messages and those who did not. Additionally, we tested the following moderators on the effectiveness of the treatment for the primary and secondary outcomes: baseline anxiety level (dichotomized by the severity of GAD-7), motivation for change (dichotomized by the median of the sum motivation score on the 2 motivation items), and mindset group (fixed vs growth). The corrected quasi-likelihood under the independence model criterion (QICC) for the models with and without the moderator was examined, with evidence of a moderation effect indicated by a smaller QICC for the models including the moderator. Multiple comparisons were not conducted, and a *P* value of <.05 was considered statistically significant. Data analysis was performed using SPSS version 26 (IBM Corp.).

Results

Recruitment

Figure 4 depicts the CONSORT (Consolidated Standards of Reporting Trials) diagram of the recruitment and participation flow (also see Multimedia Appendix 1). A total of 731 participants were recruited and randomized into 4 groups: SIGMA-Booster (n=172, 23.5%), SIGMA (n=211, 28.9%), SSIGP (n=154, 21.1%), and ST (n=194, 26.5%). All participants received the interventions and were contacted for follow-ups. All participants were included in the intention-to-treat analysis. No participants explicitly requested to be removed from the trial.

Figure 4. CONSORT (Consolidated Standards of Reporting Trials) flowchart. SIGMA: single-session intervention of a growth mindset for anxiety; SSIGP: single-session intervention of a growth mindset of personality; ST: support therapy.

XSL•FO
RenderX

Baseline Characteristics of Participants

Table 1 summarizes the baseline characteristics of the recruited participants. Of the 731 participants, 421 (57.6%) were girls. Statistical differences in grade and age were observed among the 4 groups, as some schools selected classes from 2 different grades. However, there were no statistical differences in ethnicity or SES.

There were no significant differences between the intervention groups on the primary and secondary outcome measures at baseline: anxiety symptoms, $F_{3,727}$=0.25, P=.86; depressive symptoms, $F_{3,727}$=0.13, P=.94; suicidal/self-hurting thoughts, χ^2_3 (N=731)=3.66, P=.30; perceived control, $F_{3,727}$=0.31, P=.82; hopelessness, $F_{3,727}$=0.74, P=.53; attitude toward seeking help, $F_{3,727}$=0.61, P=.61; and psychological well-being, $F_{3,727}$=0.63, P=.60.

Changes in Primary and Secondary Outcomes

For the primary outcome, we found a significant main effect of time (P<.001), but no significant main effect of group (P=.88) or group-by-time interaction (P=.54). Participants in all 4 intervention groups showed significant improvement in anxiety symptoms at both the 2- and 8-week follow-ups: $P_{2\ weeks}$=.02 and $P_{8\ weeks}$=.02 for SIGMA-Booster; $P_{2\ weeks}$=.006, $P_{8\ weeks}$<.001 for SIGMA; $P_{2\ weeks}$<.001, $P_{8\ weeks}$<.001 for SSIGP, and $P_{2\ weeks}$<.001, $P_{8\ weeks}$=.003 for ST. This improvement was sustained at the 8-week follow-up, and no significant differences were observed between the 2- and 8-week follow-ups: P=.99 for SIGMA-Booster, P=.17 for SIGMA, P=.46 for SSIGP, and P=.59 for ST (Multimedia Appendix 2 and Figure 5). When comparing the changes from baseline to follow-up between each pair of groups, the SSIGP intervention appeared to be more effective than SIGMA (including SIGMA and SIGMA-Booster) in reducing general anxiety symptoms. However, the effect sizes ranged from very small to small (Table 2).

Figure 5. The 7-item Generalized Anxiety Disorder scale (total score) changes over time. Each dot represents the mean score of each group at each time point. Each line around the dot represents the 95% Wald CI of the mean. SIGMA: single-session intervention of a growth mindset for anxiety; SIGMA-B: SIGMA-Booster; SSIGP: single-session intervention of a growth mindset of personality; ST: support therapy.

[a]Effect size values were calculated by subtracting the latter group's mean gain score from the former group's mean gain score for each outcome from baseline to the 2- and 8-week follow-ups, then dividing by the pooled SD of all participants at baseline.

[b]SIGMA-Booster: SIGMA with boosters.

[c]SIGMA: single-session intervention of a growth mindset for anxiety.

[d]SSIGP: single-session intervention of a growth mindset of personality.

[e]ST: support therapy.

For the secondary outcomes, all the main effects of time were significant, while the main effects of group and the interaction effects of group and time were insignificant (main effects of group: *P*=.87 for depressive symptoms; *P*=.41 for suicidal/self-hurting thoughts; *P*=.97 for perceived control; *P*=.73 for hopelessness; *P*=.87 for help-seeking attitude; *P*=.39 for psychological well-being and interaction effects; *P*=.85 for depressive symptoms; *P*=.10 for suicidal/self-hurting thoughts; *P*=.20 for perceived control; *P*=.23 for hopelessness; *P*=.33 for help-seeking attitude; and *P*=.68 for psychological well-being), similar to the primary outcome. Specifically, the results for depressive symptoms mirrored those for anxiety (main effect of time, *P*<.001 and main effect of group, *P*=.87). All 4 groups showed a reduction in depressive symptoms at follow-ups, and the effects observed at the 8-week follow-up were comparable to those at the 2-week follow-up (see Multimedia Appendix 2 and Figure 6). Moreover, the effect sizes for the comparison between groups on the changes from baseline to follow-ups were all very small (Table 2). Second, a significant main effect of time was found for suicidal/self-hurting thoughts (*P*=.005), but the main effect of group was not significant (*P*=.41). Specifically, the SIGMA group showed a reduction in suicidal/self-hurting thoughts at both the 2- and 8-week follow-ups, with the effect sustained at the 8-week follow-up compared with the 2-week follow-up. The SSIGP group showed a significant reduction in suicidal/self-hurting thoughts at the 8-week follow-up (*P*<.001), but not at the 2-week follow-up (*P*=.14). The other 2 groups did not report significant changes in suicidal/self-hurting thoughts at either follow-up with $P_{2\ weeks}$=.50, $P_{8\ weeks}$=.96 for SIGMA-Booster and $P_{2\ weeks}$=.75, $P_{8\ weeks}$=.61 for ST (see Multimedia Appendix 2 and Figure 7). Both the SIGMA and SSIGP interventions appeared to be more effective in reducing suicidal/self-hurting thoughts than the SIGMA-Booster and ST, although the effect sizes were small (Table 2). For the other secondary outcomes, the main effects of time were significant for all variables (for perceived control, *P*=.03; for hopelessness, *P*<.001; for help-seeking attitude, *P*<.001; and for psychological well-being, *P*<.001). However, the main effects of the group were not significant (*P* values ranged from .39 to .97). For perceived control, only the ST group reported significant improvement at both the 2- and 8-week follow-ups ($P_{2\ weeks}$=.02, $P_{8\ weeks}$=.007). The ST intervention appeared to be more effective than the other 3 groups in improving perceived control, though the effect sizes were small (Table 2). For hopelessness, both the SIGMA and ST groups showed significant improvement at both the 2-week (*P*<.001 for SIGMA and *P*<.001 for ST) and 8-week follow-ups (*P*=.001 for SIGMA and *P*=.005 for ST), while the SSIGP group only reported significant improvement at the 8-week follow-up (*P*=.02). The SIGMA group seemed to outperform the SIGMA-Booster group in reducing hopelessness, although the effect sizes were small (Table 2). For help-seeking attitude, both the SIGMA-Booster and SSIGP groups reported significant improvement at both the 2-week (*P*=.01 for SIGMA-Booster and *P*<.001 for SSIGP) and 8-week follow-ups (*P*=.01 for SIGMA-Booster and *P*=.003 for SSIGP), while the SIGMA and ST groups showed significant improvement only at the 2-week follow-up (*P*=.006 for SIGMA and *P*<.001 for ST). For psychological well-being, the ST group showed significant improvement at both the 2- and 8-week follow-ups with *P*=.01 and *P*<.001, respectively, while the SIGMA-Booster and SIGMA groups demonstrated significant improvement only at the 8-week follow-up with *P*=.02 (Multimedia Appendix 2). The effect sizes for changes in attitude toward seeking help and psychological well-being were all very small between groups. The only effect size that reached a small magnitude (>0.2) was for the improvement in psychological well-being at the 8-week follow-up, where the ST group showed greater improvement compared with the SSIGP group (Table 2).

The sensitivity analysis conducted for the per-protocol population showed results similar to those of the intention-to-treat population. The specific results of the sensitivity analysis can be found in Multimedia Appendix 3.

Moderation Analysis

We conducted moderation analyses based on baseline anxiety (high/low), motivation to change (high/low), and mindset (growth mindset vs fixed mindset). Including these moderation factors improved model fit, as indicated by the decreases in QICC, ranging from 210 to 31,519.23. This was true for all outcomes, except for suicidal/self-hurting thoughts when motivation level was used as the moderator. These results indicate that baseline anxiety level and mindset had moderating effects on all outcome measures, while motivation level moderated all outcomes except for suicidal/self-hurting thoughts. Participants with higher baseline anxiety, greater motivation to change their situation, and a more fixed baseline mindset showed greater improvements in the outcome measures (see Multimedia Appendices 4-6 for details).

Intervention Feedback

Participants' feedback on the SSIs is detailed in Table 3. Most participants reported understanding (536/731, 73.3%) and

XSL•FO
RenderX

agreeing (504/731, 68.9%) with the intervention content. More than half found the intervention helpful (465/731, 63.6%) and interesting (417/731, 57.0%). Some indicated that they liked the course (404/731, 55.2%) and expressed a willingness to recommend it to others (402/731, 55.9%). Additionally, 437 out of 731 (59.8%) reported increased confidence in their ability to cope with emotions following the intervention. Meanwhile, very few found this course burdensome (28/731, 3.8%) or interfering (70/731, 9.58%). The findings showed that 459 out of 731 (62.8%) participants indicated that they accept or highly accept the intervention. However, about 237 (32.4%) participants were neutral, indicating that there is still significant room for improvement.

Table 3. Feedback on the intervention.

[c]SSIGP: single-session intervention of a growth mindset of personality.

[d]ST: support therapy.

Discussion

Overview

Contrary to our hypotheses, we found that all 4 SSIs, including ST, significantly reduced general anxiety symptoms and improved some secondary outcomes. Although the core messages delivered in approximately 40 minutes differed among these interventions, nearly all improvements in the 4 groups were sustained from the 2-week to the 8-week follow-ups. These findings provide evidence for the effectiveness of low-dosage nonpharmacological interventions in improving youth mental health outcomes. SIGMA, which enhances the belief in change regarding negative emotions, showed an intervention effect on all outcome measures except perceived control. The SSIGP, targeting personality mindset, was more effective in reducing self-harm and suicidal thoughts. ST had a greater effect on perceived control. Surprisingly, the SIGMA-Booster group, which received booster messages, did not achieve better results than the SIGMA group. By contrast, the SIGMA group outperformed the SIGMA-Booster group in outcomes such as reducing suicidal and self-harming thoughts as well as hopelessness. The SIGMA interventions were not more effective than SSIGP, particularly in the primary outcome of reducing anxiety symptoms. Moreover, the ST intervention was especially effective in improving perceived control, outperforming the other 3 interventions. Moderation tests revealed that some adolescents benefited more from the interventions. Consistent with our hypotheses on moderation effects, participants showed greater improvement if they had more severe anxiety symptoms, stronger baseline fixed mindsets, and a greater motivation to change. Although the effect sizes for group comparisons on outcome changes were small, it is encouraging that SSIs produced sustained outcomes over 8 weeks.

Our findings align closely with existing research on SSIs for youth psychiatric problems. A previous meta-analysis by Schleider and Weisz [14] found that a young person receiving an SSI had a 58% likelihood of performing better than a youth in the control group. The effect sizes varied depending on the control conditions, with larger effect sizes observed in studies with no-treatment or waitlist controls (0.41) compared with those with active controls (0.14). In our study, the effect sizes for SIGMA versus SSIGP at the 2-week follow-up were approximately 0.14 (SIGMA vs SSIGP: 0.14 and SIGMA-Booster vs SSIGP: 0.13), while the effect sizes for SIGMA versus ST were smaller. The finding that SSIs were effective for multiple outcomes, including anxiety and depression symptoms, aligns with a recent umbrella review on SSIs, which showed that over 80% of reviews reported significant positive effects on at least one outcome [21]. In summary, our study provides additional evidence supporting the modest yet significant clinical utility of certain SSIs for youth, including those targeting anxiety symptoms [21].

The design of the interventions and the implementation of the RCT for SSIs provided valuable insights and implications for local practice. Generally, these SSIs were designed following recommended guidelines to ensure the efficacy of brief

XSL•FO
RenderX

interventions [45-47]. First, we formed a youth advisory group to ensure the content was relevant to the target users. Second, we incorporated cartoons and animated videos into the intervention. The cartoon heroine, "Hong Dou" (the Red Bean), and her friends were created by artists and digital designers to make the animations and videos more engaging. As a result, the intervention videos effectively captured participants' attention. Third, because SSIs should be highly focused on delivering 1 or a few core messages, each SSI in our study conveyed a single core message to participants. We reinforced learning through multiple methods, including examples, testimonials, authoritative research findings, and saying-is-believing exercises. Fourth, to ensure active participation in the online web-based intervention, we embedded it in the Qualtrics survey tool and included interactive exercises after each session. Participants received timely feedback on these exercises. Feedback from participants indicated that the SSIs in our study were well-suited to adolescents' needs and expectations for mental health care. This study provides a clear protocol for implementation, including content and strategies, which will be valuable for the future use and development of SSIs.

This study is a pioneering investigation into web-based SSIs among Chinese adolescents. The efficacy of SSIs, particularly self-administered web-based interventions, has been understudied. This study examined the effects of SSIs on mental health among Chinese adolescents using a cluster RCT design. The 4 conditions in this study showed improvements in mental health over 2 weeks, with the effects sustained after 8 weeks. There were no significant group differences among the 4 conditions. As the interventions were implemented at different times across the academic year in different schools, any potential school schedule effects were minimized. On the one hand, these results suggest that providing low-dosage self-help interventions may help adolescents gain insights and strategies for managing their emotions and coping. On the other hand, an RCT with an added waitlist control group would be valuable for further testing the effectiveness of the intervention.

The SIGMA-Booster group did not show a better effect at the 8-week follow-up. There may be several reasons for this. First, there may be no difference between the booster and nonbooster groups. If an SSI has instilled changes in the emotional mindset, those changes could be long-lasting. Second, the booster group might have a greater effect in the longer term, so a more extended follow-up would be necessary to capture any differences between the booster and nonbooster groups. Third, the booster design in this study may not have been effective. Future studies should carefully examine the format and content of booster interventions.

This study makes several significant contributions. First, the SSIs developed and tested with an RCT could serve as an alternative mental health service for adolescents. Although the effect size of the SSI was small, it can benefit a proportion of youth who would otherwise go without services. It can also support youth on the waitlist for psychiatric services by fostering intrinsic motivation and reducing hesitation to seek treatment. It can also complement multisession psychosocial treatments [21]. Second, these SSIs expanded existing mindset interventions to include emotional mindset and adapted them to the Chinese context. This project may provide a generalizable model for the development and implementation of SSIs for youth in the Chinese context. Third, this study initiated the development and evaluation of boosters for SSIs. Although we did not find significant differences among the groups, the findings of this study could serve as a foundation for further research. In summary, the easy-access self-help program enables adolescents with anxiety symptoms to receive timely help and may help reduce the risk of worsening anxiety symptoms and the development of comorbid mental health issues before they can access therapy from a trained therapist or psychiatrist.

Limitations

There are limitations to consider. First, because this study did not exclude individuals based on the severity of their anxiety symptoms, the efficacy of the interventions in reducing anxiety symptoms among students without anxiety or with very low levels of anxiety may not have been significant, potentially affecting the overall statistical significance. However, future RCT studies could examine the differentiated impacts on youth across a broader range of anxiety problems through subgroup analyses. In this study, we simply divided participants into 2 groups (high baseline anxiety and low baseline anxiety) and examined the moderation effects. Second, there was no waitlist control group, as all groups received specific interventions, with even the control group receiving ST (active control). Adding a waitlist control group would help provide a better understanding of the overall effect of SSIs. Third, although we used cluster randomization at the classroom level to balance the risk of contamination between groups and school heterogeneity, and employed multilevel modeling to account for the clustering of classes within the same school, it was still challenging to completely eliminate the risk of contamination. Students in different classes may interact and share information about their interventions, which could potentially influence the outcomes. Fourth, the study only included a follow-up period of 8 weeks, which may not have allowed us to capture the long-term effects. Future studies with a longer follow-up period will be necessary to better understand the sustained impact of the interventions.

Conclusions

This study presents evidence-based implementation of web-based single-session growth mindset interventions for adolescent anxiety and compares the efficacy of SSIs using growth mindsets on negative emotions and personality, along with an active control group. The findings support that the easy-access self-help program led to improvements in adolescent anxiety, depression, and suicidal and self-harm thoughts at the 8-week follow-up. These interventions may enable adolescents with anxiety symptoms to access timely help, reducing the risk of worsening anxiety symptoms and the development of comorbid mental health issues before they can access therapy from a trained therapist or psychiatrist. This study also provides an example of implementing SSIs among Chinese adolescents and will contribute to the development of easy-access, low-cost, and scalable interventions for mental health promotion among young people.

Acknowledgments

This study was supported by a grant funded by the Hong Kong Research Grants Council (grant 15601621) that was awarded to SZ. The funding body played no role in the study design, data collection, or manuscript writing. We acknowledge the contributions of the principals, school counselors, and social workers who share their insights into students' mental health care needs. We are grateful for school principals' invaluable suggestions on digital intervention implementation in school, including Principals Cheung Fung, Wan Ho-yin, Tu Sze Ching, Annissa Wong, Cheng Hong Yung, Sen Chun Wing, and Lui Sze Yan. We thank our design team, including Angel Lee, Hui Lok Chan, Jie Deng, Emma Kong, and Zijie Zhao. We are thankful for the suggestions from Mr Yau Tak Yu and Ms Wong Ka Ka, local experts in single-session intervention.

Data Availability

Data are not publicly available but can be obtained for proper purposes by contacting the corresponding author.

Authors' Contributions

SZ designed the intervention and the evaluation study initially. YH assisted in the intervention design and implementation. SZ and DQ drafted the first draft of the report. PL contributed to the data analysis plan. ST, KLC, QC, and JS provided comments and revised the first draft. SZ developed all aspects of the proposal and manuscript related to the implementation of intervention and data collection. All authors edited and approved the final manuscript.

Abstract

Background: Approximately 39% of young people (aged 16-24 y) experience mental ill health, but only 23% seek professional help. Early intervention is essential for reducing the impacts of mental illness, but young people, particularly those from culturally diverse communities, report experiencing shame and stigma, which can deter them from engaging with face-to-face services. Digital mental health (DMH) tools promise to increase access, but there is a lack of literature exploring the suitability of DMH tools for culturally diverse populations.

Objective: The project was conducted in partnership with a large-scale national DMH organization that promotes evidence-based early intervention, treatment, and support of mental health in young people and their families. The organization wanted to develop a self-directed web-based platform for parents and young people that integrates psychological assessments and intervention pathways via a web-based “check-in” tool. Our project explored the views of culturally diverse parents and young people on the opportunities and barriers to engagement with a web-based DMH screening tool.

Methods: We conducted a 2-phase qualitative study aiming to identify potential issues faced by culturally diverse communities when engaging with DMH tools designed for the Australian public. We worked with 18 culturally diverse participants (parents: n=8, 44%; young people: n=10, 56%) in a series of design-led workshops drawing on methods from speculative design and user experience to understand the opportunities and barriers that organizations might face when implementing population-level DMH tools with culturally diverse communities. NVivo was used to conduct thematic analyses of the audio-recorded and transcribed workshop data.

Results: Five themes were constructed from the workshops: (1) trust in the use and application of a DMH tool, (2) data management and sharing, (3) sociocultural influences on mental health, (4) generational differences in mental health and digital literacy, and (5) stigma and culturally based discrimination in mental health support.

Conclusions: The emergent themes have important considerations for researchers wishing to develop more inclusive DMH tools. The study found that healthy parent-child relationships will increase engagement in mental health support for young persons from culturally diverse backgrounds. Barriers to engagement with DMH tools included culturally based discrimination, the influence of culture on mental health support, and the potential impact of a diagnostic label on help seeking. The study’s findings

suggest a need for culturally safe psychoeducation for culturally diverse end users that fosters self-determination with tailored resources. They also highlight important key challenges when working with culturally diverse populations.

Introduction

Background

Approximately 13% of the global population living with mental health problems are young people (aged 16-24 y) [1]. Young people with mental health disorders also experience higher rates of morbidity and mortality risk than the general population, leading to a 10- to 20-year reduction in life expectancy [2,3]. These rates were compounded during the COVID-19 pandemic, during which globally 1 in 4 young people experienced clinically elevated levels of depression, and 1 in 5 experienced clinically elevated levels of anxiety [4]. Nevertheless, during this period, there was no concurrent increase in the uptake of mental health support [5]. For young people, untreated mental health problems can have long-lasting impacts due to the important social, emotional, and cognitive developmental changes that are being experienced simultaneously [6].

Cultural Diversity in the Context of Australia

Australia is a culturally diverse society, with 27.6% of its population born overseas [1]. This diversity spans across differences in cultural identity, language, country of birth, religion, heritage, and national origin [7]. Shaped by a legacy of colonialism, racial inequality has influenced Australia and its relationship with racial and ethnic minority immigrants [8] and First Nations peoples [9].

Studies have identified higher rates of mental ill-health among culturally diverse groups compared to the broader Australian population [10,11]. This is, in part, due to mental health risk factors, such as language barriers, cultural adjustment, the loss of family connection, and an inability to apply knowledge and occupational skills to attain meaningful employment, all of which hinder active participation in society for people from culturally diverse backgrounds [12]. Young people from culturally diverse backgrounds tend to be the most reluctant to seek help, and if they do, they typically turn to informal sources such as family, friends, and elders [13,14]. Among those who have sought professional support, many report that the types of support they were offered were inaccessible, culturally inappropriate, or lacking cultural relevance [15-17].

Common barriers to mental health care for culturally diverse communities include a lack of information and knowledge about available services, language differences, culturally specific conceptions of mental health, and lengthy waitlists [18-22]. Discrimination can be experienced throughout a person's mental health journey, with studies showing that culturally diverse people are far less likely to engage in mental health visits or seek specialist care than White ethnic groups [23]. Research has also found that clinicians are less likely to involve culturally diverse patients in friendly discussions or include them in the treatment decision-making process [24]. Instead, people from culturally diverse backgrounds tend to access mental health services through clinical emergency services during an acute crisis rather than accessing early interventions before the problem is severe, hindering their prospect of recovery [25,26]. People from culturally diverse backgrounds in Australia also experience more involuntary hospital admissions for mental health treatment [16].

Current Landscape of Digital Mental Health Tools and Opportunities

Digital mental health (DMH) tools (eg, apps and web-based services) delivered through smartphones [27-31], computers [32,33], and wearable devices [34,35] hold promise for overcoming many of the aforementioned barriers [36]. DMH tools can include self-directed online interventions [37,38], mental health screenings or "check-ins" to assess mental health status [39], digital health apps that allow the real-time monitoring of mental health [40,41], chatbots to support help seeking [42], and even interventions on specialist technologies such as virtual reality headsets [43,44]. Studies have shown that young people and parents prefer digital treatment over face-to-face care [45,46]. DMH tools offer easily accessible, low-cost services to address common mental health problems [47,48]. Self-directed DMH tools may offer alternative or complementary options to face-to-face clinical care, with the potential to provide support to people on waitlists for clinical care in remote locations or those who may not have the financial means to seek face-to-face treatment [43]. There is increasing interest in developing culturally sensitive DMH tools [17,49], with some DMH apps and online platforms being designed especially for ethnically diverse groups [50]. However, such examples remain limited; moreover, considerations of diversity, equity, and inclusion are rarely integrated into their design or evaluation [51].

Online self-screening tools provide useful information about self-reported mental health symptoms, offering clinical cutoffs to indicate when further assessment or support is needed, along with relevant resources for support. They also allow anonymous pathways for disclosing mental health symptoms and offer digital interventions [4,52,53] that have been shown to be fundamental for the mental health journey of culturally diverse users because digital interventions and resources are more likely to reach culturally diverse populations who may not have access to or are not yet engaging in mental health support [54]. Large-scale DMH platforms that incorporate screening, access to online clinicians, self-directed resources, and curated suites of trusted apps are increasingly being adopted by public health organizations across Western contexts (eg, the UK National

XSL•FO
RenderX

Health Service's Talking Therapies program) [48]. However, while these public-facing DMH tools are intended for use by all of society, they tend to be designed by and for the dominant Western culture [55].

In addition, DMH tools hold the potential for supporting mental health beyond traditional 1-to-1 contexts. Online health-oriented communities offer benefits such as peer support networks (eg, Headspace and Orygen both offer online youth mental health support in Australia). Similarly, social media groups focused on mental health have been shown to play a substantial role for end users in rural areas, where geographic location limits access to mental health service providers [56]. These groups provide support for guided online therapy [57], skills building [58], symptom monitoring [59], and social connection [60,61]. However, among culturally diverse communities, where English may be a second language, willingness to engage in these types of peer support offerings tends to be lower [50].

Designing With Diverse Populations

There is increasing recognition of the importance of designing digital services tailored for culturally diverse populations using responsive and inclusive design processes. Many researchers and designers in this space have adopted participatory research and user-centered approaches wherein members of the community are involved in the design process to identify their unique needs, goals, and concerns and to ensure that these are considered and integrated into the final service design [62-67]. Technologies developed for an underserved community are most impactful when designed with members of that community [68]. The use of user-centered approaches has been shown to improve the acceptability, effectiveness, and contextual relevance of novel technologies for communities [55]. Engaging members of the community in a design process often requires creative methods and tools to ensure that it is safe, beneficial, and easy for them to participate. Some studies have used creative tool kits, personas, and vignettes to scaffold design thinking [69,70].

User-centered design approaches that recommend the inclusion of meaningful engagement with consumers and carers in the service design are also increasingly recognized among mental health researchers and practitioners, including government agencies [71]. Research interest in culturally sensitive design through participatory research and user-centered design methods is mounting [72-74]. However, despite the political and cultural shift, there is still only a small, though growing, body of work in the field of human-computer interaction that explores the needs of culturally diverse populations in the area of DMH services [17,49,75,76]. While these studies provide useful insights, they tend to focus on a single community or culture and offer specific rather than generalized interventions. While there are steps being taken to engage culturally diverse communities in technology design across various fields of research, there are still various mental health factors that could impact the uptake of novel DMH tools (eg, cultural concepts of mental health and stigma around mental health). As such, it is vital that we aim to better understand how to design tools that account for these factors and enhance service engagement for culturally diverse communities. For the successful implementation of clinical innovations at a public scale, novel digital solutions need to be designed *with* diverse populations to ensure that these solutions meet their needs [17,77]. Engaging with the perspectives of groups considered marginalized and those outside Western traditional norms will help ensure that DMH tools are designed more inclusively [78,79].

Building on these insights, we worked with culturally diverse young people and parents to design a national digital self-directed mental health check-in tool, called Growing Minds Check-In (GMCI), for the Australian public. The GMCI aims to provide an assessment of mental health and well-being symptoms as well as recommendations to tailored online mental health services and information. This study engaged with user-centered design due to the restrictions on the level of involvement the participants would have on the final production of the GMCI. Due to the narrow development timelines, the participants in this study were able to contribute to the design process but did not have decision-making powers; instead, they were involved in appropriate ways throughout the development of the GMCI [80]. We conducted a 2-phase study aiming to identify potential issues faced by culturally diverse communities when engaging with DMH tools such as the GMCI. The purpose of this study is to describe the attitudes, barriers, and benefits associated with DMH tool engagement among culturally diverse parents and young people. This information is likely to be relevant to DMH interventions for parenting and child well-being; it may also be relevant to other online programs, especially those delivered as universal public health interventions. We propose a set of design strategies for developing public-facing DMH tools and provide reflections on our own design process and the challenges we faced while engaging with culturally diverse communities in research.

Methods

Study Context

This project was conducted in partnership with the Growing Minds Australia Clinical Trials Network, Australia's first clinical trials network for child and youth mental health research [81]. It is part of the first phase of design for the Growing Minds Australia Clinical Trials Network flagship trial, the GMCI: a national online platform for parents and young people that integrates a mental health and well-being "check-in" with personalized feedback and suggestions for online mental health services and resources. We came into the project with the aim of focusing inquiry on how the future-facing platform could be designed more inclusively to ensure that it is relevant and accessible for diverse communities. We used a speculative DMH app containing features similar to those proposed by digital phenotyping software that could collect both passive and active data.

The study comprised 2 phases to engage groups of parents and young people from culturally diverse backgrounds with lived experience of mental health challenges. The first was a scoping phase that applied user-centered design methods, which included using speculative DMH tools to tease out potential benefits, concerns, and trade-offs. The second was a prototype exploration phase, whereby a proposed nationwide mental health screening

XSL•FO
RenderX

tool was used as an artifact for participants to determine possible challenges and ethical issues that culturally diverse populations may face when engaging with DMH tools. This included a facilitated emotional walk-through of the screening tool using a workbook, followed by a data consolidation workshop where participants reflected on their experiences of using the tool. We aimed to identify the potential benefits and possible challenges of using a large-scale web-based check-in service and incorporate these insights into a more inclusive design for future DMH technologies. The design justice framework was applied to the design of the research questions (RQs), the activity schedule, and the analysis of the findings. This approach promotes the exploration of how benefits and burdens are distributed across groups, challenging design-driven inequalities by using an intersectional lens that considers race, gender, sexual orientation, and culture [82,83]. This framework incorporates participatory and user-centered design methods that prioritize community needs and encourage researchers to consider how power can shape participation in the design processes [82] (Figure 1).

Figure 1. Visualization of the study design. DMH: digital mental health.

Ethical Considerations

Our study received ethics approval from Monash University (31138). All participants were provided with an explanatory statement detailing the project and were asked to read and sign a consent form before participating. These documents were provided to participants in advance of the workshops. Consent and demographic information (eg, country of origin and culture they identify with, years lived in Australia, and languages spoken at home) were collected before the workshops began. Participants across all study phases were compensated Aus $40 (US $24) per hour for their time. Data was anonymized with all names removed from the data. Names were changed during transcription before any analysis commenced.

Recruitment

We partnered with a multicultural community mental health organization to recruit participants and facilitate the workshops. We used the organization's advertising channels to recruit participants who were involved as volunteers with the organization and were likely to be mental health literate. Workshop participants were required to have a high school level of spoken English due to time limitations and budget restrictions, which precluded the use of translators. Calls for participation in the workshops were advertised through flyers distributed via the community organization. For inclusion in the study, participants needed to identify as either having lived experience with mental health problems or having children who had experienced mental health challenges. These workshops were conducted in person and therefore limited to communities living in Victoria, Australia. A majority of the participants (12/18, 67%) were from South or East Asia, reflecting the demographic composition of the Australian population [1]. In phase 2, we included an Anglo-Australian participant (P8) who was recommended as a research participant by the mental health organization. Although not from a culturally diverse background, this participant was an experienced peer support worker with multicultural populations, had lived experience of complex mental health challenges, and was a parent. Phase 1 and phase 2 participant demographics are presented in Table 1.

Phase 1: Contextual Inquiry Through User-Centered Design

Overview

We conducted 2 user-centered design workshops: one with 10 young people (female: n=7, 70%; male: n=3, 30%; aged 16-25 y) and another with 8 parents of young people (female: n=4, 50%; male: n=4, 50%; aged 21-67 y). Each workshop included a researcher facilitator and a cofacilitator provided by the mental health organization who assisted with recruitment. Power imbalances were mitigated by conducting the workshops at an office space provided by the multicultural organization, where participants were affiliated and felt comfortable. The workshops ran for 3 hours with a 20-minute refreshment break. We examined 3 broad RQs:

1. How do culturally diverse end users perceive the value of mental health data? With whom would they share their mental health data? How might their mental health data differ in the future?
2. How is screening information communicated and understood? What impact would this have on therapeutic relationships?
3. What are the social factors that influence the likely use and application of DMH technologies? Are culturally diverse users concerned about third-party use of their data?

We aimed to not only explore the inclusion of culturally diverse communities in the design of a digital platform but also consider the impact of future data use, particularly how an end user's sensitive data may later be used. Given the propensity for alternative data use by third parties, we wanted to better understand the degree to which culturally diverse end users

XSL•FO
RenderX

worried about how their data may be used and whether they felt it would have future implications.

The workshop sessions followed a semistructured activity guide that was developed by the authors and reviewed by colleagues independent of the study (refer to Multimedia Appendix 1 for details). We began each session with an icebreaker activity and initiated a group discussion to set the context for the following activities. Using a whiteboard and markers, we asked participants about their understanding of mental health and what makes for good and poor mental health. This activity was intended to provide insight into the participants' mental health literacy. We then provided participants with a speculative design probe, the "mental health vault" (Figure 2), to unpack abstract conceptions of sensitive digital health data. The vault included 3 layers to indicate varying levels of personal information that may be uncovered by DMH tools: (1) a locked safe represented by a metal box (most personal), (2) an inner layer bound by a thick metal chain, and (3) an outer layer framed by a thin rope (least personal). The activity schedule included four activities: (1) digital vault, (2) blank keys, (3) data sharing, and (4) future forecasting. These activities were centered on an imagined DMH tool that could actively and passively collect end user data, which differs from the GMCI's intended use and functionality as a web-based tool that provides personalized feedback and suggestions for online mental health services and information matched to need.

Figure 2. The "digital vault" activity in phase 1.

Activity 1: Digital Vault

The aim of this activity was to address RQ 1 by gauging participants' level of understanding of mental health data, how sensitive they perceived the data to be, and with whom they would want to share the data. To scaffold their thinking, we provided stimuli picture cards of potential mental health data points (eg, a diary, a mobile phone, GPS data, survey test results, and social media data) and asked participants to place each card, depending on how secure they felt each data point was, within the different layers of the vault (ie, inside the metal box, within the chain, or in the outer rope layer). The most private data points were placed inside the metal box, while the least private were positioned in the outer rope layer. After participants arranged the cards according to their preferences, we asked them to describe what each layer represented to them and why they placed each data point where they did (eg, why they would be okay with sharing social media data publicly but not their survey test results).

Activity 2: Blank Keys

The aim of this activity was to understand whom the participants were willing to share their data with and their reasons, addressing RQ 1. Using an inductive approach, we used this component of the activity to leverage and broaden the discussion to generate ideas on new "trusted" or "nontrusted" people that the participants could think of on their own, without the researcher's prompts or suggestions. We gave participants 6 blank paper "keys" and asked them to write down the individuals (eg, their imam, family member, or teacher) to whom they would be willing to grant access to the vault. They then placed each key in the vault layer they felt most comfortable allowing that individual to access. Next, we asked participants to use these blank keys to write down who they thought might "rob" the vault and to place the newly labeled keys in the layer of the vault they felt the "data robber" might access. The activity schedule script included the following prompt: "Now let's imagine digital bank robbers broke into your vault. What is the worst thing that can happen? Who might the robbers be? Why would they want your data? Which specific area of the vault would they be most interested in?"

XSL•FO
RenderX

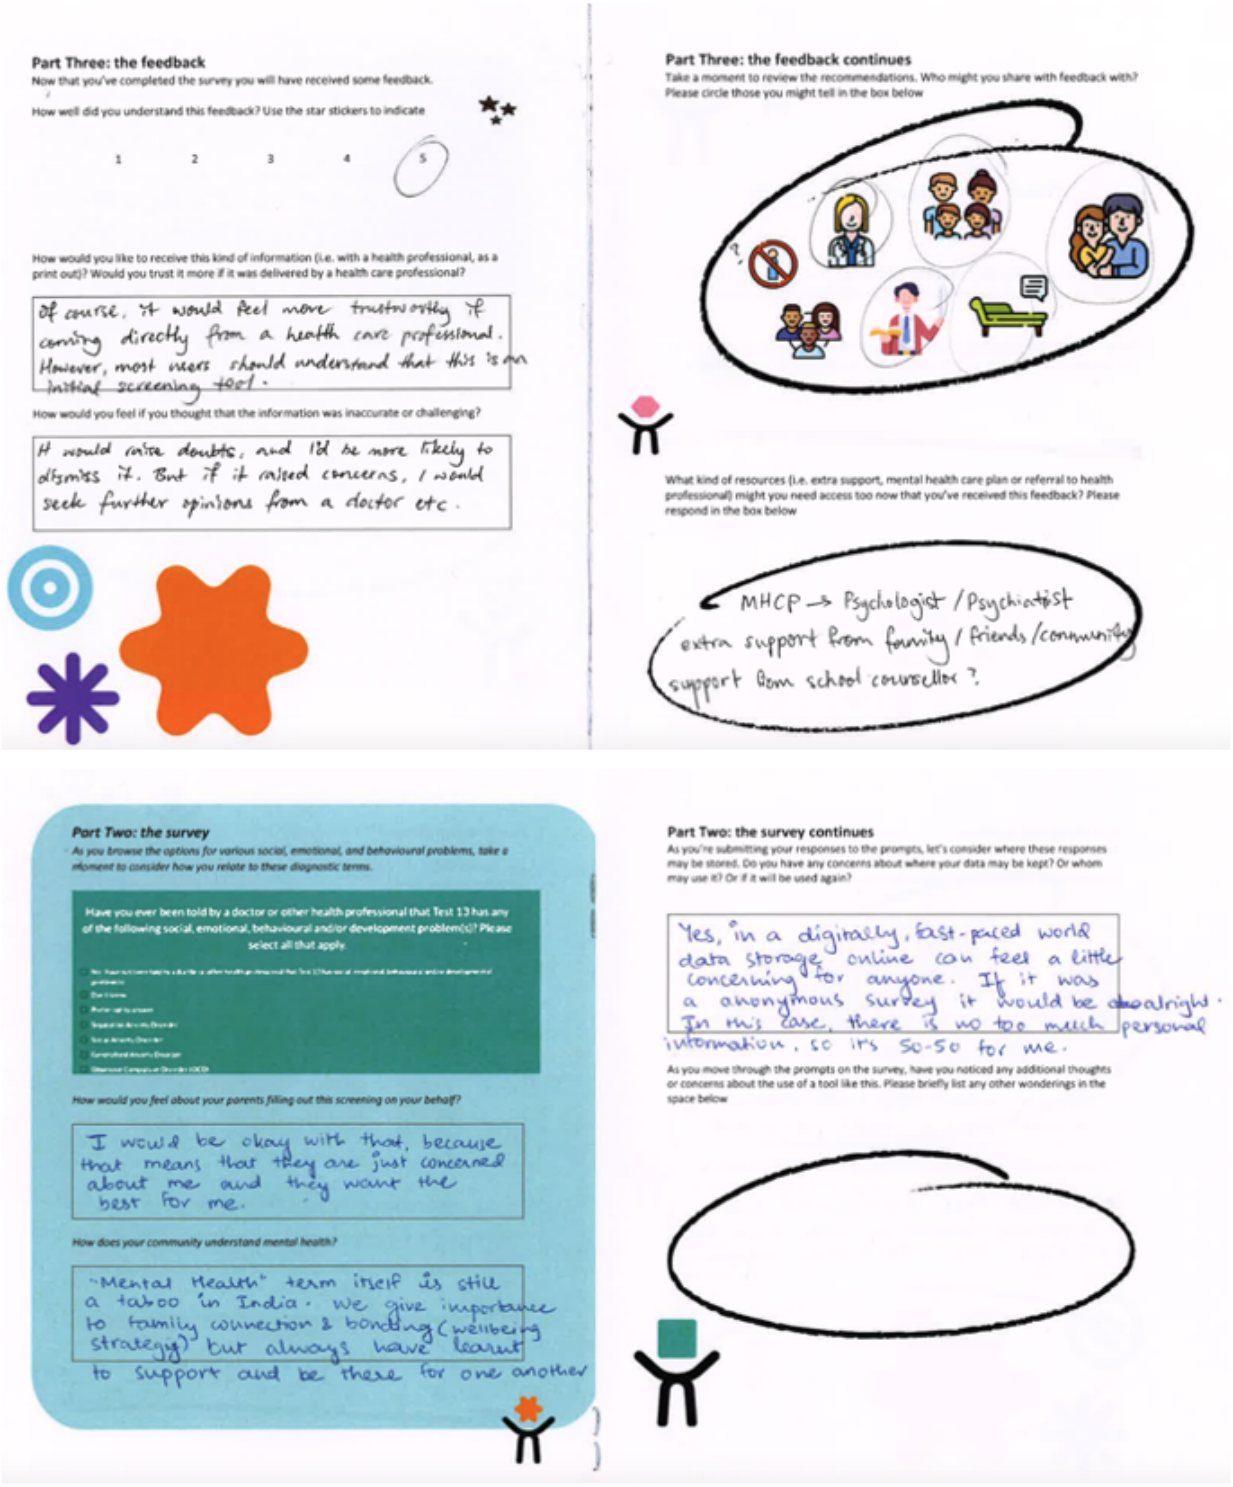
Activity 3: Data Sharing

Building on the digital vault scenario, we introduced a "digital vault manager" who has access to the data contained in the digital vault and could use the data to identify mental health issues. This activity addressed RQ 2 and RQ 3. We then asked the participants whether they would want anyone to know about mental health challenge identified, and if so, whom they would share it with. This activity was designed to get participants thinking about their individual perspectives as well as how others may feel about having their personal data shared with the intention of helping individuals or their community (eg, whether a school or current employer should be notified).

Activity 4: Future Forecasting

This activity examined how screening information is likely to be communicated, understood, and applied in face-to-face sessions with a clinician. This activity addressed RQ2 and RQ3. We asked participants to imagine that the digital vault had been passively collecting data and had generated a prediction about their mental health over the next 20 years. First, we gathered emotional reactions to the prediction using printed emoji faces and by asking participants to indicate how they felt about having predictions made about them. Next, through a discussion-based activity, we explored how the prediction their trust, and sense of empowerment, and agency, as well as how and by whom the prediction would best be communicated. The activity schedule script included the following prompt: "Do you feel empowered knowing this prediction in advance so you can seek help? Do you trust its accuracy? Would you prefer your GP [general practitioner] or mental health clinician had told you? Would you trust it more if your GP told you? Are you concerned about who else is accessing this digital vault from some years ago?"

The findings from the future-facing DMH tool discussion in phase 1 were used to frame the emotional walk-through activity and focus groups with parents and young people in phase 2. We considered the benefits, burdens, and trade-offs that the culturally diverse participants discussed in these workshops and wove them into the emotional walk-through activity in an attempt to highlight challenges with an existing system that could then feed into a future design. This activity series was designed to address RQs 1 to 3.



Phase 2: Emotional Walk-Through

Using a user experience technique traditionally referred to as a cognitive walk-through, we aimed to explore participants' emotional responses as they engaged with the interface [84,85]. We adapted a walk-through user testing methodology [86] and created a 6-page emotional walk-through booklet (Figure 3) that was distributed to participants along with a link to a prototype of the web-based mental health screening platform intended for national deployment in the near future. This was a written task that was designed to help facilitate discussion and ideas about the issues we intended to explore in the prototype testing workshop. Participants (parents and young people) were then invited to take part in a joint consolidation workshop to discuss their thoughts in further detail. We supplied participants with a booklet that was designed by the team, 2 weeks before the workshop to allow them time in their daily schedule to complete the booklet and explore GMCI prototype. Participants used their completed booklets during the session as mnemonic aids to recall their thoughts and experiences. A total of 6 participants (parents: n=3, 50%; young people: n=3, 50%; female: n=3, 50%; male: n=3, 50%) agreed to participate in the joint consolidation workshop. The aim was to elicit their thoughts and feelings about DMH data as they completed the web-based mental health check-in journey. The booklet included a range of questions designed to gauge emotional reactions as well as rating scale assessments as participants used the web-based screening platform. Within each section of the booklet, we included ethical considerations to encourage participants to consider the social impact of the DMH tools, including their understanding of mental health, how their community understands mental health, views on data privacy and management, how they would like to receive feedback about their mental health, and whether they felt they could challenge a mental health assessment. Participants then took part in the consolidation workshop to discuss their experience of using the prototype and to consolidate their ideas and expectations of engaging with an online mental health screening service. The session was broken down into four parts:

1. What are the motivations, benefits, and challenges of accessing such a tool?
2. Where does the data entered on the web go?
3. How well did the participants understand the feedback supplied? Did it resonate with their cultural background?
4. What suggestions did the participants have to make this tool more accepted within specific communities (dos and don'ts).

Figure 3. A completed emotional walk-through booklet in phase 2.1.

Positionality Statement

Our authorship team represents a variety of cultural backgrounds and perspectives on the topic, shaped by our own experiences. We took part in this research because we believe strongly in fostering equal access to mental health services for culturally diverse end users. Our team comprises 8 authors: 5 (62%) female individuals with European, Anglo-Celtic, and Irish heritage; and 3 (38%) male individuals with Anglo-Celtic, Anglo-Australian, and Filipino heritage. Of the 8 authors, 3 (38%) are first-generation migrants to Australia; 4 (50%) identify as parents; and 3 (38%) work with young people, parents, caregivers, and families. Our team consists of clinical and registered psychologists, a neuroscientist and bioethicist, a human-computer interaction and design practitioner, and researchers working in DMH and responsible innovation. We are committed to extending our knowledge and understanding of culturally diverse research practice to empathize and engage with research involving culturally diverse parents and young

XSL•FO
RenderX

people in this work. This commitment has informed our approach to the study design and data analysis.

Data Analysis

Audio recordings from all 3 face-to-face workshops (phase 1: n=2, 67%; phase 2: n=1, 33%) were transcribed and thematically analyzed using NVivo software (Lumivero). An inductive thematic analysis was conducted on all transcripts, without a preexisting coding framework, to identify themes and subthemes [87]. Initial codes were generated by IB to organize the data from phase 1 into potential items of interest. Three additional researchers (AC, RM, and JPS) familiarized themselves with the data from phase 1 and reviewed the initial codes. Iterative coding was then completed by IB, and 21 subthemes were generated that informed the design of the emotional walk-through. Three additional research members (AC, RM, and JPS) cross-coded themes from the emotional walk-through booklets and transcripts from the consolidation workshop. The codes were reviewed to ensure that the themes were clear and descriptive. The coded data from both phases were combined for analysis with 5 themes. In each workshop, an activity schedule was used to scaffold free-flowing discussion among participants. Variations in participant opinions were coded and contrasted to develop the subthemes. Participants were collaborative and brought culturally diverse and unique experiences, offering rich anecdotes in each session.

Results

Five major themes were developed from the analysis of the data collected from both phases: (1) trust in the use and application of a DMH tool, (2) data management and sharing, (3) sociocultural influences on mental health, (4) generational differences in mental health and digital literacy, and (5) stigma and culturally based discrimination in mental health support.

The Potential Impact of DMH Tools on Interpersonal and Therapeutic Relationships

The discussions on how DMH tools may impact the therapeutic relationship with a current or future clinician varied; however, both groups (parents and young people) expressed greater trust in a clinician in a face-to-face setting than in a digital tool. Participants in both groups also agreed that they would be more likely to trust a mental health recommendation or diagnosis generated by a DMH tool if a clinician was involved at some point:

> *I feel like I would still and then like accept whatever the app tells me, but it will be very helpful if the psychiatrist or psychologist are linked with this app. Like they sort of like, acknowledge that this app is useful or something like that.* [YP5]

Participants acknowledged that they would seek advice from a DMH platform if a clinician was hard to access or as a first step in help seeking. However, some participants (YP10, YP7, YP5, and P2) felt that it was hard to know where to search and stated that they would use DMH tools as a screening tool but would seek help from a trusted health professional, such as a GP, psychiatrist, or psychologist, regarding the information provided by a DMH tools. Conversely, other participants found face-to-face interactions to be "embarrassing" (YP10), "confronting" (P8), or rushed:

> *I feel like because GPs usually see patients 15 minutes per block, it feels that it's quite rushed and sometimes GPs wouldn't take the time to go over time...it will make us feel that we're not as like important.* [YP9]

Once a recommendation or treatment suggestion has been provided by DMH tools, participants in both groups (P6, YP5, and P3) expressed a desire to process it on their own first:

> *I would want to see the information first and then several steps down the road, consulting with a specialist might be an option.* [P3]

Once they had reached a point of acceptance regarding the recommendation or treatment suggestion, there was variability in whom they would share the data with, with disclosures to family, friends, and practitioners varying within both groups. Some parents (P1, P2, and P3) preferred to be given the recommendation before sharing it with their children. Two younger participants (YP2 and YP5) were happy to share the information with their parents and siblings, while many of the other young participants (YP1, YP3, YP8, YP9, and YP10) indicated that they would prefer to share it with a trusted contact or friend—rather than with their parents and siblings—who they believed would help put them in touch with a professional or assist in accessing additional resources.

One young person (YP3) suggested having the option to choose to download feedback from a DMH tool depending on the severity of the user's mental health problems. Another young person made the following suggestion:

> *If you delete it, they ask you, "Are you sure?" or like, "Are like are you too busy?" "Is it distracting?" Like it ask you the reasons why you are downloading it. Have you met your match? [similar to a dating app] I think the same should be with the app. Like if you don't like the app, but you still, you downloaded this, but you still feel like you need someone to talk to, call these numbers. And it shouldn't be triple zero, because why would I call triple zero in my, like I don't...maybe triple zero can be like the last thing, but like call this person or locate the nearest center or psychologist, or locate your nearest person or something else.* [YP8]

Suggestions were made in regard to having a trusted contact who would receive a notification if a user was determined to be at high risk for poor mental health, with the understanding that the trusted person would not be obligated to assume responsibility. Two parents (P7 and P8) emphasized the importance of a DMH tool's recommendation or resource that offered access to peer support networks. Another suggestion was for the user to predetermine a lower threshold for a risk notification if they were at risk of increased suicidality, allowing earlier intervention:

> *There's blurred lines to it, but at least like...having an accountability system...accepting, declining, being able to be there, or if I'm not, if I can be an emergency contact, but I'll accept, just going through*

XSL•FO
RenderX

> *this with you. Like, being there with you but I will not be your emergency contact. Like, I can share experience. In the case where it is an emergency, I don't want to be an emergency contact, but I can maybe assist you in contacting your emergency contact or something.* [YP8]

Participants agreed that DMH tools should offer additional resources and alternative options once a screening or check-in is initiated, such as "resources to learn more about what I might be going through" (YP4). Both parents and young people emphasized that healthy parent-to-parent and child-to-parent relationships were important in cases where parents chose to complete a screening on behalf of their child. A parent elaborated as follows:

> *Obviously we agree to disagree on a lot of topics, but you know, after a certain years, you know your child very well. And...it depends on the relationship between the father and the mother as well.* [P2]

The closeness between parent and child would be a significant factor in the quality of input into a DMH tool's screening process, which would then impact the meaningfulness of any subsequent recommendation or prediction:

> *It'd be a case of if you could offer it as a dual package. So if the child was up to do it with their parents as one option, then you'd have, so you'd have three options, you'd have an adult, you'd have the youth separate, and then you'd have a child and a youth and a parent combo...there's something to suit everyone depending on their communication space with their family members and how open they are to their mental health.* [P10]

DMH tools were suggested as a complementary support alongside a clinician in both phase 1 workshops. Additional benefits of using DMH tools included setting reminders or nudges to promote healthy activities such as going for a walk or engaging in mindfulness meditation. A participant in the workshop for young persons also suggested that DMH tools could be useful for users with acute mental health challenges:

> *I think it would be good for bipolar disorder. For example, if you were able to get a new notification about your hyper episode, then you would able, you wouldn't be able to change your episodes like change your, arrange your calendar according to that.* [YP1]

In relation to the technology, a young person described enjoying how music apps and YouTube catered to her mood:

> *So I relate how I'm feeling, even if it's like a chronic like mental illness, like how I'm feeling is through my algorithm of my music. So like I'd be on YouTube and I'd probably right now I'm, like...I just figured out I had ADHD so like I'm like constantly watching things that have to do with that. So like I feel like different platforms can algorithmize my personal experience.* [YP8]

Another young person echoed this and made the following suggestion:

> *I think technology in essence should be supporting humans and human work, rather than trying to replace it. Um, if my GP or my psychologist fails to diagnose or intervene with me early, I recognize that everything they know about me is what I've told them, and those people are human. It's people they might miss things. So I'll be more than happy for this sort of data to assist in diagnosing me. Um, and together it will be more valid that just one source or the other.* [YP7]

In summary, when considering how results are communicated and what impact DMH tools may have on clinical practice, culturally diverse end users wanted to first process a recommendation or prediction on their own, viewed DMH tools as complementary to face-to-face clinical intervention, and were open to having a trusted contact with whom a recommendation or prediction could be shared.

Data Management and Sharing

Conversations in both phases established that participants had a moderate level of understanding about their personal data and how to manage the data. They acknowledged being aware of daily data collection via internet searches and app use and that the data can be outsourced to different countries and third parties through data harvesting (P3, YP10, P2, P7, YP7, YP8, and YP5). A participant in the workshop for young persons suggested that some data have to be shared to build more accurate and personalized apps:

> *I feel like data collection should be a two-way street. If you, I mean, like it should be mutual benefit, right?* [YP7]

Unauthorized data access by governments, concerns after experiences with surveillance measures during the COVID-19 pandemic, recent government health data breaches, and identity theft were key concerns of participants (P8, P7, P2, YP9, P6, and P5). A participant shared another concern:

> *It could be mental health related or something else related. And then that information goes to your doctor, you consult a specialist or a GP or someone. And then it goes back to your insurance provider. And the insurance provider knows about it and straight away your premium goes up because they classify you as a high risk.* [P3]

By contrast, young people were more open to having their data tracked or shared, having grown up with much of their information already available on the web and accessible by others. However, a young person acknowledged the difficult dilemma of accepting data collection in exchange for a more personalized online experience but described it as a "gray area" when it comes to broader data collection, stating as follows:

> *When they click "Accept All," that gives a warrant basically, and that's nothing that you can do because the website can just say, "You said, 'Accept All'" and continue. That's the warrant for me to say...to collect all your data and personalize it for you. And I feel like it's, it's quite a grey area basically.* [YP7]

XSL•FO
RenderX

Another young person expressed uncertainty regarding their preference for certain data points to be collected or tracked by specific services:

> *I would want my location to be tracked by medical services. Say, for example, I get hurt and then, um, my phone...like my watch has this thing where it says, "Accident Detected." But I think about who gets access to what data and what they do with it and I think that's also really hard to track so it depends.* [YP2]

In summary, culturally diverse mental health service users valued data about mental health, with variation in openness to data sharing and how the data may be shared in future.

Sociocultural Influences on Mental Health

Participants' experiences with mental health were grounded in sociocultural complexities, with variations in cultural understandings of mental health, help seeking, parental influence, community and spiritual support, and migration status, all playing a role in diverse communities' engagement with DMH support.

Many of the participants (YP7, YP1, YP8, and P8) self-identified as having lived experience with mental ill-health and discussed the importance of self-understanding when it came to mental well-being. Parents, in particular, recognized the importance of acceptance and education around mental health:

> *Probably because nobody wants to tell anyone, I'm going through not a very nice day or I'm going through mental health issues, so basically we have to come out of that state so we have to educate ourselves there's no point in just keeping everything to yourself.* [P2]

Participants agreed that, outside of the family unit, their ethnic communities placed more importance on family connection and bonding than mental health specifically. This was highlighted in the comment written by a young person in the emotional walk-through booklet:

> *The "Mental health" term itself was still a taboo in India. We give importance to family connection and bonding (as a well-being strategy) but always have learnt to support and be there for one another.* [YP4]

In addition, some participants (P1, P7, and YP4) discussed how their communities relied on religious leaders for mental health support rather than accessing formal care. However, the dominant cultural lens within a household impacted whether mental health was openly discussed. A parent explained as follows:

> *I would say it's very culturally influenced. From my perspective, the culture which we're connected to, you know. For everything there is a step-up process for you to understand, you know, why this is done, why it is not done. The reasons behind it. So where we grew up in our culture, we explain to them why we are doing this, to keep them on track. To keep you calm. It will protect you. The faith base.* [P1]

Migratory experiences and differences in the availability of support depending on visa status were also significant:

> *When I came from Turkey to here, one of the biggest surprises I have come across was the, how common suicide was among younger generations of Turkish people here. I was shocked, I lived in Turkey for 19 years, and I'd never even heard of someone who has heard of someone else's suicide. Like, never even came across it from the third degree or fourth degree. Many here, I spoke to a family member of someone who was a victim to suicide. The mother told me about her son's suicide, and I was so shocked. And then I heard the same story from multiple other people as well, and it just made me realize how widespread it was here, in younger generations of Turkish people.* [YP1]

In summary, sociocultural factors influenced the use and application of DMH tools, with culturally diverse end users describing how their culture informed their understanding of mental health and help seeking.

Generational Differences in Mental Health and Digital Literacy

There were notable differences between the 2 generations across both study phases, particularly in terms of accessing mental health professionals, digital literacy, and whether participants were first- or second-generation migrants. Language barriers were identified, with a parent stating as follows:

> *That support is lacking. So you can imagine for some of these cultural communities, English might be a barrier, language might be a very big barrier.* [P6]

Parents (P6, P2, P8, and P3) preferred confiding in a close friend and face-to-face interactions over digital therapies. By contrast, young people (YP8, YP10, YP3, and P8) seemed more willing to share their mental health experiences. A young person stated as follows:

> *I know that like when I was a young teenager, going through my rebellious phase in an ethnic household where I didn't feel like it was safe to open up to my parents, the online anonymous aspect was what made online like, Tumblr, a safe place for me to, I guess, voice my mental health concerns about myself.* [YP5]

Some parents also believed that young people were more mentally healthy and digitally literate:

> *I think teenagers today are really, because they do things like that in school now, they understand about self-care, they do mindfulness, they do all that sort of thing as teenagers now in high schools and things. I think that the word self-care is so synonymous now, everyone knows what that means. There's depths of it, of course, but to a teenager even knowing, and they know how much time they spend, too much time on social media, they know they need to get more sleep, but you know, when they do all those things and they know they shouldn't eat McDonald's every day, they're not silly, these kids are smart.* [P8]

XSL•FO
RenderX

As a first-generation migrant, a parent felt that it was important not to impose her own cultural rules on her Australian-born children:

> *Because they're going to be Indian Australians, or Indian whatever it is. Deep down, they're Indian, they grew up as Australian children. They're more Australian than Indian sometimes. So we don't, um, there's no hard and fast rules. We can't tell them, you have to get up at 5 o'clock and pray.* [P2]

The discrepancy between how young people perceived mental health challenges compared to their parents was regularly raised, with a young person elaborating as follows:

> *I think another aspect of like, immigrant parents on things about mental health, gender identity, sexuality that's a big thing that, I know people, who are even single parents, who come from the immigrant background, they don't understand what their young child is going through with gender identity and all that stuff, because it's...it wasn't really a thing when they were growing up, and, suddenly it's become something now, and they don't know how to deal with it.* [YP10]

In summary, generational differences were a central social factor that influenced the use and application of DMH tools.

Stigma and Culturally Based Discrimination

Challenges with mental health stigma were discussed in both phases, with participants explaining that different cultural beliefs informed alternative explanations for poor mental health. Moreover, concerns were expressed that assigning a mental health diagnosis to a young person could lead to further marginalization because it might trigger defensive barriers in community members and contribute to increased ostracization. These experiences were centered on both internalized and externalized mental health stigma from family, friends, and extended cultural communities (P6, P3, P2, YP7, and YP3).

When discussing a potential mental health diagnosis for a child or young person, a parent stated as follows:

> *It's denial first, thinking that nothing is wrong with your child...automatically you think, my child is fine, there's nothing wrong...So the acceptance [of poor mental health] is going to be very difficult.* [P2]

For a young person with culturally diverse parents, the experience of mental ill-health was particularly challenging:

> *When my parents found out that I had some mental health issues...I noticed changes in their behaviors and in terms of my parents and carers being from an ethnic environment, they're very judgmental. I just feel like my parents have zero understanding on mental health and mental illness so they wouldn't take any of that as a form of "I need help." They'll take it as I'm being ungrateful.* [YP7]

A parent described how "mental illness ignites defensive barriers within people" (P6), suggestive of an internalized resistance that may impact help seeking in a community. A young person stated as follows:

> *It might also depend on the person and if they have internalized stigma. I think if an app has some sort of measure that can account for that [internalized stigma]. And that can frame the message depending on that, it would be really nice. So, even in ethnic communities, even if somebody is seeking help, for example. Learning that you're depressed can be quite burdensome on your own mental health. The diagnosis might actually worsen your situation. Because the view of depressed people within your culture might always be these helpless people who cannot do anything basically.* [YP1]

Regarding the diagnostic potential of DMH tools, parents were cautious about making their children "feel like they're different" (P8). A parent described how the diagnosis could be enduring and punitive:

> *You're assuming the parent can put a diagnosis on a condition and that's going to stick somehow. Because you're sort of leading them down a particular path. I'm a great believer in diagnoses, but a diagnosis can be a sentence. Rather than a word, you know.* [P7]

There were concerns that a diagnosis can result in "lifelong stigma for a child or young person" (P7). A parent put it as follows:

> *You know what, suddenly my kid gets this thing as a mental health patients, that's the end of their life. For the rest of their life they'll be on medication or for the rest of their life they'll be on this. They're branded like that.* [P2]

There was a perception among some parents that they would "lose face" and be stigmatized in the eyes of their community if they or their child received a mental health diagnosis:

> *When we talk about the ethnic communities, for them, their saving face becomes a very big issue. And you know, none of them want to lose face in the community in public and what have you. If somebody else doesn't even use their name then, for them, that stigma sort of stays, it's always going to take me years to rebuild that trust again.* [P6]

Participants in both phases raised concerns about culturally based discrimination when seeking mental health support, including an inequity in the availability of psychological assessments, screenings, and support. Psychological assessments and mental health screenings were identified as a form of systemic discrimination by the young participants, who noted how most tools are only available in English, with questions reflecting Western understandings of mental health. This often results in people performing poorly due to an inability to understand the questions and being misdiagnosed. A young person described her lived experience of working in a Turkish-speaking psychologist's office in Australia and raised her concern about the limited number of bilingual psychologists:

> *They were one of the few Turkish-speaking psychologists we had, four or five months of waitlists. So, it was cheaper than private practitioners. Only 20% of the fee would be paid out of pocket. And it*

XSL•FO
RenderX

> *was impossible to get through. Even if you have, um, some sort of government supplement like Medicare or some sort of private insurance, it was just impossible to make an appointment with her. And the same thing was the case for our Bosnian psychologist and our other psychologist as well.* [YP1]

Difficulties accessing mental health support were raised across both groups, with participants discussing the challenges, such as visa status, that migrants face when accessing mental health services, which can prevent them from receiving the same standard of support as other residents. This was particularly important for young international students waiting for permanent residency visas:

> *But because they're still waiting for that process to get their PR [permanent residency visa]. They're [asylum seekers] still in our schools. They go to private schools. They're living a good life. But because they're asylum seekers. We're international students. We don't have access to Medicare.* [YP2]

Discrimination from family members, friends, ethnic communities, and third-party systems upon receiving a mental health diagnosis was a concern raised by both groups (YP5, YP6, P6, and YP1). Both groups identified concerns about future discrimination from third parties who may use their mental health diagnoses to deny visa applications, steal their identities, or charge them higher insurance premiums (P1, P3, P5, P6, YP5, and YP6). In summary, stigma and diagnostic barriers, culturally based discrimination, and third-party access that may impact visa status and migration were central concerns.

Discussion

Principal Findings

The aim of the project was to explore the views of culturally diverse parents and young people on the opportunities and barriers to engagement with a web-based DMH screening tool. Through this work, we have explored the benefits, burdens, and trade-offs of using DMH tools from the perspectives of culturally diverse end users. On the basis of these findings, we provide our provisional set of reflections on the future of culturally sensitive DMH tools. Consideration of parental influence based on their country of origin, culture, and level of mental health literacy and how that is paired with raising a child in Australia is complex. Young people were perceived to have a higher level of general mental health and digital literacy, with greater awareness of their mood and self-care routines, as well as an understanding of healthy diet and lifestyle routines. They were also more willing to share information about their mental health with others. These generational differences highlight the importance of accounting for perceived barriers such as the influence of culture on mental health support, culturally based discrimination in seeking mental health support, and how a diagnostic label may impact the likelihood of engaging in help seeking.

Leveraging Family Connectedness

We found that our participants' understanding of their mental health was centered on their connection to family and parent-child relationships. Our findings suggest that family ties and family connectedness may influence the uptake of mental health treatments or interventions or whether and with whom DMH tool recommendations are shared. For culturally diverse youth, families provide an immediate social context (eg, as YP4 wrote in the emotional walk-through booklet: "The 'Mental health' term itself was still a taboo in India. We give importance to family connection and bonding [as a well-being strategy] but always have learnt to support and be there for one another"). Previous research found that the pace of cultural adaptation differs between parents and young people who resettle in Australia, with young people adapting faster but finding it hard to become independent from their families [16,88].

Family connectedness has been linked with lower odds of significant stress and despair for youth during acculturation and may protect them from other risk factors. In fact, the quality of family relationships can have a positive effect on well-being [89-91]. More research identifying positive family processes (eg, closeness with both mother and father) that build emotional well-being in culturally diverse young people is needed [92]. We found that familial influence informed young people's understanding of mental health, which, according to some parents, could be explained and managed through religious practices or alternative methods. This is an important finding because it suggests that future iterations of DMH tools should emphasize the inclusion of culturally sensitive parental support and psychoeducation on mental health problems. It also highlights the importance of engaging community leaders, elders, religious leaders, or mental health advocates from different cultures and communities to gather their insights on and explanations of well-being and mental health to ensure that the technologies are culturally safe. We suggest that culturally appropriate and culturally informed psychoeducation for families is needed to encourage community buy-in, ultimately leading to more effective DMH tools for culturally diverse populations. This education would have to be offered thoughtfully, paired with data governance education to promote digital literacy and awareness of the insufficiently regulated data industry and unregulated practices that exist currently.

Culturally Based Discrimination: Stigma, Loss of Face, and Collectivist Approaches to Mental Health

Barriers such as stigma, shame, and perceived judgment from community members were regularly raised. Many parents voiced concern about losing face in their community. Collectivist cultures that share a collective identity, emotional dependence, and shared duties and obligations operate under a "we" consciousness. These cultures are common outside Western societies that prioritize individualism [93]. The difference between individualism and collectivism ought to be considered when creating DMH tools, building an awareness that psychological support may be shared within a broad family network and that the "burden of results" may not be carried by the individual alone in collectivist communities. People from many collectivist cultures may struggle to understand the typical individualistic approach to treatment because they expect to receive care within the context of their family [94].

XSL•FO
RenderX

Some people may also have deeply held negative beliefs or attitudes toward those experiencing mental health challenges, making it important to design mental health services that incorporate informal support avenues (eg, friends and family) on which individuals may rely for help [95,96]. Loss of face is an important cultural factor in the Asian context and has been found to be a significant predictor of self-stigma and public stigma that impacts attitudes toward help seeking [97-99], especially given that community belonging plays a large role in migrant mental health [12].

Culturally diverse communities may minimize the reporting of psychological symptoms or may be resistant to sharing personal health information because of mistrust, perceived racism, or a sense that public mental health services do not accommodate or respect their cultural beliefs [100,101]. Culturally sensitive psychoeducation within communities is needed to combat stigma. To achieve this, we suggest engaging with community and religious leaders as well as mental health advocates with lived experience of mental health challenges, given their influential reach among diverse end users, to promote community-informed education, self-determination, and self-advocacy. DMH tool designs should offer transparent data collection policies, with tiered consent, to ensure that end users feel comfortable sharing their data, and this should be paired with the inclusion of digital navigators, who are members of health care teams dedicated to help end users [102].

Young people in our study voiced concern about the lack of culturally and linguistically diverse clinicians and assessment tools, noting that information was mostly communicated in English using a Western framework for assessing mental health. Research has found that diagnostic assessments tend to not be sensitive to racial and ethnic minority populations due to their exclusion from mental health research [103,104]. Furthermore, culturally diverse community members are less likely to have satisfactory access to mental health support and are less likely to receive a diagnosis for a mental health condition [105,106]. If DMH tools are to be relevant, accessible, and effective for culturally diverse populations, future designs and implementations must be available in languages other than English and incorporate cultural approaches to mental health. The very term *mental health* is a Western concept, and Western cultural traditions and understandings have informed much of the theory, practice, and understandings of mental health, including within psychology and psychiatry, with a central focus on individual pathology instead of sociocultural contexts and determinants [107,108]. Furthermore, how patients from culturally diverse backgrounds express their symptoms may vary, making it challenging to accurately diagnose or treat their conditions [104]. Individualized models of care may not be appropriate for those who are accustomed to community- or family-focused models of care [108]. The British Psychology Society proposed the power threat meaning framework as a nonmedicalized and nondiagnostic approach that instead describes how coping and survival mechanisms are adapted based on lived experience, previous threats, and social context, accounting for cultural differences in the experience and expression of distress, with less emphasis placed on Western views [109].

We ought to consider how to design culturally sensitive DMH tools that are informed by attitudes from diverse communities and encourage self-determination and cultural context within a well-being framework. One suggestion is for DMH tool developers to offer enhanced psychoeducation that is culturally safe and fosters self-determination, with tailored psychological assessments and resources that account for language variations and barriers for users coming from collectivist cultures whose conceptions of mental health vary from the Western medicalized understanding.

Medicalization by Design

Concerns were raised about making a child or young person feel different. Participants worried that “a diagnosis may worsen your situation,” suggesting that a diagnostic label or the detection of a mental health problem, as well as the diagnostic process itself, may further marginalize diverse communities through the medicalization of culturally appropriate cognitions or behaviors. Medicalization pathologizes behaviors according to a Western psychiatric framework, putting the responsibility back on the individual to stay healthy without considering other important social factors [110,111]. Online screening tools and mobile apps are being designed to promote well-being and provide psychological support, but they can also work to endorse ongoing surveillance [112] of mood and activity and set expectations about healthy behaviors and cognitions. A shift is needed in how mental health is conceptualized and designed for in a way that accounts for cultural barriers that may limit engagement and usability for diverse end users of DMH tools [109]. Importantly, we need to invest in community-led practices that promote community leadership in the design and innovation of DMH tools [82] to avoid built-in discrimination that reproduces inequities due to normative or Western-oriented assumptions about mental health [113]. We suggest that when designing DMH tool outputs, such as the communication of health information, recommendations for services and interventions, and referral pathways, the reported symptoms entered by the end user are phrased in a way that avoids pathologization and diagnosis. Currently, DMH platforms tend to recommend resources on anxiety, depression and suicidal ideation, and eating disorders [39,114]; however, we believe that it is imperative that symptoms are spoken about in clusters, rather than specifying specific diagnostic criteria that may then pigeonhole or “label” an end user without appropriate access to clinical care.

Attitudes Toward Data Collection Are a Two-Way Street

When using DMH tools, participants felt that there was less concern about privacy and data sharing when the data collected were more generalized. This is consistent with a recent study on diverse communities using mindLAMP, a DMH platform, where participants wanted their DMH apps to pull data from their current health care records to enhance app personalization [115]. Participants acknowledged that innovations and interventions require consent for collecting substantial amounts of data to tailor services or for platforms to “algorithmize my personal experiences”; however, research has found that DMH tools are often not culturally tailored or responsive due to

XSL•FO
RenderX

culturally diverse or racial and ethnic minority populations often not being considered in their development and evaluation [116,117]. Young people from culturally diverse communities recognized that they would need to provide access to personal digital health data to realize the benefits promoted by DMH tools. Critics have argued that young people may not comprehend the longevity and potential harms of a digital footprint and that thoughtful education and support around this is important for their future privacy [118]. While research has demonstrated an unwillingness from end users to share their sensitive health data with commercial organizations [23,119-121], there was a sense in our findings that participants expected an "algorithmized experience," which would require health data to be treated as open data [122]. Due to the sensitive nature of mental health data, further education on data governance and the potential reuse of big data is recommended for young people, given the nature of cross-sectoral data sharing. One approach may be incorporating speculative design approaches, such as the one suggested in the study by McNaney et al [23], to engage young people in discussions around their digital futures, the potential harms of data sharing, and the misuse of their data.

In both phases, the participants identified concerns about data breaches, including potential identity theft and the impact it could have on visa and migration status. These concerns are reflected in the literature, with 1 study finding that nearly half of the DMH apps surveyed did not have a privacy policy, although it is known that health care apps often share data points (eg, age, contact information, and other user data) with multiple third parties for commercial purposes [123,124]. Efforts have been made to establish ethical standards for digital data gathered from DMH tools, including accounting for data breaches, which advise developers to account for hidden assumptions and unintended consequences [125]. Regulations such as the General Data Protection Regulation in Europe and similar privacy acts being developed in Brazil, Chile, and Canada aim to protect data privacy. However, even the General Data Protection Regulation has limitations, particularly in the context of emerging generative artificial intelligence innovations.

Reflections and Limitations

This study sought to engage with culturally diverse representatives in relation to cultural background and lived experience of mental health challenges. To achieve this, we approached an organization focused on multicultural mental health that advertised the study, recruited participants, and supplied bicultural workers for our study. While we were able to have meaningful discussions in our workshops, the participants were all affiliated with the organization, meaning that the sample was not necessarily representative of a truly culturally diverse population, given that each participant was already mental health literate, able to communicate in English, and held a preconceived understanding of mental health, rather than being a layperson. The addition of an Anglo-Australian participant was also a limitation. Future research needs to engage with a broader range of culturally diverse participants, including those with less digital and mental health literacy and those who may be in a more contemplative stage of their mental health journey and possibly unaware of support services. Future research might consider recruiting through youth organizations or well-being counselors who may have access to a more culturally diverse range of participants who reflect a more culturally diverse picture of mental health literacy and help seeking. Future research should also engage in participatory action research methods (eg, co-design and coproduction) that allow end users to develop RQs and study designs. However, this approach can present additional challenges to building social capital and gaining trust to engage with culturally diverse end users in a meaningful way, and this needs to be factored into study timelines. Our study was bound to an innovation timeline, making the recruitment of a truly diverse sample impossible. We were conscious that we did not invite the participants to review the data analysis or final manuscript, which could have reduced the power imbalances further by allowing the participants to join as coresearchers in the project from start to finish. Future iterations would benefit from inviting culturally diverse participants on board as coresearchers, not just as participants. We believe that it is important to embed the voices of diverse community members within a research project throughout its lifespan.

Most of our participants were from South-East Asia. While this is an accurate reflection of the majority of culturally diverse Australians [1], it may not capture the views of ethnic and racial minority cultures within Australia. We hoped to avoid essentializing all experiences as one by including quotes from individuals because we believe that culturally diverse communities do not share a single common experience due to varying sociopolitical differences such as age, culture, and citizenship. The median age of the young participants was relatively high, with one aged 16 years and one aged 18 years, while the remaining participants were aged 20 to 22 years. As such, our findings may not reflect the views of younger adolescents. Future endeavors should aim to apply the insights gained from this research in the development and pilot testing of DMH interventions and applications by evaluating their effectiveness and refining them based on the outcomes.

Conclusions

Inclusive design considerations for the future development of DMH tools that account for culturally based discrimination, are culturally safe, consider family and cultural influence on mental health support, and are thoughtful in how mental health problems are detected and communicated to end users would improve engagement in DMH tools and help seeking. We recommend encouraging culturally sensitive psychoeducation, thoughtful nonpathologizing language that avoids providing a specific diagnosis, and the inclusive involvement of community leaders and mental health advocates in the future design of DMH tools to ensure that they are designed to meet the needs of culturally diverse end users.

Abstract

Background: More than 5 million US adolescents experience mental or behavioral health conditions, yet two-thirds remain untreated, and suicide is the second leading cause of death. These gaps highlight the urgent need for accessible care. Digital mental health interventions that integrate measurement-based care (MBC) and personalized mental health care provider matching offer a promising solution, but few studies have examined their real-world impact among adolescents at elevated suicide risk.

Objective: This study aims to evaluate symptom improvements among adolescents with and without elevated suicide risk receiving care from Rula Health, an MBC-based digital mental health intervention with personalized intake through mental health care provider matching. We aimed to (1) compare baseline demographic and clinical characteristics between adolescents with and without elevated suicide risk at intake and (2) examine depression and anxiety symptom trajectories over the first 12 visits between adolescents with and without elevated suicide risk at intake.

Methods: We conducted a retrospective analysis of real-world clinical data from adolescents who received mental health services through Rula Health. Adolescents were classified as no suicide risk or elevated suicide risk based on the Columbia-Suicide Severity Rating Scale. Depression and anxiety symptoms were assessed using the Patient Health Questionnaire-9 (PHQ-9) and the Generalized Anxiety Disorder-7 (GAD-7) at baseline and before each session. Minimal clinically important differences were defined as a reduction of 5 more points for PHQ-9 and 4 or more points for GAD-7. Symptom changes were examined up to 12 visits. We used *t* tests and chi-square tests to compare baseline characteristics between suicide risk groups and linear mixed-effects models (adjusted for demographics and clinical factors) to assess symptom change and trajectory differences over time.

Results: The sample included 3533 adolescents in the no suicide risk group and 2712 in the elevated suicide risk group. The elevated suicide risk group had a greater proportion of female adolescents, younger adolescents (P<.001), non-Hispanic individuals (P=.002), and those with a primary depressive diagnosis, comorbid conditions, psychiatric involvement, and higher baseline PHQ-9 and GAD-7 scores (P<.001). The no suicide risk group attended more sessions and stayed in care longer (P<.001). Depression and anxiety scores decreased over visits (PHQ-9: B=–0.39; P<.001; GAD-7: B=–0.35; P<.001), with average improvements exceeding minimal clinically important difference thresholds. The elevated suicide risk group's depression and anxiety symptoms decreased at a higher rate than those of the no suicide risk group (PHQ-9: B=–0.32; P<.001; GAD-7: B=–0.18; P<.001).

Conclusions: Adolescents with elevated suicide risk showed greater and faster improvement in depression and anxiety symptoms, reaching similar levels as those without elevated suicide risk by 12 visits. Rula Health's model can support high-risk youth in real-world settings. Future research should assess the impact of MBC and mental health care provider matching, including study designs that isolate their specific effects on outcomes.

Introduction

Background

Adolescence is a critical developmental period marked by heightened vulnerability to mental health disorders, with more than 5 million adolescents in the United States diagnosed with a mental or behavioral condition, most commonly depression and anxiety [1]. Depression and anxiety symptoms can deeply impact how adolescents function in their daily lives, affecting their relationships, academic performance, and overall well-being [2,3]. Even more concerning is the fact that these symptoms are strongly linked to suicide, the second leading cause of death among adolescents, with rates rising to 62% from 2007 to 2021, even as they plateau or decline in other populations in the United States [4-6]. One in 5 high school students has seriously considered suicide, with more than 1 in 10 reporting that they attempted suicide [7]. Rates of hospitalization for suicide-related behaviors in adolescents have sharply increased, placing added strain on families, school systems, and the broader health care system [8,9]. Despite the urgency of these trends, 61% of adolescents with mental health needs report difficulty accessing treatment due to barriers, such as mental health care provider shortages, long waitlists, stigma, and cost [1]. These realities underscore the urgent need for timely, accessible, and effective mental health interventions.

Digital mental health interventions (DMHIs), including virtual therapy and psychiatric services, have emerged as a scalable and flexible solution to address the growing demand for adolescent mental health care [10]. By offering therapy and psychiatric services through virtual platforms, DMHIs can help overcome many of the barriers that limit access to traditional in-person care, such as geographic limitations, mental health care provider shortages, long wait times, and stigma [11], though access may remain uneven due to disparities in broadband connectivity, device availability, and digital literacy [12,13]. These platforms are particularly well-suited to adolescents, who are often comfortable with technology and may prefer the privacy and convenience of engaging in care from home [14,15]. In addition to expanding access, DMHIs offer the potential to deliver more personalized care by adapting treatment to individual needs, goals, and preferences in a flexible, user-centered format. While emerging evidence suggests that DMHIs can reduce depression and anxiety symptoms among youth experiencing suicidal thoughts [16,17], their effectiveness depends on how care is tailored and monitored over time. Consequently, there is a growing need for digital platforms to deliver care that is both personalized and informed by structured symptom monitoring.

Measurement-based care (MBC) is an evidence-based approach that uses standardized assessments to monitor symptoms and guide clinical decision-making throughout treatment [18]. It has been linked to improved outcomes and stronger therapeutic alliance across diverse mental health settings [18,19]. Although some studies in routine outpatient care have found modest or variable effects [20], and meta-analytic evidence suggests MBC does not consistently improve symptom outcomes [21], this variability highlights the importance of examining MBC in populations where its impact may be most critical. For adolescents at elevated suicide risk, MBC may offer a mechanism to detect rapid symptom changes, support timely adjustments in treatment, and complement clinical decision-making in high-stakes contexts. In parallel, personalization strategies, such as offering a curated list of mental health care provider options tailored to clinical needs and individual preferences, may help ensure that care is well-aligned from the outset [22,23]. DMHIs are well-positioned to implement both approaches efficiently, using technology to support structured symptom tracking and individualized mental health care provider selection at scale.

Despite the promise of DMHIs, including virtually delivered therapy and psychiatry, important gaps remain, particularly for adolescents at elevated risk for suicide. DMHIs have demonstrated effectiveness in reducing depression and anxiety symptoms among adolescents in both clinical trials and real-world settings [24-26]. However, relatively few studies have assessed whether adolescents with elevated suicide risk experience similar patterns of symptom improvement compared to those without such risk [27]. While emerging research on DMHIs has begun to include adolescents with elevated risk for suicide [16,28], most studies do not stratify outcomes by suicide risk status, limiting our understanding of whether this subgroup benefits equally from care. Moreover, a recent systematic review and multiple studies show that adolescents with suicidal thoughts or behaviors are often excluded from DMHI studies for safety reasons, which limits generalizability and contributes to the lack of real-world evidence for this high-risk group [16,29-31]. In addition, little is known about how digital care models that incorporate both MBC and intake personalization perform for adolescents at elevated suicide risk. Addressing these gaps is essential for designing digital mental health services that are not only scalable but also safe, effective, and equitable for the youth who face the greatest clinical challenges.

Objectives

The purpose of this study was to evaluate symptom improvements among adolescents with and without elevated suicide risk receiving care from Rula Health, an MBC-based DMHI with personalized intake through mental health care provider matching. We aimed to (1) compare baseline demographic and clinical characteristics between adolescents with and without elevated suicide risk at intake and (2) examine depression and anxiety symptom trajectories over the first 12 visits between adolescents with and without elevated suicide risk at intake.

Methods

Study Design and Participants

This retrospective study examined secondary data from Rula Health, a DMHI that connects individuals across the United States with licensed therapists and psychiatry providers. Rula Health's care model is grounded in MBC and personalized treatment approaches aimed at improving clinical outcomes. Adolescents (aged 12-17 years) were included in this study if they received therapy and psychiatry services from Rula Health between August 24, 2022, and June 30, 2025, and completed the Columbia-Suicide Severity Rating Scale (C-SSRS) during their initial visit as part of standard clinical procedures. Patients were sent the C-SSRS when their baseline total Patient Health Questionnaire-9 (PHQ-9; refer to the description mentioned subsequently in the Study Measures section) score was above 15 or if PHQ-9 item 9 indicated risk. In this study, participants were classified as no suicide risk (total C-SSRS score=0) or elevated suicide risk (total C-SSRS score ≥1) [32]. This threshold aligned with clinical practice, where any endorsement of suicidal ideation or behavior on the C-SSRS was considered a positive screen requiring further evaluation [32,33].

Ethical Considerations

Before beginning care, all individuals receiving services through Rula Health were required to provide informed consent. The consent process included an explanation of the nature and scope of the services, confidentiality protections, and how personal data may be used. In addition to the informed consent process, patients reviewed and accepted Rula Health's privacy policy, which detailed how personal information was collected, used, and protected in accordance with applicable regulatory standards. In accordance with US regulations governing research on human participants, this study was determined to be exempt from further informed consent requirements. Therefore, no additional consent procedures were conducted. The protocol was reviewed and approved by the institutional review board of the Biomedical Research Alliance of New York (25-035-2061). No compensation was provided to individuals whose data were included in this study.

Treatment

Rula Health's therapy and psychiatry care models have been detailed elsewhere [34]. Patients accessed Rula Health through a range of referral sources, including primary care providers, insurance partners, employer-sponsored mental health benefits, health care organizations, and direct online searches. The platform is designed to simplify access to mental health services while supporting patient autonomy in mental health care provider selection. After completing a brief intake questionnaire, individuals were matched with a curated list of licensed therapists or psychiatric providers based on their clinical needs, insurance coverage, and personal preferences (eg, provider specialty, background, and availability), from which they selected the mental health care provider who best fits their needs.

Treatment was delivered virtually via secure video sessions. For therapy, initial visits focused on collaboratively developing a personalized treatment plan that includes therapy goals, intervention strategies, and a schedule of care. Therapists drew from a range of evidence-based modalities, such as cognitive behavioral therapy, dialectical behavior therapy, and acceptance and commitment therapy, tailoring care to each patient's needs. Data related to fidelity or adherence to specific evidence-based treatment protocols were not collected. For psychiatric care, initial visits included a comprehensive review of medical and psychiatric history, discussion of presenting concerns, and the development of an individualized treatment plan that may include medication management. Provider quality was monitored through clinical tools and quality assurance protocols. For example, mental health care provider quality was monitored by clinical quality specialists, who were licensed clinicians who provided consultation and feedback to providers. Providers were also flagged for issues related to documentation quality and were given targeted feedback and ongoing monitoring until issues were resolved.

As part of MBC, patients completed standardized symptom assessments at regular intervals, and mental health care providers were encouraged to use these data to inform treatment decisions. For therapy, these scores supported progress tracking and treatment adjustment, while in psychiatry, they informed decisions related to medication, referrals, or other interventions. Rula Health implemented rigorous safety protocols for managing elevated suicide risk, including proactive risk identification (eg, using the C-SSRS), crisis response, and care coordination. The patient safety and clinical risk (PSCR) team guided providers to ensure best practices in clinical risk management and patient safety. When elevated risk was detected, mental health care providers developed and documented a safety plan and reached out to the PSCR team for consultation and help with referrals. Patients also had access to a 24×7 crisis support line. When a patient accessed the crisis line, the PSCR team followed up with the mental health care provider and helped initiate referrals when appropriate.

Study Measures

Overview

At the start of care, patients provided demographic information, such as age, sex assigned at birth, race, and ethnicity. Primary diagnoses were documented by the treating provider. Beginning August 20, 2020, measures of mental health symptoms were administered before each scheduled visit or up to once weekly. As of December 8, 2024, the frequency of assessment shifted to biweekly. This analysis focused on symptom data related to depression and anxiety.

Depression

Depression symptoms over the past 2 weeks were assessed using the first 9 items of the PHQ-9 modified for adolescents [35,36]. Patients rated each item on a 4-point Likert scale ranging from 0 (*not at all*) to 3 (*nearly every day*), yielding a total score from 0 to 27. Higher scores indicated greater levels of depression. The PHQ-9 has demonstrated strong internal consistency (Cronbach α=0.89) and excellent test-retest reliability (Pearson r=0.84) [37,38]. Results were contextualized using minimal clinically important difference (MCID) in the PHQ-9, the change

XSL•FO
RenderX

in symptom severity that is perceived as meaningful by patients (defined as a reduction of ≥5 points [39]).

Anxiety

Anxiety symptoms were assessed using the Generalized Anxiety Disorder-7 (GAD-7), a 7-item tool that assesses symptom severity over the past 2 weeks [40]. Each item is rated on a 4-point Likert scale from 0 (*not at all*) to 3 (*nearly every day*), yielding a total score from 0 to 21. Higher scores indicate greater levels of anxiety. The GAD-7 demonstrates high internal consistency (Cronbach α=0.89-0.92) and strong test-retest reliability (intraclass correlation=0.83) [40-42]. Results were also contextualized using MCID in the GAD-7, defined as a reduction of 4 or more points [43].

Statistical Analyses

Data were limited to the first 12 visits because this is a common length of treatment for adolescent mood and anxiety disorders [44] and represents a relative episode of care at Rula Health. Demographic and baseline descriptive statistics were calculated for those in the no suicide risk (ie, total C-SSRS score=0) and those in the elevated suicide risk group (ie, total C-SSRS score ≥1), and differences between the groups were tested using independent sample 2-tailed *t* tests for continuous variables and chi-square tests for categorical variables. Effect sizes were calculated using Cohen d for the *t* tests and Cramér V for the chi-square test.

To examine changes in depression and anxiety symptoms over time and determine whether trajectories differed by suicide risk group, linear mixed-effects models were fit. Separate models were fitted for depression and anxiety outcomes. The following elements were added subsequently and tested using the likelihood ratio test to determine the best-fitting model: main effect of visit number, main effect of baseline suicide risk group, and the visit number×suicide risk group interaction (this tested whether the rate of change in symptoms differed between groups). All models were adjusted for covariates, including patient age, sex, race, ethnicity, primary diagnosis, and comorbid diagnosis (ie, whether patients had at least 2 diagnoses or not). A random intercept was included in all models to account for repeated measures nested within patients. Random slopes for visit number were also included and retained if they improved model fit based on the likelihood ratio test. If random slopes models did not converge, models were refitted assuming an independent covariance structure (ie, uncorrelated random effects). Significance of fixed effects was assessed using the Satterthwaite approximation of degrees of freedom [45]. To visualize model-predicted symptom trajectories, model-predicted depression and anxiety scores over visits were calculated using the fixed effects from each best-fitting model. Predicted values were calculated for each suicide risk group at each visit, and 95% CIs were derived from the model-based SEs of the predicted means. Assumptions, including multicollinearity and normality of residuals, were checked (Multimedia Appendix 1 [46]). All analyses were conducted in R (version 4.3.1; R Foundation for Statistical Computing; [47]).

Results

Descriptive Statistics and Group Comparisons

Both the no suicide risk and elevated suicide risk groups consisted of individuals, on average, aged 15 years (SD 1.46), and they were mostly female, White, and non-Hispanic. The no suicide risk and elevated suicide risk groups differed on several demographic and clinical characteristics. The elevated suicide risk group had a greater proportion of female adolescents, younger adolescents (aged 12-14 years), non-Hispanic adolescents, and adolescents with a primary diagnosis of a depressive disorder. These differences were largest in age (Cramér V=0.17) and primary diagnosis (Cramér V=0.17). The elevated suicide risk group also had a greater proportion of adolescents with a comorbid diagnosis and adolescents receiving psychiatry services and also greater baseline PHQ-9 and GAD-7 scores. These differences were largest for baseline PHQ-9 score (Cohen *d*=–0.90) and baseline GAD-7 score (Cohen *d*=–0.61). The no suicide risk group had a greater number of visits up to 12 and were in treatment for a longer time on average (Table 1).

Trajectories of Depression and Anxiety Symptoms

Raw trajectories of PHQ-9 and GAD-7 for both suicide risk groups are presented in Figure 1. In Figure 1, the blue line represents adolescents with elevated suicide risk and the red line represents those with no suicide risk; "n" indicates the number of patient observations at each visit. Successively including a main effect of visit number, a main effect of suicide risk group, and an interaction between visit number and suicide risk group improved model fit at each step (Table S1 in Multimedia Appendix 1). At all steps, a random intercept-only model was compared to a model that included a random slope. At all steps, models with random slopes fit best, as indicated by the likelihood ratio test. Thus, the best-fitting models for both PHQ-9 and GAD-7 trajectories were the final models that included random slopes for visit number and an interaction of suicide risk group and visit number.

Figure 1. Raw trajectories of depression (A) and anxiety (B) symptoms by baseline suicide risk group.

Results of the best-fitting models adjusted for covariates showed that, on average, adolescents' depression and anxiety scores decreased over visits (PHQ-9: B=–0.39; *P*<.001; GAD-7: B=–0.35; *P*<.001) and that, on average, the elevated suicide risk group had greater depression and anxiety scores over time than the no suicide risk group (PHQ-9: B=4.95; *P*<.001; GAD-7: B=2.83; *P*<.001). The significant visit number×suicide risk group interaction terms showed that the elevated suicide risk group's depression and anxiety symptoms decreased at a higher rate than the no suicide risk group (PHQ-9: B=–0.32; *P*<.001; GAD-7: B=–0.18; *P*<.001; Table 2; Figure 2). As shown in Figure 2, model-estimated trajectories were adjusted for age, gender, race, ethnicity, primary diagnosis, and comorbidity; the blue line represents the elevated suicide risk group and the red line represents the no suicide risk group, with shaded areas denoting 95% CIs. The covariate effects of these models are presented in Table S2 in Multimedia Appendix 1. Briefly, older age and comorbidities were associated with higher symptom scores, while male sex and African American or Black race (vs White race) were associated with lower scores. Depressive disorders predicted higher depression scores, and anxiety disorders predicted higher anxiety scores.

To contextualize our findings, the no suicide risk group's slope of –0.39 on the PHQ-9 corresponded to an average reduction

XSL•FO
RenderX

in PHQ-9 of 4.68 points over 12 visits, and the elevated suicide risk group's slope of –0.39 to –0.36 (=–0.75) corresponded to an average reduction in PHQ-9 of 9 points over 12 visits. The no suicide risk group's slope of –0.35 on the GAD-7 corresponded to an average reduction in GAD-7 score of 4.2 points over 12 visits, and the elevated suicide risk group's slope of –0.35 to –0.19 (=–0.54) corresponded to an average reduction in GAD-7 of 6.48 points over 12 visits. Average reductions in the no suicide risk group approached the MCID threshold for PHQ-9 (at least a 5-point reduction) and exceeded the threshold for GAD-7 (at least a 4-point reduction). Average reductions in the elevated suicide risk group were well over these established MCID thresholds.

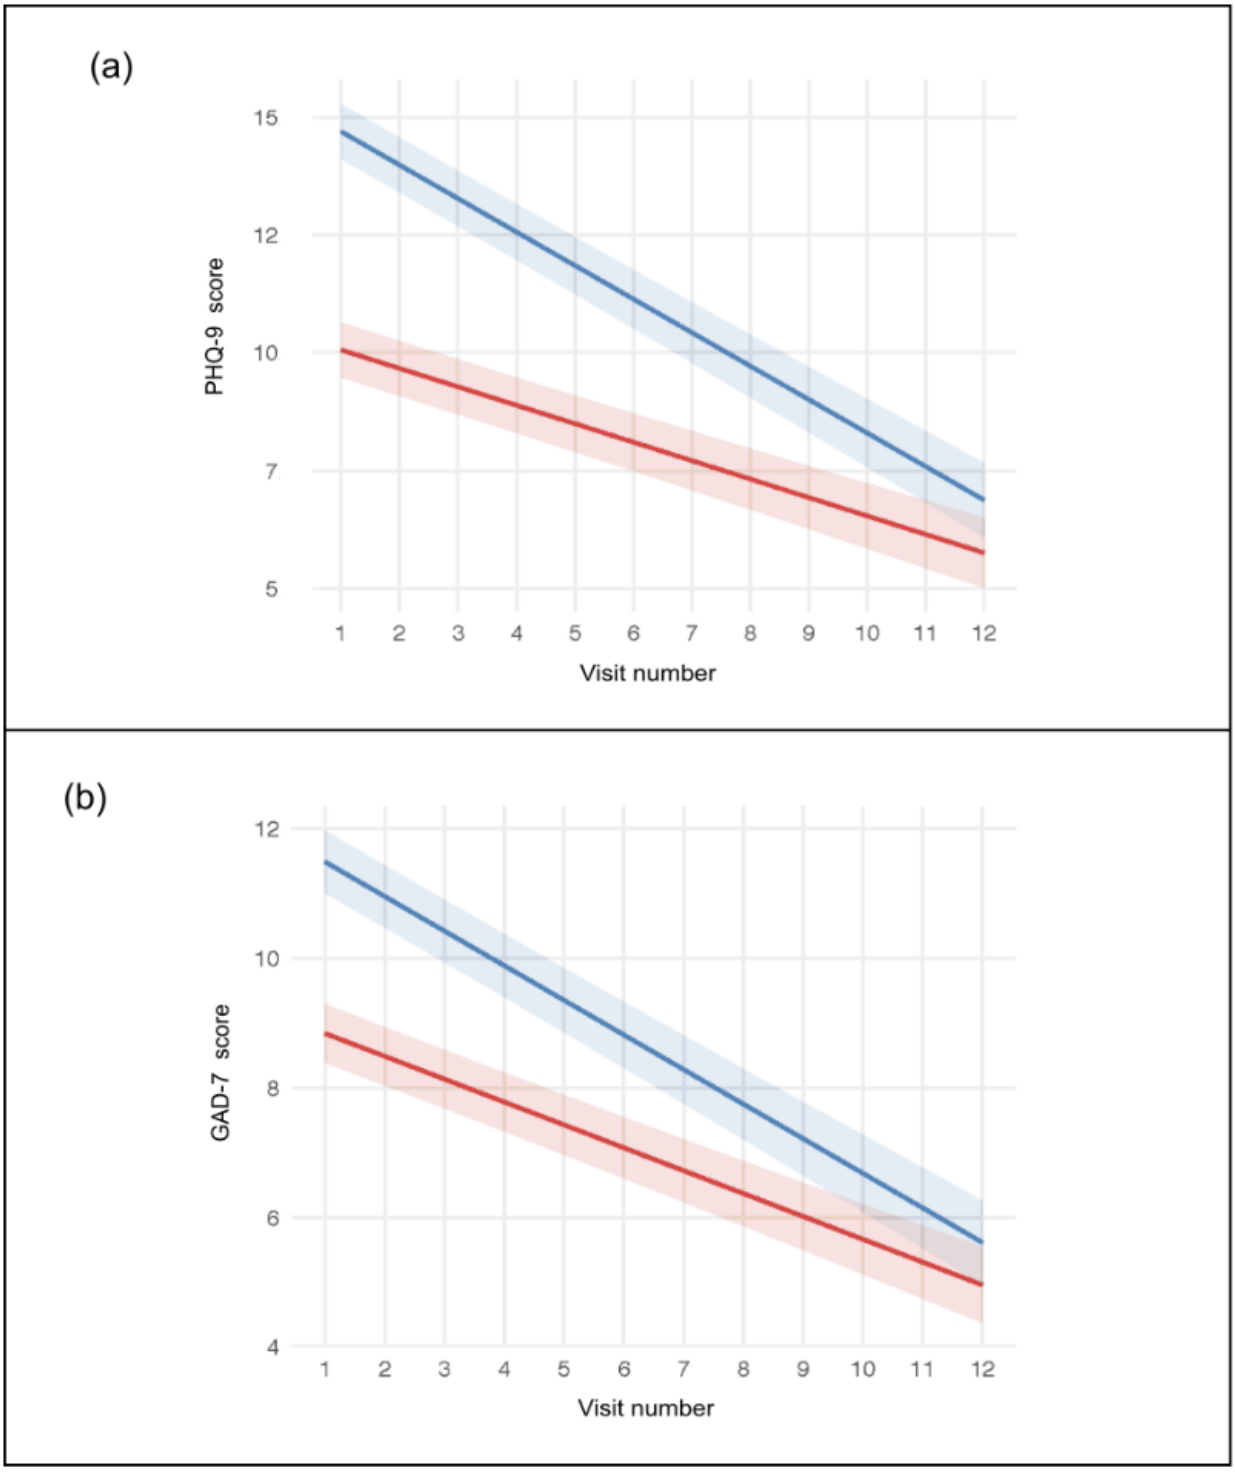

Table 2. Results (fixed effects) for best-fitting models for depression and anxiety symptom trajectories.

Figure 2. Depression (A) and anxiety (B) model-estimated symptom trajectories by suicide risk group.

Discussion

Principal Findings

The purpose of this study was to evaluate symptom improvements among adolescents with and without elevated suicide risk receiving care from Rula Health, an MBC-based DMHI with personalized intake through mental health care provider matching. We aimed to (1) compare baseline demographic and clinical characteristics between adolescents with and without elevated suicide risk at intake and (2) examine depression and anxiety symptom trajectories over the first 12 visits between adolescents with and without elevated suicide risk at intake. The elevated suicide risk group had more female adolescents, younger adolescents, non-Hispanic adolescents, and adolescents with depressive disorder diagnoses. The elevated suicide risk group had more adolescents with comorbid diagnoses, more adolescents receiving psychiatry services, and greater baseline depression and anxiety scores. The no suicide risk group attended more visits (up to 12) and was in treatment for a longer time than the elevated suicide risk group. Across all adolescents, depression and anxiety scores decreased over

XSL•FO
RenderX

12 visits. The elevated suicide risk group's depression and anxiety symptoms decreased at a higher rate than the no suicide risk group, and the elevated suicide risk group achieved similar depression and anxiety scores as the no risk group by 12 visits.

Among adolescents who received care through Rula Health, those with elevated suicide risk at intake differed from their no-risk peers. This group included higher proportions of female adolescents, non-Hispanic adolescents, and younger adolescents. These differences largely mirror national epidemiological patterns. For example, data from US adolescents, including national-level surveys, consistently show that adolescent girls report higher rates of suicidal ideation and attempts than boys [48-51]. National survey data also show that non-Hispanic White adolescents are more likely to report suicidal ideation than Hispanic youth [51,52], which aligns with our finding that elevated risk was more common among non-Hispanic participants. The overrepresentation of non-Hispanic adolescents aligns with research indicating that Hispanic and Latino identity may be protective against suicidality, possibly due to cultural values, such as familism and religiosity [53,54], and that Hispanic and Latino youth face barriers to accessing mental health care [55,56]. Interestingly, greater proportions of younger adolescents were in the elevated suicide risk group. This is different from national surveillance data and previous longitudinal studies showing that risk for suicidal ideation, suicide attempts, and death by suicide increases from early to midadolescence [57,58]. Emerging evidence points to a sharp rise in suicidality among preteenagers, which may help explain increased help seeking in this group [59,60]. The presence of high-risk youth across multiple demographic groups in Rula Health's patient population is encouraging, suggesting that this type of DMHI may help expand access to care for adolescents at greatest risk. Building on this, future research should examine how Rula Health's personalized intake and mental health care provider matching systems influence access and outcomes across sex, ethnicity, and age groups.

Adolescents with elevated suicide risk at intake presented with greater rates of depressive disorder as well as greater clinical complexity as indicated by higher rates of comorbid diagnoses, greater use of psychiatric services, and more severe baseline depression and anxiety symptoms. Major depressive disorder and co-occurring conditions are strongly linked to heightened suicide risk [61,62]. Clinically complex adolescents at risk of suicide need more intensive, frequent, and specialized care [63,64]. However, more than two-thirds of adolescents who die by suicide had no treatment contact within the month before death, highlighting the critical gaps in traditional service access and engagement [65]. Our findings point to the critical importance of DMHIs, such as Rula Health, in reaching and serving clinically complex adolescents who may otherwise face significant barriers to accessing timely evidence-based care [66,67]. Future research should examine whether there is an optimal type of treatment or therapy modality for adolescents with elevated suicide risk, high symptom severity, and multiple comorbidities.

The individuals in the elevated suicide risk group attended fewer sessions and were in treatment for less time than the individuals in the no suicide risk group. Adolescents at risk of suicide face attitudinal barriers to care, such as shame and stigma, which can impact how they engage with mental health services, including contributing to premature dropout [68-70]. Alternatively, some adolescents in the elevated suicide risk group may have had fewer sessions because they were transitioned appropriately to higher levels of care or experienced a more rapid reduction in symptoms, warranting discharge from care. Rula Health is known for both retention and appropriate transitions with data-driven monitoring via MBC and established referral pathways. However, distinguishing between premature dropout versus clinically appropriate transition is critical, as each has different implications for continuity and safety. Future research should use methods, such as survival analyses and qualitative follow-up, to clarify reasons for disengagement and should further investigate the mechanisms underlying engagement (eg, perceptions of safety, trust, and therapeutic alliance) to better understand how adolescents interact with digital care and inform strategies to support continuity of care.

Rula Health's model, which included personalized intake and MBC integration, decreased depression and anxiety symptoms over the course of 12 visits across the entire adolescent sample. Both groups showed clinically meaningful improvements, with average reductions meeting or exceeding established MCID thresholds. This study is one of the few real-world evaluations of the effects of a commercial MBC-based DMHI on depression and anxiety symptom trajectories in adolescents with and without suicide risk. Recent research shows that virtual therapy is as effective as face-to-face treatment for adolescents with anxiety and depression [24,71]. However, few studies have disaggregated outcomes by suicide risk status or included high-risk populations due to safety and liability concerns [29,72]. Our findings address these gaps by demonstrating that a virtual therapy DMHI, Rula Health, decreases depression and anxiety symptoms among adolescents with varying levels of suicide risk in the real world. Future research should identify which specific components of Rula Health's digital platform (eg, personalized matching, MBC, or their combination) most strongly contribute to treatment effectiveness in this real-world setting.

MBC-based DMHIs (such as Rula Health) have the potential to deliver rapid, meaningful clinical improvement for high-risk youth. Adolescents with elevated suicide risk experienced a decrease in both anxiety and depression symptoms at a greater rate than adolescents with no suicide risk. The elevated suicide risk group also achieved similar depression and anxiety scores as the no-risk group by 12 visits, after accounting for demographic and clinical characteristics. These findings align with previous research showing that adolescents with severe symptoms and suicidality can improve rapidly in outpatient treatment, often at rates comparable to those with lower symptom severity or no suicide risk [16,73]. MBC delivered digitally, as in Rula Health's model, may accelerate symptom relief in adolescents with elevated suicide risk by flagging patients who are in crisis and prompting timely adjustments to treatment. Rula Health patients can select mental health care providers based on characteristics such as demographics and clinical specialty, which may enhance therapeutic alliance, an especially important factor for individuals experiencing

XSL•FO
RenderX

suicidality [74]. Alternatively, the differences between risk groups might partly reflect regression to the mean, where those starting with more severe symptoms tend to show greater improvement over time regardless of treatment [75]. Although our mixed-effects models account for individual baseline severity, regression to the mean remains a plausible alternative explanation. Future research should use designs that can disentangle regression to the mean from treatment effects and more directly test the unique contribution of MBC to adolescent outcomes.

Strengths and Limitations

This study had several strengths. First, the large, naturalistic sample of more than 6000 adolescents from Rula Health, a widely available commercial DMHI, enhanced the generalizability of our findings. Second, this study examined treatment delivered under naturalistic conditions with real-world constraints, increasing the external validity of our findings compared to research in controlled settings. Third, the inclusion of adolescents with elevated suicide risk offers rare outcomes data on this important group that is usually underrepresented in DMHI research due to safety or liability concerns [29,72]. Finally, collecting MBC measures at regular intervals and using validated clinical outcomes measures (PHQ-9 and GAD-7) enabled us to model symptom trajectories instead of less nuanced pre-post analyses.

This study also had limitations; it lacked a more thorough assessment of suicidality, including the range of suicidal ideation and behaviors, as well as nonsuicidal self-injury. This study also lacked additional outcomes that could be important for adolescents, such as functioning at school and home, stress, and substance use. This study's naturalistic design involved collecting neither data on specific treatment content, therapy modality, or fidelity to evidence-based practices nor other potentially important variables, such as treatment completion, dropout, or referrals. This means we could not assess either the variability in how care was delivered across mental health care providers or true attrition. Future studies should collect data on fidelity to clarify how treatment delivery influences outcomes while balancing real-world applicability with methodological rigor. In addition, because our sample was predominantly White and non-Hispanic, future research is warranted among more diverse populations to increase the generalizability of our findings. Finally, follow-up was restricted to 12 visits without any postdischarge data. Thus, the long-term effectiveness of treatment on adolescent outcomes remains unknown. Future research should include both self-report and clinician assessments of suicide risk and collect outcomes over longer follow-up periods to establish the long-term effectiveness of DMHIs for adolescents across the suicide risk spectrum.

Conclusions

Results from this retrospective analysis highlight the potential of commercial DMHIs, such as Rula Health, to effectively reduce depression and anxiety symptoms in adolescents across varying levels of suicide risk. Baseline demographic and clinical characteristics revealed important differences between risk groups and extended current research on growing high-risk populations. All adolescents experienced substantial symptom improvements, with those at elevated suicide risk showing steeper rates of symptom reduction and ultimately achieving similar symptom levels as their no-risk peers by 12 visits. These findings highlight the capacity of structured, virtual care platforms, such as Rula Health, to deliver timely and effective support to high-risk youth. Future research and implementation efforts should explore concrete strategies for optimizing digital personalization and MBC (eg, using machine learning to enhance mental health care provider matching and comparing different schedules for symptom monitoring), particularly by including more racially and ethnically diverse adolescent populations to ensure equity and generalizability. At the policy level, integrating DMHIs into school-based mental health programs and expanding insurance reimbursement models for virtual care could help translate these findings into scalable solutions within public health systems.

Abstract

Background: Caregivers of children living with type 1 diabetes (T1D) face multiple challenges that significantly impact their mental health and quality of life. The well-being of caregivers directly affects the management of the child's condition. The Adhera Caring Digital Program (ACDP) is a comprehensive, digitally delivered program, designed to support family caregivers in enhancing self-management and well-being. This study aims to assess how the ACDP influences caregivers' mood, emotional well-being, and health-related quality of life within the context of T1D.

Objective: This study aimed to evaluate the impact of ACDP on caregivers' psychological well-being and caregiving outcomes.

Methods: This was a two-step, prospective, mixed methods study targeting caregivers of children living with T1D who were under the care of a pediatric endocrinologist at Miguel Servet Children's University Hospital in Zaragoza, Spain. In substudy 1 (SS1), qualitative and quantitative data were collected to optimize the ACDP. In substudy 2 (SS2), caregivers used the optimized ACDP for three months. Psychometric assessments were conducted at baseline and follow-up to evaluate positive mood states, general well-being, self-efficacy, and lifestyle behaviors. This paper focuses on SS2.

Results: Ninety caregivers participated in SS2. Positive affect significantly increased (P<.001), and negative affect decreased (P<.001) on the Positive and Negative Affect Schedule (PANAS). Depression, anxiety, and stress scores were reduced (P<.001) on the Depression, Anxiety and Stress Scale-21 Items (DASS-21). General well-being, measured by the Mental Health Continuum-Short Form (MHC-SF) and self-efficacy, assessed using General Self-Efficacy Scale (GSE), improved significantly (P<.001). Health-related quality of life (HrQoL) scores and Mediterranean Diet Quality Index scores increased modestly (P=.03, and P=.04, respectively).

Conclusions: The ACDP intervention improved caregivers' psychological well-being and self-efficacy. These findings highlight the potential of digital solutions to support caregiver mental health and positively influence diabetes management. Future research should explore long-term outcomes and scalability.

Trial Registration: ClinicalTrials.gov NCT05483803; https://clinicaltrials.gov/ct2/show/NCT05483803

Introduction

Children living with type 1 diabetes (T1D) face unique challenges, including deficient insulin production, psychosocial stress, stigmatization, social isolation, and bullying, which can negatively impact their quality of life [1,2]. Caregivers' are often the primary source of support for these children, and experience significant emotional burdens that are closely linked to the children's health–related quality of life (HrQoL) [3-7]. Therefore, addressing caregiver well-being is critical for holistic diabetes management [6].

Comprehensive strategies and programs that prioritize caregiver emotional health have shown promise in improving outcomes for both caregivers and children [8,9]. For instance, programs

XSL•FO
RenderX

such as PRISM-P (Promoting Resilience in Stress Management for Parents) have demonstrated the efficacy of resilience-building interventions for parents of children living with serious illnesses [9]. Positive mood states in caregivers are critical predictors of HrQoL in adolescents with T1D [10]. The diagnosis of a chronic condition such as T1D in a child is often stressful and potentially traumatic [11]. Furthermore, scalable digital interventions such as the Remedy to Diabetes Distress (R2D2) program underscore the growing need for innovative, technology-enabled solutions to address caregiver distress [12].

Achieving optimal HrQoL for children living with T1D may also require providing caregivers with personalized emotional and behavioral support [13]. This issue should be examined from the perspectives of mental health and technology acceptance theoretical frameworks [14]. The psychological well-being of caregivers is closely tied to the HRQoL and treatment adherence of children living with T1D [15]. For example, the PsyVoice study highlights the importance of understanding expectations surrounding voice-based digital health solutions to manage diabetes distress among children and their caregivers [16]. Furthermore, a recent narrative synthesis of systematic reviews underscores ongoing developments in the design and delivery of self-management support for children and young people with diabetes, emphasizing the necessity of tailored interventions to meet diverse needs [17].

The Adhera Caring Digital Program ACDP is a comprehensive, digitally delivered program designed to support the physical and mental well-being of caregivers of children living with chronic conditions. By providing personalized emotional and behavioral support, the ACDP seeks to improve self-management, mental health. and overall well-being for both patients and their families. This study evaluates the impact of the ACDP on caregivers' positive mood states, emotional health, and perceived HrQoL in the context of T1D.

Methods

Design and Setting

This study used a two-step, prospective, mixed methods (qualitative-quantitative) feasibility trial, composed of two substudies. Substudy (SS1) gathered qualitative and quantitative data to inform the optimization of the ACDP. Substudy 2 (SS2) evaluated the optimized intervention over a three-month period. Caregivers of children living with T1D under the care of a pediatric endocrinologist at the Miguel Servet Children's University Hospital (Zaragoza, Spain), following general clinical Spanish practices, participated in this study.

Sample Size and Eligibility Criteria

One hundred caregivers were recruited for SS2. Inclusion criteria were (1) caregivers who are legal guardians of children living with T1D under 18 years of age; (2) child's T1D diagnosis for at least three months; (3) use of continuous glucose monitor; (4) caregivers' willingness to use the mobile solution and share data.

Exclusion criteria included only one legal guardian per child could participate, prior participation in SS1, and incomplete or refusal to provide consent.

Digital Solution

The ACDP supports the physical and mental well-being of family caregivers of individuals with chronic conditions, enhancing self-management and health outcomes. This noninvasive, digitally delivered program offers condition-specific educational content, personalized motivational messages, and self-management tools, using data from wearables and patient-reported outcomes. It includes Adhera Collaboration, a health coaching service, and leverages the Adhera Health AI-driven Health Recommender System for personalized interventions. ACDP is part of the Adhera Health Precision Digital Companion Platform, developed according to best practices in data protection and quality management, following ISO 27001 and ISO 13465 guidelines. The family caregivers accessed the digital program via a mobile application which is compatible with both Android and Apple operative systems. Screenshots of the ACDP can be found in the Multimedia Appendix 1.

The ACDP was applied to families managing T1D due to the significant caregiving demands associated with this condition. The program was tailored to address the psychological and emotional challenges faced by caregivers in supporting children with T1D, including continuous glucose monitoring, insulin management, and responding to hypoglycemic and hyperglycemic events. These challenges made T1D an optimal use case for evaluating the intervention's impact on caregiver well-being.

Study Procedures

SS1 aimed to identify caregivers' psychological burdens and perceived barriers and facilitators associated with adopting the ACDP. Participants used the digital intervention for one month, and their feedback was used to generate an optimized version of the platform. Full details of SS1 can be found in Multimedia Appendix 1.

SS2 assessed the impact of the optimized ACDP on caregivers' psychological well-being, mood and HrQoL. Demographic data collected included caregiver gender, age, marital status, and education level, as well as the children's gender, age, and time since T1D diagnosis. These characteristics were analyzed to understand the context and diversity of the caregiving population. Furthermore, psychometric assessments used in this study included the following validated surveys:

- Positive and Negative Affect Schedule (PANAS**)** measures positive and negative affect. Higher scores on the positive affect subscale indicate greater positive emotions, while higher scores on the negative affect subscale indicate greater negative emotions.
- Depression, Anxiety, and Stress Scale (DASS-21) evaluates emotional distress across three domains, including depression, anxiety, and stress. Higher scores indicate greater levels of distress in each domain.
- Mental Health Continuum-Short Form (MHC-SF) assesses general well-being across emotional, psychological, and

XSL•FO
RenderX

social domains. Higher scores reflect better overall mental well-being.
- General Self-Efficacy Scale (GSE**)** measures confidence in managing challenging situations. Higher scores indicate greater self-efficacy.
- Clarke Questionnaire typically applied to patients with diabetes to assess hypoglycemia awareness; in this study. it was adapted to capture caregivers' awareness and understanding of hypoglycemic episodes in their children. Higher scores suggest better awareness and understanding of hypoglycemia.
- KIDSCREEN-10 measures HRQoL in children. Higher scores indicate better HRQoL.
- Mediterranean Diet Quality Index (KIDMED**)** assesses adherence to a Mediterranean diet. Higher scores reflect greater adherence to a Mediterranean dietary pattern.

While KIDSCREEN-10 and KIDMED are primarily validated for ages 8 - 18, caregivers completed them to provide insight into their perception of the child's quality of life and dietary habits, respectively. Their inclusion aimed to explore indirect caregiver influences on child health behaviors.

Intervention and Measures

The recruitment for SS2 took two months, and participants joined ACDP for three months. Caregivers were onboarded to the Adhera platform through an initial in-person training session at the study site. This session included a demonstration of platform functionality, account setup, and navigation support. Data were collected through the Adhera platform's integrated survey tools, which allowed participants to complete assessments digitally. Additionally, demographic and baseline data were gathered via paper forms during the initial study visit. At baseline and at follow-up, the data collected included (1) demographic data; (2) multiple daily injections and continuous subcutaneous insulin infusion questionnaire (insulin delivery methods); (3) positive mood by PANAS, (4) distress by DASS-21, general wellbeing by MHC-SF, self-efficacy by GSE; (5) lifestyle questionnaires by KIDMED; (6) hypoglycemia awareness by Clarke questionnaire; (7) Quality of life (HrQoL) by KIDSCREEN-10; (8) system usability scale (SUS; only at 3 months), and (9) continuous glucose monitoring.

Data Management and Quality Control

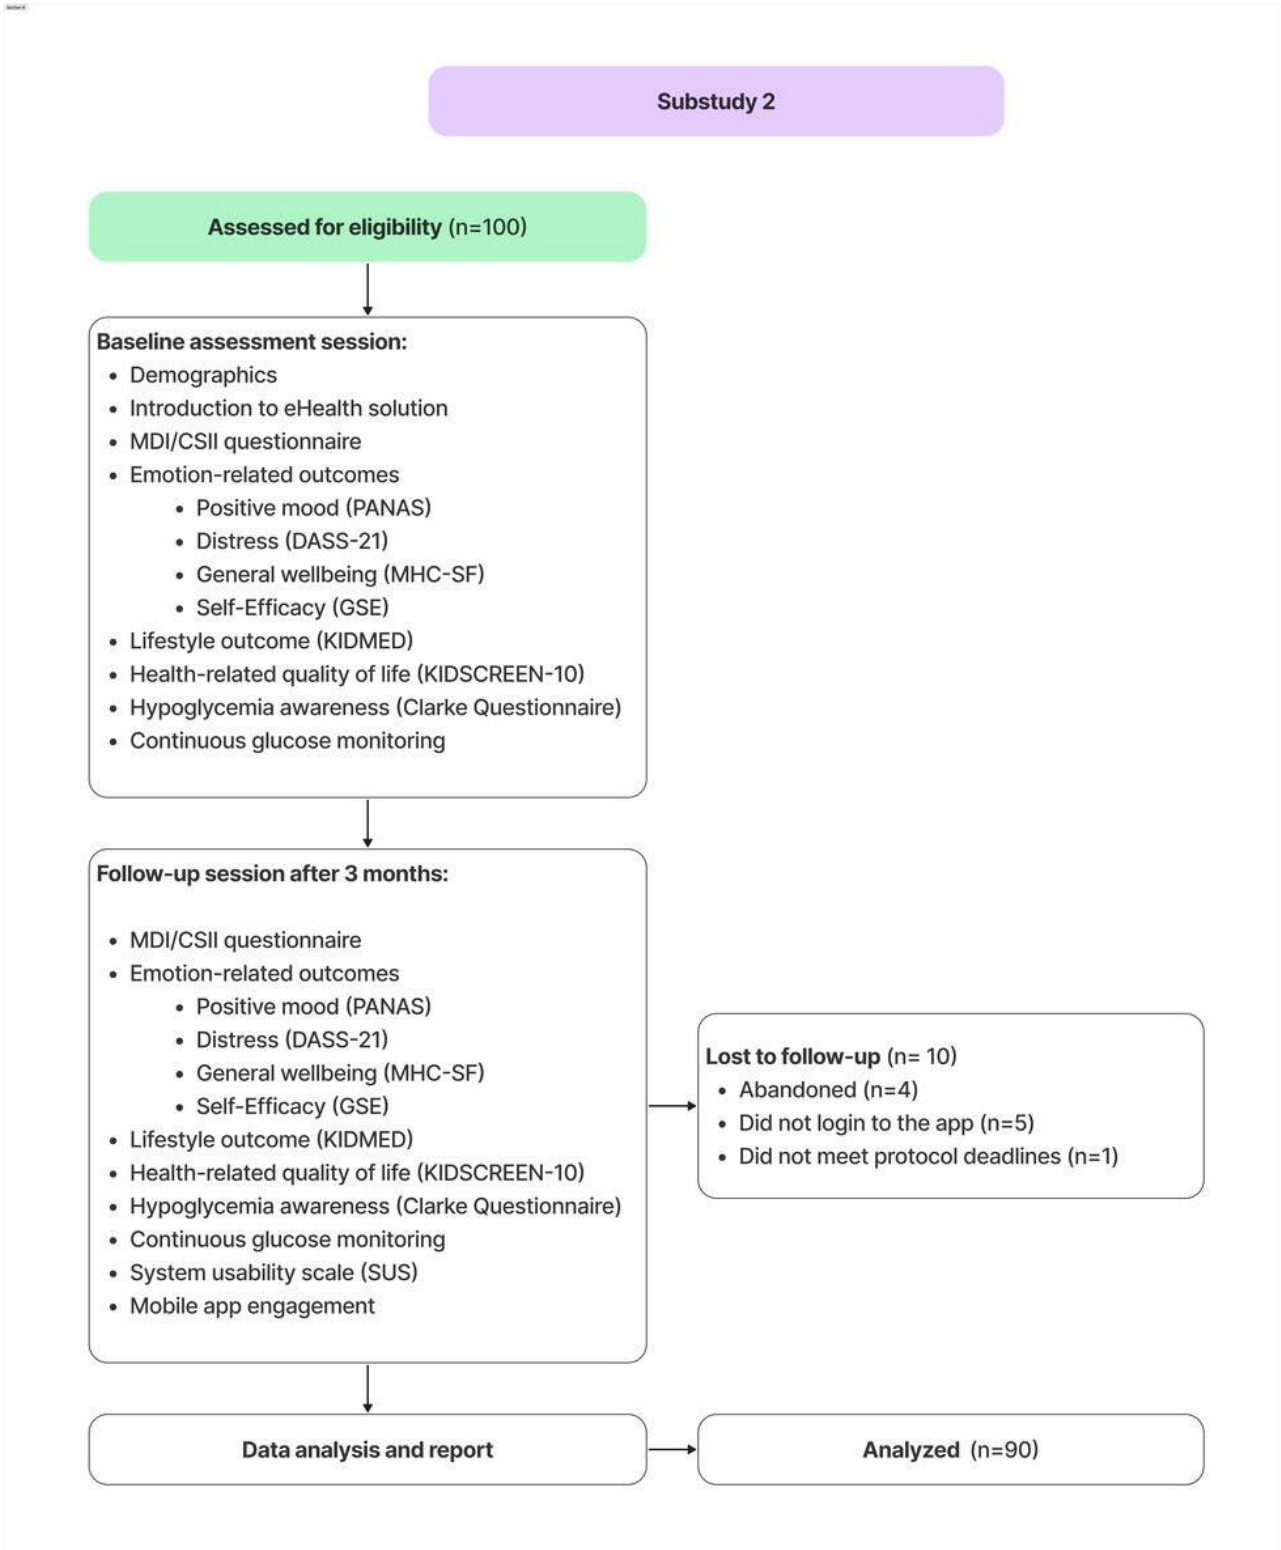
All the data gathered in the study was recorded in MicroSoft Forms at Adhera Health servers. Data were processed, evaluated, and stored in an anonymous form following the General Data Protection Regulation (GDPR) regulations. Adhera Health was responsible for data processing in accordance with its data management and quality procedures. Data quality and integrity were ensured through ISO 27001, which is related to the quality management system for ensuring information security.

Statistical Analysis

Baseline demographic and clinical characteristics of the study cohort were summarized using means (SD) for continuous variables, and frequencies with percentages for categorical variables. Mean values (SD) were presented for each psychometric outcome (eg, stress, quality of life, depressive symptoms) were calculated at baseline (preintervention) and after the 3-month intervention (postintervention). Differences in pre- and postintervention questionnaire scores were assessed using a parametric paired *t* test or a nonparametric Wilcoxon signed-rank test, as appropriate, depending on whether the normality and homogeneity assumptions of the *t* test were met. Effect sizes (η^2) were calculated to gauge the magnitude of any significant differences. All hypothesis tests were two-sided, and statistical significance was defined as $P<.05$. The statistical analysis was conducted using the Python packages *scipy* (version 1.14.1) and *pingouin* (version 0.5.5).

Ethical Considerations

All procedures performed in this study were in accordance with the ethical standards of the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. The study posed minimal risk to the participants. The anonymized information collected was handled following the right of privacy and anonymity according to the rules of GDPR (EU Regulation 2016/679). Prior to the commencement of the study at Miguel Servet University Hospital, the protocol and its associated documents (information sheet for the patient and informed consent form) were submitted to the CEICA (Aragonese Ethical Committee for Clinical Research). A written favorable opinion or approval was obtained from CEICA. Written informed consent to participate in the study was obtained from all patients before any study-related activities were carried out. Moreover, to comply with local regulations, for children 12 years and older, additional consent was obtained. Data were anonymized as per GDPR standards. The study participants were not compensated monetarily. However, they were provided with free access to the digital health platform for the duration of the study, which included tailored support and resources.



Results

Demographics

Of the 100 caregivers recruited, 90 completed the study (Figure 1). Reasons for drop out were as follows: 4 caregivers abandoned the study, 5 did not log in to the application, and 1 did not meet the protocol deadlines. Participants' mean age was 45.15 (SD 6.03) years, and they were predominantly female (71/90, 78.9%). The mean age of the children was 10.78 (SD 3.34) years, with a mean time since diagnosis of 4.42 (SD 3.38) years. Full demographic details are provided in Table 1. The differences in pre- and postintervention questionnaire are presented in Table 2.

[b]PANAS: positive and negative affect schedule.

[c]*t* test (89).

[d]Nonparametric test.

[e]DASS-21: depression, anxiety and stress scale-21 item.

[f]MHC-SF: mental health continuum-short form..

[g]GSE: general self-efficacy scale..

[h]T1D: type 1 diabetes.

Pre-Post Intervention Results

Significant improvements were observed across multiple outcomes (see Table 2). Positive affect increased from 34.26 (SD 7.69) to 37.40 (SD 6.95; *P*<.001) on the PANAS. Negative affect decreased from 24.34 (SD 8.83) to 21.23 (SD 8.36; *P*<.001) on the PANAS. Depression, anxiety, and stress scores on the DASS-21 significantly reduced across all domains, including significant decreases in depression (mean difference =1.25, *P*<.001), anxiety (mean difference=1.04; *P*<.001), and stress (mean difference=3.23; *P*<.001).

General well-being, as assessed by the MHC-SF, showed significant improvements across domains such as general well-being (mean change=0.06; *P*=.001), emotional (mean change=0.08; *P*<.001), psychological (mean change = 0.04; *P*=.02), and social well-being (mean change=0.06, *P*<.001). The GSE scores increased from 30.44 (SD 5.18) to 32.28 (SD 4.81; *P*<.001) and the HRQoL scores improved significantly (*P*=.03). The Mediterranean Diet Quality Index scores were also improved (*P*=.04).

Discussion

Principal Findings

This feasibility study shows that a 3-month digital intervention can significantly improve the psychological wellbeing and emotional health of caregivers of children living with T1D. The intervention effectively increased positive affect, decreased negative affect, and reduced depression, anxiety, and stress levels among caregivers. These findings align with existing

XSL•FO
RenderX

research emphasizing the importance of caregiver support in pediatric chronic condition management [18,19].

The observed improvements in survey scores suggest clinically meaningful benefits. For example, reductions in DASS-21 scores correspond to a shift from moderate to mild emotional distress categories for many participants, reflecting improved mental health. Similarly, increases in PANAS positive affect scores and MHC-SF well-being scores indicate enhanced emotional and psychological resilience. These clinically significant changes underscore the impact of the ACDP on caregiver well-being and its potential to support families managing T1D. Higher self-efficacy is associated with better coping strategies and more effective problem-solving [15,20]. Although improvements in T1D knowledge and hypoglycemia awareness were not statistically significant, the observed trends suggest potential benefits [21]. It is possible that with a larger sample size or a longer intervention period, these trends could reach statistical significance, providing a more comprehensive understanding of the intervention's impact.

Caregiver burden has been strongly linked to adverse psychological effects, including depression, family dysfunction, and difficulties in glycemic control [7,22]. Addressing these challenges is essential for both caregiver well-being and effective diabetes management in children. The combination of digital coaching, motivational messaging, and tailored interventions in ACDP offers a structured approach to alleviating caregiver distress. Additionally, resilience plays a crucial role in mitigating the negative impact of caregiver burden on quality of life [11]. The improvements in self-efficacy and emotional well-being observed in this study highlight how digital interventions can empower caregivers with better coping mechanisms and stress management strategies.

Moreover, the observed improvements in caregiver psychological well-being and self-efficacy align with prior studies, such as PRISM-P and R2D2, which have demonstrated the efficacy of resilience-building and digital health interventions in supporting families managing chronic conditions [9,12]. For instance, the PANAS and DASS-21 score changes in this study are comparable to those reported in similar interventions, indicating a meaningful reduction in caregiver distress and an increase in positive affect. Furthermore, the MHC-SF improvements reflect better emotional and social functioning, consistent with findings from resilience-focused digital interventions. These results underscore the potential of personalized, tech-enabled support to fill critical gaps in caregiver support, as highlighted by Yu et al [21]. However, this study uniquely integrates personalized modules and psychometric assessments tailored to caregivers of children living with T1D, addressing a distinct population need. The significant improvements observed in this study demonstrate the scalability and real-world applicability of the ACDP for enhancing caregiver and family well-being.

This study has several strengths. First, it leverages a personalized digital intervention tailored specifically for caregivers of children with T1D, addressing an important but often overlooked population. The integration of psychometric assessments and AI-driven personalization ensures that the intervention adapts to individual caregiver needs, enhancing its real-world applicability. Additionally, the study employs a mixed methods approach, combining validated psychometric tools with engagement metrics to provide a comprehensive understanding of both subjective and objective outcomes.

Despite these positive outcomes, the study has limitations. The sample size, although adequate for a feasibility study, limits the generalizability of the findings. Additionally, the intervention's three-month duration may not capture long-term sustainability of the observed benefits. Potential biases in self-reported data and a lack of a control group further constrain the robustness of conclusions. Future research should focus on exploring the long-term effects of digital interventions and their potential to include other domains of caregiver and child well-being. Additionally, examining the cost-effectiveness of such interventions could provide valuable insights for health care providers and policymakers considering the implementation of digital support programs for caregivers.

However, the study's findings are promising, indicating that digital interventions can effectively support caregivers' psychological and emotional well-being. The significant improvements in affect, mental health, self-efficacy, and quality of life highlight the potential of such interventions to enhance the caregiving experience and ultimately benefit the well-being of children living with T1D [21]. While improvements in emotional well-being and self-efficacy may indirectly influence caregiving behaviors, these were not directly targeted or assessed in this study. Future research could explore the potential behavioral impacts of digital interventions such as the ACDP.

Conclusions

The ACDP has demonstrated significant potential in supporting caregivers of children living with T1D. By improving psychosocial well-being and self-efficacy, the intervention offers a scalable solution for enhancing caregiving experiences and, ultimately, child health outcomes. Further studies are warranted to explore long-term impacts and broader applications.

Abstract

Background: Chronic ankle instability (CAI) is a common musculoskeletal problem in children, characterized by mechanical instability, perceived instability, and recurrent sprains. Inadequate rehabilitation can cause symptoms to persist, increase the risk of reinjury, and negatively affect long-term quality of life. Research on the rehabilitation of children with CAI concerning ankle stability, running speed, and agility has been limited. Therefore, the Jump Step Kids (JSKs) program was developed as a rhythmic, multidirectional jumping program to improve functional movement and agility in children with CAI.

Objective: This study aimed to investigate the effects of the JSKs program on functional movement and self-reported outcomes in children aged 7 to 12 years with CAI.

Methods: A stratified, randomized controlled trial was conducted involving 34 school-aged children with CAI. Participants were randomly allocated to either the intervention group (n=17), which underwent the JSKs program supervised by a physiotherapist, or the control group (n=17), which performed a home-based stretching program for ankle instability. Both groups participated in 30-minute sessions, 3 times per week, for 4 weeks. Outcome measurements were the heel raise test (HRT), standing long jump test, 6-meter crossover hop test, the Bruininks-Oseretsky Test of Motor Proficiency-second edition (BOT-2), and the Foot and Ankle Ability Measure questionnaire. Assessments were performed at baseline and after 4 weeks of training.

Results: After 4 weeks, both groups improved in the 6-meter crossover hop test (JSKs: mean 6.60, SD 2.47 s; P=.02; and control: mean 6.82, SD 3.45 s; P=.04). The JSKs group performed better than the control group in the HRT (mean 37.88, SD 11.85 repetitions vs mean 27.65, SD 7.65 repetitions; P=.005), whereas the standing long jump test improved in the control group (mean 104.56, SD 21.88 cm to mean 112.05, SD 19.95 cm; P=.04). For BOT-2 outcomes, the 1-legged stationary hop decreased in controls (mean 35.35, SD 5.45 repetitions to mean 30.24, SD 9.21 repetitions; P=.01), with significant between-group differences (mean 38.18, SD 9.53 repetitions vs mean 30.24, SD 9.21 repetitions; P=.02). The 2-legged side hop improved in both groups (JSKs: mean 12.24, SD 4.54 repetitions to mean 25.24, SD 7.40 repetitions; control: mean 11.47, SD 3.81 repetitions to mean 26.53, SD 6.88 repetitions; P<.001). Self-reported outcomes, including Foot and Ankle Ability Measure-Activities of Daily Living and sports scores, did not differ significantly between groups (P>.05).

Conclusions: The 4-week JSKs program improved functional performance in children with CAI compared with the control group in HRT and BOT-2 outcomes, although self-reported function remained unchanged. These findings provide preliminary evidence supporting the potential efficacy of the JSKs program for children with CAI. The program may serve as an addition to conventional therapy to improve physical performance in the pediatric population.

Introduction

Chronic ankle instability (CAI) is a common musculoskeletal condition, especially among active populations, notably children [1]. CAI consists of mechanical instability (MI), recurrent sprains, and perceived instability, which can occur separately or together [2]. In children, the prevalence is notably high in those with a history of lateral ankle sprain, 23% to 71% develop instability symptoms, and 18% to 47% develop MI [1]. A recent study on school-aged children found that 36.6% of those aged 7 to 12 met CAI criteria, with MI, perceived instability, and recurrent sprains reported at 11.6%, 35.3%, and 27.3%, respectively [3].

An updated CAI model suggests that primary injury to the lateral ankle ligaments may cause sensory-perceptual and motor-behavioral impairments, which in turn impact clinical outcomes [4]. These include joint laxity, pain, reduced range of motion, decreased joint position sense, altered reflexes, and perceived instability, all of which negatively affect quality of life. In children, ankle instability has been linked to reduced functional movement, such as standing long jump performance, balance, and physical activity, compared with those without instability [5]. While perceived ankle instability influences function, self-reported outcomes, such as the Foot and Ankle Ability Measure (FAAM), have not shown noticeable differences between groups [6]. Additionally, other functional aspects—such as ankle function, stability, running speed, and agility—have not been systematically evaluated or trained in children with CAI.

Inadequate rehabilitation can extend symptoms, raise reinjury risk, and compromise long-term quality of life [4]. Therefore, effective programs are crucial. Plyometric training, which utilizes rapid stretch-shortening cycles to enhance neuromuscular control, has been demonstrated to improve balance, power, agility, and functional performance in individuals with functional ankle instability [7]. However, traditional programs may lack engagement and reduce adherence, especially in children. Recent studies using exergaming and active video games have demonstrated benefits in balance, foot and ankle function, and motivation in children with CAI, but their progression and challenge levels remain limited [6,8].

To address this gap, the Jump Step Kids (JSKs) program was created as a structured, plyometric-based intervention designed for children with CAI. Incorporating rhythm, music, and agility-based jump patterns, the program aims to improve functional outcomes while maintaining an enjoyable experience. This study examines the effects of the JSKs program on functional movement and self-reported outcomes in children aged 7 to 12 years with CAI. We hypothesized that participation would improve functional movement and foot and ankle ability, offering practical guidance for pediatric rehabilitation programs.

Methods

Study Design and Participants

This study was a single-blind (assessor-blind), stratified randomized controlled trial. The sample size was calculated using G*Power (v3.1.9.4; Heinrich Heine University Düsseldorf) for comparing 2 independent means, with α=.05 and a power of 0.80 [9], accounting for a 20% dropout rate, resulting in 34 participants (17 per group).

Thirty-four children aged 7 to 12 years with CAI from rural primary schools were recruited to participate in this study. The inclusion criteria are as follows: (1) a history of unilateral ankle sprain at least 1 year before the study [10], (2) had experienced ankle instability or *giving way* at least twice within the 6 months before the study [10], (3) Cumberland Ankle Instability Tool-Youth Thai version score ≤25 [9], (4) BMI within the normal range (5th to 85th percentile) according to the United States Centers for Disease Control and Prevention (CDC) growth chart [11], (5) no pain in the lower extremities at the time of participation, (6) ability to understand and follow instructions given by the researchers, and (7) ability to recognize and read numbers 1 to 9. The exclusion criteria were as follows: (1) acute ankle injury within 3 months before the study, (2) presence of comorbidities such as heart disease, attention deficit hyperactivity disorder, autism spectrum disorder, or asthma, (3) foot deformities, (4) history of surgery on the lower extremities, (5) history of bone fractures in the lower limbs, (6) uncontrolled health conditions including seizure disorders or uncorrected vision problems, and (7) receiving other ongoing treatments related to lower limb injuries.

Ethical Considerations

This study was approved by the Human Research Ethics Committee of Mae Fah Luang University (EC 23146 - 25, COA No. 250/2023) and conducted in accordance with the Declaration of Helsinki. Before participation, written informed consent was obtained from the legal guardians, and an assent form for the children included in the study guaranteed the protection of participants' rights and safety. All research activities were conducted in accordance with ethical standards, including strict adherence to privacy and confidentiality principles, to protect the data and identities of participants. Participants received compensation of 100 Thai Baht per visit to cover time and travel expenses, with no coercive intent.

Outcome Measurements

Overview

The 34 eligible participants were randomly stratified by age and gender and assigned to 2 groups: 17 participants received the JSKs program, and 17 participants received a home-based stretching program. Functional movement and self-reported outcomes were assessed before and after the 4-week training period. All assessments were conducted by a single trained assessor who was blinded to the group assignment. The assessments included the following tests.

XSL•FO
RenderX

Heel Raise Test

The heel raise test (HRT) was used to assess calf muscle strength and endurance [12]. Before testing, participants performed their highest possible heel raise to establish a reference height. They were then instructed to perform as many single-leg heel raises as possible within 30 seconds. The number of valid repetitions—completed without allowing the non-testing foot to touch the ground or losing balance—was recorded for analysis [13].

Standing Long Jump Test

The standing long jump test (SLJT), a strength subtest of the Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2), was used to assess lower extremity muscle strength [14]. Participants stood behind a starting line with their feet shoulder-width apart and performed a forward jump as far as possible. The distance from the starting line to the nearest heel upon landing was measured in centimeters. Each participant completed 1 trial, with a second trial permitted only if they stumbled or fell during the first attempt.

Six-Meter Crossover Hop Test

The 6-meter crossover hop test (6mCHT) is a dynamic test that assesses ankle function and stability. Participants stood on their injured leg, arms free, and jumped as fast as they could in a diagonal pattern across 2 parallel lines spaced 15 cm apart for 6 meters. The test was repeated if the untested foot did not contact the ground, lost balance, or crossed the tape line incorrectly. The assessor recorded the time taken in seconds. The test was performed 3 times, and the average time was analyzed [15].

Shuttle Run

The shuttle run, a subtest of the BOT-2, was used to assess speed and agility in children [14]. Participants stood behind the starting line and sprinted as fast as possible to retrieve blocks placed 15.24 meters away, then returned to the starting line. One trial was performed, with a second trial administered only if the participant tripped or failed to retrieve the blocks. The time in seconds was used for analysis [14].

Stepping Sideways Over a Balance Beam

This is a running speed and agility subtest of the BOT-2. Participants stood beside the beam with feet together and hands on hips, then stepped laterally across it, alternating feet continuously for 15 seconds. A second trial was allowed only if they tripped or fell. The number of correct steps was recorded for analysis [14].

One-Legged Stationary Hop

This is another running speed and agility subtest of the BOT-2. The participants stood on the injured leg, hands on the hips, then hopped up and down on the injured leg for 15 seconds. A second attempt was performed only if the subject tripped or fell during the first attempt. The number of correct attempts for statistical analysis [14].

One-Legged Side Hop

This is also a running speed and agility subtest of the BOT-2. Participants stood on the injured leg behind a line, hands on hips, and hopped vertically on the injured leg across the line to the left and right continuously for 15 seconds. A second test was performed if the participant tripped or fell during the test. The number of successful jumps was used for analysis [14].

Two-Legged Side Hop

This is a running speed and agility subtest of the BOT-2. Participants stood feet together parallel to a line with hands on hips, hopped both feet sideways across the line simultaneously for 15 seconds. A second trial is performed if they trip or fall. The number of correct hops was recorded [14].

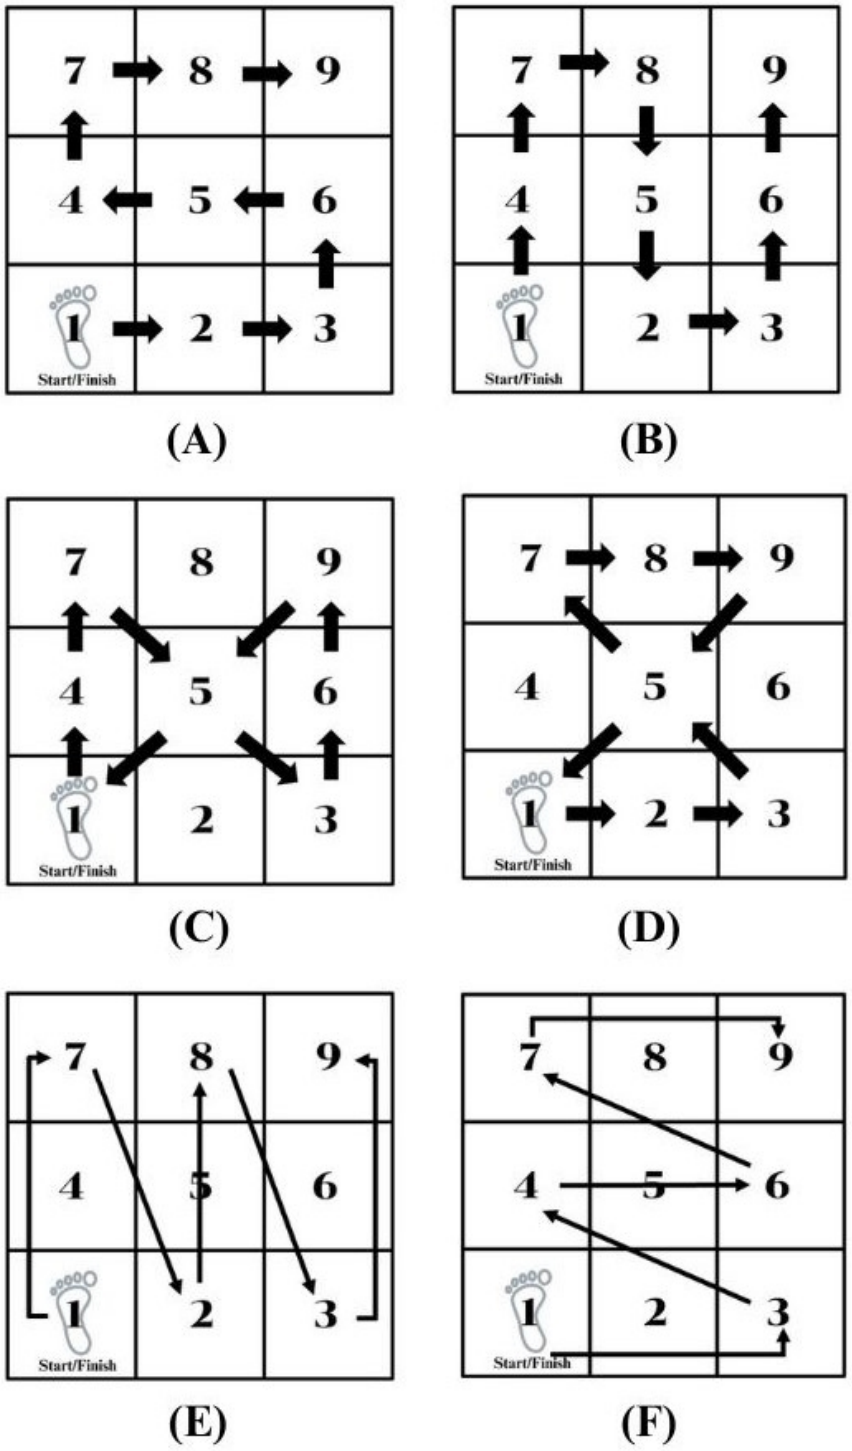
FAAM-Thai Version

The FAAM is a 5-point scale self-reported questionnaire used for foot and ankle conditions [16]. It comprises 2 subscales including the 21 Activities of Daily Living (ADL) and 8 Sports scale, with a total score of 84 (ADL) and 32 (Sports), then converted into percentages (100%=full function; 0%=complete disability). Items not completed for reasons unrelated to foot or ankle conditions were marked as “not applicable or N/A” and excluded from the final score [17]. Participants reported their function over the past week. To ensure reliability, the FAAM questionnaire was conducted by a single trained researcher who interviewed each participant throughout the study period.

Intervention Programs

Participants were randomly assigned to either the intervention or control group, with sessions lasting 30 minutes, 3 times a week, over 4 weeks.

The JSKs Program



The JSKs program is supervised by a licensed physical therapist with over 15 years of experience working with children. All participants were instructed to perform the intervention under the guidance of a physical therapist. Each session includes 3 parts: a 5-minute warm-up, a 20-minute core exercise period, and a 5-minute cool-down. All sessions are carried out using a 3×3 agility training grid.

Warm-Up and Cool-Down

Participants stood on the center mat (square 5 of a 3×3 agility grid) and performed dynamic stretching by stepping 1 leg as far as possible in 8 directions adapted from the Star Excursion Balance Test [18]. The order for stepping the left leg started from numbers 9 to 6, and the right leg started from numbers 7 to 4 (Figure 1). Then, they were instructed to practice a single-leg stand with eyes closed for 30 seconds each side.

Jump Step Kids program exercises: (A) 1-leg lateral side hopping; (B) 1-leg forward-backward hopping; (C) 1-leg figure-of-eight hopping (vertical pattern); (D) 1-leg figure-of-eight hopping (horizontal pattern); (E) 1-leg long jump (N-Shape pattern); and (F) 1-leg long jump (Z-shape pattern).

Main Exercise

Overview

Participants completed a 20-minute JSKs program, consisting of 4 progressive tasks, each lasting 5 minutes (Figure 1). Exercises were presented in sequence, from easy to difficult, moving from Exercise 1 to Exercise 4. Surface conditions changed from a hard surface during weeks 1 to 2 to a foam surface in weeks 3 to 4. All movements were demonstrated via video and practiced on both sides of the body.

Exercise 1: 1-Leg Lateral Side Hopping

Participants stood on 1 leg in square 1 with their hands on their hips and performed single-leg lateral hops across the grid in this sequence: 1 → 9 (Figure 1A). When they reached square

XSL•FO
RenderX

9, they balanced statically for 5 seconds, then reversed the path back to square 1, followed by another 5-second pause. The exact sequence was then repeated on the other leg. Each leg completed 3 sets.

Exercise 2: 1-Leg Forward-Backward Hopping

Participants stood on the supporting leg in square 7 with their hands on their hips and performed single-leg forward and backward hops along the sequence: 1 → 9 (Figure 1B). Upon reaching square 9, they maintained balance for 5 seconds, then returned along the same path to square 1, followed by another 5-second pause. The sequence was repeated on the opposite leg. Each leg completed 3 sets.

Exercise 3: 1-Leg Figure-of-Eight Hopping

Participants stood on the supporting leg in square 1 with their hands on their hips and performed single-leg hops following a vertical figure-of-eight pattern: 1 → 1 (Figure 1C, vertical pattern). After completing the sequence, they paused for 5 seconds before repeating the task on the opposite leg. Each leg completed 3 sets. Then, participants stood on the supporting leg in square 1 with their hands on their hips and performed single-leg hops following a horizontal figure-of-eight pattern: 1 → 1 (Figure 1D, horizontal pattern). After finishing the sequence, they paused for 5 seconds and repeated the task on the opposite leg. Each leg completed 3 sets.

Exercise 4: 1-Leg Long Jump

Participants stood on the supporting leg in square 1 with their hands on their hips and performed single-leg long jumps laterally, following an N-shaped sequence: 1 → 9. Upon reaching square 9, they paused for 5 seconds before returning along the same path in reverse order (Figure 1E, N-Shape Pattern). A second 5-second pause was observed upon return. The task was then repeated on the opposite leg. Each leg completed one full N-pattern in both directions. After that, participants stood on the supporting leg in square 1 with their hands on their hips and executed single-leg long jumps along a Z-shaped sequence: 1 → 9. After reaching square 9, they paused for 5 seconds before retracing the path in reverse order (Figure 1F, Z-Shape Pattern). A final 5-second pause was observed at square 1. The sequence was repeated on the opposite leg. Each leg completed one full Z-pattern in both directions.

Control Group Program

Participants were asked to follow a home-based stretching program outlined in the brochure. This program is adapted from a general exercise used in their school. It included 6 exercises designed to actively stretch the hip, knee, and ankle muscles in sitting and standing positions. Each exercise was held for 15 seconds and repeated 10 times, with 3 sets per leg. Each session lasted approximately 30 minutes, 3 times a week, for a period of 4 weeks. A researcher contacted the participants to remind them and their parents to follow the stretching protocol. Additionally, all participants recorded their stretching sessions in a child logbook throughout the 4 weeks.

Statistical Analysis

The data were analyzed using SPSS (version 20.0; IBM Corp). Descriptive statistics are shown as mean (SD) for continuous variables and frequency (percentage) for categorical variables. The normality of continuous data was checked with the Shapiro-Wilk test. Between-group differences were tested using univariate analysis of covariance (ANCOVA) with Bonferroni post hoc corrections. Within-group differences were examined using two-tailed paired sample *t* tests. A $P<.05$ was considered statistically significant.

Results

A total of 34 children with CAI were analyzed. Participant enrollment, allocation, follow-up, and analysis are presented in the CONSORT (Consolidated Standards of Reporting Trials) flow diagram (Figure 2). In the JSKs program group, all participants completed all 12 training sessions as scheduled over a 4-week period. Similarly, in the control group, all participants attended every scheduled session. Descriptive statistics were used to describe the baseline characteristics of participants, including sex, age, height, weight, side of CAI, and Cumberland Ankle Instability Tool-Youth Thai version scores. No significant differences were found between the JSKs program and control groups at baseline ($P>.05$; Table 1).

Foot and ankle function outcomes were assessed within and between groups at baseline and after 4 weeks of training. Within the JSKs program group, significant improvements were observed in the 6mCHT after week 4 (P=.02). Similarly, the 2-legged side hop test of BOT-2 showed a significantly increased score (P<.001). No significant within-group changes were observed in the HRT, SLJT, shuttle run, sideways stepping over a balance beam, or FAAM scores in the JSKs group (P>.05).

In the control group, there was a significant decrease in the 6mCHT at week 4 (P=.04), and the 1-legged stationary hop test also decreased significantly (P=.01). Additionally, there was a significant improvement in the SLJT (P=.04), and the 2-legged side hop test of BOT2 increased substantially in the control group (P<.001). Other outcomes did not show significant changes over the 4 weeks (Table 2).

Between-group comparisons using ANCOVA adjusted for baseline values revealed significant differences for the HRT ($F_{1,32}$=4.39; P=.005; ηp^2=0.12) and the 1-legged stationary hop test of BOT-2 ($F_{1,32}$=6.17; P=.02; ηp^2=0.20), with the JSKs program group showing greater improvements than the control group at week 4. Other outcomes did not change over the 4-week training period (Table 2).

Table . Comparison within and between-group analysis of functional movement and self-reported outcomes between Jump Step Kids (JSKs) program and control groups.

Variables	JSKs[a] program group (n=17)			Control group (n=17)			Effect size (Cohen *d*)	Between groups *P* value	95% CI

Discussion

Principal Findings

This study is the first to evaluate a program designed to improve functional movement and agility in children with CAI. The purpose of this study was to investigate the effect of the JSKs program on functional movement and self-reported outcomes in children with CAI. After 4 weeks, the JSKs program significantly enhanced the 6mCHT (P=.02) and 2-legged side hop (P<.001), with improvements in the HRT (P=.04) and 1-legged stationary hop (P=.02) observed between groups. The control group improved in SLJT (P=.04) and 2-legged side hop (P<.001) but declined in HRT and 1-legged stationary hop (P=.01). No significant differences were found for FAAM-ADL or Sport (P>.05).

The effects of the intervention on functional muscle strength were evaluated using the HRT and the SLJT. The HRT was used to assess both the strength and endurance of the ankle plantarflexor and dorsiflexor muscle groups [13,19]. After 4 weeks of training, the HRT performance remained stable in the JSKs group, while the control group showed a decline in this performance. The absence of improvement in ankle strength within the JSKs group may be attributed to the nature of the training program, which primarily consists of multidirectional jumping tasks. These exercises emphasize the development of explosive power, neuromuscular responsiveness, and dynamic muscle strengthening, rather than isolated static muscle strengthening or slow, fully controlled concentric contractions—precisely the type of muscular demand assessed by the HRT [20,21]. In addition, although jumping exercises use body weight as resistance, they focus on building momentum rather than maintaining a constant muscle load. In contrast, the HRT involves continuous, controlled resistance, thereby offering a more accurate measure of calf muscle endurance and strength [21,22]. Consequently, it is likely that the JSKs program did not provide sufficient training stimulus to induce measurable gains in ankle muscle strength. Nevertheless, this study demonstrates that the JSKs program was effective in maintaining ankle muscle strength in children with CAI when compared to the control group.

In contrast, the SLJT is widely used to assess overall lower extremity muscle strength and explosive power and requires coordinated force generation from both legs [14,23]. In this study, only the control group revealed a statistically significant improvement in jump distance (from 104.56 cm to 112.05 cm). This improvement may be attributed to increased muscle flexibility and joint range of motion resulting from regular stretching, which can increase muscle compliance and optimize force production during jumping [24]. In contrast, the JSKs group demonstrated a nonsignificant increase in jump distance (from 107.85 cm to 113.23 cm). The JSKs program emphasizes multidirectional jumping activities, focusing on balance, speed, and agility rather than maximal jump distance. Consistent with Legnani et al [25], who demonstrated that side hop tests could be more accurate than vertical jump tests for detecting functional impairment in patients suffering from CAI, our findings may explain the lack of significant improvement in SLJT performance in this group. Moreover, the bilateral nature of the SLJT may conceal unilateral impairments, supporting prior recommendations for single-leg assessments using force plates [26,27].

The 6mCHT assessed dynamic balance capability and ankle stability [15]. The findings of this study indicated a significant improvement in both groups after 4 weeks. The JSKs group demonstrated improvements through program components that promoted multidirectional jumping, dynamic balance, and lower extremity coordination. This training has likely enhanced ankle stability, body position awareness, and motor control, which are essential for effective performance in crossover hopping tasks. The findings align with a prior study by Myer et al [28], who indicated that youth athletes exhibited enhanced dynamic stability and hop performance after engaging in plyometric and neuromuscular training. Moreover, the control group also showed significant improvements over 4 weeks of training. These changes may result from natural developmental progress, increased awareness of physical activity during the study period, or learning effects linked to repeated test exposure. Gribble et al [29] observed that performance increased on repeated hop tests without specific training. This improved performance may be due to task familiarity and motor learning. However, the magnitude of improvement was greater in the JSKs group, reinforcing the efficacy of a structured, progressive training program. The JSKs protocol, which included exercises progressing from stable to unstable surfaces, is consistent with the approach used in the previous study [30]. Eils and Rosenbaum [30] found improved hop performance after a balance-focused intervention in individuals with CAI. Therefore, this study suggested that multidirectional jumping activity in the JSKs program could be beneficial for ankle movement to maintain dynamic balance control for children with CAI.

For the agility test, it was assessed using the BOT-2 subtests of running speed and agility. Agility is an important characteristic of motor development, which is crucial for maintaining and controlling body posture when changing direction. The results of this study indicated that both the JSKs program and a self-stretching program increased the number of jumps in 2-legged side hop test after 4 weeks of training. These findings support the role of agility as an important aspect of motor development, which is closely related to physical coordination, speed, and balance skills [31]. In the experimental group receiving the JSKs program, the children practiced alternating forward-backward and side-to-side hops, stimulating the central nervous system and the proprioceptive system through postural control and rapid direction changes in movement. These findings align with previous studies showing that hop-based training enhances ankle stability, functional performance, and postural control in individuals with CAI [32,33]. In addition, Hale et al [34] aimed to examine the effects of a 4-week rehabilitation program for CAI on postural control and lower extremity function. This comprehensive rehabilitation program consisted of range of motion exercises, strength exercises, neuromuscular control, and functional tasks. Their findings showed that rehabilitation effectively improves postural control and functional limitations in individuals with CAI. In addition, the results showed a significant decrease in the 1-legged stationary

XSL•FO
RenderX

hop test in control groups when compared with the JSKs group. This finding suggests that the JSKs program is more effective in enhancing single-limb control, unilateral coordination, and maintaining strength over time. These findings are supported by previous studies which demonstrated that hopping, balance, and proprioceptive training can improve motor control and stability in children with CAI [26,28]. Thus, this finding suggests that the JSKs program has an impact on the improvement or maintenance of performance in children with CAI. Although the 2-legged hop test does not fully replicate real-world situations, it provides a safe and specific test of agility for children, supporting the development of coordination, balance, and spatial awareness. These skills are essential for activities requiring speed, such as running, avoiding obstacles, playing sports, and participating in physical education, thereby enhancing safety in daily life.

The FAAM was used to assess physical functioning in individuals with foot and ankle disorders [18]. Self-reported questionnaires may be influenced by children's mood, confidence, or understanding, as they reflect perceived rather than actual physical changes. This study revealed no statistically significant differences between the intervention and control groups after 4 weeks of training. This finding was similar to Kim et al [35], who also reported no difference between a jumping training and control group even though the training period was 6 weeks in adults with CAI. In contrast, Kim et al [36] and Ardakani et al [37] reported both FAAM-ADL and FAAM-Sport improved in hop-stabilization and balance training between pre- and posttraining for 6 to 8 weeks. The 4-week training period in this study may be too short to produce significant changes in self-perceived ability, especially in children with CAI [23]. The authors of the present study further suggest that longer interventions may be necessary.

Limitations

This study only investigated the short-term effects of the JSKs program on functional movement and self-reported outcomes related to the foot and ankle in children with CAI. Therefore, future research should include ongoing follow-up to assess the sustainability of the training effects over time. Additionally, this study did not evaluate factors associated with ankle function and movement control that could help elucidate the underlying mechanisms behind the observed outcomes. Future studies should incorporate additional assessments, such as measurements of muscle strength, to gain a more comprehensive understanding of the training effects. Furthermore, the FAAM used in this study has not been validated for pediatric populations, which may limit the interpretability of the self-reported functional outcomes. Therefore, future studies should consider using or developing validated outcome measures for children to ensure more accurate assessment of ankle function.

Conclusions

After 4 weeks of training, the JSKs program showed greater improvement in functional movement than the home-based stretching program in children aged 7 to 12 years with CAI, as measured by HRT and the 1-legged stationary hop test. Additionally, both training programs enhance performance in the 6mCHT and 2-legged side hop. However, the self-reported outcomes (FAAM-ADL and FAAM-Sport subscales) did not change between groups. For clinical applications, the JSKs program offers a practical, accessible, and time-efficient plyometric training protocol that can be easily integrated into the rehabilitation of children with CAI. Clinicians should consider incorporating this program alongside conventional treatment to promote ankle stability and potentially reduce the risk of recurrent ankle sprains.

Acknowledgments

The authors sincerely thank all the participants and their families for their time and dedication to this study.

Abstract

Background: Children with cancer are at risk of reduced physical activity. Gaining insight into physical activity using smartwatches could improve understanding of individual potential during treatment, support early recognition of aberrant physical activity, and enable tailored support.

Objective: This study aimed to explore the feasibility, barriers, facilitators, and considerations of long-term physical activity tracking using a smartwatch during childhood cancer treatment.

Methods: In this prospective study, 30 children (age 8 - 18 years) under active cancer treatment were included in 2 phases. During phase 1, 15 children wore a smartwatch daily for 12 consecutive weeks, and in-depth interviews were conducted to identify principal considerations used to optimize wearability and the methods for phase 2. In phase 2, another 15 children wore the smartwatch, and semistructured interviews were conducted at weeks 1, 3, 6, and 12. These interviews were thematically analyzed to identify barriers and facilitators. An iterative process of alternating data collection and analysis allowed for ongoing method refinement and deepening thematic analysis during the study period.

Results: Key considerations for improvement identified in phase 1 led to refinements in phase 2, including enhanced engagement, regular prompts, customized plans, personalized setup, and improved aesthetics and comfort. The interviews conducted during phase 2 identified barriers and facilitators. The 4 most prominent themes were burden and resilience, motivational drivers and perception, insight and evaluation, and user experience and functionality. Feasibility was influenced by the child's physical state and perceived burden. Motivation, perceived value, and expectations played crucial roles in sustaining adherence, while also the balance between positive reinforcement and potential confrontation affected long-term use. User experience, including attractiveness, comfort, and usability, impacted acceptance.

Conclusions: Real-time and long-term physical activity tracking using a smartwatch in children during cancer treatment was not feasible in our cohort. A personalized approach, incorporating individual preferences and physical condition, is essential to support adherence.

KEYWORDS

physical activity; tracking; smartwatch; pediatric oncology; feasibility

Introduction

The overall 5-year survival of childhood cancer has improved tremendously over the past decades, reaching around 80% [1-3]. Despite this improvement, pediatric cancer and its treatment are often accompanied by adverse health effects, such as muscle deficits, pain, and fatigue, that negatively influence physical functioning [1,4,5]. Physical activity may help mitigate these adverse health effects by improving body composition, muscle strength, flexibility, and cardiorespiratory fitness and subsequently enhancing physical functioning and quality of life [6-8].

However, children with cancer may experience physical weakness, limited opportunities to engage in physical activity, and a shift in focus due to emotional strain because of their disease, its treatment, and other medical needs [9-12]. Although it is well established that children with cancer are at risk of reduced physical activity [5,10,11,13], there is limited

XSL•FO
RenderX

knowledge about variation in physical activity levels both between and within children during treatment. These variations depend on the child's diagnosis, treatment type and intensity, and medical complications, as well as personal and environmental factors [11,12,14,15]. Gaining insight into physical activity levels could improve understanding of children's physical potential during different treatment phases, support early recognition of aberrant physical activity levels, and enable tailored advice and guidance to promote physical activity that aligns with the child's needs, their family, and the treatment phase they are in. Understanding variations in physical activity levels requires accurate and continuous measurement of physical activity.

Currently, the most commonly used methods to monitor physical activity levels in children with cancer include questionnaires and accelerometry devices [10-13,16]. Questionnaires are prone to subjective inaccuracies, as children and parents have to recall and may under- or overestimate their physical activity [17]. Accelerometry addresses these limitations but has notable drawbacks that restrain usability, including the need for installation to collect data, the lack of real-time accessible data for children, parents, and health care professionals, and a nonmodern design that does not offer visual feedback to the user. Furthermore, objective devices have primarily been used for short-term monitoring (1 - 2 weeks) [10,11,13,15,18], which limits their ability to capture variations in physical activity levels across different treatment phases of childhood cancer.

Consumer-level smartwatches are increasingly being used in health care and research to track physical activity [19-25]. A major advantage of smartwatches is that they provide insight into real-time data and visual feedback for the patient. Their use during treatment for childhood cancer would enlarge knowledge about physical activity levels during different treatment phases and therefore support both patients and their health care professionals in managing expectations of physical activity. Moreover, using smartwatches to track physical activity would facilitate early recognition of children with aberrant physical activity levels and enable timely initiation of interventions to prevent aggravation. In children with a brain tumor who received an intervention, including the use of a smartwatch combined with coaching by a physiotherapist for 12 weeks during treatment, no adverse effects of using the smartwatch were reported [26]. In addition, children with acute lymphoblastic leukemia were able to use a fitness tracker clipped on clothing for around 3 weeks during their treatment, consistently with low effort [27]. During the maintenance phase of childhood acute lymphoblastic leukemia and after treatment for childhood cancer, the daily use of a smartwatch for 6 months was feasible as measured by retention, receptivity, and belief of utility [28]. However, in healthy children and adolescents, several issues concerning the use of smartwatches, including technical difficulties, a novelty effect, and lack of comfort, were identified, which limit long-term use [29,30]. There is limited knowledge about the feasibility and wearing experiences of long-term physical activity tracking using smartwatches during different phases of childhood cancer treatment [31].

Therefore, the aim of this study was to determine the feasibility and to identify barriers, facilitators, and key considerations of real-time and long-term physical activity tracking using a consumer-level smartwatch in children during cancer treatment. We hypothesized that physical activity tracking using a smartwatch in children undergoing cancer treatment would be feasible and imagined that factors, including treatment phase, medical needs, and personal desires, could hamper long-term use.

Methods

Study Design

This prospective study consisted of 2 phases in which quantitative data and qualitative data were collected to determine feasibility and to identify barriers, facilitators, and key considerations for long-term physical activity tracking in children with cancer during treatment, respectively.

Participants and Inclusion

Children aged 8 - 18 years, diagnosed with a malignancy, and undergoing active treatment in the Princess Máxima Center for Pediatric Oncology were eligible for participation. Inclusion criteria were the ability to walk at least 50 meters without aid, adequate understanding of the Dutch language, and access to a digital device capable of downloading an app (eg, a smartphone). Exclusion criteria included not being able to attend evaluation moments, undergoing stem cell transplantation during the study period, and pre-existing intellectual disabilities that prevented participation in interviews or long-term smartwatch use.

Potential participants were recruited by the researcher (EdH) in collaboration with their pediatric physiotherapist or oncologist.

Ethical Considerations

Written informed consent was obtained from participants aged ≥12 years and parents or caregivers of participants aged 8 - 16 years. The Medical Research Ethics Committee (MREC) confirmed this study was not subject to the Medical Research Involving Human Subjects Act (23-003). Data were pseudonymized. Participants were not compensated.

Study Procedure

In phase 1, conducted between May and September 2023, 15 children undergoing active cancer treatment were asked to wear a smartwatch daily for 12 consecutive weeks. A time frame of 12 weeks was chosen, as this was the first effort to explore the potential of a smartwatch to track long-term physical activity in children with cancer during different phases of treatment. Moreover, we expected that if wearing the smartwatch was feasible for 12 weeks, it would remain so for a longer period. In addition, within 12 weeks, they usually undergo several treatment courses that vary in type and intensity, allowing them to experience the smartwatch during different phases of treatment. After 12 weeks, in-depth interviews were conducted to identify key considerations for long-term physical activity tracking during childhood cancer treatment. These findings were then used to optimize the methods for phase 2.

In phase 2, conducted between February and June 2024, another 15 children wore the smartwatch for 12 consecutive weeks.

XSL•FO
RenderX

After having optimized the methods for phase 2 during phase 1, total wear time was calculated, and semistructured interviews were conducted at weeks 1, 3, 6, and 12 during phase 2. The total wear time and interviews were used to evaluate feasibility and identify barriers, facilitators, and key considerations. The iterative approach of alternating data collection and analysis enabled ongoing method refinement based on children's experiences, while incorporating emerging topics and deepening thematic analysis during the study period.

Upon inclusion, children were instructed to wear the smartwatch daily during the upcoming 12 weeks. An app (Health Mate, Withings) was installed on a smartwatch or tablet of children or their parents. The smartwatch was linked to an account created in the app, which enabled the researcher to gain insight into physical activity data, which was transferred to a dashboard developed by the Information Technology, Data Provision, and Technology department of the Princess Máxima Center. In the app, physical activity, including steps and heart rate, was displayed for children themselves. Children received a notification on the smartwatch and in the app when they reached their self-chosen, adjustable daily step goal. Moreover, during phase 2, children or their parents received prompts with feedback on wearing behavior and tips for smartwatch use. These prompts were sent as text messages to their phones or via emails every other week.

Smartwatch

In this study, children wore a Withings (Withings, Issy-les-Moulineaux, France) Steel Heart rate (HR) (Model: HWA03b-36black/white-Inter) or Pulse HR (Model: WAM03-Black Mirror-All-Inter) smartwatch. The model for each child was determined by the researcher in agreement with the child to optimize wearability. Generally, larger children were assigned a Steel HR, while those with a slim wrist received a Pulse HR. The device measured step count and HR and was able to track a variety of sport activities. Withings smartwatches have been used in a number of previous clinical studies as a method to evaluate physical activity [20,21,23,25]. Also, in healthy children (8 - 11 years old), a Withings smartwatch has previously been used to evaluate an intervention aiming to increase physical activity [22]. In healthy adults, Withings smartwatches have been validated against a reference device (ActiGraph) for counting steps [32]. Among a set of smartwatches, these were found to be the most user-friendly, satisfactory, accurate, and repeatable for tracking steps [33] and showed excellent test-retest reliability (intraclass correlation: 0.92, 95% CI 0.83 - 0.96, p<0.01) [34].

Data Collection

Feasibility

Feasibility was evaluated by acceptance (ie, the percentage of eligible participants who agree to take part after being invited), attrition (ie, the percentage of participants who remain in the study until the end), and adherence (ie, the total wear time) [35]. Adherence was examined only in the 15 children included in phase 2 after 12 weeks of wearing the smartwatch, as the goal of phase 1 was to optimize the methods for phase 2. We defined that the adherence feasibility target for long-term physical activity tracking in children with cancer during treatment was reached when at least 60% (9/15) of the children in phase 2 adhered to wearing the smartwatch for a minimum of 75% of the study period. This target was based on previous studies using activity trackers in childhood cancer survivors [28,36,37].

Key Considerations, Barriers, and Facilitators

Key considerations for improvement, along with barriers, facilitators, and future key considerations of long-term physical activity tracking during childhood cancer treatment, were identified through in-depth interviews at the end of phase 1 and semistructured interviews during phase 2, respectively.

During the interviews, an interview guide was used that covered topics, including reasons for wearing or not wearing the smartwatch, barriers and facilitators, and children's thoughts on wearing it for the entire treatment and sharing their physical activity data with their physiotherapist. The interview guide for the in-depth interviews was developed based on previous studies and experiences raised during phase 1, while the interview guide for the semistructured interviews was constructed and adjusted according to findings of phase 1 and experiences during phase 2. The interview guides used in both study phases are shown in Sections A and B in Multimedia Appendix 1, respectively. All interviews were conducted by EdH and planned on the same day as participants' medical appointments at the Princess Máxima Center, or they were held via a phone or video call to avoid extra study visits to the hospital. For children aged <12 years, children themselves and their parents were interviewed. Children aged ≥12 years were interviewed themselves or with the help of their parents, depending on the family's preferences. In case of questions or issues between the evaluation moments, participants contacted the researcher via email or phone.

Data Analysis

Descriptive statistics were used to describe patient characteristics, acceptance, and attrition. Categorical variables were presented as numbers with percentages. Continuous variables were presented as mean with SD for normally distributed data or as median with IQR for non-normally distributed data. Analyses were performed in IBM SPSS Statistics version 30.0.0.

To determine adherence, the total wear time was calculated as a percentage by dividing the total number of valid days children wore the smartwatch by the total number of days a child was included in the study. A day was considered valid when HR was measured at least once per hour for a minimum of 8 hours between 6 AM and 12 PM.

The interviews were recorded on a mobile phone and transcribed verbatim. The in-depth interviews from phase 1 were analyzed using Braun and Clarke's [38] thematic approach. Transcripts were initially coded by EdH, and the final codes and themes were formulated in discussion with EJV and SBBB. Themes were subsequently discussed within the entire research team to identify key considerations that were used to guide the development of phase 2.

The interviews from phase 2 were analyzed using Braun and Clarke's [38] inductive thematic approach, which included an

XSL•FO
RenderX

iterative process of data collection and analysis [39,40]. The first step involved reading interview transcripts to familiarize yourself with the data. In the second step, EJV and EdH independently coded 12 transcripts. These codes were discussed with SBBB, resulting in a preliminary thematic map, which EdH used in the remaining transcripts. In the third step, subthemes and themes were collaboratively established by SBBB, EJV, and EdH and further discussed within the entire research team. The last step involved finalizing the codes, subthemes, and main themes while identifying connections within and across themes. The thematic analysis was conducted using ATLAS.ti (Scientific Software Development GmbH, v8.3.0).

Results

Cohort

Most of the 15 children included in phase 1 were male (11/15, 73%) and diagnosed with a hematological malignancy (13/15, 86%) (Table 1). They had a mean age of 12.2 (SD 2.9) years at the time of inclusion, and the median time since diagnosis was 262.0 (IQR 108.5 - 325.5) days. The acceptance and attrition rates were 45% (15/33) and 93% (14/15), respectively. Reasons for refusing participation included already owning a smartwatch, unwillingness to wear a smartwatch, disliking the smartwatch's feeling or appearance, not perceiving the need for a smartwatch to measure physical activity, and considering the smartwatch as an additional burden alongside medical needs.

Of the 15 children included in phase 2, 7 (47%) were male, and 12 (80%) were diagnosed with a hematological malignancy (Table 1). Children had a mean age of 12.5 (SD 2.9) years at time of inclusion, and the median time since diagnosis was 96.0 (IQR 80.5 - 151.0) days. The acceptance and attrition rates for phase 2 were 83% (15/18) and 93% (14/15), respectively. Reasons for refusing participation included unwillingness to wear a smartwatch that measures physical activity during treatment and parental concerns related to their child's autism.

An overview of the number of dropouts and patients included in quantitative and qualitative data analyses is shown in Table 1. During both study phases, 1 child dropped out because wearing the smartwatch was considered too much of a burden in combination with medical needs. All available data of these children were used for data analysis, and no new children were recruited. In 71% (10/14) of the in-depth interviews at the end of phase 1, parents were present during the interview. During phase 2, parents were involved in 79% (11/14), 73% (11/14), 50% (6/12), and 71% (10/14) of the semistructured interviews at weeks 1, 3, 6, and 12, respectively.

Phase 1

The in-depth interviews highlighted that children were generally willing to wear the smartwatch during cancer treatment, as it motivated them to remain physically active and achieve their daily activity goal. Parents mentioned that the smartwatch provided valuable insights into their child's symptoms linked to physical activity. However, some children found the smartwatch occasionally annoying or burdensome. The primary reasons for not wearing the smartwatch were having a lack of knowledge about potential benefits or a sense of relevance for its use, having a lack of stimulating environment, and not perceiving it as beneficial, especially when not engaging in physical activity. Moreover, children did not feel attached to the smartwatch, forgot to wear it due to not being used to wearing a watch, had a lack of external assistance, and had no desire to wear it or had issues with their preferences or comfort. Quotes from the in-depth interviews emphasizing the barriers for not wearing the smartwatch mentioned by children and their parents are reported below.

XSL•FO

> *It would help wearing the smartwatch more often when showing us the usefulness. For example, we only really realized how useful the smartwatch was once he started wearing it.* [Father of an 11-year-old boy]

> *Sometimes during the day when I did not do anything, I either forgot the smartwatch or I thought "Well, yes, I am not really doing anything right now thus it is not so much use."* [17-year-old boy]

> *If you have worn the smartwatch continuously, you get…*
>
> *Father: …maybe something like a small reward. Something that shows appreciation — it does not have to be expensive or big, but something that says 'thank you for your help'. A card, a little thing, just something — yeah, I think that would be motivating.* [9-year-old boy and his father]

> *I only took the smartwatch off because it irritated my skin. Maybe a fabric strap would be more comfortable.* [13-year-old girl]

Based on the barriers to wearing identified in phase 1, several key considerations were identified and implemented to optimize phase 2 (Table 2). The considerations were structured into the following points:

(1) Enhanced engagement: When children received the smartwatch, they were extensively informed about the importance of wearing it, personal benefits, and its features. The information provided by the researcher was tailored to individual children. If a child, for example, was eager to move a lot, the benefits of seeing its own physical activity were emphasized. Parents were actively engaged in the process to ensure support and understanding.

(2) Regular prompts: Children or their parents, depending on the family's preferences, received prompts with feedback on wearing behavior and tips for smartwatch use as a text message on their phone or via email. Such prompts looked like:

> *When you start moving, your muscles and bones become stronger, making it easier to stay physically active. Tip: You can track your heart rate over the day, week, or month in the application by clicking on 'Heart Rate.' Did you know your heart rate goes up when being physically active?*

These prompts were sent after the first week of wearing and subsequently every other week. Prior research has demonstrated that such prompts were effective in maintaining engagement in children with acute lymphoblastic leukemia [41] and sustaining health-enhancing behaviors in adolescents [42,43].

(3) Customized plans: To address practical challenges, a personalized plan was created with input from children to ensure the smartwatch was not forgotten. Examples of issues addressed in such a personalized plan included placing the smartwatch on the child's bedside table or next to the child's smartphone during the night and putting it on directly after waking up. Parents were encouraged to assist their child in wearing the smartwatch daily if needed by giving them an active role in incorporating the smartwatch into the daily routine.

(4) Personalized setup: The smartwatch was tailored to each child's preferences. If desired, features, such as phone call and message notifications were activated, and a daily step goal was set.

(5) Improved aesthetics and comfort: To meet individual preferences and address potential irritation, children were provided with a variety of wristbands in different colors and made of different materials.

XSL•FO
RenderX

Table . Principal considerations for long-term physical activity tracking during childhood cancer treatment gathered during phase 1 and used to optimize phase 2.

Key considerations and barriers for wearing	Specific considerations
Enhanced engagement	
Lack of knowledge about potential benefits and relevance	Provide extensive information on the benefits and relevance of wearing the smartwatch, also when not being physically active
No perceived benefit	Provide information regarding potential benefits of wearing and using the smartwatch, with a focus on benefits for children themselves
Lack of stimulating environment	Increase social support and engage parents
Regular prompts	
No attachment	Send 2 weekly prompts, including feedback on wearing behavior and tips for smartwatch use
Customized plans	
Forgotten to wear	Create a plan to not forget the smartwatch using input from children themselves to optimize wearability
Lack of external assistance	Encourage parents to assist children in wearing the smartwatch
Personalized setup	
No desire to wear	Activate incoming phone calls and messages and set a daily step goal
Improved aesthetics and comfort	
Issues with preferences or comfort	Offer a variety of wristbands in different colors, which are made of different materials

Phase 2

Technical difficulties while synchronizing the smartwatch with the app occurred in 2 children, resulting in incomplete data retrieval. Therefore, these children were not included in the calculations of adherence. One child dropped out after 36 days because wearing the smartwatch was considered too much of a burden in combination with medical needs but was still included in the analysis. Thirteen children had a median adherence of 68 % (IQR 39% - 92%) of total days included in the study (Table 1). Overall, 6/13 children (46%) adhered to wearing the smartwatch for a minimum of 75% of the 12-week study period and reached the adherence target.

All interviews performed during phase 2 were analyzed according to an iterative approach to define themes during as well as after the study period. These interviews identified key barriers and facilitators of real-time and long-term physical activity tracking using a smartwatch in children during cancer treatment. The most prominent themes were (1) burden and resilience, (2) motivational drivers and perception, (3) insight and evaluation, and (4) user experience and functionality (Table 3). These themes are elaborated in the following paragraphs and supported with quotes from children and parents.

XSL•FO
RenderX

Table . Barriers and facilitators of real-time and long-term physical activity tracking using a smartwatch in children during cancer treatment.

Main themes, subthemes, and codes	Barrier	Facilitator
Burden and resilience		
Physical state		
Being fatigued	Feeling too exhausted during admission or intensive treatment courses.	—[a]
Feeling ill	Children find the smartwatch too burdensome when feeling sick, nauseous, and unwell.	—
Low resilience	It is too much and burdensome to wear the smartwatch on top of medical needs, such as taking medication, being hospitalized, having a drip line, receiving radiation, or tube feeding.	—
Perception of burden		
Overload	Children expect that the smartwatch is not something they could focus on shortly after diagnosis or have no interest in the smartwatch during intensive treatment courses and do therefore not expect to be willing to wear it during the entire treatment. For some parents, the smartwatch would feel like an overload during early treatment phases, as it would have been too much to deal with.	—
(No) pressure to wear	Some children feel pressured to wear the smartwatch continuously, which can become overwhelming.	Other children feel no such pressure to wear the smartwatch, enabling flexible use.
Not burdensome to wear		Wearing the smartwatch is considered not burdensome.
Enforcing the obligation may lead to resistance	The feeling of wearing the smartwatch being an obligation is unpleasant and would make wearing it during the entire treatment unbearable.	—
Motivational drivers and perception		
Motivation and stimulus		
(No) stimulus for physical activity	The smartwatch is no additional stimulus for physical activity for some children. Parents question the smartwatch's ability to motivate or provide value if the child does not experience it as a stimulus.	For other children, the smartwatch is an additional stimulus for physical activity.
Stimulus despite pain	—	Despite experiencing treatment-related nerve pain, the smartwatch is a stimulus for physical activity.
Reward for sufficient physical activity	—	Willingness to wear the smartwatch for the visual reward after reaching the step goal.
Value and meaningfulness		
Attachment to the smartwatch	—	Feeling proud to wear the smartwatch.
Lack of obligation	The absence of expectation or mandate allows children to deprioritize the smartwatch. Therefore, children consider it as one of the first things they can let go.	—
Decreasing novelty	The initial enthusiasm for the smartwatch diminishes over time.	—

XSL•FO
RenderX

Main themes, subthemes, and codes	Barrier	Facilitator
Not useful during inactivity	Depending on the intensity of treatment and its effect on how physically active children can be, wearing the smartwatch may not be doable for some children. Especially when children are physically inactive, such as when they feel unwell or tired, are resting, or shortly after diagnosis, they are unsure about the meaningfulness of the smartwatch.	For other children, it might be doable to wear the smartwatch during treatment with varying intensity and effect on physical activity.
Lack of intrinsic motivation	—	Some children wear the smartwatch out of habit or external expectation rather than personal interest.
Concerns around smartwatches		
Inaccurate tracking of physical activity	Children are disappointed when steps or other activities are not tracked accurately, as they want all their physical activity to be captured.	—
Parental concerns about overemphasis on physical activity	Some parents feel their child places too much focus on the smartwatch, potentially leading to excessive physical activity or obsession with activity tracking.	—
Insight and evaluation		
Self-monitoring and positive evaluation		
Tracking physical activity for self-monitoring and evaluation	—	Having insight into steps, heart rate, sleep, distance covered, calories burned, and time is convenient and used as an evaluation of the number of steps taken on different days and during and after physiotherapy consultations.
Confirmation of sufficient physical activity	—	Insight provides confirmation of being sufficiently physically active.
Insight and health evaluation by parents	—	Parents appreciate having insight, linking their child's physical activity to its feelings or complaints, and using the smartwatch as an additional medical tool. Also for parents, the smartwatch motivates them to be physically active or helps with seeking opportunities.
Sharing insight with the environment		
Providing insight into physical activity for oneself and others	—	Children feel positive about having insight into their own physical activity and being able to share this with others. It helps them show others that being ill does not prevent them from staying physically active.
Support from a pediatric physiotherapist	—	Children find it beneficial when their pediatric physiotherapist has access to their physical activity data and supports them through encouraging messages to stay active.
Challenges with tracking and insight		
Negative feelings about tracking and external feedback	Failing to meet daily step goals can feel confronting for some children. Parents worry that such confrontation could have a discouraging effect. Furthermore, children might find it unpleasant if their pediatric physiotherapist had insight into their low physical activity levels and pointed out their physical inactivity.	Other children do not perceive it as problematic when failing to meet daily step goals.
User experience and functionality		
Comfort and fit		
Appearance	Some children find the smartwatch unattractive.	Other children consider the smartwatch attractive, appreciating features like a preferred strap color or matching it with their clothes.

XSL•FO
RenderX

Main themes, subthemes, and codes	Barrier	Facilitator
Wearing comfort	Particularly shortly after diagnosis or during early treatment, wearing the smartwatch is sometimes considered unpleasant. The smartwatch sometimes leaves an imprint, presses on the skin or bone, or causes skin irritation, which makes children not willing to wear the smartwatch for the entire treatment.	For most children, the smartwatch feels comfortable and unobtrusive, and they think it is doable to wear the smartwatch throughout the entire treatment.
Skin irritation	The smartwatch can cause skin irritation, such as itching, bumps, or small lesions, particularly shortly after diagnosis, when combined with certain medications, such as treatment with glucocorticoids, or sweating.	—
Fit	The smartwatch can sometimes be too tight or too loose, shifting on the wrist.	Even the smallest smartwatch may feel oversized for young children due to their small wrists, but they may still prefer to keep it on.
Strap material	Some children think that a fabric strap is not better than a rubber strap.	Other children think that a strap made of a different material than rubber, such as metal or fabric, might be more comfortable or attractive.
Needs and preferences		
Ease of use	—	The smartwatch is considered easy to use.
Features and functionalities	—	The long battery life and waterproof design are appreciated. Preferences vary: one child prefers a smartwatch without a digital screen while another favors a fully digital display.
Preference for phone-based physical activity tracking	One child prefers to wear an attractive, nontracking watch and use a phone to track physical activity rather than wearing a less attractive smartwatch that tracks physical activity.	—
Technical functionality		
Phone notifications	Inconsistent visibility of notifications on the smartwatch can be frustrating.	Receiving phone notifications on the smartwatch is considered convenient and enjoyable.
Difficulty synchronizing with the app	When the smartwatch is not properly connected to a phone or tablet, some activity data may not be recorded in the app, limiting its usefulness.	—
Incorrect setup limits functionality	If the smartwatch screen is not set up correctly, physical activity data may not be displayed.	—
Reliability and sustainability		
Strap quality	The strap and its loops are of low quality, which is seen as inconvenient.	—
Inconsistent activity measurement	Steps or heart rate do not always seem to be measured continuously or consistently.	—

[a]Not available.

Burden and Resilience

The experience of wearing the smartwatch varied widely among children, with some who found it overly burdensome, particularly during periods of fatigue, nausea, or general illness. For children with low resilience or high medical needs, the additional effort of wearing the smartwatch could be perceived as overwhelming.

> *But everything that came with it, was too much for her. She no longer wanted to take medication. In the meantime, she has been given a feeding tube. She was very ill, so she had absolutely no interest in the smartwatch anymore, you know.* [Mother of an 11-year-old girl]

The timing of introducing the smartwatch played an important role. Shortly after diagnosis or during intensive treatment phases, children may not be emotionally ready to engage with the smartwatch. Parents noted that during the initial month of treatment, the smartwatch could feel like an overload on top of an already overwhelming situation. While some children found the associated expectations and pressure of wearing the smartwatch overwhelming, making it unsustainable, others experienced no such difficulty and wore it with ease. When children had the feeling that wearing the smartwatch was mandatory and that they were not supposed to take it off,

XSL•FO
RenderX

wearing it became unpleasant and unsustainable for the entire treatment.

> *I could have worn the smartwatch at the beginning of the treatment, closer to the diagnosis, but I do not know if it would have been very useful, because at that time I could not really do anything. So I am not sure if it would have helped much. I think probably yes, but I do not know for sure, because I was not thinking about that back then. It was more like, "Oh shit, I cannot walk," you know?* [16-year-old girl]

> *The thought that you are not supposed to take it off is exactly what makes you want to take it off.* [12-year-old boy]

Motivational Drivers and Perception

The smartwatch served as a motivator for physical activity for some children, even in the presence of pain. For others, however, it did not provide an additional motivation. Parents questioned its value when their child did not perceive it as a stimulus for physical activity.

> *I wore the smartwatch to track how much I moved during the day and things like that. At the end of the day, I would check what I did — like how many steps, how many meters. And it was really very little. That made me realize that I could probably do a little bit more.* [17-year-old boy]

> *At the moment when it does not provide any benefit to yourself, so if it does not provide that stimulation, I am not sure how fun or motivating it is. … Then, yeah, it does not really offer you anything directly.* [Father of a 13-year-old girl]

Without clear expectations or a sense of obligation, some children may deprioritize the use of the smartwatch, and the initial excitement may fade. While some children found it challenging to use the smartwatch during intensive treatment phases, others continued to wear it. Uncertainty about its usefulness emerged when children were physically inactive.

> *Yeah, only when I received Dexa (dexamethasone) — I found it a bit irritating then, so I did not wear it for a few days. Especially during those 2 or 3 days when I was really at my peak, I took it off for a bit. But after that, I pretty much always wore it again. Yeah, but that was really just because of Dexa — and that kind of speaks for itself, you know. That was the only reason.* [16-year-old girl]

> *Well, it is more like, I wear it mainly because it is practical, and if you are just lying in bed all day, yeah, then it is basically useless.* [12-year-old boy]

Accurate tracking of physical activity was crucial for maintaining engagement. Children sometimes expressed disappointment when the smartwatch failed to capture their physical activity correctly. In addition, some parents worried that their child might become overly focused on the smartwatch, potentially leading to excessive physical activity or an unhealthy preoccupation with tracking.

> *The only downside is that when you are on the treadmill, I think it does not count all the steps — it seems to miss some of them.* [17-year-old boy]

Insight and Evaluation

Self-monitoring through the smartwatch provided the opportunity to evaluate physical activity levels and confirmed that the child had been sufficiently physically active. Parents particularly appreciated having insight into their child's physical activity, with some who used it as an extra tool to assess their child's health status.

> *But it is also helpful for me personally, especially now, because I can start feeling unwell quite quickly — so it is good to be able to see how things are going.* [16-year-old boy]

> *Actually, it was really practical because we saw that suddenly her resting heart rate was much higher and this helped also with, well let's say, she needed a blood transfusion and probably this was related to her too low hemoglobin level. So it did help us as we thought: 'Well, her heart rate is really very high'. Yes, so that is really practical. In that way, we can also make use of it to know in time what is going on. … So, it is also, we now have an extra tool. Convenient, right?* [Mother of a 9-year-old girl]

For children, tracking and sharing physical activity data may be empowering and provide proof that they can remain active despite their illness. Positive reinforcement from their pediatric physiotherapist, enabled by access to their physical activity data, would be valued.

> *To prove to myself and others that, even though you are sick, you can still do a lot and you can definitely stay fit.* [12-year-old boy]

However, the experience of activity tracking was not uniformly positive. While some children found it encouraging, others perceived it as confronting, particularly if their activity levels were low. This perception may discourage using the smartwatch. Children expressed discomfort at the thought of their pediatric physiotherapist having insight into their low physical activity levels and pointing this out.

> *I think that if you get a smartwatch at a time like that, and you just cannot reach your goal of the minimum number of steps because you feel too unwell, I think it works counterproductively.* [Mother of a 9-year-old girl]

User Experience and Functionality

The design and comfort of the smartwatch influenced its usability during treatment. Most children found the smartwatch attractive and comfortable to wear throughout the entire treatment, while others found the design unattractive or experienced irritation or pressure on their skin. These issues were more likely during early or intensive treatment phases. Factors, such as loose or oversized straps as well as material preferences, impacted wearability.

XSL•FO
RenderX

> *Well, it is just — I mean, it is not like it really bothers me. I wear bracelets too, so why would I not be able to wear a watch?* [16-year-old girl]
>
> *Uh, when I move, it keeps sliding forward and backward, and that was just really annoying.* [11-year-old boy]

The smartwatch was considered easy to use, though children's preferences varied. Some children favored a nondigital or visually appealing watch, which may present a barrier to using a smartwatch designed to track physical activity.

Technical limitations also affected the smartwatch's functionality and reliability. Issues, such as inconsistent visibility of phone notifications, difficulty connecting to digital devices, incorrect setup, improper material, and inaccuracies in physical activity measurements diminished its overall functionality.

Key Considerations for Long-Term Physical Activity Tracking During Childhood Cancer Treatment

Based on the barriers and facilitators suggested by children and their parents and interpreted by the researchers, the following key considerations are proposed for the future (Table 4):

(1) Personalized approach: A consideration should be made whether the smartwatch is a stimulus or a burden. Daily life feasibility should be discussed, tailoring usage to the individual child and its treatment phases. Providing information on its benefits and relevance may help to reduce perceived burden.

(2) Enhanced persistence: Children who do not perceive a motivational stimulus from the smartwatch should be timely identified, and strategies to wear should be adapted to their needs. Having the ability to set an adjustable, achievable step goal could be motivating for those who fail to reach the lowest daily step goal. Sending motivational and empowering prompts when not being sufficiently physically active might help to reduce negative feelings about sharing physical activity data.

(3) Aligned design and comfort: The smartwatch should align with preferences of children, including color, size, display, strap material, and comfort.

(4) Expanded functionalities: Children suggest additional functions, such as tracking various sports and calling parents, while parents value functions like monitoring temperature.

Table . Future key considerations for long-term physical activity tracking during childhood cancer treatment gathered during phase 2.

Key considerations and barriers for wearing	Specific considerations
Personalized approach	
Too burdensome for children with low resilience or low physical activity	Consider whether the smartwatch acts as a stimulus or a burden, discuss its feasibility in daily life and tailor its use to each individual child and their treatment phases
High perceived burden by child or parent	Provide information regarding the benefits and relevance of the smartwatch
Enhanced persistence	
No stimulus for physical activity	Identify and guide children who do not perceive motivational stimulus and adapt strategies to needs
Negative feelings about insight into low physical activity	Allow adjustable, achievable daily goal
Negative feelings about sharing insight	Send motivational and empowering prompts by enabling access to children's physical activity data
Aligned design and comfort	
Unattractive smartwatch	Align the smartwatch with preferences of children, such as features, color, size, and display
Uncomfortable smartwatch	Align the smartwatch with preferences of children, such as size, strap material, and comfort, and consider the effect of treatment on wearing comfort
Expanded functionalities	
Limited features and functionalities for children	Add functions, such as selecting more types of sports or calling
Limited features and functionalities for parents	Add functions, such as measuring additional health outcomes, for example, temperature

Discussion

Principal Findings and Comparison With Previous Work

In this study, we showed that long-term physical activity tracking using a smartwatch during childhood cancer treatment was not feasible in our cohort according to the feasibility target we set. Furthermore, we defined barriers, facilitators, and key considerations of real-time and long-term physical activity tracking using a smartwatch in children during cancer treatment.

The result from our study that physical activity tracking using a smartwatch in children with cancer was not feasible is not in line with a previous study in children with acute lymphoblastic leukemia who used a fitness tracker for around 3 weeks during their treatment [27]. This previous study showed that these children were able to consistently use the fitness tracker with

XSL•FO
RenderX

low effort. However, 40% (11/28) of eligible patients refused participation, which might induce a potential selection bias. Moreover, the fitness tracker used in the previous study was clipped to clothing rather than a watch worn on the wrist, and the study period was substantially shorter as compared to our study. The authors of the previous study suggested that the use of the smartwatch might only be feasible in a subset of children. Contrary to the results of our study, another previous study in children with a brain tumor reported no adverse effects of using a smartwatch combined with coaching by a physiotherapist for 12 weeks during treatment [26]. However, in the previous study, only children with a brain tumor were included, while in our study, children with a variety of cancer diagnoses were included, which entails a more heterogeneous population. Moreover, the children in the previous study received coaching by a physiotherapist, which was not the case for the children included in our study. Also, inconsistent with the results of our study, during the maintenance phase of childhood acute lymphoblastic leukemia and after treatment for childhood cancer, the daily use of a smartwatch for 6 months was reported to be feasible [28]. Nonetheless, in the previous study, children at the end of their treatment were included while we included a more diverse group of children during different phases of treatment. According to our results, we emphasize the need to consider whether the smartwatch is a stimulus or a burden, discuss daily life feasibility, and tailor usage to the needs and preferences of a child. Furthermore, in our study, tracking physical activity was feasible in some of the children. For the future, it would be of added value to study the characteristics of those who adhered to wearing the smartwatch to find out for which children wearing the smartwatch is feasible.

Besides feasibility and in contrast to the aforementioned studies, our study aimed to identify barriers, facilitators, and key considerations of real-time and long-term physical activity tracking using a consumer-level smartwatch in children during cancer treatment. We found that some children perceived wearing the smartwatch as confronting and felt a pressure to wear it, which may become overwhelming. Although knowledge about wearing experiences of using smartwatches in children with cancer during different phases of treatment is limited, a previous study, exploring the influence of smartwatches on motivation for physical activity in healthy children, reported a potential negative internal pressure to reach a certain step goal, which might have a negative effect on self-image [44]. The authors emphasized the importance of personalizing goals, which is in accordance with our key considerations to apply a personalized approach and tailor the smartwatch to each child individually. Furthermore, empowering children using motivational prompts might help to reduce negative feelings about having and sharing insight. Finally, providing information on its benefits and relevance may aid in reducing perceived burden.

We found that children might perceive the smartwatch in diverse ways, where motivation, value, and expectations play key roles in the success of wearing the smartwatch. These factors not only influence how the smartwatch is perceived but also affect how engaged children and parents feel with the smartwatch. During phase 1, we highlighted the importance of enhancing engagement. Both reducing perceived burden and enhancing engagement are essential for ensuring the smartwatch's long-term use. Previous literature also mentioned the importance of feeling engaged as a key determinant of the success of physical activity interventions in adolescent and young adult survivors of childhood cancer [36], a smartwatch intervention in children with a chronic health condition [45], or the use of wearable devices to measure physical activity in healthy children [46,47]. For the future, we suggest increasing interest and creating value and meaningfulness by, for example, explaining the possibility of early recognition of aberrant physical activity levels and providing tailored advice and guidance when wearing the smartwatch.

In our study, children reported that the initial excitement of the smartwatch may fade over time. A decrease in the use of a smartwatch during physical activity interventions has earlier been reported in adolescent, young adult childhood cancer survivors [28] and healthy children [29]. Such a novelty effect might be the result of a reduced perceived usefulness. This might consequently have a negative effect on the smartwatch's wearability in the long term. Based on children's experiences and previous literature [48,49], we suggest identifying children who do not perceive a motivational stimulus from the smartwatch in a timely manner and adapting strategies to wear it according to their needs. Persistence might be enhanced by, for instance, allowing adjustable, achievable goals for those who fail to reach the lowest daily step goal, sending motivational and empowering prompts when not being sufficiently physically active, and keeping on aligning the smartwatch with the preferences and needs of the child. Moreover, it might be helpful to consider the first period of use as an opportune moment to incorporate the smartwatch into children's daily living. During this period, children should be informed about the use of the smartwatch, and ideally, this should be continued to encourage them to keep on using it [48-50]. Furthermore, developing and implementing an app that fits with a child's preferences might be helpful to increase wearability of the smartwatch, especially for those who experienced wearing the smartwatch as overwhelming or confronting.

Children had mixed experiences with wearing the smartwatch during treatment, where attractiveness, comfort, and usability played key roles in its acceptance. These findings are in line with the literature on healthy children [29,50]. We advocate aligning the smartwatch with preferences of children, including color, size, display, strap material, and comfort. Moreover, we suggest incorporating additional functions, as this might increase usefulness. For the future, the importance of personal preferences, comfort, and practical and technical performance should not be underestimated, and appropriate functionality, reliability, and sustainability should be ensured to promote sustained use.

Although a strength of this study is that the feasibility, barriers, facilitators, and considerations of real-time and long-term physical activity tracking using a consumer-level smartwatch in children during cancer treatment were examined using both quantitative and qualitative methods, it does have limitations. First, biases should not be overlooked. Selection bias should be considered, as especially children who are interested in a

XSL•FO
RenderX

smartwatch to track their physical activity might have been enrolled. However, in particular, the recruitment rate of 83% for phase 2 undermines selection bias. Confirmation bias should be recognized, as only 1 researcher conducted all interviews. Nonetheless, by using an interview guide and refining the methods and incorporating emerging topics based on children's experiences, we tried to prevent confirmation bias. Second, the differences in sex and time since diagnosis between children included in phase 1 and 2 might have influenced acceptance as well as the proposed key considerations. Finally, as a qualitative approach has been used, issues of credibility, transferability, and dependability should be acknowledged. We tried to consider these issues by prolonged engagement and persistent observation, thick description, and methodological transparency, respectively [51].

The barriers and facilitators we identified in this study might be helpful for improving the feasibility of physical activity tracking using a smartwatch in children during cancer treatment by acknowledging the key considerations we propose. In addition to these, identifying which children can feasibly wear a smartwatch would provide additional value for them. Furthermore, for future implementation, it would be helpful to explore the fine line between creating a certain commitment without overwhelming children. In addition, understanding how pediatric physiotherapists' access to children's physical activity data might be supportive during physiotherapeutic treatment would be valuable. Finally, developing a smartwatch in line with these and other needs of children with cancer and expanding functionalities according to their preferences would be of added value.

Conclusion

Real-time and long-term physical activity tracking using a smartwatch in children during cancer treatment was not feasible in our cohort. The success of wearing the smartwatch depends on the child's physical state and the perceived burden by both children and parents. Motivation, perceived value, and expectations play key roles in enhancing persistence, while the balance between positive reinforcement and potential stress from data interpretation affects long-term use. User experiences, including attractiveness, comfort, and usability impact acceptance, emphasizing the essence of a personalized approach, incorporating individual preferences and physical condition, to support adherence.

Abstract

Background: Juvenile idiopathic arthritis (JIA) is a chronic rheumatic condition requiring long-term, multidisciplinary treatment, which consumes significant health care resources and family energy. This study aims to analyze the effectiveness of digital interventions on patient outcomes in individuals with JIA.

Objective: This meta-analysis aimed to evaluate the impact of digital interventions on alleviating symptoms and improving overall well-being in children and adolescents with JIA.

Methods: A systematic search of 5 databases identified randomized controlled trials assessing the impact of digital interventions on physiological and psychological outcomes in adolescents and children (average age ≤19 y). Outcomes included pain, physical activity, health-related quality of life, self-efficacy, and disease-related issues. A total of 2 reviewers independently screened papers and extracted data on intervention functionalities and outcomes, assessing the risk of bias. A meta-analysis using a random-effects model synthesized the results.

Results: The review included 11 studies involving 885 patients with JIA. Digital interventions included educational (eg, self-management training), therapeutic (eg, pain management), and behavioral (eg, promoting physical activity) approaches. These were delivered through websites, telephone consultations, video conferences, apps, and interactive games, with durations ranging from 8 to 24 weeks and no clear link observed between intervention length and outcomes. Compared with conventional control groups, digital interventions were significantly effective in alleviating pain (standardized mean difference [SMD] −0.19, 95% CI −0.35 to −0.04) and enhancing physical activity levels (SMD 0.37, 95% CI 0.06-0.69). Marginal improvements in health-related quality of life, self-efficacy, and disease-related issues were observed, but these did not reach statistical significance (SMD −0.04, 95% CI −0.19 to 0.11; SMD 0.05, 95% CI −0.11 to 0.20; and SMD 0.09, 95% CI −0.11 to 0.29, respectively). The Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach rated the quality of evidence for pain, health-related quality of life, self-efficacy, and disease-related issues as moderate, while the evidence quality for physical activity was assessed as low.

Conclusions: Digital interventions can alleviate pain and enhance physical activity in patients with JIA. However, given the limited sample size and high risk of bias in some studies, further high-quality research is needed to improve the treatment and management of JIA.

KEYWORDS

juvenile idiopathic arthritis; digital intervention; application; children health care; pediatrics

Introduction

Juvenile idiopathic arthritis (JIA) is a prevalent chronic rheumatic ailment affecting children, causing joint pain and inflammation that can disrupt their daily lives [1]. During flare-ups, it can hinder academic performance, social interactions, and normal activities [2], while the complexity of treatment and associated complications further strain health care systems and drive up costs [3-6]. Since JIA requires ongoing monitoring and treatment [7,8], patients face a lifelong responsibility for managing the disease as they grow older [9]. Consequently, patients are encouraged to actively engage in lifestyle modifications and health-related decision-making [10]. Physical activity, including aerobic fitness and strength training, is recognized as a helpful nondrug intervention, offering

XSL•FO
RenderX

potential benefits in improving overall well-being and lessening the impact of JIA symptoms [11-13].

Internet-based digital tools, including mobile applications, websites, and other platforms, have become essential components of nonpharmaceutical interventions. These tools enable remote interaction and offer timely responses, making health care resources more accessible [14]. They can provide tailored rehabilitation interventions for pediatric chronic diseases and transitional care [15], such as fostering healthy behavioral habits through social media–based peer coaching [16]. Several mobile medical applications have been developed for adolescents and young individuals with JIA [17-22]. However, the research on their effectiveness has yielded varied results. While some studies have shown promising outcomes in terms of pain alleviation and physical function improvement, others have not replicated these results [22-24]. This variability in research findings highlights the need for further investigation and systematic evaluation to better understand the most effective components and digital health solutions in this domain, ensuring an accurate assessment of the evidence.

To date, previous reviews have assessed the effectiveness of mobile and e-medical interventions in aiding children and adolescents with JIA [25,26]. However, existing reviews have not focused on analyzing randomized controlled trials (RCTs), which could yield more precise results and reduce heterogeneity. The inclusion of only a minimal number of relevant outcomes (n≤3) in some meta-analyses, such as physical activity, limits the interpretation of findings cautiously and results in the absence of an effective theory of digital interventions for patients with JIA. Consequently, it remains unclear whether such interventions enhance clinical outcomes. Furthermore, as research on mobile medical interventions for JIA patients continues to evolve, it is essential to promptly integrate new research findings. This underscores the necessity for a fresh comprehensive evaluation of clinical interventions in this domain.

Therefore, our study aims to address these gaps by conducting a thorough analysis of digital interventions and their impact on clinical outcomes for patients with JIA.

Methods

Overview

This study follows the guidelines published in Preferred Reporting Items for Systematic reviews and Meta-Analyses [27] and the Cochrane Handbook of Systematic Reviews [28]. The priori protocol for the review is published in the International Prospective Register of Systematic Reviews (PROSPERO CRD42023471223).

Search Strategy

The research was conducted with the guidance and support of institutional librarians. A subject-specific librarian, along with researchers ZR and YC, developed a search strategy without language restrictions, which was used to conduct a comprehensive search in PubMed, Embase, Cochrane Library, Ovid, and Medline [29], covering records from the earliest available to the latest date. The search used Boolean operators in combination with Medical Subject Headings terms and free-text keywords to identify studies on the impact of digital interventions on JIA. The following search string was used as an example: (“Juvenile Idiopathic Arthritis” OR “Pediatric Rheumatic Diseases” OR “Juvenile Chronic Arthritis”) AND (“mHealth” OR “Digital Health” OR “Mobile Health”) AND (“Randomized Controlled Trial” OR “RCT” OR “Clinical Trial”). The full search strategy is provided in Multimedia Appendix 1, the specific keywords used for the search are provided in Multimedia Appendix 2.

The studies identified through this strategy were managed through the literature management software, Zotero (Corporation for Digital Scholarship). The 2 authors, ZR and YC, screened the identified studies, in line with predefined inclusion and exclusion criteria. Any discrepancies during this process were resolved through discussion between the researchers. Multimedia Appendix 1 shows the detailed search formulas. RCTs of any design, including crossover, multicenter, and cross-over trials, that were published in English are included in this review.

Participants

Episodes of JIA typically manifest in individuals before the age of 16 years [30]. However, considering the chronic nature of the condition and the need for ongoing treatment, the minimum age for inclusion in international pediatric treatment reference populations has risen to an average of 18.7 (SD 2.6) years.

Hence, for the purpose of this review, the term “children and adolescents” refers to individuals between the ages of 1 and 19 years [31]. The study population comprises children and adolescents diagnosed with JIA by a rheumatologist, ranging from 1 to 19 years old. Infants and neonates under the age of 1 year were excluded from the study population.

Intervention

In assessing the effectiveness of interventions for JIA recovery, the study focused on digital platforms such as somatic gaming, smart applications, teleconferencing, televideo, and health websites.

Control Condition

All types of control groups were considered in this study, including waitlists, physical therapy or minimal intervention groups, alternative treatments, and standard care delivered through web-based health care websites and apps. For example, the control group may use platforms like jong-en-reuma.nl, which provides information on medical issues and emotional support [32].

Outcome

Primary Outcome

There were 2 primary outcomes: pain (47-item Recalled Pain Inventory and 11-point Numeric Rating Scale) and physical activity (7-day activity diary [subjective], accelerometer [objective measurement], and Duruoz Hand Index Questionnaire.

XSL•FO
RenderX

Secondary Outcome

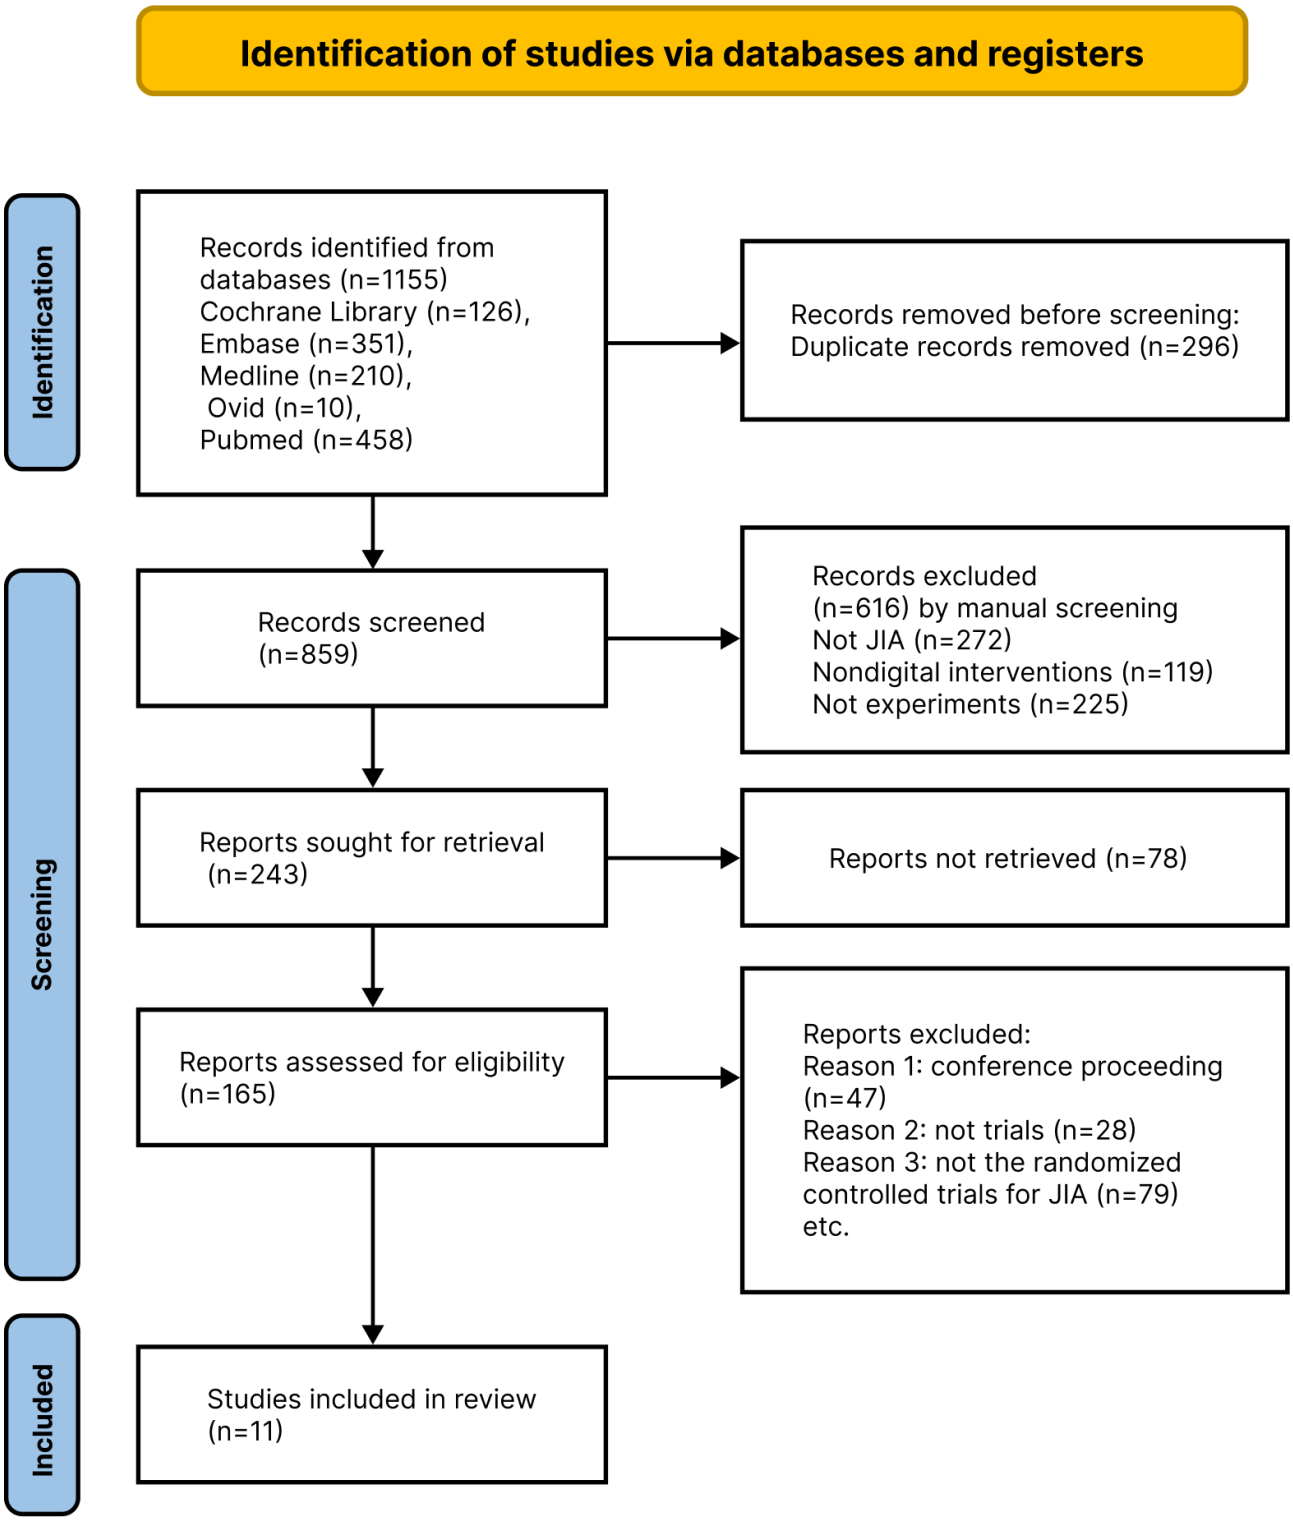
There were 2 secondar outcomes: health-related quality of life (Juvenile Arthritis Quality of Life Questionnaire, Pediatric Quality of Life Arthritis Module, Dutch Consensus Health Assessment Questionnaire Disability Index, and Pediatric Quality of Life Inventory [version 4.0]), self-efficacy (Children's Arthritis Self-Efficacy scale and Dutch Arthritis Self-Efficacy Scale), and illness-related issues (Medical Issues, Exercise, Pain, and Social Support questionnaire).

Risk of Bias

Risk of bias was assessed using the risk of bias tool of the Cochrane Handbook for Systematic Reviews [28]. Quality of evidence for outcomes was assessed according to the 5 Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) domains, including study limitation (risk of bias), inconsistency, indirectness, imprecision, and publication bias [33]. The bias was assessed by the 2 independent authors, ZR and YL. Any discrepancies were resolved through discussion and reexamination within the research group.

Data Extraction and Analysis

In order to identify and present common statistical descriptions of methodological heterogeneity, a descriptive integrated methodology was used. All findings were interpreted within the context of each study, considering the total number of studies and the assessed risk of bias. Using Review Manager (RevMan) software (version 5.4; Cochrane), this study conducted a random-effect meta-analysis to compare the standardized mean difference (SMD) for parameters across at least 3 studies between patients receiving general care and those using internet-based interventions. SMD and 95% CI were calculated using baseline and study end scores inputted into RevMan 5.4. Forest plots were generated using random-effect models for continuous data, presenting a summary of the effect distribution. Cohen's general rule of experience was applied, where an SMD of 0.2 signifies a "small" effect, 0.5 denotes a "moderate" effect, and 0.8 indicates a "large" effect. Furthermore, subgroup analysis was conducted to assess the impact of professional caregivers and intervention tools on the efficacy of e-medical intervention outcomes. Heterogeneity within the compiled studies was evaluated using I^2 statistics, and the carat test was used to assess significance. Heterogeneity levels were classified as low (I^2<25%; P>.1), moderate (I^2=25% - 49%), or high (I^2>50%).



Results

Literature Selection

We initially identified 1155 studies. After excluding duplicate studies (n=296) and irrelevant studies (n=694), 165 studies remained for abstract evaluation. A total of 154 studies were excluded for the following reasons: conference proceedings (n=47), not trials (n=28), and not RCTs for JIA (n=79). Ultimately, 11 RCTs were included in the meta-analysis. The screening process is illustrated in Figure 1.

XSL•FO

Figure 1. Summary of the study selection process using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses). JIA: juvenile idiopathic arthritis.

Participant Statistics

Table 1 shows the population characteristics, interventions, outcomes and study types of the 11 studies. Of these studies, 3 were from the Netherlands [32,34,35], 5 from Canada [36-40], and 1 each in the United States, Switzerland, and Turkey [38,40,41]. These studies included 289 individuals, predominantly female children and adolescents (663/885, 74.9%). A variety of juvenile arthritis subtypes were observed, with oligoarthritis being the most prevalent subtype (259/885, 29.3%). Almost all studies, with the exception of one [42], accounted for disease activity. The duration of the disease since diagnosis was documented in the majority of studies (7/11) [32,35-37,39,40,42].

Intervention Group

Overview

Table 2 demonstrates main digital tools and methods. A total of 6 studies implemented internet-based physical activity intervention programs, health management websites, and telephone support initiatives. Among these, 4 studies included routine telephone consultations and interviews. In addition, 1 study used video conferences for skills training [38], while another used self-management pain applications on mobile phones for experimentation [40]. In addition, an emotional games-based task-oriented activity training study was conducted [42]. All interventions examined lasted at least 8 weeks, with the longest intervention cycle spanning 18 months [35].

Functional Classification of Interventions

Digital interventions for patients with JIA are versatile, serving multiple functions. The purposes of these interventions include promoting physical activity (n=4), facilitating self-management for establishing healthy habits and reaching milestones (n=4), providing education on disease and health-related knowledge (n=8), offering stress relief to improve mood (n=4), and enhancing communication skills for better integration into school and society (n=7). Furthermore, half of the studies (n=7) supplemented the digital intervention program with telephone and video communication to augment its positive impact on children.

Statistics of Digital Interventions

A total of 8 studies used internet-based interventions based on previously developed projects or applications (Table 3). In addition, 3 studies used the Teens Taking Charge website as an intervention [36,39,41]. Furthermore, 2 studies used Rheumates@Work as an intervention [34,35]. For the experimental group's digitization project, 1 study used iPeer2Peer [37], Challenge your arthritis [32], and iCanCope [40]. Of all the intervention schemes, only 1 study referenced the theoretical framework as nursing guidance for their intervention schemes [43]. Care assessments conducted by nurses were guided and documented using Cox's interaction model of client health behavior [44] to ensure the continuity of care for children and their families.

[a]Not available.

While enhancing self-management skills is vital for facilitating health care transition [45], only 2 RCTs [32,37] explicitly reported on self-management outcomes. The remaining articles primarily integrated self-management as a core component of digital interventions, with considerations on health education, goal setting, and mood management.

Control Group

One study in this review did not specify the care received by the control group [34]. A total of 5 studies compared the intervention group to a control group that received standard or offline care (without internet and eHealth interventions) [35,37,38,42,43]. One study solely used telephone coaching communication [36]. A total of 4 studies compared a control group using a public website or eHealth with limited functionality to an intervention group receiving a specific digital design program [32,39-41]. The control groups in all trials assessed patients' results at pretest and posttest.

Risk of Bias Assessment

The results of the risk of bias assessment indicate that the criteria most commonly unmet were the blinding of outcome assessment and the adequacy of outcome data (Figure 2). Half of the studies (5/11 and 6/11) were deemed to have a high risk of bias in these 2 categories. In contrast, studies concerning randomized sequence generation were predominantly evaluated as having a low risk (9/11). Furthermore, 7 studies exhibited a medium risk of bias, while 4 studies were categorized as having a high risk of bias.

Meta-Analysis Results

Pain

Figure 3 depicts the impact of digital medical intervention on pain outcomes relative to all other control conditions. This analysis is based on findings from 5 studies involving 653 participants. A significant effect in favor of the intervention was observed (SMD −0.19, 95% CI −0.35 to −0.04; *P*=.86; I^2=0%). Several studies posed a high risk of bias, resulting in a moderate GRADE rating for the quality of evidence after the intervention.

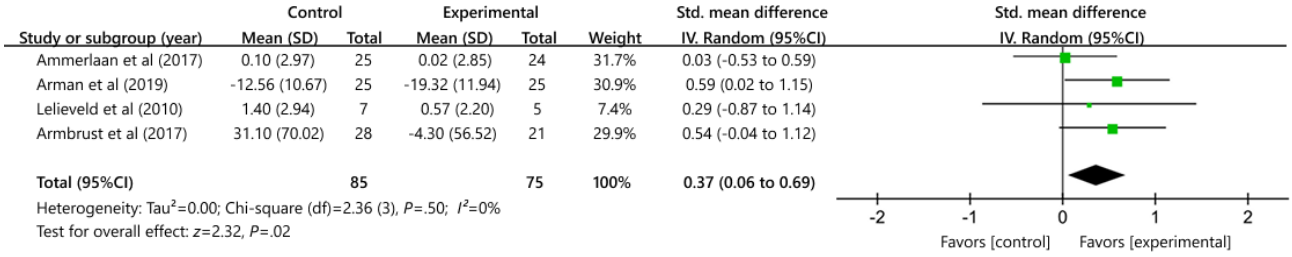

Figure 3. Effectiveness of digital health on pain outcomes [32,36,37,39,41].

Physical Activity

Figure 4 demonstrates the results of the effectiveness of using digital health care on patients' physical activity compared to using usual care and public websites. This analysis is based on findings from 4 studies involving 160 participants. The digital intervention had a statistically significant positive effect (SMD 0.37, 95% CI 0.06-0.69), and the results were not highly heterogeneous (*P*=.50; I^2=0%). Several studies posed a moderate-to-high risk of bias and inconsistency, resulting in a low GRADE rating for the quality of evidence after the intervention.

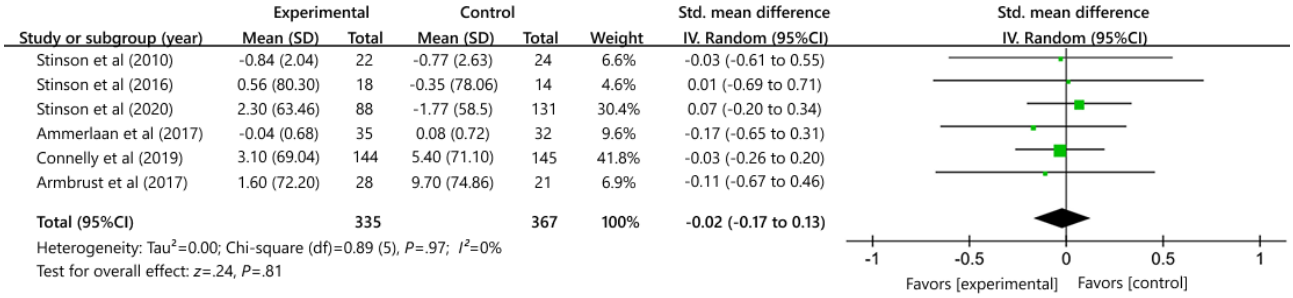

Figure 4. Effectiveness of digital health on physical activity outcomes [32,34,35,42].

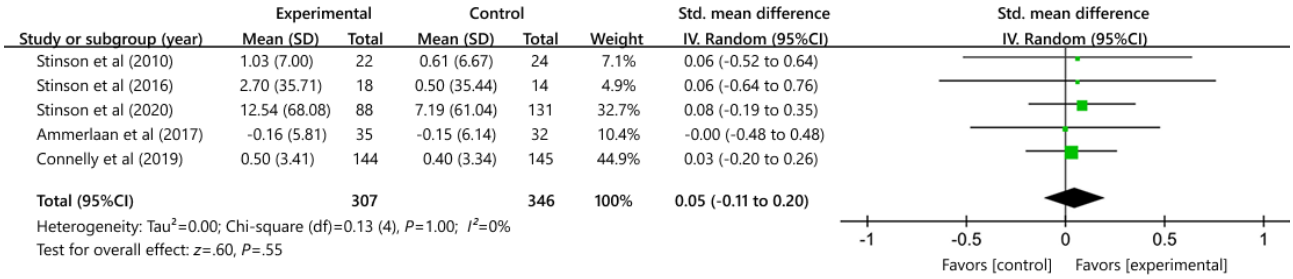
Health-Related Quality of Life

A total of 6 studies with 702 participants comparing digital interventions and control conditions did not show a difference in health-related quality of life between the 2 intervention conditions (SMD 0.02, 95% CI −0.17 to 0.13); heterogeneity (*P*=.97; I^2=0%; Figure 5). Using the GRADE approach, the quality of evidence was rated moderate because of the high risk of bias in most studies (ie, incomplete data).

Figure 5. Effectiveness of digital health on health-related quality of life [32,35-37,39,41].



Self-Efficacy

A total of 5 studies with 653 participants comparing digital interventions and control conditions did not show a difference in self-efficacy between the 2 intervention conditions (SMD 0.05, 95% CI −0.11 to 0.20); heterogeneity (*P*=1.00; I^2=0%; Figure 6). Using the GRADE approach, the quality of evidence was rated moderate because of the high risk of bias in most studies (ie, incomplete data).

XSL•FO
RenderX

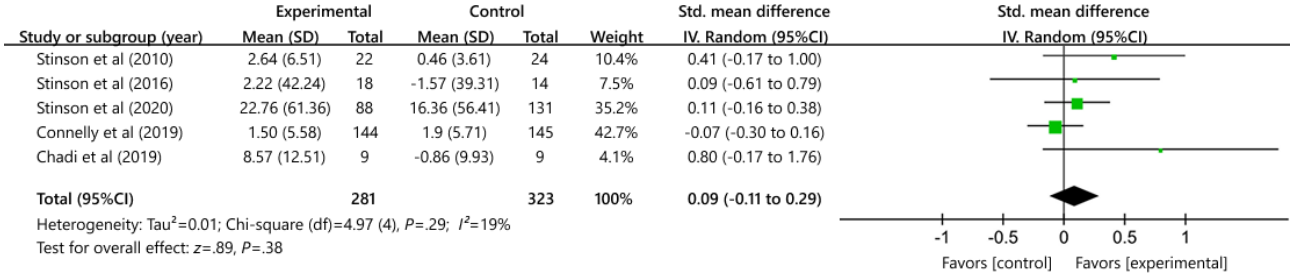


Figure 6. Effectiveness of digital health on self-efficacy outcomes [32,36,37,39,41].

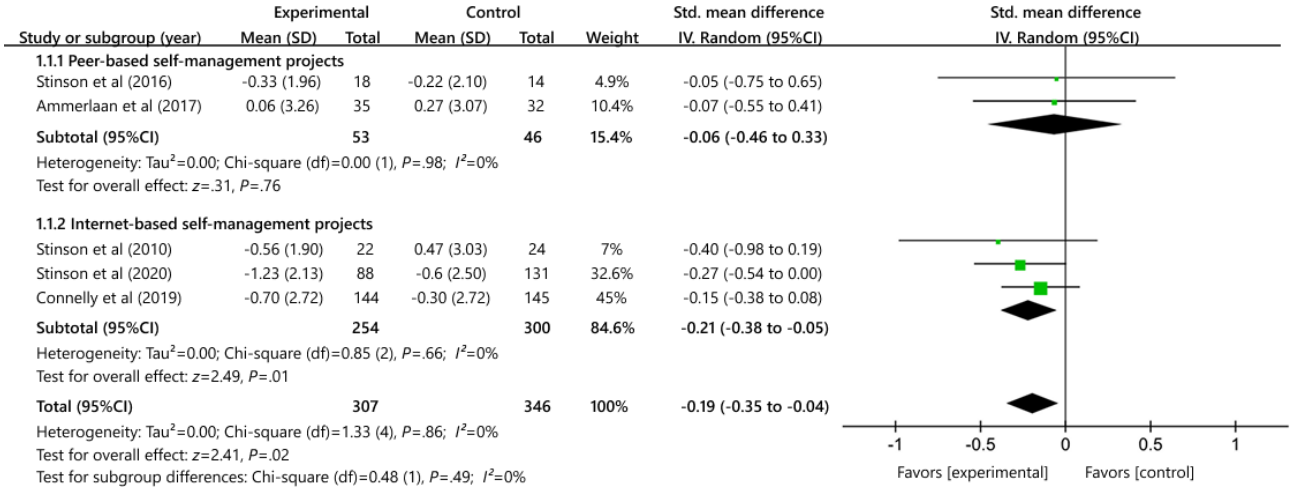
Disease-Related Issues

Figure 7 demonstrates the effectiveness of interventions using digital health technology on patient outcomes for disease-related problems compared with other control conditions. A total of 5 studies included 604 participants (SMD 0.09, 95% CI −0.11 to 0.29) suggests that the effect is ultimately insignificant. The results exhibit minimal heterogeneity (P=.29, I^2=19%). The evidence following the intervention was assessed as moderate in quality using the GRADE methodology, owing to the presence of bias risk and inconsistency across certain studies.

Figure 7. Effectiveness of digital health on disease-related issues [36-39,41].

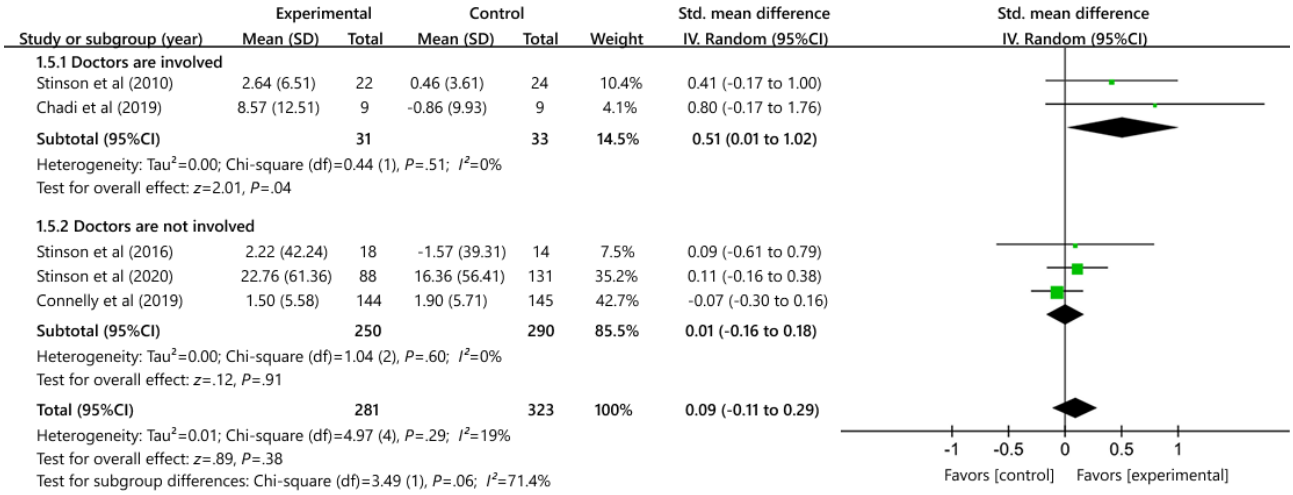


Subgroup Analysis

Effects of Peer Mentoring on Pain Outcome

The subgroup analysis revealed that the internet-based self-management program (n=3) resulted in a moderate effect size in pain reduction (SMD −0.21, 95% CI −0.38 to −0.05; heterogeneity χ^2_2=0.85; P=.66; I^2=0%; Figure 8). However, our findings showed no significant effect of iPeer2Peer and Challenge Your Arthritis (n=2) on pain (SMD −0.06, 95% CI −0.46 to 0.33; heterogeneity χ^2_1=0.00; P=.98; I^2=0%). Subgroup differences in pain outcomes were not significant between peer mentoring programs and other internet programs (P=.49; I^2=0%).

Figure 8. Effects of peer mentoring on pain outcomes [32,36,37,39,41].



Effects of Physicians on Disease-Related Issues Outcome

The disease-related issues in studies with physicians improve more than those without physicians as the main component of the intervention (SMD 0.51, 95% CI 0.01 to 1.02 and SMD 0.01, 95% CI −0.16 to 0.18, respectively; Figure 9). However, the difference was not statistically significant (SMD 0.09, 95% CI −0.01 to 0.29; heterogeneity χ^2_4=4.97; P=.29; I^2=19%).

XSL•FO
RenderX

Figure 9. Effectiveness of e-health on disease-related issues when physicians are involved [36-39,41].

Discussion

Principal Findings

This systematic review comprehensively assessed studies on the effectiveness of digital interventions in aiding children and adolescents with JIA from physical and psychologically perspectives. According to the findings, patients who received digital medical technology interventions had significantly better physical activity outcomes (SMD 0.37, 95% CI 0.06-0.69) and experienced a reduction in pain outcomes (SMD −0.19, 95% CI −0.35 to −0.04) in comparison with those who received standard care. However, our research did not identify significant enhancements in disease-related issues (SMD 0.09, 95% CI −0.11 to 0.29), health-related quality of life (SMD −0.02, 95% CI −0.17 to 0.13), or self-efficacy (SMD 0.05, 95% CI −0.11 to 0.20).

Primary Findings

Overview

The use of digital interventions delivered through the internet or mobile devices has expanded mental health practices for children and adolescents facing JIA in local contexts [46,47]. These interventions offer flexible training schedules, overcome constraints of space and time [48], ensure anonymity, and allow for behavioral adaptation. Nevertheless, our findings indicate that interventions using digital medical technology have a more pronounced impact on physiological outcomes, aligning with earlier research conducted by Butler et al [26]. This emphasis on physiological outcomes may be attributed to the inclusion of components targeting physical activity and motor skills in the interventions, such as fitness regimens, varied exercises, and intensive training. However, the interpretation of psychological outcomes is more complex, influenced by various factors including personal psychological state, social environment, and cultural background. In addition, achieving and sustaining psychological transformations often requires an extended period. While these potential reasons have not been examined, our findings indeed illuminate the distinct physiological and psychological effects of digital medical interventions, offering a new perspective for understanding and evaluating their merits. Further investigation is needed to compare the impacts of digital medical interventions on physiological and psychological outcomes, and to identify strategies for optimizing intervention effectiveness in diverse contexts.

Pain

Our findings demonstrated a notable reduction in pain-related outcomes following the implementation of digital interventions. Two of these studies focused on young patients with JIA transitioning to adult care facilities, who demonstrated high self-efficacy and positive attitudes. In addition, 3 studies implemented a telephone-based therapeutic communication intervention. Subgroup analysis outcomes revealed that patients using an internet-based self-management program (Teens Taking Charge) [36,39,41] experienced a great reduction in pain symptoms compared with those using a peer-directed self-management program [32,37]. These findings align with a pilot feasibility study on peer coaching for adolescents with chronic pain [18], where the control group showed superior pain reduction status. This discrepancy may be attributed to the absence of explicit pain symptom sections in the self-management programs examined, which focused instead on social relationships and goal-setting. In contrast, the control group's website included comprehensive content addressing pain understanding and management, alongside audio and video features. In addition, Dennis et al [49] demonstrated that trained peer mentors could provide informational, evaluative, and emotional support to individuals with similar conditions, albeit without explicitly addressing pain relief. Hence, there is a need for studies about the usability of digital tools for managing pain symptoms in future research. These tools should go beyond mere documentation of pain symptoms and incorporate functionalities aimed at alleviating functional limitations, providing medication and exercise guidance, and offering strategies for managing low mood. Such enhancements are essential for improving the quality of life for patients coping with pain [50].

Physical Activity

Engaging in physical activity is essential for managing arthritis in patients [51]. Consistent with previous research findings [26], 4 findings emphasized the positive impacts of the internet interventions on physical activity. The majority of these studies

XSL•FO
RenderX

incorporate clinically recommended activity training, which increases physical activity levels and improves endurance among patients. Studies suggest that individuals with arthritis can prevent disability and complications by promoting healthy physical activity throughout their lives [52]. However, as demand for face-to-face health care interventions for supporting physical activity adoption and maintenance increases, resource constraints become more pronounced [53]. In a previous study, serious games were used in joint rehabilitation for patients with JIA [54-56]. The findings indicated that these interventions led to increased levels of physical activity among the patients. Our findings support this observation, as 1 of the 4 studies using video games for task-oriented activity training [42] showed improvements in patient outcomes. However, concerns have arisen regarding potential inaccuracies in the effectiveness of exercise diaries and activity monitoring accelerometers used by children. Therefore, there is a need for more accurate methods of data acquisition. We advocate for the development of additional digital tools that integrate health education and physical activity-focused content.

Secondary Findings

The secondary outcomes such as self-efficacy, health-related quality of life, and perception of disease-related issues did not show statistical significance. The previous research shows similar results. Lancaster et al [57] and Newby et al [58] did not find positive impacts of digital interventions on self-efficacy and quality of life. This discrepancy may be attributed to the measurement of self-efficacy which may not be adequately tailored to the conceptual, linguistic, and objective needs of children [32]. However, it is anticipated that improvements in quality of life may require more time to manifest [59], and changes might not be evident during shorter intervention periods. The Medical Issues, Exercise, Pain, and Social Support questionnaire, encompassing inquiries regarding medical matters, physical activity, psychological well-being, and social support [60], may experience compromised efficacy if a patient is insensitive to one of its components, indicating a limited awareness of disease-related concerns.

Other Findings

It is worth noting that not all psychological interventions are ineffective. The subgroup findings show that when physicians are involved in intervention implementation, children and adolescents show improved understanding of disease-related issues. Previous research shows that online health communities involving both patients and health care providers can improve mental health in chronic conditions by allowing patients to consult and interact with physicians [61,62]. Physicians provide essential health knowledge, emotional support, and guidelines for the use of medical supplies, which is crucial for improving the health status of individuals with chronic conditions [63]. To improve intervention outcomes, digital interventions should incorporate features for real-time interaction with healthcare providers, enabling physicians to offer clinical insights and socioemotional support, thereby strengthening the doctor-patient relationship and improving health outcomes.

Furthermore, video-based mindfulness interventions have shown benefits for populations with chronic illnesses and other conditions [64,65]. A study comparing the efficacy of online mindfulness interventions and in-person interventions in enhancing the mental well-being of patients with JIA observed a notable decrease in anxiety and depression [38]. This reduction may be attributed to adolescents experiencing greater ease and relaxation in the familiar setting of their homes [66]. Furthermore, Voerman et al [67] found that digital interventions incorporating cognitive behavioral therapy led to significant improvements in the psychological and social outcomes of patients. Specifically, relaxation exercises and cognitive behavioral therapy effectively reduced pain frequency in children and adolescents, alleviating depressive symptoms and functional disorders [68]. Future investigations should aim to integrate a theoretical framework that addresses the psychological dimensions of the condition, ensuring a more comprehensive approach to intervention design.

Limitations

Half of the studies (5/11) used digital tools that have been developed for over a decade, they may thus fail to represent the latest advancements in communication technologies and platforms. However, our findings indeed show their continued relevance and effectiveness. Second, the results of this review demonstrate that, from a statistical perspective, digital interventions are effective for certain patient outcomes. However, considering factors such as individual differences and variability in clinical environments, their clinical significance remains to be further validated. Future research should provide stronger evidence from a clinical perspective. Furthermore, the included studies are predominantly conducted in North American and European nations. As such, the findings of this analysis may not be universally applicable and may only offer insights into the integration of digital interventions within this specific population.

Conclusions

This systematic review analyzes self-reported outcomes in patients with JIA, including pain, physical activity, quality of life, self-efficacy, and disease-related issues. The findings from 11 RCTs demonstrate that digital interventions significantly alleviate pain and improve physical activity. These results highlight the potential of digital tools to enhance JIA management and patient outcomes, providing a strong case for their integration into clinical practice. Future studies should consider the inclusion of physicians in digital interventions to better understand their impact on outcomes.

Abstract

Background: Management of children with functional abdominal pain (FAP) or irritable bowel syndrome (IBS) is difficult in primary care. When education and reassurance do not alleviate symptoms, primary care physicians lack treatment options for children with FAP or IBS. Home-based guided hypnotherapy is a promising treatment because of its accessibility. To address feasibility, it is of utmost importance to take experiences from children and their parents into account.

Objective: We aimed to explore children's and their parents' experiences with home-based guided hypnotherapy for children with FAP or IBS.

Methods: This qualitative study used open-ended questions from a questionnaire and in-depth semistructured interviews with children and their parents who had a hypnotherapy intervention prescribed. The interviews were audio-recorded and transcribed verbatim. Data were collected and analyzed iteratively using thematic content analysis.

Results: A total of 76 children were eligible, and we collected questionnaire data from 56 children. A total of 23 interviews were conducted with 10 children and 15 parents. Six themes emerged from questionnaire data and interviews: impression of the exercises, not for everyone, influence of perceived effect, integrating exercises in daily life, content and practicalities of the website, and customization to personal preferences. Children with FAP or IBS experienced home-based guided hypnotherapy and the exercises differently, ranging from boring to fun. From interviews with the parents, it emerged that hypnotherapy is not suitable for everyone; for example, when children are very young or have a low developmental level, cannot sit still, cannot surrender to the exercises, or are too energetic or stressed, it might be difficult to comply. Experiences were shaped by the influence of a perceived effect and to which extent children were able to integrate exercises in daily life. The content and practicalities of the website also influenced experiences, and hypnotherapy that is adaptable to personal preferences, including by appearance and content, would be highly appreciated.

Conclusions: The children and parents experienced home-based guided hypnotherapy differently, ranging from boring to fun. Hypnotherapy might be difficult or boring for some children. The children enjoyed hypnotherapy when they liked the topic or story, felt positive effects, could easily integrate exercises in daily life, or enjoyed the website in general. The children's experiences and adherence can be further improved by adding short exercises and customizing hypnotherapy to their personal preferences on the website's appearance and content. This could increase effectiveness but must be studied further.

Introduction

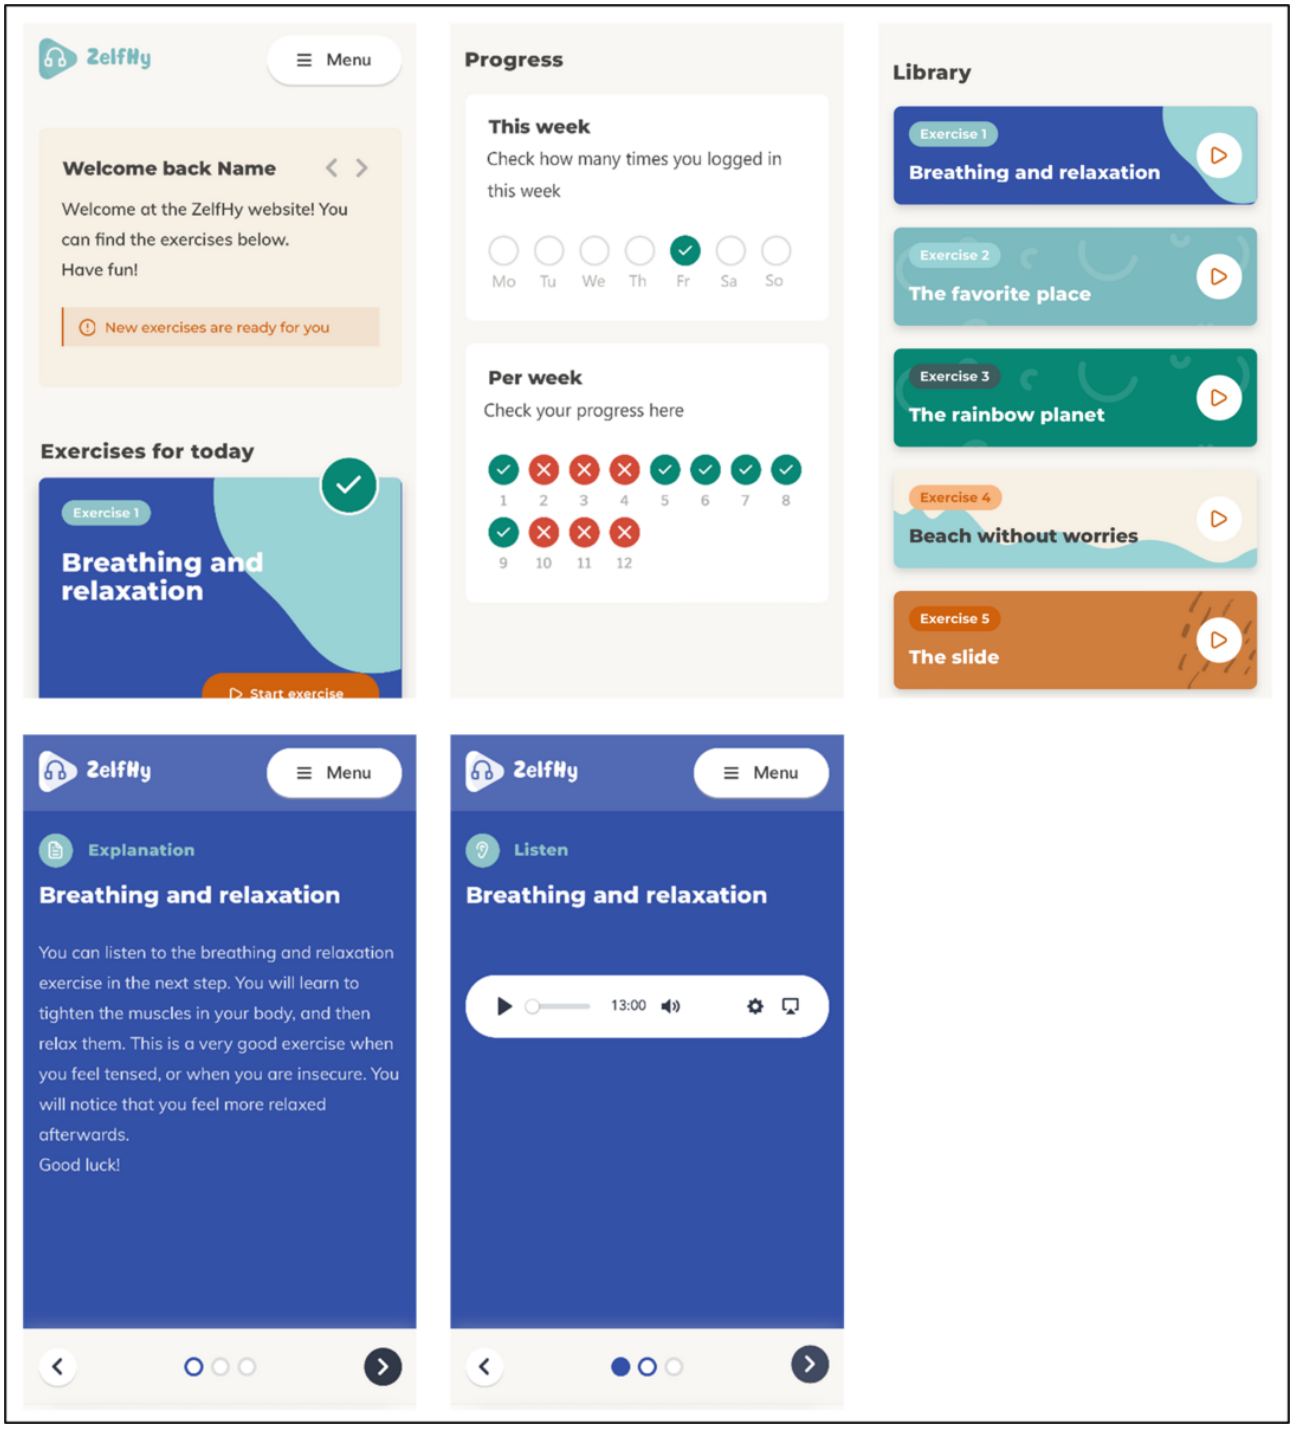
Disorders of gut-brain interaction such as functional abdominal pain (FAP) and irritable bowel syndrome (IBS) are chronic pain conditions without organic cause [1]. These disorders are common in primary care, as a general practitioner (GP) sees approximately 10 children with disorders of gut-brain interaction each year [2,3]. Dutch GPs diagnose FAP or IBS when after medical history and physical examination, no underlying tissue damage, somatic causes, or metabolic or anatomic abnormalities can explain the symptoms of the child [4]. FAP and IBS are associated with lower quality of life, school absence, and higher anxiety and depression scores [5,6], and around 50% of children in primary care still report abdominal complaints one year later [7]. Management consists of education and reassurance, but if this fails to alleviate symptoms, there are few evidence-based treatment options in primary care. Children with abdominal pain and their parents report a desire for receiving a specific diagnosis and a need for information about its cause and treatment options [8-10]. Children often adopt coping mechanisms by themselves, such as reassurance and a calm approach, distraction techniques, breathing exercises, and bedtime meditation [11]. Hypnotherapy could be a treatment option, as it has shown to be effective in children referred to secondary pediatric care [12,13]. However, it has not been studied in primary care. Research in primary care is important because a different setting, selection of patients, and organization of care might influence treatment effects.

With hypnotherapy, a patient is induced into a hypnotic state and guided to suggestions by a therapist or by listening to audio-recorded exercises in their home environment (ie, home-based guided hypnotherapy) [13,14]. Home-based guided hypnotherapy is promising in primary care because of its accessibility [15]. Very few mild to moderate side effects of hypnotherapy are reported [16], and the fact that children can do it by themselves without involvement of others makes primary care an interesting setting. Experiences with home-based guided hypnotherapy in children with FAP or IBS have not been studied yet. Insights in experiences of children and their parents are important for successful implementation [17]. In this study, we aimed to explore experiences of children with FAP or IBS and their parents with home-based guided hypnotherapy, and to capture their ideas about potential areas for improvement.

Methods

Design

This qualitative study is part of the ZelfHy study, a randomized controlled trial (RCT) evaluating the effectiveness and cost-effectiveness of home-based guided hypnotherapy in children with FAP or IBS in primary care (ClinicalTrials.gov NCT05636358) [18]. The participants in the intervention group had access to a 3-month, home-based, guided hypnotherapy program. This study used questionnaire data of open questions and log data from the ZelfHy study of participants who received the intervention, and in-depth, semistructured interviews with a purposively selected sample of children and their parents.



We followed the Consolidated Criteria for Reporting Qualitative Research [19].

Home-Based Guided Hypnotherapy Program

The children in the intervention group of the RCT received standard care and home-based guided hypnotherapy for 3 months. Before starting, a researcher explained hypnotherapy, its benefits for abdominal pain, and access methods during a video call with the child, parent, or both. They were also advised not to discuss the pain. The hypnotherapy program included 5 exercises: 1 breathing and relaxation exercise and 4 visualization exercises: “the favorite place” or “the favorite place+ rainbow” (age-dependent), “the rainbow planet” or “air balloon” (age-dependent), “the beach without worries,” and “the slide.” Two exercises comprised 2 versions with adjustments in language: for children aged <12 years and ≥12 years. Exercises were audio-recorded by a hypnotherapist. Instructions and exercises were hosted on a responsive website, as shown in Figure 1. All exercises were immediately available, but the children were guided to listen to the first 2 exercises for the first 2 weeks, adding new exercises every 1 to 2 weeks. They could choose and repeat exercises whenever they wanted. The children were encouraged to practice at least five times a week for 15 - 20 minutes daily for over 3 months. Automatic email reminders were sent after 14 and 28 days of inactivity to improve compliance.

XSL•FO
RenderX

Figure 1. Screenshots of the website taken from a smartphone.

Patient Participation

One mother of a girl aged 9 years and one male adolescent aged 19 years who both finished the intervention were engaged, and both received a voucher. Patient participation included attending 2 research team meetings and member checking the final results. The 2 research team meetings included discussion of the interview guide before the interviews, and discussion of topics, codes, and preliminary themes after the first interviews.

Recruitment and Participants

In this qualitative study, all the children and their parents in the intervention group of the RCT were included. Children aged 7 - 17 years with FAP or IBS according to their GP participated in the RCT. Exclusion criteria for participation in the RCT were a concomitant organic gastrointestinal disease, being managed for abdominal pain by a pediatrician, intellectual disability, psychotic disorders, a history of hypnotherapy in the past year, and poor comprehension of the Dutch language. Detailed information of recruitment methods for the ZelfHy study are described elsewhere [18].

All the children and their parents were invited to answer the questionnaire. Additional inclusion criteria for in-depth interviews for this study were that the children had to be within the 3-month intervention time frame at that time, and live in the

XSL•FO
RenderX

Northern or Middle part of the Netherlands because of travel convenience. Purposive sampling was used to achieve diversity in age, gender, and therapy adherence based on automatically logged data for the user interactions. The first author, a female primary care researcher, invited parent-child dyads for interviews via telephone approximately 6 weeks after they started the intervention. We assumed that halfway through the intervention, the children listened to all exercises and were able to recall and express their experiences. In practice, with time delay such as decision to participate and setting a date for the interview, interviews would be held in weeks 8 - 12. The authors believe that this was enough time to shape experiences.

Data Collection

Questionnaire data consisted of open-ended questions regarding what they liked and disliked generally, and for each exercise separately (Multimedia Appendix 1). Questionnaire data were collected through an electronic data capture system at 3 months follow-up between March 2021 and January 2024. The parents completed the questionnaire for the children aged <12 years, and the children aged ≥12 years completed the questionnaire themselves, with parental help as needed. Additionally, we collected log data from the intervention consisting of how long the children listened to each exercise per session. A session was defined as a log-in and start of at least one exercise. In accordance with a previous study on the effectiveness of hypnotherapy, we defined adequate use as starting at least four different exercises [18,20].

From May 2023 to December 2023, a female primary care researcher and trained interviewer (ING) and a female social scientist with expertise in qualitative research and trained interviewer (MAA) conducted semistructured interviews. The first author had contact via telephone with the parents for study procedures for the ZelfHy study before the interview. The interviews took place at the participant's home, except for the children with low adherence. For convenience, the parents of these children were interviewed by telephone and they did not necessarily have to live in the Northern or Middle part of the Netherlands. Interviews were recorded using a digital voice recorder and transcribed verbatim. Field notes and short memos were written during and after each interview.

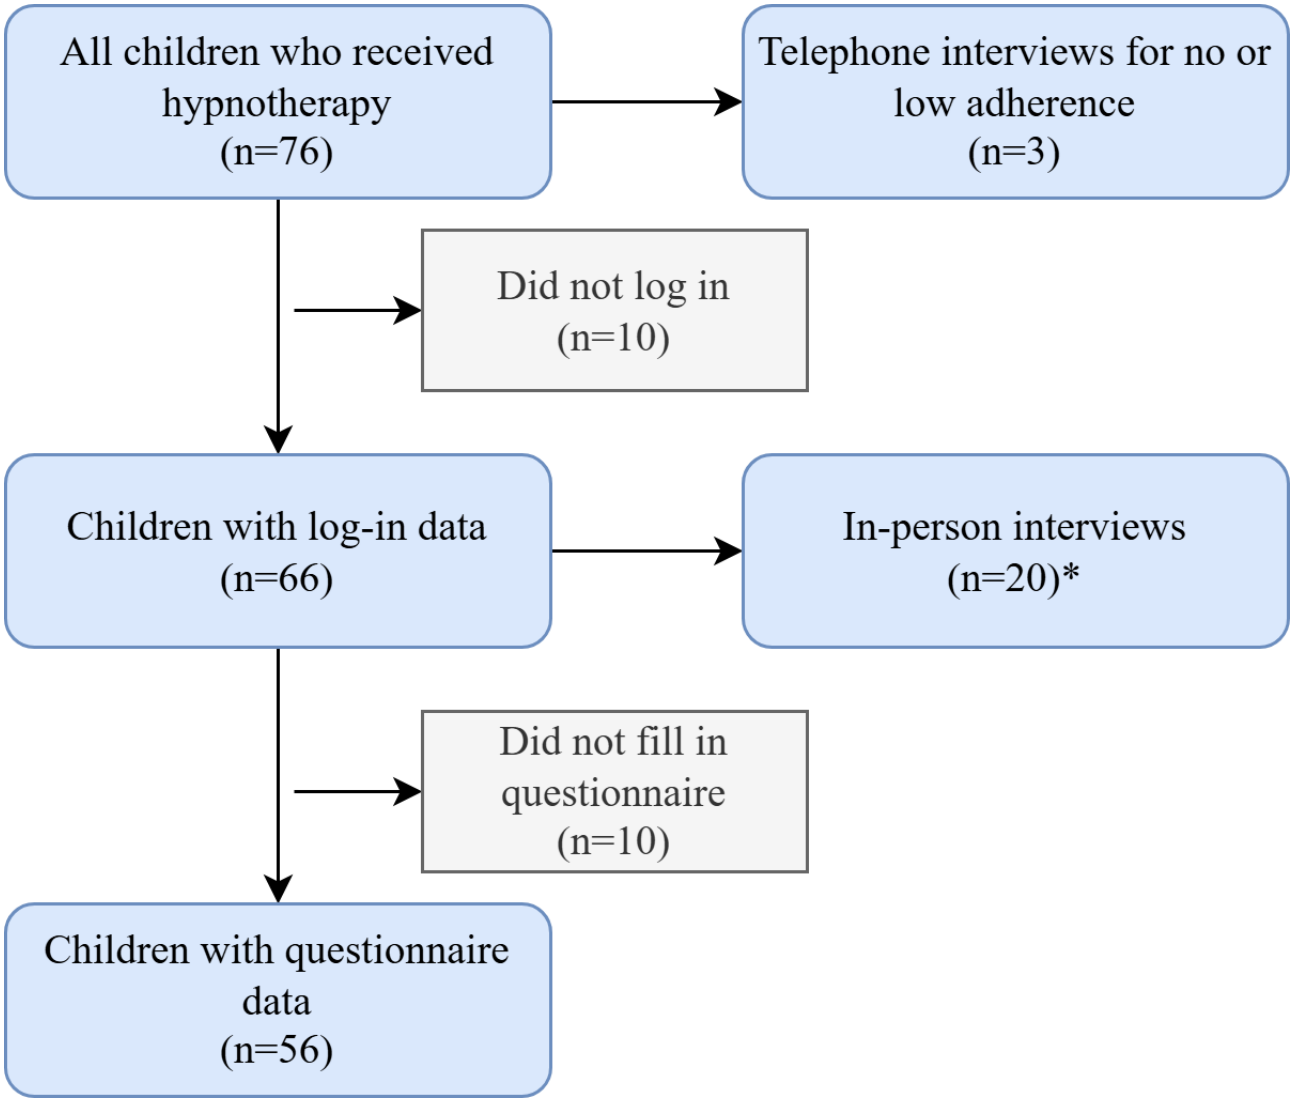
To develop the semistructured interview guide, we used sensitizing concepts from literature and expert discussion with the research team which consisted of a female primary care researcher, a female primary care research assistant, one female epidemiologist, one female social scientist, and two female GPs. The interview guide consisted of open-ended questions about the children's and parents' experiences with the therapy (Multimedia Appendix 2). Interviews were performed until data saturation was reached (ie, interviews no longer generated relevant concepts). We completed 3 additional interviews with the children and their parents in which no new codes were found. Iterative meetings with the research group were held to evaluate and update the interview guide for new concepts and discuss data saturation.

Data Analysis

Thematic content analysis was conducted as proposed by Braun and Clarke for questionnaire data and interview transcripts [21]. First, all questionnaire data and 10 interview transcripts were read and inductively and independently coded by ING (both questionnaire data and interview transcripts), GAH (questionnaire data and female epidemiologist), and ALvdV (interview transcripts and female primary care research assistant). ING coded the remaining transcripts and ALvdV checked the coding of these transcripts. Inconsistencies between coders were discussed until consensus was reached. Consequently, emerging themes and subthemes were discussed and redefined with the research team until consensus was reached. In one of these meetings, a mother and adolescent were part of the research team. Illustrative quotes were translated from Dutch to English by a native English speaker and editor, and the first author checked whether their meaning was retained. All analyses were facilitated using Atlas.ti (version 23; ATLAS.ti Scientific Software Development GmbH) software.

Ethical Considerations

The Medical Ethics Review Committee of the University Medical Center Groningen, the Netherlands, confirmed that the Medical Research Involving Human Subjects Act which includes the Declaration of Helsinki, did not apply to this qualitative study (number 202200110). All the participants gave informed consent. Participant data were deidentified after the interviews. No compensation was provided.



Results

Participants

In total, 76 children were eligible from the intervention group of the RCT. Their median age was 9.1 (IQR 8.1 - 11.2) years and 51 (67.1%) children were female. Of these 76 children, 20 children did not log in (n=10) or failed to complete the questionnaire for other reasons (n=10), resulting in questionnaire data from 56 children (Figure 2). For in-person interviews, 29 children were eligible because they were within the 3-month intervention period and lived in the Northern or Middle part of the Netherlands. We invited 19 children to participate in an in-person interview, of which 9 declined to participate because of personal circumstances (n=3), no interest (n=3), or no further reason (n=3). In addition, 3 parents of the children with low adherence were invited for a telephone interview. Interviews contained 13 children, of which 4 did not fill in the questionnaire. A total of 23 interviews were conducted, which lasted 19 - 63 minutes for in-person interviews and 5 - 11 minutes for telephone interviews. The in-person interviews included 10 children and 12 parents, of which 2 interviews were performed with both parents. The telephone interviews included 3 parents of the children with low adherence (Table 1).

[a]Educational level was considered low (primary and lower secondary), intermediate (secondary vocational), or high (Bachelor's degree or higher).

[b]Number of sessions until the date of the interview.

[c]Telephone interviews were conducted with a parent only.

Adherence to Hypnotherapy

Of the 66 children that did log into the website, 3 children did 1 exercise, 3 children did 2 exercises, 8 did 3 exercises, 8 did 4 exercises, and 44 children did all 5. Consequently, 52 of 76 (68.4%) children adequately adhered to the intervention. The children did on average 25.5 (SD 23.2) sessions (median 17, range 1 - 89), and listened to more than one exercise in an average of 6.8 (SD 9.0) sessions (median 4, range 0 - 43). Log data per exercise are described in Table 2.

Experiences From Children and Their Parents

Overview

From questionnaire data and interviews, we found 6 themes that capture experiences from the children and their parents: impression of the exercises, not for everyone, influence of perceived effect, integrating exercises in daily life, content and practicalities of the website, and customization to personal preferences. For every quote, corresponding IDs from Table 1 are listed.

Impression of the Exercises

We found varying impressions of the therapy, ranging from nice, fun, and easy to stupid, boring, and difficult.

> *Then you have the feeling that you are really on a beach, and you can put all the feelings you don't want into a sand castle, so I really like that.* [Child 10]

> *The exercises themselves are a bit boring, because you have to keep doing the same thing every day.* [Child 2]

Most children felt relaxed during or after listening to an exercise and often had a positive association with a topic or liked the story in the exercises. The children enjoyed that they could choose what they wanted to see or do in their imagination.

> *And I really like the slide exercise because I like sliding a lot, and you can choose a color, and you can choose how fast you want to go.* [Child 1]

Although most of the children liked to visualize during the exercises, some of the children thought too little was happening. The children had conflicting ideas about exercises that required more physical activity such as stretching and relaxing muscles, or writing down colors and feelings.

> *I find the exercises boring because you just have to listen. I would rather have something to do, like filling in the colors of the rainbow planet.* [Child 1]

> *I liked just listening instead of having to actually do things.* [Child 5]

The children particularly enjoyed exercises in the beginning, when they were new and the children did not yet know what would happen. For some of the children, exercises became boring over time.

> *Because I know the exercise very well I can't really imagine anything different than what I do now when I listen to the exercise.* [Child 3]

The other children enjoyed knowing the exercises well.

> *Now I already know a few pieces by heart, so then I enjoy listening to them over and over again.* [Child 4]

Each exercise was experienced differently with diverse positive and negative aspects. An overview of impressions per exercise is presented in Multimedia Appendix 3.

Not for Everyone

From interviews with the parents it emerged that they expected both boys and girls with FAP or IBS to be suitable for hypnotherapy. However, some of the parents were more skeptical about a child's age or developmental level. Although children of all ages thought that the exercises were easy or somewhat childish, a few of the children noted that exercises were too difficult; they included difficult words or were spoken too fast. Some of the parents of children aged 7 or 8 years noted that their child was around the minimal age or level to remain focused for the entire exercise or understand why these exercises could help.

XSL•FO
RenderX

> *If she is just a bit older maybe then it might be a bit more effective. That she would understand it a bit better, and be better able to recall things in certain situations.* [Mother 7]

The parents also noted that certain characteristics could help the children in doing hypnotherapy successfully, such as being calm, creative, less rational, and having patience and high imaginary skills. The parents mentioned that energetic children might benefit most from relaxing but might need more time and practice. Indeed, some of the children did not like that they had to sit or lay still.

> *Because then I start thinking, shall I sneak and read something or just keep my eyes open, because I'm bored. I can't sit still. Look, I'm always fidgeting with my fingers.* [Child 1]

Some of the children needed time to become used to the exercises and understand how to follow instructions. A few of the children were never able to surrender to the exercises because, for example, they could not imagine the suggestion, they did not like the stories, or they felt something and could not give in to the feeling.

> *My child often strongly resisted doing the exercises because they made her sleepy and she didn't want to give in to that. "Because of them I can't hear my own dreams anymore."* [Mother of girl aged 8 years, 24 sessions, reported in the questionnaire]

The parents mentioned that sometimes when their child was too energetic or too stressed from events or stimuli, they could not concentrate and do the exercises in order to relax.

> *Now I had the idea that it even worked against her, that she first had to deal with her own things, and that hypnotherapy… that it wouldn't go together.* [Mother 1]

Influence of Perceived Effect

Feeling an effect of the therapy affected experiences of the children. Although a few of the children experienced less abdominal pain but did not like the exercises, most did. Primarily because it made their belly feel good, or because their pain decreased or disappeared. They also experienced other effects such as greater confidence, better sleep, more energy, more relaxation, a clearer mind, and more frequent school attendance.

> *I really like it, because you know that it relaxes you a lot.* [Child 3]

When the children experienced less abdominal pain either through the exercises or for another reason, some of the children and parents felt less need to continue the exercises and quit.

> *When she was in pain and started an exercise, it helped to reduce the pain. But when she did not have pain, she did not feel like doing the exercises or see the benefit of them.* [Mother 13]

Some of the children were not able to relax during the exercises, and felt that the exercises did not help to remove their pain. They felt stressed because it did not work for them. Doing hypnotherapy felt like an obligation; this resulted in resistance or discontinuation.

> *We have decided not to do the exercises anymore because they led to more frustration than success.* [Mother of girl aged 9 years, 9 sessions, reported in the questionnaire]

Integrating Exercises in Daily Life

Many of the children enjoyed doing the exercises on their own, without involvement of others who could distract them. A few of the children mentioned that they would not do hypnotherapy in the presence of friends, because they would not like to explain what it is, or be different from their friends or classmates. The other children sometimes listened together with their parents or siblings which made them feel more relaxed. The parents also played an important role by reminding their children to do the exercises, because they did not come up with it themselves, were not in the mood, or forgot it.

> *Stimulate her to do the exercises. She doesn't think to do them or ask for them. So I have to motivate her a bit.* [Mother 1]

Most of the children listened to exercises before going to sleep. Taking a device to their room was sometimes difficult for the parents because they usually withhold their children from screen time before bedtime. The children and parents appreciated that the exercises were easily accessible for the children to listen at home where they felt comfortable and at ease, such as on their bed.

> *I really like that you don't have to go anywhere. That you can just sit or lie down in your own house, in your comfort zone.* [Child 8]

Most of the children accomplished making it a routine in their daily schedule which made listening to the exercises easier and more fun.

> *He definitely doesn't want to skip it in the evening. It becomes a kind of evening ritual: tooth-brushing, pajamas on and listen, and then to bed.* [Mother 8]

The parents appreciated being able to use this as a tool when necessary, such as when their child was stressed or energized and needed to relax. Not all of the children and parents managed to integrate hypnotherapy into their routine. Some of the children were put off by doing hypnotherapy again because of the time constraint. A few of the parents noted that there is not enough time in a day to add 15 minutes of hypnotherapy, because it was not feasible to do it before school or before bedtime.

> *Because sometimes the exercises are long, you sometimes practice a bit less, or maybe even not at all.* [Mother 9]

The parents from the children with low adherence mentioned that they never started hypnotherapy because the children and their parents could not find a good moment in the first place.

> *Several times we thought of it, but then we thought, ah, we'll do it later. And every time that later never came.* [Mother 11]

XSL•FO
RenderX

Content and Practicalities of the Website

Information was perceived as clear and interesting, though there might have been somewhat too much information for younger children according to the parents. The distinction between exercises and explanation was not always clear on the website. The children thought that there was an extra exercise, but felt disappointed when they saw it was an explanation only.

Insight in log-in data (ie, a small red cross for not logging in, or a green check for logging in, both per day and weekly over the entire 3 months) was experienced both positively and negatively. For some of the children this insight motivated them to do the exercises and obtain more green checks, and for others this worked counterproductively; they felt frustrated, angry, or ashamed.

> *If I haven't practiced for a couple of weeks, for example, because I am busy, then I feel a bit, uh different, that I haven't done it right, that there will be red crosses.* [Child 3]

For most of the participants, the website functioned well technically. However, some of the children experienced that the exercise stopped when the screen automatically turned off. This got them out of their concentration and affected their experiences negatively.

> *So then she's totally caught up in the story, and then she has to turn all the way around, click on that thing and install herself again.* [Mother 1]

The children preferred using different devices, such as a smartphone, tablet, or computer. Many of the participants noted that a website was unpractical, since the children needed to fill in their log-in codes every time, were dependent on a parent nearby, or were unable to do it on the go. Sometimes, this made doing the exercises a barrier for the children. The parents suggested the use of an app instead of a website.

> *If he could just do it in an app, that you just use a password one time and then you can just turn it on, then it would have been easier and he would have done it more quickly.* [Mother 6]

Customization to Personal Preferences

The first aspect that the children would have liked to customize is appearance of the website and the exercises. The children and parents would have preferred to choose from different voices which can differ in speed. Overall, the children liked the looks of the website, but they had different ideas: some liked it simple as it is, others would have liked brighter colors such as pink and purple. The children would have liked to choose between colors on the website, change the background, and add illustrations to the exercises.

> *I thought that the colors could have been brighter. And just as with the iPad you can choose a background, I would like that you could also choose a background here. It really doesn't look so nice, so you think, now, I'm going to do some ZelfHy exercises.* [Child 1]

The second aspect that the children and parents would prefer to customize relates to the content. Most importantly, the participants would have liked more exercises. Only a few of the participants found 5 exercises sufficient. Animals, love, music, flowers, favorite animation, traveling, games, hobbies, and sports were recommended by the children as preferred topics to add more attractive exercises. According to the parents, topics should also be suitable for a child's age or level to be more effective.

> *Because I notice that not every exercise is suited for her. That you could better, yeah, make more personalized exercises. And with things going on in her own environment, because that is, of course, different for a 7-year-old than for a 17-year-old.* [Mother 7]

Additionally, choosing from exercises with different duration, particularly exercises of shorter duration (eg, between 5 and 10 min) is expected to enhance adherence. Shorter exercises would allow children to do an exercise quickly during a weekday, and to combine more exercises in 1 session. In contrast, a few of the parents hypothesized that shorter exercises might yield less effect than long exercises. The participants noted that a combination of shorter and longer exercises would be nice. Longer exercises are deemed useful in the beginning, and once children understand how they work, shorter exercises are expected to keep children more focused and satisfied.

> *I certainly think that the more often you practice, then I can imagine that at a certain point you want to go through such an exercise more quickly, because you have already formed a certain image of it, or you have given it certain colors, or you have associated a certain emotion with it. Then it doesn't have to take so much time.* [Mother 6]

Some of the participants noted that it would be more motivating if the website contained games, or if they could unlock new exercises. The parents also noted that a scoring or rewarding system could help to increase adherence.

> *You could attach a kind of gamification to it, so that the child gets a certain reward when she has done it, so that she wants to do the exercises.* [Father 4]

Discussion

Principal Results

Adherence to hypnotherapy varied greatly: some of the children never started hypnotherapy, some only logged in a handful of times, and most of the children adequately adhered to hypnotherapy by starting at least four exercises. The children experienced home-based guided hypnotherapy differently, both in general and per exercise. From interviews with the parents it emerged that hypnotherapy was sometimes difficult for those children who were young or had a low developmental level, could not sit still or surrender to the exercise, or were too energetic or stressed. Experiences were shaped by the influence of perceived effects, the ability to integrate exercises in daily life, and content and practicalities of the website. Ultimately, the children and parents would appreciate a therapy that can be customized to personal preferences for appearance and content.

XSL•FO
RenderX

Comparison With Prior Work

This is the first study to evaluate experiences of children and their parents with home-based guided hypnotherapy, other studies evaluated other self-guided interventions for children with abdominal pain. A mixed methods study assessing an online self-guided intervention found that children aged 9 - 15 years were satisfied with the intervention [22]. In our sample, we found more variation in the children's experiences, ranging from boring to fun. Possible explanations for this disparity could be that we included a larger sample, also included children with low adherence, and that children with questionnaire data had a broader age range, namely 7 - 17 years. Notably, it was a different intervention and this study showed that characteristics of the website or intervention also influence a child's experiences. The mixed methods study found that children learned to cope with their pain through relaxation or distraction and felt better in general [22]. This is consistent with our findings that experiences of children were influenced by a perceived effect.

In our study, a long duration of the exercises was one of the reasons why everyday adherence was difficult. Some children easily integrated the exercises into daily life, but others had difficulties to make it a routine. The parents who motivated and stimulated their child to listen to an exercise were helpful in integrating exercises in daily life. A mixed methods study assessing a guided imagery app also found no consensus on preferable exercise duration when asking children and parents [23]. In contrast, another study assessing guided imagery found that sessions lasting 10 to 25 minutes were enjoyable, children needed no help or reminders from parents, and most children listened to the exercises more often than instructed [24]. Our results add to the knowledge that preferences for duration of exercises are dependent on children's characteristics, ability to do the exercises, parental involvement and ability to integrate exercises in daily life. Home-based guided hypnotherapy that includes exercises with varying durations would allow that it is suitable and fitting for everyone, because it can be adjusted to children's preferences and time available at that moment.

The children and parents liked the look of the website in general, and a few experienced small technical issues that negatively affected their experience. Another study also mentioned small technical issues in an online intervention [25]. Consistent with a previous study using an app, the log-in procedure was easy [23]. However, in our study, the log-in procedure was also perceived as inconvenient, because it was not easy to use on the go. The parents suggested that an app could solve this inconvenience. A study assessing desirable components in a digital management app for children with long-term, chronic conditions found no agreement on preferences for either a website that is suitable on multiple devices versus an app [26]. This is consistent with our results and suggests that an app is favored, but flexibility of use on other devices should also be taken into account.

This study amplifies what has been found before, that children enjoy being able to do an intervention at home. eHealth interventions can increase adherence to treatment and improve outcomes which might influence effectiveness of the therapy [20,27]. Between the children and parents, there are many individual preferences regarding number and duration of exercises, topics, voices, and looks. Additionally, the child's age or level plays an important role. Consistent with prior literature, rewarding systems or gamification is important in eHealth interventions for children [23,28]. Our study emphasizes the importance of tailoring hypnotherapy to children's age or developmental level, customizing it according to their personal preferences regarding appearance and content, and incorporating gamification components to enhance engagement.

Strengths and Limitations

An important strength of this study is that we interviewed both children and their parents, with varying adherence ranging from zero adherence to daily adherence for 3 months. Interviews with the parents followed after interviews with children and allowed for more depth. Interviews were performed in their home environment, which allowed for a safe environment, and we therefore believe that we captured honest answers.

One limitation is that we primarily interviewed children and young adolescents (age range 7 - 13 y). Therefore, our results might not be generalizable to adolescents. We aimed to interview adolescents aged 14 to 17 years old, but failed because very few adolescents participated in the RCT. Although questionnaire data did include adolescents, and we included an adolescent for member checking, more research is needed on experiences of hypnotherapy among adolescents. Another limitation is that we failed to interview more fathers, as they were not at home during the interview. We believe that this minority of fathers did not influence our study results, because the 2 included fathers did not introduce new themes.

Clinical and Research Implications

This study highlights the importance of personalized home-based guided hypnotherapy to improve a child's experience, and possibly to increase adherence. This is of essence in eHealth, where patients themselves are responsible for following the therapy. Hypnotherapy that is fun to do at home and fitted to each child might be easy to adhere to and more prompting for GPs to promote. Primary care might be a beneficial setting for home-based guided hypnotherapy, as GPs manage most children with these complaints. Providing a self-managing intervention in this setting might prevent referrals to pediatric care and reduce costs [29,30].

Conclusions

The children's and parents' experiences varied greatly and were partly influenced by the topic or story in the exercise. For children who are young or have a low developmental level, cannot sit still, are unable to surrender to exercises, or are too energetic or stressed, home-based guided hypnotherapy might be difficult and needs optimization. Children liked hypnotherapy when they felt positive effects, could easily integrate the exercises in their daily life, or enjoyed the website's content and usability. Children who did not feel effects or found exercises too long often disliked hypnotherapy. A website or an app that is easily accessible and contains short exercises could increase its use. Hypnotherapy that is adaptable to personal preferences on appearance and content could boost the

experiences. In turn, positive experiences might lead to higher adherence, which potentially increases the effect of hypnotherapy and should be studied further.

Acknowledgments

The authors would like to thank all the respondents who took part in this study. We thank Quinten and Angelique for sharing their patient perspective and member checking our study results. We also thank Liesbeth AB, MD, for her general practitioner perspective during the entire research process, and JoAnn van Seventer, MA, for translating the quotations. This project was supported by the Dutch Organization for Health Research and Development, ZonMW (852002035).

Abstract

Background: In the digital age, adolescents increasingly rely on online sources for health-related information. eHealth literacy—defined as the ability to find, evaluate, and apply online health information—plays a crucial role in health outcomes. However, limited research exists on eHealth literacy among Japanese high school students, particularly on its association with menstrual health and psychological well-being.

Objective: This study aimed to assess the eHealth literacy of Japanese female high school students and examine its association with premenstrual symptoms, psychological distress, loneliness, and self-esteem.

Methods: A cross-sectional, web-based survey was conducted in December 2024 among 1607 female students from 2 public high schools in Sendai, Japan. A total of 909 students with regular menstrual cycles completed all survey items. The survey included the eHealth Literacy Scale (eHEALS), Premenstrual Symptoms Questionnaire, Kessler Psychological Distress Scale (K6), Revised UCLA Loneliness Scale, Rosenberg Self-Esteem Scale, and a numerical rating scale for menstrual pain. Statistical analyses, including Student t tests, chi-square tests, correlation analyses, and logistic regression analyses, were used to examine the relationships between eHealth literacy and various health outcomes.

Results: The mean eHEALS score was 22.8 (SD 7.3), with 32.1% (292/909) of participants classified as having high eHealth literacy (eHEALS≥26). Students with higher eHealth literacy reported significantly lower levels of loneliness and higher self-esteem. The severity of premenstrual symptoms, particularly feeling overwhelmed, was significantly lower in the high eHealth literacy group. Additionally, interpersonal difficulties related to premenstrual symptoms were less prevalent among students with high eHealth literacy. Pearson correlation analysis indicated negative associations between the eHEALS score and psychological distress (K6) and loneliness, whereas a positive association was observed with self-esteem. Logistic regression analysis showed that high self-esteem was significantly associated with high eHealth literacy.

Conclusions: This study highlights the importance of eHealth literacy in adolescent health care. Higher eHealth literacy is linked to lower levels of loneliness, higher self-esteem, and reduced premenstrual symptom severity, particularly feeling overwhelmed. Although the cross-sectional design limits causal conclusions, these findings suggest that higher eHealth literacy is associated with better mental and reproductive health in adolescents. Future research should adopt longitudinal designs, include more diverse populations—such as male adolescents—and explore additional contributing factors to better elucidate these associations.

Introduction

Growing Role of eHealth in Adolescent Health

In recent years, many people have begun to use eHealth information to manage their own health [1]. As internet accessibility continues to expand globally, more individuals are obtaining health-related information online. Internet use is also high in Japan, standing at 86.2% in 2023, according to data from the Ministry of Internal Affairs and Communications [2]. The usage rate is particularly high among adolescents aged 13 years to 19 years (98.7%). Adolescence is an important transition period from childhood to adulthood, during which adolescents undergo many physical, cognitive, and psychosocial changes; establish their ego; build their own world; and develop healthy lifestyle habits. During this period, adolescents seek information on topics such as sexual health, nutrition, beauty, and infectious diseases through websites and social media [3].

Concept and Importance of eHealth Literacy

Health literacy is the ability to find, understand, and use health information to make informed decisions. These include reading medical instructions, understanding prescriptions, and evaluating health information from various sources. Good health literacy helps individuals manage diseases, correctly follow treatment, and effectively communicate with health care providers. It also involves numeracy skills such as understanding dosages and medical test results. Low health literacy can lead to poor health outcomes and medication errors. Therefore, promoting health literacy empowers individuals to take charge of their well-being and make healthier choices. Among digitally native adolescents, the internet has replaced traditional sources such as books for gathering health information [4,5].

Assessment of eHealth Literacy Among Adolescents

Given this shift, eHealth literacy—the ability to find, evaluate, and use health information from the internet to solve one's health problems—has become increasingly important [6]. The 6-item Lily Model of eHealth literacy, comprising traditional, health, information, scientific, media, and computer literacy, was previously proposed [6]. An 8-item rating scale called the eHealth Literacy Scale (eHEALS), based on this model, has been developed [7], translated into many languages, and used worldwide [8-11]. As adolescents continue to rely on the internet for health-related information, assessing their eHealth literacy is essential. However, despite increasing reliance on digital health information, research on eHealth literacy among adolescents remains scarce. Most studies have focused on university students or adults, leaving a significant knowledge gap regarding younger adolescents [4,12]. Moreover, global studies on adolescent eHealth literacy are sparse, with only a few investigations conducted in specific regions such as Turkey, Serbia, and Brazil [13-15]. These studies suggest variations in eHealth literacy levels among different populations, further highlighting the need for region-specific studies.

Premenstrual Symptoms and Psychological Well-Being

Premenstrual symptoms are characterized by unpleasant psychosomatic symptoms that impair the quality of life of many women from adolescence to adulthood [16-18]. Premenstrual syndrome (PMS) is characterized by various premenstrual symptoms and is classified as premenstrual dysphoric disorder when psychological symptoms become particularly severe [19]. Recently, the concept of premenstrual disorders was introduced, considering both conditions as part of a continuum [20]. Menstrual pain and premenstrual symptoms are correlated and, as menstrual symptoms, have a significant impact on performance [21,22]. In Japan, a study with working women found that those with higher health literacy reported lower presenteeism and better performance at managing menstrual symptoms [22]. However, this study did not examine premenstrual symptoms or social dysfunction in detail. In addition, few studies have examined the relationship between health literacy, including eHealth literacy, and menstrual symptoms in adolescents.

Psychological Distress, Loneliness, and Self-Esteem in Adolescents

High school students are at an increased risk of psychological distress, depression, anxiety, loneliness, and trauma [23]. Loneliness, the subjective feeling of isolation, has gained attention as a major public health concern owing to its strong association with mental health conditions such as depression and anxiety. It is also a key risk factor for poor mental health outcomes, particularly during adolescence [24-26]. A survey of Japanese high school students conducted in 2021 found that psychological distress was correlated with the severity of premenstrual symptoms, whereas loneliness was independently linked to both conditions. Self-esteem, which reflects an individual's overall sense of self-worth [27], is another critical factor affecting the mental health of adolescents. Low self-esteem is linked to depression, eating disorders, risky behaviors, and academic decline [28]. Additionally, it has a strong reciprocal relationship with loneliness [27,28]. Low self-esteem and loneliness are particularly concerning during adolescence, which is the formative period for developing self-identity [29]. As adolescents increasingly rely on online health information, eHealth literacy may play a role in their psychological well-being by influencing their access to and interpretation of health-related content.

Study Objectives

The purpose of this study was to assess the current level of eHealth literacy among Japanese female high school students, with a particular focus on examining its association with premenstrual symptoms. In addition, we investigated how eHealth literacy is related to other key aspects of adolescent health, including psychological distress, loneliness, and self-esteem. We hypothesized that students with higher eHealth literacy would report fewer premenstrual symptoms, lower levels of psychological distress and loneliness, and higher levels of self-esteem. These associations were examined to better understand the potential role of digital health literacy in promoting reproductive and mental well-being among adolescents.

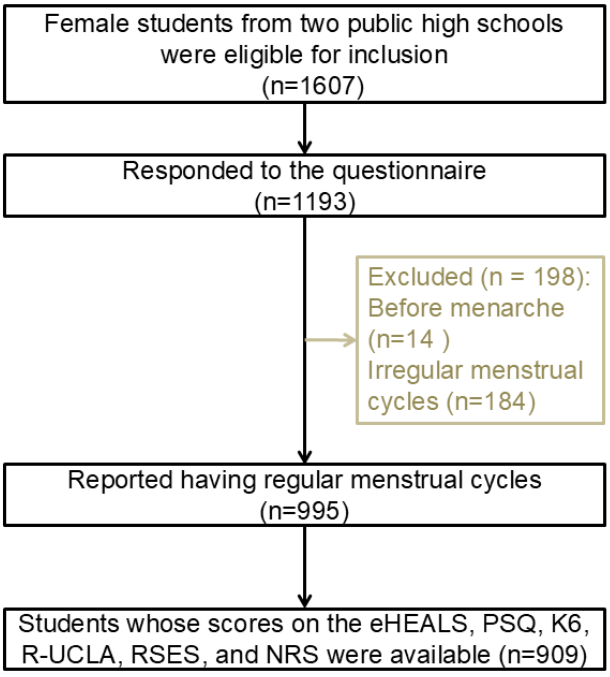
Methods

Ethical Considerations



This study was conducted in accordance with the principles of the Declaration of Helsinki, and the Kindai University Ethics Committee approved the research protocol (approval number: R06-131; approval date: October 2, 2024). Students who participated in the study provided informed consent.

The Kindai University Ethics Committee approved the waiver of parental informed consent, and the students' consent and willingness to participate were considered sufficient. The omission of parental informed consent was in accordance with the Ethical Guidelines for Medical and Health Sciences Research Involving Human Subjects issued by the Ministry of Education, Culture, Sports, Science, and Technology, and the Ministry of Health, Labour and Welfare. The data were anonymized and did not contain identifiable information regarding the participants. Participants were not compensated.

Settings and Participants

In mid-December 2024, a school survey was conducted among 1607 female students attending 2 public high schools in Sendai, Japan. We conducted a web survey using Google Forms. The link to the self-administered survey form was distributed through school classes, and the survey was administered over the internet with consent. Given the sensitive nature of the questions, students were instructed to complete the survey independently at home after school hours, rather than during class time. A total of 1193 students responded to the survey. Of these, 995 had regular menstrual cycles of 25 days to 38 days (Figure 1). Because premenstrual symptoms appear solely during ovulatory cycles, only those with regular menstrual cycles were selected. Furthermore, 909 students who completed all items from the following measures were selected: eHEALS, Premenstrual Symptoms Questionnaire (PSQ), 6-item Kessler Psychological Distress Scale (K6), 3-item Revised UCLA Loneliness Scale (R-UCLA), Rosenberg Self-Esteem Scale (RSES), and numerical rating scale (NRS) for menstrual pain intensity.

Figure 1. Study flowchart. eHEALS: eHealth Literacy Scale; K6: 6-item Kessler Psychological Distress Scale; NRS: numerical rating scale; PSQ: Premenstrual Symptoms Questionnaire; R-UCLA: 3-item Revised UCLA Loneliness Scale; RSES: Rosenberg Self-Esteem Scale.

Questionnaires

eHEALS

The eHEALS is the only questionnaire that examines online health literacy [7]. In this study, we used the Japanese version, which has demonstrated validity and reliability [10]. The eHEALS is composed of 8 items and is scored on a 5-point scale (1=strongly disagree to 5=strongly agree). The total eHEALS score ranges from 8 to 40: the higher the score, the better the eHealth literacy. In this study, the Cronbach α coefficient for the scale was 0.935. Participants were divided into 2 groups—a high-scoring group (eHEALS≥26; n=292) and a low-scoring group (eHEALS<26; n=617)—according to criteria reported previously [29].

PSQ

The PSQ, previously used in research, was chosen for this study as a simple screening tool for premenstrual symptoms [18,30]. Its reliability and validity are well established [31]. The PSQ starts with: "In the past three months, have you experienced any premenstrual symptoms that start a week before menstruation and stop a few days after it begins?" It includes 11 items based on the Diagnostic and Statistical Manual of Mental Disorders–premenstrual dysphoric disorder criteria and assesses the impact of symptoms on (1) work and family responsibilities, (2) social activities, and (3) relationships. Severity and impact are rated on a 4-point scale (1=not at all to 4=severe). The total score (range: 14-56) indicates symptom severity. The Cronbach α was 0.936.

XSL•FO
RenderX

K6

The K6 was chosen for this study because it is a widely used screening tool for psychological distress in the general population [32,33]. Psychological distress was measured using the Japanese version of K6 [34], with established reliability and validity. The K6 consists of 6 items rated on a 5-point scale (0=not at all to 4=all). The total score ranges from 0 to 24, with higher scores indicating greater distress. The Cronbach α was 0.957.

R-UCLA

The R-UCLA was chosen for this study because it is a widely used and simple assessment tool for evaluating loneliness [35]. The Japanese version of the 3-item R-UCLA was used, and its reliability and validity have been well established [36]. This scale consists of 3 items rated on a 3-point scale (1=hardly ever, 2=sometimes, and 3=often), yielding a total score between 3 and 9. Higher scores indicate greater loneliness. The scale demonstrated strong internal consistency, with a Cronbach α of 0.913.

RSES

The RSES is a widely used self-esteem assessment tool that was selected for this study owing to its broad applicability [27]. The Japanese version of RSES (RSES-J) was used to measure self-esteem, and its reliability and validity have been confirmed [37]. The RSES-J consists of 10 items: 5 positive and 5 negative. Negative items are rated on a 4-point scale (1=strongly agree, 2=agree, 3=disagree, and 4=strongly disagree), whereas positive items are scored inversely. The total score ranges from 10 to 40, with higher scores indicating greater self-esteem. In this study, the Cronbach α for the RSES was 0.873.

NRS

Menstrual pain is closely linked to premenstrual symptoms [21,31]. In this study, pain severity was assessed using the NRS, a standard tool for measuring pain perception. Participants rate their pain on an 11-point scale ranging from 0 (no pain) to 10 (worst imaginable pain).

Participant data included age, school grade, weight, height, age at menarche, menstrual cycle length, internet usage time, and sleep duration. Menarche marks the onset of puberty and is linked to health issues such as early pregnancy, sexually transmitted diseases, depression, and anxiety [38,39]. It has been identified as a key factor in adolescent health. A regular cycle was defined as 25 days to 38 days. BMI was calculated by dividing weight by height squared (kg/m²). As obesity is associated with PMS, low self-esteem, and loneliness, BMI was included in the analysis [40,41].

Statistical Analysis

The Cronbach α coefficient was used to assess the reliability of each scale (eHEALS, PSQ, K6, 3-item R-UCLA, and RSES). We calculated the means and SDs for continuous variables and proportions for categorical variables. Differences in the background characteristics of the high and low eHealth literacy groups were compared using Student *t* tests and Pearson chi-square tests. The Steel-Dwass test was used to compare differences in eHEALS scores between school years. The exact Wilcoxon signed-rank test was used to compare the severity of 11 premenstrual symptoms and 3 social disability items on the PSQ between the high and low eHealth literacy groups. Correlations among the 5 psychological questionnaires (total eHEALS, PSQ, K6, 3-item R-UCLA, and RSES) were examined using Pearson correlation coefficients. The factors significantly associated with high eHealth literacy were determined using multivariable logistic regression analysis. A total of 10 items—age, BMI, age at menarche, menstrual pain intensity, duration of internet use, sleep duration, total PSQ score, total K6 score, R-UCLA, and RSES—were included in the model.

Statistical analyses were performed using JMP Pro 18.1.0 (SAS). A *P* value<.05 was considered statistically significant.

Results

Participant Characteristics

The characteristics of all participants are presented in Table 1. The mean eHEALS score was 22.8 (SD 7.3). Approximately one-third (292/909, 32.1%) of the participants belonged to the high eHealth literacy group. The high eHealth literacy group had lower R-UCLA scores and higher RSES scores than the low eHealth literacy group.

Comparison of eHealth Literacy Between School Years

Differences in eHEALS scores between school years were analyzed in terms of the total score and each of the 8 items (Table 2). We found no differences in total eHEALS scores between school years. Of the 8 items, second-year students' scores were significantly higher than those for first-year students for Q6 (I find on the Internet, I know how to use the Internet to answer my questions about health) and Q7 (I can distinguish high-quality health resources from low-quality health resources on the Internet). This suggests that some aspects of eHealth literacy may improve with age or school experience, but the overall literacy level remains consistent across the years.

eHealth Literacy and Premenstrual Symptoms

Next, the differences in premenstrual symptoms and level of social impairment were examined according to the level of eHealth literacy (high and low literacy; Table 3). Of the 11 premenstrual symptoms listed in the PSQ, only feeling overwhelmed was significantly lower in the high eHealth literacy group than in the low eHealth literacy group. In terms of social life impairment, only interpersonal impairment was significantly lower in the high eHealth literacy group than in the low eHealth literacy group. However, there were no significant differences in work productivity nor participation in social activities between the 2 groups.

Correlations Between eHealth Literacy and Psychological Measures

Subsequently, we examined the correlations between the eHEALS and the 4 psychological questionnaires used in this study (Table 4). The Pearson correlation coefficient analyses showed that the eHEALS score was negatively associated with the K6 total score (*r*=–0.071) and the R-UCLA score (*r*=–0.086) and positively associated with the RSES score (*r*=–0.170).

Discussion

Principal Findings

This study examined the eHealth literacy levels of female Japanese high school students and their associations with premenstrual symptoms, psychological distress, loneliness, and self-esteem. The findings highlight the importance of eHealth literacy in adolescent health and suggest that students with higher eHealth literacy tend to experience better mental and reproductive health outcomes. Additionally, this study contributes to the growing body of evidence indicating that digital health literacy plays a significant role in adolescent development and well-being—particularly as reflected in their health-related decision-making processes.

eHealth Literacy Level

The results showed that the mean eHEALS score among participants was 22.8, with 32.1% classified as having high eHealth literacy. Compared with eHEALS scores of 23.6 and 23.5 for university students and the general population in Japan, respectively [10,12], the values obtained in this study appear to be slightly lower. As the data on adolescents overseas in the same age group are limited, performing comparisons becomes challenging. However, among 702 high school students in Serbia (mean age: 16.5 years), the average eHEALS score was 26.0 [14], and among 260 high school students in Brazil (mean age: 15.6 years), the average eHEALS score was 28.1 [15]. Based on these values, Japanese students appear to have a lower eHEALS score. The eHealth literacy of Japanese high school students obtained in this study was lower than that of Japanese university students, adults, and overseas high school students, suggesting a need for further improvement. The results of this study showed that eHEALS scores increased for some items in the second year compared with those in the first year, but there was no difference in scores between the years when assessed as a whole. Therefore, it is difficult to expect an improvement in eHealth literacy during the natural course of events, and educational interventions may be necessary.

eHealth Literacy, Psychological Well-Being, and Social Connectedness

The negative association between eHealth literacy and loneliness suggests a potential link between digital health literacy and social connectivity. Adolescents with higher eHealth literacy may be more likely to engage with credible online health communities, which could help alleviate feelings of isolation. Additionally, the positive correlation between eHealth literacy and self-esteem indicates that adolescents with stronger digital health literacy may feel more empowered to make informed health decisions, potentially contributing to greater confidence and a more positive self-image.

Association Between eHealth Literacy and Menstrual Symptom Severity

The intensity of menstrual pain and premenstrual symptoms, as assessed using the total PSQ score, did not differ according to the level of eHealth literacy. In terms of premenstrual symptoms, the high eHealth literacy group reported significantly lower levels of “feeling overwhelmed” than the low eHealth literacy group. However, other PMS symptoms, such as mood swings, fatigue, and irritability, were not significantly different between the groups. This suggests that, although higher eHealth literacy may be related to better psychological resilience, its direct relationship with overall premenstrual symptom severity remains unclear. Further investigation is needed to determine whether increased eHealth literacy leads to improved symptom management or whether other factors, such as coping strategies and social support, mediate this relationship. It is possible that individuals with high eHealth literacy possess more accurate knowledge of premenstrual symptoms, which might help them manage symptoms more calmly and avoid feeling overwhelmed, potentially reducing interpersonal difficulties. These findings suggest that higher eHealth literacy may be associated with

XSL•FO
RenderX

improved psychological resilience and coping strategies for menstruation-related issues. Moreover, our results are consistent with those of prior research linking higher health literacy to improved management of menstrual symptoms among working women [22]. However, this study extends these findings by focusing on younger adolescents and exploring the relationship between eHealth literacy and premenstrual symptoms in relation to more detailed symptoms and details of social dysfunction, an area that has received less attention in previous studies.

Correlation Between eHealth Literacy and Psychological Measures

The Pearson correlation analysis revealed a negative association between eHEALS scores and psychological distress (K6: r=–0.071; P=.03), as well as loneliness (R-UCLA: r=–0.086; P=.01), whereas a positive association was observed between the eHEALS score and self-esteem (RSES: r=0.170; P<.001). Although these associations were statistically significant, the effect sizes were small, suggesting that eHealth literacy alone may not be a strong predictor of psychological well-being. Additional factors, such as social relationships and coping mechanisms, should be considered in future research. These results suggest that adolescents with higher eHealth literacy are better equipped to access and interpret mental health information, which may help explain the lower psychological distress and higher self-worth observed in this study. Future research should investigate the causal relationships between eHealth literacy and mental well-being using longitudinal data.

Factors Associated With High eHealth Literacy

The multivariate logistic regression analysis showed that high self-esteem was significantly associated with high eHealth literacy. These results align with previous findings among university students in the United Kingdom [42]. This finding highlights a strong link between self-esteem and eHealth literacy, suggesting that positive self-perception may be an important factor to consider in adolescent eHealth literacy programs.

Limitations and Future Directions

Despite its strengths, this study has some limitations. First, the cross-sectional design precludes causal inference; therefore, longitudinal studies are needed to establish temporal relationships between eHealth literacy and health outcomes. Second, the study sample was limited to female students from 2 public high schools in Sendai, which may limit the generalizability of the findings to other regions and populations. Future studies should include more diverse samples, including students from different geographic and socioeconomic backgrounds. Expanding this research to include male adolescents and individuals from rural areas would provide a more comprehensive understanding of how eHealth literacy affects various demographics. Third, this study used self-administered online questionnaires completed by participants in their home environments. Although this approach offers convenience and accessibility, it has the following limitations: (1) potential response bias, including social desirability bias and misinterpretation of questions resulting from lack of direct supervision; (2) the home setting, which may have allowed outside influences or noncompliance with instructions, potentially affecting the authenticity of responses; and (3) collecting sensitive psychological and health-related information in an uncontrolled environment, which raises concerns about data integrity. However, discussing reproductive health is often taboo worldwide, especially in Asia, including Japan, with its conservative cultural and religious background [43]. Openly discussing menstrual issues in Japanese school classrooms is very difficult, and online after-school surveys are more likely to reveal the true status of students. Fourth, the study did not evaluate other participant-related factors that may influence eHealth literacy, such as parental education level, family economic status, and participants' medical history [13,44-46]. Although the survey was administered online and completed by students after school, these questions were considered sensitive and difficult to ask. Therefore, it was challenging to include them in a study conducted as part of regular high school activities. Moreover, we acknowledge that other factors—such as access to internet resources, support from family and the community, and a family or maternal history of symptoms or gynecological or endocrine conditions—may also influence eHealth literacy and its related outcomes. Although these variables were not assessed in this study, their potential impact on health-related factors, such as self-esteem, should not be overlooked. These factors may interact with the psychosocial and reproductive health outcomes examined here. We recommend that future studies incorporate these elements to enhance the understanding of adolescent health in relation to eHealth literacy. Fifth, the logistic regression analysis in this study included 10 variables but did not account for potential confounders such as socioeconomic status, academic stress, home environment, and previous digital health education. As mentioned previously, items related to socioeconomic background and home environment were excluded because of ethical and practical limitations inherent in this school-based survey. Although past health education could have been included as a question, there are very few systematic digital health education programs for high school students in Japan. We judged that there was little variation in this factor and thus did not consider it meaningful as an analytical variable. Nevertheless, the omission of these factors may limit the comprehensiveness of the regression analysis, and future studies should include these variables as much as possible, depending on the circumstances.

Furthermore, this study focused only on specific health outcomes—namely, premenstrual symptoms, psychological distress, loneliness, and self-esteem. Future research should investigate additional physical and mental health outcomes to develop a more comprehensive understanding of how eHealth literacy influences adolescent health. Further research should explore potential interventions to enhance eHealth literacy and examine their long-term impact on adolescent health. In fact, a study with secondary school students in Spain demonstrated the educational impact of training sessions on eHealth literacy [47].

Conclusions

In conclusion, this study highlights the importance of eHealth literacy for adolescent well-being. We found that higher eHealth

XSL•FO
RenderX

literacy was associated with lower loneliness, higher self-esteem, and a reduced premenstrual symptom burden, particularly regarding feelings of being overwhelmed. These findings suggest that integrating eHealth literacy education into school programs could potentially benefit adolescents' mental and reproductive health, although this should be confirmed in future studies. Future studies should aim to include more diverse populations—such as male adolescents and students from various socioeconomic backgrounds—and adopt longitudinal approaches to better understand the causal relationships between eHealth literacy and adolescent health outcomes. Future research should also focus on developing and evaluating interventions aimed at improving eHealth literacy and its long-term impact on adolescent health outcomes. By prioritizing digital health literacy initiatives, educators, health care professionals, and policymakers may help cultivate a more informed and health-conscious future generation.

Abstract

Background: Web-based patient portals can benefit adolescents and their caregivers by increasing access and providing greater understanding of one's health information, enhancing communication with clinicians, and supporting caregiver influence. Despite these benefits, adolescent uptake has been low with high attrition rates. Feedback from adolescents and caregivers is essential to improve the uptake and usability of the web-based patient portal.

Objective: The aim of the study is to identify advice for medical informatics administrators and clinicians directed at improving the adolescent and caregiver experience with the web-based patient portal.

Methods: Caregivers completed a demographic survey followed by separate qualitative, semistructured interviews with adolescent-caregiver dyads with and without chronic illnesses. Caregivers and adolescents were interviewed separately regarding advice for administrators and clinicians on several topics, including (1) providing adolescent and caregiver portal access, (2) how doctors should discuss the portal with families and the content of their notes, and (3) what general advice they had to improve portal access for families. We performed thematic analysis to develop a codebook, and team members applied these codes to the transcripts and analyzed for overlaps and contrasts.

Results: We performed 102 interviews with 51 dyads of caregivers and adolescents (26 with chronic illness and 25 without chronic illness). The majority of adolescents and their caregivers were White (adolescents: n=28, 55% and caregivers: n=28, 55%) or Black (adolescents: n=21, 41% and caregivers: n=21, 41%) and female (adolescents: n=30, 59% and caregivers: n=50, 98%). The majority of caregivers had accessed their child's portal (n=33, 65%), whereas the majority of adolescents had not (n=17, 33%). We identified three themes related to adolescent and caregiver advice: (1) encouraging and supporting portal use, (2) recognizing the emotional experience of portal use, and (3) improving portal usability, understandability, and individualization. Adolescents and their caregivers provided specific recommendations regarding initial access or enrollment including improving resources and clinician encouragement as well as improving the usability in terms of user-friendly design, understandable language, and clear expectations. Finally, caregivers and adolescents had varied opinions on confidentiality and access but emphasized the importance of understanding the emotional impact and providing guidance to caregivers and adolescents.

Conclusions: Adolescents and caregivers outlined critical advice to medical informatics administrators and clinicians to improve the patient portal uptake and usability. Further research is required to determine the best application for these recommendations, including the potential use for advance technologies to simplify results and clinical documentation, strategies to improve the

XSL•FO
RenderX

user-friendly design, and how clinicians should communicate with families now that clinical documentation is viewable to patients and caregivers.

KEYWORDS

web-based patient portal; electronic health records; adolescent health care perspectives; qualitative research; adolescent; caregivers

Introduction

Web-based patient portals are resources that allow patients to access their electronic health information (EHI) and communicate with their clinicians through portal messages. Availability of portals has been bolstered by the 21st Century Cures Act, which was signed into US law on December 13, 2016. This law prohibits US health care systems and electronic health record (EHR) vendors from information blocking, "a practice [by a health care clinician or health IT developer, exchange, or network] that except as required by law or covered by an exception ... is likely to interfere with access, exchange, or use of EHI" [1]. This portion that expanded transparency in health care and access to EHI went into effect on April 5, 2021. Additionally, portal use surged during the COVID-19 pandemic when electronic communication, including video visits, increased, spurring uptake on a national scale [2].

In pediatrics, caregivers can access their child's EHI through a proxy version of the portal. When children reach the age of adolescence (ranging from 10 to 16 years, depending on the US state) [3], most health care systems also provide adolescents with the option to register for their own portal account. However, each US state has laws that dictate which adolescent health information must be protected, usually related to sexual and reproductive health, mental health, and substance use disorders [4]. Each pediatric health care system must determine how to comply with these laws, and caregiver access may be limited to varying degrees when a child becomes an adolescent. As such, the usefulness of the caregiver proxy portal is often in tension, with restrictions required to ensure confidentiality of the adolescent's sensitive, protected information.

Providing portal access can benefit both adolescents and their caregivers by improving understanding of one's health, empowering adolescent self-management and autonomy, enhancing communication with clinicians, and supporting caregiver influence [5]. These benefits of improved medical competency and autonomy are especially critical for adolescents who are beginning to transition to adulthood and self-management. However, many adolescents demonstrate limited interest in using their portal [5], and their use has been low with studies citing variable rates of uptake between 15% and 64% [6-10]. In those who do use the portal, there is a high attrition rate, with one study finding that over 50% of portal accounts were actively used for less than 1 year [8].

Health care systems and administrators must consider devising strategies to simultaneously increase the usefulness of adolescent and caregiver proxy portals, support adolescent interest in using the portal, and maintain confidentiality of sensitive information. Input from adolescents and caregivers will be essential to inform these strategies, but few studies have explored these perspectives in depth. Most of this literature has focused on protecting confidentiality and increasing enrollment [11-16]. In this analysis, we aimed to address this gap by identifying adolescent and caregiver advice for medical informatics administrators and clinicians directed at improving the web-based patient portal experience.

Methods

We report this study following the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [17].

Participants and Recruitment

We conducted semistructured interviews with caregiver and adolescent dyads who received care in St Louis. We stratified sampling for adolescents with and without chronic illnesses and purposively sampled for racial and ethnic minorities and fathers. Adolescents with chronic illness were recruited from specialty clinics at a major academic medical center, including sickle cell disease (SCD), inflammatory bowel disease (IBD), and diabetes mellitus (DM). We chose these 3 chronic illnesses because they create lifelong medical complications and represent diverse racial and ethnic populations. Adolescents without chronic illness were recruited from 3 pediatric clinics and 1 adolescent medicine clinic associated with the academic medical center.

Patient Portal Policies

All clinics used the same patient portal (called MyChart) with the same requirements for creating portal accounts. This portal allows participants to view scheduled appointments, clinician notes, and diagnostic results, communicate with their providers or clinics, and request medication refills, among other functions. Children aged 11 years and younger cannot have their own MyChart account, and caregivers may obtain full access to a proxy account by completing a proxy access form. When a child turns 12 years, caregivers lose proxy access by default. Adolescents can create their own account if they call the help desk during business hours. To provide proxy access for parents of adolescents, caregivers need to obtain signed forms of approval by the adolescent and the patient's primary doctor. Every child in a family requires a separate proxy portal account with a unique password. There was no ability to link accounts of family members or to link accounts across institutions that used a different patient portal. There is no phone app available, though individuals can log in through an internet browser on their phone or computer.

Data Collection

As part of a larger qualitative study [5], we performed semistructured interviews, in which we asked adolescents and caregivers to provide advice for administrators and clinicians

XSL•FO
RenderX

regarding (1) providing adolescent and caregiver portal access, (2) how doctors should discuss the portal with families and write their notes, and (3) what general advice they had to improve portal access for families (Multimedia Appendix 1). This guide was informed by literature review, our prior work, and a stakeholder advisory board. BAS, CB, and another team member performed interviews between May and December 2022 via telephone or Zoom videoconferencing software (Zoom Video Communications) based on participant preference. Caregivers and adolescents were interviewed separately and privately. Interviews were audio-recorded and professionally transcribed. We collected demographics via a Qualtrics survey that was sent via email to caregiver participants.

Data Analysis

BAS, CB, and JMG developed a codebook following validated phases of thematic analysis [18]. Coding involved multiple iterative steps: (1) read transcripts to familiarize themselves, (2) descriptively coded 5 transcripts to formulate preliminary codes, (3) grouped codes into categories and collapsed categories into representative themes, and (4) refined definitions for themes through 3 cycles of independent coding and consensus meetings. After reviewing 20 adolescent transcripts and 19 caregiver transcripts, we reached saturation for representative themes.

CB and REG independently applied this codebook to all transcripts using Dedoose qualitative software, reviewed each other's application of codes, marked disagreements, and resolved disagreements via discussion. Subsequently, REG reviewed transcripts for each dyad, identifying overlaps and contrasts between caregivers and adolescents, as well as overlaps and contrasts for adolescents with a chronic medical condition and their caregivers compared to adolescent-caregiver dyads who do not have a chronic medical condition. Quantitative data on patient-reported demographics were analyzed using SPSS Statistics (version 29.0.2.0; IBM Corp).

Ethical Considerations

The institutional review board at Washington University approved this study (202203147). We obtained informed consent from caregivers and assent from adolescents. All transcripts were deidentified prior to analysis. Participants were provided with a US $40 electronic gift card for their participation in the interviews.

Positionality Statement

BAS is a pediatric oncologist and communication researcher with training in qualitative research. REG is a fellow in pediatric hematology/oncology with a master's degree in public health and prior training in qualitative research. CB is a research coordinator with a master's degree in social work and prior qualitative experience. Another team member who performed interviews has a master's degree in public health and qualitative methods experience. JMG was a medical student with training in qualitative research. All team members have prior experience in qualitative research.

Results

Demographics

There were 102 separate interviews performed with 51 dyads, averaging 25 (SD 11) minutes. The majority of adolescents and their caregivers were White (adolescents: n=28, 55% and caregivers: n=28, 55%) or Black or African American (adolescents: n=21, 41% and caregivers: n=21, 41%), non-Hispanic (adolescents: n=46, 90% and caregivers: n=47, 92%), and female (adolescents: n=30, 59% and caregivers: n=50, 98%). Many caregivers had accessed their child's portal (n=33, 65%), but fewer adolescents had accessed their portal (n=17, 33%; Table 1).

Non-Hispanic	22 (85)	24 (96)

Encouraging and Supporting Portal Use

Improving Accessibility

Caregivers reported significant challenges with the enrollment processes for the proxy portal. These caregivers advised that the entire procedure should be easier, stating that the experience was “confusing” and requesting that more information be provided. Both caregivers and adolescents reported that the login process could be easier, stating the requirements for adolescents to have their own email made accessing the portal difficult. In addition, the sign-up process for the adolescent proxy portal required the adolescent to call the help desk during business hours, which conflicted with school and sports schedules. Further, institutions had rules about required characteristics of passwords, such as numbers and symbols, that frustrated some participants. Adolescents and caregivers thought it would be beneficial to have increased resources to assist in the sign-up and usability of the portal platform, including a website, pamphlet, or an individual that could guide families through the process.

Clinician’s Role in Educating and Promoting Use

Caregivers and adolescents acknowledged that the portal should be “brought up more” (Adolescent 26, no chronic medical condition) by the clinician to encourage use, with one caregiver stating that it should be “a part of the visit every time” (Caregiver 26, no chronic medical condition). Only one respondent stated that they did not know “if that’s really a doctor’s responsibility to worry about the portal” (Caregiver 13, IBD). Some felt it would be useful for clinicians to “be more informational” (Caregiver 46, SCD) about the portal components and sign-up process, with one person stating that they felt the doctor should have experience using the portal to better understand the patient perspective. Others recommended that clinicians outline acceptable uses of the platform, including types of portal messages that are acceptable and how to best communicate with them.

XSL•FO
RenderX

Recognize the Importance of the Portal for Chronic Illness

Nearly all caregivers and adolescents acknowledged the importance of respecting and protecting adolescent confidentiality. However, many caregivers of children with chronic illness described the importance of retaining access to nonsensitive information in the portal, such as notes, appointments, laboratory results, and medication lists. These caregivers worried that limiting parental access to this actionable information could be "very detrimental" (Caregiver 51, SCD), especially because adolescents are often not mature enough to navigate health care on their own (Table 2).

Table 2. Illustrative participant quotes on encouraging and supporting portal use.

Theme and subtheme	Illustrative quote
Improving accessibility	
Easy sign-up	• "The sign-up process took a while. It was kind of confusing. I think I had to have a code or something and I didn't get it, so I remember that was kind of difficult. Making it just easier to actually get an account" [Caregiver 4, DM[a]].
Easy access	• "Just make it very simple to access it, not having to go through a lot of steps and give parents really good instructions on how to access it" [Caregiver 10, DM].
Improved resources	• "Maybe if it's your first time using it, you do a step-by-step page or whatnot to show you where everything is and the layout" [Adolescent 47, no chronic medical condition]. • "I think there needs to be better instruction and explanation on how to set it up, why it has to be set up that way. A lot of people just want you to, oh, set up the portal, but no one explains that you need a special code. You need consent. You need—so it's never explained very well" [Caregiver 45, no chronic medical condition]. • "If there's a place that could have helped us, like a phone number we could've called, someone that could have walked us through it besides the doctor's office themselves, that would've been more helpful too" [Caregiver 26, no chronic medical condition].
Clinician's role in educating and promoting use	
Educate	• "I think that my doctors have been very good about telling us about the medical records, but again, I think they should just give a more precise knowledge about how to access the records" [Adolescent 41, no chronic medical condition]. • "I think that they should just tell the family about it. Maybe they could show them on their phone. It's like a demo, so it doesn't show any personal stuff. Like they could show them on their phone, so they could see what the app looks like and show how user-friendly it is" [Adolescent 25, SCD[b]]. • "I'm not sure that doctors understand how to use it. I think they need to have used it themselves, logged in, checked it out, seen it from a patient view, and—I don't know—have better detailed description and notes of how to get in, who to call, what to do" [Caregiver 45, no chronic medical condition].
Promote	• "I would suggest the doctor tell the family that they should regularly look at the online medical records. Just so they know everything, all the information that's on there that they need to know. If there's something serious or even if there's not, just to make sure that everything's okay" [Adolescent 40, no chronic medical condition]. • "Oh, I think they should definitely encourage it with every patient because it is a useful tool, and I thought should be presented. It's not just information. It's a useful tool that you can use to help take an active part in the health of the child" [Caregiver 5, IBD[c]].
Outline acceptable uses	• "Educating parents and teenagers, this is how you access it, this is what it's good for, this is a positive use of it, and this is what you shouldn't use it for" [Adolescent 20, no chronic medical condition]. • "Just making clear how they prefer to communicate and how they want us as the patients to communicate with them or how they will choose to communicate. 'I will send you a message through MyChart.' We just recently went to our endocrine appointment and the nurse practitioner said, 'I will call you.' He did, he called and left a message because that was all clear. He told us how he was gonna communicate. Now that we do have MyChart, we have the phone, we have all these different ways and the after-hours communication just to be clear how they want, what method they would prefer, and what's most effective for them" [Caregiver 2, DM].
Recognize the importance of the portal for chronic illness	
—[d]	• "I think it's a good idea to let parents access it because they need to know what's going on with their child's health, and if they don't, then their child could worsen their own health without them knowing" [Adolescent 16, SCD]. • "I would tell them that these are minor children, and it is very important that parents are an integral role in the health of their children, and that they should have access to all of it" [Caregiver 12, IBD].

Recognizing the Emotional Experience of Using the Portal

Mitigate Stress Through Discussion and Resources

To decrease stress, caregivers advised that clinicians discuss with families the maturity level of the adolescent prior to granting access to ensure that the adolescent is ready for access. Caregivers also recommended that adolescents should be walked through the portal at their first time of access. A few adolescents worried about portal access being problematic for parents who were "helicopter parents" or overbearing. These adolescents advised that clinicians discuss the types of information that might be released through the portal, prepare them for potentially stressful results, and encourage them not to become fixated on every abnormal result. One caregiver and one adolescent noted the importance of maintaining the option for verbal communication with clinicians outside of the portal, especially when worrisome test results are released.

Modify Note Content

Adolescents and caregivers advised that notes should be tailored to remove and protect confidential discussions that occurred between the adolescent and their clinician. Some adolescents and caregivers advised a collaborative discussion between clinicians and adolescents about what specifically should be excluded from the notes to ensure confidentiality tailored to the comfort level of that patient and the patient-caregiver dynamic. Another caregiver suggested the clinician inform the adolescent that the confidential portion would not be included in the note to build trust.

Caregivers and adolescents also had recommendations for the content and language that were included in the portal. Many caregivers and adolescents stated the importance of considering adolescents' emotions when writing notes, which involved using professional language and "stay[ing] positive and to stay just on facts. Maybe not put personal thoughts" (Caregiver 4, DM). A few participants discussed concerns that comments about the adolescent's weight could have a negative emotional effect. These participants advised clinicians to be "sensitive and mindful" (Caregiver 42, no chronic medical condition) and use "very gentle phrasing" (Adolescent 23, no chronic medical condition). One adolescent reflected that they had "a doctor make jokes about me in my medical notes before ... It just made me not trust the doctor really, and withhold information from them because I didn't wanna be judged about it" (Adolescent 10, DM) (Table 3).

Table 3. Illustrative participant quotes on recognizing the emotional experience of using the portal.

Theme and subtheme	Illustrative quote
Mitigate stress through discussion and resources	
Prepare parents	• "Then to the parents, be like, 'If you see something that's worrisome, don't become overbearing,' because I definitely think, especially with mental health, a step in the right direction is telling the doctor—maybe not your parent, but telling the doctor or someone else that you trust, and I definitely think if a parent becomes super overbearing or super controlling because they have access to these records, there's the chance that the child won't give that information and won't be very open with their doctor. Then that could spill out into a bigger problem down the road" [Adolescent 29, no chronic medical condition]. • "I think there's maybe a possibility with other teenagers of parents who are striving for those perfect numbers, and that can put a lot of stress on children, so I think maybe in terms of the parents' access, and it may not be restricting access to anything, but it could just be reminders that parents have lots of impact on their children, obviously, even if a child doesn't have a condition, but especially with children that have a medical condition. Parents have a very big impact on how their child will view their health, and so I think that could be a good reminder to parents as well" [Adolescent 2, DM[a]].
Communication of big news	• "A worry I would have is if they have this big disease or something, just something big, something that's a very big deal, it might be best to first tell them and then give the medical records" [Adolescent 23, no chronic medical condition]. • "I feel like if there's something that is detrimental, knowing that either an adolescent or a parent has access to that, that should be a verbal conversation versus seeing something like that written. You know what I mean? When you have that information, when you see that information, there are so many questions that go through your mind, and I think that would be unfair to the patient to have to read that and not be able to access the doctor immediately to have a discussion about that information" [Caregiver 27, no chronic medical condition].
Modify note content	
Protect confidentiality	• "I don't think they should be putting things that they ask the parents to leave the room for because if they had the parents leave the room, they're trying to get the teenager to be completely truthful and completely comfortable. Maybe I don't think it's the best idea for them to put that information in the Doctor's Note, unless maybe it's like a serious issue, and they got permission from the teenager during the doctor's appointment" [Adolescent 3, DM].
Sensitive language	• "Very gentle phrasing, not saying this child is overweight. They need to work out now, something like that. Not that way, but something more like kind, considering people's feelings and stuff" [Adolescent 23, no chronic medical condition]. • "I would hate to see in a doctor's note somethin' that could be hurtful by the patient, where they need to lose a certain amount of weight by this time or they're gonna have horrible—they're gonna develop diabetes" [Caregiver 1, DM].

[a]DM: diabetes mellitus.

Improving Portal Usability, Understandability, and Individualization

Improving Interpretation of Laboratory Results and Notes

For interpreting laboratory results, adolescents and their caregivers noted that having a dictionary, glossary of medical terms, or additional information such as reference values would be beneficial. Some specifically stated that without these resources, they resort to web-based searches to interpret results. Adolescents without chronic medical conditions did not have advice regarding improving laboratory understanding for individuals accessing the portal, presumably because they had few or no laboratory values in their medical records. Regarding clinician notes, many adolescents and caregivers described a "language barrier" (Adolescent 2, DM) due to the medical terminology and complexity of notes. They advised that notes should be understandable to the average person, with "everyday language instead of medical terms" (Adolescent 13, IBD). One caregiver specifically advised how clinicians' notes could be a "bridge from the labs or the records" (Caregiver 8, IBD), with notes providing an explanation for difficult-to-understand laboratory results. Others advised that the notes did not need to change but that clinicians should speak with adolescents and their caregivers about the readability of these notes. A few adolescents and caregivers had suggestions regarding the content of notes, stating that they should contain next steps, address the concerns of the caregiver and patient, and be transparent and detailed.

Improving Portal Design

Some adolescents and caregivers reflected that the patient portal should be overall "user-friendly" (Caregiver 30, SCD) and "making sure that everything is findable, that needs to be found" (Caregiver 28, no chronic medical condition) with an organized layout. Caregivers of children with a chronic medical condition noted the potential benefits of having the office and doctor's contact information "in case we need to get ahold of them quickly" (Caregiver 9, IBD). Several adolescents noted that "it would be more acceptable if it was an app" (Adolescent 46, no chronic medical condition).

XSL•FO
RenderX

Individualizing the Interface

Caregivers and adolescents recommended improving the level of customization of portal contents for adolescents and their caregivers. Suggestions included having a simpler interface for adolescents, having a more summarized note personalized to the adolescent, or personalizing the interface with users selecting for desired or undesired features.

Linking Accounts

Caregivers and adolescents recommended a feature by which portal accounts could be linked, such that caregivers could have one sign-in for all children or family members. Participants noted that this would ease usability and access, which can be hindered by requiring multiple logins and passwords. Caregivers also recommended an additional feature where records could be linked and shared across institutions, which would enable the streamlining of medical care (Table 4).

XSL•FO
RenderX

Table 4. Illustrative participant quotes on improving portal usability, understandability, and individualization.

Theme and subtheme	Illustrative quote
Improving interpretation of laboratory results and notes	
Dictionary	"In bloodwork, there are a lot of medical terms that teens might not know. Try to make it easier for people to access information on that ... Well, maybe by the term, like white blood cell count for example, you just have a little info button that you can press it and it pops up some information about what that is" [Adolescent 5, IBD[a]].
Understandable language in notes	"Just make it as simple and as easy to understand and follow as possible. Maybe if they're using medical terminology, to explain what that medical terminology means. What condition is going on, where it is affecting them physically, and treatment. Very specific and easy to understand" [Caregiver 10, DM[b]].
Note as a bridge to understand laboratory results	"I think they should be thorough and in layman's terms. I think the labs can be, obviously, more medical terms, but the doctor's notes should be the bridge from the labs or the records to better—to make it easier to understand" [Caregiver 8, IBD].
Prepare families for medical terminology	"I think they should write them according to how they were trained to write notes. I don't think they should alter how they were taught to write notes. Write 'em as they should, but also let families know that these—prep 'em they contains medical terminology" [Caregiver 32, no chronic medical condition].
Improving portal design	
User-friendly	"Probably go to a graphic designer, somebody that designs websites, and just make an easily accessible app. Also make it look clean, I guess, because that makes you want to use it more" [Adolescent 46, no chronic medical condition].
Organized layout	"Maybe if there's a way to organize it to where even if a teenager, even if I was there without my mom, I would be able to understand where to find things and just make it easier to understand where everything is. I think that would help" [Adolescent 13, IBD].
Contact information	"I think adding the doctors' contact information for their office right there with their name in case we need to get ahold of them quickly" [Caregiver 9, IBD].
App form	"If they can make an app that would be easier to use" [Adolescent 7, DM].
Individualizing the interface	
Individualized notes	"Maybe they can make like a note for the kid, the teen, and a note for the parent. The note for the parent could be more in detail and stuff, and the note for the kid could be more summarized so they understand" [Adolescent 25, SCD[c]].
Simpler interface	"When I open the website, it makes sense to me, but it would be overwhelming to a child. Looking at the menu and the visits and the messages, and test results, scheduling appointment, those are things that—maybe it would just be like a little more child-like. To say a smiley face, you're seeing your pediatrician in two weeks, how are you feeling? To be able to—instead of saying, 'Send a message' 'Is there anything you wanna ask your doctor?'" [Caregiver 15, no chronic medical condition].
Personalized interface	"I would consider is having multiple sign-ons for each patient. That way, my son could have his sign-on. I could have my sign-on. Then if, let's say, we both make it clear that he only wants to see certain things, his level could be set for that, but then I could see everything or vice versa. That way, it's specific to what each user needs to see" [Caregiver 5, IBD].
Linking accounts	
Caregivers can link family member accounts	"They should make it so that the parents could have one account. Then the kids can come out of that account, where the parent doesn't have to log in with the other kids. 'Cause in my family, I have four other siblings, so my mom is gonna have to deal with that and having four other accounts" [Adolescent 25, SCD].
Link across institutions	"That's confusing that every institution has their own MyChart. If there was a way to make 'em universal that they flow in together, that would be more helpful to the families and the patients" [Caregiver 53, no chronic medical condition].

Discussion

Principal Findings

Using the technology acceptance model framework, we consider the 2 key factors of perceived ease of use and perceived usefulness that influence the attitude, behavioral intention, and actual portal system use [19]. Adolescents and caregivers provided advice on how to improve the perceived ease of use, including improving the accessibility of portal enrollment and access, the understandability of its contents, and mitigation methods for potential emotional distress that could result from portal use. Regarding its perceived usefulness, while some recognized the usefulness and importance of the portal, many

XSL•FO
RenderX

stressed that the perceived usefulness could be bolstered by clinician promotion of the portal and by improving the understandability and customization of its contents. There were three overarching themes that permeated the adolescent and caregiver recommendations: (1) encouraging and supporting portal use, (2) recognizing the emotional experience of portal use, and (3) improving portal usability, understandability, and individualization.

Increasing resources for accessing, using, and understanding the portal was nearly universally recommended. Areas that were identified to benefit from increased resources were establishing portal access and initial use as well as improving the understandability of laboratory results and clinician notes. This is particularly salient when discussing portal design for the adolescent age range, as the target audience's maturity level and reading skills evolve over time. Some resources could be standardized, such as handouts to understand the enrollment process, a tutorial to demonstrate display features, or a glossary that explains basic medical terms. Other aspects, such as interpreting radiology reports or understanding the potential impact of an abnormal laboratory result, may require a more nuanced and personalized approach. Improvement on these more nuanced aspects could involve efforts to improve communication with clinicians or the incorporation of advanced technologies, such as large language model (LLM)–powered chatbots. Prior work demonstrated that LLMs can improve the readability of radiology reports [20,21]. Another study found that LLMs were able to generate accurate and comprehensive responses with minimal risk of harm to radiation oncology patient care questions, though with a higher-than-recommended readability level [22]. Additionally, LLMs can provide inaccurate information or generate "hallucinations," which "include a vast array of failures of faithfulness and factuality" of the LLM [23]. More research, particularly in its application to the pediatric and adolescent population, is required to determine the safety, acceptability, and usefulness of LLMs in supporting portal use.

This study further emphasizes and expands on the idea that clinicians should be discussing patient portals with families. While clinician endorsement can influence portal engagement [24,25], this study is novel in identifying other important roles of clinician communication for the portal experience, including setting up parameters for confidentiality, alleviating emotional distress, and outlining expectations and communication preferences. Many caregivers and adolescents had recommendations for how clinicians may improve communication by way of their notes. These recommendations included using sensitive language that recognizes the potential emotional impact, using layman terms, and removing confidential information [26]. This research underscores the importance of clinician communication in promoting appropriate use and enhancing the effectiveness of the patient portal. Furthermore, it raises difficult questions about the purpose and audience of clinical notes. Should these notes primarily be written for medical documentation and communication with other clinicians, for understandable communication with caregivers and patients, or for liability or billing purposes? The same note might not be able to fulfill these divergent purposes [27].

Many caregivers and adolescents provided recommendations on improving the layout, as well as how EHR vendors could improve portal engagement and use by focusing on a user-centered design, which seeks to adapt the design and functionality of the portal based on user feedback and goals. Research in adult populations has found that identifying user goals and interests and then tailoring portal design and function to meet these needs improves engagement in the portal [28,29]. Furthermore, as research in adolescent and adult populations shows that portal engagement is associated with better medical adherence and understanding, as well as a better perception of control over one's health, this engagement could have significant downstream effects [30-33]. Given that many adolescents show limited interest in using the portal [5-8], engaging in user-centered design might increase the perceived usefulness and ease of use of portals, which are central drivers of uptake and acceptance of novel technologies [34].

Strengths and Limitations

This study had several limitations. First, while we purposively sampled for racial and ethnic minorities, as well as fathers, our study was limited by excluding non-English speakers and having few Hispanic participants and few fathers as participants. Therefore, these perspectives may not be appropriately reflective or generalizable to these populations. Second, adolescents with greater concerns about privacy and confidentiality might have been less inclined to participate in this study, which may result in a decreased emphasis on this aspect compared to a more generalized adolescent population. Third, as patients were recruited from a single health care system in St Louis, MO, using a single EHR platform, the results may not be generalizable to other regions of the United States or to other hospital systems using a different EHR platform.

This study also had several strengths. First, the unique perspective of this qualitative research evaluates not just the barriers and benefits of portal engagement for adolescents and their caregivers, but uniquely identifies potential solutions. Second, while the study was limited in having few fathers, few Hispanic participants, and excluding non-English speakers, it still represents a diverse population by including both adolescents and caregivers, those with and without chronic medical illnesses, and purposively sampling for racial and ethnic minorities. This improves generalizability by providing advice for clinicians and administrators that serves a broader group of patients and families, particularly when considering those with versus those without a chronic medical condition, who may have different priorities when using the portal.

Conclusions

Caregivers and adolescents had specific recommendations for administrators and clinicians to improve the usefulness of the patient portal. Adolescents and caregivers universally recommended more resources for accessing and using the portal, improved clinician communication regarding the portal, and enhanced user-centered design of the portal. Clinicians can take steps to better understand and inform families about portal

XSL•FO
RenderX

access and functions. However, the onus lies with administrators and EHR vendors to make structural changes to the portal user interface and functionalities that can improve the usefulness and usability of the portal. The advice provided in this study should guide these improvement efforts.

Abstract

Background: Invasive meningococcal disease has a high fatality rate and can lead to severe long-term health issues. In Europe, serogroup B meningococcal disease (MenB) accounts for over half of invasive meningococcal disease cases. In Italy, MenB vaccination is recommended for all newborns, but the uptake is below the Ministry of Health Vaccination Plan target (uptake: 80.91%; target: 90%).

Objective: A vaccine-based digital educational tool, Meningioca, was designed to increase primary care pediatricians' (PCPs') knowledge on the value and proper timing of MenB vaccination and to support communication of this value to parents.

Methods: Meningioca was developed using Articulate, an authoring software, and released via the TalentLMS online platform. Players engaged in a sequence of activities and mini-games, taking on the role of a PCP and progressing through 7 modules. Each module corresponds to a different age group and follows a fixed sequence of topics, simulating typical discussions that might occur during health checks for each specific age group. At the launch, members of the Italian Federation of PCPs were invited to play the game via an email link and rated the game based on aspects such as overall enjoyment, the difficulty of modules, and usefulness of the game as a teaching tool.

Results: Between March 2023 and May 2024, 471 PCPs accessed Meningioca, completing 1206 modules and 482 hours of learning. Meningioca received a mean rating of 4.4/5 (5 being the highest score), with many participants noting that they would recommend Meningioca to a colleague. "Communicating with the parent" and "health checks" were voted as participants' favorite module topics; "general culture" and "child growth and development" were voted as the most difficult. At the end of Module 3, 75% (n/N=50/67) of players agreed that Meningioca was a teaching tool to refresh and strengthen knowledge to a high or very high extent.

Conclusions: User feedback from Meningioca's first year suggests that the game is enjoyable and a potentially valuable learning tool for increasing PCPs' knowledge on vaccination.

KEYWORDS

primary care pediatricians; health education; immunization; meningococcal serogroup B; vaccination

Introduction

Invasive meningococcal disease (IMD) is caused by *Neisseria meningitidis*. Despite its low incidence in Europe (0.1 cases per 100,000 individuals), IMD is a public health concern due to its high fatality rate (13% in infants aged <1 y) and severe long-term health implications [1].

In Europe, serogroup B meningococcal disease (MenB) is the leading cause of IMD, responsible for more than 50% of serogroup-documented cases. Recent national surveillance data from Italy also highlight MenB as the most common cause of IMD in the country [1,2]. MenB vaccination in Italy is offered as a 2-dose primary course (starting from ≥2 mo of age and subsequent dose 2 mo later) and 1 booster dose (at 13 - 14 mo of age; a 2+1 schedule) [3]. However, MenB vaccination is recommended, not mandatory, in Italy [4] and nonmandatory vaccinations may be viewed as less important than mandatory vaccinations by citizens and health workers [5].

XSL•FO
RenderX

Due to the high incidence of invasive MenB cases in individuals aged under 1 year, studies analyzing both Italian and UK cohorts have highlighted the importance of starting a vaccination schedule as early as possible [6-8]. In two retrospective, observational studies, MenB vaccination in children aged <6 years was shown to be highly effective at preventing the disease [7,8]. However, despite the proven efficacy of MenB vaccination, mean MenB vaccination coverage in Italy for the 2020 birth cohort was reported to be 80.91% and therefore, lower than the Italian Ministry of Health's target of 90% [3,9].

In Italy, primary care pediatricians (PCPs) are expected to perform scheduled health checks, recommend vaccinations, and verify the vaccination status of children. In a survey conducted by the Italian Federation of Pediatricians (FIMP) in 2019, out of over 1000 responses, approximately 80% of PCPs said they stress the importance of vaccinations during health checks, but nearly half said they do not proactively arrange such health checks [10]. Although it is widely understood that vaccination is important for disease prevention, parental vaccine hesitancy is a known barrier to adherence to childhood vaccinations, with reasons for vaccine hesitancy including concerns about the busy pediatric vaccination schedule, vaccine effectiveness, and vaccine safety [11]. Between below-target vaccination coverage and vaccine hesitancy among parents, there is a need for effective communication about the value of recommended vaccinations in order to increase vaccine uptake [12].

Serious games and gamification allow participants to learn in an experiential, learning-by-doing way through making content more engaging, facilitating improvement of knowledge, and offering a measure of progress to create healthy competition, encouraging participants to learn more [13]. The use of serious games to improve knowledge and skills of health care professionals has been shown to be as effective as traditional learning methods, such as learning from written text or lectures [13]. In the context of vaccines, digital gamification has been suggested to hold potential to increase vaccination knowledge and thereby coverage. The use of gamification to enhance vaccine uptake is a rapidly expanding field [14,15]; a scoping review published in 2020 found only 7 peer-reviewed articles evaluating gamified digital tools to increase vaccine knowledge; a similar study published in 2024 identified 28 such articles, a four-fold increase [14,15].

The aim of this project was to develop a digital gamified educational training tool, Meningioca, to inform PCPs of the value and proper timing of vaccination with a focus on MenB and to improve communication of this value to parents and caregivers.

Methods

Game Concept

Meningioca was designed in partnership with the FIMP, which comprises of over 5300 Italian PCPs (the target audience for Meningioca). Meningioca was designed by a multiprofessional core team comprised of family pediatricians (end-users), professionals with experience and skills in online or remote learning, and professionals with documented scientific expertise in vaccines and vaccinations, through a design-thinking approach [16].

For Meningioca, the design-thinking approach began with understanding the needs of the end-users (ie, PCPs). To ensure all required information was included, a map of topics discussed during health checks was generated (Textbox 1). Unique ideas to communicate this information to end-users in an innovative and engaging way were discussed, and gamification was identified as a potential solution. The map of health check topics was then adapted to suit a serious game, forming the basis of Meningioca's content.

XSL•FO
RenderX

Textbox 1. Contents discussed during each health check-up formed the basis of Meningioca's modules. Each health check is intended to occur at a specific age. The contents of each health check are in line with this age and aim to monitor the physiological development of children and inform parents about preventable diseases.

Health check 1

- Tasks to be done
- Vaccination status
- Meningitis B – characteristics and diagnosis
- Early autism diagnosis
- Communicate with the caregiver
- Nutrition and breastfeeding

Health check 2

- Tasks to be done
- General culture
- Vaccination status
- Hunger signals
- Meningitis B – lethality and disability
- Communicate with the caregiver

Health check 3

- Tasks to be done
- General culture
- Meningitis B – symptoms
- Vaccination status
- External body obstruction
- Communicate with the caregiver
- Weaning

Health check 4

- Tasks to be done
- Meningitis B – doses and serogroups
- Vaccination status
- Neurodevelopmental assessment of the child
- Communicate with the caregiver
- Babbling and language development

Health check 5

- Tasks to be done
- Child's oral hygiene
- Vaccination status
- Meningitis B – spread and transmission
- Risks of using digital devices
- Live attenuated virus vaccination
- Communicate with the caregiver

Health check 6

- Tasks to be done
- Scoliosis and posture

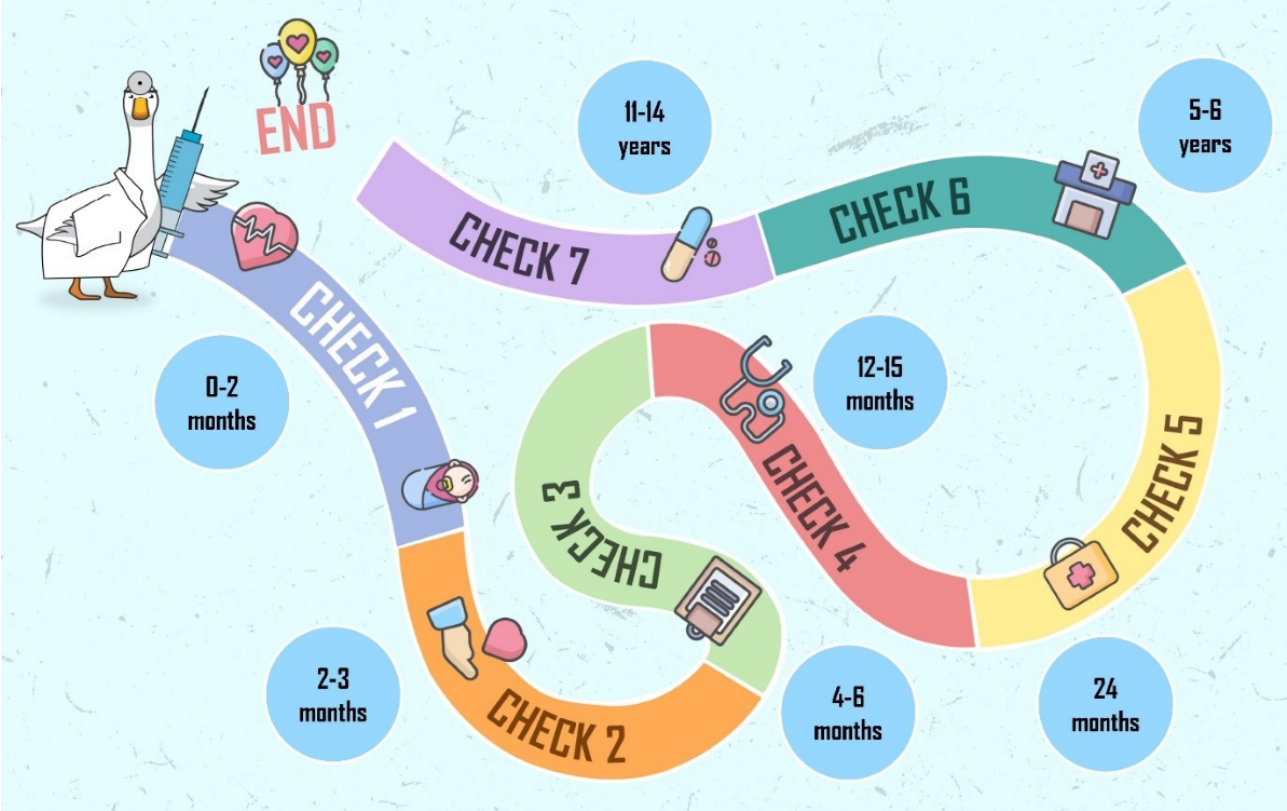
XSL•FO
RenderX

- Vaccination status
- Meningitis B – permanent disabilities
- Communicate with the caregiver
- Abilities at every age group

Health check 7

- Tasks to be done
- Sense of risk
- Vaccination status
- Meningitis B – contagion in adolescence
- General knowledge (adolescent language)
- Communicate with the caregiver
- Sexual experience

Game Design



Meningioca was developed using Storyline 360 (a suite of Articulate 360), an authoring software, SCORM 1.2 (standard format), and TalentLMS, a learning management platform [17-19]. Participants play as an avatar of a goose, inspired by the Game of the Goose (a well-known board game that originated in Italy in the 15th century) and take on the role of a PCP. Using a narrative approach, players participate in a series of activities and mini-games, using and improving vaccination knowledge. Examples of the mini-games include a drag-and-drop activity, where users separate actions they would and would not carry out during health checks, as well as a quick-fire selection game, where users scroll through a video and click on correct answers to questions posed. Participants received points and feedback after each mini-game, with points gained the first time a module is played and players ranked against all other participants. Once each module had been unlocked, it was freely accessible for review or to refresh training. All data included in Meningioca are supported by a reference, either from scientific or gray literature, to ensure all information is confirmed with a reliable source.

Game Refinement and Structure

A prototype of one module was played by 10 PCPs. Feedback from these testers suggested that the game was enjoyable, and further modules were produced. At launch (March 2023), Meningioca was comprised of 6 modules, with each module focusing on a different age group (0 - 2, 2 - 3, 4 - 6, 12 - 15, 24, and 60 - 72 mo of age), selected to be in line with the Italian national immunization calendar. In April 2024, a 7th module focusing on adolescents (11 - 14 y of age) was added (Figure 1).

XSL•FO
RenderX

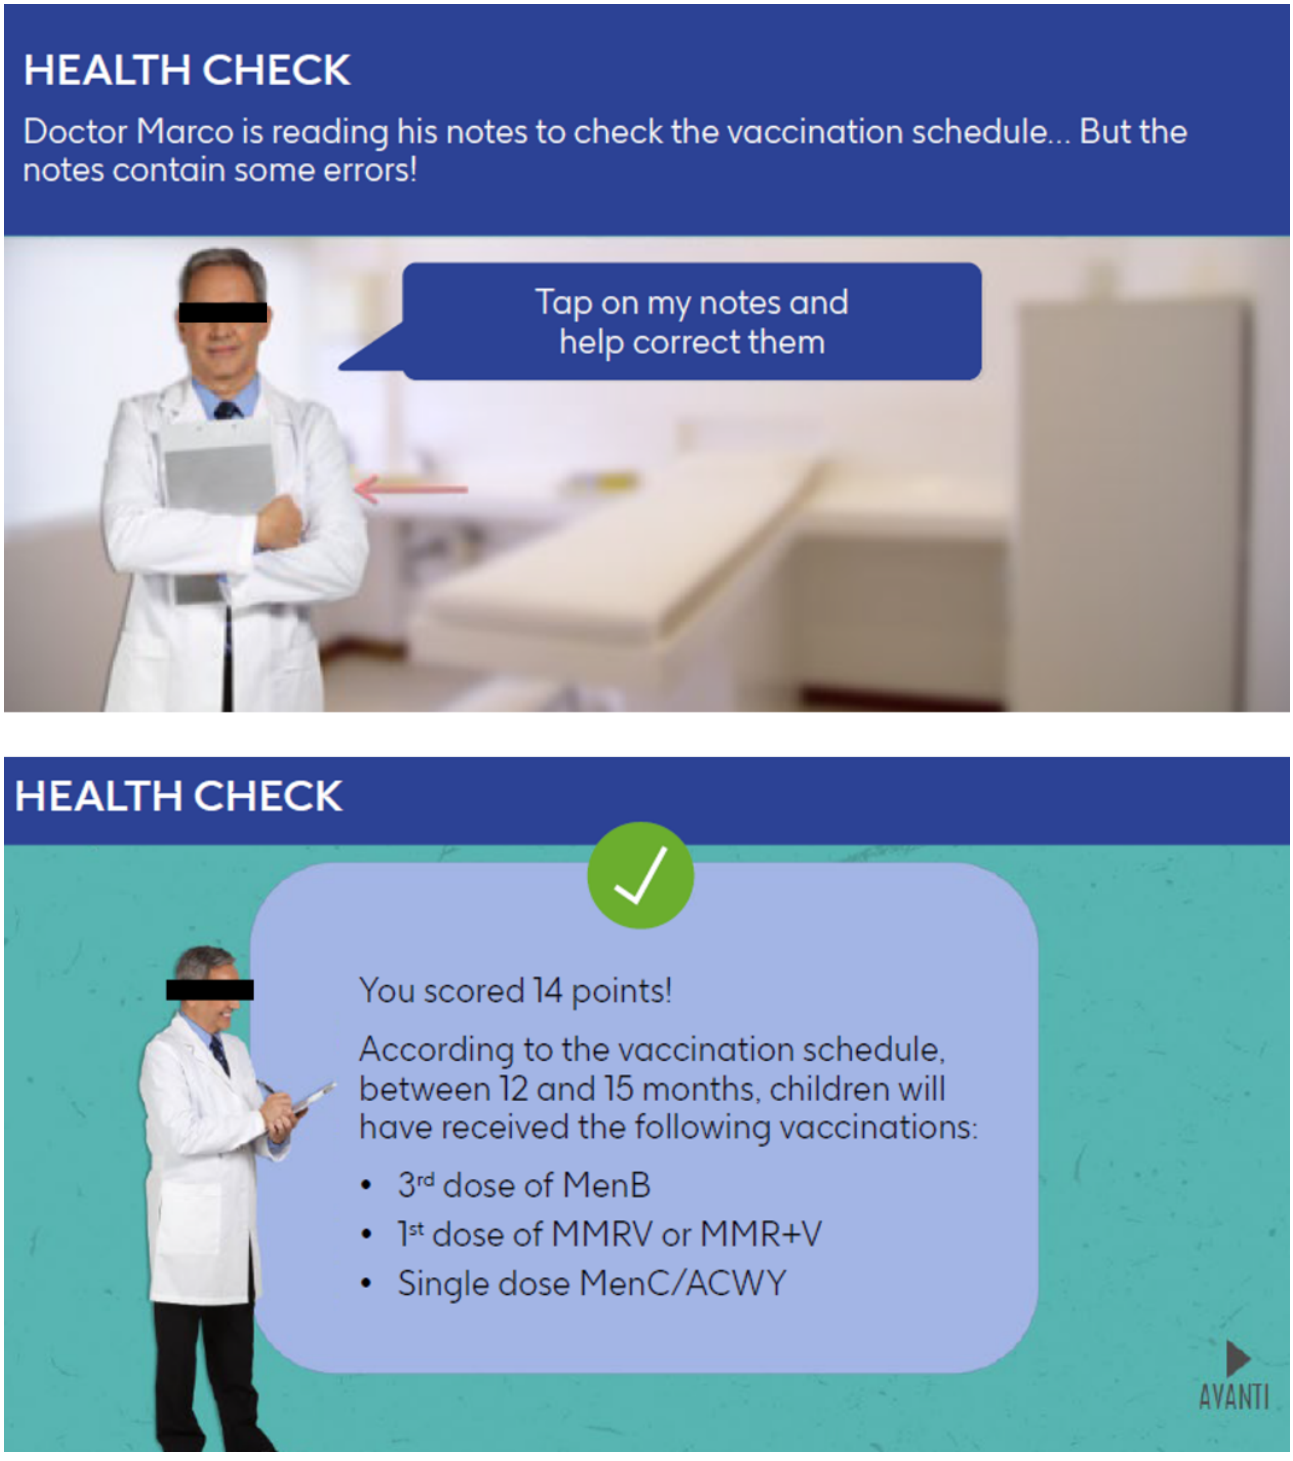


Figure 1. Meningioca modules.

All modules within Meningioca are based on a fixed sequence of topics, mirroring discussions that could be expected during health checks for each age group. In brief, the following main themes are covered: health checks in general, child growth or development, vaccination calendar and immunization status check, deepening MenB understanding, communicating with the parent, and Italian general culture. The modules use elements of surprise via quizzes and involve role-playing scenarios where users interact with avatars of colleagues (Figure 2) and caregivers (Figure 3).

XSL•FO
RenderX

Figure 2. Example scenes from Meningioca depicting interactions with colleagues. Text from the game has been translated from Italian into English.

XSL•FO
RenderX

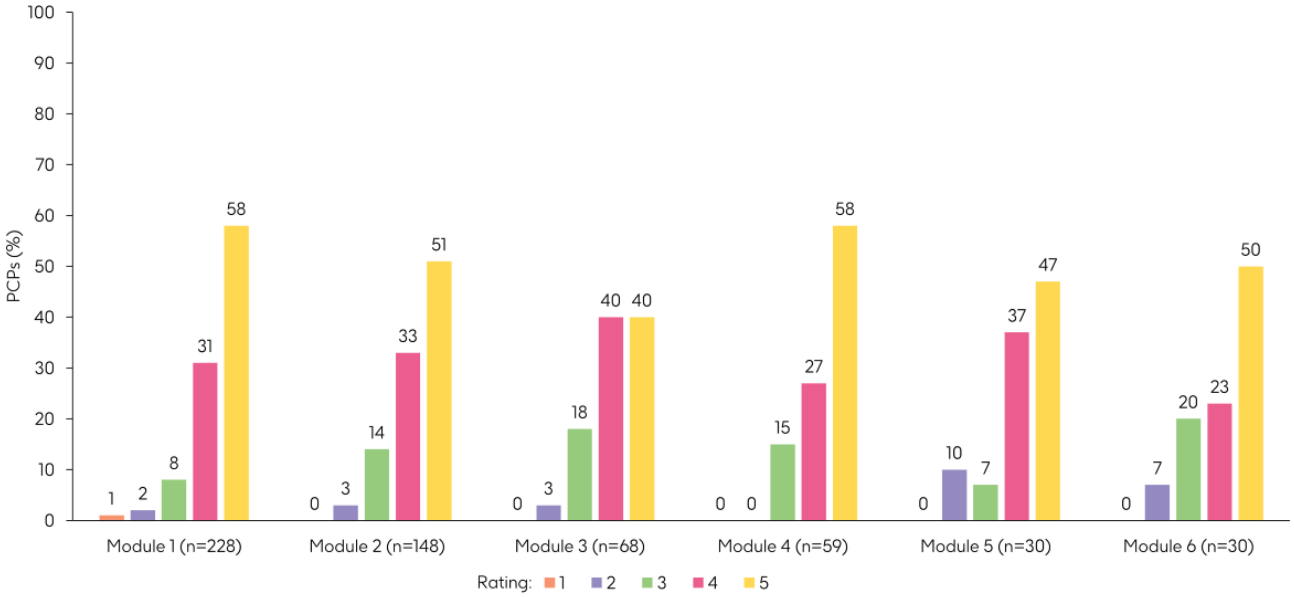
Figure 3. Example scenes from Meningioca depicting interactions with caregivers. Text from the game has been translated from Italian into English.

Game Launch

At the launch of Meningioca in March 2023, members of the FIMP were invited to play the game via an email link. Members who subscribed to the game were notified of the launch of the module in April 2024. The effectiveness of Meningioca to educate PCPs on the value and proper timing of vaccination with a focus on MenB was measured via feedback questionnaires at the end of each module (Multimedia Appendix 1).

Ethical Considerations

Meningioca was an educational project, not involving a human subject scheme nor collecting human data. Therefore, this project did not require ethics review as per the Linea Guida per la classificazione e conduzione degli studi osservazionali sui farmaci (GU Serie Generale n.76 del 31-03-2008) [20].



Results

Between March 2023 and May 2024, 471 PCPs accessed Meningioca and 1206 modules were completed, comprising 482 hours of learning. After Module 6, players were asked to

XSL•FO
RenderX

rate their enjoyment of Meningioca on a scale from 1 to 5, with 5 being the highest score. Meningioca received a mean rating of 4.4/5. Participants were also asked to rate individual modules at the end of Modules 1 - 6, and a breakdown of ratings is reported in Figure 4.

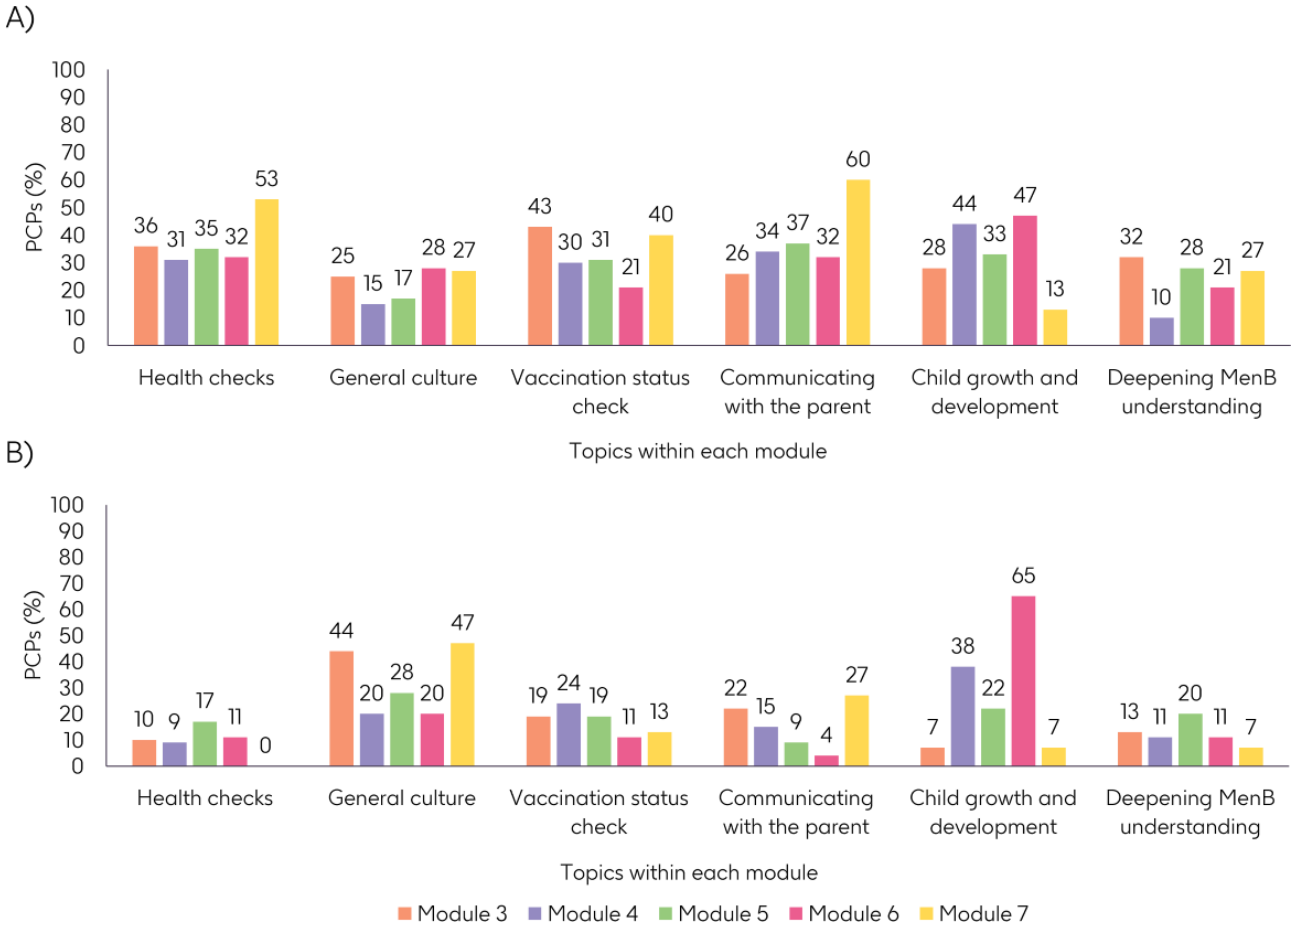


Figure 4. Proportion of PCPs rating each module on a scale of 1 - 5 from March 2023 to September 2023. At the end of each module, PCPs were asked to rate how much they liked the module on a scale of 1 - 5, with 5 as the highest score. PCP: primary care pediatrician.

After Modules 3 - 7, participants were asked to select their favorite topic and the topic that they found most difficult. There was a relatively even split regarding participants' favorite topics; "communicating with the parent" and "health checks" received the most votes and "general culture" received the fewest (Figure 5A). "General culture" and "child growth and development" were voted as the most difficult module topics (Figure 5B).

XSL•FO
RenderX

Figure 5. Proportion of PCPs that rated different topics within Meningioca as (**A**) the topic they liked the most and (**B**) the topic they found the most difficult. At the end of Modules 3 - 7, PCPs were asked to choose their favorite topic within the module and the topic they found most difficult. MenB: serogroup B meningococcal disease; PCP: primary care pediatrician.

On completion of certain modules, participants were asked whether they would recommend Meningioca to a colleague. Overall, 93% (n/N=63/68) answered "yes" at the end of Module 3, 90% (n/N=53/59) at Module 4, 90% (n/N=53/59) at Module 5, with the remaining participants answering "No." Additionally, at the end of Module 3, participants were asked to what extent Meningioca could be considered a teaching tool to refresh/strengthen knowledge, with a response scale from "very little" to "very much"; 43% (n/N=29/67) of participants answered "a lot" and 32% (n/N=21/67) of participants answered "very much".

Discussion

Principal Findings

To the best of our knowledge, Meningioca is the first gamified educational training tool developed within the field of vaccination, specifically designed for PCPs in Italy. The primary aim of Meningioca is to increase PCPs' knowledge on the importance of health checks within the context of childhood vaccination and, on a larger scale, boost the below-target MenB vaccination coverage in Italy and decrease general vaccine hesitancy among parents. Early results from the first 14 months of use indicate that Meningioca is not only an enjoyable game but also serves as an effective teaching tool to refresh and strengthen vaccination knowledge.

Comparison to Prior Work

Meningioca adds to the rapidly expanding field of digital vaccination-based serious gamification tools. Over the past 10 years, digital learning methods aimed at enhancing vaccination knowledge and programs have transitioned from being limited in use to becoming well established, with this evolution evidenced by the increasing number of these games available [14,15,21]. Meningioca, like many vaccine-based digital gamification tools, was aimed at a specific population [22,23]. Understanding the needs of the end-user is key for an engaging learning tool, and by focusing on one target group, the effectiveness of digital gamification tools can be maximized. PCPs were closely involved in the development of Meningioca, both as part of the initial multiprofessional design team and as testers of the pilot module. Involving the end-user from an early stage of development is a valuable strategy for tailoring the needs of a game and may have contributed to players' enjoyment of Meningioca [15]. Furthermore, Meningioca reinforces the idea that digital gamification tools can be effective even in cohorts with a high level of base knowledge, as demonstrated in a previous study involving antibiotics and vaccination games, where senior students' knowledge improved despite already possessing high baseline knowledge in these areas [22]. At present, the majority of vaccine-based digital gamification tools focus on one type of disease, such as influenza or human papillomavirus [15]. While Meningioca focuses on MenB vaccination, it also includes information on other childhood

XSL•FO
RenderX

vaccinations, topics discussed during health checks, and general Italian culture. By including information on multiple childhood vaccinations, Meningioca ensures PCPs gain interconnected knowledge between different vaccinations, which may lead to a more comprehensive understanding and an increased ability to apply this knowledge more broadly. The web-based nature of Meningioca enhances its ease of use, as no downloadable content or additional devices are required to participate. While the impact of the type of platform used to deliver the tools, eg, web-based, mobile, or virtual reality has not currently been evaluated in terms of user preference, this web-based approach aligns with the majority of vaccine-related digital gamified tools [15].

Feedback from Meningioca's first year indicated that the game is well-rated among players and enjoyable, as evidenced by Meningioca's mean rating of 4.4/5. The even split between players' favorite topics within modules suggests that the game offers a balanced experience, with each aspect developed to a high quality throughout. Enjoyment has been shown to have a positive effect on learning and memory, suggesting that Meningioca may be more effective at increasing knowledge if players enjoy it [24]. "Communicating with parents," consistently one of the PCPs' favorite topics, was voted as one of the least difficult, suggesting enjoyment and difficulty may be linked. As no single topic received an overwhelming majority of votes as the most difficult, it could be implied that players of a digital gamification tool need to experience a balanced level of challenge. This balance is crucial for effective learning, as players should feel challenged enough to engage in the game's content, but not too much that it becomes overwhelming. Overall, early results suggest Meningioca was well received and is an effective tool to increase vaccination knowledge.

In Italy, regular health checks from birth to the age of 14 years are recommended to monitor the physiological development of children and inform parents about preventable diseases, including raising awareness of these diseases and encouraging caregivers to ensure their children receive available vaccinations. Nonetheless, many PCPs do not proactively schedule these appointments, potentially leading to gaps in preventive care and lapses in vaccination schedule adherence, ultimately impacting the child's overall immunization profile [10]. Enhancing PCPs' knowledge on the importance of vaccination may not only encourage them to proactively arrange future health checks but also improve their ability to effectively communicate this information to parents, thereby reducing parental vaccine hesitancy, fostering increased vaccine adherence, and helping to prevent the spread of disease. While it is not possible to measure this directly, by encouraging both PCPs to carry out more health checks and parents to take their children to receive vaccinations, Meningioca could boost childhood vaccination uptake, potentially leading to Italy meeting its national MenB vaccination coverage target.

Strengths and Limitations

The ability of Meningioca to act as an effective teaching tool was strengthened by the inclusion of PCPs in its development. A large number of Italian PCPs were invited to play the game, improving the game's generalizability and aiming to ensure that the players accurately represent PCPs overall. Despite these strengths, Meningioca was associated with limitations. First, feedback questionnaires were not consistent across modules, leading to data gaps when synthesizing responses. Consistent questions across modules may help in building a more comprehensive view of the perceptions of end-users. Second, the impact of Meningioca, in terms of its ability to reduce caregiver vaccine hesitancy and increase vaccine uptake, cannot be directly measured. Surrogate measures such as enjoyment and Meningioca's use as a learning tool could instead be used as proxies.

Future Directions

Further feedback from users will be essential for the improvement of Meningioca as a tool to increase vaccine knowledge among Italian PCPs. Meningioca will continue to be a live game for PCPs to access, in order to increase their knowledge on health check activities as well as their knowledge on vaccinations. Specific questions that test PCPs' vaccine knowledge before and after using the training tool may help to quantify the effectiveness of Meningioca as a resource for increasing PCPs' knowledge. Further validation will need to be carried out to assess whether Meningioca could be effective in reducing caregiver vaccine hesitancy and increasing MenB vaccine uptake.

Conclusions

Digital gamification tools are an innovative and promising option for developing vaccination-related learning tools. Meningioca is an enjoyable and potentially effective educational resource for increasing PCP knowledge on the value and proper timing of vaccination, particularly MenB vaccination.

Abstract

Background: Unintentional injuries are the leading cause of death and disability among young children. Preventive strategies for unintentional injuries are mainly based on surveillance data and identifying risk factors.

Objective: This study aimed to review and synthesize published literature that determined the effectiveness of interventions for preventing unintentional injuries among children.

Methods: The methodological framework was supported by The Joanna Briggs Institute Reviewer's Manual – Methodology for JBI Scoping Reviews as well as the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. The inclusion criteria to include the studies in the review were unintentional injuries in children, interventions to prevent injuries, a brief description of the intervention and the outcome of the intervention, and articles published in a peer-reviewed journal and written in the English language.

Results: In total, 21 articles were included in the review following the systematic search of key databases such as Web of Science, PubMed/MEDLINE, Scopus, ScienceDirect, and gray literature for studies published between July 2013 and May 2023. Of the 21 articles, 16 were randomized controlled trials, 4 were nonrandomized controlled trials, and 1 was a mixed method study. The findings of the review showed that interventions, either as a single measure (video-based teaching, testimonial story-based teaching, health education, storybook reading) or in combination (knowledge quiz and simulation test, module-based teaching along with personal counseling, and teaching with the help of video and poster), have shown a considerable decline in the number and severity of injuries. The studies included various target populations, including children and adolescents between 0 and 19 years old.

Conclusions: The review results indicate the need to plan, implement, and reinforce preventive measures and techniques to reduce unintentional injuries among children. They can also serve as a useful indicator for policymakers.

(JMIR Pediatr Parent 2025;8:e67877) doi:10.2196/67877

Introduction

Background and Significance

Unintentional injuries among children are a major public health concern and result in significant childhood morbidity and mortality [1]. In addition to mortality risk, unintentional injuries can result in significant disability and disruption to quality of life [2,3]. Unfortunately, over 95% of all child injury deaths occur in low- and middle-income countries, resulting in a highly inequitable burden [4]. In India alone, unintentional injuries contribute to 9.1 deaths per 100,000 population, while transport injuries account for 2.8 deaths per 100,000 population [5].

Childhood encompasses different stages of emotional, physical, and brain development, ranging from newborn to adolescence. The age between birth and 5 years is a time of rapid changes in children's physical and cognitive abilities that can increase their

XSL•FO
RenderX

risk of unintentional injury [6]. Temperamental attributes such as increased activity level and impulsiveness in young children have been associated with proneness to injury [7]. Each of the new developmental stages in children brings changes in their physical, cognitive, or social development and the emergence of new injury hazards, thus emphasizing the importance of awareness of how injuries occur in certain populations to anticipate and avoid the risks [8].

Unintentional injuries were noted among children of younger mothers, overactive children, children belonging to extended or joint families, and children from urban dwellings, which assists in the identification of contributing risk factors to formulate strategies aimed at risk reduction and prevention of childhood injuries [9]. The environmental risk assessment found unsafe electrical points, unsafe stairs, unsafe kitchens with access to sharps, access to active fire, and unsafe furniture and objects as the most common risk factors leading to home injuries among young children [10]. Children left unsupervised or inadequately supervised may sustain negative physical, mental, or social outcomes [11].

The most challenging aspect for caregivers is to provide a safe environment for children to minimize injuries at home [12]. Toddlers and preschoolers are fragile as per their physical development and they spend most of their time at home compared to school-age children. This might impose a higher risk of developing unintentional injuries among children of this age [13]. The development of effective home hazard reduction educational materials could have a significant impact on the burden of home injuries in children, particularly in lower-income countries [14].

Studies are available on interventions to prevent unintentional injuries that are effective in improving various parameters such as knowledge, attitude, practice, and home environment.

Objectives

This scoping review aimed to review and synthesize published literature that determined the effectiveness of interventions for preventing unintentional injuries among children and the magnitude of the outcomes to support children and families. Additionally, it aims to provide an overview of the various interventions and understand those that are effective in preventing unintentional injuries. The results of this review can assist researchers and health care professionals in implementing injury prevention interventions and creating awareness among caregivers. The search question guiding this scoping review study was: what evidence exists that determines the implementation and effectiveness of interventions to prevent unintentional injuries in children? The review also focused on the most cost-effective interventions for the prevention of unintentional injuries for implementation in resource-limited settings.

Methods

Overview

This scoping review examined the relevant literature on interventions addressing unintentional injuries among children. The methodological framework was supported by the Joanna Briggs Institute Reviewer's Manual – Methodology for JBI Scoping Reviews, which builds on the framework introduced by Arksey and O'Malley [15] of Population, Concept, and Context, to create our search terms, with the population being parents or caregivers of children aged <12 years and children with age ranging from 0 to 19 years. The core concept is the prevention of unintentional injuries and includes interventions designed within the context of home, community, well-baby clinic, and preschool settings.

The review process followed 5 stages as outlines by Arksey and O'Malley [15]: stage 1, identifying the research question; stage 2, identifying relevant studies; stage 3, selecting studies; stage 4, charting the data; and stage 5, collating, summarizing, and reporting the results. The optional stage 6 is a consultation exercise to inform and validate the review findings with critical stakeholders, which was not carried out in this review. The methodological rigor of the individual studies was not assessed. However, each study was assessed for importance and coherence with the review question. We used the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines to enhance transparency in our approach to the scoping review study [16]. The PRISMA-ScR guidelines checklist is depicted in Checklist 1.

Stage 1: Identifying the Research Question

The review question was as follows: what evidence exists that determines the implementation and effectiveness of interventions to prevent unintentional injuries in children? The objectives of the review were (1) to provide a comprehensive overview of interventions to prevent unintentional injuries at home and (2) to identify the impact of interventions and outcomes on reducing the occurrence/incidence of unintentional injuries and improving the knowledge of parents/families regarding preventive strategies. The keywords used for the search were "injuries," "unintentional injuries," "children," "prevention," and "interventions."

Stage 2: Identifying Relevant Studies

The literature research included studies published between July 2013 and May 2023. Two independent reviewers (BSN and SS) searched the MEDLINE/PubMed, Scopus, ProQuest, Embase, and CINAHL databases for relevance. Search strategies specific to each database were developed. Any discrepancy in the extracted data was again rechecked by a third reviewer (AG) to resolve the discrepancy. AS provided subject expertise, and VG provided statistical input. The free-text terms and controlled vocabulary terms were combined via the relevant Boolean operators—AND, OR, and NOT. The bibliography and citations of the included studies were further searched to identify any additional studies pertinent to the review.

Stage 3: Selecting Studies

The articles identified through searches were exported to Rayyan software for duplicate removal and title and abstract screening. Concerns with data extraction were resolved in consultation with the team members. Based on the eligibility criteria, relevant articles were reviewed and selected.

XSL•FO
RenderX

We included peer-reviewed, free, full-text articles published in the English language. Narrative reviews, critical reviews, systematic reviews, and meta-analyses, as well as nonempiric publications like editorials, opinion pieces, case reports, conference abstracts, and commentaries, were excluded. Studies that reported any interventions targeting a reduction or prevention of the incidence/occurrence of unintentional injuries among children or improved knowledge or change in behavior of parents were included. Quantitative interventional studies such as randomized controlled trials (RCT), non-RCT studies, quasi-experimental studies, before-and-after design, crossover designs, and mixed methods studies, which include interventions, were included. Observational studies and qualitative studies were excluded from the scope of this review.

Stage 4: Charting the Data

The data extraction was carried out by 2 reviewers (BSN and SS), and any discrepancy in the extracted data was again rechecked by a third reviewer (AG). Data from the articles were extracted into an extraction table. The table included columns for authors, country of origin, year of publication, objectives, research design, sample size, target population, details of intervention, time frame of data collection, and main findings. Pilot testing of the data extraction framework was performed on 3 studies that were reviewed before the data extraction. No modifications were carried out in the data extraction framework. The summary of data extraction is depicted in Table 1.

Table . Description of data gathering measures of selected studies.

Author, year, country	Objective and study design	Target population	Intervention details	Measures and data collection	Findings and outcomes
Feng et al [17], 2023, China	To explore the mechanisms by which online social-network–based health education is effective in reducing unintentional injuries. RCT[a].	Parents of children aged 0-3 years (n=138)	Health education intervention to improve knowledge, skill, and behavior of parents regarding unintentional injuries through a WeChat account for 12 weeks, and communication of parents with each other and community childcare doctor for 9 months.	The knowledge, skills, and beliefs of parents regarding unintentional injuries in children were assessed before and after the intervention.	Of 76 parents in the intervention group, 49 (64.5%) demonstrated better understanding and effective communication compared to 11 (31.9%) parents of 66 in the control group. A positive impact on enhancing parents' knowledge, skills, and beliefs about unintentional childhood injuries was noted.
Ning et al [18], 2019, China	To assess the effectiveness of an app-based intervention to prevent unintentional injury. RCT.	Caregivers of preschool children aged 3-6 years (n=1980)	An app-based parenting education on unintentional injury prevention, with submodules to support interaction among users, surveys, and feedback.	Assessment of injury incidence, caregiver's attitude toward injury prevention, and safety behaviors measured at baseline and at 3- and 6-month follow-up visits.	No change in the incidence of injury and caregiver's attitude in either of the groups noted during the 6-month follow-up. Changes in injury prevention behavior were greater in the intervention group (B=.87, 95% CI 0.33 - 1.42).
Feng et al [19], 2022, China	To evaluate the effectiveness of an online social community–based parental health education intervention in preventing unintentional injuries in children between 0 and 3 years of age. RCT.	Parents of children aged 0-3 years (n=365)	WeChat Group and WeChat official account named, "Children Safety and Health." Thirty studies and 30 text messages on unintentional injury prevention and videos on first aid measures were produced and sent to the parents' WeChat group (intervention group).	Beliefs about unintentional injuries, skill in first aid measures for injuries, and behavior toward unintentional injuries were measured.	A significant difference in the occurrence of injuries was observed between the intervention and control groups (OR[b] 1.71, 95% CI 1.02 - 2.87; *P*=.04). The skill component showed a significant difference (*P*=.06) in the area of first aid for a tracheal foreign body.
Shen et al [20], 2016, China	To evaluate the efficacy of a testimonial-based video intervention in reducing drowning risk among school-aged children. RCT.	Children in third and fourth grade (n=280)	Testimonial-based intervention on drowning prevention; a 36-minute video of 4 testimonial stories about actual near-drowning experiences.	Safety knowledge on prevention of drowning, child-perceived vulnerability, and child-simulated behavior in and around the water measured at baseline and a week after the intervention.	A significant improvement was observed in children's safety knowledge of drowning risk ($F_{1,250}$[c]=7.04; *P*=.008) and safe, simulated behaviors ($F_{1,245}$=8.27; *P*=.004) related to playing in and near water. A minimal impact on children's perceived vulnerability to drowning risk was found.

XSL•FO
RenderX

Author, year, country	Objective and study design	Target population	Intervention details	Measures and data collection	Findings and outcomes
Wang et al [21], 2018, United States	To evaluate the effectiveness of an intervention grounded in social cognitive theory on the reduction of home safety problems. RCT.	Mother-toddler (12 - 32 months) dyad (n=277)	Safety intervention through health education, goal setting, and social support on fire and fall prevention, poison control, and car seat use.	Assessment of home safety problems and self-efficacy behavior measured at baseline and 6 and 12 months after the intervention.	There were fewer safety problems in the intervention group (between-group difference in change over time β=−0.54, 95% CI −0.05 to −1.03; *P*=.035) and decreased self-efficacy scores were noted at 12 months follow-up.
Weaver, et al [22], 2019, United States	To evaluate the effectiveness of a tailored parenting program on parenting behaviors. RCT.	Caregivers of children between 0 and 5 years (n=125)	RISE UP, a tailored parenting program to promote nurturing, child development, resiliency, social connection, and support within the context of unintentional injury prevention.	Safety behaviors of parents related to unintentional injury areas were assessed.	Postintervention follow-up showed a decrease in parenting injury risk scores (95% CI 25-42) and the intervention promoted positive parenting behaviors.
Swartz et al [23], 2013, United States	To evaluate the effectiveness of Keeping Baby Safe In and Around the Car, a video-based DVD on child safety seat installation and use. RCT.	Parent or custodian of a child aged 0-24 months (n=195)	Self-directed viewing of Keeping Baby Safe In and Around the Car, a video-based DVD lasting 45 minutes	Pre- and posttest assessment of vehicle safety knowledge quiz and child safety seat installation simulation test.	A significant improvement in parents' knowledge (*F*-value 103.71; *P*<.001) of car seats and their ability to discriminate the critical elements of correct car seat installation was found among the intervention group.
McKenzie, et al [24], 2021, United States	To evaluate the effect of a mobile technology–based health behavior change intervention on parental safety knowledge and behavior in preventing unintentional injuries. RCT.	Parents and caregivers of children aged between 0 and 12 years (n=5032)	The Make Safe Happen App was developed to help parents and caregivers learn about making their homes safer for children. It includes room-by-room safety checklists and links to purchase home safety products from Amazon.com.	Safety knowledge and safety actions of parents/caregivers were assessed during the pretest and posttest.	Mean knowledge score significantly increased between the pretest and posttest: intervention (8.45 - 10.32; *P*<.0001) and control participants (8.51 - 8.87; *P*=.0064). There was an increase in the percentage of participants who reported doing all repeated safety actions from 71.1% (pretest) to 77.3% (posttest) for the intervention group (*P*=.0001).
Banerjee et al [25], 2021, India	To evaluate the effectiveness of the child-to-child approach in preventing unintentional injuries in children. Non-RCT.	Children and adolescents from 0-19 years (n=397)	Older adolescents of the family were trained in first aid and CPR[d], road safety, traffic rules, injury prevention, and immediate care. They were made to disseminate the knowledge to their younger siblings and other family members.	The magnitude of injuries, time taken for recovery from injuries, knowledge of participants, and practice of the family were assessed during the pre- and postintervention period.	The postintervention measurement showed a significant reduction in the incidence of injuries (intervention: 16; 2.03, 0.06 - 4.0; control: 29; 3.62, 1.03 - 6.2; *P*<.001) and improvement in knowledge and practice on injuries in the intervention group. The total time taken for recovery was also evident in the intervention group (143 vs 95 days).

XSL•FO
RenderX

Author, year, country	Objective and study design	Target population	Intervention details	Measures and data collection	Findings and outcomes
George et al [26], 2021, India	To examine the effect of a home safety supervisory program on childhood safety, self-reported home hazards, and caregivers' supervisory attitude. RCT.	Caregivers of children aged between 2-5 years (n=130)	The Home Safety Supervisory Program consisted of a video and poster on "safe home, safe child" and individual home visits.	Injury patterns, home safety practices, and self-reported home hazard practices were assessed at baseline and 1 month after the intervention.	Significant difference in the mean baseline scores of caregivers' self-reported home hazard practices between the 2 groups (P<.001) and an improvement in the supervisory attitudes of caregivers in the intervention group (P<.001) were observed.
Holla et al [27], 2021, India	To evaluate the effectiveness of school-based interventions in promoting child safety and reducing unintentional injuries. RCT.	Children from classes 5 to 7 (n=1100)	A comprehensive pictorial child safety and injury prevention module was taught by 2 teachers on a regular basis (25 - 30 hours on average/school)	Incidences and types of unintentional injuries were assessed during the pretest and at follow-up visits at 3, 6, and 10 months after the intervention.	The incidence of unintentional injuries declined from baseline until the end of the study in the intervention and control groups. However, the decline in incidence was higher in the intervention group (50.4% vs 12.7%; P<.001).
Taylor et al [28], 2023, United Kingdom	To assess the effectiveness of systematically delivered, evidence-based home safety promotion for improving child home-safety practices. Non-RCT.	Families consisting of parents or caregivers of children between the ages of 2 and 7 months (n=361)	Stay One Step Ahead, a multievidence-based intervention for families, consisted of monthly safety messages through quizzes, posters, and flyers; home safety activities; home safety checklists; and educational safety weeks for families on common injuries.	Home safety outcomes measures were assessed at baseline and 12 and 24 months of follow-up.	The families in the intervention group showed significantly more improvement in storage of poisons out of reach (OR 1.81, 95% CI 1.06-3.07; P=.029). The total number of home safety measures used by the intervention families was significantly more than the control group families at 12 months (β=0.34, 95% 0.06-0.63; P=.019) and 24 months follow-up (β=0.46, 95% CI 0.13-0.79; P=.006).
Cowley et al [29], 2021, United Kingdom	To assess the impact of SafeTea on the knowledge and behavior of parents with regard to the prevention of scalds and first aid for burns. Mixed method design.	Parents or caregivers of children less than 5 years of age	SafeTea, a community-based intervention that provides information to parents regarding the risk factors for hot drink scalds and first aid for burns. The campaign included video clips, posters, leaflets, and charts distributed to schools, nurseries, and parent groups.	Knowledge and behavior of parents related to the prevention of scalds and first aid for burns were assessed.	Qualitative analysis under 4 themes: "reach," "engagement", "acceptability," and "impact/behavioural change." Reach and engagement declined after the first month due to decreased publicity and social media promotion. Changes in parents' behavior to minimize the risk of burns noted. Awareness of parents on the dangers of hot drinks and use of appropriate first aid measures improved.

XSL•FO
RenderX

Author, year, country	Objective and study design	Target population	Intervention details	Measures and data collection	Findings and outcomes
Morrongiello et al [30], 2013, Canada	To evaluate the efficacy of the Supervising for Home Safety program on mothers' supervision practices. RCT.	Caregivers of children between 2 and 5 years of age (n=186)	Watchful Parents, Safe Children video (20 minutes), followed by a structured discussion for 40 minutes. Mothers were given supervision diary recording forms for an 8-week baseline period.	Two time points of diary-based recording of postintervention practices—after 1 month and 3 months.	Significant decrease in time the children were unsupervised ($F_{1,83}$=4.81; *P*=.04), higher levels of supervision (t_{166}=2.99; *P*<.01), and an increase in attention to the child, immediately (t_{67}=5.22; *P*<.01) and 3 months (t_{67}=3.84; *P*<.01) after the intervention.
Morrongiello et al [31], 2021, Canada	To evaluate the effectiveness of a storybook about home safety on preschoolers' safety knowledge and injury risk behaviors. RCT.	Preschool children aged 3.5 to 5.5 years (n=59)	A storybook, "Careful Puppy Saves the Day," with information on different hazards in and around the home. Mothers were instructed to read the book with their children for 10 min/day, 4 times/week.	Knowledge about hazards and injury risk behavior was assessed at baseline and 4 weeks after the intervention.	Children in the intervention group were able to identify more hazards, showed fewer risky behaviors, and provided a more comprehensive explanation of safety (ηp2=0.13, 0.19, and 0.51, respectively).
Khan et al [32], 2023, Pakistan	To evaluate the effectiveness of the long-term effect of 2 injury prevention interventions on the prevalence of home injury hazards. Non-RCT.	Caregivers of children under the age of 5 years (n=312)	Two interventions were included: an educational pamphlet and a tutorial. Both consisted of information on injury hazards for children that are commonly found in homes along with the strategies to reduce or eliminate those hazards.	Reduction in home injury hazards was classified into 6 types: falls, burns, poisoning, drowning, cut injuries, and choking, which were assessed at baseline, 3 months after the intervention, and 2 years after the intervention.	The long-term outcome showed a significant reduction in injury hazards in the tutorial group when compared to the educational pamphlet group: falls (IRR[e] 0.24, 95% CI 0.08 - 0.71), drowning (IRR 0.45, 95% CI 0.85 - 0.98), burns (IRR 0.56, 95% CI 0.33 - 0.78), poisoning (IRR 0.53, 95% CI 0.44 - 0.77), and breakable objects within reach of child (IRR 0.62, 95% CI 0.39 - 0.99).
Tajiki et al [33], 2022, Pakistan	To examine the efficacy of a training program based on the health belief model in burn prevention knowledge in mothers of children aged 1-3 years. RCT.	Mothers of children aged between 1 and 3 years (n=64)	The educational intervention on preventing burns was delivered using lectures and PowerPoint slides, educational pamphlets, and illustrated books. It was a 45-minute session per week for a period of 6 weeks.	The questionnaire on the Health Belief Model for the prevention of burns in children was administered before the intervention, immediately after the intervention, and 2 months after the intervention.	There was a significant difference between the groups in terms of perceived susceptibility and severity during immediate and 2 months postintervention (control: 11.9, SD 0.53 vs 13.34, SD 0.82; intervention: 18.06, SD 0.24 vs 15.93, SD 0.24; *P*<.001). Significant difference in mean scores of perceived barriers and benefits (control: 9.78, SD 0.49; 9, SD 0; *P*=.6; intervention: 11, SD 0; 11.5, SD 1.04; *P*<.001).

XSL•FO
RenderX

Author, year, country	Objective and study design	Target population	Intervention details	Measures and data collection	Findings and outcomes
Choi and Ahn [34], 2021, Republic of Korea	To evaluate the effectiveness of mobile-based parental education programs in preventing unintentional childhood injuries. RCT.	Parents or relatives caring for infants and toddlers (n=167)	Two groups. First group: e-learning program for preventing unintentional injuries. Second group: electronic document distribution group, which received a PDF of e-learning content.	Safety knowledge and safety behavior regarding unintentional injuries were assessed during the pretest and 2 weeks after the intervention.	There was no significant difference found in the safety knowledge of the participants in both intervention groups. However, the safety behavior between the 3 groups showed statistically significant differences (F=10.09; P<.001).
van Beelen et al [35], 2014, the Netherlands	To evaluate the effectiveness of web-based, tailored safety information combined with personal counseling on parents' safety behaviors. RCT.	Parents with a child aged 5-8 months (n=1292)	E-health4Uth module, along with personal counseling on safety in and around the home on prevention of falls, poisoning, drowning, and burns in children aged between 12 and 24 months.	Parents' child safety behavior on prevention of falls, poisoning, drowning, and burns was assessed at baseline and 6 months after the intervention.	Parents in the intervention group showed significantly less unsafe behavior when compared with control group parents. Parents positively rated the E-health4Uth home safety intervention as an effective source of information (mean 4.05, SD 0.62).
Myers et al [36], 2022, Israel	To evaluate the effect of the intervention on injuries in children aged 0-4 years. Non-RCT.	Children aged 0-4 years and 5-17 years through home visits (n=6334)	The multifaceted intervention included a youth leadership program, workshops in well-baby clinics and preschools, home visits, and a media campaign.	Data on visits to the emergency room and hospitalization were obtained from the hospital records during the pre- and postintervention periods.	There was a significant reduction in emergency room visits (7.6%) in children between 0 and 3 years during postintervention period. Admissions to the hospital for burns and falls reduced. A greater reduction in emergency room visits (P=.038; P=.004) was observed for children aged 0-4 years in towns that started the intervention earlier.
Cheraghi et al [37], 2014, Iran	To assess the effect of the Health Belief Model on the education of mothers for promoting safety and preventing injury. RCT.	Mothers with at least 1 child below the age of 5 years (n=120)	Four sessions, 1 hour each, twice per week, on factors affecting mothers' knowledge and practices and Health Belief Model constructs.	Assessment of mother's knowledge, practice, Health Belief Model constructs, and injury history before and 2 months postintervention.	There was a significant mean difference in mothers' knowledge (3.98), practice (2.47), and Health Belief Model constructs in the intervention group (P<.001). The number of injuries decreased from 7 to 2 in the intervention group.

[a]RCT: randomized controlled trial.

[b]OR: odds ratio.

[c]*F*: analysis of variance.

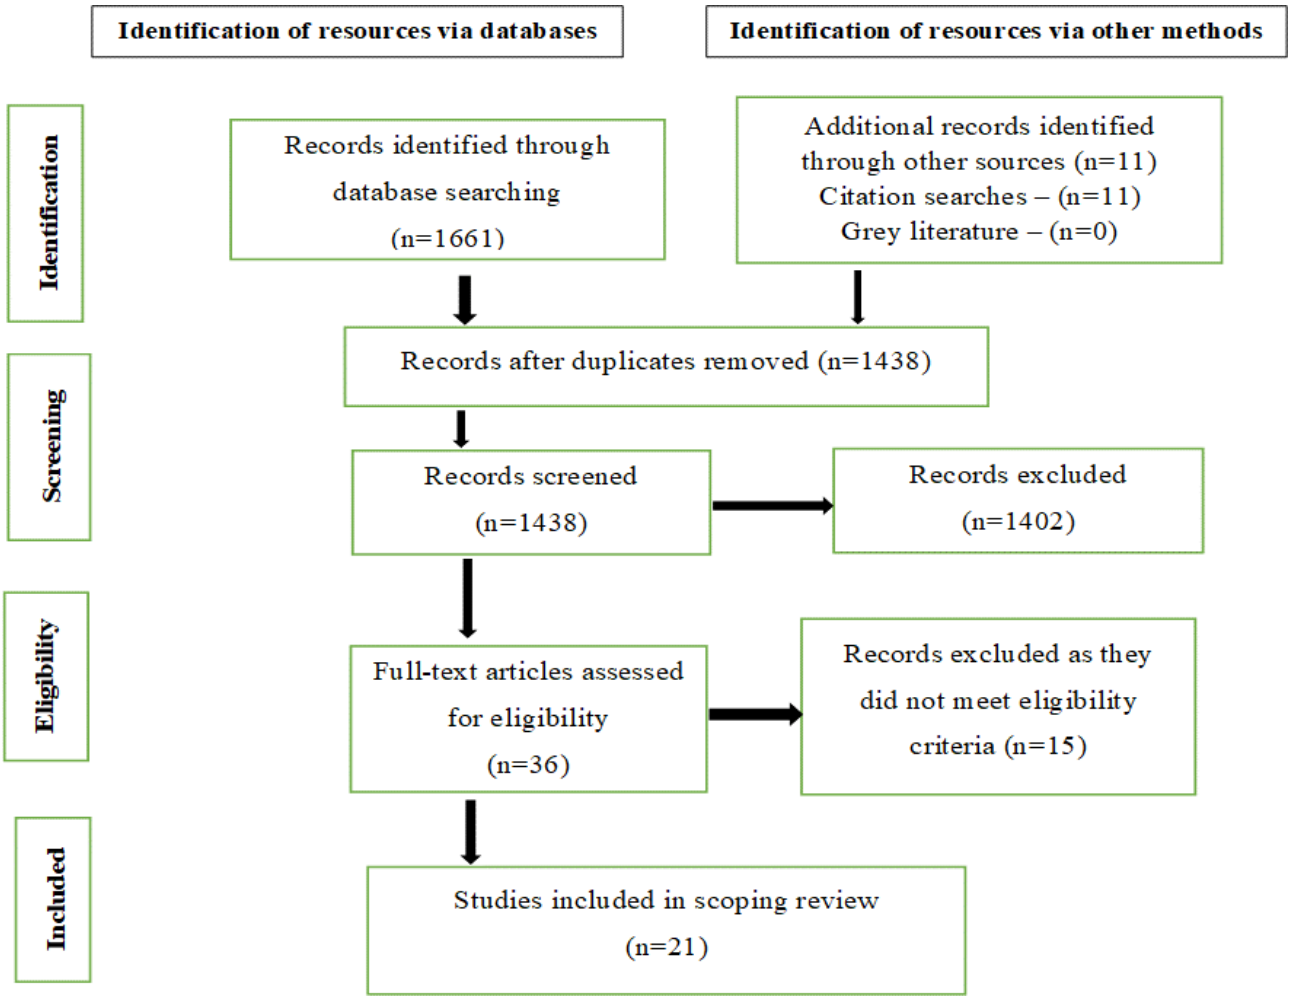
[d]CPR: cardiopulmonary resuscitation.

[e]IRR: incidence risk ratio.

Stage 5: Collating, Summarizing, and Reporting the Results

Data extracted from the included studies were collated and textually summarized and findings were tabulated as key categories.

Results



Overview

The database search identified 1683 articles, of which 245 (14.56%) were duplicates, so we screened the titles and abstracts

XSL•FO
RenderX

of 1438 (85.44%) articles. A total of 36 studies were evaluated for eligibility, and 21 studies were included in the review. Most studies that remained included parents or caregivers as participants (16/21, 76%), while some studies examined children specifically (5/21, 24%). Figure 1 provides an overview of the study selection process and the reasons for the exclusions of full-text articles.

Figure 1. PRISMA flowchart. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Study Characteristics

All 21 articles included were published in peer-reviewed journals. The review included 4 (19%) studies conducted in China [17-20], 4 (19%) in the United States [21-24], 3 (14%) in India [25-27], 2 (10%) in the United Kingdom [28,29], 2 (10%) in Canada [30,31], 2 (10%) in Pakistan [32,33], 1 (5%) in Korea [34], 1 (5%) in the Netherlands [35], 1 (5%) in Israel [36], and 1 (5%) in Iran [37]. The sample size of the studies ranged from 59 to 6334. The studies identified various target populations, including children and adolescents aged between 0 and 19 years. Diverse interventions such as teaching, training, workshops, technology-based training, storybooks, educational book–based training, and model-based training were identified. The target population included parents, caregivers, or family members, as well as children and adolescents with ages ranging from 0 to 19 years. Table 1 provides a detailed overview of the study characteristics.

Interventions Targeting Parents, Caregivers, and Family

Parents or caregivers supervise the activities of young children at home and are accountable for their environment. Hence, it is critical to assess their knowledge, attitudes, and practices regarding unintentional injuries and plan and implement effective interventions.

Parents or caregivers were the focus of intervention in 17 of 21 (81%) articles presented in this review. Caregivers of children below the age of 3 years were addressed in 8 of 17 (47%) articles [17,19,21,23,28,33-35], which focused on the knowledge of parents on vehicle safety, home safety, self-efficacy behaviors, and skill in first aid measures. Of the 17 articles, 6 (35%) highlighted interventions for parents of children aged less than 5 years [22,26,29,30,32,37], which assessed the levels of supervision and attention toward their children, and knowledge, practice, and safety behavior of parents regarding unintentional injuries. Two articles of 17 (12%) focused on caregivers of children between the ages of 3 and 6 years [18,31], and 1 article (6%) reported an intervention among caregivers of children younger than 12 years [24], which assessed the safety knowledge

XSL•FO
RenderX

and safety actions of parents/caregivers, knowledge about hazards, injury risk behavior, and attitude toward injury prevention.

Interventions Targeting Children as Change Agents

Injury prevention strategies, especially for individual-level factors, may be implemented using different learning approaches and theories. Approaches such as demonstrations, role-play, and simulation at the school level may help children understand how injury prevention interventions could work. Children learn about a health subject and share that information with their parents or the community, encouraging parents and others to enhance their knowledge and engage in health-promoting behaviors.

Of 21 articles, 3 (14%) focused on children of different age groups, evaluating the effectiveness of interventions to prevent unintentional injuries. Children in the third and fourth grades were assessed for their knowledge on the prevention of drowning, perceived vulnerability, and simulated behavior in and around the water [20]. Incidences and types of unintentional injuries were assessed among children in classes 5 to 7 [27]. In another study, through a child-to-child approach [25], adolescent children taught younger siblings and other family members regarding the prevention of unintentional injuries, whereby the knowledge of participants and the practices of the family were assessed.

Effectiveness of Educational Interventions

Education provides individuals with the necessary knowledge and awareness of the benefits and risks associated with certain behaviors. Education stands as a powerful catalyst for change, enabling people to acquire skills, information, and perspectives that shape their attitudes and perceptions.

This review found that 5 of 21 articles (24%) reported various educational interventions as a single strategy or in combination with other modalities to prevent unintentional injuries in children. RISE UP is a tailored parenting program to promote nurturing, child development, resiliency, social connection, and support to prevent unintentional injuries, which showed a decrease in parenting injury risk scores and promoted positive parenting behaviors [22].

Safety education prepares children for specific situations, whereas risk education prepares them for unanticipated or unknown situations, where they may have had no specific instruction or learning opportunity. The child-to-child approach [25] is one such method wherein the older adolescents of the family were trained in first aid and cardiopulmonary resuscitation, road safety, traffic rules, injury prevention, and immediate care. As a next step, they were made to transfer the information to their younger siblings and other family members. In another study, a comprehensive pictorial child safety and injury prevention module, as part of a school-based intervention to prevent injuries and promote child safety, was evaluated [27]. A significant reduction in the incidence of injuries in younger children and improvement in knowledge and practice regarding injury prevention were noted.

A multifaceted intervention with components such as a youth leadership program for adolescents, workshops in well-baby clinics and preschools, home visits, and a media campaign showed a greater reduction in emergency room visits in children between 0 and 3 years of age, as well as reduced hospital admission due to burns and falls injury [36]. A significant reduction in injury hazards was identified in a group that received tutorials when compared to an educational pamphlet [32].

Effectiveness of Home Safety Interventions

Home is a place where children spend lots of time during their younger days. It is the responsibility of the caregivers to ensure a safe place for the kids to learn, play, and explore. Home safety interventions are implemented to reduce the risk of accidents, injuries, and other hazards within households. In total, 4 of 21 articles (19%) reported on the effectiveness of home safety interventions.

Implementation of home-based injury prevention programs through the “Watchful Parents, Safe Children” video, “Safe Home, Safe Child” video, and a poster followed by a structured discussion with mothers and home visits showed a significant decrease in time during which the children were unsupervised, higher levels of supervision, an increase in attention to the child, a significant reduction in the injury pattern in children, and improved mean scores of caregivers’ home safety practices [26,30].

Implementation of innovative teaching strategies and playful approaches aimed at children can have a long-lasting effect in reducing unintentional injuries. A storybook, “Careful Puppy Saves the Day,” with information on different hazards in and around the home, read by mothers with their children beside them, was incorporated as a change agent. Significant changes were noted in the form of better identification of injury hazards, fewer risky behaviors, and a more comprehensive explanation of safety by the children [31]. Furthermore, Stay One Step Ahead, a multievidence-based intervention for families, incorporated monthly safety messages through quizzes, posters, and flyers; organized home safety activities; and educational safety weeks for families on common injuries. The findings showed a significant improvement in the storage of poisons out of children’s reach and improved use of home safety measures [28].

Technology-Based Interventions

Technology-based interventions can provide individualized and tailored interfaces enriched with interactive elements [38], which can be accessed anytime and anywhere. This review identified 9 articles that dealt with the effectiveness of technology-based interventions to prevent various forms of unintentional injuries in children.

A video-based DVD on child safety seat installation and use [23]; a web-based, E-health4Uth module along with personal counseling on the prevention of falls, poisoning, drowning, and burns [35]; a testimonial-based video intervention in reducing drowning risk among school-aged children [20]; and an app-based parenting education intervention to prevent unintentional injury [18] are a few of the studies that used

XSL•FO
RenderX

technology as a medium to disseminate the information to children and caregivers. The results of the studies show an improvement in their respective areas of assessment, which include the ability of caregivers to rightly install the car seat, less unsafe injury-prone behaviors, and children's safety knowledge of drowning risk.

SafeTea is a community-based intervention that incorporates video clips, posters, leaflets, and charts to educate parents regarding the risk factors for hot drink scalds and first aid for burns [29]. Choi and Ahn [34] conducted a mobile-based parental education program to prevent unintentional injuries in children, and McKenzie et al [24] studied the effectiveness of the Make Safe Happen App, which helped caregivers keep their homes safe and also provided links to purchase home safety products from Amazon.com. Two studies [17,19] used WeChat accounts for social-network–based health education to enhance the knowledge, skill, and beliefs of parents about unintentional injuries.

Interventions Based on Models and Theories

A theory is a comprehensive framework for explaining and predicting phenomena, while a model is a focused and practical tool that represents parts of a theory, helping to visualize or analyze specific aspects. We found that 3 of 21 articles (14%) reported on the effectiveness of interventions based on theories and models.

Two studies [33,37] evaluated the effect of training programs on mothers' knowledge regarding the prevention of unintentional injuries in children based on the Health Belief Model. Wang et al [21] assessed the effectiveness of an intervention grounded in social cognitive theory. The outcome of the reviewed article showed an improvement in the mothers' knowledge and practice, a decrease in the number of injuries, a significant difference in the Health Belief Model constructs, and fewer safety problems. Health education models can be used when planning educational programs at the individual or community levels.

Discussion

Principal Findings

The study aimed to answer the following scoping review question: what is known globally from the existing research literature about interventions to prevent unintentional injuries in children?

This review highlights the different areas of unintentional injuries, the interventions to prevent them, the outcomes of the interventions, and the diverse population on whom an intervention is being implemented. It provides an overview of how the interventions have been conceptualized and applied with the use of various data collection instruments measured at different timelines and their outcome measures. Of 21 studies considered for review, 16 (76%) studies were RCTs, 4 (19%) articles were non-RCTs, and 1 (5%) article had a mixed method design. Due to the heterogeneous nature of the included studies, the level of evidence of this review is considered as moderate.

Interventions Targeting Parents, Caregivers, and Family

In this review, 17 articles described interventions focusing on caregivers or parents to prevent unintentional injuries in children. Parents' or caregivers' involvement in educational interventions has been shown to improve safety knowledge and behaviors. In addition, the distribution of safety supplies to keep the home safe has improved the safety-related behavior of parents. Similar evidence was reported by the authors of a review [39] that interventions targeting parents are effective in reducing child injuries and that parenting interventions appeared to have a greater effect on home safety practices and the reduction of hazards at home. The findings of this review suggested that the beneficial effects were attributable to interventions targeting changes in parents' knowledge, attitude, and behavior.

Interventions Targeting Children as Change Agents

Three articles highlighted the interventions for preventing unintentional injuries in diverse modalities focusing on children of different age groups. The analysis showed improved knowledge and safety practices and a decrease in the incidence of injuries. However, there are fewer studies focused on children, who need to be considered further. There is a need to integrate appropriate and well-designed programs, especially focusing on children, such as school-based injury prevention modules, adolescent-targeted interventions, and simulation-based training. The cost of preventing unintentional injuries is much lower than the cost of treating their direct and indirect consequences [40]. In resource-limited settings, children can act as change agents to bring about change in their homes and neighborhoods. Future research on children should engage parents and teachers to develop, implement, and evaluate a more comprehensive and integrated intervention to prevent unintentional injuries.

Effectiveness of Educational Interventions

Five articles in this review addressed the effectiveness of educational interventions for both parents/caregivers and children. Educational interventions targeting changes in the behavior of parents and a hazard-free home environment were proven effective in reducing the incidence of unintentional injuries at home. The results of the studies demonstrate a positive outcome and ensure their feasibility of being implemented in low-income and resource-limited settings. Despite the high incidence of unintentional injuries among children in low- and middle-income countries, few interventional studies have been conducted in these countries. Multimodal educational interventions play a crucial role in sensitizing and creating awareness among children and caregivers to prevent unintentional injuries and injury hazards.

Effectiveness of Home Safety Interventions

Four articles reported on home safety interventions to prevent unintentional injuries. The analysis showed improved home safety practices, an increased level of supervision, and an environment free from injury hazards. Greater reductions in injury rates were found for interventions delivered in the home; however, there was a lack of evidence that home safety

XSL•FO
RenderX

interventions reduced rates of thermal injuries or poisoning [41]. It is particularly important that children in low-income families have close supervision, as the caregivers may have difficulty acquiring safety materials, and the presence of poor housing quality can impose an additional risk on children. Hence, the implementation of low-cost and locally available measures in an accessible and efficient manner could prove beneficial for both children and their caregivers to reduce the risk of injuries within the community context. Failure to invest in programs for preventing injuries among children will further increase the number of dependents in future generations and negatively impact society. Policymakers need to be involved in the evaluation and implementation of policies related to injury prevention, especially in resource-limited countries.

Technology-Based Interventions

Nine articles addressed the effectiveness of technology-based interventions in the prevention of unintentional injuries. Studies using interventions through mobile apps, web-based education, and social online health education provided an impactful result among the participants who used them effectively on a timely basis. Information and communication technologies can accelerate progress toward the achievement of the United Nations Sustainable Development Goals [42]. The use of technology-based interventions and an online platform can be adapted to deliver preventive health care information for large-scale community users. Nevertheless, the digital mode of interventions and app-based programs play a significant role in covering the large and diverse range of participants to create awareness, instill knowledge, improve their practice, and bring about a positive change in their behaviors. However, such interventions have drawbacks in low- and middle-income countries with a lack of resources and a lack of participant awareness of different gadgets.

Interventions Based on Models and Theories

This review highlighted 3 articles that used models and theories as a basis for interventions to prevent injuries. The Health Belief Model is a theoretical model used to guide health promotion and disease prevention programs, which explains and predicts changes in health behaviors [43]. Accordingly, the previously mentioned studies proved useful in applying a similar approach to evaluate the impact of interventions and thus bring about change in the practice and behavior of parents.

Strengths and Limitations

A strength of this review was that a comprehensive literature search of articles published from 2013 to 2023 was conducted using different databases that covered studies focusing on interventions to prevent unintentional injuries in children. A limitation of our review was that only articles published in the English language were included. Additionally, the present study area is an active field of research, so it is important to note that this scoping review is a snapshot at a particular point in time.

Conclusion

The articles included in this review addressed interventions of different magnitudes, data measurements taken at varying time points, and participants of a diverse nature. Cost-effective, accessible, and multifaceted interventions represent effective strategies to prevent unintentional injuries in children. Further studies in the form of online social networks and app-based interventions could be considered to reach out to the larger population with long-term outcome measurements.

Abstract

Background: Consistent medication use and proper inhaler technique are essential in pediatric asthma, and young children require supportive tools to maintain these practices.

Objective: This study aimed to investigate the caregivers' ability to use a companion robot–assisted app for children with asthma, their attitudes toward the usage, and the characteristics that hinder or facilitate the implementation.

Methods: This study employed a descriptive design. The sample group consisted of 30 children with asthma aged 3 - 6 years who received treatment at an asthma clinic and their caregivers. The companion robot for children with asthma called "Pukkabot," which is an innovation that is developed to teach inhalation techniques and to raise awareness about consistent medication administration through positive reinforcement, was examined. Data collection included personal information questionnaires, the System Usability Scale (SUS) for evaluating usage and overall satisfaction, and interviews to gather attitudes toward apps and characteristics that hinder or facilitate. Data were analyzed with descriptive statistics and content analysis.

Results: The study revealed that the scores for usability and overall satisfaction were 80.6, which is above the standard threshold and rated at grade A or an excellent level. Additionally, caregivers stated that the companion robots were easy to use, not complicated, had appropriately sized screens, and demonstrated clear images and sounds. The detailed steps for inhalation were exhibited, and reminders included those of medication times. The children with asthma enjoyed the app and were very interested, making most caregivers want to continue their use.

Conclusions: Caregivers were generally satisfied with the usability, finding it easy to use and engaging, which successfully attracted the interest of the children with asthma. Therefore, the companion robot may be used further, with the following recommendations: improving its physical design, adding content, incorporating tracking and symptom assessment systems, and creating a downloadable mobile app for greater accessibility and convenience.

KEYWORDS

companion robot; app; asthma; children; caregiver; model

Introduction

Asthma is a chronic respiratory condition that is characterized by bronchial tube inflammation, causing a heightened response to allergens and environmental factors. This causes symptoms, including bronchial hyperreactivity, bronchoconstriction, swelling, and increased mucus production [1]. Asthma affects individuals of any age, but it is particularly prevalent in children under 6 years of age, who are more susceptible to respiratory infections that worsen bronchial inflammation. Early detection and effective management of asthma exacerbations are crucial for preventing chronic inflammation and improving long-term health outcomes as children develop. The World Health Organization reported that approximately 262 million people globally experience difficulties from asthma, with a significant proportion being children from low- to middle-income countries, where the prevalence is increasing [2]. Approximately 2 million children with asthma are affected in Thailand, with 9.8% experiencing exacerbations annually and a significant cost associated with treatment [3].

The Global Initiative for Asthma (GINA) provides comprehensive guidelines for pediatric asthma management, focusing on symptom control through medication, decreasing environmental trigger exposure, and continuous symptom monitoring [4]. The key treatment goals include achieving satisfactory symptom control, minimizing acute exacerbations,

XSL•FO
RenderX

allowing normal daily activities, and maintaining optimal lung function. Children with asthma require both relief medications for acute symptoms and long-term controller medications to prevent future exacerbations and maintain symptom control [4]. However, many children face difficulties with consistent and correct inhaler use, which is crucial for effective medication delivery [5,6]. Literature emphasizes issues, such as incorrect inhaler techniques and irregular medication adherence, frequently stemming from caregivers's misconceptions about inhalers, fears of side effects, and concerns over costs [6,7]. Therefore, both children and their caregivers need to receive a thorough education on proper inhaler use and the significance of consistent medication adherence.

Environmental pollutants, particularly particulate matter (PM) with a diameter of <2.5 microns (PM 2.5), are significant triggers for asthma exacerbations, causing bronchial inflammation and irritation [8]. Children with asthma who are exposed to high air pollution levels may experience worsened symptoms, which impair lung function and require emergency medical interventions [9,10]. Various smartphone apps provide real-time air quality data, but challenges associated with accessibility and technological literacy among caregivers may limit their effectiveness in managing asthma triggers [11]. Effective asthma management requires collaboration between the pediatric patient and their caregiver, tailored to the child's developmental stage. Instilling health-promoting behaviors during this critical period facilitates the teaching of consistent inhaler use for preschool-aged children.

Recent technological advancements have resulted in the creation of devices aimed at improving inhaler use among children with asthma [12]. In particular, the JOE robot, which assists with demonstrating inhaler techniques, currently supports only English and French, limiting its accessibility for users who speak other languages [13]. Other innovations, such as the Whizz smart inhaler [14] and CapMeDicTM [15], provide various features to encourage proper inhaler utilization but may not fully engage young children or be widely available in Thailand. Hence, Thammasat University (Thailand) has developed the "Asthma Care" app, which provides comprehensive guidance on asthma management. However, further innovations that are specifically designed for preschool-aged children to meet their unique needs are highly warranted.

This study aimed to assess caregivers' ability to use "Pukkabot," a companion robot-assisted app designed to teach correct inhaler techniques and promote consistent medication adherence through positive reinforcement, considering the necessity for accessible and effective asthma management tools for young children. Additionally, the study investigated caregivers' attitudes toward "Pukkabot," determining features that may either facilitate or hinder its use. "Pukkabot" seeks to improve symptom control, reduce severe asthma attacks, and enhance overall treatment efficacy by fostering early awareness and proper inhaler techniques in children with asthma, ultimately minimizing hospitalizations and lowering the risk of severe complications. The results from this research provided valuable information into the development of effective and user-friendly asthma management tools for young children in Thailand, contributing to improved health outcomes and quality of life for children with asthma.

Methods

This descriptive study aimed to explore the feasibility of using "Pukkabot," and to explore barriers and facilitators to its use.

Recruitment Process

This study recruited caregivers and children with asthma from the Allergy and Immunology Clinic in the asthma clinic, Pediatric Outpatient Department of a tertiary hospital from February to September 2024. The children included were aged 3 - 6 years, physician-diagnosed with asthma of any severity for at least 6 months, receiving treatment with at least 1 inhaled medication, and without a history of uncertain clinical symptoms or learning disabilities. Caregivers were required to be ≥18 years old and related to the child.

A convenience sample of 30 children with asthma was recruited for this single-arm interventional trial. The sample size was guided by recommendations for pilot and feasibility studies [16]. According to Brooke [17], a general rule of thumb is to include at least 30 participants to allow for reasonable estimation of study parameters.

Study Design

The researcher instructed the caregiver and the child to interact with the companion robot. The process began with the caregiver setting a medication reminder (set for 5 min) and selecting an air quality monitoring option within the app, which displays the real-time Air Quality Index (AQI) to raise awareness about environmental triggers. Afterward, the child was invited to select a preferred pet (rabbit, dog, cat, bear, and dragon). When the reminder alarm was triggered, the child practiced medication administration steps by following on-screen instructions, using an empty inhaler device that contained no active medication. This activity was conducted solely as a demonstration to simulate proper inhaler technique, without actual medication use. The demonstration lasted approximately 5 minutes, during which the researcher provided verbal guidance and support. The entire process was completed within approximately 15 minutes.

Afterward, the caregivers were instructed to complete a 10-item System Usability Scale (SUS) regarding the companion robot. The caregivers completed the questionnaire, whereas the researcher recorded personal information from the patient's medical records.

Finally, the researcher interviewed the caregivers to gather their attitudes toward using the asthma management companion robot, as well as any perceived barriers or facilitators to its implementation. This aimed to determine areas for system improvement. The interview included 6 questions and lasted approximately 5 - 10 minutes.

Research Instruments

In this study, various instruments were used to gather data effectively, ensuring a comprehensive understanding of the participants' backgrounds and experiences. The instruments included personal information questionnaires, patient medical

XSL•FO
RenderX

record data forms, the SUS, and caregiver interviews focused on attitudes toward asthma management companion robot-assisted app for children with asthma.

Personal Information Questionnaires

The interview form designed for children with asthma collected vital information, including age, sex, age at diagnosis, prescribed medications, comorbid conditions, and asthma exacerbation-related hospitalization history. This comprehensive data helped develop a baseline profile of the pediatric participants, enabling a nuanced analysis of their health status and treatment history.

The personal information interview form for caregivers collected critical details, including age, sex, educational level, marital status, occupation, income, and relationship to the pediatric patient. Understanding the caregivers' backgrounds is crucial, as their socioeconomic status, educational level, and relationship to the child significantly affect asthma management strategies and the usage of health care resources.

Patient Medical Record Data Form

The Patient Medical Record Data Form was used to collect clinical data directly from the medical records of children with asthma. This form provided comprehensive information regarding asthma severity, which was classified according to the GINA guidelines by health care professionals, age at diagnosis, prescribed medications for symptom control and relief, other treatments received, comorbid conditions, and any asthma-related hospitalization history.

System Usability Scale (SUS)

The SUS, developed by John Brooke in 1986 [17], is a widely recognized tool for evaluating the usability and overall satisfaction of a companion robot-assisted app. The SUS consists of a 5-point Likert scale, with response options ranging from 1 ("strongly disagree") to 5 ("strongly agree"). The scale includes 10 items—5 positively worded and 5 negatively worded—that assess the usability of the asthma management app. Scoring involves assigning values from 1 to 5 for the positive items while applying reverse scoring for negative items. The total score is calculated and then multiplied by 2.5 to convert the range from 0 to 40 to a scale of 0 - 100. A score of ≥68 indicates acceptable usability, corresponding to the 50th percentile, whereas scores below this threshold indicate areas for improvement in design and usability [17-19].

Caregiver Interviews on Attitudes Toward Using a Companion Robot for Asthma Management

In-depth interviews were conducted with a semistructured format to gain information about caregivers' perceptions of the asthma management app and the pediatric asthma model. This approach facilitated a nuanced exploration of caregivers' attitudes, including barriers and facilitators to app. The interview consisted of 7 main questions developed to prompt discussion on previous experiences with similar technologies, willingness to use the asthma model, and opinions on the model's design. In particular, caregivers were asked the following questions: "Have you ever encountered a similar app or model before?"; "If not, after learning about or using this system, would you consider using this asthma model for your child?"; "What are the main reasons for your decision?" Another sample question included the following: "Which aspects of the model's design do you think are not well-developed or convenient for use?" The interviews were used to collect qualitative data that complemented the quantitative results, providing information on how to improve the effectiveness and user acceptance of asthma management tools.

In summary, the diverse range of research instruments used in this study—personal information questionnaires, patient medical record data forms, the SUS, and caregiver interviews—enabled a comprehensive assessment of both the clinical and experiential aspects of asthma management in children. The research aimed to provide actionable information for improving asthma care delivery and technology usage among caregivers and health care professionals by integrating quantitative and qualitative data.

Pukkabot

The tool used in this study is the companion robot-assisted app for children with asthma, named "Pukkabot," an innovative device designed to teach proper inhaler use and promote medication adherence through positive reinforcement (Figure 1). The design of the companion robot is tailored to each child's treatment plan, specifically focusing on those who require both inhaled controller medications and quick-relief medications. The app operates on the Android 13 platform, featuring a touch-sensitive screen that displays both video and audio content. The model, shaped like an animal, measures 23.5 cm in width, 23.1 cm in length, 21 cm in height, and 800 g in weight, including the screen. Its structure is composed of polylactic acid plastic, providing strength and lightweight durability during use. Polylactic acid is a form of plastic derived from natural sources, making it non-irritating during use. It can be cleaned with an alcohol spray. The model is developed to be placed on a flat surface, with the weight supported by its 2 legs and tail for balance while using the screen. The screen area is recessed by approximately 2 inches to prevent damage in case of impact or if it falls from a height. The main display screen provides the following 5 operational modes.

XSL•FO
RenderX

Figure 1. Appearance of the Pukkabot companion robot and screenshots of its mobile app interface designed to support caregivers of children with asthma.

1. My pet: the user must select a pet by tapping on the desired pet when entering for the first time. Afterward, the screen will display the virtual pet. This screen will enable the user to feed the pet, which receives 1 food item per completed inhaler use.
2. Timer: the screen displays a timer to remind the user of the medication inhalation schedule. The screen shows an image of the eyes when in standby mode. The screen changes to display the message "It's time to recharge" along with a cartoon sound alert as the scheduled inhalation time approaches. The timer can be set for 2 reminders per day.
3. Inhaler use: this displays images and step-by-step instructions for using the inhaler, with accompanying audio. Users navigate through the steps via control buttons, enabling them to administer medication in real time alongside the instructions displayed.
4. Rewards: this displays the rewards earned, with the virtual pet growing according to the number of completed inhaler uses and the food it receives. This is designed to motivate children to use their inhalers consistently.
5. Air quality: this displays the local air quality in terms of AQI levels. It is used along with the daily usage of inhalers to alert the user of the severity and provide information on avoiding triggers.

In total, 1 pediatric nurse with expertise in asthma care and 1 pharmacist with expertise in respiratory care validated the "Pukkabot" for content accuracy, structure, and language. Feedback from these experts was incorporated to refine and improve the system.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Review Board Committee of the Faculty of Nursing and the Faculty of Medicine, Siriraj Hospital, Mahidol University (MU-MOU CoA no. IRB-NS2023/824.1212, dated December 12, 2023). All caregivers and children were informed of the study's purpose and procedures and provided written informed consent before participation. Data were anonymized prior to analysis to protect the confidentiality and privacy of participants. No financial compensation was provided; however, caregivers received small tokens of appreciation in recognition of their time and participation.

Data Analysis

Personal data and usability assessment results were analyzed with descriptive statistics. Content analysis was conducted to assess the system's usability, determining both barriers and facilitators based on caregiver interviews.

Results

General Characteristics of Children With Asthma and Their Caregivers

Among the children with asthma, 63% (19/30) were male and 37% (11/30) were female, with an average age of 5.3 (SD 0.7) years. The onset of asthma occurred at an average age of 2.9 (SD 1.2) years, with 77% (23/30) of the children being diagnosed with allergic rhinitis. A majority (21/30, 70%) of children used both the controller and reliever inhaler medications. Only 7% (2/30) of the children had partly controlled asthma, whereas the majority (28/30, 93%) demonstrated well-controlled asthma. Asthma control was classified according to GINA guidelines, with "well-controlled" defined as symptoms occurring no more than twice per week, minimal nighttime symptoms, infrequent use of rescue medication, and no limitations on daily activities.

Of the caregivers of children with asthma, 80% (24/30) were female, with an average age of 40.7 (SD 6.8) years. A large proportion (22/30, 73%) were mothers, with only 7% (2/30) being grandmothers. Regarding educational background, 50% (15/30) completed a bachelor's degree, whereas 20% (6/30) completed a master's degree. Regarding occupations, 57% (17/30) were employed. Most caregivers (19/30, 63%) reported a monthly household income of > 20,000 (approximately US

XSL•FO
RenderX

$570), which is considered a moderate-income level and is above the country's median household income.

Usability and Overall Satisfaction

The average SUS score from the 30 caregivers was 80.6 (SD 12.2), with scores of 52.5 - 97.5 based on the results of the usability and satisfaction assessment, as measured by the SUS. These scores are higher than the standard benchmark of 68, indicating a level of usability above average. The SUS score is categorized in the grade A range, indicating a high level of usability and acceptability.

The highest rated aspects of usability and overall satisfaction in reviewing the individual items were item 7, "I believe others will quickly understand how to use this app," and item 3, "I find this app easy to use." In contrast, the lowest rated aspect was item 4, "I believe I need assistance to use this app," indicating that most users did not feel the need for additional help and could use the app independently.

Attitudes Toward Using a Companion Robot for Asthma Management

The results in this section depend on interviews about attitudes toward the use of the companion robot-assisted app for children with asthma, as well as user behavior observations. The results are categorized into 3 main areas: attitudes toward use, barriers and facilitators, and improvement suggestions.

Attitudes Toward the Use of the Companion Robot

Caregivers' experiences and perspectives on the tools were largely positive.

There was a lack of previous experience. None of the caregivers had previous experience with similar apps for asthma management, although 3 had learned about inhaler use through videos or YouTube.

There were also positive reactions to the companion robot. After being introduced to the tools, 26 (87%) caregivers expressed an interest in using them. They considered the tools easy to use and believed they could motivate their children to use their inhalers regularly. The cute, pet-themed design was particularly appealing to the children, making the process more engaging.

> *I've never used it before, but I would like to. My child and I have used the inhaler for a long time, but this doll could motivate my child to want to use it more. I like that it has a pet, which makes it fun for my child and serves as good motivation.* [Mother, aged 38 years]

> *I haven't used it, but I've watched videos on how to utilize the inhaler and have an app that monitors air quality, although I rarely check it. This seems useful, and my child seems interested. It may help motivate my child to use the inhaler properly, as they frequently avoid it. I like the presence of a cartoon pet to capture their attention.* [Mother, aged 30 years]

Barriers and Facilitators in the Use of Companion Robot

Caregivers identified both positive aspects and challenges to the use of the companion robot. The feedback is categorized into 2 sub-themes: (1) external features of the companion robot and (2) usability.

External Features of the Companion Robot

In terms of facilitators, 9 (30%) caregivers felt that the model's design was appealing and stable, with a pet-like appearance that caught children's interest.

In terms of barriers, 21 (70%) caregivers emphasized several design issues, including that the model was too large to be portable, its surface was not smooth, and the colors were not vibrant.

> *It demonstrates a complete range of functions, but the size is a drawback. It is too large to carry around, and an app would be more convenient. I think the app would only be initially engaging for children unless additional features are added.* [Mother, aged 43 years]

Usability

In terms of facilitators, all caregivers reported that the app was easy to use. The content, images, and audio instructions were concise and suitable for young children, enabling them to follow the steps independently. The cute cartoons and pet-care game kept the children motivated to regularly use their inhalers. Additionally, the app included helpful features, such as medication reminders, air quality monitoring, and health guidelines. Most (26/30, 87%) caregivers felt that the light, colors, and sounds of the app exhibited no negative effect on children's eyesight due to the short usage duration.

In terms of barriers, some (3/30, 10%) caregivers stated that the medication preparation steps were too long and that users had to manually advance through the inhaler steps. In total, 4 caregivers (4/30, 13%) expressed concerns about screen addiction from using the app frequently.

> *I like the reminder feature for medication timing, as it helps us not forget. The model's large size is inconvenient to move, and I would prefer it as a mobile app. I'd also like a feature to count the number of doses administered.* [Mother, aged 38 years]

> *I like the cartoon that captures my child's attention, and the images and sounds are clear. I appreciate the advice on when to use emergency inhalers according to breathing difficulty. A mobile app would be more convenient.* [Father, aged 37 years]

Suggestions for Improving the Companion Robot

Caregivers provided recommendations to improve both the companion robot for asthma management:

- App development: a majority (27/30, 90%) of caregivers recommended developing the app into a smartphone-compatible version for easier access.
- Model design: a smaller group (3/30, 10%) indicated retaining the model but making it more portable by adjusting the design to be rectangular and flat for easier storage.
- Functional enhancements: several additional features were proposed, including (1) instructions for cleaning the inhaler device, (2) tracking inhaler use and remaining medication

XSL•FO
RenderX

doses, (3) an action plan for asthma exacerbations, (4) videos showing asthma symptoms, (5) videos demonstrating nasal irrigation techniques, (6) notifications about environmental triggers (eg, high dust levels), and (7) contact channels for health care teams.

Discussion

Principal Findings

The study revealed that caregivers reported an average post-use satisfaction score of 80.6 (SD 12.2) on the SUS, which exceeds the standard threshold and falls within the "Grade A" category. This high score indicates that caregivers of children with asthma were highly satisfied after their initial trial of the companion robot. Such a positive reception may affect their decision to continue using these tools in the future. Further analysis revealed that most caregivers expressed satisfaction due to the app's ease of use, its simplicity, and because they did not require assistance during the operation.

Interviews with caregivers indicated that none had previous experience using an app or model specifically designed for children with asthma, although some had learned inhalation techniques from videos or web-based media primarily intended for adults. However, all caregivers considered the app user-friendly, with a comprehensive set of functions. The content, audio, and animated illustrations of inhaler usage were deemed suitable for young children, enabling them to independently follow the steps. Additionally, the pet-care game included in the app helped motivate children to consistently use their inhalers. The app can reduce disease severity and improve treatment outcomes, enabling children to live healthy, normal lives, by encouraging early asthma control and fostering self-discipline in inhaler use. Motivation in children under 6 years of age is significantly improved through interactive and engaging tools. Research reveals that interactive learning media, such as game-based learning and multimedia presentations, foster intrinsic motivation by providing dynamic learning experiences that cater to diverse learning styles [20].

A majority of caregivers indicated that the app could be optimized for use on mobile platforms, but the design of the companion robot for children with asthma, "Pukkabot," in this study specifically aimed to provide preschool-aged children (ages 3 - 6 y) with a tangible companion during inhalation therapy. The model functions as a motivator for consistent inhaler use to help control asthma symptoms. Familiar toy-like designs in therapeutic devices improve children's emotional connections, thereby increasing treatment engagement and adherence, as evidenced by positive feedback from children and parents regarding the respiratory aid for inhalers (RAFIhaler) experience [21].

Caregivers stated that the asthma inhaler details provided in "Pukkabot" aligned well with their requirement for managing children with asthma. This result aligns with research by Lio et al [22], who developed an app for children with asthma aged 2 - 12 years. Their study revealed that children and caregivers were more likely to use the app when it was engaging, easy to use, and contained essential content, including disease pathophysiology, self-care practices, and asthma management strategies [22]. Similarly, Li et al [23] established an app for asthma self-management in children that featured symptom evaluation, treatment planning, inhaler usage, and communication with doctors in emergencies, further improving asthma management. Together, these studies emphasize the importance of user-friendly, comprehensive apps in enhancing asthma care for children and their caregivers.

The ability of apps to set multiple reminders for inhaler use significantly benefits children with asthma, particularly those requiring frequent medication doses. A study revealed that setting multiple alarms ensures timely medication adherence, which is crucial for asthma management in children who may require varying inhaler schedules based on the severity of their condition [24]. Additionally, the inclusion of the AQI monitoring function enables both caregivers and children to be vigilant about daily air quality changes. PM 2.5 significantly affects respiratory health, especially in children with asthma [9]. Children with asthma are particularly vulnerable to air pollution such as ozone and PM 2.5, which have been associated with increased respiratory symptoms, hospitalizations, and long-term impairment in lung function [25]. Therefore, it is essential for children and their caregivers to stay informed and take precautions based on daily air quality. This feature enables children and caregivers to make informed decisions about daily activities, including staying indoors, wearing masks to prevent exposure, or adjusting outdoor routines.

In this study, most (22/30, 73%) caregivers were mothers, and 50% (15/30) held a bachelor's or master's degree. Furthermore, 20% (6/30) of them were employed, and 57% (17/30) reported a household income higher than the national minimum wage, with 63% (19/30) exhibiting a family income above the country's median. A study of parental attitudes towards artificial intelligence in children with asthma found that socioeconomic factors influenced technology adoption, with parents from disadvantaged backgrounds more likely to be reluctant to adopt technology [26]. Therefore, socioeconomic factors may affect caregivers' readiness to adopt technology for health management. Moreover, this research was conducted at a tertiary hospital with access to high-standard care and advanced medical technology. Most caregivers had received ongoing training and education on asthma management for children, which may have contributed to their interest in using technology, such as this app, for at-home care.

Raising awareness and educating caregivers on asthma management in children remains crucial, and health care professionals must prioritize this. Based on the study's recommendations, additional features, such as instructions for cleaning inhalers, tracking medication usage and remaining doses, establishing action plans for asthma exacerbations, videos demonstrating key symptoms and nasal irrigation techniques, and alerts for environmental triggers, such as air pollution levels, along with direct communication with health care teams, can improve asthma care tools. These improvements will increase the treatment efficacy.

This study highlights the importance of health care professionals in prioritizing caregiver education, emphasizing that improved

XSL•FO
RenderX

asthma care tools—with features such as inhaler cleaning instructions, medication tracking, action plans for exacerbations, videos demonstrating key symptoms, and alerts for environmental triggers—can significantly enhance asthma management. These improvements will boost treatment adherence and overall effectiveness, causing better health outcomes for children with asthma, although continuous monitoring remains necessary as they grow older.

Limitations

One limitation of this study is that it primarily focused on establishing tools for asthma management without fully addressing the individual variability in caregiver readiness and technological literacy. Additionally, the generalizability of the results may be limited due to the specific demographic and technological context of the study participants.

Suggestions for Future Study

Special attention should be given to the design of these tools for future research, ensuring that they are engaging for children, portable, and nontriggering to prevent exacerbating asthma symptoms. Studies should focus on the long-term effectiveness of these tools and the way they can be seamlessly integrated into routine clinical practice. Additionally, further investigation into the effect of technological innovations on caregiver engagement, particularly across diverse populations and health care settings, is crucial. These tools may improve asthma management, but recognizing that children with asthma will still require continuous monitoring and treatment as they grow older remains important. Therefore, future studies should prioritize establishing adaptable and dynamic educational content that supports asthma care for children across all stages of development.

Data Availability

The datasets used or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JS initiated the concept of the innovation, and SR collaborated in planning and supervising the study. JS conducted the primary investigation, while RS and KP assisted in data development and collection. All authors contributed to, revised, approved, and are accountable for the final manuscript.

Abstract

Background: Pediatric asthma is the most common chronic illness among children in the Netherlands. Scheduled hospital visits provide limited insight into therapy adherence and inhalation technique, which are critical for disease control. Smart inhalers that provide immediate feedback may offer a solution for monitoring and improving these parameters at home, leading to better asthma control.

Objective: This study aimed to improve asthma control through immediate feedback on therapy adherence and inhalation technique, with the use of a smart inhaler.

Methods: The IMAGINE (Improving Adherence by Guiding Inhalation via Electronic Monitoring) study was a randomized controlled trial consisting of 3 phases: an observational run-in phase in which adherence and technique were recorded, a randomized phase with feedback for the intervention group and recording for the control group, followed by an observational phase with only recording for both groups. Asthma control was measured with clinical outcomes including predicted forced expiratory volume in 1 second, lung function reversibility, lung function variability, the Asthma Control Test, and the Childhood Asthma Control Test.

Results: Between October 2019 and October 2023, a total of 34 children were enrolled and randomized. Overall, improvements were observed at the end of phase 2 in clinical parameters (reversibility, lung function variability, Asthma Control Test, and Childhood Asthma Control Test), except for predicted forced expiratory volume in 1 second. However, no significant differences between the intervention and control groups over time were observed. At the end of phase 2, 87% (13/15) of control participants and 78% (10/13) of intervention participants met one or more predefined clinical criteria. Inhalation technique and therapy adherence did not differ over time between the groups (P=.70 and P=.14, respectively).

Conclusions: While smart inhaler feedback did not lead to better outcomes compared with no feedback, clinical improvements were observed in both groups. Future studies should explore how adaptive smart inhaler interventions can be optimized to support personalized care and enhance patient ownership in asthma management.

Introduction

Pediatric asthma is the most prevalent chronic disease among children in the Netherlands, affecting between 5% and 10% of children up to 12 years of age [1]. Asthma is defined as a chronic inflammatory disorder of the airways resulting in airflow limitation and is characterized by bronchial hyperresponsiveness to a variety of stimuli [2]. The initial management of asthma is guided by the activity of the disease [3,4], requiring ongoing monitoring of asthma control to determine whether current therapies should be maintained or adjusted [3,5,6]. Accordingly, international guidelines [3,7] recommend that physicians reassess therapy adherence, the quality of inhalation technique, environmental factors, and associated comorbidities before considering escalation of pediatric asthma therapy [5,6,8,9].

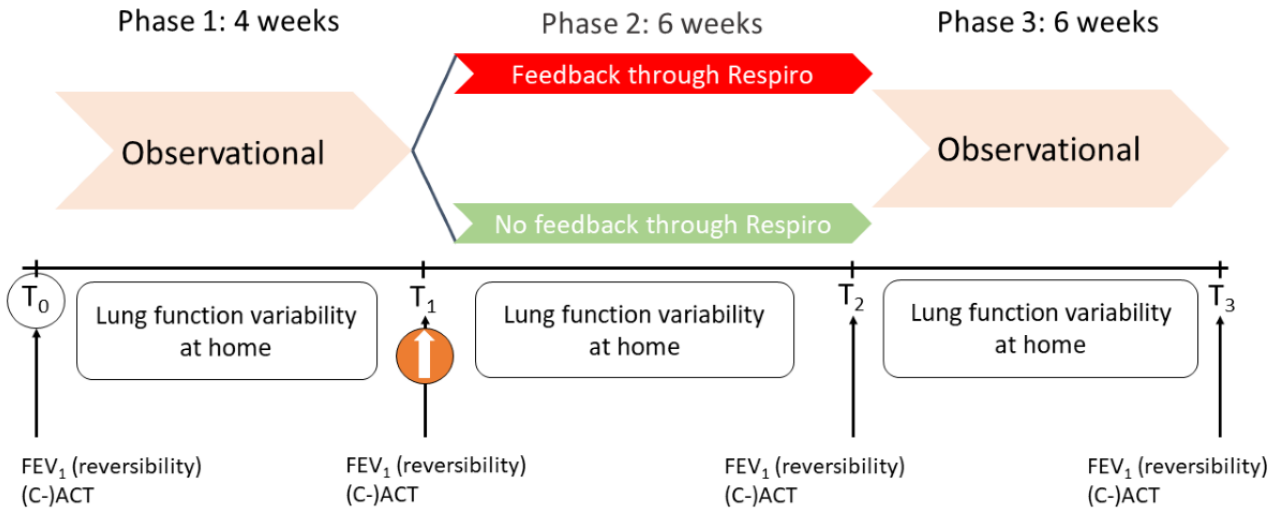
The two prevalent factors leading to asthma control failure in children are poor therapy adherence and an inadequate inhalation technique, as evidenced by multiple studies [9-12]. Approximately 50% of children exhibit poor adherence to asthma medication, a factor linked to an increased frequency of exacerbations [13-17]. Good adherence has been significantly associated with improved asthma control [18]. Additionally, a substantial proportion of incorrect inhaler handling has been reported among children with asthma, with appropriate use remaining low, which may lead to incomplete drug delivery and increased asthma morbidity [19].

Given that therapy adherence and the inhalation technique followed at home cannot be reliably assessed during a hospital visit [20], home-based monitoring using smart inhalers offers a promising solution [21]. A randomized controlled trial demonstrated that electronic adherence monitoring with daily reminder alarms can enhance adherence, reduce the need for oral steroids, and decrease hospital admissions [22]. Other systematic reviews have emphasized that education combined with repeated feedback on inhaler technique is critical for improving proper device use [19,23].

In this context, AMIKO developed the Respiro device [24], an innovative add-on for conventional inhalers that measures both therapy adherence and inhalation technique by recording vibration patterns. The device captures key parameters including the time of use per inhalation, dosing intervals, peak inspiratory flow, inhalation duration, and the orientation of the device during medication administration. Connected to a patient app, Respiro delivers immediate smart feedback on adherence and technique. The first randomized controlled trial using this device, known as Improving Adherence by Guiding Inhalation via Electronic Monitoring (IMAGINE), was designed to evaluate its impact on asthma control in children [25,26].

The primary hypothesis of this study was that participants assigned to the feedback group would more often demonstrate clinical improvement—defined by 7 pediatric clinical criteria related to predicted forced expiratory volume in 1 second ($predFEV_1$), lung function reversibility, lung function variability (LFV), and Childhood Asthma Control Test (C-ACT)—compared with participants assigned to the control (no feedback) group. Secondary aims included the assessment of therapy adherence and inhalation technique across both study groups.

Methods



Study Design

The IMAGINE study was a 3-phase randomized controlled interventional study (Figure 1). For more detailed information, see the published protocol by Sportel et al [27]. The CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guideline (version 1.6.1) was followed (Multimedia Appendix 1) [28]. Recruitment took place from October 2019 through October 2023.

Phase 1 was a 4-week observational period in which adherence and technique were measured by the Respiro device, without providing any feedback to children. At T1, randomization to feedback or no feedback took place (1:1). The randomization at T1 was a 1:1 blocked randomization, performed by an independent researcher. In addition, the randomization was stratified by age (≥12 years vs <12 years) and the use of nasal corticosteroids (prescribed vs nonprescribed). Patients in the intervention group received feedback from their smart device, while patients in the control group received no feedback. This interventional phase (phase 2) lasted 6 weeks. Blinding was not possible for either the participants or the staff due to the nature of this study. Phase 3 consisted of a 6-week observational follow-up during which adherence and technique were measured by the Respiro device but none of the patients received feedback. Treating physicians did not have access to adherence or inhalation technique data at T1 or T2, and no feedback based on these data was provided to patients.

XSL•FO
RenderX

Figure 1. Study design and outcome measurements. The measurements were done at 4 points: T0, the start of the study; T1, the start of phase 2; T2, the start of phase 3; and T3, the end of the study. At T1, the participants were randomized. C-ACT: Childhood Asthma Control Test; FEV1: forced expiratory volume in 1 second.

Ethical Considerations

The protocol was approved by the medical ethics committee of the University of Twente (P19-09), registered in Clinical Trials Registry Platform (trial number NL-OMON50093), was conducted in accordance with the Declaration of Helsinki, and was consistent with International Council for Harmonization of Technical Requirements for Pharmaceuticals for Human Use and Good Clinical Practice and the applicable regulatory requirements. Written consent was obtained from all children and their parents. In case participants were younger than 12 years, both parents or guardians signed the informed consent, for participants aged between 12 and 16 years both the child and the parents or guardians signed the informed consent, and for participants older than 16 years, the child was allowed to sign independently. The ethics committee approved the informed consent procedure, including the provision that participants aged 16 years and older could provide written consent independently, without requiring parental or legal guardian consent.

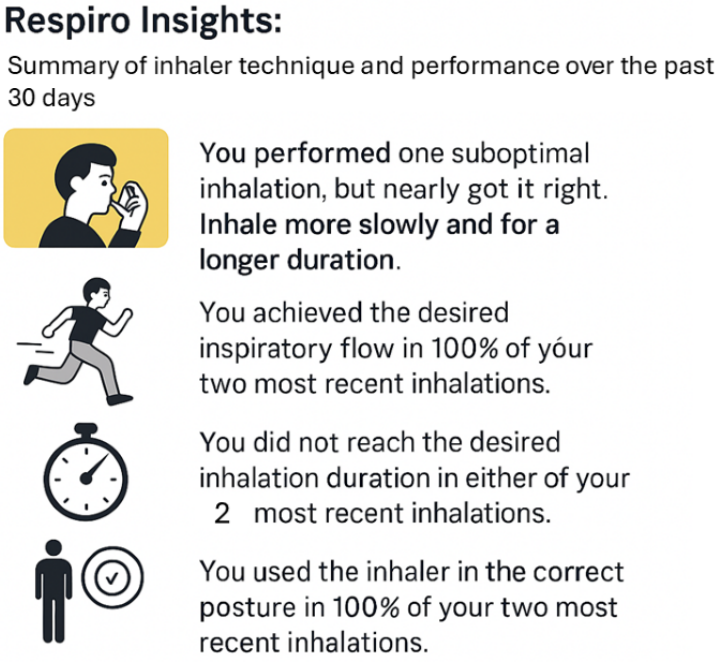
All research activities were conducted in accordance with ethical standards, including strict adherence to the principles of privacy and confidentiality to safeguard participants' data and identities. No compensation was offered for participation in the study.

Recruitment

All participants were aged between 6 and 18 years, had uncontrolled moderate to severe asthma, and were outpatients at a large teaching hospital in the Netherlands. Asthma was considered uncontrolled when the C-ACT score was below 20 or lung function reversibility on short-acting bronchodilator of at least 12% [6]. The diagnosis of moderate or severe asthma was made by the same pediatric pulmonologist for every child based on recommendations in the Global Initiative for Asthma (GINA) guidelines [29].

The Respiro device had to be compatible with the controller medication of the participants, which was possible for the Nexthaler (Chiesi Farmaceutici SpA). Switching from a metered dose inhaler to a dry powder inhaler was allowed, as long as the medication remained the same. Participants were instructed in the use of the new inhaler before entering the study and were required to use this device for at least 1 month before inclusion. If children, or their parents (if aged <12 years), were unable to speak or understand the Dutch language, they were excluded from participating in this study. The same applied to children with other chronic conditions that could potentially influence lung function.

The Respiro Add-On Device



The Respiro add-on device is an attachment to the patient's controller medication inhaler. This add-on device automatically tracks the generated flows of the user through the inhaler. The device uses an accelerometer that measures acceleration forces to determine orientation relative to gravity. It analyzes vibration patterns associated with inhaler use, which allows the identification of critical inhalation errors, such as failing to reach a sufficient peak flow, insufficient inhalation duration, and incorrect orientation of the inhaler. Respiro is connected via Bluetooth to an app on the patient's smartphone, named the Respiro Mobile (Amiko Digital Health) app, and can be used for synchronizing the Respiro device. No major content changes were made to the system during the study.

Intervention

Participants in the intervention group received the Respiro Mobile app, which reminded them when it was time to inhale a dose. The app also provided personalized feedback to help participants optimize their inhalation technique. The feedback included motivational push messages immediately after each inhalation and provided feedback on inhalation quality trends with visuals and text (see Figure 2 for examples of messages, translated into English). The control group received an adapted Respiro Mobile app without reminders or feedback on the inhalation technique; it only registered inhalation use and technique observationally.

XSL•FO
RenderX

Figure 2. Examples of Respiro insights, motivational feedback messages, and visuals.

Measurements

The children visited the hospital before the study began and after every phase. During the first appointment, the C-ACT and FEV_1 reversibility tests were performed by a trained researcher to check if the children were eligible for the study. After being included, the following parameters were measured at fixed time points throughout the study duration (Figure 1). Baseline lung function reversibility and C-ACT were measured at the start of phase 1 to determine asthma control, and at the end of each phase. Lung function reversibility was determined by performing spirometry before and after administration of a short-acting beta-agonist and calculated using equation 1 (Multimedia Appendix 2). The C-ACT is a self-report, internationally accepted questionnaire assessing the patient's perception of asthma complaints and asthma control for the previous 4 weeks. The regular Asthma Control Test was used for children 12 years and older and consisted of 5 questions. The C-ACT was used for children aged below 12 years and consisted of 4 questions for the child and 3 additional questions for the parents.

All participants received a handheld NuvoAir spirometer (Air Next, NuvoAir) [30] to perform spirometry at home. This device is connected via Bluetooth with the Air MD app (NuvoAir) on a mobile phone of the participant to register the spirometry results. The participants were trained and instructed to perform spirometry twice a week at home for the entire duration of the study. If deviations from the protocol were noticed regarding adherence to the twice-weekly home spirometry, the researcher actively contacted participants to encourage and maintain adherence as much as possible. In addition, each participant attended 4 scheduled study visits at the hospital, during which spirometry was performed together with the researcher. This ensured that reliable measurement points were consistently obtained throughout the study. After each phase, LFV was determined using the minimum and maximum value of the home FEV_1 measurements of a specific participant during a particular phase using equation 2 (Multimedia Appendix 2).

Asthma Control

The primary outcome of the IMAGINE study was the degree of asthma control, measured at the end of phase 2 [27]. Asthma control was evaluated based on 4 clinical parameters: FEV_1, C-ACT, lung function reversibility, and LFV. Additionally, 7 predefined criteria were used to specifically assess pediatric asthma control. Clinical improvement in asthma control was defined as the fulfillment of one or more of these criteria. Criteria 3 and 5 were excluded from the primary outcome if they had already been met at baseline. An overview of these criteria and the corresponding categories for clinical improvement is provided in Multimedia Appendix 3.

The 7 criteria were as follows [6,31]:

1. A relative FEV_1 increase of ≥10% at the end of phase 2, compared with the baseline value measured at the start of phase 1
2. An absolute C-ACT score increase of ≥3 points at the end of phase 2, compared with the baseline C-ACT score measured at the start of phase 1
3. A C-ACT score of ≥20 at the end of phase 2
4. A relative lung function reversibility decrease of ≥9% at the end of phase 2, compared with the baseline lung function reversibility measured at the start of phase 1
5. A lung function reversibility of <12% after administration of salbutamol at the end of phase 2
6. A relative LFV decrease of ≥10% during phase 2, compared with the LFV of phase 1
7. An LFV of ≤15% measured during the entire phase 2

Therapy Adherence and Inhalation Technique

Therapy adherence and inhalation technique were considered secondary outcome measures. Therapy adherence was assessed as the actual medication intake during a specific phase divided

XSL•FO
RenderX

by the prescribed medication intake per day, multiplied by the number of days during that phase (equation 3 in Multimedia Appendix 2). In addition, the percentage of adherence was qualified as insufficient (<75%) or good (≥75%).

The quality of the inhalation technique was assessed using two critical errors: (1) the peak inspiratory flow of less than 30 L/min [32] and (2) the inhalation duration was less than 1 second [33]. An inhalation was classified as incorrect when at least one of these 2 critical errors occurred. The overall inhalation technique was calculated as the percentage of correct inhalations (not containing a critical error) divided by the total number of inhalations during a specific phase (equation 4 in Multimedia Appendix 2). Inhalation technique was qualified as poor when ≥25% of the inhalations contained a critical error.

Statistical Analysis

Baseline characteristics were presented as means with SD or medians with IQR for continuous variables depending on the distribution of the variable; categorical variables were presented as numbers with corresponding percentages. First, baseline characteristics were compared between the 2 groups. Continuous variables were tested with the independent 2-tailed *t* test or Wilcoxon rank-sum test, depending on distribution, and categorical variables were tested with a chi-square or Fisher exact test as appropriate.

Second, the mean changes over time for the continuous variables (the predFEV$_1$, C-ACT scores, lung function reversibility, and LFV) were assessed using mixed model repeated measures analysis with fixed effects. A mixed model was created for each of these variables using the optimal covariance structure. Baseline values were subtracted from the follow-up values to obtain normally distributed values. The main parameter of interest was not only the group-by-time interaction but also the time and group effect that was assessed. All participants enrolled at baseline were included in the analyses.

Third, between-group analyses were performed to assess differences in performance for each of the 7 criteria by the Wilcoxon rank-sum test. Percentages of participants reaching the thresholds for improvement per criterion were compared with Fisher exact test.

Percentages of therapy adherence and critical inhalation errors were also assessed with a mixed model repeated measures analysis. For this, the mean percentage of therapy adherence and the mean percentage of inhalations containing critical errors for each participant in every phase were calculated. Percentages of adherence and critical errors during phase 1 were subtracted from the values of the following phases to obtain normally distributed values. In addition, a between-group comparison of participants achieving good therapy adherence and a proper inhalation technique in phases 1 and 2 was performed using the Fisher exact test.

As detailed in our published protocol (Sportel et al [27]), the sample size was calculated based on a 2-sample comparison of independent proportions (2-sided *Z* test), assuming improvement in asthma control in 10% of controls versus 40% of the intervention group, with 80% power; calculations were performed in PASS 11 (NCSS LLC). An interim analysis at 50% information was planned using O'Brien-Fleming spending (target final α=.049), with stopping for futility if the observed difference was ≤10% and early stopping for efficacy if P<.005; participants already enrolled completed all study phases. The resulting minimum required sample was 62, inflated by 10% for anticipated attrition to a recruitment target of 68 participants.

All these analyses were performed according to the intention-to-treat principle. The data were analyzed using SPSS (IBM Corp). P<.05 was considered statistically significant.

Results

Overview

Between October 2019 and October 2023, a total of 62 children with presumed uncontrolled asthma were approached to participate in the study, of whom 34 (55%) children were included and randomized (Figure 3). At T0, the children had a mean age of 11.7 (SD 2.7) years, 24 (71%) were male children, and the median C-ACT score was 18 (IQR 15-21). All demographic and baseline characteristics are presented in Table 1. These characteristics did not differ significantly between the control and intervention groups (Table 1). No significant difference in lung function reversibility at baseline was observed between the groups.

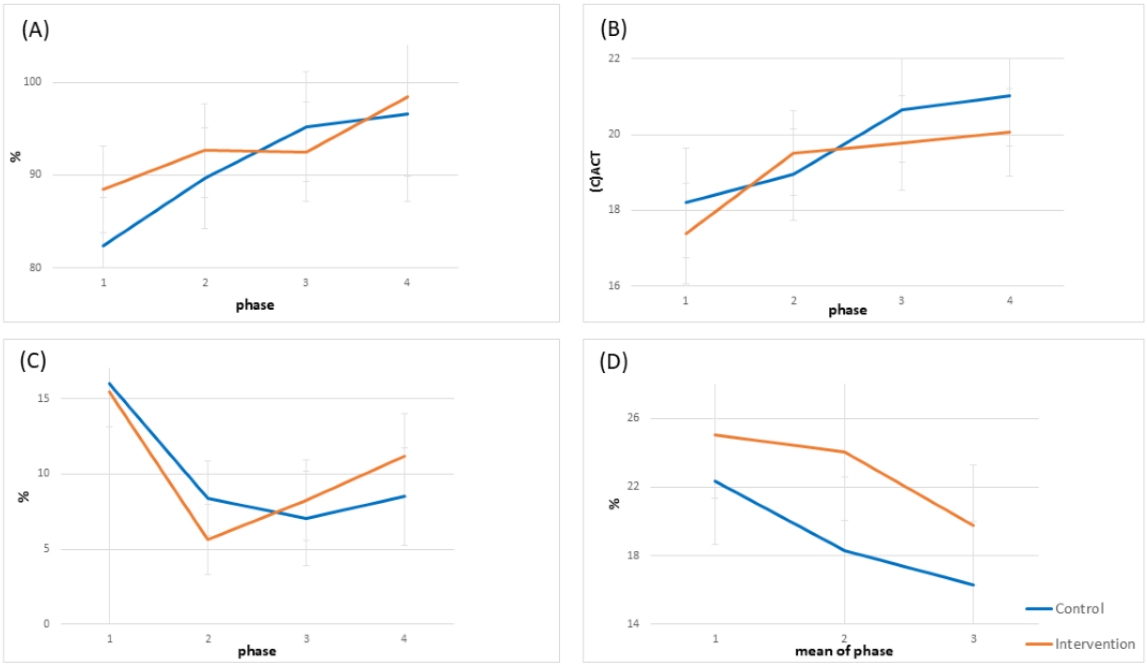
[a]C-ACT: Childhood Asthma Control Test.

[b]FEV_1: forced expiratory volume in 1 second.



[c]SABA: short-acting beta-agonist.

Clinical Parameters of Asthma Control

In Figure 4A to 4D, the trends in the clinical parameters of asthma control over time for both groups are presented, with estimated means and standard errors.

XSL•FO
RenderX

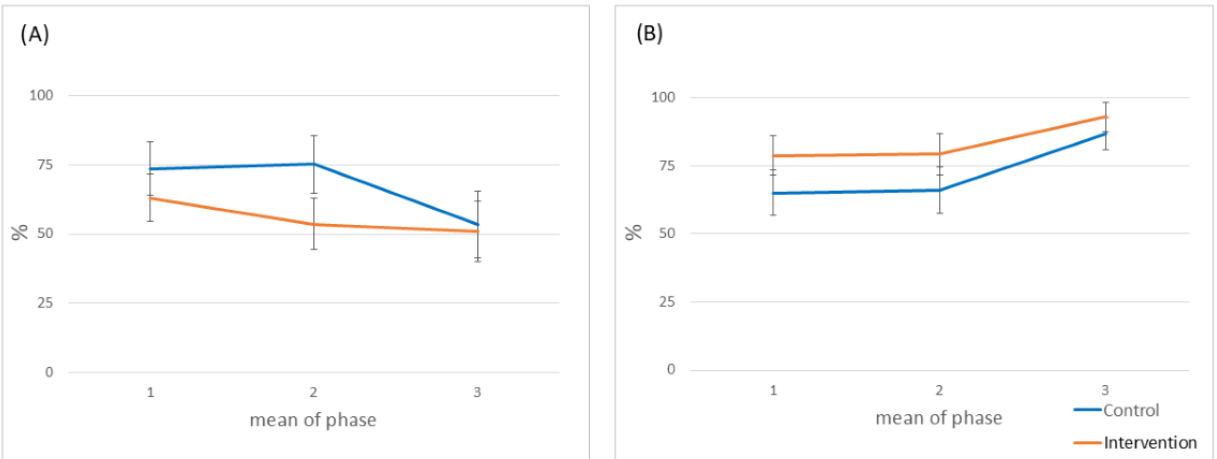
Figure 4. Time-by-group interaction of the mean change with reference to the baseline measure. (A) Predicted forced expiratory volume in 1 second percentage. (B) Asthma Control Test scores. (C) Lung function reversibility. (D) Lung function variability. The estimated marginal means of the mixed model with repeated measures are presented for each study visit measure per group: T0 (1) is the start of the study. T1 (2) is the start of phase 2, etc. In D, 1 is the mean of phase 1, 2 is the mean of phase 2, and 3 is the mean of phase 3.

Predicted Forced Expiratory Volume per Second

Both groups exhibited a nonsignificant upward trend in predFEV$_1$ percentage over time (P=.13 for the control group and P=.10 for the intervention group; Figure 4A). The between-group difference in the change in predFEV$_1$ percentage over time did not reach statistical significance either (P=.36).

Asthma Control Test

Both groups showed a significant increase in the C-ACT score over time (P=.01 for the control group and P=.04 for the intervention group), as shown in Figure 4B. The between-group difference in the absolute change in C-ACT score over time was not significant (P=.57).



Lung Function Reversibility

The lung function reversibility for both groups showed a decrease over time (P=.02 for the control group and P=.12 for the intervention group). The between-group difference over time was not significant (P=.71; Figure 4C).

Lung Function Variability

A decrease in LFV for both groups was observed over time. The decrease was significant in the intervention group (P=.02) but not in the control group (P=.28; Figure 4D). The between-group difference in change in variability over time was not significant (P=.84; Figure 5D).

Figure 5. Time-by-group interaction of the mean change with reference to the baseline measure. (A) Adherence per phase. (B) Correct inhalations per phase. The estimated marginal means of the mixed model with repeated measures are presented for each phase per group: 1 is the mean of phase 1, 2 is the mean of phase 2, and 3 is the mean of phase 3.

Clinical Improvement

Multimedia Appendix 4 displays both the actual scores (performance) as well as the percentages of children fulfilling each of the 7 clinical criteria at the end of phase 2 in a table. Overall, no significant differences were observed between the control and intervention groups.

Criteria 4 and 5, which pertain to lung function reversibility, exhibited the highest fulfillment rates. A relative lung function reversibility decrease of ≥9% by the end of phase 2 was achieved in 73% of the participants in both the control (8/11) and intervention (11/15) groups. Furthermore, the criterion requiring a lung function reversibility of ≤12% following salbutamol administration at the end of phase 2 was met by 91% (10/11) of cases in the control group and 73% (11/15) in the intervention group. This criterion was already met at baseline, with 55% (6/11) and 53% (8/15) of the patients achieving this criterion during phase 2 (Multimedia Appendix 3).

In contrast, criteria related to LFV (criteria 6 and 7) demonstrated the lowest fulfillment rates in both groups, together with C-ACT score of ≥20 at the end of phase 2 (criterion 3). The criterion specifying an LFV of ≤15% throughout phase 2 was met by 27% (3/11) of participants in the control group versus 31% (4/13) in the intervention group. Furthermore, 36% (4/11) versus 46% (6/13) of the patients in the control and intervention groups, respectively, met the criterion for a relative LFV decrease of ≥10% during phase 2 compared with phase 1. Criterion 3 was met by 33% (4/12) and (5/15) of the participants in both groups, not including the children who had already fulfilled this criterion at baseline.

In total 87% (n/N) of the patients in the control group showed clinical improvement (ie, fulfilling one or more criteria at the end of phase 2) versus 78% (n/N) in the intervention group; this difference was not statistically significant (P=.52). The mean number of fulfilled criteria at the end of phase 2 in the control group was 2.33 (SD 1.54) versus 2.61 (SD 1.79) in the intervention group (P=.64). Criteria that were already completed at baseline were not included in the total percentage of fulfillment per criterion.

Therapy Adherence and Inhalation Technique

Figure 5A shows that, overall, both groups demonstrated a significant declining trend in adherence—significant in the control group (P=.03) and borderline significant in the intervention group (P=.05). The between-group difference over time was not significant (P=.14).

Both groups exhibited an upward trend in correct inhalations, with statistical significance in the control group (P=.005) and a similar borderline significant trend in the intervention group (P=.07). This overall improvement was particularly evident after phase 2. The between-group difference in change in correct inhalations over time was not significant (P=.70; Figure 5B).

The percentages of children who had good adherence (75%-125%) and a correct inhalation technique (≥75% correct inhalations) were calculated for each phase. Good adherence was observed in 57% (8/14) of participants in the control group and 50% (9/18) in the intervention group in phase 1. In phases 2 and 3, adherence remained relatively stable in the control group (54% and 50%, respectively). In the intervention group, it declined to 33% in phase 2 before returning to 50% in phase 3.

In phase 1, 43% (6/14) of participants in the control group and 72% (13/18) in the intervention group demonstrated good inhaler technique. In phase 2, these proportions increased to 62% (8/13) in the control group and remained relatively stable at 67% (10/15) in the intervention group. In phase 3, these increased to 90% (9/10) and 85% (11/13), respectively.

Discussion

Principal Findings

In this study, both the control and intervention groups demonstrated improvement over time in the clinical parameters—predFEV$_1$ percentage, C-ACT, LFV, and lung function reversibility; however, there was no difference between the groups at the end of phase 2. In accordance with the study protocol, an interim analysis indicated futility, leading to early termination of the trial.

This is the first study that investigates the effects of smart immediate feedback and monitoring on objective and subjective clinical end points, providing valuable insights into patient and group characteristics and behavior in relation to pediatric asthma. Both the control and the intervention groups exhibited a high rate of clinical improvement at the end of phase 2 (87% vs 78% fulfilling one or more clinical criteria). Although we identified a clinical improvement for both groups at the end of phase 2, we did not observe improvement in adherence or inhalation technique during phase 2. Adherence declined during phase 2, which we believe reflects a component that is less related to skill acquisition and more to behavior. It is likely that adherence was overestimated at the start of the study—possibly due to participants initially demonstrating more favorable behavior than was truly representative—which then gradually decreased over time. Interestingly, a more notable improvement in inhalation technique emerged in phase 3 in the control group. This delayed effect may reflect the time required for a skill acquisition change to take hold, as is known from the stages of change in adherence and other health settings [34,35]. Initial exposure to feedback in phase 2 may have laid the foundation, known as the contemplation or preaction phase, with actual skill acquisition becoming evident only later. Participants may also have needed time to become familiar with the smart inhaler and its feedback mechanisms, leading to more effective use and readiness for the feedback over time [36]. However, this also raises the question of whether the feedback system was sufficiently intuitive for children. In our study, we used a system designed suitable for both adults and children, incorporating clear pictograms as part of the feedback. Nevertheless, a more child-specific and intuitive design might have facilitated faster adaptation. In addition, the auditory reminders used in the system may have elicited resistance, potentially leading participants to disable them. Although we were unable to monitor the exact frequency of reminder deactivation in our study, prior research by Knauer et al [37] in a different population suggests that social acceptance in this context is a

XSL•FO
RenderX

critical factor in pediatric settings. Furthermore, the lack of an observed effect on inhalation technique and adherence suggests that other important factors may influence clinical asthma control beyond the parameters measured in this study, such as lifestyle, allergic exposure, or parental and environmental smoking habits. Standard care was not fully represented in our study, as both groups received a smart monitoring device—one group with active feedback and the control group with monitoring data transferred only to the researcher. Therefore, improvements observed in both groups may partly be explained by the monitoring principle itself, especially for adherence. This observation may also be partially attributable to the Hawthorne effect, in which improvements in observable behaviors, such as inhalation technique or adherence, are driven by the awareness of being observed [38]. However, these effects were not consistently observed in our study. It is possible that the Hawthorne effect instead manifested through other behavioral changes, such as lifestyle adjustments, which were not directly measured but may have contributed to the observed clinical improvements.

Given the episodic nature of asthma, patients experience fluctuations in symptoms throughout the year, with considerable interindividual variability. These dynamics underscore the potential value of continuous digital monitoring and feedback mechanisms. By capturing real-time changes in symptoms and behavior, such systems may support more personalized and responsive care. Moreover, a model based on objective monitoring to identify pitfalls could facilitate focused interventions and could potentially lead to more effective care. As part of a decision support tool, the smart inhaler must be able to work under various conditions, inconsistencies, and different patient needs [39]. More extensive monitoring may be used for a short period at the start of an eHealth strategy to identify personal cues that disrupt asthma control and to develop a personalized eHealth treatment strategy. Thereafter, monitoring intensity could be personalized to prevent alert fatigue, as observed in other decision support systems [40], while continuing the monitoring of the personal disrupting cues to allow timely short-term detection of asthma control deterioration. This resembles a just-in-time approach, in which the device is delivering when the need is high and receptiveness is likely [41,42], thereby empowering patients to take greater ownership of their condition [43,44].

A key strength of this study is the continuous use of the Respiro smart add-on device, which enabled objective assessment of both adherence and inhalation technique in an ambulatory, real-world setting. This approach enhanced the validity of our findings, ensuring that the results were representative of actual inhaler use in daily clinical practice. Another strength is the comprehensive approach to defining the clinical end points of asthma. The C-ACT questionnaire is the current validated gold standard in modern Dutch health care for assessing asthma control in children. However, the C-ACT comes with several drawbacks [45-47]. Asthma control in children fluctuates greatly, and the C-ACT questionnaire fails to account for this variability. The C-ACT score tends to underestimate asthma control, as defined by GINA [48,49]. However, to compensate for the drawbacks of the C-ACT questionnaire, other objective parameters, such as predFEV$_1$, lung function reversibility after intake of medication, and LFV, were included.

Limitations

Several limitations must be acknowledged. A substantial number of participants already met one or more of the criteria (eg, ACT score or lung function reversibility) at baseline, potentially limiting the scope for observable improvement. Additionally, for both groups, adherence to protocol, particularly concerning home measurements, was suboptimal, which may have affected the reliability of LFV as an outcome measure and should therefore be considered when interpreting its suitability as a parameter. The auditory warning signals provided by the smart inhaler were sometimes disabled by the participants in the feedback group, although no exact data on this were available. Although the intervention group initially demonstrated a significantly higher absolute FEV$_1$ (in liters), no substantial effect was expected from this baseline difference, as predFEV$_1$ percentage values were comparable between both groups. The study was limited by reduced statistical power, generalizability, and therefore by a limited ability to detect smaller effects. However, according to the stopping rule in the protocol, an effect size of less than 10% compared with the control group indicated futility, and therefore no substantial changes in outcomes were to be expected from including additional participants.

Comparison With Prior Work and Future Perspectives

We believe that adding a smart monitoring feedback device (eg, Respiro) to the arsenal of asthma management provides a clearer view into patient behavior and presents an opportunity to enhance the efficiency and precision of asthma management strategies. Data from the observational phase of the IMAGINE study show that adherence and the inhalation technique are distinct and separate pitfalls in asthma care, each representing independent challenges [50]. In our study, adherence declined significantly in both groups, a finding similar to the Outcomes following Tailored Education and Retraining: Studying Performance and Adherence (OUTERSPACE) study, in which the intervention group showed a similar decline in adherence over time [51]. The authors explained this decline by the improvement in inhalation technique, which might reduce the need for strict adherence as the effectiveness of each inhalation increases. Furthermore, the absence of auditory reminders may also partly explain the decline in adherence observed in the OUTERSPACE study, a finding that could likewise apply to our study [51]. The INCA Sun study reported better adherence in the group treated with a digital inhaler compared with the control group. Similar to our study, the Inhaler Compliance Assessment (INCA) device measured data on treatment use and the inhaler technique in both study groups. However, feedback was not provided immediately, and therefore did not closely resemble our intervention [52]. In the Connected Electronic Inhalers Asthma Control Trial (CONNECT) 1 and 2 studies, the smart inhaler provided direct feedback on adherence and the inhalation technique through a patient-facing app. Both studies demonstrated improvements in clinical outcomes. Two key differences from our study are that the CONNECT trials included participants aged 13 years and older, and that their

XSL•FO
RenderX

control groups received standard care without monitoring, whereas our control group was also monitored. Consequently, these differences in design and population may explain the contrasting findings regarding the impact of feedback on clinical outcomes [53,54]. Future research should focus on the optimal form of feedback, particularly adaptive and real-time interventions. As a first step, a prospective study could be designed in which a cohort of children with moderate to severe asthma is provided with a smart inhaler for an extended period [55]. At predefined moments—specifically when asthma control deteriorates or issues with adherence and the inhalation technique arise—additional tailored support could be offered to the intervention group, in contrast to standard nonadaptive care in the control group. Key questions include whether a just-in-time approach can improve outcomes, prevent exacerbations, and enhance self-management and user experience; an example of a protocol with this design is the Mobile Health for Kids With Asthma study [56]. Current clinical guidelines addressing pitfalls in asthma management may be too generic in mitigating issues of adherence and inhalation technique [55,57]. In contrast, objective monitoring and targeted attention to inhalation technique and adherence appear to contribute to more effective and efficient care. Such approaches not only improve outcomes but also enable a more personalized focus, fostering patient ownership in disease management [58].

Ultimately, this could pave the way for a study in which multicomponent adaptive interventions are delivered in a personalized manner, providing care for the right patient at the right time.

This creates a whole new opportunity to offer patient-tailored advice, enabling individuals to take responsible ownership of their condition while allowing health care providers to make optimal use of the just-in-time resources and opportunities for this disease with an episodic nature in the current health care landscape.

Conclusions

In summary, this study investigated both objective and subjective clinical end points in the context of smart immediate feedback and monitoring for pediatric asthma management. Although the intervention did not lead to superior outcomes compared with the control group, the overall clinical improvements observed across both groups suggest that increased awareness and objective monitoring positively influence asthma control in children with uncontrolled asthma. The integration of smart monitoring feedback devices (eg, Respiro) offers valuable insights into patient behavior, thereby highlighting opportunities for more personalized and effective asthma management strategies. Based on our findings, we propose that future research should focus on refining assessment criteria and exploring the potential benefits of more targeted, personalized adaptive feedback interventions in asthma management.

Abstract

Background: The proliferation of smartphones raises worries over their impact on adolescent development, especially problematic smartphone use. This research investigates the intricacies of problematic smartphone usage in adolescents, particularly in light of significant increases in screen time, from a developmental psychology perspective.

Objective: This study aimed to examine the association between adolescent-perceived parental monitoring strategies and problematic smartphone use in Taiwan, while also exploring variations across age, gender, and socioeconomic status.

Methods: A nationwide dataset from Taiwan's annual survey (n=1673; aged 10 - 18 y) was analyzed using descriptive analysis and moderated multiple serial mediation regression. In total, 3 parental mediation styles—restrictive monitoring, evaluative mediation, and unfocused monitoring—were examined for their effects on smartphone usage.

Results: Rigorous surveillance is more beneficial for younger adolescents (aged 10 - 12 y), significantly reducing smartphone addiction. Conversely, as teenagers mature, the efficacy of restrictive approaches wanes. Adolescents aged 16-18 years benefit more from parental mediation strategies that foster autonomy and encourage appropriate digital conduct. Restrictive monitoring significantly diminishes addiction by constraining internet access; yet, the diverse outcomes of assessment methods highlight the importance of qualitative engagement. Conversely, unfocused surveillance is ineffective, necessitating the use of targeted parental strategies.

Conclusions: This study highlights the significance of developmentally suitable parental strategies to mitigate digital addiction and enhance teenage self-regulation. We urge policymakers to implement age-specific, evidence-based methods to improve digital literacy and overall well-being in youth. Future research should investigate the enduring psychological and behavioral impacts of parental mediation and analyze cross-cultural differences in digital parenting methodologies.

Introduction

Background

In the digital era, smartphones have become indispensable tools for communication, education, and entertainment. Among adolescents, smartphone penetration is rapidly increasing, with more than 80% of individuals aged 12-17 years owning such devices [1]. While digital access fosters connectivity and learning, it also presents growing concerns about problematic smartphone use (PSU), characterized by compulsive checking, excessive screen time, and withdrawal symptoms upon separation [2,3]. PSU has been associated with disrupted sleep, impaired academic performance, and hindered emotional development, establishing it as a pressing public health issue.

Previous studies suggest rising smartphone addiction among adolescents, with prevalence rates ranging from 10% in the United Kingdom to more than 30% in South Korea [4,5]. Moreover, the COVID-19 pandemic significantly reshaped

XSL•FO
RenderX

digital media usage. Remote learning, physical distancing, and prolonged home confinement have intensified adolescents' reliance on digital devices for social interaction and emotional coping [6]. This shift has sparked increased risks of excessive use and internet addiction, with adolescents turning to social media and gaming to alleviate pandemic-induced stress and loneliness [7,8]. These behavioral shifts are particularly concerning given adolescents' developmental vulnerabilities, such as immature impulse control and heightened sensitivity to peer influence [9].

Parental mediation is a critical factor influencing adolescent digital engagement and well-being. Empirical evidence consistently demonstrates that parental involvement is associated with a reduction in adolescents' risky online behaviors and problematic media use [10,11]. Specifically, studies have established a significant, although complex, association between various parental mediation strategies (eg, restrictive, active, and technical mediation) and attitudes, as well as reduced levels of adolescent problematic media habits [12-15]. Strategies such as screen-time limits, content monitoring, and open communication are commonly used, yet the effectiveness of these measures may be mediated by adolescents' perceptions of control and autonomy [15]. Thus, the parent-adolescent dynamic and the child's perception of mediation are crucial variables determining its success.

Theoretical models like parental mediation theory emphasize that youth interpretations of parental actions, whether perceived as autonomy-supportive or controlling, determine their behavioral responses [16,17]. Recent studies continue to apply these models to examine how evolving parental strategies shape adolescents' online experiences [18]. Although pioneering work has begun to effectively incorporate adolescent perspectives on parental mediation, particularly concerning social media use [19,20], research on smartphone-specific problematic use (PSU) continues to rely more heavily on parents' self-reported practices. Consequently, the adolescent's subjective experience of mediation strategies applied to the unique challenges of smartphone use remains less explored. This limits the development of tailored, context-sensitive approaches to digital well-being.

Goal of This Study

This study aims to examine the association between perceived parental oversight and PSU among adolescents, guided by parental mediation theory. By integrating quantitative assessments of PSU with adolescents' subjective interpretations of parental strategies, the research seeks to illuminate how different mediation styles influence digital behavior. The findings will inform interventions that align more closely with youths' psychological needs, especially in contexts shaped by increased digital dependency, such as during public health crises. In doing so, this study positions parental oversight as a dynamic and influential factor in designing effective interventions for adolescent digital well-being.

Literature Review

Adolescent media use significantly influences psychological well-being, with excessive screen exposure linked to body dissatisfaction, anxiety, and distraction [21-23]. During the COVID-19 pandemic, digital reliance intensified, exacerbating emotional vulnerability and compulsive behaviors [6,7]. While mobile technology offers educational and social benefits, unregulated use can harm development, particularly in environments lacking effective parental mediation [24,25]. Cross-national studies reveal varied addiction rates, underscoring sociocultural and familial influences [5]. Despite the known risks, few studies integrate youth perceptions of parental oversight into intervention frameworks. To address this, this study draws on 2 complementary theoretical frameworks. First, family systems theory posits that individual behavior, including media use, is shaped within the dynamics of the family unit. Parent-child interactions, including monitoring strategies, are seen as bidirectional and mutually influential, making parental mediation a relational, rather than merely regulatory, process [26,27]. Also, the positive youth development (PYD) framework emphasizes the importance of nurturing environments and adult support in fostering adolescents' internal assets, such as self-regulation and resilience [28]. From this view, autonomy-supportive parental involvement can help adolescents build healthy digital habits. The existing research attempts to bridge the research gap by synthesizing family systems theory with PYD, positioning parental supervision as a dynamic moderator of self-regulated smartphone engagement (SRSE) [16,17]. Their approach reframes oversight not as a static constraint but as a modifiable factor that shapes the efficacy of SRSE-based interventions.

PSU and Adolescent Health Risks

The increasing ubiquity of smartphones has reshaped adolescent behavior and well-being. While moderate digital engagement can foster social connection and access to diverse information [29,30], excessive and unregulated use contributes to a range of psychosocial challenges. PSU refers to a behavioral pattern characterized by compulsive use, impaired control, and continued use despite experiencing negative consequences in daily functioning [24,25,31]. Common manifestations include preoccupation with the device, withdrawal symptoms (eg, anxiety when separated from it), tolerance (needing increased use for satisfaction), and a significant disruption to academic, social, or sleep routines [32,33].

Adolescents are a particularly vulnerable population for PSU. Empirical studies have consistently linked PSU to adverse outcomes, including diminished mental well-being, reduced self-esteem, sleep disturbances, academic difficulties, and increased feelings of loneliness [23,34-37]. The COVID-19 pandemic intensified digital reliance, especially among youth, exacerbating digital overexposure and mental health strains [6,7]. In Taiwan, smartphone usage surpasses 94.9% [38], raising significant concerns about youth digital addiction. The prevalence of smartphone addiction in adolescents much surpasses that in adults, with estimates suggesting that 1 in 3 teenagers is at risk [38].

Previous studies explore the implications of smartphone use among different age groups, highlighting the associated health risks of PSU among adolescents. Park and Park [39] introduce a conceptual model of smartphone addiction specifically

XSL•FO
RenderX

targeting early childhood, discussing factors that contribute to the development of compulsive smartphone behaviors and their potential impacts on young children's social and cognitive development. In contrast, 1 study [40] conducted a cross-sectional survey focusing on middle- and high-school students in China, revealing the prevalence of PSU within this demographic and identifying significant correlations with mental health issues, academic performance, and social interactions. Together, these studies underscore the need for targeted interventions to mitigate the risks associated with excessive smartphone use and promote healthier digital habits among adolescents.

Sex-based differences also shape PSU patterns. While males more frequently engage in compulsive gaming and exposure to violent content [41], females report higher levels of internalizing symptoms, such as anxiety and depression, due to screen overuse [36,37]. These variations suggest the importance of tailored strategies in addressing PSU across demographic groups.

In addition, adolescents' perceptions of parental oversight, whether controlling or autonomy-supportive, can significantly moderate the outcomes of interventions targeting smartphone habits [16,17]. As such, understanding PSU requires a multifaceted perspective that incorporates developmental, behavioral, and social determinants. Effective responses should consider not only individual behaviors but also relational factors, particularly the evolving role of parents in managing adolescents' digital environments.

Predicting Digital Behaviors

Parental monitoring has emerged as a key factor influencing adolescents' digital engagement and their susceptibility to PSU [10,11]. Parental monitoring is traditionally defined as parental efforts to supervise and regulate children's activities, including digital media use [42,43], and updated with reduced exposure to online risks such as violent content, gambling, and inappropriate interactions in the current digital era [44,45]. Scholars commonly categorize parental mediation into 3 distinct types. The first category is restricted mediation. This involves setting rules and limits governing screen time or access to specific apps and content [10,43]. Evaluative mediation, often referred to as educational or active mediation, involves parent-child discussions about media content aimed at fostering critical understanding and resilience [10,43,46]. Unfocused mediation describes co-use without explicit educational or restrictive intent, often characterized by shared but unsupervised media consumption [43]. One of the research gaps in the existing research usually relies on parents' self-reported practices, overlooking the impact of adolescents' subjective perceptions.

Recent studies highlight that the effectiveness of parental supervision hinges not only on behavioral enforcement but also on how adolescents interpret these efforts. Perceived overcontrol may elicit resistance, while autonomy-supportive practices foster self-regulation [16,17]. For instance, research in Taiwan found no significant association between parental monitoring and adolescent smartphone addiction, suggesting that the mere presence of supervision does not guarantee behavioral change [47]. Furthermore, some data show that heightened parental control may paradoxically increase digital risk-taking when perceived as intrusive [48,49].

Given the inconsistencies across contexts and measurement approaches, this study centers on adolescents' perceived parental monitoring rather than parental self-report. By capturing children's subjective experiences, this research seeks to clarify how parental regulation interacts with psychological factors to shape digital behavior, offering a more dynamic understanding of preventive strategies in adolescent technology use. Thus, the first hypothesis is raised, which states that adolescents' perceptions of higher restrictive, evaluative, and unfocused parental supervision will be associated with lower levels of (1) daily internet usage and (2) PSU.

Family Structures

Sex

Parents are anticipated to use distinct regulatory approaches with male as opposed to female children in accordance with the sex roles established within their society. Research suggests that parents use distinct control tactics based on the gender of their children, and the degree to which this occurs varies between fathers and mothers. For instance, research has shown that parents give less independence to their girls and protect them more than boys [50]. Moreover, research on adolescents' media use of several kinds revealed that females were more likely than boys to have phone-using restrictions [51]. However, some research reported that parents tend to supervise their male children to a somewhat higher degree compared with their female children [52]. Some others have discovered that there is no discernible disparity in parental supervision based on the gender of the child [53].

Currently, there is a scarcity of evidence and inconclusive findings about the impact of parental mediation on cell phone addiction in children, specifically in relation to gender disparities. Based on the discussions made in the previous research, the objective of this study is to investigate the following research question (RQ) and propose one hypothesis to guide our analysis.

RQ1 was to examine how adolescents' genders impact parental supervision and the prevalence of internet use and mobile phone addiction among teenagers.

Hypothesis 2 states that parental monitoring has a greater impact on girls' intention to use the internet and their levels of mobile phone addiction compared with boys.

Age

Monitoring by parents elicits varied responses from children of different age groups. Not surprisingly, evidence regularly demonstrates that parents supervise the television and media consumption of their younger children to a greater extent than they do with their older children [54]. Furthermore, due to the concern that younger children are more prone to acquiring mobile phone addiction, research suggests that parents are more inclined to implement restrictive mediation and evaluative mediation with their younger children [39,53,55].

XSL•FO
RenderX

To go deeper into the studies of specific ages and the effect of parental monitoring differences, 1 study [56] done in Korea in 2015 proved that parents usually use restrictive mediation to monitor their kids in elementary school. A later study [57] in 2018 highlights that higher restrictive parental monitoring is correlated with a lower risk of mobile phone addiction among adolescents aged 11-13 years. Similar results were also found from a study by Chang and other researchers [47] who surveyed 2621 kids and 2468 parents from the main cities of Taiwan. They indicated that only the restrictive parental monitoring mediation could effectively decrease smartphone addiction risks among fifth-grade kids (aged 10-11 y). Accordingly, similar results are also found among middle-school and high-school kids (age range from 14 to 19 y old) in China, Japan, Thailand, and Portugal; their results suggested that parental neglect was significantly positively associated with adolescents' mobile phone addiction, and perceived parental monitoring of smartphones was negatively related to adolescent mobile phone addiction [58-61].

The study investigates the threshold at which the efficacy of parental monitoring starts to decline or vanish to discover whether age is a significant mediator. Thus, RQ2 and another hypothesis (hypothesis 3) of the effectiveness of parental monitoring are raised:

RQ2 seeks an answer to whether parental monitoring has universal effectiveness across adolescents of varying ages, and at what age does the effectiveness of parental monitoring begin to diminish or disappear.

Hypothesis 3 states that younger adolescents experience higher levels of parental monitoring regarding their internet usage and mobile phone addiction compared with older adolescents.

Income and Parental Educational Level

Family socioeconomic status, particularly parental income and education, plays a significant role in shaping adolescents' vulnerability to smartphone addiction. Previous research demonstrates that lower household income and parental education are associated with higher risks of problematic mobile phone use in adolescents [62,63]. A scoping review [64], synthesizing findings from 67 studies, supports this trend by identifying socioeconomic disadvantage as a consistent predictor of mobile phone addiction. Parents with limited education may lack awareness of the psychological risks associated with excessive smartphone use, increasing the likelihood of early and unrestricted access [65]. Financial constraints may also reduce parental capacity to offer alternative recreational or social resources, leading to greater screen dependence among youth [66]. Without access to structured extracurricular activities or supervised community spaces, adolescents from lower-income households may rely more heavily on smartphones for entertainment and socialization, thereby increasing their risk of problematic use.

The connection between socioeconomic status and parental mediation remains inconclusive. Previous studies suggest that adolescents from higher socioeconomic backgrounds may exhibit elevated levels of digital dependency, driven by feelings of isolation or pressure to remain socially connected via advanced devices [65,67]. This duality highlights the need for a nuanced understanding of how different economic and cultural contexts shape digital behaviors. While some research reports no significant association [68], others suggest that low-income families may favor restrictive or evaluative mediation strategies [69,70]. These inconsistencies underscore the complex interplay between structural constraints and parenting styles, emphasizing the need to account for family background when designing interventions for adolescent smartphone addiction. Thus, 2 RQs (RQ 3 and RQ 4) and 2 hypotheses are raised.

RQ3 aims to examine whether there is a relationship between household income and the practice of parental monitoring styles, and how this relationship affects adolescent mobile phone addiction. RQ4 aims to examine whether there is a relationship between parental education levels and the practice of parental monitoring styles, and how this relationship affects adolescent mobile phone addiction.

Hypothesis 4 states that higher household income is associated with more effective parental monitoring styles, which in turn reduces the vulnerability to mobile phone addiction among Taiwanese adolescents aged 10-18 years. Hypothesis 5 states that higher parental education levels are associated with more effective parental monitoring styles, which in turn reduces the vulnerability to mobile phone addiction among Taiwanese adolescents aged 10-18 years.

Methods

Ethical Considerations

Our study is a secondary data analysis based on the Taiwan Communication Survey (TCS), a nationally representative dataset administered by the Institute of Sociology, Academia Sinica (Taipei, Taiwan). The dataset was fully anonymized before public release and made available for academic research. The Academia Sinica Humanities and Social Science Research Ethics Committee reviewed and approved the project "Taiwan Communication Survey – Phase II, Year 4-5" under approval AS-IRB-HS-19027. This study used data from this approved project.

During the original data collection, written informed consent was obtained from all adolescent participants and their legal guardians before participation. To protect participants' privacy, personally identifiable information was anonymized and restricted to use only during the implementation period of the TCS. Upon study completion, all physical and digital contact lists were destroyed and archived on record. Furthermore, participant information was strictly handled in an anonymized form and used solely for academic research purposes.

Participants received a gift card worth NT $100 (approximately US $3.2) upon completion of the survey as a token of appreciation. No additional compensation, insurance, or risk-related arrangements were deemed necessary due to the minimal risk nature of school-based data collection.

XSL•FO
RenderX

Research Design

The predicted number of smartphone users in Taiwan is expected to reach 20.81 million by 2029, representing an increase of 0.7 million individuals [71].

The TCS project has been using structured questionnaire surveys and interview methods at the national level since 2012. The data used in this study were extracted from the TCS database available through the website [72] to learn the trend of media usage, social engagement, and social capital concern. TCS is a research program supported by the Government's Ministry of Science and Technology to conduct an annual survey of the population with representative samples. It centers on monitoring shifts in consumption media patterns. Besides media use data analysis, the survey uses several specialized modules to discover current trends in health communication.

Procedure

The TCS cohort project used a mixed methods approach, combining quantitative and qualitative interviews to comprehensively examine young users' online information-seeking behaviors. The TCS report indicates that the sample selection included a multistage and stratified random methodology to guarantee a representative cross-section of participants [73]. The approach involved a substantial number of students who completed a survey, offering insights into their preferences, sources, and motivations for accessing online knowledge. In a subsequent study, certain respondents were invited to participate in qualitative interviews, facilitating a more profound examination of their experiences and perceptions regarding online information.

The TCS project and data collection received approval from the members of the Taiwan Institutional Review Board before implementation. All data were gathered from September to October 2020. Trained supervisors who conducted the survey were mandated to visit the sampling classes at 62 schools across the nation.

A total of 1696 respondents aged 9-18 years included 19 elementary schools with 446 valid surveys and 20 junior high schools with 582 valid responses. A total of 15 secondary schools and 8 technical high schools were selected for sampling from high school students. A total of 668 surveys were completed. Data from participants aged 9-18 years in the 2020 TCS project were collected. To maintain analytical consistency aligned with the study's objective, individuals aged 10-18 years were examined in this research (n=1673). The research achieved a confidence level of 95%, with a sampling error not exceeding 2.38%.

Measurements

Parental Monitoring

This analysis examines the potential influences on the relationship between parental monitoring and mobile phone addiction, focusing on PSU, parental monitoring, and demographic factors. Parental mediation consists of 3 components: restrictive mediation (questions 1 to 3, Cronbach α coefficient=0.761), evaluative mediation (questions 5 and 6, Cronbach α coefficient=0.674), and unfocused mediation (question 4). Restrictive mediation encompasses parental limitations on specific websites, regulations regarding media consumption, and imposed time constraints. Evaluative mediation entails parents engaging with media and subsequently discussing their usage and experiences with their children. Unfocused mediation denotes a parental approach in which children are encouraged to use media without any form of guidance or limitations.

PSU

The evaluation of mobile phone addiction was conducted using 5 questions that used a 5-point scale, ranging from "I strongly disagree" to "I strongly agree." The final PSU score represents the average (mean) of the 5 items, where higher scores indicate greater levels of mobile phone addiction. These questions were designed to evaluate the participants' behavior and their views on the use of mobile phones. Items assessed loss of control, functional impairment, and preoccupation (eg, "You daydream about your phone"). The formation of these 5 questions was done following previous studies on PSU [74]. The purpose of these questions was to assess the participants' behaviors and views regarding mobile phones. The Cronbach α coefficient for 5 questions is 0.769, and the McDonald omega is 0.788.

Sociodemographic Characteristics

The demographic data included age, gender, school grade, parental educational achievement, family income level, and marital status. In addition to descriptive results, multiple linear regression analysis and moderated multiple serial mediation analyses unveiled the substantial predictive capacity of sociodemographic characteristics and general parental supervision in shaping internet usage and effects on mobile phone addiction. Concretely, the regression models explained how and to what extent each of the demographic variables influenced the relationship between parental monitoring and mobile phone addiction. Demographic variables like age, gender, parents' education levels, and household income were identified as significant factors influencing individuals' internet usage, PSU, and parent monitoring.

This comprehensive methodology, involving meticulous sampling, data collection over various time periods in 2020, and advanced statistical analysis, serves as the foundation for understanding the intricate relationship between demographic factors and online information-seeking behavior within the context of the specified information categories. The complete list of variables, their descriptions, question phrasing, and scaling details can be found in Multimedia Appendix 1.

Data Processing

The statistical software IBM SPSS 29 was used to perform both descriptive and regression analyses of the collected data. Descriptive statistics were used as measures of overview tendencies to give general information regarding the frequencies and general patterns regarding internet usage, mobile phone addiction, and parental supervision among adolescents.

Besides descriptive analysis, multiple linear regression analysis, and moderated multiple serial mediation analyses unveiled the substantial predictive capacity of sociodemographic

XSL•FO
RenderX

characteristics and general parental supervision in shaping internet usage and effects on smartphone addiction. Concretely, the regression models explained how and to what extent each of the demographic variables—age, gender, parents' education levels, and household income—influenced the relationship between parental monitoring and smartphone addiction.

Results

Descriptive Statistics

An analysis of internet and digital device usage patterns was performed among children and teenagers in 2020. A total of 1673 valid data were evaluated. It is found that 92.3% (n=1545) of children and teenagers accessed the internet in Taiwan, among the respondents, with a mean age of 13.31 (SD 2.294) years. Out of the total number of respondents, 51.8% (n=867) were male and 48.2% (n=806) were female. A significant proportion of the participants' parents possessed a high school diploma or a higher level of education, specifically 29.2% (n=488) and 27% (n=451), respectively, with a total sample size of 939. Approximately 73.7% of respondents, namely 1233 individuals, believe that their household income level is relatively affluent. Among adolescents, 83.9% (n=1423) own mobile phones and 92% (n=1561) use their mobile phones to access the internet. The mean score of PSU was 3.29 (SD 0.84). The descriptive results for parental monitoring revealed that restrictive mediation had a mean score of 2.39 (SD 0.90), followed by evaluative mediation with a mean of 2.22 (SD 0.86), and unfocused mediation with a mean of 2.11 (SD 0.95). Multimedia Appendix 2 provides the statistical information for adolescent respondents from Taiwan in 2020.

Effects of Parental Monitoring

Among the 3 types of parental monitoring, restrictive monitoring was the most effective. This approach had a significant indirect effect on mobile phone addiction through decreased internet usage (b=−0.029, SE 0.007, 95% CI −0.044 to −0.017). The direct effect of restrictive monitoring on phone addiction (controlling for internet use) was significant (b=−0.154, SE 0.024, P<.001). Further analysis showed that restrictive monitoring significantly decreased internet usage (b=−0.338, SE 0.036, P<.001). These findings confirm that reducing screen time is a key pathway by which strict parental rules help lower mobile phone dependency.

In contrast, evaluative monitoring, which involves discussing media use with teens, had mixed effects. It was associated with slightly higher internet use (b=0.090, SE 0.038, P=.02), but its direct effect on phone addiction was not statistically significant (b=−0.037, SE 0.024, P=.13). This suggests that while open communication may encourage greater digital engagement, it does not necessarily reduce problematic mobile phone use.

Unfocused monitoring, where parents offer little structure or guidance, was linked to higher internet use (b=0.145, SE 0.035, P<.001) but showed no significant effect on mobile phone addiction (b=−0.010, SE 0.022, P=.66). This indicates that inconsistent or vague monitoring is ineffective at managing digital behavior.

These findings partially support the first hypothesis that parental monitoring helps prevent mobile phone addiction among adolescents. Concretely, restrictive monitoring was the most effective in reducing both internet use and phone addiction. While restrictive monitoring was protective, both evaluative and unfocused monitoring were associated with increased internet use, which in turn was linked to higher levels of PSU. Table 1 provides the details of the regression analysis illustrating the impact of parental monitoring and internet usage on mobile phone addiction.

Variable of Sex

Sex does not moderate the effect of any form of parental monitoring; for instance, restrictive monitoring, internet use, and mobile phone addiction (b=0.0008, SE 0.009, 95% CI −0.019 to 0.019). When sex was introduced into the analysis, it was revealed that it had no effect on the relationship between the level of parental monitoring, internet use, and mobile phone addiction. Thus, it was found that there was a lack of sex differences in terms of perceived parental monitoring, internet use, and mobile phone addiction. This result, illustrated in Table 2, failed to reject the null hypothesis of the second hypothesis, which proposed that girls were likely to experience more parental monitoring than boys in the use of the internet and mobile phone addiction.

Variable of Age

The influence of internet usage on PSU differed depending on the age group. Internet use was found to be a significant predictor of mobile phone addiction among teenagers aged 10-14 years. However, this prediction was not significant for those aged 15-18 years. Among 10-year-olds, heightened unfocused parental monitoring had a significant negative effect on mobile phone addiction (b=−0.333, SE 0.160, t_{51}=−2.084, *P*=.04). This indicates that unfocused parental monitoring can lower mobile phone addiction, but it did not have a significant influence on internet usage.

Concomitantly, 11-year-old users' heightened restrictive parental monitoring led to a substantial decrease in internet usage and mobile phone addiction (b=−0.066, SE 0.028, 95% CI −0.129 to −0.019). Furthermore, restrictive monitoring also has a negative direct impact on the development of mobile phone addiction (b=−0.185, SE 0.085, t_{189}=−2.173, *P*=.03). Additionally, evaluative monitoring negatively correlated with mobile phone addiction (b=−0.164, SE 0.071, t_{189}=−2.322, *P*=.02). In contrast, unfocused mediation did not exert a substantial direct impact on mobile phone addiction.

Among 12-year-olds, implementing stricter parental monitoring (restrictive monitoring) resulted in a substantial decrease in internet usage (b=−0.033, SE 0.017, 95% CI −0.073 to −0.038). However, restrictive parental monitoring did not have a significant effect on mobile phone addiction. On the other hand, when parents are using unfocused monitoring, there is a substantial rise in internet usage. Additionally, higher levels of internet usage are associated with a greater likelihood of developing mobile phone addiction (b=0.042, SE 0.018, 95% CI 0.011-0.083).

Among 13-year-olds, stricter parental monitoring (restrictive monitoring) was found to be directly linked to a decrease in mobile phone addiction (b=−0.240, SE 0.073, t_{226}=−3.288, *P*=.001). Users among 16-year-olds with heightened unfocused parental monitoring have a significant negative impact on internet usage. However, unfocused did not have a significant effect on mobile phone addiction (b=−0.004, SE 0.007, 95% CI −0.022 to 0.008).

The findings support hypothesis 3, indicating that younger adolescents benefit more from restrictive parental monitoring in reducing both internet usage and mobile phone addiction, while older adolescents are less affected by such monitoring techniques. The results imply that there are differences in various types of parental supervision regarding the age of the child. The effects of parental oversight are not uniform on both internet use and mobile phone dependency, which answered the RQ2. Table 3 displays the overview of results for the significant result of synergy of the mediation effects for age groups 10 to 13 and 16 as identified in this study.

[a]Not applicable.

Household Income and Parents' Education

Parental use of restrictive monitoring is influenced by 2 main factors: household income and the mother's education level. Higher-income families are more likely to adopt restrictive strategies, which effectively reduce adolescent smartphone addiction. The analyses revealed that the mediator (restrictive mediation) and income (X) were significant predictors of mobile phone addiction (b=−0.022, SE 0.010, 95% CI −0.043 to −0.003). It is found that households with higher incomes tend to use restrictive control measures, which successfully reduce the likelihood of cell phone addiction among adolescents.

The findings also show that higher-income families are more likely to use evaluative mediation, which involves discussing phone use with their children. This approach was positively associated with wealth (b=0.189, SE 0.037, t_{1582}=5.060, P<.001). Similarly, there was a positive association between higher household income (b=0.092, SE 0.041, t_{1582}=2.228, P=.03) and increased use of unfocused mediation. The findings indicate that specific socioeconomic characteristics have an impact on the evaluative and unfocused type of parental supervision used, but they do not have an indirect influence on the decreasing probability of adolescent mobile phone addiction. The third RQ delves into the intricate relationship between income, mobile phone addiction, and internet usage patterns. Table 4 displays the results of the third RQ and fourth hypothesis, which answered the mediation relationship between income, mobile phone addiction, and restrictive parental monitoring.

[a]Not applicable.

Mother's education was found to influence adolescent smartphone addiction. Higher maternal education was linked to lower phone addiction (b=−0.001, SE 0.0007, t_{1582}=−2.709, *P*=.006), and it also predicted greater use of restrictive parental monitoring (b=0.001, SE 0.0006, t_{1582}=2.879, *P*=.004). Thus, it is reported that mothers who have greater levels of education tend to use restrictive meditation practices, which successfully reduce the likelihood of kids developing cell phone addiction. Also, children of mothers with greater levels of education are less likely to develop mobile phone addiction (b=−0.0004, SE 0.0002, 95% CI −0.008 to −0.0001). RQ4 was solved based on this finding, and the result is presented in Table 5.

[a]Not applicable.

The data also showed that parents with lower education levels, both fathers (b=−0.003, SE 0.0006, t_{1582}=−5.063, *P*<.001) and mothers (b=−0.002, SE 0.0006, t_{1582}=4.181, *P*<.001) were more likely to use evaluative mediation. Nevertheless, this type of mediation also had a measurable impact on reducing smartphone addiction. Meanwhile, lower parental education levels were associated with the use of unfocused mediation, both for fathers (b=−0.002, SE 0.0006, t_{1582}=−3.406, *P*<.001) and mothers (b=−0.001, SE 0.0007, t_{1582}=−2.624, *P*=.008). However, this technique was found to have little or no predictive value for cell phone addiction.

Hence, the study partially supports hypothesis 5, which hypothesizes that household income and parental education are

XSL•FO
RenderX

the 2 main factors that influence the style of monitoring by parents, with only restrictive monitoring as being effective in preventing addiction to mobile phone use. However, the sociodemographic variables, such as income and parent education level, are often linked to evaluative and unfocused monitoring but have little impact on the likelihood of mobile phone addiction.

Discussion

Principal Results

This study examined the complex interplay between parental monitoring, adolescent development, and PSU. Findings demonstrated a strong association between parental supervision strategies and digital behaviors, corroborating previous research that links monitoring to reduced internet addiction [75,76]. Notably, restrictive mediation was more effective among younger adolescents, significantly curbing internet and smartphone use for those aged 10 - 12 years. This supports earlier findings that younger children are more responsive to parental authority [53,55]. However, as adolescents matured, restrictive strategies proved less effective. According to past studies, older adolescents, particularly those aged 15 - 18 years, demonstrated greater resistance to control [48,49,77]. With advanced problem-solving skills and critical thinking, they are able to manage their digital lives independently and evade parental detection [78].

Evaluative mediation, characterized by open dialogue and critical reflection, was associated with increased internet use; however, it did not significantly reduce problematic mobile phone use. Unfocused monitoring yielded inconsistent outcomes: among 11 - 12-year-olds, it increased internet use, but by age 16, it was linked to reduced usage. These results underscore the developmental dimension of digital behavior regulation and emphasize the need for age-sensitive parental strategies.

Age emerged as a key moderator in the relationship between parental oversight and adolescent smartphone behavior. As cognitive maturity develops, adolescents increasingly prioritize peer affiliation and autonomy over parental control [79,80].

Consequently, the study reinforces that while restrictive strategies may work for younger cohorts, autonomy-supportive and collaborative forms of oversight are more effective for older adolescents. These findings directly inform SRSE-based interventions by identifying parental style as a modifiable determinant that mediates their effectiveness.

Developmentally Adaptive Parental Mediation

The developmental trajectory of adolescence demands flexible parental mediation strategies [81]. Research findings suggest that parental oversight functions not merely as a passive background variable, but as a dynamic moderator that either enhances or inhibits SRSE-based interventions. When adolescents perceive parental control as autonomy-supportive, emphasizing trust, communication, and shared decision-making, they are more likely to internalize self-regulatory behaviors. In contrast, controlling or punitive oversight may provoke psychological reactance and lead to resistance, especially in older adolescents [48,49,77].

This aligns with parental mediation theory, which positions parenting as an adaptive, interactive process shaped by both the parent's approach and the adolescent's developmental stage. Integrating this with the PYD framework allows for a more holistic understanding of adolescent digital well-being. Rather than viewing smartphone use as inherently problematic, this perspective emphasizes fostering competencies, such as critical thinking and emotional regulation, that enable responsible digital engagement. Parental mediation strategies that evolve in tandem with adolescent cognitive and social maturity can effectively bridge these models, guiding healthier digital development.

Socioeconomic Influences and Theoretical Implications

While the developmental stage significantly shaped the effectiveness of parental strategies, our findings also illuminated how socioeconomic variables influenced smartphone addiction and mediation style. Consistent with previous research, adolescents from low-income and lower-education households demonstrated higher levels of smartphone addiction [63-65]. These families often lack alternative recreational resources or digital literacy [66], which may lead to greater reliance on smartphones as surrogate caregivers. In contrast, high-income families, benefiting from greater resources and parental availability, implemented more diverse and effective mediation approaches, thereby reducing smartphone dependency.

Interestingly, while parental education was inversely related to adolescent smartphone addiction, it also influenced the choice of monitoring strategy. Parents with higher education tended to favor restrictive mediation, while parents with lower education leaned toward evaluative or unfocused approaches [69]. These findings indicate that effective digital parenting is shaped not only by knowledge and resources but also by attitudes and awareness regarding digital risks. Importantly, this supports the argument that interventions must account for both perceptual and structural determinants of parenting behavior.

Contrary to some earlier assumptions, this study found no significant sex differences in parental monitoring or smartphone use. Both male and female adolescents were subject to similar levels of parental oversight, aligning with research that documents diminishing sex-based parenting distinctions in the digital age [52,82]. This neutrality in parental response further emphasizes the relevance of focusing on developmental and contextual factors rather than demographic stereotypes when designing digital well-being interventions.

These results advance theoretical integration by situating parental mediation within a bidirectional model of digital development. The convergence of parental mediation theory with SRSE and PYD frameworks underscores the importance of tailoring interventions to the evolving cognitive, emotional, and environmental realities of adolescents. Parental oversight should be understood not as a fixed constraint but as an evolving, context-dependent factor with the potential to amplify or hinder the success of digital health initiatives.

This study used a nationally representative dataset from Taiwan, where adolescents aged 10 - 18 years encounter one of the highest rates of digital saturation in East Asia. Its

XSL•FO
RenderX

Confucian-influenced parenting norms and academic pressures create a culturally unique yet regionally relevant context.

Insights obtained from the Taiwanese context can therefore enhance the comprehension of parental mediation in other industrialized East Asian nations, namely South Korea, Japan, and Singapore, which possess analogous sociocultural and educational attributes. In both settings, the efficacy of parental mediation measures is significantly affected by developmental stage and perceived autonomy, rendering Taiwan a crucial case study for comparative digital parenting research.

Limitations

Despite offering valuable insights into adolescent digital behavior and parental supervision, this study has several limitations. Primarily, the data were self-reported, which introduces potential biases such as social desirability and recall errors [83,84]. Previous research involving 3401 participants shows that only one-third of respondents accurately report internet usage, while 42% (n=1428) overestimate and 26% (n=884) underestimate it [85]. Heavy users tend to underreport, whereas light users often overreport [86]. Such inaccuracies can distort key behavioral metrics, especially when relying on survey-based primary data.

Furthermore, the COVID-19 pandemic likely influenced both adolescent behavior and parental monitoring. Shifting family routines, including remote work and increased household responsibilities, may have altered parents' capacity to supervise screen time effectively [87]. As families transitioned back to prepandemic structures, supervision patterns likely changed, complicating interpretations of consistency over time.

This study did not directly measure smartphone ownership, which recent research suggests can be a significant moderator of parental mediation efficacy and associated child outcomes [88]. In our high-penetration context (94.9%), ownership variance was minimal, likely limiting its moderating effect within our sample. However, this limits the generalizability of our findings to cultures or socioeconomic contexts where smartphone access among adolescents is not near-universal. Future studies should include this variable to better elucidate its role across different environments.

Additionally, the measurement of parental mediation was constrained by the limited number of items in each subdimension, especially unfocused mediation. This restricts the internal consistency of the overall scale and limits the interpretive power of the unfocused mediation category, which cannot yield a reliability estimate.

Future research should incorporate both subjective and objective digital usage metrics, include perspectives from both adolescents and parents, and consider cultural and demographic contexts. Longitudinal approaches would better capture evolving behavioral dynamics and improve the reliability of assessments across diverse environments.

Conclusions

This study investigated how parental monitoring shapes adolescents' digital well-being in Taiwan, using data from the nationwide survey. The findings highlight the critical role of age-specific parental strategies in mitigating excessive internet use and mobile phone addiction. Restrictive monitoring proved effective for younger adolescents, but its influence declined with age, emphasizing the need for adaptive, communication-centered approaches as adolescents develop greater autonomy.

As digital devices become integral to education and social interaction, especially in the postpandemic context, balancing screen use with psychosocial health is increasingly complex. Our results suggest that instead of relying solely on rigid restrictions, parents should promote constructive digital engagement, particularly among older adolescents. Equipping adolescents with self-regulatory skills through open dialogue and guidance may prove more effective in fostering responsible smartphone use.

While this research focuses on Taiwanese adolescents, its findings may resonate across culturally similar East Asian contexts. Taiwan's high smartphone penetration, academic intensity, and Confucian-rooted family dynamics make it a meaningful case study for digital parenting in developed Asian societies. Thus, the insights gained from this study are not only locally relevant but regionally informative, contributing to broader comparative understandings of adolescent digital regulation in Asia.

This research carries implications for families, educators, and policymakers. Awareness campaigns and parental support programs—particularly targeting lower-income and less-educated households—are essential in promoting effective mediation strategies. Community institutions, such as schools, can serve as platforms for delivering digital literacy interventions that empower families to navigate adolescents' digital lives with confidence and care. Future efforts should aim to develop developmentally sensitive, culturally attuned tools that support both youth well-being and healthy digital integration.

Acknowledgments

We thank the editors and anonymous reviewers for their careful reading of our manuscript and many insightful comments.

Data analyzed in this study were collected by the research project of the Taiwan Communication Survey (TCS), which is supported by the Ministry of Science and Technology of Taiwan, Republic of China, and available from Survey Research Data Archive, Academia Sinica [89]. The authors appreciate the assistance in providing data by the institute aforementioned. The views expressed herein are the authors' own.

Abstract

Background: Over the past 3 decades, digital and screen media have evolved from broadcast, stationary platforms to a complex environment of interactive, omnipresent, mobile media. Thus, clinical guidance centered around unidimensional concepts such as "screen time" must be modernized to help families navigate the intricate digital ecosystems of readily available entertainment and information.

Objective: This study aimed to identify and examine distinct latent profiles of media use in families with young children. We hypothesized that latent profile analysis (LPA) would identify different media use profiles characterized by more heavy, reactive, individual, and permissive media use and more intentional, regulated, or shared uses of media.

Methods: We analyzed data from 398 preschool-aged children. English-speaking parents were recruited through community settings. Participants completed surveys regarding several aspects of family media use, such as child device use or activities, parent concerns and attitudes, limit setting and mediation, parent media use, and technology interference, examined in an LPA. The number of latent media profiles was determined using Bayesian Information Criteria. Parents also completed validated scales of parenting stress, depression symptoms, parenting style, child behavior, child sleep, and household disorganization. Multivariable logistic regression was used to examine parent, child, and household predictors of group membership.

Results: The LPA yielded 2 distinct groups that differed in the duration of media used by parents and children, to calm children or help them fall asleep. Statistically significant differences between groups included: families in group 1 (n=236, which we termed social-emotional drivers) had parents who preferred interactions via text or email to in-person (P=.01) and were more likely to use media to calm their children (P=.03); in contrast, families in group 2 (n=162, intentional media) used more task-oriented media, like audio and nongame apps (P=.01), had more concerns about effects of media on child language development (P=.04), and used more media restrictions (P=.01). In regression models, female sex of the parent respondent, greater number of siblings, and later child sleep midpoint independently predicted group 1 membership.

Conclusions: Findings suggest divergent family media use patterns that can be categorized into 2 main media user groups: those using media to buffer social situations or regulate emotions and those planning mobile device use around functional purposes and concerns around media exposure. Profiles were associated with household size and child sleep. More research is needed to examine the impact of social and emotional uses of media on child outcomes.

Introduction

Background

The landscape of digital technology use has changed dramatically over the past few decades. Digital and screen media have evolved from broadcast, stationary platforms, where screens stay put, plugged into the wall, and messages are transmitted broadly in a one-to-many model, to a world of interactive, mobile media, where screens can follow users wherever they go and interact in a bidirectional manner. For this reason, researchers have questioned whether clinical guidance centered around unidimensional concepts such as "screen time" are helpful to parents trying to navigate digital ecosystems of readily available entertainment and information [1], particularly considering families' increased technologic dependence during and following the COVID-19 pandemic.

Distinctions between traditional (eg, television [TV]) and mobile, interactive media are important for several reasons.

XSL•FO
RenderX

First, the portability and easy accessibility of mobile media inherently allows for more spontaneous and reactive use patterns in which the technology becomes increasingly integrated into daily routine and activities [2,3]. Second, small, handheld screens are more difficult for parents to monitor [4]. And third, mobile media use has rapidly become exceedingly common, even in infants and toddlers. As of 2017, 98% of homes of children 0 - 8 years old had a mobile device, and one third of all screen time in that same age group, who use on average almost 2.5 hours of screen media per day, was mobile [5].

Previous Work

In light of modern technologic advances, new ways of studying, conceptualizing, and framing media use guidance have been proposed. Young children's media use has been conceptualized as the "3 Cs", that is, content, context, and the individual child given the important role each of these factors plays in shaping child responses to media [6]. However, pervasive use of mobile media by families with young children requires new concepts such as use of devices for on-demand calming and keeping children occupied during daily activities.

To capture holistic patterns of family media use, it is also important to consider parents' mobile device use, which interrupts parent-child interaction [7] and is associated with less responsiveness [8], but is an important part of parent social connection, work-life, and day-to-day functioning [9]. Parents' mediation behaviors (practices such as coviewing, teaching children about media content, or setting limits) also shape children's responses to media [10]. Finally, child and parent media use are highly correlated [11], yet are usually studied in isolation. One previous attempt to describe family-level media behaviors [12] primarily focused on viewing duration and type of media use, rather than the several contextual variables or social-emotional drivers of media use in the current digital environment.

Goal of This Study

The current study aims to identify patterns that include the aforementioned concepts, examined through latent profile analysis, to try to identify patterns and concepts that might generate insights for clinical guidance and future research. Specifically, we sought to identify novel patterns of family media use that consider child duration and frequency of media activities; child use to keep occupied, regulate behavior, or fall asleep; parent attitudes about child use; limit setting and mediation; parent media use; and "technoference" (ie, technology interference in parent-child activities). We hypothesized that latent profile analysis (LPA) would identify different media use profiles characterized by more reactive, heavy, individual, and permissive media use; and more intentional, regulated, or shared uses of media. We examined these patterns and their associations with parent, child, and household characteristics within a large cohort of preschool-aged children, as early childhood is an important time of establishing media use habits [13].

Methods

Overall Study Design

We analyzed data from the Preschooler Tablet Study, a longitudinal cohort study (NICHD R21HD094051) examining associations between early childhood digital media use and social-emotional development. The present analysis used REDCap (Research Electronic Data Capture) [14] and Qualtrics survey data from the baseline data collection wave (August 2018-May 2019).

Ethical Considerations

The study was approved by the University of Michigan Institutional Review Board (HUM00131980). Parents provided electronic informed consent for themselves and on behalf of their young children. Participants were informed that they could opt out of the study at any time. Data downloaded from REDCap and Qualtrics were stored on secure password-protected servers at the University of Michigan. Data was not de-identified prior to analysis; all participants were assigned a study ID number that only linked to identifying information on REDCap, a HIPAA-secure database to which only approved study personnel had access. Participants received $40 for completing data collection procedures.

Participants

Parents of young children were recruited through flyers posted in community centers, preschools, childcare centers, and pediatric clinics in southeast Michigan, as well as our university's online participant registry and social media advertisements. Interested parents who contacted the study team were emailed a link to an eligibility questionnaire. Eligibility criteria is shown in Textbox 1. To improve generalizability, participating children did not need to regularly use mobile devices to be included in the study.

Textbox 1. Study inclusion and exclusion criteria.

Inclusion criteria:

- Parent was legal guardian of a 3 - to 4.99-year-old child.
- Parent lived with the child at least 5 days per week.
- Parent understood English sufficiently enough to complete questionnaires and provide consent.
- The family owned at least 1 Android or iOS tablet or smartphone.

Exclusion criteria:

- Child developmental delays.
- Use of psychotropic medication.

XSL•FO
RenderX

Survey Measures: Child, Parent, and Household Characteristics

After providing electronic informed consent, respondent parents completed web-based surveys with a variety of questionnaires to assess characteristics of the child, parent, and household, as well as family media use practices. Demographic characteristics were collected for children's age, sex, race, ethnicity (investigator-defined categories shown in Table 1), daycare or preschool enrollment, average sleep pattern (sleep onset and wake time, from which duration and midpoint were calculated, as well as sleep latency and overnight awakenings), prematurity, and whether they were an only child; parent age, gender, educational attainment, marital status, and employment status. We also used validated questionnaires to assess parent depression symptoms (Centers for Epidemiologic Studies-Depression Scale) [15], parenting stress (Parenting Stress Index-Short Form) [16], and parenting styles (laxness and harshness subscales of The Parenting Scale) [17]; as well as household income, size, composition, and disorganization (Chaos, Hubbub, and Order Scale) [18]. Child self-regulation abilities were assessed with the Emotional Reactivity subscale of the Child Behavior Checklist-Preschool [19], the Surgency subscale of the Rothbart Child Behavior Questionnaire-Very Short Form [20], and the Behavior Rating Inventory of Executive Function-Preschool [21].

Survey Measures: Media Use

Parents also completed a 75-item questionnaire about family media use derived from the CAFE (Comprehensive Assessment of Family Exposure) Consortium Qualtrics Survey, which has been described elsewhere [22]. This survey asks about technology and device ownership, content and context of media use, parent media use, and mediation practices (refer to Textbox 2 for constructs assessed). Questions on the survey addressed types of devices in the home and locations of those devices, parent attitudes toward media and concerns regarding child use of media, duration of use on weekdays versus weekends, time of use and environmental context of use (for example while falling asleep or while in transit), usual content (for example streaming video versus playing games), family interactions around media, and media-use functions.

XSL•FO
RenderX

Textbox 2. Media-related constructs assessed through the CAFE (Comprehensive Assessment of Family Exposure) questionnaire.

A. Child ownership and frequency of activities

A1. Child ownership of mobile media device

A2. Child keeps device in bedroom

Frequency of mobile device use for specific activities:

(A3. Watch TV; A4. Watch movies; A5. Play games; A6. Use apps that are not games; A7. Read electronic books; A8. Listen to music or audiobooks; A9. Take photos; A10. View photos/videos)

B. Child instrumental or regulatory uses of media

B1. Use of media during travel in car or public transit

B2. Use of TV to calm when upset

B3. Use of mobile devices to calm when upset

Use of all types of screen media by parent for specific purposes related to child:

(B4. To educate child; B5. Calm child down; B6. Keep child busy; B7. Communicate with family and friends; B8. Because child enjoys it)

B9. Use of devices at bedtime

B10. Use of devices while falling asleep

C. Parent media knowledge and attitudes

Parent concerns that child will:

(C1. Be exposed to inappropriate content; C2. Become inattentive as a result of using screen media; C3. Become addicted to screen media; C4. Miss out on other important opportunities that are more valuable than screen media; C5. Be exposed to harmful electromagnetic waves; C6. Have poorer language development).

D. Mediation strategies

Presence of media content limits:

(D1. Parents blocks specific media content on TV/devices; D2. Parent uses web blockers/controls; D3. Parent only allows child to watch “child-friendly” content; D4. Parent uses ratings to decide what child will watch; D5. Child media use only allowed if parent is in the room).

D6. Media time limits are consistently enforced

D7. Media content limits are consistently enforced

D8 – D22: Valkenburg Mediation Scale (Social Coviewing, Instructive Mediation, and Restrictive Mediation)

E. Parent media use

Outside of work hours, parent feels:

(E1. The need to stay connected to work almost constantly; E2. The need to stay connected to friends and social media almost constantly; E3. It is easy to multitask between children and using a phone or mobile device; E4. Sometimes overwhelmed by how much they have to do on their phone or mobile device; E5. That they prefer to interact with others via texting, email, or social media, rather than in person; E6. Using their phone or mobile device allows them to “escape” a little bit while they’re with their children; E7. Sometimes “addicted” to mobile media like smartphones or tablet devices).

Frequency of specific activities during a typical weekday (Monday-Friday):

(E8. Watch TV; E9. Use the computer; E10. Read traditional books; E11. Read electronic books; E12. Play videogames on console game player; E13. Use an iPad, iTouch, or similar device (not including a smartphone); E14. Use a smartphone for things like texting, playing games, watching videos, checking email, or surfing the internet).

Frequency of specific activities during a typical weekend day (Saturday-Sunday):

(E15. Watch TV; E16. Use the computer; E17. Read traditional books; E18. Read electronic books; E19. Play videogames on console game player; E20. Use an iPad, iTouch, or similar device (not including a smartphone); E21. Use a smartphone for things like texting, playing games, watching videos, checking email, or surfing the internet).

F. Technoference

Frequency of parent phone use during specific activities:

(F1. During meals; F2. While getting child(ren) ready for school; F3. During playtime; F4. During bedtime routine; F5. While driving child(ren) to or from activities or when riding on public transportation; F6. At the playground).

XSL•FO
RenderX

Data Analysis

Of the 423 participants who provided consent and completed surveys, we excluded participants who did not complete (n=19) or had substantial missing data (n=6) on the media use questionnaire. This left 398 participants in this study available for the LPA. All media variables were included in LPA, a person-centered statistical method to identify distinct groups of participants with similar median profiles within each group. Using Bayesian Information Criteria (BIC), the LPA with the lowest BIC value yielded 2 distinct groups.

Wilcoxon Mann-Whitney tests were used to compare media use questionnaire items between the groups identified by the LPA. Then separate multivariable logistic regression models were built to estimate the odds of being in group 1 versus group 2 for each set of parent (Model I), child (Model II), and household (Model III) predictors. As our approach was exploratory, we started with including all parent, child, or household characteristics in each respective model and conducted backward elimination, resulting in the most parsimonious model that retained only variables showing significant associations at a *P* value of <.05. For all characteristics significantly associated with group membership in Models I, II, or III, we built a combined Model IV to test which characteristics were independently associated with group membership.

Results

Participant Demographics

Parents were 93.7% female (373/398), 34 (SD 4.7) years old, and 62% (247/398) had a 4-year college degree or more; children were 3.8 (SD 0.54) years old, 76.3% (302/398) were White and non-Hispanic, and 82.7% (329/398) had siblings in the household (Table 1).

Evaluation Outcomes

Latent profile analysis yielded 2 distinct groups of media users (Figure 1). Families in group 1 (n=236) were more likely to prefer interactions through text, email, or social media rather than those in person (*P*=.01) and more likely to use TV shows or DVDs to calm their children (*P*=.03). Parents in group 1 used their mobile device more frequently during the week to read electronic books (*P*=.04). In contrast, group 2 (n=162) used more task-oriented media, including more audio and nongame apps (*P*=.01), had more concerns about effects of media on language development (*P*=.04), and used more media restrictions (*P*=.01).

XSL•FO
RenderX

Figure 1. Latent Profile Analysis: media use profiles. Standardized means by variable for group 1 versus group 2. Lettering describes variable type: A. child ownership and frequency of activities; B. child instrumental or regulatory uses of media; C. parent media knowledge and attitudes; D. mediation strategies; E. parent media use; F. technoference.

XSL•FO
RenderX

As shown in Figure 1, several additional variables approached significance (P<.20) that warrant mention. Parents in group 1 were more likely to feel overwhelmed by how much they have to do on their phone or mobile device (P=.12) and reported that using the phone or mobile device allowed them to "escape" a little bit while with their children (P=.14). They were more likely to watch TV or DVDs (P=.15) or use the computer (P=.10) over the weekend than were families in group 2. Group 1 families also reported using more content restrictions for what their children see in the media with internet filters, parental controls, or apps to block certain websites (P=.11) , as well as use of parental media websites (eg, common sense media) to decide what types of programs are appropriate for their child. Finally, group 1 families were more likely to use their mobile device to take photos (P=.11).

Group 2 families preferred using their mobile devices to view photos or home videos (P=.13) in addition to the other task-oriented media described above. They also noted concerns that children will become inattentive as a result of using screen media (P=.11) and more frequently restrict the amount of child viewing (P=.06).

In logistic regression models (Table 2), the only parent characteristic that was significantly associated with group 1 membership (vs group 2) in Model I was female parent sex. In Model II, children with longer duration of sleep had lower odds of group 1 membership, while those with later sleep midpoint and prematurity showed increased odds of group 1 membership. Households with more siblings had a borderline increased odds of group 1 membership in Model III. With all characteristics considered in the same model (IV), independent associations remained for female parent sex, greater number of siblings, and later child sleep midpoint.

Table . Multivariable logistic regression models predicting group assignment.

Model and variable		Group 1 (social-emotional drivers) versus group 2 (intentional media), aOR[a] (95% CI)
Model I: parent characteristics		
	Parent sex (male vs female)	0.36 (0.16-0.84)
Model II: child characteristics		
	Sleep duration (per 1 hour)	0.72 (0.55-0.95)
	Sleep midpoint (per 1 hour)	1.5 (1.13-1.98)
	Prematurity (no vs yes)	2.26 (1.06-4.8)
Model III: household characteristics		
	Number of siblings (per sibling)	1.23 (0.998-1.5)
Model IV: all characteristics		
	Parent sex (male vs female)	0.3 (0.12-0.76)
	Number of siblings (per sibling)	1.27 (1.02-1.57)
	Sleep midpoint (per 1 hour)	1.51 (1.1-2.07)

[a] aOR: adjusted odds ratio

Discussion

Principal Findings

This study used a wide range of questions about child, parent, and household context of media use to identify coherent patterns of media use that are relevant to pediatric research or clinical intervention. Latent profile analysis results suggest that people may be predisposed to different media-use patterns based on individual motivations. Group 1 preferred text and email interactions to those in-person and used media to calm their children. These behaviors may be interpreted as use of media based on social-emotional drivers. In contrast, group 2 used media for more functional purposes. This group preferred more nongame and audio applications. They seemed warier of media, placed more restrictions around child media use, and had more concerns about the effect of media on child development. Though these findings in some way confirmed our initial hypothesis, that some types of media users are predisposed to more reactive-use patterns (group 1), while others are more predisposed to intentional and regulated uses of media (group 2), the tendency to use media as a sort of social-emotional buffer was not a factor we considered in our initial hypothesis.

When examining the overall patterns of media use between groups, a few theoretically coherent concepts arise. In group 1, described as using media based on social-emotional drivers, there appeared to be more parent use of media as an "escape" from childrearing demands, such as more parental media during the weekends, which is typically time families are together during the day. In previous qualitative work, parents have described using mobile devices and social media as a "virtual escape" when their child stresses them out [9], when they want to avoid parenting tasks [23], or when intentionally not wanting to engage with difficult child behavior [24]. Furthermore, compared with parents in group 2 who were more likely to view, but not take, photos or home videos on a mobile device, group 1 families took photos on their device more frequently, an action that by definition interrupts a social moment and introduces a

XSL•FO
RenderX

physical barrier between the individual taking the photograph and the subjects.

In group 2, parent media use appeared more goal oriented, and more limits and restrictions were placed on child media use, which may be related to greater concerns about media's effects on child wellbeing. This pattern of device usage has been described as "instrumental" (ie, goal directed and purposeful) rather than "ritualistic" in previous work [25], and is hypothesized to be related to the individual motivations for engaging with technology. In this study, we describe this pattern of device usage as intentional, similarly noting that this type of media use is meant to fulfill a purpose rather than for pleasure or distraction. Though we did not observe increased odds of group 2 membership based on measures of parental mental health or child behavior, a recent study using latent class analysis found stronger well-being indicators for "family-engaged adolescents" who live in families with family-owned devices, positive parent relationships, and lower parental social media use [26]. Higher wellbeing also occurred in teens who placed lower importance on technology and were expected to follow household technology rules. Future research may therefore examine the relationship between these multiple classes of media users in a longitudinal manner to determine if "intentional" media-use families who set early boundaries around child media use are more likely to have "family-engaged adolescents" with better social-emotional outcomes.

It is surprising that socioeconomic status, parenting stress, household disorganization, and child behavioral difficulties were not associated with membership in group 1. In previous research, longer screen time duration and higher parent technology interference have been linked with higher parenting stress [27-29]. Recent work has also suggested that children's screen time is a marker of family distress due to multiple psychosocial factors [30]. However, these studies only examined the variable of screen time, while our approach identified larger family media use patterns that appear independent of socioeconomic factors in this cohort.

We did find that mothers are more likely to use media as a social-emotional buffer and that this type of media use is more common in larger families. It is possible that mothers or parents of larger families may experience higher caregiver burden and, as a result, are using media for more self-regulatory purposes and to calm or manage child behavior more frequently. Indeed, use of digital technology as a "babysitter," to provide caregiver respite or allow parents time to tend to other tasks, is a concept that is well-described in research literature and mainstream news, albeit with some differences in acceptance across cultures [31-35]. Evidence suggests that use of media to occupy children may be especially relevant in homes where children require more attention or behavioral management due to temperament differences [36], or where there is limited support for the primary caregiver. One study found that parents who lack support from a partner or who are uncertain about their parenting skills were more likely to use media as a distractor and concluded that "media are thus especially used as a distractor in the family when parents feel that it is difficult to keep the household going by themselves" [34].

Another correlate of group membership was later sleep midpoint (ie, the calculated midpoint between reported average sleep onset and wake time), with group 1 having later sleep midpoints than group 2. This may be explained by the fact that group 2, despite any significant difference in overall parenting style, seemed more prone to limit setting. What is perhaps most surprising about our study findings are the variables that did not predict group membership including parent education, marital status, employment, and child behavior variables such as emotional reactivity and surgency. Although human-computer interaction research has identified individual predictors of smartphone usage habits such as personality [37], attachment style [38], and executive functioning [39], we found no associations of parenting style (such as laxness vs harshness), parenting stress, or depression symptoms with group membership.

Limitations

Our study was limited in generalizability due to our study population which included mostly White, non-Hispanic, higher-educated, and female-parent responders. While our cohort reflected the racial and ethnic diversity of our local area, results may not be generalizable to other populations. In addition, the data we analyzed on media use was all from self-report questions, which can lead to single-reporter bias. We also reported on several associations that did not achieve significance, but were near significant, that we included in our results as we felt the data helped to demonstrate an overall trend. Greater insight into the reasons for media use may have been gleaned from a mixed methods approach, where follow up semistructured interviews could have explored themes related to media as a social-emotional buffer versus to fulfill a desired goal.

Conclusions

Results of our study suggest that people likely do have different motivations behind their use of digital media that may be reflected in their usage patterns. The significance of these different media usage patterns for the long-term outcomes of children and families is yet to be determined. It is possible, and in fact likely, that each pattern of media use may be considered adaptive in certain situations and maladaptive in others. By having a better understanding of why and how different families use media in their daily lives, pediatric care providers can provide more individualized anticipatory guidance regarding technology use by the whole family, including limit setting, use of media for calming, and how devices impact family dynamics. For example, by understanding that a parent is more prone to using mobile media to calm their child, a pediatrician might suggest that such a parent reflect on the frequency with which they use such calming techniques to ensure that they are also providing their child opportunities to practice frustration tolerance using techniques that go beyond distraction with media.

The research implications of our study may allow us to classify the media use patterns of families to better examine the long-term effects of media use on child health and development. Follow up studies could examine trajectories of profiles over childhood to determine their stability and how they relate to

XSL•FO
RenderX

child outcomes over time. Future research directions should also include nationally representative populations, objective device use data, or reports from multiple household members (eg, parents and children).

Acknowledgments

All phases of this study were supported by the National Institute of Child Health and Human Development grant (#1R21HD094051-01; Radesky, PI). The National Institute of Child Health and Human Development had no role in the design and conduct of the study.

Authors' Contributions

NH conceptualized and contributed to the design of the study, reviewed all data, participated in the statistical analysis, drafted the initial manuscript, and reviewed and revised the manuscript. JR was the primary investigator on the grant award for the original study, contributed to the conceptualization of the current study, advised on study design, reviewed data, participated in the statistical analysis, and reviewed and revised the manuscript. HMW advised on study design, conducted the statistical analysis, summarized the study data, developed related figures and tables, and contributed to, reviewed, and revised the manuscript. ALM advised on study design, reviewed data and outcomes, reviewed and revised the manuscript. NK advised on study design, directed and oversaw the statistical analysis, reviewed study data, and reviewed and revised the manuscript. All authors approved the final manuscript as submitted and agree to be accountable for all aspects of the work.

Conflicts of Interest

NH has ownership interest in Arbor Autism Centers LLC. In the past year, JR received fees from Melissa & Doug LLC and research funding from Common Sense Media. HMW reported receiving grants from the National Institute of Child Health and Human Development outside the submitted work. ALM reported receiving grants from the National Institutes of Health outside the submitted work. NK reported receiving grants from the National Institutes of Health outside the submitted work.

Abstract

Background: Smartwatch activity trackers are devices that measure physical activity levels with features that aim to encourage physically active behaviors. These devices have shown promise for increasing physical activity levels and reducing sedentary behaviors among school-aged children, adolescents, and adults. Recently, commercially available products have been adapted so that they are suitable for use by preschool-aged children. However, it is unclear whether the intended use of these devices is feasible and effective in young children.

Objective: The purpose of this study was to explore parents' perspectives on the use of smartwatch activity trackers by young children.

Methods: Semistructured interviews were conducted with 22 parents (17/22, 77% female) of children aged 3-5 years. Interviews explored perspectives on the feasibility of their children wearing the devices, implications of use by young children, and how families could make use of these devices to support their children's physically active behaviors. Interviews were audio-recorded, transcribed verbatim, and data analyzed using thematic analysis.

Results: Parents perceived that the use of these devices by young children is feasible, with developmental stage or abilities and personality or temperament being important individual determinants of feasibility. However, parents expressed concerns related to the devices providing extrinsic motivation to move, being disruptive or distracting, being a burden on parents, and for the safety and privacy of their child's information. Most parents believed that young children are inherently active and do not need devices to support physical activity. Furthermore, most parents expressed an interest in knowing how physically active their children were and thought that there may be a role for these devices for children who are less physically active.

Conclusions: Parents reported developmental stage or abilities and temperament as relevant considerations related to the feasibility of smartwatch activity tracker use by young children. Parents also indicated that there is a potential role for these devices in young, less active children.

Introduction

Higher levels of physical activity are associated with reduced adiposity and better cognitive and motor skill development, psychosocial health, bone and skeletal health, and cardiometabolic health in preschool children [1,2]. Furthermore, in this age group, participation in physical activity helps to offset the risks of excessive sedentary behavior, with higher levels of sitting associated with increased adiposity and reduced psychosocial health and cognitive development [3,4]. Establishing physically active behaviors at this age also influences engagement in physical activity throughout childhood, adolescence, and adulthood [5].

International health guidelines recommend that preschool children (aged 3 to 5 years) spend at least 180 minutes per day in a variety of physical activities at any intensity, of which, at least 60 minutes is moderate to vigorous physical activity [6,7]. In addition, replacing restrained sedentary behaviors and sedentary screen time with physical activity is suggested to provide additional health benefits [6,7]. Unfortunately, many preschool children in developed countries do not meet current physical activity recommendations [8-10] and spend significant proportions of their waking time sitting or inactive [10,11]. Therefore, a current public health priority is to develop intervention programs that aim to increase physical activity levels among young children, when these formative experiences can shape future behaviors.

Smartwatch activity trackers are wrist-worn devices that incorporate accelerometers to provide measures of physical activity such as the number of steps taken, distance travelled, time spent active or inactive, and the intensity of activity. This information is typically shared with the user via a small digital interface on the wearable device itself and additionally via synchronization to mobile or web-based apps that collect and summarize the physical activity data. These devices also include features that aim to encourage physically active behaviors and disrupt sedentary behaviors. For instance, users can set daily physical activity goals and receive notifications about their progress. These devices have been shown to provide valid and reliable estimates of physical activity in children [12]. They have also shown promise for increasing physical activity levels and reducing sedentary behaviors among school-aged children, adolescents, and adults [13,14]. Specifically, interventions that incorporate these activity trackers have shown small to moderate favorable effects on physical activity minutes per day, steps per day, and moderate to vigorous physical activity levels in children and adults [13-17]. However, it is unknown whether smartwatch activity trackers can have similarly favorable effects on physical activity in preschool children. In a recent systematic review, we showed that while the use of these devices may be feasible in preschool children, to date, no studies have evaluated their efficacy for increasing physical activity in this age group [18].

With the increase in commercially available smartwatch activity trackers designed for use in preschool-aged children, evidence is needed on the feasibility and efficacy of influencing the physical activity of young children. Given the important role parents would have in mediating the use of this technology by preschool children, this study aimed to explore parents' perspectives on the feasibility of young children wearing activity trackers, potential implications of young children using these devices, such as advantages, disadvantages, and unintended consequences of use, and possible roles for activity trackers in this age group.

Methods

The description of the methodology follows established Standards for Reporting Qualitative Research [19].

Study Design

This qualitative study used single time-point semistructured interviews, following an exploratory, cross-sectional, observational design [20]. An interpretive description approach was chosen, where the perceptions and experiences of the participants were explored by analyzing concepts, themes, and patterns in the interview data, with the view to generating practically useful outcomes [21]. This follows a constructivist or interpretivist paradigm, with our rationale being that the perspectives and experiences of our participants are necessary to meet our study aims. This approach may limit the transferability of our research findings to people in different contexts to those of the participants of this study.

Participants

The participants were parents or primary caregivers of children aged 3 to 5 years. Parents or primary caregivers were defined as the primary person providing support to the child over a long period of time and involved in daily care routines such as feeding, hygiene, play, sleep, or health. Participants were recruited through purposive and snowball sampling from existing networks of the Curtin Healthy Digital Child research team including the networks of their community advisory groups [22]. In addition, recruitment flyers were distributed nationally using the Australian Research Council Centre of Excellence for the Digital Child social media [23]. The recruitment material provided links to the participant information statement and consent form. Once informed consent was obtained, the participants were provided with a link to an online preinterview questionnaire (Qualtrics XM). Following this, the participants completed an interview either in person or online using videoconferencing technology.

Preinterview Questionnaire

The preinterview questionnaire (Multimedia Appendix 1) included questions on sociodemographic characteristics (eg, age of participant and age and sex of child, number of children, suburb of residence, occupation, and highest education level). This information was used to tailor each participant's semistructured interview and support data analysis.

Qualitative Semistructured Interview

The interviews followed a semistructured format guided by open-ended questions to allow parents to express a broad range of perspectives openly and honestly without their responses being directed by the question itself. The researcher (RJD) who conducted the interviews is the father of a preschool child with a background in health research and education. Although the

questions were designed to allow free expression, it is possible that these interviewer characteristics may have introduced biases or influenced the relationship with the participants through shared experiences. The interview questions related to the use of wrist-worn smartwatch activity trackers by 3- to 5-year-old children. In particular, the questions explored their perspectives on the feasibility of young children wearing these devices, the potential implications of young children using these devices, and the potential roles or applications for these devices in the lives of young children. The questions were developed by a multidisciplinary team of researchers in consultation with the Curtin Healthy Digital Child Parent and Professional Advisory Groups. Each question was mapped to at least one of the three themes directly aligned with the research aims: (1) feasibility, (2) implications of use, and (3) potential roles. The average duration of interviews was 33 (SD 8; range 20-53) minutes. Each interview was audio-recorded (with consent), and the recordings were professionally transcribed verbatim.

Feasibility has been defined as the extent to which the devices are suitable for the target population, can be successfully delivered to the target population, or show promise of being successful within the intended population [12]. Based on this definition, the following open-ended questions were posed to the participants to capture their perceptions of the feasibility of activity tracker use by young children: Does your child use an activity tracker? Do you think young children could use these devices? Do you see a role for activity trackers in your child's life?

Implications were broadly defined as any advantages, disadvantages, or unintended consequences of use that may or may not be related to the device's primary purpose of physical activity monitoring. The open-ended questions that were posed to the participants to capture their perceptions of the implications of activity tracker use by young children included the following: What issues do you think parents might raise? Can you think of any other considerations for young children using activity trackers?

Potential roles included any application for smartwatch activity trackers identified by the participants in either their child's life or the lives of other 3- to 5-year-old children. The open-ended questions that were posed to the participants to capture these potential roles included the following: Do you see a role for activity trackers in your child's life? Do you think parents have a good sense of how much physical activity their child does? Would you be interested to know?

Data Analysis

Data from the preinterview questionnaire were analyzed using descriptive statistics, reported as counts and percentages, to provide a summary of participants' characteristics. The audio recordings of the open-ended questions were transcribed verbatim, and transcriptions were then analyzed by inductive thematic analysis [24] using NVivo (Lumivero). Data collection and analysis were conducted simultaneously to allow the research team to respond to evolving study findings. This iterative process also allowed the research team to identify saturation of emergent themes [22], which informed the decision to stop recruitment and data collection naturally.

Ethical Considerations

This study was approved by the Curtin University Human Research Ethics Office (approval: HRE2023-0608). Prospective participants were provided with a detailed information sheet describing the purpose of the study; the benefits, risks, and expected outcomes of the study; and the research team. Following this, the participants provided informed consent before completing a questionnaire, and an interview was conducted either in person or using secure videoconferencing software. At the beginning of each interview, the participants were asked to provide verbal confirmation of their consent for the interview to be audio-recorded. The interview questions were not sensitive in nature and open-ended to allow free expression of perspectives. The participants were reminded that they were not obliged to answer the questions and that they could stop the interview at any stage. To ensure participant privacy, the data collected were either deidentified or coded and stored on secure Curtin University research drives, accessible by the research team only. The participants were not paid for their involvement in the study but were offered a US $32.7 gift card for their time.

Results

Participant Characteristics

The participant characteristics are presented in Table 1. In total, 22 parents aged 31 to 43 years (mean 36.5, SD 3.6 years) of children aged 3 to 5 years, inclusive (mean 4.3, SD 0.9 years) completed this study. This included 17 mothers and 5 fathers of 1 to 3 (mean 2.1, SD 0.6) children. The most common occupations were health professionals (5/22, 23%), academics (4/22, 18%), clerical and administrative workers (3/22, 14%), education professionals (3/22, 14%), and stay-at-home parents (3/22, 14%), with 18/22 (82%) who had completed tertiary education. Most participants lived in Western Australia (16/22, 73%), with others located in Victoria (3/22, 14%), New South Wales (2/22, 9%), and South Australia (1/22, 5%).

Feasibility

Overview

When parents considered the feasibility of smartwatch activity tracker use by young children, the following subthemes were identified: age and developmental abilities, personality and temperament, capacity for independent use, novelty and maintenance of use, and wearability. Supporting quotes for each of the subthemes are presented in Table 2.

XSL•FO
RenderX

Table 2. Parental perspectives on the feasibility of smartwatch activity tracker use by young children.

Subthemes	Supporting quotes
Age and developmental abilities (17/22, 77%)	• "I think there's a big difference between a three-year-old and a five-year-old" [Participant 2, mother of 3 children including a 3-year-old]. • "I think definitely a five-year-old would probably be more engaged and have more of an understanding of the device" [Participant 2, mother of 3 children including a 3-year-old]. • "... as a three-year-old, I just don't think that she would make the link yet" [Participant 2, mother of 3 children including a 3-year-old]. • "I think for [my 5-year-old child] I think she'd definitely be capable in appreciating—I guess engaging with it, and I think that she would interact with it and understand and equate the game with moving more. [My 3-year-old child] I'm not so sure about just because of his age. I don't think [my 3-year-old-child] would be at that level to make that connection" [Participant 3, father of 3 children including a 3-year-old and a 5-year-old].
Personality and temperament (16/22, 73%)	• "... it would depend on the child and what motivates them" [Participant 21, mother of 2 children including a 4-year-old]. • "... he has that kind of personality where he responds really well to challenges or to goals" [Participant 1, mother of 2 children including a 5-year-old]. • "I think for kids that are really rewards-focused or goal-oriented, it could be really valuable to them to motivate them to do a bit more" [Participant 1, mother of 2 children including a 5-year-old].
Capacity for independent use (21/22, 95%)	• "I feel like he would need quite a bit of help still ... I think at this age; you'd probably need to make good use of those incentives and those rewards and walk him through that. And then once he gets the hang of it, I think he'd probably be okay, but it would take a bit of work" [Participant 11, mother of a 3-year-old child]. • "I think it would be pretty led by the parents. I think they're probably still too young to do it independently, I would think" [Participant 7, mother of 2 children including a 5-year-old].
Novelty and maintenance of use (15/22, 68%)	• "... maybe initially they would find it really exciting and they would use it like a toy, and then I think the novelty would probably wear off if they weren't that engaged with it and it ... prompted them to do something and they didn't want to, it would become a chore and not a game anymore" [Participant 15, mother of 2 children including a 4-year-old]. • "I wonder whether the novelty of it would wear quickly, so I'm not sure how long-term it would make changes for either parents or as a family unit" [Participant 15, mother of 2 children including a 4-year-old].
Wearability (11/22, 50%)	• "I think the biggest thing would be keeping it on them and having them wear it all the time. Because even just getting her to keep shoes on can be a bit of a hassle, so I imagine something that's around her wrist, I think that she wouldn't necessarily want to keep on" [Participant 18, mother of 2 children including a 3-year-old]. • "I think that actually wearing it would be the biggest hurdle for her" [Participant 18, mother of 2 children including a 3-year-old]. • "... she might find wearing a watch to be uncomfortable or irritating" [Participant 2, mother of 3 children including a 3-year-old]. • "... going in the sandpit, sand caught under it, hot and sweaty in summer ... not tolerated from a sensory perspective" [Participant 2, mother of 3 children including a 3-year-old].

Subtheme: Age and Developmental Abilities

This subtheme relates to perspectives that 3 to 5 years is a developmentally diverse age range with children at different stages of cognitive development and having varied literacy, understanding of the purpose or intention of the device (including the rewards and prompts), and abilities to respond to it. Most parents (17/22, 77%) reported this as a key determinant of feasibility.

Subtheme: Personality and Temperament

This subtheme relates to perspectives that individual differences would influence the uptake and maintenance of use of these devices. Most parents (16/22, 73%) reported that these devices would suit children who are goal- or reward-focused, competitive, or compliant.

Subtheme: Capacity for Independent Use

This subtheme relates to perspectives on the capacity of children to use and engage with the device independently as intended, for example, receive and respond to information, purposefully aim to achieve movement goals, and understand and seek rewards. Almost all parents (21/22, 95%) expressed a view related to this subtheme, but their perspectives were mixed, with the child's age, abilities, and personality being key determinants of their capacity for independent use and their need for support.

Subtheme: Novelty and Maintenance of Use

Many parents (15/22, 68%) reported that novelty may encourage uptake and engagement by young children, but that the maintenance of use would be limited in this age range, as interest might diminish over time.

Subtheme: Wearability

Half of the parents (11/22, 50%) also indicated that issues related to wearability (eg, tolerance to wear and comfort) would impact the feasibility of use of these devices by their children.

XSL•FO
RenderX

Implications

Overview

When considering the implications of smartwatch activity tracker use by young children, the following subthemes were identified: the potential negative influence of extrinsically motivating physical activity, disrupting positive behaviors, the burden on parents, and the safety and privacy of information. Supporting quotes for each of the subthemes are presented in Table 3.

Table 3. Parental perspectives on potential implications of smartwatch activity tracker use by young children.

Subthemes	Supporting quotes
Extrinsically motivating physical activity (17/22, 77%)	• "... kids would then place emphasis on rewards for activity rather than just enjoying and initiating activity of their own accord" [Participant 14, mother of 2 children including a 5-year-old]. • "I think the games are a good motivator, but whether or not this is going to affect their overall intrinsic motivation for exercise in the long term, I'm not sure" [Participant 2, mother of 3 children including a 3-year-old]. • "I like the idea that it can help foster better physical activity, but I just wonder whether it comes at the expense of driving an implicit and internal motivation to engage in exercise, whether it's going to the playground for enjoyment, engaging with friends, playing sport" [Participant 3, father of 3 children including a 3-year-old and a 5-year-old]. • "I'd like them to engage in physical activity and exercise because they enjoy the activity, not because they're motivated by what's on their wrist" [Participant 3, father of 3 children including a 3-year-old and a 5-year-old].
Disrupting positive behaviors (16/22, 73%)	• "Will they stop what they are currently so intently focused on to do what this thing is telling them to do?" [Participant 13, mother of 2 children including a 3-year-old]. • "... these ones are very visible, so that sense of being almost a distraction at times, or intrusive to what's going on in the present" [Participant 6, father of 3 children including a 3-year-old and a 5-year-old]. • "I do have concerns about the interactive nature of it ... as much as they would use them, I wouldn't want them to overuse them" [Participant 12, mother of 3 children including a 3-year-old and a 4-year-old]. • "I do fear that it would be more a case of them sitting on the lounge looking at their watch, rather than actually getting up and doing stuff" [Participant 12, mother of 3 children including a 3-year-old and a 4-year-old].
The burden on parents (18/22, 82%)	• "... has the potential to just be another source of guilt that we're not doing enough as parents" [Participant 10, mother of 2 children including a 4-year-old]. • "... you're adding to parents' burden and that feeling that we're never doing enough" [Participant 12, mother of 3 children including a 3-year-old and a 4-year-old]. • "I think if the information goes to the parent or the parent is managing that feedback, it would be up to the parent to be careful in the way they—what they do with that information in relation to the child and how much information they want to share with their child especially if there's a need for improvement" [Participant 11, mother of a 3-year-old child].
Safety and privacy of information (14/22, 64%)	• "Can people find out where my child is or what they're doing?" [Participant 16, mother of 2 children including a 4-year-old]. • "... some parents would be concerned about the tracking of their children's movements and whether or not that could be hacked" [Participant 18, mother of 2 children including a 3-year-old]. • "I think maybe the privacy stuff around the data and how secure that is, and where it goes and what it's used for" [Participant 6, father of 3 children including a 3-year-old and a 5-year-old].

Subtheme: Extrinsically Motivating Physical Activity

This subtheme relates to perspectives that activity trackers are a source of extrinsic motivation (eg, rewarding achievement) that may displace children's intrinsic motivation to move simply for fun and enjoyment. Most parents (17/22, 77%) reported this implication of use.

Subtheme: Disrupting Positive Behaviors

This subtheme relates to perspectives that the device may be intrusive and disrupt children from positive behaviors including physical activity itself, as well as immersive, creative play, or rest. Most parents (16/22, 73%) reported this concern.

Subtheme: The Burden on Parents

Most parents (18/22, 82%) expressed the concern that the use of these devices by young children would impose a burden on parents because of their essential role in interpreting and delivering the information from the devices to their children, together with the guilt parents may feel when recommendations or goals are not met.

Subtheme: The Safety and Privacy of Information

Two-thirds of parents (14/22, 64%) indicated that safety and privacy of information is a concern, primarily related to the security of identifiable data and location information as well as the possibility of companies gathering information about children's behaviors and lives.

Potential Roles

Overview

When the possible roles for smartwatch activity trackers for young children were considered, the following subthemes were identified: a limited need for a device to encourage physical activity in young children because they are inherently active; benign activity tracking to measure, but not influence, physical activity levels to improve parents' awareness of their child's

XSL•FO
RenderX

physical activity behaviors; creating opportunities to discuss physical activity in a family setting; as a means to encourage physical activity in children who are less active, and as a supporting tool that is part of a broader program to increase physical activity levels in young children. Supporting quotes for each of the subthemes are presented in Table 4.

Table 4. Parental perspectives on the potential roles of smartwatch activity tracker use by young children.

Subthemes	Supporting quotes
Limited—young children are inherently active (20/22, 91%)	• "... she's motivated to move her body regardless of the activity tracker or not. I think intrinsically as a three-year-old, she does a lot of activity without even thinking about it or without even really knowing, comprehending what it is and what it means" [Participant 2, mother of 3 children including a 3-year-old]. • "... it wouldn't ever cross my mind that a typical preschooler would need one only because of how much my own child loves sport and movement already. It's hard to get him to rest" [Participant 11, mother of a 3-year-old child]. • "I'm not too concerned because I just have a general impression that she's busy and she's active and she's enthusiastic and she's happy to be active when we are. So, I'm not particularly worried" [Participant 5, mother of 3 children including a 3-year-old].
Increase awareness of physical activity levels (20/22, 91%)	• "I would be super interested to ... see how much he actually does" [Participant 1, mother of 2 children including a 5-year-old]. • "... it would be interesting ... to know how much (her child) is doing and when he's active, maybe the circumstances" [Participant 1, mother of 2 children including a 5-year-old]. • "Yeah, so it would be interesting to know how much she really is moving during the day" [Participant 14, mother of 2 children including a 5-year-old]. • "I would definitely be interested to know exactly how much physical activity she's doing and when, and then how that might potentially affect other things like sleep and things like that" [Participant 2, mother of 3 children including a 3-year-old].
Opportunities to discuss physical activity (13/22, 59%)	• "You can have little discussions with them about, what did you do today? Did you feel puffed afterwards? Was it fun?" [Participant 4, mother of 2 children including a 3-year-old]. • "How many steps have I done? And how many steps have you done? And what's yours saying? And what's mine saying?' So, that social element of it I think would bring more interest, rather than it being a personal thing" [Participant 6, father of 3 children including a 3-year-old and a 5-year-old].
Special circumstances (17/22, 77%)	• "I think that activity trackers could play a role for those sorts of kids who don't or don't have an interest in being active" [Participant 3, father of 3 children including a 3-year-old and a 5-year-old]. • "I mean, maybe if there was an obvious problem and the specific child didn't get enough physical activity, or they were really against going to the park and doing all those things" [Participant 2, mother of 3 children including a 3-year-old]. • "I think if I was worried that I had a really sedentary kid ..." [Participant 5, mother of 3 children including a 3-year-old]. • "I can imagine that if you lived in a flat or an apartment and you only had a very small space and not much access to outdoors, you might also be worried" [Participant 5, mother of 3 children including a 3-year-old]. • "I think there are plenty of situations where these trackers would be beneficial and would potentially help kids and families [without adequate] education, knowledge, and background [related to the benefits of physical activity to health]" [Participant 10, mother of 2 children including a 4-year-old].
Part of a broader program (10/22, 45%)	• "I can see that (it) would be another tool in their belt on how to help a family" [Participant 15, mother of 2 children including a 4-year-old]. • "I think it's probably best to have a range of approaches. So this could be one of a package of—if you're looking to increase activity in young children, have this as part of a broader package, not the only thing that we're relying on" [Participant 14, mother of 2 children including a 5-year-old].

Subtheme: Limited—Young Children Are Inherently Active

This subtheme relates to perspectives that there may not be a role for these devices in this age range because young children are naturally physically active without encouragement or support and parents are generally not concerned about their children's physical activity levels. Almost all parents (20/22, 91%) reported this view.

Subtheme: Increase Awareness of Physical Activity Levels

This subtheme relates to perspectives that there may be a role for these devices to support parents' awareness of their children's physical activity levels and the settings or circumstances that either facilitated or constrained this behavior. Almost all parents (20/22, 91%) reported that they would be interested in using these devices for this purpose.

Subtheme: Opportunities to Discuss Physical Activity

This subtheme relates to perspectives that the use of activity trackers may facilitate discussions about physical activity between parents and their children. Some parents (13/22, 59%)

XSL•FO
RenderX

indicated that there may be a role for activity trackers to prompt conversations about physical activity with their children to both encourage the behavior and educate their children on its benefits.

Subtheme: Special Circumstances

This subtheme relates to possible applications for activity trackers in circumstances where the ability or opportunity to participate in physical activity may be limited. Most parents (17/22, 77%) could see a potential benefit in instances where children are not getting enough physical activity due to health issues, a natural inclination to be physically inactive, or other family, social, or environmental factors.

Subtheme: Part of a Broader Program

Almost half of the parents (10/22, 45%) suggested that there may be an application for activity trackers as an adjunct or supporting strategy to encourage physical activity levels but not the sole strategy.

Discussion

Principal Findings

The purpose of this study was to explore parents' perspectives related to the feasibility, potential implications, and possible roles for smartwatch activity tracker use by young children. While the parents in this study perceived the use of smartwatch activity trackers by young children as feasible, the potential negative influence of extrinsic motivation to physical activity, disruption of positive behaviors, parental burden on parents to mediate the information from the device, and the safety and privacy of their child's information are important implications to consider. These implications, together with the pervasive view that young children are naturally physically active, could explain why these parents did not see a broad role for smartwatch activity trackers to promote physical activity in this age group. However, these parents indicated that there may be a role for the use of these devices to increase parents' awareness of their child's physical activity levels and patterns, to create opportunities to discuss physical activity, and in specific circumstances when children may not be getting enough physical activity for individual or family or social or environmental reasons.

Feasibility

The overarching view from parents was that the use of smartwatch activity trackers by young children is feasible. This view is supported by findings of recent systematic reviews that report 80% to 100% adherence to wear by young users (aged 3-7 years) as a proxy measure of feasibility [12,18]. However, parents reported that child characteristics related to their age, developmental abilities, and temperament, as well as the potential need for parental support to use the device and interpret its information, are likely to be key determinants of uptake and ongoing use by young children. Aligned with these perceptions is the observation that a sense of competence and self-efficacy are drivers of engagement in physical activity [25]. This could explain why individual factors that influence this sense of competence, including age or development or abilities and personality or temperament, are key in determining the feasibility of activity tracker use by young children. Smartwatch activity trackers incorporate behavior change techniques, including goal setting, action planning, and behavioral practice or rehearsal, which have been developed based on frameworks derived from theories of adolescent or adult motivation. Although such frameworks may not be the most relevant for young children, they have shown some promise in interventions to increase physical activity in children younger than 6 years of age [26]. However, the degree to which these devices influence a sense of competence and other key tenets of self-determination theory that support motivation for physical activity may depend on individual factors in addition to developmental stage [25]. For instance, goal setting and self-monitoring may support competence and self-efficacy in some children [27-29] but perhaps not in others who do not place as much value on goal achievement. Furthermore, parent involvement and support may be important for promoting relatedness, which also underpins intrinsic motivation for physical activity behaviors [27,30]. This may be particularly relevant for younger users who rely on the involvement of their parents.

Parents also indicated that the novelty of using an activity tracker may encourage uptake initially, but ongoing use may be limited in this age range. This view is consistent with findings in older children (aged 5 to 19 years), where adherence to wear declines after 2 to 4 weeks of use [31]. Poor maintenance of activity tracker use over time has also been reported in young children [18]. Furthermore, the view that comfort and wearability would also influence feasibility has been previously reported by parents of preschool children [32,33] and is corroborated by studies in young children [18] and older children (aged 5 to 19 years) [31,34]. This may be an important consideration for practical applications including intervention studies.

Implications

While parents in this study could see the positive intention of the devices to encourage or support physically active behaviors, they also raised some relevant considerations about this approach. These included that the device may be a source of extrinsic motivation for physical activity that could displace intrinsic desires to simply move and play for fun and enjoyment. Specifically, many devices include certain features designed to motivate movement (eg, prompts or reminders to move, daily physical activity goals with updates on progress, and rewards for achieving certain milestones or targets). In support of this implication raised by the parents, extrinsic rewards for completing tasks or activities have been shown to reduce subsequent intrinsic interest and motivation for these behaviors in young children [35,36]. Furthermore, intrinsic motivation has been shown to be the only type of motivation that is associated with physical activity behavior in children, and it has been recommended that interventions to increase physical activity in children should aim to optimize enjoyment and inherent satisfaction in being active rather than relying on forms of extrinsic motivation [37]. Thus, the extrinsic motivation theory basis for activity trackers may not be appropriate for young children. Additionally, the potential for the feedback from the device to be misinterpreted or create feelings of

XSL•FO
RenderX

pressure to achieve physical activity goals or guilt associated with not meeting goals has been reported in school-aged children and adolescents [38]. Relatedly, some parents indicated that how the information from the activity trackers was interpreted by young children has the potential to shape their involvement in physical activity (eg, children interpret low numbers or missed goals as failures, not being good enough, or being naughty). However, the potential negative effect of smartwatch activity trackers on intrinsic motivation to be active and feelings of pressure or guilt associated with meeting goals have not been specifically investigated in young children.

Parents also indicated that the devices could disrupt or distract positive behaviors, with the potential to interrupt learning or immersive play. This perception may be related to the importance that parents place on opportunities for immersive, enriching play that contributes to learning, socialization, and emotional and physical development [39,40]. It may also reflect parents' reluctance to overuse technology. It has been reported that parents have mixed perceptions of young children engaging with digital technologies with both perceived benefits (eg, supporting learning and education) and risks (eg, detrimental to cognitive and social development) [41]. It is possible that parents may be reluctant to use these devices if they do not perceive a clear benefit to their use. This possibility is supported by the parents' view that young children are naturally active and do not need a device to support physical activity behaviors.

Another commonly reported implication was that the information provided by the devices is a potential burden on parents since they see the mediation and messaging of this information as their responsibility, and this information may also be a source of guilt for parents in instances where their child's physical activity targets or recommendations are not met. Parents believe that in younger users, they would play a key role in interpreting and delivering feedback to the child and that they have a responsibility to deliver this information in a manner that is positive and encouraging. Some parents suggested that the opportunity for parents to present the feedback positively (eg, "let's go outside for a walk") or negatively (eg, "you have not met your goals, you need to do more") would influence the child's engagement in physical activity. Given that parents are integral to shaping early childhood physical activity behaviors [42], how parents respond to and deliver this information to their child has the potential to affect the child's sense of achievement, self-worth, and relationship with physical activity. Activity tracker use could therefore have unintended consequences if parental framing of the information provided is not helpful. When reflecting on the intention of the smartwatch activity trackers to promote physical activity, some parents indicated that they see this as their role through modeling, providing opportunities, and expressing family values. This perspective is supported by studies that show strong associations between parental support of physical activity and their child's participation in physical activity [43,44]. Parents believe that this role is particularly important in this age range, given the limited autonomy of young children (eg, ability to control their environment). In agreement with this view is the observation that the relationship between physical activity levels of parents and their children is strongest when their children are preschool-aged [45].

Potential Roles

The perception by parents that young children are naturally active is consistent with previous findings and could explain why parents in this and other studies have reported that their children are sufficiently active, and they are not concerned about their children's physical activity levels [33,46-49]. However, this view is not supported by population studies that show that many preschool children in developed countries do not meet current physical activity guidelines [8-10]. It is possible that parents overestimate the physical activity levels of their children compared to objective measures of physical activity, which has been reported in parents of less active children [49,50]. However, it has also been reported that while young children are perceived to be sufficiently active overall, their levels of moderate to vigorous physical activity may be low [48]. This observation is consistent with objectively measured physical activity levels in preschool children [51]. In this study, all children aged 3 to 5 years met the recommended 180 minutes per day of total daily physical activity, but only one-third of children met the 60 minutes per day of energetic play component of the guideline [51]. This could explain the incongruence between parents' perceptions of their children's physical activity levels and population data and suggests that strategies to support young children to achieve 60 minutes of energetic play per day are needed. While there may be a role for smartwatch activity trackers to support this goal, this remains to be investigated.

Despite the view that young children do not need a device to support their engagement in physical activity, many parents indicated that they would be interested to know how and when their children were physically active and that there may be a role for smartwatch activity trackers to increase their awareness of their children's physical activity. This awareness of their child's physical activity could inform decisions about their child's physical activity as well as challenge the perception that increasing physical activity requires significant effort and instead can occur with small changes with little or no preparation. Thus, there could be a role for smartwatch activity tracker use in changing attitudes toward physical activity and helping to identify opportunities for increasing physical activity [52]. However, as discussed previously, some parents indicated that how the information was received by parents and delivered to children would shape the potential benefit of this opportunity. Furthermore, some parents indicated that there may be a role for smartwatch activity trackers to prompt conversations about physical activity with their children to both encourage the behavior and educate their children on the benefits of this behavior. In support of this view, it has been reported that short-term use of smartwatch activity trackers in families of preschool-aged children may encourage physical activity by prompting discussions about physical activity [52].

The perspective of most parents that the use of these devices may be beneficial for increasing physical activity levels in physically inactive children is supported by previous findings in school-aged children where programs that incorporated wearable activity trackers were more effective in inactive

XSL•FO
RenderX

children [13]. Some parents indicated that smartwatch activity trackers may have a role as a supplementary tool in a toolkit of resources that encourage physical activity or address inactivity in children. These parents suggested that smartwatch activity trackers could be used as an adjunct or supporting strategy to encourage physical activity but not the only strategy. This may reflect the importance of mediating how the information the devices capture is received and interpreted by the children. Programs that incorporate wearable activity trackers in school-aged children have been shown to have a greater effect on physical activity when complementary strategies are used [13].

Limitations

The participants included a high representation of well-educated parents in health and education professions located in Australia (primarily Western Australia) with access to parks and gardens, low-density living, and a favorable climate for engaging in outdoor physical activities. For these reasons, the perspectives reported in this study may not be transferable to other socioeconomic and geographical contexts.

Conclusions

For most parents, the potentially negative implications of the use of these devices, together with the pervasive view that most young children are inherently physically active, meant that they see a limited role for the use of smartwatch activity trackers for supporting physically active behaviors in active young children. However, parents indicated that there may be a role for these devices to increase awareness of and promote discussions about physical activity, as well as encourage physical activity in children who are less active.

Acknowledgments

This project was partly funded by a Curtin School of Allied Health 2023 Teaching and Research Grant (A0000001575) and the ARC Centre of Excellence for the Digital Child.

Abstract

Background: It is challenging to recruit vulnerable populations such as pregnant individuals, particularly during the perinatal period, which involves significant life changes and stressful situations that may create barriers to participation. Barriers to participation are even more prominent in historically marginalized populations, such as minoritized and low-income populations. Current literature is limited on recruitment methods, and specific activities may be best to recruit diverse pregnant individuals into online studies for the promotion of perinatal mental health.

Objective: The aim of this paper is to describe recruitment methods and strategies used to recruit a large sample (n=1953) of diverse pregnant individuals to an online nationwide large-scale randomized controlled trial, the Mamma Mia Study.

Methods: The Mamma Mia study is a multisite randomized controlled trial of an online- and mobile-based intervention for preventing and reducing perinatal depressive symptoms, based in the United States. The study intended to ensure a diverse national representation in the study population, with internal team demographic goals of at least 50% of participants identifying as a race or ethnicity other than White and at least 25% low-income (defined as a household income of less than US $50,000). Institutional review board–approved active and passive recruitment methods, both online nationally and in-person locally, were used to recruit eligible pregnant individuals.

Results: Combining local and in-person with national and online recruitment methods allowed for successful recruitment of a large and diverse sample of pregnant individuals, despite the necessity for several pivots due to national events (eg, the COVID-19 pandemic). In addition, this layered approach allowed the study to continue during an unplanned world event and be responsive to pivoting to meet recruitment goals. Recruitment approaches and methods that were the most successful were establishing community partnerships both online nationally and in-person locally, dedicated research time to focus on recruiting historically marginalized groups for a more representative sample, allocation of study time and resources to recruitment preparation, and dedicated internal research team recruitment planning and tracking.

Conclusions: Researchers should continue to publish and disseminate specific details about recruitment efforts and results, highlighting both aspects of success and lessons learned, as well as the pivot points in their recruitment methods for shared learning.

Introduction

Studies that promote mental health and well-being in pregnant populations are often statistically underpowered due to small sample sizes that fail to meet recruitment goals [1-3]. It is challenging to recruit vulnerable populations such as pregnant women, particularly during the perinatal period, which involves significant life changes and stressful situations that create barriers to participation [1]. Barriers to participation are even more prominent in historically marginalized populations, such as minoritized and low-income populations [4,5]. Low

XSL•FO
RenderX

recruitment rates in these groups are commonly associated with reported issues such as access to research sites due to location, time commitment required, hesitancy due to lack of trust and knowledge in the research process due to misinformation, and concerns for privacy and confidentiality [1-4]. Other extenuating circumstances, such as time of year (eg, holidays) and world events (eg, COVID-19 pandemic), can intensify these challenges to an even greater extent. Participation of underrepresented groups in perinatal mental health research is necessary to understand and mitigate health disparities and to have findings that are generalizable to the population at large [4]. Research teams must be strategic about their study design and recruitment methodologies to ensure an adequate and representative sample of pregnant individuals is obtained.

Conducting online and mobile-based interventions that promote mental health and well-being for pregnant women during pregnancy and postpartum may be a way to decrease barriers to participation associated with in-person research [2]. The use of digitally delivered mental health programs reduces participation barriers related to travel costs, access, time, and the potential health risks of the public [2]. However, online and mobile-based studies with pregnant populations still struggle to be representative of historically marginalized groups [6,7]. A commonly used recruitment method, in general, is face-to-face in-person local recruitment that uses recruitment methods such as printed recruitment materials (eg, flyers, brochures, and postcards) that can be used both actively (eg, flyer handed to potential participant) and passively (eg, potential participant sees a posted flyer) [1-9]. Online recruitment is another recruitment method that has been increasing in popularity due to digital advancements. Online recruitment methods commonly used to recruit study participants, including pregnant individuals, are digital flyer postings through social media, email, and digital newsletters. These online methods promote greater reach and dissemination of the study participation opportunity [2]. Preliminary studies suggest online recruitment methods may help researchers successfully reach pregnant women [2], but there are still challenges to recruiting individuals who are traditionally underrepresented in research, such as historically marginalized populations by race, ethnicity, income, geolocation, and education [6,7].

It is unclear what general recruitment methods (ie, in-person, online, active, and passive) and associated specific recruitment methods for each strategy are best to recruit diverse groups of pregnant people into online studies for the promotion of perinatal mental health. It is timely and important for researchers to share with each other best practices for ensuring appropriate recruitment of diverse pregnant individuals. Transparency about challenges and opportunities is critical, whereby researchers can share their experiences and lessons learned to better equip future research with the strategies and tools needed to conduct studies with samples of participants that are representative of the target population effectively and credibly. Therefore, the purpose of this paper is to describe recruitment methods and strategies used to recruit a large sample of diverse pregnant individuals to an online nationwide large-scale randomized controlled trial (RCT). We explore methods and strategies used for recruitment and the successes and failures of these over the course of 4 years.

Methods

Study Design

The Mamma Mia study is a multisite randomized controlled trial of an online- and mobile-based intervention for preventing and reducing perinatal depressive symptoms that was conducted in the United States. The Mamma Mia study protocol and methods were published elsewhere [10]

Participant recruitment for the Mamma Mia Study occurred in the United States and used nationwide and local recruitment efforts. Local recruitment occurred at 2 geographical hubs: the central east coast region of the United States (East Central [EC] hub in Richmond, Virginia, led by study authors affiliated with Virginia Commonwealth University) and the southwestern region of the United States (Southwest hub, led by study authors affiliated with Arizona State University).

The study intended to ensure a diverse representation in the study population, with internal team demographic goals of at least 50% of participants who identified as Black or African American, Asian or Pacific Islander, Native American or Alaska Native, other or 2 or more races, or Latino or Hispanic and at least 25% low-income (as defined as a household income of less than US $50,000). Local active and passive recruitment was used to complement national recruitment efforts, given that online recruitment can have varying success in reaching individuals from historically marginalized populations [11,12]. We sought to recruit 1950 pregnant individuals who were: (1) less than 25 weeks gestation, (2) at least 18 years of age, (3) able to speak, read, and understand English as the intervention was available in English, and (4) had the ability to access an internet- or mobile-based program (via computer, tablet, or smartphone), and had access to a phone number and email address for study-related and safety protocol–related check-ins. All data collection occurred via digital platforms (eg, REDCap; Research Electronic Data Capture) via participant self-report survey, including the data about demographic questions (eg, race, ethnicity, income, and geolocation) and recruitment method (eg, “How did you hear about this study?”).

Recruitment Plan

This study was designed to integrate nationwide online recruitment alongside local passive and active recruitment at both the EC Hub and Southwest Hub. Based on our team’s experience with previous studies [13-16] in combination with extant literature [17,18], we expected that online recruitment may not accurately represent the diverse pregnant populations in the United States. Therefore, the recruitment plan for this study was intentionally designed to incorporate passive and active recruitment at local hubs in a layered recruitment plan.

In this study, we conceptualized “community” and “partnerships” as layered and dynamic, extending beyond formal health care and research settings. Consistent with frameworks for authentic community engagement [19], we understood “community” to include formal organizations (eg, Women Infants and Children clinics, community health resource centers,

XSL•FO
RenderX

Birth in Color) as well as informal networks (eg, community health workers, peer advocates) embedded within the lived realities of pregnant individuals, particularly those from historically marginalized groups. "Partnerships" were not limited to advisory or consultative relationships; rather, they reflected shared efforts to co-develop culturally relevant recruitment strategies, build trust, and foster mutual investment in the study's goals. By adopting this layered and relational approach, we sought to create a more inclusive, trust-centered recruitment model, better positioned to reach diverse pregnant populations across geographic regions.

Recruitment Preparation

Recruitment preparation included: (1) developing a recruitment plan and strategy, (2) building credibility and trust with an online presence, and (3) a recruitment tracking plan. Recruitment methods in our recruitment plan included where recruitment should take place (eg, online, in-person, and specific locations), who might have access to the target population (community partners), contact strategies for potential partners (email, phone, and social media), and developing recruitment materials (eg, flyers and recruitment scripts for both in-person and online communication). Community partner outreach and support included connecting with potential online community partners who would be willing to share about the study via their own established online platforms (eg, listserv emails and social media postings). Other recruitment preparation methods included developing a study website and developing social media accounts. These study-specific websites and accounts were used as landing pages to build credibility and trust with an online presence. Recruitment tracking was set up using the data collection tool REDCap, a secure web-based data collection and management system. Our recruitment tracking collected data related to the type of recruitment method each enrolled participant endorsed (eg, how did you hear about this study) in addition to tracking data about the type of recruitment material (eg, which flyer) was used throughout the recruitment period.

Recruitment Methods

Internal Team Recruitment Strategies and Tracking

Internal team strategies for planning and tracking recruitment methods used included weekly team meetings for brainstorming, planning, and goal setting, as well as constant consideration of feedback from the community. Additional internal team methods included internal team accountability, such as weekly and monthly data updates to monitor progress and recruitment tracking (inclusive of our internal diversity benchmarks, how participants heard about the study, etc). Study team members also attended webinars and training focused on health equity and social justice to be able to design recruitment strategies and material most appropriate for collaborating with community partners and recruiting our target demographics.

Study Eligibility and Intake Procedures

An essential aspect of data integrity for studies that use online recruitment methods is data integrity and sample validity by ensuring that enrolled study participants are a potential human research participant (eg, not a bot) and they are accurately representing themselves during the enrollment screening process [8,20]. Therefore, we implemented the following layered strategies. First, we posted the link to our study-specific website (rather than the direct survey link) in public open forum online spaces. Second, we activated a reCAPTCHA (Completely Automated Public Turing test to tell Computers and Humans Apart) tool on the eligibility screening form on REDCap. Third, we required an enrollment phone call during which the research team reviewed the consent form and had participants verify several free-text items from the enrollment form, including where they heard about the study. This allowed us to track our recruitment efforts, including snowball recruitment. Fourth, we cross-referenced each new enrollment participant's email address with our recent enrolled database to screen for multiple concurrent enrollments by the same individual.

Ethical Considerations

This study, including all recruitment materials and study plans, was approved by the Virginia Commonwealth University Institutional Review Board (IRB; HM20017197), with reliance on the VCU IRB by the Arizona State University IRB. All participants provided electronic consent prior to participating in the study. To protect privacy and confidentiality, all data collected were deidentified, with personal information securely stored and accessible only to authorized personnel. Financial compensation was offered to all study participants (up to US $140 in gift cards) and provided for each study task (eg, survey completion).

Results

Overview

Our final sample consisted of n=1953 participants. The study sample included participants who self-identified as African American or Black (367/1953, 18.8%), Asian or Pacific Islander (95/1953, 4.9%), Native American or Alaska Native (14/1953, 0.7%), White (1255/1953, 64.3%), Other (61/1953, 3.1%), and Latino or Hispanic (158/1953, 8.1%). In addition, this sample consisted of at least one participant from each of the 50 states and the District of Columbia, and participants were distributed across the nation with regional representation as follows: 17% from the Northeast, 20.6% from the Midwest, 38.9% from the South, and 23.6% from the West. The majority of participants were recruited from Virginia (611/1953, 31.3%), California (132/1953, 6.8%), North Carolina (86/1953, 4.4%), Texas (74/1953, 3.8%), and New York (71/1953, 3.6%). Our sample is comparable to the US Census population data of women of reproductive age (15-44 years) as of July 2023 (13.4% Black or African American, 6.8% Asian or Pacific Islander, 1.2% Native American or Alaska Native, 51.8% White, 13.7% two or more races, and 22.2% Latino or Hispanic) [21].

As mentioned previously, the team identified internal benchmarks for race, ethnicity, and income to track as a metric of study sample diversity. In addition, the team tracked how many participants heard about the study from each recruitment method (see Table 1): online and national recruitment (including social media posts and email blasts from community partner organizations), in-person local recruitment (including active and passive recruitment methods surrounding each regional hub), and snowball recruitment (including participants that

XSL•FO
RenderX

actively spread the word to their connections regarding the study).

Our team began recruitment on October 15, 2020 (Y 1 Q3) and ended on September 1, 2023 (Y 4 Q2). Figure 1 depicts overall recruitment data for this RCT, along with world events and pivots during recruitment, and benchmark details by year/quarter.

World Event

Of note, this study launched in the Spring of 2020, which co-occurred with the major world event of the SARS-CoV-2 (COVID-19) pandemic; this is noted as "World Event" in Figure 1. As such, no direct in-person recruitment was possible in local clinics and community events. However, because our recruitment plan included a dual approach of online and in-person recruitment, the study was able to continue operating when many research studies had to completely suspend operation.

Pivots in Recruitment Approaches

Pivot 1: After deploying online recruitment methods (eg, social media) that yielded high recruitment and enrollment numbers initially, we noticed a majority of these participants identified as White and reported higher income brackets. The team had originally planned to integrate in-person recruitment at each of our local hubs to account for this potential issue; however, due to pandemic-related restrictions, that was not possible. To be able to reach our diversity goals, as a team, we enacted Pivot 1. In this pivot, we aimed to focus our online recruitment efforts on potential participants who identified as a person of color by (1) connecting with online community partners on social media who specifically focused their content on pregnant individuals identifying as people of color, (2) updating our recruitment materials and images, and (3) adding language adjustments to our recruitment materials and study website specifically highlighting the study's goal of including pregnant individuals identifying as people of color.

Pivot 2: As pandemic-related restrictions shifted, our team enacted Pivot 2. In this pivot, we allocated intentional time and efforts toward in-person recruitment at both local hubs in addition to continued online and national efforts. Continuing the focus to recruit a diverse and representative sample, we intentionally focused on posting recruitment materials and attending in-person events in a variety of community-based locations. For example, our study teams attended community events such as powwows for local indigenous tribes in rural areas of Virginia and multicultural festivals in several urban areas in central Virginia. We also collaborated with our local community partners who held community baby showers and other celebratory events for the pregnant and postpartum community in Virginia (eg, Black Maternal Mental Health Week). We activated our professional and clinical network to engage in active recruitment through presence at our academic clinical partner sites. Specific to our academic clinical partner site, we obtained a waiver of consent through the IRB for prescreening of medical records. In this prescreening process, no data was recorded about potential participants. This process allowed team members to actively engage with potential participants who met the team's internal benchmarks for race, ethnicity, and income.

Also, during this pivot, we mentioned that participants were welcome to share about the study with their communities or other pregnant individuals during the enrollment phone call. This was an organic process that arose after several participants asked permission to share with friends or family, or even via private social media groups (eg, Reddit). At the time of Pivot 2, we intentionally integrated this discussion into the enrollment call script with every newly enrolled participant with a simple offering of, "Also, you are welcome to share about this study with anyone else who may want to hear about it. You can share our website or are welcome to give them my (the research coordinator's) contact info if they would like additional information." Having an easily shareable study-specific website

XSL•FO
RenderX

that served as a direct way to share the study was critical to this process.

Pivot 3: Throughout the study, our team tracked enrollment by state, given an internal team goal to have representation across the nation. As our team neared our goal completion date for recruitment, we completed a final overall review of our study enrollment progress to date and noticed that we had minimal representation from the Midwest region of the United States. As such, we engaged with an online community partner who had tailored social media content for pregnant women in the Midwest to share study recruitment materials. In addition, to meet total enrollment goals, we re-engaged with study partners about re-sharing recruitment materials.

Discussion

Overview

The purpose of this paper was to describe recruitment methods and strategies used to recruit a large sample (n=1953) of diverse pregnant individuals to an online nationwide large-scale RCT. The intent of sharing these details is to inform other research studies intending to conduct similar large-scale online studies. The study was successful in meeting total enrollment goals and partially successful in meeting goals of enrolling participants identifying as Black or African American, Asian or Pacific Islander, Native American or Alaska Native, other or two or more races, or Latino or Hispanic, and low-income. We discuss our experiences and future considerations for researchers below.

A combination of in-person and local, online and national, and passive and active recruitment, combined with internal team recruitment planning and tracking strategies, helped us reach our recruitment goals in a timely manner. The most successful recruitment methods were: (1) establishing community partnerships both in-person locally and online nationwide, (2) ensuring team-wide dedication to recruiting individuals from historically marginalized groups, and (3) maintaining a nimble internal team approach. Recruitment approaches that did not yield many participants included mailed postcards, newsletters, and "boosted" posts on Facebook (Meta Inc) and Instagram (Meta Inc). In line with extant literature, mailed postcards and newsletters often result in low response rates (typically <10%) and overrepresent older, White, and more educated populations compared to more active approaches [22]. Similarly, "boosted" social media posts may yield high traffic but produce lower eligibility and completion rates [23,24].

We established community partnerships by engaging with physicians and perinatal-focused organizations in person and by working with individuals and organizations online nationally who had large followings and were willing to share information about our study. Given our experiences and the extant literature, we believe that research teams should strive for sustained, bi-directional engagement when building relationships with community partners both in person and online; intentionally focusing on relationships based on aligned missions that can grow toward true engagement and collaboration through a program of research rather than a one-time recruitment engagement. We ensured team-wide dedication to recruitment goals through internal team recruitment strategies, including (1) intentional dedication to recruiting diverse participants, (2) recruitment preparation through website and social media development, (3) online and social media community partner feedback collaborations, and (4) remaining flexible and open to pivoting recruitment efforts and goals based on recruitment performance and community feedback.

In-Person and Local Recruitment

In-Person and Local Methods

In-person and local recruitment methods included building collaborations with community partners such as practitioners (eg, clinic partnerships), researchers (eg, other research teams working with perinatal populations), businesses or individuals (eg, local and regional organizations or members focused on perinatal health), events, and mailed postcards. For community partners who were a part of the study team, financial compensation was provided for their time and efforts. Although funding was not available for every community partner, some other ideas for extending gratitude to community partners who were interested included adding their logo on the study website with a clickable link; the research team collaborating to create educational content to be shared through the organization (eg, website, blog, and social media); and sharing the community partner's content or social media posts as mutually agreed upon and appropriate by both the study team and the community partner.

The use of purposeful in-person recruitment allows for focused recruitment of diverse populations in the community via community partnerships and professional networks. In-person methods that were most successful included the presence of research personnel in community and clinical settings commonly attended by pregnant individuals. Our research team established new relationships and expanded existing relationships with local primary care and obstetric clinics and organizations (eg, Women Infants and Children Program, Birth in Color RVA, Postpartum Support Virginia, Urban Baby Beginnings, Huddle Up Moms). These methods are consistent with previous literature suggesting that obstetrician and midwife support is essential for introducing patients to research studies for patients to feel comfortable participating in clinical research while pregnant [25]. When applicable, research team presence in clinic settings and taking the time to meet with clinic professionals to present study methods and answer questions gave our team the opportunity to be fully integrated in prenatal clinical settings.

Most importantly, this study included collaboration with a local community partner as a part of the research team, and this community partnership was an essential part of recruitment planning, recruitment material development, and community engagement planning at the local EC hub. For example, our primary community partner, "Birth in Color," provides a myriad of services to pregnant women of color—from community baby showers, to parenting classes, to prenatal yoga, including events held in public housing communities. In addition, the study team sought additional community partner relationships with organizations serving pregnant women at the local level, developing relationships for bidirectional support, including supporting community events with volunteers. Research team

XSL•FO
RenderX

members' presence alongside community partners in community spaces is a first step toward community engagement and collaboration to develop research that is integrated into the community. In this way, research teams can include individuals who may not have been included in research through more typical clinical avenues; team members can answer questions in real-time and build relationships with potential participants [25].

Online and National Recruitment

Online national recruitment methods included engaging with community partners online to build relationships, credibility, and trust with influencers and leaders of online communities that engage with diverse pregnant individuals in the United States. Online community partners included nonprofit organizations that shared our recruitment materials via their email listservs or websites and social media sharing by individuals or groups with large followings on various social media platforms. Additional recruitment strategies included paying for advertisements and "boosted" posts, as well as creating a study website for interested individuals to access information about the study and engage in enrollment activities. The study website included research team and study funding transparency, study coordinator contact information for questions, and information about community partners to support credibility and trust.

The greatest benefit of online recruitment methods we observed was being able to connect with community partners who treat, advocate for, or serve the target population nationwide. These methods allowed us to reach diverse populations and increase the generalizability of research findings. Online community partner outreach and support can begin during the project planning phase, grant development phase, and during the IRB approval stage. Preparation support includes letters of support or verbal (eg, email) agreement and receiving feedback on recruitment language and images and referrals to other potential community partners. Asking community partners to follow the study's social media accounts can be a first step to begin establishing rapport in the community the research is targeting. Once community partners agree to collaborate, logos made clickable to partners' websites or social media accounts can be uploaded to the study website. Securing online relationships with community partners is important for trust and credibility to be felt by the potential participant [21]. For example, multiple participants communicated they had signed up for our study because a trusted health care provider or public figure had shared the Mamma Mia study on their social media account. Our study website and social media presence allowed the community partners to direct potential participants to places online where they could learn more about the study, find contact information to ask questions, and see other community partners and followers who support the research. Researchers should consider following credible individuals in their field of study on their study social media accounts and ask community partners to follow the account back, effectively creating a well-integrated online community. Of note, some larger, national groups and organizations as well as nonprofits that serve both pregnant individuals and underserved groups were less likely to share via online platforms than smaller regional or local groups for a myriad of reasons; for example, some had multiple other concurrent social media campaign priorities or other research they were supporting, while others had a mission that did not align with the current recruitment goals, and some never responded or stopped responding to our outreach. Research teams may consider this when planning for engaging with online and social-media partners, as local and regional organizations with an online presence may be more impactful for study recruitment purposes.

The use of the internet for both recruitment of study participants and tracking recruitment efforts can be a cost-effective and high-yield strategy [2,8,20,26]. More specifically, the use of social media, email list-servs, websites, and online data collection tools can be highly effective online recruitment methods [8,20]. However, the technology literacy of team members and partners can impact the success of these strategies. Study teams who use online and digital recruitment strategies must be educated on social marketing and how a social media platform works (eg, how the algorithm works), how to best communicate with potential partners via email versus direct messages on social media, how to design and manage a website, and how to track recruitment efforts digitally for insight into what is working and what is not. Researchers should be aware of the level of experience and technology literacy of their teams and consider training team members in online strategies before study recruitment begins, even if they are experienced in study recruitment. Further, if the target population of a research study is historically marginalized populations, it is critical to ensure teams are trained in health equity and social justice concepts before starting recruitment activities. This training is essential for all health research professionals.

Partnering with individuals and organizations who already have established large followings can help spread the word about the study opportunity to a greater degree, effectively reaching the target potential participant population much more effectively than sharing via the research-specific accounts. In addition, when working with pregnant individuals, it is important to acknowledge that many participants wanted to share with others in their own communities about the research participation opportunity, leading to a snowball recruitment effect. Having relationships with community partners nationwide can increase recruitment reach, leading to more diverse samples that are more representative of the general population.

Recruitment Materials

IRB-approved recruitment materials were used for both in-person and online recruitment, as well as for our active and passive recruitment methods. Recruitment materials included, but were not limited to, flyers, brochures, email scripts, images optimized for digital use, short videos, and social media post-scripts. Graphic design software was used to create study flyers, brochures, and digital graphics. All recruitment materials included inclusive images intended to reflect the many types of pregnant individuals. All recruitment materials, including emails without images, presented appropriate IRB-approved wording that had been cocreated with a consulting community partner. Recruitment materials were then updated and improved based

XSL•FO
RenderX

on feedback from community partners, participants, and potential participants.

Recruitment material design and recruitment language are essential to successful study enrollment. The content of both paper and online recruitment materials must be professional, eye-catching, and well-received by the intended population [2]. Research teams should also be flexible when working with social media partners and consider methods to effectively and efficiently meet the needs of both the partners and the IRB to streamline this process. For example, simple techniques such as flexibility around the color scheme of the digital graphic used can be impactful, allowing the social media partner to keep their posts "on brand." Researchers should seek feedback from their community partners during the design phase of recruitment materials.

Collaboration with community partners should occur regarding the recruitment flyers and digital graphics, email and social media wording used, as well as the design and information on a study's website. For example, we collaborated with the community partner on our team to develop study recruitment materials and integrated their valuable feedback before launching study recruitment. This is particularly important when recruiting vulnerable and historically marginalized populations. Researchers must acknowledge historical exclusion and well-earned mistrust by medical and research communities and move toward language and images in recruitment materials that are intentionally inclusive [27]. Researchers should make sure that all study materials appropriately disclose the study purpose, personnel, and funding to support transparency and trust between the researchers and potential participants, and they should be open to constructive feedback from the community.

Internal Team Support

Study recruitment cannot be successful without internal team strategies that emphasize training and accountability [28]. Researchers should consider frequent team meetings that include planning and goal-setting that align with the study timeline, recruitment data reporting based on goals, accountability for meeting goals, and being open and flexible to pivoting recruitment strategies as needed. Our internal team strategies are consistent with the literature that demonstrates recruiting historically marginalized pregnant women is most successful when studies combine in-person and remote recruitment with internal team coordination methods [17,18]. Recruitment management that includes preparation, training, and tracking will also ensure that various strategies are being used correctly and are providing the results intended. Insights from those who have recruited participants during pregnancy underscore that training in recruitment strategies can reduce gatekeeping and enable flexible adaptation [29].

Recruitment Cost

Community partners often prefer and sometimes require financial support for their efforts. Although in-person recruitment has been found to be less cost-effective than online methods [2,30], we found that the typical cost for social media partners to advertise about the study through a website, social media post, or series ranged from US $150-US $7000. Studies planning to incorporate online advertising as part of their recruitment strategies should plan for this expenditure in the budget planning phase. Because this type of recruitment funding is often limited or not included in grant proposals at all, other forms of compensation should also be considered. For example, potential partners may find it valuable if direct links to their website or social media accounts are included on the study website; partners may also appreciate having their information shared with study participants through newsletters, blogs, and study landing pages. These strategies may allow researchers to reciprocate support with partners despite limited funding. We recommend that researchers plan ahead for and justify these costs for recruitment preparation time, active efforts, and costs in grant proposals.

Protecting Data Integrity and Sample Validity

Ensuring sample validity, and therefore protecting data integrity, is of paramount concern for online studies using online recruitment strategies. Online studies should have systems in place to detect both robotic or spam involvement as well as deceptive enrollment (eg, human participants who do not meet the study enrollment criteria that may use deception in eligibility screening in order to participate in the study). In this study, useful strategies included sharing a study-specific website rather than the direct enrollment survey link via social media, implementing a reCAPTCHA tool on the eligibility screening survey, and requiring an enrollment and consent verification phone call before confirming enrollment, where participants were required to verify free-text items from the eligibility screener. Although not done in our study, we suggest that researchers may consider additional approaches such as (1) adding hidden fields to eligibility surveys that will be "seen" and filled out by robotic or spam respondents but not human participants, (2) activating a timestamp on online surveys to evaluate time spent completing each survey, and (3) requiring a video call for enrollment and consent verification [8,20]. Future studies should consider the tension between data integrity and ensuring that study enrollment procedures are not overly burdensome for participants.

Our findings confirm and extend previous work demonstrating the value of a multiapproach, community-engaged recruitment strategies that integrate both digital and in-person methods to reach underserved populations. While previous studies have suggested the efficacy of social media in perinatal research recruitment [31], our findings suggest the use of online methods alone, without community partners, may not be sufficient to meet diversity goals [31]. These findings align with concerns in recent literature of a digital divide and underrepresentation of marginalized populations in digital health research [20,32].

Limitations and Future Considerations

While we were partially successful in recruiting a diverse sample, we did not fully achieve all of our internal benchmark goals. This study encountered several limitations to recruitment that are important to consider when interpreting the findings and planning for future research. First, using a low-income benchmark of US $50,000 may have been too high for some US regions, potentially limiting the generalizability of our findings for low-income individuals. Second, the study was

XSL•FO
RenderX

conducted exclusively online and in English, which may have been a barrier to participation from non-English speaking populations or low-income individuals who may not have access to a tablet, smartphone, or computer. Future research should consider providing materials in multiple languages, offering tech support, or providing study devices to increase accessibility. Third, the recruitment period overlapped with the COVID-19 pandemic, which limited the ability to conduct in-person recruitment activities during the early phases of the study. Although the pivot to online recruitment was successful, the inability to rely on traditional in-person methods may have impacted the diversity and reach of the study sample. Fourth, our team encountered several barriers associated with online community partnerships. We recommend that research teams engage with online and social media partners early on, particularly in the grant budget planning phase, to allocate adequate budget line items for successful partnership compensation. Future research should consider the demographics of their local communities, resources for supporting local entities in assisting in recruitment, as well as the intended goals for the study and how dissemination of findings will directly impact the population being studied when deciding where and how to recruit.

Fifth, despite our efforts to recruit a geographically diverse sample, representation from some regions, such as the Midwest, was lower than anticipated. While we adapted our recruitment strategies to targeted community partnerships and online outreach, this imbalance highlights the ongoing need for tailored region-specific approaches to recruitment. Finally, we used multiple approaches to prevent fraudulent or duplicate enrollments, and this may add administrative burden that may not be feasible for all research teams. Additional research into scalable, automated approaches to ensure data integrity is needed.

Conclusion

Recruiting participants to research studies is a complex and ever-changing process due to the importance of sample size and diversity, as well as advancements in technology. Best recruitment results for recruiting very large samples of historically marginalized groups to online and mobile-based RCTs are achieved with an integration of both in-person and online recruitment. This paper aimed to describe the recruitment plan, inclusive of recruitment methods, approaches, and strategies, used to recruit a large sample of diverse pregnant individuals to an online mobile-based RCT. Combining local and in-person with national and online recruitment methods allowed for successful recruitment of a large sample of pregnant individuals. In addition, this layered approach allowed the study to continue during an unplanned world event and be responsive to pivoting to meet recruitment goals. Recruitment approaches and methods that were the most successful were establishing community partnerships both online nationally and in-person locally, dedicated research time to focus on recruiting historically marginalized groups for a more representative sample, allocation of study time and resources to recruitment preparation, and a dedicated internal research team for recruitment planning and tracking. Researchers should continue to publish and disseminate their recruitment efforts and results, highlighting both aspects of success and lessons learned, as well as the pivot points in their recruitment methods for shared learning. As such, future studies may reach their intended sample sizes with appropriate, diverse representation of the population intended to benefit from the study findings.

Abstract

Background: The COVID-19 pandemic significantly impacted primary health care–seeking behavior of the general population. The extent to which health care–seeking behavior of pregnant women in general practitioner (GP) care was affected remains largely unknown. The unique health care needs of pregnant women necessitate regular monitoring and care to ensure the well-being of expectant mothers, fetuses, and neonates, as timely interventions and screenings can profoundly influence the long-term health outcomes. Understanding how pandemic-related changes have influenced pregnant women's primary health care–seeking behavior is essential for developing targeted interventions and informing policy decisions to improve health outcomes for expectant mothers, fetuses, and neonates, both during public health emergencies and in routine health care settings.

Objective: This study aims to examine the impact of different COVID-19 pandemic phases on health care–seeking behavior among pregnant women in Dutch GP practices throughout 2020 and 2021. By analyzing clinical electronic health record (EHR) GP data, we aim to evaluate the health care consumption, occurrence of pregnancy-relevant symptoms and diagnoses, and types of contact (ie, regular consultations, phone consultations, home visits, and digital consultations) during different pandemic phases.

Methods: Using a retrospective cohort design, EHRs of selected pregnant women from 3 Dutch GP networks between 2019 and 2021 were analyzed, comparing 6 pandemic phases divided into 13 subphases with a prepandemic phase. Contact rates were analyzed by interrupted time-series analyses, pregnancy-relevant symptoms, and diagnoses by comparing the frequency of pregnancy-relevant International Classification of Primary Care (ICPC) code registrations and type of contact by descriptive statistics.

Results: In total, 10,985 pregnant women were included, yielding 39,023 patient-GP contacts. Contact rates fluctuated significantly across pandemic phases, with the sharpest declines at the onset and the end of the pandemic. Pregnancy-relevant symptoms and diagnosis in the category related to pregnancy showed the highest variability across the pandemic phases, such as an increase in the frequency of health care consumption concerning gestational diabetes mellitus and nausea or vomiting of pregnancy. Detailed statistical results are reported in the main text. Contacts for symptoms and diagnosis like digestive or urinary tract problems did not fluctuate across the pandemic phases. The number of physical contacts decreased, while telephone contacts increased.

Conclusions: By analyzing EHR data from over 10,000 pregnant women, this study highlights the pandemic's impact on pregnant women's GP health care–seeking behavior, including declining health care consumption trends during the initial and end phases of the pandemic (2020 - 2021). The observed increase in GDM and its potential long-term effects underscore the need for enhanced public health strategies within GP practices, ensuring continuous access to prenatal care and striving for improved outcomes of expectant mothers, their fetuses, and neonates during times of pandemics and in routine health care settings.

Introduction

The COVID-19 pandemic has caused profound changes in health care–seeking behavior globally, especially within primary general practitioner (GP) care settings, where a significant decline in use was observed following the outbreak of the pandemic [1-5]. This decline in GP health care visits was shown to be driven by factors such as lockdown measures and heightened fears of viral transmission [1]. These shifts have resulted in reduced experienced accessibility and continuity of GP care, leading to postponed chronic care and increased interactions with unfamiliar health care providers [6].

Prenatal health care is managed collaboratively by midwives and obstetricians in secondary health care, and by midwives and GPs in primary health care. In the Netherlands, every citizen is registered with a GP who serves as a gatekeeper to secondary care [7]. Midwives and GPs typically oversee low-risk pregnancies in primary care, while obstetricians handle high-risk cases in secondary hospital care. GPs play a pivotal role in prenatal health care, providing comprehensive support that encompasses health promotion (eg, advices concerning diet and exercise in the case of diabetes mellitus, smoking cessation, and COVID-19 infection and vaccination), timely interventions for routine health care problems (eg, treatment of urine tract infections and mental health problems) and specialist referrals [8-10]. In addition, pregnant women can rely on GPs for certain medication needs (eg, antibiotics, thyroid medication, and mental health medication), especially since midwives do not have prescription authority in the Netherlands. A previous national study showed that before the pandemic, pregnant women typically consulted their GPs around 6 times on average during pregnancy and the postpartum period [10]. Common reported symptoms and diagnoses included intercurrent diseases, vomiting, urogenital problems, mental health issues, and work-related concerns [10,11]. Most pregnant women saw their GP, alongside their midwife or obstetrician, as an essential prenatal care provider, fostering long-term trusted health relationships with their registered GPs [10]. Therefore, GPs play an important role in providing additional prenatal health care for pregnant women.

Postponing or cancelling this important prenatal care may lead to negative consequences for maternal, fetal, or neonatal health [12-14]. Pregnant individuals are inherently vulnerable and susceptible to both physical and psychological illness, which may be exacerbated if the necessary prenatal GP care is not provided. Therefore, sustainable GP care for pregnant women, in addition to regular perinatal care, is needed for a robust public health care system [2].

Consequently, understanding the impact of the COVID-19 pandemic on health care–seeking behavior among pregnant women in GP practices is imperative. However, the extent to which the pandemic influenced pregnant women's health care–seeking behavior within Dutch GP practices across different pandemic phases remains largely unknown. For that reason, this study aims to examine the impact of different COVID-19 pandemic phases on health care consumption among pregnant women in Dutch GP practices throughout 2020 and 2021. By analyzing routine clinical electronic health record (EHR) data registered by GPs, this study aims to evaluate health care consumption, the occurrence of pregnancy-relevant symptoms and diagnoses, and the types of contact (ie, regular consultations, phone calls, home visits, digital consultations) during different pandemic phases. It is important for informing policymakers, health care providers, and expectant mothers to understand how external factors such as a pandemic and associated restrictive measures influence health care–seeking behaviors among pregnant women. By providing these insights, this study ultimately aims to contribute to the improvement of prenatal GP care delivery, impacting public health in both pandemic and routine health care settings.

Methods

Study Design and Population

This retrospective observational cohort study used data retrieved from routinely registered clinical EHRs from GP practices from 2019 (prepandemic) to 2021 (pandemic). Data from 3 regional Dutch GP research networks were used: (1) the northern Academic General Practitioner Development Network (Academisch Huisartsen Ontwikkel Netwerk, AHON), including 59 GP practices managed by the University Medical Center Groningen (UMCG) [15]; (2) the eastern Family Medicine Network including 6 practices managed by Radboud University Medical Centre Nijmegen [16]; and (3) the southern Research Network Family Medicine Maastricht, including 28 practices managed by Maastricht University Medical Centre [17]. The network populations are a good reflection of the population in these regions [15,17,18]. The dataset included anonymized EHR data from approximately 410,000 patients, encompassing patients' medical history, clinical findings, diagnoses, types of contact, and demographic characteristics [1].

In the Netherlands, GPs are required to assign an International Classification of Primary Care (ICPC) code to each patient contact [19]. Contacts were defined as either a physical consultation (at the clinic or at home), a telephone consultation, or any type of digital contact between a patient and a GP or practice nurse, with registration of a free text note (physician's note) and at least 1 ICPC code.

Selection of Pregnant Women

Women in the reproductive age (20 - 45 y) with a confirmed pregnancy status in their EHR were selected for inclusion in the study. To select pregnant women, all EHR records of women of reproductive age were screened to determine pregnancy status during the studied period, using 3 methods. First, pregnancy status was determined based on the registration of at least one of the 24 pregnancy and childbearing related ICPC codes, such

XSL•FO
RenderX

as W78 (“pregnancy, confirmed”), see Multimedia Appendix 1. Second, to identify pregnant and postpartum women without pregnancy-relevant ICPC codes, physician’s notes (free text notes) were screened for text patterns indicating pregnancy, using a regular expression (see Multimedia Appendix 2). To enhance validity, this regular expression was reviewed by a data scientist. Third, physician’s notes of contacts of potentially pregnant women selected by the aforementioned methods were manually assessed by the study team (WB-H and MH) to confirm pregnancy status (see Multimedia Appendix 3). Only contacts where pregnancy status was confirmed at the time of the contact were included irrespective of their pregnancy duration.

Women miscarrying were also retrospectively labelled as being pregnant. If neither of these 3 methods were irrefutable about pregnancy status, women were excluded. Registrations of the ICPC code W90 (“normal delivery liveborn”) were excluded for data integrity reasons, as some of these were identified as false registrations from previous pregnancies. Women were excluded when they had died during the study period, were deregistered from one of the included practices, had a reason for deregistration without deregistration date, had an unknown date of birth, were registered less than 3 months, or had missing data that hindered pseudonymization (eg, zip code). Only dates of weekdays were included. Weekend days, holidays, and consults outside of regular office hours were excluded from the analysis (see Multimedia Appendix 4).

Outcome Variables

The primary outcome variables included pandemic health care consumption (ie, contact rates), pregnancy-relevant symptoms and diagnoses, and type of contact (ie, regular, phone, home visit, or digital contact), and were compared with the prepandemic baseline (2019). Pregnancy-related symptoms and diagnoses were determined by listing pregnancy-relevant ICPC codes that represented symptoms or diagnoses that commonly occur during pregnancy or require clinical attention in pregnant women. The selection was based on relevant ICPC codes from previous research [10], and supplemented with manual evaluation of all ICPC codes for their relevance in pregnancy. To validate the list of pregnancy-relevant ICPC codes, a general practitioner (MH) and a midwife evaluated the relevance of each code to pregnancy (see Multimedia Appendix 5). Contacts could involve one or more ICPC codes.

Pandemic Phases and Subphases

Previous research showed that health care consumption fluctuated during the pandemic in response to both changes in COVID-19 incidence rates and the implementation or relaxation of restrictive measures in the general population [1]. Therefore, this study is conducted in accordance with a previously described framework that divides the pandemic into 6 main phases based on the restrictive measures mandated by the Dutch government [1,20]. These phases were subdivided into subphases based on turning points in the national COVID-19 incidence rates within each main phase (Table 1), using data from the National Institute for Public Health and Environment (Rijksinstituut voor Volksgezondheid en Milieu). In the general population, for example, health care consumption initially decreased in phase 1 and then increased again midway through phase 1 as incidence rates declined, leading people to gradually visit their GPs more often again [1].

Table . COVID-19 pandemic phases in the Netherlands based on infection rates and restrictive measures, and subphases based on highest and lowest infection rates.

Phase and subphase		Year	Week within year	Description of COVID-19 infection rates and containment measures
Phase 0				• No confirmed COVID-19 infections in the Netherlands.
	Phase 0	2019	1 - 52	
	Phase 0	2020	1 - 8	
Phase 1				• First wave of COVID-19 infections. • First lockdown (ie, hand hygiene, social distancing, working at home, and schools, restaurants, amusement and industry closed). • Highest infection rates: week 15.
	Phase 1a	2020	9 - 13	
	Phase 1b	2020	14 - 22	
Phase 2				• Decrease in infection rates. • Gradual relaxation of restrictive measures. • Lowest infection rates: week 28.
	Phase 2a	2020	23 - 28	
	Phase 2b	2020	29 - 40	
Phase 3				• Second wave of COVID-19 infections. • Stricter containment measures, start of a partial lockdown followed by a strict lockdown (ie, curfew, schools, stores, and sport facilities closed). • Highest infection rates: week 44 and 52.
	Phase 3a	2020	41 - 44	
	Phase 3b	2020	45 - 53	
	Phase 3c	2021	1 - 3	
Phase 4		2021	4-17	• Emergence of the Alpha variant (B1.1.7) of concern, further increase in infection rates, and continued lockdown measures. • Highest infection rates: week 16.

XSL•FO
RenderX

Phase and subphase		Year	Week within year	Description of COVID-19 infection rates and containment measures
Phase 5				• Decrease in infection rates. • Gradual opening-up of society and only minor restrictions. • Lowest infection rates: week 26.
	Phase 5a	2021	18 - 26	
	Phase 5b	2021	27 - 43	
Phase 6				• Epidemic rise with the Delta variant (B.1.617.2) of concern and a steep increase in infection rates. • Lockdown measures reintroduced. • Highest infection rates: week 48.
	Phase 6a	2021	44 - 48	
	Phase 6b	2021	49 - 52	

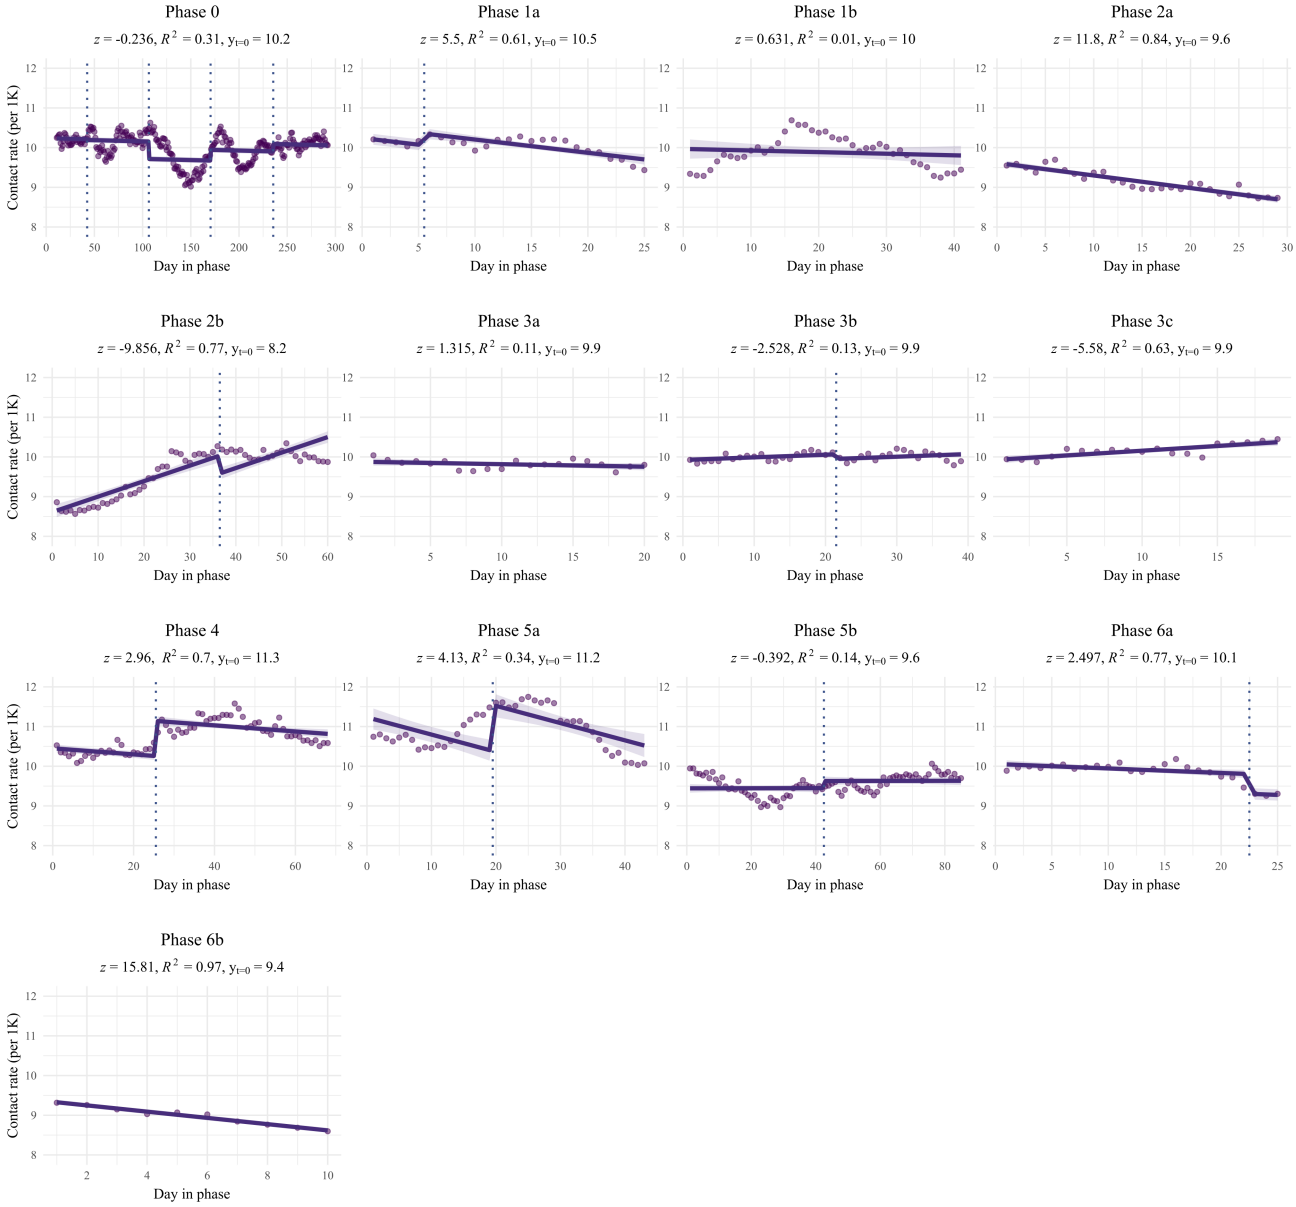
Data Analysis

Overview

Descriptive statistics were performed to describe the study population characteristics for each studied year (2019, 2020, and 2021). This included the total number of included pregnant women per (pre)pandemic year and region, the total number of contacts, the mean number of contacts per patient with SD, the mean number of ICPC code registrations per contact, and the mean age with SDs. Statistical differences between the studied years were tested using a G-test for goodness-of-fit.

All statistical analyses with a $P<.05$ were considered significant. All data were analyzed using R (version 4.0.5; R Foundation for Statistical Computing).

Analysis of Health Care Consumption



Health care consumption was calculated by normalizing daily contact rates per 1000 registered pregnant patients. An interrupted time-series analysis was conducted using a segmented linear regression model to assess the impact of the COVID-19 incidence rates and societal measures on health care consumption during each pandemic subphase. For each (pre)pandemic subphase, a linear regression model was used, assuming a linear relationship between time and the contact rates within each subphase and fitted to generate a least squares regression line. Linearity was checked through visual inspection of the fitted models, while autocorrelation was assessed visually using autocorrelation plots. To enhance the stability of contact rates, a 3-week centered moving average was applied before modeling. Seasonality was accounted for by adding seasonal intercepts to the model, with spring as the baseline. For each subphase P, the linear regression model was described mathematically (Equation 1).

$$(1) YT(P)=\beta 0+\beta 1\cdot T+\beta 2\cdot S1+\beta 3\cdot S3+\beta 4\cdot S4$$

In this equation, Y_T represents the contact rate at time T, P the phase being modelled (ranging from 0 to 6b), β_0 the intercept value at the start (t=0) of phase P, β_1 the slope of the linear model during phase P, and T the time variables (in days within phase P). β_2, β_3, and β_4 are the seasonal intercepts. S_1, S_3, S_4 are dummy variables indicating the season (Winter, Spring, Summer, and Autumn), taking value 1 if the season is within the studied phase, and value 0 otherwise (see Figure 1). S_2 was considered the baseline, always having value 0. This model captures the variation in the health care consumption during each phase, considering both the overall time trend ($\beta_0 + \beta_1 \cdot T$) and the seasonal effects introduced by the dummy variables $\beta_2 \cdot S_1 + \beta_3 \cdot S_3 + \beta_4 \cdot S_4$, taking spring S_2 as the baseline.

XSL•FO
RenderX

Figure 1. Linear models of health care consumption per phase, shown by day in phase and per 1000 registered pregnant patients. The *z* scores represent the comparison of the slope of each pandemic phase as compared to the slope of the prepandemic phase (Phase 0) along with their significance. As the prediction models for health care consumption were adjusted for seasonality, the linear regression lines may shift within a phase; these shifts are marked by vertical dashed lines at the seasonal transitions. The distributions of the x-axes are not equal for each phase, as phases did not consist of an equal number of days.

Beta coefficients (ie, intercept β_0 and slope β_1) were computed for each subphase. Intercept values and their SEs were calculated at the start of each subphase (t=0) to determine immediate effects at the start of a new subphase. In addition, slopes and their SEs were computed to model and assess the trend in health care consumption within each subphase, where a negative slope indicated a decrease, and a positive slope indicated an increase in health care consumption. To compare intercept values and slopes of pandemic subphases to the prepandemic baseline, *z*-scores of the β-coefficients and their accompanying *P* values were calculated. Coefficients of determination (R^2) and adjusted R^2 were calculated to describe the proportion of variance that was explained by the independent variables within each model. Differences between a pandemic subphase and the prepandemic baseline were considered significant if the *P* value of the *z* score of either the intercept or the slope was <.05.

Analysis of Pregnancy-Relevant Symptoms and Diagnoses

The changes in the most prevalent pregnancy-related symptoms and diagnoses were examined by identifying the 10 most frequently registered ICPC codes from the created list of pregnancy-relevant ICPC codes (ie, symptoms and diagnoses) within the studied population during the studied period. Focusing on the most prevalent conditions allowed for a structured analysis of variation over time while maintaining analytical feasibility. The number of ICPC code registrations was calculated by normalizing the number of ICPC code registrations per 1000 contacts. To assess whether these proportions differed substantially between each pandemic subphase and the prepandemic baseline, statistical analysis through Fisher Exact tests for each specific ICPC code was conducted.

XSL•FO
RenderX

Analysis of Type of Contact

The type of contact was visualized as a percentage of the total number of contacts within each phase. Visualization was done using a centered moving average of 3 weeks and smoothed using Locally Estimated Scatterplot Smoothing. This nonparametric smoothing technique uses locally weighted polynomial regression to fit a smooth curve through points in a scatter plot, providing a visual trend of the data without assuming a specific parametric model.

Ethical Considerations

Ethical approval for the collection and analysis of COVID-19 EHR data was conducted by the Medical Ethics Committee of the UMCG (2020/309). In this study, no patients were directly involved, and thus, this research was ruled not to be subject to the Medical Research Involving Human Subjects Act (Article 9, paragraph 2, EU-GDPR 2016/679). The EHR data were anonymized and deidentified before being made available to the researchers.

Results

Population Characteristics

A total of 975,545 contacts of 78,941 women in the reproductive age (20 - 45 y) were screened for pregnancy status, of which 10,985 women (13.9%) were labelled as pregnant and had 39,023 contacts with the GP (see Table 2). Pregnant women had a mean age of 30.4 (SD 4.6) years during the total studied period. These women had an average of 2.8 (SD 2.6) contacts in 2019, 2.8 (SD 2.6) in 2020, and 2.9 (SD 2.8) in 2021.

Table . Demographic characteristics of the study population of pregnant women per year (2019 - 2021; n=10,985).

	Total population[a] (N=10,985)	Population in 2019 (n=4414)	Population in 2020 (n=4553)	Population in 2021 (n=4836)	*P* value
Pregnant women, n	10,985	4414	4553	4836	<.001
Age (years), mean (SD)	30.4 (4.6)	30.5 (4.6)	30.3 (4.6)	30.5 (4.5)	≥.99
Total contacts, n	39,023	12,384	12,686	13,953	<.001
Number of contacts per patient, mean (SD)	3.6 (3.5)	2.8 (2.6)	2.8 (2.6)	2.9 (2.8)	.99
Number of ICPC[b] code registrations per contact, mean (SD)	1.13 (0.38)	1.14 (0.39)	1.13 (0.37)	1.12 (0.37)	≥.99

[a]Populations partly overlap in the 3 studied years.

[b]ICPC: International Classification of Primary Care.

Changes in Health Care Consumption

Health care-seeking behavior differed significantly in each pandemic subphase compared to Phase 0 (see Figure 1 and Table 3). At the onset of the pandemic (Phase 1a), an immediate significant increase in health care consumption was observed (β_0=10.54; *P*=.04), evident from the elevated intercept value compared to Phase 0. During Phase 1a, there was a substantial and significant decrease in health care consumption following the initial peak intercept value (β_1=–0.03; *P*<.001), indicating reduced contacts with the GP at the beginning of the pandemic. In Phase 1b, an immediate effect was noted, with a significantly lower intercept value (β_0=9.97, *P*<.001). However, the subsequent period did not significantly differ from Phase 0, indicating consistently lower health care consumption during Phase 1b, though this model was unable to explain most of the variance (R^2=0.02).

RenderX

Table . Interrupted time series analysis of health care consumption for the different pandemic subphases (2020 and 2021) compared to the prepandemic year 2019 (phase 0) of the total studied population of pregnant women, showing intercepts (β_0) with SE, slopes with SEs (β_1), *z* scores, and *P* values for intercepts.

Phase	Intercept of the linear model			Slope of the linear model			Model's goodness of fit	
	Intercept β_0 (SE)	*z* score, intercepts	*P* value, intercepts	Slope β_1 (SE)	*z* score, slopes	*P* value, slopes	R^2	Adjusted R^2
0 (baseline)	10.22 (0.04)	—[a]	—	−0.00 (0.00)	—	—	0.31	0.30
1a	10.54 (0.10)	–4.10	.04	–0.03 (0.00)	5.50	<.001	0.61	0.57
1b	9.97 (0.13)	0.97	<.001	–0.00 (0.01)	0.63	.53	0.02	0.01
2a	9.62 (0.05)	7.83	.33	−0.03 (0.00)	11.80	<.001	0.85	0.84
2b	8.16 (0.20)	9.33	<.001	0.04 (0.00)	−9.86	<.001	0.77	0.76
3a	9.88 (0.05)	3.31	<.001	−0.01 (0.00)	1.32	.19	0.11	0.06
3b	9.92 (0.04)	3.05	.001	0.01 (0.00)	−2.53	.01	0.13	0.08
3c	9.92 (0.05)	2.74	.002	0.02 (0.00)	−5.58	<.001	0.63	0.61
4	11.34 (0.11)	−10.13	.006	−0.01 (0.00)	2.96	.003	0.70	0.69
5a	11.23 (0.14)	−7.61	<.001	−0.04 (0.01)	4.13	<.001	0.34	0.31
5b	9.62 (0.14)	3.33	.001	0.00 (0.00)	−0.39	.70	0.14	0.11
6a	10.06 (0.06)	0.59	.56	−0.01 (0.00)	2.50	.01	0.77	0.75
6b	9.41 (0.03)	13.26	<.001	−0.08 (0.01)	15.81	<.001	0.97	0.97

[a]Not applicable.

The start of Phase 2a did not significantly differ from Phase 0 (β_0=9.62; *P*=.33). Nevertheless, a significant negative slope indicated a sustained decline in health care consumption during this phase (β_1=–0.03; *P*<.001). Phase 2b marked the lowest intercept value in health care consumption in the studied period (β_0=8.16; *P*<.001). Subsequently, there was a significant increase in health care consumption during Phase 2b (β_1=0.04; *P*<.001).

In Phase 3, all subphases (3a, 3b, and 3c) exhibited significantly lower intercept values (respectively, β_0=9.88, *P*<.001; β_0=9.92, *P*=.001; and β_0=9.92, *P*=.002). Health care consumption remained stable during Phase 3a (β_1=–0.01; *P*=.19), while significant increases occurred during Phases 3b and 3c (β_1=0.01, *P*=.01 and β_1=0.02, *P*<.001, respectively), though the models of Phase 3a and 3b were unable to explain most of the variance (R^2=0.11, and R^2=0.13, respectively).

The onset of Phase 4 marked the highest intercept value since the beginning of 2019 (β_0=11.34; *P*=.006). However, health care consumption significantly declined during Phase 4 (β_1=–0.01; *P*=.003).

Phase 5a began with a significantly higher intercept value (β_0=11.23; *P*<.001). During Phase 5a, health care consumption declined significantly (β_1=–0.04; *P*<.001). This decline led to a significantly lower intercept value at the beginning of Phase 5b (β_0=9.62; *P*=.001), with health care consumption remaining relatively stable during Phase 5b. Phase 6a initiated with an intercept value comparable to Phase 0 (β_0=10.06; *P*=.56). However, health care consumption declined significantly during Phase 6a (β_1=–0.01; *P*=.01), resulting in a significantly lower intercept value of Phase 6b (β_0=9.41; *P*<.001), followed by a further significant decline during Phase 6b (β_1=–0.08; *P*<.001).

Pregnancy-Relevant Symptoms and Diagnoses

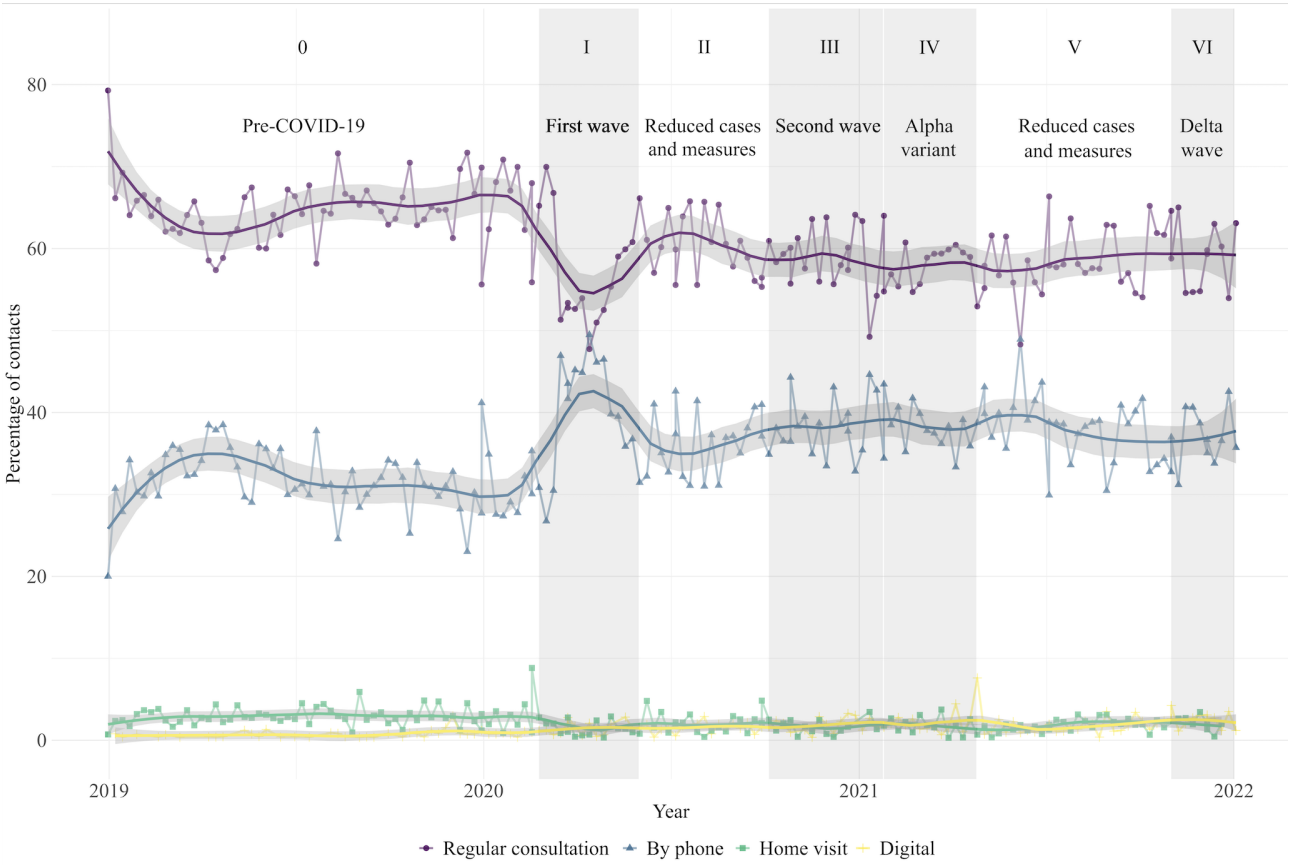
Most Frequent Registered Symptoms and Diagnoses

The top 10 pregnancy-relevant symptoms and diagnoses (ie, ICPC codes) presented by pregnant women to their GP during the studied period were examined (see Multimedia Appendix 6). These symptoms and diagnoses were (1) pregnancy confirmed (ICPC W78), (2) cystitis or other urine infection (U71), (3) vomiting or nausea of pregnancy (W05), (4) abortion spontaneous (W82), (5) unwanted pregnancy confirmed (W79) (6) frequent or urgent urination, (U02), (7) urogenital candidiasis (X72), (8) GDM (W84.02), (9) other localized abdominal pain (D06), and (10) constipation (D12). Contacts related to these top 10 symptoms and diagnosis covered 65.6% (n=25,587) of all contacts of pregnant women during the studied period.

Changes in Pregnancy-Relevant Symptoms and Diagnosis

The normalized and absolute number of contacts concerning the top 10 symptoms and diagnoses per phase were examined (Multimedia Appendix 6). Health care consumption concerning pregnancy-related symptoms and diagnoses changed statistically significant in multiple pandemic phases compared to Phase 0. Specifically, health care consumption for vomiting or nausea of pregnancy was significantly higher during Phase 2a, 2b, 3b, 3c, 4, 5b, and 6b compared to Phase 0. Conversely, confirmed pregnancy was significantly lower in Phase 1a, 1b, 4, and 6a compared to Phase 0. Confirmed unwanted pregnancy was significantly lower in Phase 2b, 3b, 4, 5a, 5b, and 6a compared to Phase 0. Spontaneous abortion was found to be significantly

XSL•FO
RenderX



higher in Phase 2a and 3b compared to Phase 0 (P=.04 and P=.048, respectively). GDM was significantly higher in the Phase 2a, 4, 5a, and 5b compared to Phase 0.

Notably, among general health symptoms and diagnoses, health care consumption for localized abdominal pain did not change significantly during the pandemic phases compared to Phase 0. Constipation declined significantly in Phase 5a compared to Phase 0 (P=.02). Frequent or urgent urination declined significant in Phase 3c compared to Phase 0 (P=.02). Cystitis or other urine infection was significantly higher in Phase 5b and lower in Phase 6a compared to Phase 0 (P<.001 and P=.04, respectively). Urogenital candidiasis showed a significant increase in Phase 5b compared to Phase 0 (P=.002).

Changes in Type of Contact

Figure 2 shows the percentages of type of contact (ie, regular consultations, telephone consultations, home visits, and digital consultations). During the initial pandemic phase, regular consultations declined, and telephone consultations increased. From Phase 2 until Phase 6, regular consultations increased, but did not reach the prepandemic baseline of 64.9% (n=9281). After the sharp increase in telephone consultations, there was a decline during the following pandemic phases. However, the percentage of telephone consultations remained higher than the prepandemic baseline of 31.7% (n=4529). Digital consultations remained comparable to the prepandemic baseline throughout the pandemic phases.

Figure 2. The proportion of types of contact for pregnant women across prepandemic and pandemic phases, with raw and smoothed percentages shown by contact date. Contact types were visualized as a percentage of the total number of contacts within each subphase, using a centered moving average of 3 weeks.

Discussion

Principal Findings

To the best of our knowledge, this is the first study examining pregnancy-relevant symptoms and diagnoses in GP practices in relation to the COVID-19 pandemic. By analyzing routine clinical EHR data registered by GPs, this study revealed statistically significant fluctuations in health care consumption among over 10,000 studied pregnant women during various pandemic phases, defined by infection rates and restrictive measures. In addition, this study demonstrated significant increases in GDM and vomiting or nausea of pregnancy, while contacts concerning confirmed pregnancies declined.

The deployed interrupted time-series analysis is a highly effective design for studying effects of interventions [21], such as the restrictive measures mandated by the government and changes in COVID-19 incidence rates during the pandemic phases. Furthermore, our combined method of selecting pregnant women led to the inclusion of a large sample of a wide range of pregnant women in the Netherlands. This comprehensive analysis of contacts, symptoms, and diagnoses of pregnant women provided valuable insights into prenatal GP care and changes in health care–seeking behavior of these vulnerable women during the COVID-19 pandemic.

XSL•FO
RenderX

Population Characteristics

Our study showed a statistically significant increase in the number of pregnancies registered at the GP practice and absolute number of contacts in 2021, which is in accordance with national birth rates [22]. The mean age of the pregnant women studied (30.4 y, SD 4.6) is slightly lower than the mean maternal age at the date of delivery of the total Dutch population (31.6 y). Our study illustrated that, if pregnant women contacted their GP, the mean number of contacts in the prepandemic year 2019 was 2.8 (SD 2.6) and remained comparable in the pandemic years 2020 and 2021.

Health Care Consumption

We show primarily declining health care consumption during the initial phases of the pandemic. The hesitation of pregnant women to seek GP care may have been influenced by the lack of knowledge about the consequences of a COVID-19 infection on both mother and fetus along with related news messages, fear of contamination, societal recommendations to stay home, or limited child care availability [23-25]. The declining trend also aligns with findings from other studies among the general population, which observed a pandemic-induced decrease in primary health care consumption initially [1-5,26]. Recent research has further highlighted a more pronounced decline in health care–seeking behavior among women compared with men during these initial pandemic phases, indicating that women may have been particularly hesitant to seek medical care amidst the pandemic [27]. Furthermore, a previously published systematic review revealed notable shifts in pregnant women's health care–seeking behavior in other health care settings such as obstetric hospital and prenatal clinic care, including a substantial decline in both routine and unscheduled prenatal care visits at their maternal health care providers [28]. This decline may indicate that important prenatal care was missed during this period, potentially resulting in delayed adverse effects on mother, fetus, and neonate. Future research should elaborate on these long-term consequences.

After reaching the lowest point of GP health care consumption in the studied period (2020 - 2021) in July 2020, health care consumption mainly increased until January 2021 and remained statistically significantly higher than the prepandemic level until mid 2021, suggesting a rebound after the initial decline. The observed increase mid-2020 may be explained by the declining infection rates and the gradual reopening of society. Furthermore, the increasing health care consumption among pregnant women may be indicative of an increased demand for GP health care, potentially compensating for earlier missed care. Other research illustrated similar fluctuating trends in health care–seeking behavior worldwide during these pandemic phases [1,27,29]. Despite this temporary rebound of health care consumption, the World Health Organisation identified a continued disruption of access to prenatal and primary health care services worldwide during this period [29].

Notably, from mid-2021 until the end of the year, a recurrent steep decline in health care consumption was observed, despite declining infection rates, minimal restrictions, and the gradual reopening of society. Possibly, pregnant women sought care with their primary care midwife again. However, the hesitation in contacting the GP may also be explained by news messaging highlighting an increased risk of serious illness from COVID-19 infection for pregnant women during this period, which was based on related published research [30]. This implies a negative impact of the rise of the Delta variant and reintroduced lockdown measures on prenatal health care, potentially resulting in recurrent missed prenatal care.

Overall, the declining trends in health care consumption during the start and end phases of the pandemic among pregnant women suggest a substantial impact on health care consumption during the pandemic, influenced by the COVID-19 incidence rates, restrictive measures, and news messaging related to COVID-19. Previous studies found that factors such as the fear of infection during health care contacts, limited understanding of the effects of COVID-19 on maternal and fetal health, and societal restrictions probably influenced this declining trend in health care consumption [1,23]. This could potentially lead to delayed adverse pregnancy outcomes, and physical and mental health problems [23,28]. Future studies should elaborate on these long-term consequences of the pandemic and on additional factors contributing to variation in health care consumption.

Pregnancy-Relevant Symptoms and Diagnoses

Building upon these fluctuating trends in health care consumption, we also explored changes in presented pregnancy-relevant symptoms and diagnoses. We show that 83.8% (n=21,621) out of the top 10 most frequently registered symptoms and diagnoses were related to pregnancy, which largely aligns with prepandemic research among Dutch pregnant women in GP care [10]. Interestingly, most changes between pandemic phases and the prepandemic baseline were found in pregnancy-related symptoms and diagnoses, while fewer changes were observed in categories related to routine health care symptoms and diagnoses. Most symptoms and diagnoses consistently declined or consistently increased in frequency, independent of pandemic phases. This suggests that changes in frequency of presented symptoms and diagnoses were driven by the nature of the specific complaint or diagnosis, rather than being influenced by the prevailing measures or incidence rates during each phase.

We have underlined a noteworthy increase in health care consumption concerning GDM during different pandemic phases, consistent with previous research [31-34]. This might be attributed to a rise in pregnancy-related weight gain, as was shown by other studies [32,35]. We speculate that this consequential increase in GDM could be due to physical limitations, sedentary behavior, and emotional distress following the severely restrictive lockdown measures [35-37]. Therefore, pandemics can be a risk factor for developing GDM. This is an important finding given the results of a recent review underlining that GDM increases risks of adverse maternal and perinatal outcomes, such as hypertensive disorders of pregnancy, induction of labor, caesarean section, large-for-gestational-age neonates, preterm birth, and neonatal intensive care unit admission [38]. Furthermore, the increase in GDM may have contributed to the statistically significant increase in cystitis or other urine infection and urogenital candidiasis in some pandemic phases.

XSL•FO
RenderX

In addition, we speculate that the previously reported decreased physical behavior [37,39], increased sedentary behavior, and emotional distress may have also contributed to the observed increase of vomiting or nausea of pregnancy. Furthermore, previous reviews underlined a negative influence of the pandemic on eating behavior, influenced by emotions, mood, cravings, and environmental factors [40,41], which could have further worsened symptoms of vomiting and nausea. Nevertheless, no previous research was found regarding this increased complaint. Further research is needed to examine these notable increases in GDM and nausea or vomiting of pregnancy, and their impact on long-term health outcomes for both mother and child. This could enable the development of appropriate lifestyle interventions for pregnant women to be provided as part of routine prenatal GP care, with a positive impact on outcomes during future pandemics.

Furthermore, our study brought to light notable declines in the registration of confirmed wanted and unwanted pregnancies during various pandemic phases, despite consistent national birth rates in 2020, and even higher rates in 2021 [22]. This implicates a decline in women reporting pregnancies to their GP or a decline in routine contacts where these codes are registered, aiming to prevent strain on GP care for what may seem like trivial reasons for care. Consequently, an important proportion of pregnant women did not consult their GP and were, therefore, not included in the study. The pandemic led to changes in the organization of prenatal health care provision by maternal health care professionals (midwives and obstetricians) and GPs, and probably contributed to a decline in the number of pregnant women consulting their GP. Further studies should elaborate on these suggestions. Yet, contacting the GP about pregnancy is important, as GPs provide essential prenatal care, including health promotion, timely interventions for general health care problems, management of medication needs, and referrals [8,9,11,42]. Furthermore, women with unwanted pregnancies experience more psychosocial problems than those with wanted pregnancies and often rely on GPs for care, highlighting the importance of contacting the GP [43].

Type of Contact

Considering the types of contact, our study showed a decrease in the proportion of regular physical contacts at the onset of the pandemic among pregnant women, accompanied by an increase of phone contacts. In line with previous research among the general population, while the proportion of regular physical contacts increased during subsequent phases, it did not return to the prepandemic levels during the studied years [1,28]. The pandemic accelerated the adoption of telehealth technologies, mainly through telephone contacts, in prenatal health care, facilitating more individualized and efficient health care [44,45]. A potential long-term shift toward a greater reliance on telehealth among pregnant women and GPs seems to have taken place. Nevertheless, further research should elaborate on whether this shift persisted postpandemic.

Limitations

There are also some limitations to this study. EHR data are not specifically intended for scientific purposes, but rather for informing other physicians. Therefore, important information could be overlooked when assessing presented symptoms and diagnoses. Despite this, it is imperative to analyze such data as they represent one of the few available sources that provide real time, longitudinal insights into patient's health care–seeking behavior. In addition, we could not assess the impact of other external factors, such as COVID-19-related news messaging and changes in other health care provision by maternal health care providers on health care consumption, due to limited data availability and the scope of the study design. However, these factors may have contributed to the limited explanation of the variation in health care consumption by the modeled independent variables across certain subphases. Future research should explore the influence of such factors. Furthermore, the endpoint of our data collection in 2021 limits our ability to assess the long-term effects or follow-up of pregnancy outcomes. To address this limitation, we recommend linking GP registration data with birth registration data over a longer term to comprehensively track the entire course of pregnancy and its outcomes. Finally, while the data are a reliable reflection of the Dutch general population, it should be noted that the results may not be fully generalizable to countries with different health care systems for pregnant women. Despite these constraints, it remains essential to analyze real-life EHR data to understand immediate trends and outcomes within the context of the health care system.

Conclusions

In conclusion, this study highlights the impact of the pandemic on pregnant women's health care–seeking behavior among more than 10,000 studied pregnant women. By analyzing routine clinical EHR data registered by GPs, we have underlined declining health care consumption trends during the initial and end phases of the pandemic (2020 - 2021), the increase in pregnancy-related symptoms and diagnosis, such as GDM and nausea or vomiting of pregnancy, and the (temporary) adoption of a renewed way of providing health care to pregnant women through telehealth. Changes in frequency of presented symptoms and diagnoses were likely driven by the nature of the specific complaint or diagnosis. Physical limitations, sedentary behavior, and emotional distress following the severely restrictive lockdown measures may have attributed to the increased presentation of certain conditions, such as GDM and nausea or vomiting of pregnancy.

Given the potential adverse long-term effects of GDM on mother, fetus, and neonate, the urgent need for enhanced public health strategies within GP practices for pregnant women is undeniable. It is crucial for health care policymakers, providers, and pregnant women to recognize the risks associated with avoiding GP health care during this vulnerable period and work collaboratively to ensure safe and high-quality care during future pandemics, but also in routine health care settings. Implementing proactive measures to address these challenges could enhance the protection of the health and well-being of expectant mothers, fetuses, and neonates during times of crisis and beyond.

Acknowledgments

The authors express their gratitude for the valuable work provided by data scientist Thijmen Kupers and midwife Dr Esther Feijen-De Jong within the Department of Primary and Long-Term Care (University Medical Center Groningen; UMCG), and general practitioners (GPs) Prof Jean Muris (Maastricht University Medical Centre; MUMC+) and Dr Tim Olde Hartman (Radboud University Medical Centre Nijmegen; RUMC) for the consortium collaboration and data. This study was funded by the Netherlands Organisations for Health Research and Development (Zorgonderzoek Nederland Medische Wetenschappen; reference 10430022010006) and was conducted as part of the COVID-GP project, "COVID-19 program") [46]. This project is a collaborative alliance between the UMCG, Nivel, and the academic GP research networks of RUMC and MUMC+. The current study was conducted within the Department of Primary and Long-Term Care at UMCG. The funder was not involved in the study design, data collection, data analysis and interpretation, or manuscript writing.

Data Availability

The datasets analyzed during this study are not publicly available due to the inclusion of sensitive and confidential patient health information and access restrictions imposed by the steering committees of the participating general practitioner (GP) networks, but are available via the corresponding author after formal permission, which may involve associated fees.

Authors' Contributions

WB-H, MH, AO, and LP initiated the study. LP performed data curation. TK, MSB, and WB-H conducted data gathering and cleaning. WB-H, MSB, and TK developed the regular expression. WB-H conducted the selection of pregnant women, with MH serving as medical advisor. WB and MSB initiated data analyses methods, which WB-H subsequently conducted and MSB assessed. WB-H and MH drafted the manuscript, which was critically reviewed by all authors.

Abstract

Background: Pregnant women are a priority group for COVID-19 vaccination due to their vulnerability as a high-risk cohort. However, the currentCOVID-19 vaccine uptake rate for COVID-19 vaccination among pregnant women in Western Australia remains largely unknown.

Objective: This study aimed to explore pregnant women's vaccination uptake rates, information sources, and experiences regarding COVID-19 vaccination during pregnancy. We hypothesized that uptake of vaccination among pregnant women is higher than indicated in previous studies, given differences in disease burden and public health restrictions at the time when data was collected.

Methods: A cross-sectional survey was administered electronically to maternity patients at a single tertiary metropolitan hospital in Perth, Western Australia.

Results: A total of 520 women participated in the study. Overall, the antenatal COVID-19 vaccination rate was 79% (n=398). Approximately, 51% (n=256) of the women felt well-informed about the vaccine, and information was sourced primarily from their general practitioner (n=301, 60%), midwives (n=174, 35%), and obstetric doctors (n=64, 13%). Compared to Caucasian women, those of non-Caucasian ethnicity (n=332, 66% vs n=170, 34%; *P*=.07) and those born outside Australia (n=235, 47%) reported lower rates of vaccine information provision by the hospital staff (n=22, 34% vs n=42, 66%; *P*=.04).

Conclusions: The COVID-19 vaccine uptake among pregnant women was encouragingly high in our study, with favorable attitudes and acceptance for the vaccine observed in the majority of pregnant women. This self-reported study also identified opportunities for enhanced cultural competence and further education and training for hospital staff regarding COVID-19 vaccine information provision to ethnically diverse women. Further studies examining such interventions are warranted.

(JMIR Pediatr Parent 2025;8:e66645) doi:10.2196/66645

KEYWORDS

pregnancy; COVID-19 vaccination; COVID-19; uptake; vaccine uptake; side effects; pregnant; Australia; public health; maternity

Introduction

Vaccination against SARS-CoV2 is a key public health strategy to combat the pandemic [1,2]. Pregnant women are a priority group for vaccination against SARS-CoV2, and therefore require education, encouragement, and adequate opportunities to receive vaccinations antenatally [1,3]. Pregnancy puts women in a state of immune deficiency, and therefore increases vulnerability to infection [1], with unvaccinated pregnant women experiencing increased severity of symptoms and higher death rates compared to their vaccinated peers [2,4-6]. Along with increased risk of stillbirth, unvaccinated women also have an increased likelihood of premature birth and neonatal death if they contract SARS-CoV-2 virus during pregnancy [7,8].

At the time of initial vaccination rollout, there was limited evidence regarding the safety of the COVID-19 vaccine in pregnancy [9]. Ongoing real-world studies are adding to the body of evidence, confirming vaccine safety and effectiveness during pregnancy [9-11]. According to advice from the Australian Government and recently completed safety and effectiveness studies, the most widely used mRNA vaccines

XSL•FO
RenderX

(eg, Pfizer and Moderna) are safe to be administered throughout pregnancy and the breastfeeding period [1,10].

Worldwide research has demonstrated a hesitancy among women to receive the COVID-19 vaccination during pregnancy, being less likely than any other high-risk cohort to do so [10,12]. Several worldwide studies demonstrate that this uptake remains inadequate, indicating the vaccine acceptance is significantly lower for pregnant women than in nonpregnant women [7,12,13]. An Australian study conducted in 2020 surveyed pregnant women and various maternity health care providers during the early stages of the pandemic and found that pregnant women were the least likely group to accept vaccination [2]. At the time of the study, only 14% of pregnant women had been vaccinated, and 48% of pregnant women indicated they had definite intentions to be vaccinated [2]. Similarly, a large survey questioning vaccine confidence spanning 16 countries reported that only 52% of pregnant women intended to receive the vaccine [10].

Based on worldwide trends, pregnant women are assumed to be an undervaccinated cohort [14]. A 2021 survey of doctors and midwives in Australia reported that 60% - 70% of pregnant women had received their first dose, while an estimated two-thirds had been double vaccinated [15]. A recent study based on data from Western Australia (WA) demonstrated a vaccination uptake rate of only 44% in their pregnant participants [15]. At the time of that study, there was no community transmission of COVID-19, and this was potentially an influencing factor for the surveyed women [15].

There remains a paucity of knowledge regarding Australian pregnant women's attitudes and their vaccination uptake rate, particularly since the emergence of COVID-19 infections within the Western Australian community and the introduction of proof of vaccination requirements and associated social mandates within WA [15]. Understanding pregnant women's attitudes toward COVID-19 vaccination may be useful in optimization of vaccination uptake rates, development of educational strategies, and identifying areas for potential interventions such as standing vaccination orders.

Methods

Study setting and design

The study's objective was to determine pregnant women's perceptions, attitudes, and knowledge regarding vaccination against COVID-19 during pregnancy, and to ascertain the uptake of COVID-19 vaccines during pregnancy within a maternity cohort in a tertiary care setting. We also aimed to explore the effect of various demographic factors on vaccine uptake and vaccine information provision to pregnant women.

This prospective cross-sectional study was conducted at a tertiary metropolitan maternity hospital over a three-month period from January 12, 2022, to April 30, 2022. All pregnant and immediate postpartum women who attended the hospital were eligible to participate in the anonymous survey. Women were approached in the antenatal clinic or the postnatal ward or recruited via a text message containing a link to the optional survey, due to many appointments being transitioned to telehealth as COVID-19 spread across WA. Women who elected to join the study accessed the survey link via a QR code or text link on their own smartphones.

Demographic data collected included gestation and open-text responses for age, ethnicity, country of birth, postal code, and religion. Other multiple-choice questions included education level and sources of information, including various health care providers. The participants were asked at what point during pregnancy information was given, using multiple-choice options for trimesters, and how well-informed they felt, using a Likert scale. In addition to demographic data, the respondents were asked about vaccination status, the number of doses received, the type of vaccine, and the time points in pregnancy when the vaccine was administered. We also gathered information on any side effects using an open-text field for reporting. The unvaccinated participants were invited to describe their reasoning; their responses were a combination of multiple-choice options and a free-text response, allowing women to choose as may answers as desired.

Statistics

Descriptive statistics were reported using mean and ranges for continuous data and frequency distributions for categorical data. Statistical analysis was performed using χ^2 test for categorical variables. SPSS statistical software (version 24.0; IBM Corp) was used for analysis. P values<.05 were considered statistically significant.

Ethical Considerations

The study was approved by the South Metropolitan Health Service Human Research Ethics Committee (RGS 5201). Written informed consent was obtained from all participants before commencing the survey. All participants were over 18 years of age and able to provide consent. Data was deidentified upon commencement of the survey, with participants being assigned a unique number. No compensation was provided to the participants.

Results

A total of 502 eligible women completed the survey in its entirety. Mean age of participants was 31 (SD 5.08; range 18 - 46) years.

Overall, 79.2% (n=398) of the pregnant population were vaccinated with at least one dose. Of the study participants, 60.0% (239/398) were double vaccinated and 35.1% (140/398) were triple vaccinated. The majority (328/398, 82.4%) of these women received their vaccinations during pregnancy, while the remaining received them before the pregnancy was identified. A total of 92.4% (368/398) of vaccinated women received the Pfizer, 3.2% (13/398) received AstraZeneca, and 3.2% (13/398) received Moderna vaccines.

Ethnicity was categorized into eight broad groups based on the state maternity database. A majority (332/502, 66.1%) of women identified themselves as Caucasian. Additionally, 2.1% (11/502) identified as Aboriginal, 11.1% (56/502) as Asian, 6.7% (34/502) as Indian, 2.9% (15/502) as Maori, and 2.7% (14/502) as African. An additional 7.9% (n=40/502) women chose to

XSL•FO
RenderX

identify as "other" ethnicity. Approximately over half (n=267/502, 53.1%) of the women were born in Australia.

Of the 502 women surveyed, 301 (59.9%) women reported receiving information from their general practitioner (GP) regarding the vaccination, and while the others received it from alternate sources (Table 1). Eighteen percent (89/502) of all participants reported that no one had given them any information about the vaccine, and 5.9% (30/502) of women reported receiving information only in the third trimester of pregnancy.

Table . Reported sources of vaccine information.

Source of information[a]	Number of respondents (N=502), n (%)
GP	301 (60%)
Midwife	174 (34.6)
Obstetric doctor	64 (12.7)
Other	55 (10.9)
No one	89 (17.7)

[a]These sources were mutually exclusive.

The GPs provided information to 59.9% (301/502) of all women in our study. Of these, 66.1% were Caucasian and 33.9% were non-Caucasian (odds ratio [OR] 0.961, 95% CI 0.66-1.40; *P*=.85). A total of 174 women reported receiving information from their midwives, and of whom 72.9% (127/174) were Caucasian and 27.1% (47/174) were non-Caucasian (*P*=.22 (OR 1.62, 95% CI 1.08-2.43; *P*=.22). Only 12.7% (64/502) of the women reported receiving information from an obstetric doctor within the hospital system. Of these 64 women, 79.6% (51/64) were Caucasian and 20.3% (13/64) were of minority ethnicity (OR 2.2, 95% CI 1.15-4.15; *P*=.02). Of the 12.7% (64/502) of women who reported receiving information from an obstetric doctor, 65.6% (42/64) were born in Australia and 34.3% (22/64) self-reported as being born elsewhere (OR 1.8, 95% CI 1.04-3.13; *P*=.04).

Sources of information had no significant effect on the uptake rate of the vaccination, whether information was obtained from a GP (OR 1.2, 95% CI 0.78-1.88; *P*=.43), midwife (OR 0.23, 95% CI 0.14-3.6; *P*<.001), obstetric doctor (OR 0.368, 95% CI 0.21-0.64; *P*=.01), other sources (OR 1.59, 95% CI 0.72-3.48; *P*=.29), or from no one (OR 1.63, 95% CI 0.86-3.07; *P*=.15).

Overall, 50.9% (256/502) of women felt well-informed. 39.2% (97/502) women reported feeling somewhat informed, and 9.5% (48/502) reported feeling not well-informed. However, the perceived level of being informed did not statistically affect the uptake rate of the vaccination.

Religion was self-reported by majority of the women and did not have a statistically significant association with vaccine uptake rates (OR 0.9, 95% CI 0.6-1.5; *P*≥.99).

The majority of women (194/398, 48.7%) received two doses of the vaccine in the second trimester of pregnancy. Table 2 shows the side effects profile reported by the participants. Of the vaccinated women, 63.3% (252/398) reported experiencing some side effects from the vaccine, most commonly fatigue (n=81, 55%)), sore arm (n=65, 44%), headaches (n=51, 35%), body aches (n=39, 26%), fever (n=31, 21%), and nausea or vomiting (n=24, 16%). There was no difference in the frequency or type of side effects among women under or over 30 years, (OR 1.14, CI 95% 0.75-1.75; *P*=.59] or across various ethnic groups: Caucasian (n=334, 67%); Aboriginal (n=11, 2%); Asian (n=56, 11%); Indian (n=34, 7%); Maori (n=15, 3%); African (n=14, 3%); Polynesian (n=2, 0.4%); Middle Eastern (n=4, 1%), and other ethnic groups (n=31, 6%) *(P*=.82).

Among the unvaccinated women, 405 reasons were cited. "Safety concerns" was the main reason for women opting not to receive the vaccination (137/405, 33.8%). Additionally, 21.2% (n=86) of the women were concerned about adverse effects on the baby, 12.5% (n=51) were concerned about effects on themselves, while 16.0% (65/405) opted to wait until after their baby was born (Table 3).

Table . Vaccination side effects profile reported by participants.

Vaccination side effects[a]	Number of respondents (N=252), n (%)
Fatigue	81 (55)
Sore Arm	65 (44)
Headaches	51 (35)
Fever	31 (21)
Nausea/Vomiting	24 (16)

[a]The side effects were not mutually exclusive.

Table . Reasons for women not receiving the vaccine.

Reasons for not receiving vaccine[a]	Number of respondents (n=405), n (%)
Adverse effect on myself	51 (12.5)
Adverse effect on baby	86 (21.2)
I am waiting until after baby is born	65 (16.0)
No immediate COVID-19 threat in WA[b]	14 (3.4)
Upcoming booking	23 (5.6)
Not getting the vaccine	14 (3.4)
Other	8 (1.5)

[a]These effects are not mutually exclusive.

[b]WA: Western Australia.

The respondents' education levels varied widely: high-school diploma (n=172, 35%); a postgraduate degree (n=224, 45%); a master's degree (n=53, 11%); a trade qualification (n=31, 61%); a doctorate (n=8, 2%); and no education (n=10, 2%). The level of education had no significant impact on the vaccine uptake rates *(P*>.05).

Discussion

Overall, the rate of the COVID-19 vaccination within our study's pregnant population was encouragingly high, although it lagged behind the state average of >95% double vaccination in the general population [15]. The diverse demographic of the cohort at our hospital reportedly had an equal uptake of the vaccination regardless of age, ethnicity, education level, or country of birth. To our knowledge, this is among the highest vaccination rates in a pregnant population globally, although a deficit of research on this topic remains [6,12,15-17].

Every two out of three women received COVID-19 vaccine information from their GPs. Although this number is higher than that of women receiving vaccine information from the hospital staff, given the context of a pandemic and pregnancy being a vulnerability, it would be reasonable to aim for all women to receive information on COVID-19 vaccine during their first consultation with GPs, midwives, or obstetric doctors. Workload pressures on GP clinics and hospitals during the pandemic undoubtedly placed strain on service and information delivery but also highlighted missed opportunities to prioritize vaccine information at the earliest opportunity. The pandemic may also have affected the ability of pregnant women to have timely appointments with their GPs due to restrictions and increased burden on practices [18,19]. In our study, 10% (n=48) of women reported that they did not feel well-informed about the vaccination, reiterating the need to educate pregnant women. Some women (n=30, 6%) reported receiving information for the first time only in the third trimester of pregnancy.

Eighteen percent (n=89) of women reported not receiving any information at all, which is a public health concern. These data were not influenced by age, ethnicity, or religion of the women. Encouraging multiple open conversations surrounding vaccination between all health care providers and pregnant women may possibly decrease the number of women who reported not receiving any information [20].

Australia's historically strong population growth is drawn from both natural increase and net overseas migration. In 2020, there were over 7.6 million migrants living in Australia, accounting for 29.8% of the population who were born overseas [21]. It was reassuring to see that there was no difference in responses on receiving information from GPs across various ethnic groups or countries of birth. However, the significantly high proportion of women from minor ethnic groups or those born outside Australia who reported receiving no information from the hospital staff is highly concerning. Potentially, language barriers, inadequate use of interpreters, or lack of cultural competence may contribute to this number in our culturally diverse study population; however, these factors were not investigated further in our study. Ensuring a diversified workforce in hospitals may benefit women through the dispersion of information from culturally diverse health care professionals.

A recent, similar study conducted within WA by Ward et al [22] explored women's vaccine uptake rate and attitudes surrounding vaccination. While similar information was obtained from the pregnant population, the results contrasted significantly between the two studies; this could potentially be attributed to differences in community transmission as well as the vaccination-related social restrictions and introduction of state government vaccine mandates within WA. The uptake rate in the aforementioned study was only 44%, compared to 79% in our study. Additionally, one-third of their study population reported not being given any information regarding the vaccine, whereas our numbers, although still concerning, were much lower at 18%. This difference may likely be attributed to increased awareness and education as the pandemic evolved in WA, along with real-time evidence of vaccine safety in pregnancy being reported worldwide. At the commencement of our study, there was no community spread of COVID-19, and therefore, no imminent urgency was experienced within WA. However, the opening of borders was announced soon after the vaccine mandates were introduced, and eventually, the interstate and international WA borders were opened during the course of our study. Both studies discovered that women's safety concerns regarding their baby and themselves were primary factors behind declining or delaying the vaccine administration.

Our study had various strengths and limitations. It was conducted throughout the community COVID-19 transmission

XSL•FO
RenderX

in WA, making our findings unique and relevant to the current pandemic situation. Our study population reflects the health status and demographic status of WA's pregnant population. It incorporated multiple ethnicities, wide age range, and both low- and high-risk pregnancies. The results are generalizable to the WA pregnant population, as a variety of ethnicities, education levels, and ages were incorporated, along with a large sample size. The limitations of our study include restriction to a single-center experience, lack of information on primary spoken languages by the women, and reliability on the self-reported responses by the pregnant women.

In conclusion, COVID-19 vaccination was widely accepted among our study population, in contrast to previously reported data. Western Australia has demonstrated a high uptake of the vaccination across all age, social, religious, and ethnic groups attending our center. There were minimally reported and mild side effects due to the vaccine. In the exploration of women's attitudes, safety concerns led to vaccine hesitancy. Optimizing the uptake rate remains a priority for this vulnerable cohort to improve maternal and neonatal outcomes. The information gained from this study can be used to encourage hesitant women by providing the positive data. The discrepancy in information provided between the groups may indicate a need to address cultural competency among staff, furthering staff education, and ensuring a diverse workforce. Further studies examining such interventions are warranted to confirm the influence of these strategies on the vaccine uptake among pregnant women.

Abstract

Background: Increasing opioid and other substance use has led to a crisis of epidemic proportions, with substance use now recognized as a leading cause of maternal morbidity and mortality in the United States. Interventions will only be effective if those who would benefit are identified early and connected to care. Apps are a ubiquitous source of pregnancy information, but their utility as a platform for evaluating substance use during pregnancy is unknown.

Objective: This study aims to explore the usability and acceptability of a pregnancy app for opioid and other substance use screening and education.

Methods: This mixed methods, exploratory pilot study examined adult pregnant people with a history of substance use who were recruited from outpatient and inpatient settings at a tertiary care obstetric hospital. After completing a baseline survey collecting demographics, substance use, and technology use, participants accessed an existing pregnancy support app for 4 weeks. Qualitative methods were used to measure the acceptability of embedding substance use screening, education, and information within the tool. App use frequency and access to substance use educational content and treatment referral information were evaluated.

Results: The 28 female participants had a mean (SD) age of 31 (0.46) years; most were White (21/28, 75%) and Medicaid insured (26/28, 93%), with an annual household income of <US $30,000 (16/28, 57%). The mean gestational age at enrollment was 22 weeks. Almost half (13/28, 46%) were taking medication for opioid use disorder (methadone or buprenorphine). Other substances used included tobacco (22/28, 79%), marijuana (20/28, 71%), illicit opioids (9/28, 32%), alcohol (6/28, 21%), and stimulants (4/28, 14%), including cocaine, amphetamines, and benzodiazepines (2/28, 7%). Most (19/28, 68%) reported previously using one or more prenatal apps and 11% (3/28) cited prenatal apps as their most frequently used source of pregnancy information. After approximately 4 weeks of app exposure, 71% (20/28) logged in at least weekly, 89% (25/28) were satisfied with the app, and 96% (27/28) reported that the app was a helpful source of support. In cognitive interviews, participants reported that app-based disclosure of substance use could be easier than disclosing in person due to reduced stigma. However, participants expressed concerns about not knowing who would have access to this information.

Conclusions: Incorporating substance use supports into a pregnancy app was found to be acceptable among those using substances. Participants reported frequent baseline use of prenatal apps, showed a high level of engagement with the pregnancy app during the study, and demonstrated interest in expanding the substance use support elements of this app. Embedding substance use screening, information, and connection to care into a tool with wide-scale use during pregnancy has the potential to identify at-risk individuals who may otherwise not be identified during routine prenatal care. It also has the potential to connect individuals, who might otherwise be hesitant to disclose their substance use, to recovery or harm reduction resources.

Introduction

Substance use during pregnancy has increased significantly over the past two decades [1-4], with almost 3% of pregnant people having a formal substance use disorder diagnosis [5]. Opioid use disorder during pregnancy has more than quadrupled in the past 20 years and is now a leading cause of maternal death in the United States [6-12]. Observed rates of other substance use during pregnancy have also increased in recent years, including cannabis, alcohol, sedatives, and stimulants. Actual numbers may be higher due to lack of reporting [5]. Additionally, concurrent substance use, such as marijuana use paired with opioid use, can further increase the risk of preterm birth and low birth weight infants [13] and may impact infant development and longer-term learning, memory, and impulsivity [10,11]. This increase in the prevalence of substance use is concerning and suggests an increased need for effective screening and resource provision to pregnant people.

Early identification and intervention are critical for reducing adverse maternal and neonatal outcomes associated with substance use [14]. As a result, major professional organizations, including the American College of Obstetricians and Gynecologists, recommend that all pregnant people be verbally screened for substance use with a validated tool at least once during pregnancy [15,16]. Despite this, 20% - 30% of obstetric providers do not routinely screen for substance use, and less than half routinely refer patients with a positive screen to substance use treatment resources [17,18]. Moreover, due to stigma, judgment, and fear of mandated reporting requirements, many pregnant people are hesitant or choose not to disclose substance use to their health care providers [12,19-21]. In a study of 422 pregnant people who presented for their first obstetric appointment, 46% of those who had a urine drug test positive for a nonprescribed substance chose to not disclose their substance use when verbally screened by their provider [22].

Mobile health (mHealth) technology has been successfully used to evaluate and deliver interventions related to tobacco, alcohol, and illicit substances, including opioid use, in nonpregnant populations [23-25]. In a study evaluating interest in using digital platforms to monitor recovery trajectories among 259 patients in substance use treatment, 70% of participants expressed interest in using a relapse prevention app [26]. Additionally, a study of 202 individuals using a recovery support app demonstrated high levels of usage of the app and articulated that further expanding the app to provide additional recovery-related resources could increase the likelihood of continuing to use the app in the future [27]. Further, in an evaluation of 316 patients engaged in a Veteran's Affairs (VA) substance use treatment program, more substance use was disclosed through an indirect method (self-completed questionnaire), as opposed to a direct method (verbal disclosure), suggesting that creating an accessible space for indirect disclosure may be beneficial for people who use substances [28].

Pregnancy apps are a common information source used by patients during pregnancy and allow for intimate, self-guided touchpoints for those seeking health-related resources, guidance, and information outside of clinical care settings [29,30]. As such, the American College of Obstetricians and Gynecologists supports mHealth as a suitable means for supplementing obstetric health care [31]. Due to their frequent use, mHealth tools may be an additional way to identify patients who are unwilling to disclose their substance use in traditional, in-person health care settings by mitigating stigma and bias associated with in-person substance use evaluations [29,32].

The purpose of this study was to explore the usability and acceptability of an existing prenatal mHealth app, MyHealthyPregnancy, as a tool in which substance use screening, education, and information could be provided as part of routine prenatal care among pregnant people with substance use. For an mHealth app to be acceptable, the patient population of interest must generally engage with mobile technology during their pregnancy, demonstrate interest in accessing information from the app, and importantly, trust the app as a setting for substance use disclosure [33-36]. Therefore, the specific objectives of this study were to understand, among pregnant people with a history of opioid or other addictive substance use, (1) general technology and mobile app usage, (2) willingness to disclose substance use through a pregnancy app, (3) interest in obtaining substance use education and information through a prenatal app, and (4) perspectives regarding how a pregnancy app could assist with substance use–related needs.

Methods

Study Sample

From April to August 2021, we conducted a mixed methods, exploratory pilot study to understand the usability and acceptability of a prenatal support app for substance use screening, education, and information during pregnancy. Pregnant people with substance use were recruited from inpatient and outpatient settings at an academic, tertiary care women's hospital including prenatal clinics, substance use treatment programs, and inpatient antepartum hospital units. Participants were eligible if they were pregnant, at least 18 years of age, less than 37 weeks gestation, had regular access to a smartphone (Android or iOS), and had a history of substance use during or within 3 months prior to their pregnancy, as determined through either self-report, *ICD-10* (*International Classification of Diseases, Tenth Revision*) diagnoses coding cord or evidence of substance use on urine drug testing in the electronic health record. In prior research, a sample size of approximately 30 participants has been determined to be sufficient to understand app usability and acceptability [37].

Ethical Considerations

The study was reviewed by the University of Pittsburgh institutional review board (STUDY18120026). Participants provided written informed consent. All audio and transcribed materials were stored on a secure, password- and firewall-protected university network drive or server, and all data were deidentified prior to analysis. Participants received US $25 for their participation in this study.

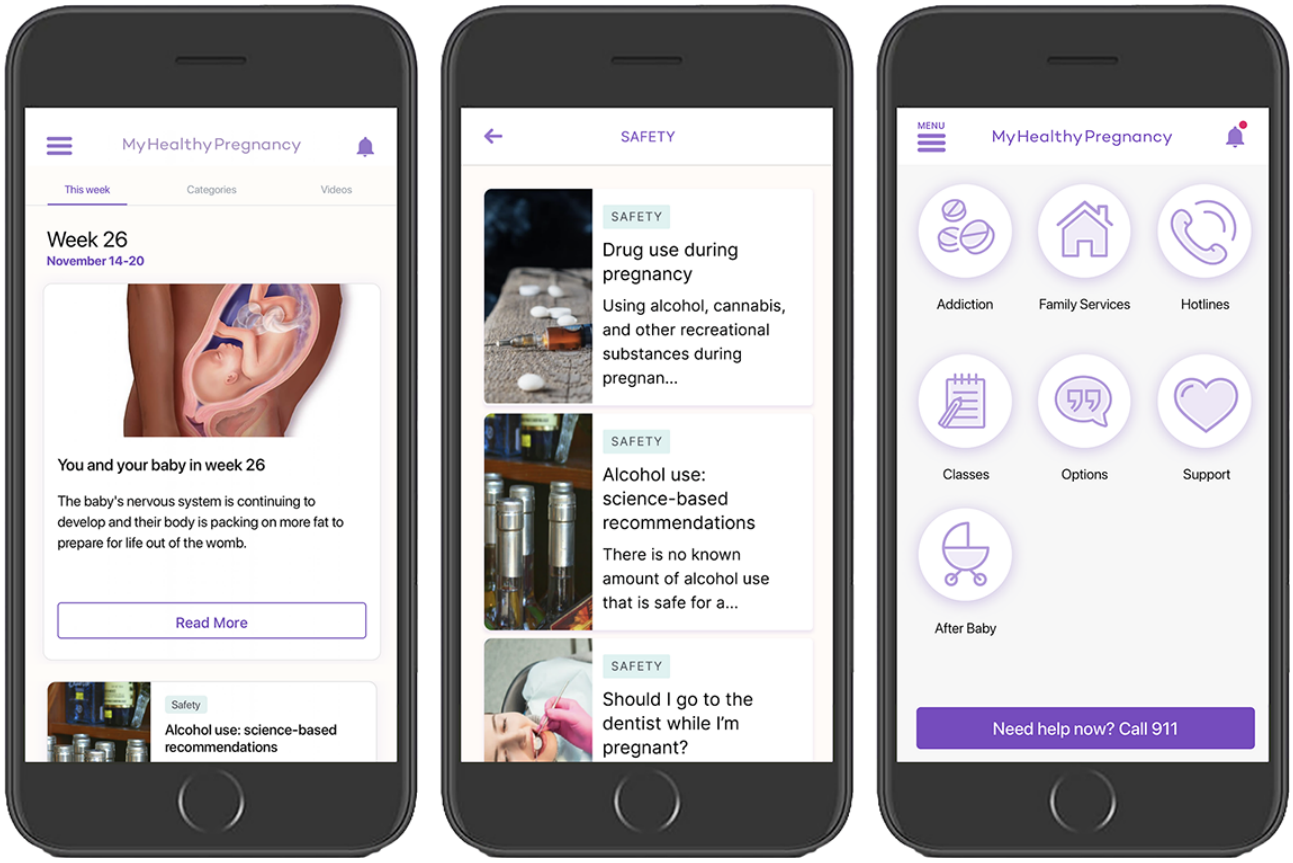
MyHealthyPregnancy mHealth App

The MyHealthyPregnancy app is a pregnancy mHealth tool that offers evidence-based, prenatal educational content organized by the user's weeks of gestation, a diary to document the user's pregnancy experiences, a fetal movement counter, a contraction timer, and routine screenings for symptoms and psychosocial risks. The app also functions as a risk assessment tool that may use patient-entered data (eg, symptoms, language, mood, sleep, and psychosocial screeners) to identify possible risks during pregnancy (eg, intimate partner violence, depression, and pre-eclampsia) and resources tailored to the risks identified. When users start the onboarding process to begin using the app, they are asked, "Do you currently use any of the following?" for various substances, including alcohol, tobacco (and vaping), marijuana, narcotics or opioids, heroin or fentanyl, benzodiazepines, cocaine or amphetamines, and other drugs. Depending on the substance disclosed, the user will be directed to substance-specific local, regional, and national recovery resources.

Educational content about substance use (eg, content regarding the risks of substance use during pregnancy, information on substance use treatment resources) is accessible to users through the app's "Learning Center" and "Resources" sections. These resources and articles were designed, in collaboration with clinical experts, to offer the same information as would be provided in routine prenatal care if substance use was disclosed to a provider. MyHealthyPregnancy was launched for beta-test evaluation at the University of Pittsburgh Medical Center health system in September 2019, with research demonstrating its effectiveness as a complementary tool to prenatal care [38-42].

Study Procedures



After signing a written informed consent, participants completed a baseline survey assessing demographics, substance use, pregnancy history, and technology and app use behaviors (Multimedia Appendix 1). Research staff then assisted participants with downloading the app on their smartphones and provided an overview of the sections of the MyHealthyPregnancy app before having participants self-navigate through the app on their phones. At this time, participants additionally consented to the sharing of identifiable data for research purposes and the publication of anonymized aggregate data through the app. Figure 1 shows sample screens from the app.

After navigating through each section of the app, research staff asked participants to relay their thoughts regarding the app and substance use–related content through a "think-aloud" technique [43-46]. Following the think-aloud sessions, participants engaged in a cognitive interview to further understand the acceptability of the app for substance screening and evaluation [47-51]. Examples of questions used during the cognitive interview included, "If you were actively using a substance, how do you think that you may feel about disclosing substance use on an app?", "How do you feel about tracking substance use–related information in an app?", and "Is there information you feel more comfortable sharing through the app compared to when you are talking directly to your provider?" Participants also completed a usability survey regarding the app's features (Multimedia Appendix 2) [52,53]. Participants were then encouraged to use the app as much or as little as they wished over the next 4 weeks.

At-home app usage was measured and transmitted through a secure HIPAA (Health Insurance Portability and Accountability Act)-compliant server to the research staff. For privacy protection, access to the app was protected by a password set up by the individual user. The password reset function required app users to provide their unique user ID and then complete instructions on resetting their password via a personalized SMS text message sent to their own, prespecified contact number. For sensitive questions embedded in the app (eg, substance use, reports of intimate partner violence), an icon was displayed that reminded users that information they shared might be transmitted to their health care provider. Participants were then recontacted by research staff by phone or in person to complete a brief follow-up survey regarding their impressions of independently using the app and any additional feedback or suggestions (Multimedia Appendix 3). The think-aloud sessions, cognitive interviews, and follow-up interviews were audio-recorded.

Data Analyses

Quantitative Analyses of Usability and Acceptability

Preliminary analyses evaluated survey and app usage data for completeness and accuracy and addressed any issues with data quality. Summary statistics were used to describe the participant characteristics, technology and mobile app use behaviors, assessments of app usability and acceptability, and participant-endorsed options for how a pregnancy app could assist with substance use. These statistics include means and standard deviations (or medians and quartiles for skewed distributions) for continuous variables and frequencies and proportions for categorical variables. Where appropriate, 95% CIs are included for means and proportions. IBM SPSS Statistics for Windows version 26 was used for quantitative statistical analysis [54].

Qualitative Analyses of Usability and Acceptability

Audio recordings from think-aloud sessions, cognitive interviews, and follow-up interviews were transcribed verbatim. Qualitative analyses were conducted using the Consolidated Framework for Implementation Research (CFIR)-based deductive analysis approach (directed content analysis), which is a rapid qualitative analytic method [53]. Prior to conducting the interviews, a preliminary codebook (in Microsoft Excel, version 16.54) was created by the research team. After the interviews were conducted, HF reviewed the transcripts using notes taken during the interviews to identify any additional codes or themes focused on understanding participants' experiences and perceptions of the app. The revised codebook was then used to code the transcripts for perspectives regarding the incorporation of substance use information in a pregnancy mHealth app.

Results

Study Sample

Over a 4-month enrollment period, 66 pregnant individuals were screened for eligibility, 24 declined to participate, and 6 did not meet study eligibility criteria. Among those that declined, the reasons provided were lack of interest in the study and limited time to attend study debriefs. Among those who did not meet the eligibility criteria, 5 participants did not have access to a smartphone due to rehabilitation facility or sober community living rules, and 1 participant was more than 37 weeks pregnant. Among the 36 participants who enrolled, 3 participants chose not to continue the study prior to using the app, 3 participants were unable to be reached for follow-up assessments, and 2 participants were found to no longer meet eligibility criteria due to fetal demise or lack of consistent access to a smartphone. Thus, 28 participants completed all study tasks and created the analytic sample.

Table 1 describes the characteristics of study participants. Most participants were White (21/28, 75%), Medicaid insured (26/28, 93%), and had an annual household income of less than US $30,000 (16/28, 57%). For 18% (5/28) of participants, this was their first pregnancy. The mean (SD) gestational age of participants at the time of enrollment was 22 (7.3) weeks. Substances used among participants consisted of tobacco (22/28, 79%), marijuana (20/28, 71%), illicit opioids (9/28, 32%),

XSL•FO
RenderX

alcohol (6/28, 21%), stimulants (4/28, 14%), including either cocaine or amphetamines, and benzodiazepines (2/28, 7%). Approximately 46% (13/28) of participants were currently taking medication for opioid use disorder (eg, methadone or buprenorphine). Some individuals (4/28, 14%) used marijuana only. All remaining participants used a combination of 2 or more substances.

Table 2 describes the technology behaviors and mobile app usage of participants. Texting (27/28, 96%) was the most commonly reported mode of communication, followed by phone (22/28, 79%), email (18/28, 64%), and social media (16/28, 57%). Health care providers (20/28, 71%) and mHealth apps (3/28, 11%) were the most frequently reported sources of pregnancy-related information followed by the internet or websites, family members, and friends. Health care providers were also noted to be the most trusted source of pregnancy-related information (27/28, 96%). mHealth apps were commonly used by participants, with 68% (19/28) reporting the use of a pregnancy app at the time of their enrollment and 26% (5/19) reporting that they used 2 or more pregnancy apps.

Table . Technology and mobile app use behaviors (n=28).

Technology use and communication during pregnancy		Values, n (%)
Source *most frequently* used for pregnancy information		
	Health care provider	20 (71)
	mHealth[a] apps	3 (11)
	Internet or websites	2 (7)
	Family members	2 (7)
	Friends	1 (4)
Source *most trusted* for accurate pregnancy information		
	Health care provider	27 (96)
	mHealth apps	1 (4)
Preferred methods of communication		
	Texting	27 (96)

Quantitative Analyses of Usability and Acceptability

Table 3 describes participants' experiences with the app. Measurements of the *usability* of the MyHealthyPregnancy app include participants' level of satisfaction with the ease of using the app and satisfaction with the time it took to use the app. Measurements of the app's *acceptability* include participants' overall satisfaction with the app, satisfaction with the interface, and how helpful the app was as a source of support. During the 4-week period, daily app use was the most common (12/28, 43%), and educational materials related to substance use were engaged with by the majority of participants (19/28, 68%). Acceptability and usability were generally high.

XSL•FO

Weekly	8 (29)
Monthly	5 (18)
Substance use resource utilization	
Participants who browsed substance use educational materials	19 (68)
Participants who accessed substance use treatment referral information	2 (7)

[a]Frequency of app logins within a 4-week period.

Participant-endorsed options for how a pregnancy app could assist with substance use–related behaviors are described in Table 4. Almost all participants (27/28, 96%) expressed a desire to use an app to block phone calls or SMS text messaging from people who had a negative effect on substance use behavior, while more than half desired the ability to track substance use, cravings, or treatment medications. The least endorsed options included information on infectious disease prevention (5/28, 18%), harm reduction (4/28, 14%), or intimate partner violence (3/28, 11%).

Table . Participant endorsed options for how a pregnancy app could assist with substance use (n=28).

Options	Values, n (%)
Blocking phone calls or SMS text messaging from people who have had a negative effect on recovery	27 (96)
Tracking incidences of substance use or cravings	19 (68)
Receiving reminders to take substance use treatment medications (eg, MOUD)[a]	16 (57)
Information about support groups for parents with substance use disorders	12 (43)
Neonatal opioid withdrawal syndrome information	9 (32)
Infectious disease prevention information	5 (18)
Harm reduction information	4 (14)
Intimate partner violence resources	3 (11)

[a]MOUD: medication for opioid use disorder (eg, methadone or buprenorphine)

Qualitative Analyses of Usability and Acceptability

In cognitive interviews, participants shared their perspectives regarding substance use disclosure through a pregnancy app and how a pregnancy app could be useful for people using substances or with a substance use disorder. Five major themes were identified from these debriefs (Table 5). Participants felt that substance use disclosure on an app may be associated with less stigma than in-person disclosure (theme 1). However, they also noted that their comfort with disclosure would vary by the type and legality of the substance (theme 2). Participants expressed concerns related to who could access substance use information (eg, health care professionals and social services providers) on a pregnancy app and concerns related to being permanently labeled as someone with an addiction (theme 3). Despite concerns, participants did believe that pregnancy apps could be a useful source of substance use information and education (theme 4) and felt that combining pregnancy and substance use information on a single app was the most desirable approach (theme 5).

XSL•FO
RenderX

Table . Participant perspectives regarding disclosure and incorporation of substance use information in a pregnancy mobile health app.

Theme	Example quote
Theme 1: Substance use disclosure on an app may be associated with less stigma than in-person disclosure	"I would feel a little more comfortable if I put it in the app than talking to an individual. The app doesn't judge you, like a human being would"
Theme 2: Disclosure comfort varies by type and legality of substance	"I definitely felt more comfortable disclosing legal drug use. For example, I do have my medical marijuana card, that is something I have no problem sharing, or alcohol and cigarettes, but yes, the non-legal ones, I would be a little nervous."
Theme 3: Concerns related to who could access disclosed substance use information	"Depending on what information I divulged, what would happen to that information? For example, would that be sent to a doctor? If it would be sent to a doctor or another professional or even a social worker… even though it would be confidential, I would just be worried I'd be labeled...and I will never be able to get away from my past addiction."
Theme 4: Prenatal apps could be a useful source of substance use information, education, and resources	"For the women who have no support or anyone to talk to, I really do think it is an effective tool to give them a little bit of encouragement and accurate information or just a guide: here are some resources, here is someone you could talk to."
Theme 5: Combining pregnancy and substance use information on a single app is desired	"Having it within a pregnancy app is kind of better personally just because it is all in one place...I've had recovery apps before, and I have fallen off of them. Actually, I completely forgot about them. So, like with pregnancy and having a kid and like getting ready for stuff, the simpler the better. So, if I don't have to go to multiple apps, that is great."

Discussion

Principal Results

Opioid use and the use of other addictive or illicit substances remain a significant and growing public health crisis in the United States. One significant barrier to providing early intervention during pregnancy is identifying individuals at risk and connecting them to care in a way that feels comfortable to them and through a mechanism which is engaging. One solution to identifying and engaging with pregnant individuals using opioids and other substances is through prenatal care apps. However, reaching pregnant individuals who use substances through more holistic prenatal care apps requires that the prenatal app be engaging and that app users who use substances must be willing to share their substance use through the app and act upon the information provided to them about recovery.

In this mixed methods, exploratory pilot study, incorporating substance use screening, information, education, and support into an existing prenatal app was found to be acceptable among pregnant people with substance use. Overall, participants showed high levels of interest in and engagement with MyHealthyPregnancy. Moreover, they reported being generally supportive of using an mHealth app as a means to access nonjudgmental resources for substance use during pregnancy. Our findings also indicate that there are multiple ways that an app could support individuals who use substances including blocking phone calls or SMS text messaging, providing information about recovery-oriented support groups, and offering resources regarding common co-occurring conditions (infectious disease acquisition, intimate partner violence, and harm reduction) [55].

Consistent with prior research demonstrating a high level of mHealth app usage among pregnant people (greater than 50%), most participants (19/28, 68%) reported that they had already used a prenatal app before starting the study, with some participants reporting the use of multiple prenatal apps [30,56-58]. In our study, apps were also identified, more generally, as a trustworthy, and easy-to-access source of pregnancy-related information, second only to health care providers. This aligns with other research findings demonstrating pregnant patients' appreciation for the accessibility and reliability of information found in prenatal apps [59]. Our study demonstrated a high level of engagement with our prenatal app, with 71% (20/28) logging in on a daily or weekly basis, similar to engagement levels that are considered high among other prenatal apps[60]. Together these findings suggest that a prenatal app-based intervention could be a beneficial strategy for information sharing between pregnant people who use substances and their providers, as this population already engages with and trusts this type of technology.

Our findings also indicate a high level of acceptability with incorporating substance use–related information into a pregnancy app. App usage data indicated that many participants browsed recovery-related educational materials on the app. These data align with other research demonstrating that people generally do not like moving between different apps to achieve their goals and prefer integrated technology tools, as well as prior findings showing that substance use screening and intervention in an app-based format has high acceptability and usability among patients [61,62]. Our participants expressed their interest in an expansion of substance use support capacity of the prenatal app, in alignment with prior research demonstrating that mHealth interventions are effective in areas including smoking cessation and addressing substance use during pregnancy[63]. Finally, many participants volunteered that disclosing substance use on an app may be easier than disclosing substance use in person, aligning with the current literature suggesting that self-report questionnaires and eHealth screenings could assist in creating more opportunities for disclosure than in-person evaluations alone [28,29,64].

XSL•FO
RenderX

However, many participants expressed concerns about disclosing substance use on an app because they would not know who might have access to this information, similar to prior research demonstrating patient concern about data security even in general prenatal apps [58]. Concerns about prosecution and child welfare involvement are previously reported barriers to substance use disclosure, which can lead to delays in seeking prenatal care and engaging in substance use treatment [65,66]. Mandatory reporting laws and the potential for child protective services involvement are major barriers to seeking treatment among pregnant people with opioid use disorder [67]. Any app that collects sensitive patient health information is required to comply with HIPAA. Moreover, any app that offers a substance use disorder treatment service must comply with the Opioid Addiction Recovery Fraud Prevention Act of 2018, which requires transparent and fair practices around how private health information is shared [68]. However, concerns about seeking and engaging in substance use treatment during pregnancy legitimately extend to disclosure and substance use treatment seeking through digital health means. In prior qualitative research, parents note that mandatory reporting regulations are biased, unjust, and stigmatizing and assert that stress stemming from the potential involvement of child welfare agencies has had a pronounced and detrimental impact on their families [67,69,70]. Moreover, since the 2022 *Dobbs v. Jackson* Supreme Court decision that ended federal protections for abortion, there have been increasing reports of digital health data being subpoenaed to criminalize pregnant individuals, further legitimizing caution around disclosure of certain health behaviors, especially during pregnancy [71,72].

Given both the concerns and interest voiced by our participants regarding embedding substance use screening and connection to care into a prenatal app, providers should familiarize themselves with any prenatal or substance use support apps available to patients prior to recommending them, including evaluating the evidence base, equity focus, and HIPAA protections afforded to such tools [73]. We additionally suggest that any providers discussing such apps with patients also educate patients about their rights and privacy related to disclosing substance use or other sensitive information in these apps. Providers can also encourage patients to share feedback about which apps they have found useful (or not) to support provider recommendations.

Limitations

There were several study limitations. First, approximately 36% (24/66) of those approached for study participation declined to enroll. Because many of those who declined to participate lacked interest in study participation, our sample may have been biased toward those who are more willing to use mHealth technology for health engagement or toward those with fewer reservations about disclosing substance use. In addition, all participants enrolled in the study had a known history of substance use. As such, their behaviors and perspectives may not be generalizable to pregnant people who have never disclosed their substance use within a health care setting. Next, our study sample was small and consisted of predominantly non-Hispanic White individuals, which limits the degree to which we can generalize our findings. Opioid overdose rates among Black individuals exceed those of White individuals by 4-6 times, and there are significant disparities in the receipt and use of medication for opioid use disorder between non-Hispanic White and Black and Hispanic pregnant individuals [74,75]. Thus, our findings cannot be generalized to those who may be at highest risk of not receiving adequate care. While the sample size for this exploratory pilot study was aligned with norms for thematic saturation for qualitative interview feedback to offer initial data on acceptability, a larger randomized trial with intentional demographic sampling would be required to adequately test implementation or intervention effects of incorporating substance use screening and content into the mHealth tool [76-78].

Conclusions

In this study, pregnant people with substance use found an existing pregnancy app to be an acceptable means of incorporating substance use supports and screening. Participants were already frequent users of prenatal apps and showed a high level of engagement with the prenatal support app in the study. At the completion of the study, participants expressed positive feelings about the usability of the app and interest in expanding the of the substance use support features of this app although some notable concerns relating to data privacy were raised. Given the prevalence of technology and app usage among pregnant people and the rise in substance use during pregnancy, mHealth technology should be considered a complement to in-person prenatal substance use screening and evaluation. Providing opportunities for substance use disclosure and resource provision through an acceptable digital platform that people are already using for pregnancy could result in earlier treatment engagement, along with improved outcomes among those who use substances. Our findings highlight this as an acceptable and desirable approach.

There is an ethical imperative for any prenatal app incorporating substance use–related content to clearly communicate both the confidentiality constraints of the tool and the potential consequences of disclosure prior to screening. As a way to address app users' concerns, developers should consider designing data collection so that any sensitive data are deleted as soon as possible or are only stored locally and not in a location that could be at risk of subpoena. App developers should also be sure to communicate clearly to app users about privacy and seek active consent for the collection or storage of any sensitive data. Finally, app developers should consider instating a policy prohibiting engagement in third-party data sharing, with the exception of HIPAA-compliant data sharing with the health care provider. Policy makers should ensure clear communication with providers about their rights related to substance use disclosure during pregnancy and potential legal repercussions. Health care providers considering using pregnancy apps, particularly for substance use screening or treatment referral, should evaluate whether the apps are evidence-based and adherent to strict policies around data protections. This may include being proactive about self-education regarding HIPAA privacy rules, as well as the state and institutional protections in place, so that they can communicate these clearly to their patients when recommending that patients share sensitive information through these tools.

XSL•FO
RenderX

Lastly, additional research is needed to prospectively evaluate and test patient-centered substance use screening and connection to recovery resources within pregnancy apps, as well as to understand and measure the rates of disclosure rates across substances. We recommend that any individuals involved in the development, use, or evaluation of pregnancy tools, which may provide these services, draw on established frameworks that center the needs and values of the target population, while proactively addressing health disparities as a strategy to advance health equity and improve health outcomes [73]. Through a personalized approach to health care, prenatal health apps can play a role in identifying and supporting pregnant people with substance use.

Abstract

Background: Offering contraceptive methods at pharmacies without a prescription is an innovative solution to reduce the incidence of unintended pregnancies among adolescents and young adults (AYA). Pharmacy-prescribed contraception may increase the convenience, simplicity, and affordability of contraceptives.

Objective: The aim of this study was to develop, pilot test, and evaluate the acceptability and feasibility of a telemedicine electronic platform app simulating pharmacist prescribing of contraceptives to AYA as well as assess agreement between pharmacist-simulated contraceptive approvals and contraception as prescribed in routine clinic visits.

Methods: This study was conducted in two phases: (1) development and usability testing of a prototype app to simulate pharmacists prescribing contraceptives to AYA and (2) pilot testing the app in a simulation for AYA requesting contraception from a pharmacist with pharmacist review and request approval or rejection. Eligibility criteria in both phases included the following: assigned female sex at birth, age 15-21 years, seeking contraceptive services at an academic adolescent medicine clinic, prior history of or intention to have penile-vaginal intercourse in the next 12 months, smartphone ownership, and English language proficiency. Phase 1 (usability) involved a video-recorded “think aloud” interview to share feedback and technical issues while using the app prototype on a smartphone and the completion of sociodemographic, sexual history, and perception of the prototype surveys to further develop the app. Phase 2 (pilot) participants completed phase 1 surveys, tested the updated app in a simulation, and shared their experiences in an audio-recorded interview. Descriptive analyses were conducted for quantitative survey data, and thematic analyses were used for interview transcripts.

Results: Of the 22 participants, 10 completed usability testing, with a mean age of 16.9 (SD 1.97) years, and 12 completed pilot testing, with a mean age of 18.25 (SD 1.48) years. Three issues with the prototype were identified during “think aloud” interviews: challenges in comprehension of medical language, prototype glitches, and graphic design suggestions for engagement. Usability testing guided the frontend and backend creation of the platform. Overall, participants agreed or strongly agreed that using an app to receive contraceptives would make it easier for teens to access (n=19, 86%) and make contraceptive use less stigmatizing (n=19, 86%). In addition, participants agreed that receiving contraception prescriptions from a pharmacist without a clinic visit would be safe (n=18, 82%), convenient (n=19, 86%), acceptable (n=18, 82%), and easy (n=18, 82%). Pharmacists and medical providers had 100% agreement on the prescribed contraceptive method for pilot participants.

XSL•FO
RenderX

Conclusions: AYA found contraceptive prescription by a pharmacist via an app to be highly acceptable and provided critical feedback to improve the design and delivery of the app. Additionally, pharmacist contraceptive approvals and contraception as prescribed in routine clinic visits were identical.

Introduction

Pregnancy rates among adolescents and young adults (AYA) 15-19 years old have dropped from 61.8 births per 1000 in 1991 to 13.5 in 2022, while AYA 20-24 years old reported a record low pregnancy rate of 60.4 births per 1000 [1]. For 2010-2019, pregnancy rates declined the most for youth 19 years old and younger, a 50% decrease, followed by a 29% drop for 20-24 year olds [2]. Evidence suggests the decline in pregnancy rates may be attributed to increased access to comprehensive sex education, use of contraceptives and health care, and not due to decreased sexual activity [3]. However, sexually active AYA, aged 15-24 years, were the most likely age group to experience unintended pregnancies in the United States [2,4]. Despite evidence showing the value of access to sex education and contraceptive services in reducing pregnancy rates among AYA, laws restricting access to both are increasingly being introduced and passed in US state legislatures. Legal restrictions intensify barriers, such as cost, attending appointments, stigma, and more to accessing contraceptives [5,6], which disproportionately affects low-income, disabled, racial or ethnic minorities, and other marginalized women and other birthing people [7]. Pharmacist-prescribed contraception—a strategy already used in high-income and many low- and middle-income countries but rarely in the United States—is one such strategy. In 2019, the American College of Obstetricians and Gynecologists recommended pharmacist-prescribed contraception without age restrictions as a necessary step to increase over-the-counter access to hormonal contraception and reduce the rate of inconsistent or nonuse of contraception [8].

In prior research, women and other birthing people voiced “convenience, simplicity, [and] affordability” as primary benefits of pharmacist-prescribed contraception [9]. In a study in California among 426 women and other birthing people, pharmacy access for emergency hormonal contraceptive (EHC) was preferred to clinician prescription as it was perceived to be faster (54%) and more convenient (47%) than seeking physician prescription [10]. Another study found that 68% of women who were at risk for unintended pregnancy reported they would prefer to obtain the contraceptive pill, patch, ring, or EHC from a pharmacy rather than a clinic if pharmacist prescribing was an option [9]. Moreover, 41% of those not currently using contraception reported they would start a contraceptive method via pharmacist prescribing if available [10]. Provision of EHC via community pharmacies has increased the use of EHCs; moreover, expanding access in this way is estimated to prevent almost half (1.3 million) of the 3 million unintended pregnancies annually [11]. Centering patient priorities for access, as well as patient preferences for method choice, is a key tenet of reproductive justice and high-quality contraceptive care.

Historically, women and other birthing peoples’ safety has been the most common concern regarding contraception delivery without a clinician-provided prescription [9]. However, multiple studies demonstrate that patients can accurately self-screen for contraindications to contraceptive use using medical checklists [12,13]. One study found greater than 93% of 328 patient-physician concordance for risk factor identification [12]. In another study, self-screening by patients using a medical checklist of contraindications was found to have greater sensitivity (83.2%) and specificity (88.8%) than a patient self-completed clinician questionnaire, which asked them to simply consider their medical history to determine the presence of contraindications (56.2% sensitivity; 57.6% specificity) [13]. This means when using a medical checklist of contraindications, women were able to accurately self-screen for contraindications to combined hormonal contraception [13]. Given the consistency of evidence supporting patient ability to medical self-screen for contraceptive contraindications, the American College of Obstetricians and Gynecologists endorses patient use of self-screening tools to determine eligibility for over-the-counter access to hormonal contraception [8].

Pharmacist-prescribed contraception innovations will need to develop strategies for successful implementation prior to widespread scaling [14]. Implementing screening tools has proved challenging for non-sexual health services for select populations, like youth [14]. Developing outreach strategies for youth and other vulnerable populations may require careful consideration. Attention to the training of point-of-service staff may facilitate service delivery and uptake. Studies of pharmacy staff indicate greater hesitancy and a desire for more intense training before providing sexual health services compared to non-sexual health services [15]. Attention to training and post-training support services may be necessary to ease implementation challenges. Newer technologies, like telemedicine, that allow skilled providers to deliver services across a distance may be valuable in bridging this gap until larger numbers of pharmacists are comfortable delivering pharmacist-prescribed sexual health services. Combining innovations such as telehealth and pyxis machines can allow pharmacists who are trained and comfortable providing sexual health services to AYA to do so.

There is limited research on pharmacist-prescribed contraception for US adolescents [4]. This study sought to develop an e-platform app called Birth Control Pass (BCPass) to simulate

XSL•FO
RenderX

pharmacists prescribing contraceptives to AYA, test the acceptability and feasibility of pharmacist-delivered contraception among AYA as a proof of concept, and determine the concordance between pharmacists and providers on the appropriate contraceptive method(s) to be prescribed to participants.

Methods

Overview

This study occurred in 2 phases. In Phase I, the e-platform was developed, and participants were recruited to engage in usability testing. In Phase 2, participants pilot-tested the e-platform.

Participants and Setting

Eligible participants for both study phases were patients seeking contraceptive initiation services at a subspecialty academic adolescent medicine clinic, ages 15-21 years old, assigned female sex at birth, with a prior history of or intention to have penile-vaginal intercourse in the next 12 months, owned a smartphone and could read and speak English. Usability testing of the prototype was completed in April of 2021. Modifications were made to the app to address participants' concerns and implement suggestions through iterative usability testing between developers and the study team. Pilot testing of the final prototype occurred between October 2021 and August 2022.

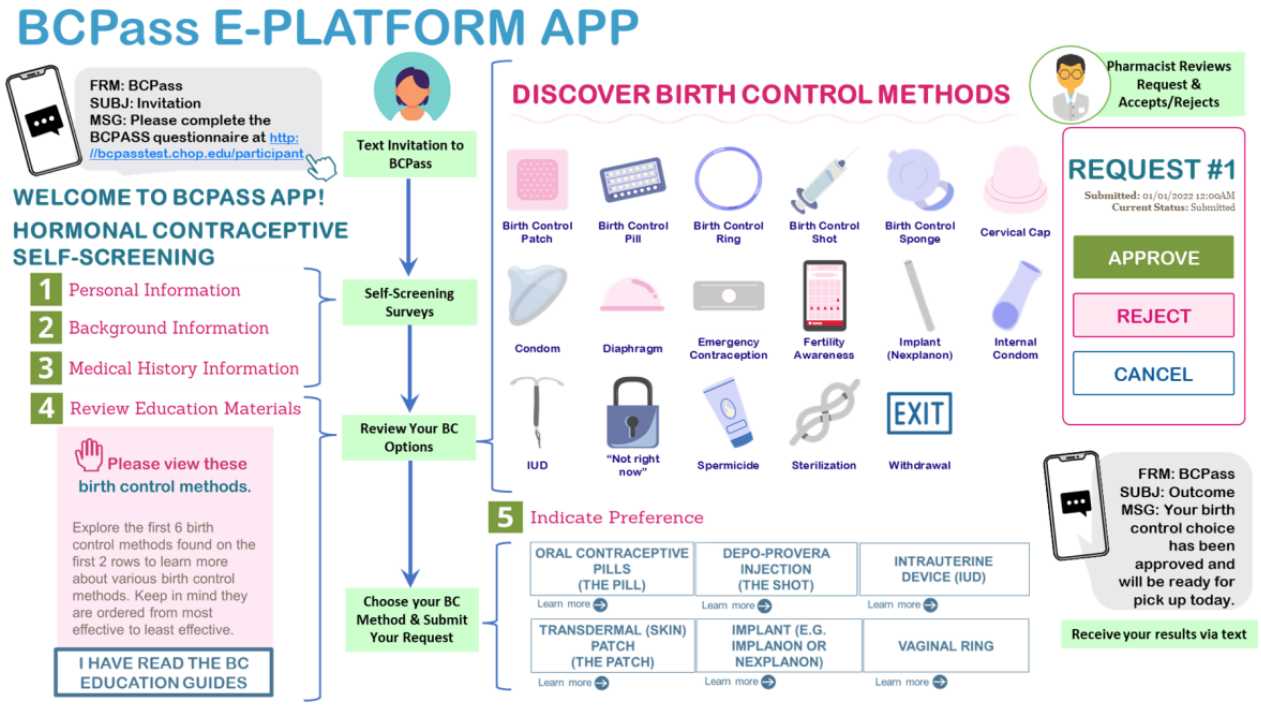
Ethical Considerations

Institutional Review Board approval was granted by the Children's Hospital of Philadelphia (20-017957). Participants received a $20 US gift card for their time and effort. Precautions were taken to secure participants' personal information to ensure confidentiality including, the use of study identification numbers that were assigned to participants and used in place of participants' name and other private information on data collection forms.

Recruitment Strategy

For both study phases, the study team reviewed clinic schedules daily to identify patients with contraceptive appointments on the same day or the following clinic day. Clinic staff also referred patients for recruitment. Patients were approached in person at their medical appointment, by phone call, or via SMS text message. Consent was obtained via wet-ink signature on paper forms or electronic consent (e-consent) on Children's Hospital of Philadelphia's Research Electronic Data Capture (REDCap) [16,17] data collection application. Consent was provided either by legal guardians who attended clinic visits with patients 17 years old and younger or by the patients themselves, who were legally eligible to consent for themselves if they attended clinic visits alone [18] or were older than 18 years old. Participants were informed that by engaging in the research study, they would be testing the e-platform interface that simulated pharmacist prescribing but that they would not receive contraception as part of the study activities. Participants understood that contraception would be provided by their clinician during their scheduled medical visit, as per usual clinical care guidelines. Participants engaged with the e-platform either before or after their scheduled medical visit.

Study Procedures



Phase 1: Development and Usability Testing

We created the BCPass prototype by modifying a large pediatric hospital system's app for employee COVID symptom check-in. The goal of the prototype was to simulate patient medical screening, patient contraceptive choice, and pharmacist contraceptive prescribing. The prototype first collected contact and self-screening information related to background and medical history. Next, participants were instructed to review content about contraceptive methods using a direct link to the educational website bedsider.org [19] and indicate their preferred method. Responses on the self-screening form were linked directly to medical contraindications to contraceptive prescribing per the Centers for Disease Control and Prevention US Medical Eligibility Criteria to facilitate rapid prescribing decision-making [20]. The prototype app included only a front-end interface for usability testing participants, but there was no backend personal health information data storage or pharmacist involvement. The study team explained to participants how the final app would work, including that if the participant had questions during the simulation, they had the option to call a pharmacist via the app ("Ask a Pharmacist" call button). Additionally, once the request for the preferred contraceptive method was submitted, a pharmacist would review and complete a "Pharmacist Approval Assessment Form" indicating if they would prescribe the contraceptive and approve dispensing or reject the request.

Participants completed web-based multiple-choice and short-answer surveys regarding their sociodemographic, sexual history, and attitudes regarding pharmacist-prescribed and app-delivered contraception. Next, they tested the prototype in a video-recorded "think aloud" interview [21], capturing the participants' initial impressions of the prototype, technical issues, and feedback while they actively engaged with the app prototype on their own smartphones. Studies using the "think aloud" methodology have proven to be successful at identifying usability problems without requiring a large number of subjects [21]. Participants were prompted to remark on ease of use, design aspects that are confusing or that slow task completion, and graphical elements, such as font size, ratios of images to words, and color schemes. The study team observed this process and took structured notes to capture information regarding domains from the sociotechnical model to ensure the optimization of service delivery [22]. Following prototype testing, participants' attitudes toward receiving contraception from a pharmacist and an app were assessed on a 5-point Likert scale: 1=strongly disagree, 2=disagree, 3=unsure, 4=agree, and 5=strongly agree. A 7-point Likert scale was used to evaluate the usefulness, ease of use, effectiveness, reliability, and satisfaction with the prototype (1=strongly disagree, 2=disagree, 3=somewhat disagree, 4=neither agree nor disagree, 5=somewhat agree, 6=agree, 7=strongly agree). Analyzed usability testing data was presented to the study team and app developers to inform the development of the app frontend and backend, along with iterative testing and weekly meetings (Figure 1). Special care was taken to thoroughly test each "click" on the app, and automated messages were reviewed to ensure ease of access and fluidity.

Figure 1. Birth Control Pass (BCPass) e-platform app overview. Overview of the BCPass app, invite link, participant-entered information, education information review [19], preferred contraception option, and the pharmacist review and outcome. "Discover Birth Control Methods" was adapted from the bedsider.org birth control dashboard webpage [19].

Phase 2: Pilot Testing

Once a fully functional app was developed, a study pharmacist was trained to implement the study protocol, and AYAs were recruited to pilot test the intervention. Pilot participants completed web-based surveys regarding their sociodemographic, sexual history, and attitudes toward receiving contraception from an app and a pharmacist. Next, participants completed a simulation exercise, which included completing a medical history form to identify contraindications to contraception, learning about contraceptive options via bedside.org [19], and selecting a contraceptive method. As part of the simulation, a text or email was sent to their smartphone with a link to the app. After they submitted their request for a contraceptive method, the study pharmacist accessed the request on the backend to review and complete the "Pharmacist Approval Assessment Form." Participants then received an automated SMS text message to confirm if the pharmacist accepted (prescribed the contraceptive and approved dispensing), rejected (shared information to call the clinic that provides contraceptive care), or requested additional information (when participants requested methods unavailable for pharmacist prescribing, such as long-acting reversible contraceptives and injectable medroxyprogesterone acetate).

Following the simulation, pilot participants completed a web-based survey to evaluate the usefulness, ease of use, effectiveness, reliability, and satisfaction on 5-point and 7-point Likert scales. Participants then engaged in a brief audio-recorded interview that solicited feedback on the app and participants' decision-making process in selecting a contraceptive method. After participants completed their clinic visit, the contraceptive method prescribed during their routine appointment was abstracted from their electronic medical record.

Analysis

Data analysis was conducted at two time points following phase 1 and phase 2, respectively. Deidentified survey demographics, sexual history, and Likert responses were exported from REDCap to Microsoft Excel for analysis. Descriptive analysis was computed for demographics and sexual history (proportions), and mean score and standard deviation were calculated for Likert questions. Audio from the "think aloud" video interview (usability) and feedback interview (pilot) were transcribed and manually coded by two coders until a 95% agreement regarding the themes was reached. For usability testing, participant comments and suggestions were categorized based on the type of modifications needed to the app (ie, wireframe, self-screening comprehension, and graphics). Interview data from the pilot testing was similarly thematically coded to reflect perceptions about the app's effectiveness, acceptability, feasibility, and participants' contraceptive decision-making. Effectiveness was defined as the e-platform success in simulating a birth control prescription. Acceptability or satisfaction with the e-platform was defined as participants' perceptions when using BCPass. Feasibility (BCPass practicality for learning about and accessing birth control) was defined by BCPass's usability or ease of use in navigating the e-platform and submitting a request for birth control. Lastly, birth control decision-making was based on participants' considerations made when indicating their birth control preference before and after using BCPass. Using the codebook, two coders not involved in usability qualitative analysis (one assisted with e-platform modifications and data collection, and the other helped with qualitative analysis only) classified statements in each thematic

XSL•FO
RenderX

area as positive, neutral, or negative. Finally, we assessed concordance between the contraceptive method selected at the medical visit (electronic medical record data) and the pharmacists' decision to approve or reject the participant's request for a contraceptive method.

Results

Participant Characteristics

In total, 22 AYA participated: 10 in phase 1 (usability testing) and 12 in phase 2 (pilot testing). On average, participants were 17.64 (1.50) years old, had some high school education (n=13), graduated from high school (n=4) or had some college (n=5), and had previously used contraception (n=17). See Table 1 for participant demographics and sexual history.

Unknown	0 (0)	1 (8)	1 (4)

[a]Race or ethnicity was not self-reported by usability participants in this phase of the study. Electronic medical record race and ethnicity data is not self-reported and may misidentify participants. Therefore, this study only reports self-reported information collected during the pilot testing phase.

XSL•FO
RenderX

[b]Due to rounding, some totals may not correspond with the sum of the separate figures.

[c]Participants were only asked about their frequency of condom use if they answered yes to using condoms during sex. Participants could have responded yes to ever using condoms, but they may not currently be using them.

Quantitative Survey: Acceptability and Feasibility of Pharmacist- and App-Delivered Contraception

Pharmacist-Prescribed Contraceptives

Usability and pilot participants (N=22) agreed receiving a contraceptive prescription from a pharmacist without a clinic visit would be safe (mean 4.27, SD 0.88), convenient (mean 4.50, SD 0.74), easy (mean 4.32, SD 0.89), and acceptable (mean 4.27, SD 1.08; Table 2). If they had the option to receive contraception from a pharmacist without a clinic visit, 14 of 22 participants reported they were likely or very likely to do so.

Table 2. Perceptions of pharmacist and app-delivered contraception (N=22, Likert Scale 1-5).

	Mean (SD)
Safety, convenience, acceptability, and ease receiving birth control	
Getting birth control prescribed by a pharmacist would be safe	4.27 (0.88)
Getting birth control from a pharmacist would be convenient	4.50 (0.74)
Getting birth control from a pharmacist would be acceptable to me	4.27 (1.08)
I think it would be easy to receive birth control from a pharmacist	4.32 (0.89)
Getting birth control from an app would be safe	3.82 (1.14)
Getting birth control from an app would be convenient	4.45 (1.01)
Getting birth control from an app would be acceptable to me	3.95 (1.17)
I think it would be easy to use an app to get birth control	4.36 (1.00)
Advantages of using an app to receive birth control	
It would be easier for teenagers to get oral contraceptives	4.55 (0.74)
It would feel less embarrassing	4.27 (0.98)
It is less stigmatizing, meaning more normal to use	4.45 (0.86)
Fewer teenagers would get pregnant	4.32 (0.99)
It would be more confidential	3.82 (1.30)
Disadvantages of using an app to receive birth control	
Teenagers might not use condoms to protect against sexually transmitted diseases	3.91 (0.87)
Teenagers need a doctor to decide if oral contraceptives are safe for them	3.73 (1.12)
Teenagers might have sex at a younger age	3.14 (1.32)
Teenagers might use oral contraceptives incorrectly	3.36 (1.05)
Teenagers might not get tested for sexually transmitted diseases	3.55 (1.26)
Oral contraceptives might cost more over the counter	3.50 (0.86)
Teenagers might not talk to their parents about birth control	4.00 (0.87)
I have no worries (concerns) about teens using a medication dispensing machine to get birth control	3.09 (1.11)
Social approval	
Most people who are important to me would approve of me using an app to get birth control	3.64 (1.14)
Most teens like me would use an app to get birth control	4.27 (0.77)
Teens my age would use an app to get birth control	4.23 (0.97)
Parents or family would support me using an app to get birth control	3.32 (1.30)
My romantic partner(s) would support me using an app to get birth control	4.09 (1.06)
The decision to use an app to get birth control would be totally up to me	4.18 (1.10)
I am confident that I could use an app to get birth control	4.09 (1.19)

XSL•FO
RenderX

Receive Contraceptives Through an e-Platform App

Usability and pilot participants (N=22) agreed that receiving contraception using an app would be safe (mean 3.82, SD 1.14), convenient (mean 4.45, SD 1.01), easy (mean 4.36, SD 1.00), and acceptable (mean 3.95, SD 1.17) (Table 2). Additionally, participants were confident they would be able to use an app to get contraception (mean 4.09, SD 1.19) and agreed most teens would use an app to get contraception (mean 4.27, SD 0.77). A potential advantage recognized by participants of using an app would include fewer teenagers experiencing an unintended pregnancy (mean 4.32, SD 0.99), getting contraception would be less embarrassing (mean 4.27, SD 0.98), and less stigmatizing (mean 4.45, SD 0.86). Participants agreed a potential disadvantage of receiving birth control from an app is that it may lead teens to not talk to their parents about birth control (mean 4.00, SD 0.87) or a possible decrease in condom use and an increase in sexually transmitted infections among teens (mean 3.91, SD 0.87). See Table 2 for additional insight into participants' attitudes toward pharmacists and app-delivered contraceptives.

E-Platform App Survey Feedback

Overall feedback on the BCPass app simulation during prototype and final productive testing was positive (Table 3). Participants agreed that BCPass was simple to use (mean 6.33, SD 1.24) and pleasant to interact with (mean 6.00, SD 1.64). Additionally, participants felt the app could do everything they would want it to be able to do for contraceptive delivery (mean 6.15, SD 1.23) and agreed they would use it again (mean 6.29, SD 1.54).

Table 3. BCPass app simulation feedback (N=22, Likert scale 1-7).

	Mean (SD)
BCPass was simple to use	6.33 (1.24)
BCPass was easy to learn and use	6.43 (1.02)
I believe I could become productive quickly using BCPass	6.05 (1.51)
The way I interact with BCPass is pleasant	6.00 (1.64)
I like using BCPass	6.00 (1.44)
BCPass can do everything I would want it to be able to do	6.15 (1.23)
I would use BCPass again	6.29 (1.54)

Clinician- and Pharmacist-Prescribed Contraception Concordance

A comparison of piloting participants who indicated a contraceptive preference (n=9) and what was prescribed revealed pharmacist contraceptive decisions and contraception methods as prescribed in routine clinic visits were identical. One of the 8 participant requests was rejected by the pharmacist because of a contraindication. This participant noted in their feedback interview that they requested a method they knew was contraindicated because it was their first choice over the contraception method they were prescribed. Three participants selected "I don't know" at the end of the simulation. One remained undecided following their clinic appointment. Another selected "I don't know" because they had an IUD at the time of the study but knew their first-choice method was contraindicated. The third selected a method at their clinic appointment. Of the 12 participants, one did not attend their clinic appointment, so it is unknown what they would be prescribed.

Qualitative Feedback

Usability Testing Think Aloud Data and Resultant e-Platform App Modifications

In an analysis of usability testing phase data, participants identified modifications related to addressing prototype wireframe glitches, self-screening comprehension, educational resource engagement, and app aesthetics. The prototype's wireframe glitches were anticipated as it was designed as a temporary test environment, and once the production frontend, patient-facing screen, backend, and developer view were created, the issues were resolved.

While navigating the prototype, participants requested clarification on the medical history questionnaire, indicating comprehension concerns. For example, participants asked if the transdermal skin patch was the same patch with which they were familiar. Additionally, participants asked what constitutes prolonged immobility or a bad reaction to hormonal contraception. The study team revised any questions that were identified as confusing and may be perceived as confusing to participants' peers. Examples and lay language were used for questions that required more medical terminology, such as including the more popular names for contraceptive methods in parentheses next to the full names (ie, oral contraceptive pill ["the pill"], transdermal hormonal patch ["the patch"], and injectable medroxyprogesterone acetate ["the shot"]).

Participants' feedback on the lack of educational material and the app's aesthetics were closely associated concerns. Numerous participants noted they skipped the mandatory contraceptive method educational website, explaining they did not see the link or felt it was not important. The color palette and ambiguity of the "Ask a Pharmacist" call button and bedsider.org weblink were noted as weaknesses. The team determined adding color and images was a solution to attract participants' attention to educational materials. A welcome page was created to introduce the purpose of BCPass and provide written instructions on how to contact the study pharmacist via the "Ask a Pharmacist" call button.

XSL•FO
RenderX

Pilot Testing Interview Feedback

The following four primary themes emerged during the coding process: (1) the perceived effectiveness of the BCPass app, (2) AYA's perceptions of using BCPass (usefulness as a standalone or compared to the standard of care), (3) BCPass practicality for learning about and accessing contraception via an app, and (4) AYA's considerations when selecting a contraceptive method before and after the BCPass simulation.

Of the 12 pilot participants, one interview was not completed because the study team could not reach the participant; thus, the results reflect 11 of the 12 participants. A quarter of the 11 pilot participants commented on receiving contraceptive prescriptions through BCPass from a pharmacist easily in the simulation. One participant expressed that BCPass may be unrealistic outside of the simulation due to safety concerns they had in making contraception more accessible to AYA without additional educational discussions with a provider. Due to the nature of the simulation, participants understood they would not receive a method as part of the study; therefore, the perceived effectiveness of BCPass was minimally mentioned.

> *"The only thing that surprised me was that um you can literally just just get it. Like you don't like need any doctor's approval like just being able to get it"* [Participant 1, selected implant in BCPass]

BCPass was highly acceptable among the 11 AYA pilot participants. The majority of pilot participants (73%) found BCPass to be quick, easy, convenient, and accessible. More than half (64%) found the process to be enjoyable and a good accessible option for other AYAs to request contraception compared to the standard of care of receiving contraception from a clinician after a medical appointment. Many participants stated they liked receiving contraception information from BCPass as well as avoiding a trip to a clinic and potentially uncomfortable conversation with a clinician (55%). Yet 18% of participants expressed they would also like the option to talk to a clinician by phone or in person in addition to the option they were given to talk to a pharmacist through BCPass. Some participants (18%) felt BCPass may not be adequate for AYA due to the possible need for more direct clinician oversight for young people and those with complex care needs.

> *"I also really liked the idea of not having to go to the doctor and have an awkward conversation about getting birth control"* [Participant 2, selected oral contraceptives in BCPass]

> *"I like that it was fast and convenient and I didn't have to go see a doctor. I could do it right on my phone. Um, I liked that it like also gave me a little feel about all the different kinds of birth control methods because I think that we are not often given information about all of them"* [Participant 3, selected IUD in BCPass]

A majority of the 11 pilot participants (91%) reported that BCPass was easy, quick, and convenient to use, with straightforward instructions and easy-to-answer questions. A third (36%) stated the information they received as part of the BCPass simulation was comparable to what they received at a medical appointment, including a participant stating the BCPass questions and education materials helped them determine what contraceptive method was best for them. While many usability concerns were addressed in the first phase of the study, 64% of participants shared feedback to further improve the experience for AYA. Suggestions included shortening the questionnaire, clarifying questions, deleting repetitive questions, and improving the delivery of educational materials.

> *"I liked how, I enjoyed how easy and self-explanatory a lot of the questions get… Sorry about that. I enjoyed mostly the descriptive questions that I was asked so that I was more sure about the pathway I would like to take while using that"* [Participant 4, selected Depo-Provera injection in BCPass]

Finally, participants were asked about their preferred contraceptive method selected using BCPass. Most of the 11 (82%) pilot participants reported prior use of the method they chose in the BCPass simulation. More than half (64%) cited their medical history and side effects associated with their preferred method when explaining their decision. Additional considerations participants noted were the delivery of contraception (eg, shot, long-acting reversible contraceptives, daily oral pill) (27%) as well as discussions they have had with family and friends (27%).

> *"I felt like it [the patch] was the easiest one to remember and it was something I didn't have to take every day and was something I only have to remember once a week. I feel like it would be easy on my time and my hobbies I tend to forget about stuff"* [Participant 5, selected transdermal patch in BCPass]

Prior to the BCPass simulation, two of the 11 (18%) pilot participants stated they did not have a single preferred contraceptive method in mind. After completing the simulation, they were able to more confidently select the method that they felt would work best for them. These participants credited the BCPass simulation questionnaire and educational materials in their decision-making process.

> *"Um I would definitely say that like IUD now. Originally, I would say 50-50 percent, like I would've leaned either way. But now using the app I would definitely say that I would have rather used the IUD because it's more, I don't want to say more protective. But like, it's better, it's like safer, better protection"* [Participant 3, selected IUD in BCPass]

Discussion

Principal Findings

We found that an app for pharmacist delivery of contraception, BCPass, was acceptable and usable for AYA. Participants liked how easy, convenient, and fast BCPass was to request contraception. Once the concerns addressed in the usability phase were incorporated, there were no glitches experienced, and few participants felt the app survey was too long or had confusing questions. Also, more education may be needed to ensure AYAs feel safe requesting contraception from a pharmacist. Finally, we identified 100% agreement between

XSL•FO
RenderX

pharmacist contraceptive approvals in the simulation and contraception as prescribed in routine clinic visits.

Our findings are consistent with prior research on this topic in older adult women. In one survey study, women and other birthing people (≥18 years) reported receiving contraception from a pharmacist may be more convenient, faster, and easier compared to getting contraception from a clinician [10], which mirrors AYA's beliefs in this study. Additionally, this study found AYA-reported advantages of using an app included improving access to contraception by reducing the stigma and embarrassment of using contraception, reducing the burden of scheduling and attending clinic visits, and reducing the number of teenagers who become pregnant. In our study's feedback interview, most pilot participants emphasized their favorite aspect of BCPass was how quick and convenient it was compared to the standard of care while still receiving the contraceptive information they desired.

We did not identify any discordance between simulated pharmacist approvals and clinicians, as prescribed in clinic visits, suggesting the safety of having youth self-screen for medical contraindications. Women and other birthing people have previously been shown to safely and accurately complete self-screening medical history questionnaires and identify contraindications [12,13]. Like the older cohort, this study has shown AYA were capable of reporting their medical history, reviewing education materials, and selecting a contraceptive method they wish to use without forgoing a medical professional's review. While this study made edits, such as including more lay language and providing examples to some questions, to the medical contraindications to contraceptive prescribing per the Centers for Disease Control and Prevention US Medical Eligibility Criteria [20], once these changes were made to accommodate AYA's readability and comprehension level, they were able to successfully communicate their own medical history with a pharmacist through the app. A few pilot participants noted in their feedback interview they were surprised how easy completing the simulation was because questions regarding medical history were primarily all yes or no with an option to write in additional information for context with the study pharmacist. Some participants even found questions on their contraception preferences and reviewing educational materials more helpful in picking their preferred contraception than speaking to a clinician. Additionally, the feedback from the pilot phase reflected AYA's thoughtful consideration and awareness of their medical history, as well as side effects when planning to request contraception.

Of note, only one participant expressed concerns that contraception prescription without a clinician's oversight could be dangerous for AYA by making contraception too accessible, but several felt that they would prefer to discuss it with a provider. This data suggests the BCPass educational materials and access to call a pharmacist were not as effective as they needed to be to assure safety. While most participants liked the educational materials, a few did not feel it was enough to educate AYA on side effects. This finding suggests a need to include multimodal educational material, including more visual and audio materials. Additionally, participants who questioned the safety of BCPass also did not view pharmacists as being as knowledgeable as clinicians in prescribing contraception, which contrasts with physicians and midlevel practitioners in other studies who have supported pharmacist-initiated access to contraceptives [15]. Safety concerns indicated educational information presented needs to not only address contraception concerns but also inform AYA of the pharmacist's credibility and remind future users that pharmacists provide medical care already, such as vaccine delivery and drug interaction information [23].

Limitations of this study include the small sample size, single-city site, and limited rounds of usability testing. In addition, current state policy allows only for the simulation of pharmacist prescriptions. Following usability testing and additional app modifications, the platform was not retested again in another usability round before it was launched in the pilot testing phase. We focused on contraceptive methods for pregnancy prevention only and did not include the myriad of other reasons AYA may use contraception (eg, menstruation management, acne treatment, gender-affirming care, and medical conditions such as endometriosis). In addition, some participants completed the BCPass simulation following their medical appointment, which was not documented but is an important consideration for future larger-scale testing of the simulation. Future studies should further inform apps' usefulness in improving access to contraception for a broad range of indications via pharmacist prescription. Additionally, future research should explore the acceptability and feasibility of BCPass for key populations, including but not limited to girls, women, and other birthing people who are low income, living with disabilities, and sexual and gender minorities, to navigate barriers to accessing contraception. At the time of this study, pharmacist dispensing of contraceptives was not legal in the state of Pennsylvania, where this study took place, and 29 other US states. During a time with increasingly restrictive laws on connecting AYAs to contraceptives and other family planning resources, implementing methods to increase access to contraception is more important than ever because AYAs are particularly vulnerable to these restrictions.

Conclusions

Our results indicate that the BCPass app has the potential to be a valuable tool to improve access to contraception more equitably by facilitating contraceptive education, person-centered decision-making, and convenient delivery. BCPass and other electronic health solutions can supplement traditional care models and can be easily scalable, time-efficient, and cost-effective to assist AYA with navigating barriers to accessing contraceptives. Our results, demonstrating high acceptability and usability, suggest the potential of apps as supplemental effective tools to expand access to contraception for AYA during this time of increasing restrictive laws and policies impacting AYA reproductive health.

Abstract

Background: Maternal mortality remains alarmingly high in the Democratic Republic of Congo (DRC), particularly in rural areas where access to quality prenatal care is limited. Despite global efforts to improve maternal health, systemic gaps persist in the delivery of antenatal services.

Objective: The objective of this study is to assess the quality of first antenatal consultations in the Malemba Nkulu health zone and identify structural and procedural factors contributing to substandard care.

Methods: A cross-sectional descriptive study was conducted in November 2023 across 8 health facilities selected through simple random sampling. Data were collected from 248 pregnant women attending their first prenatal visit and from 14 health care providers. Quality indicators were assessed using a structured checklist based on World Health Organization (WHO) standards. Variables included provider qualifications, availability of diagnostic tools, and completeness of clinical assessments.

Results: Only 2% (5/248) of first antenatal consultations met the minimum quality standards. Major deficiencies included lack of physical examinations 78% (193/248), absence of essential laboratory tests 92% (228/248), and inadequate counseling 85% (212/248). Facilities lacked basic equipment such as blood pressure monitors and hemoglobin tests. Provider training was inconsistent, and community awareness of prenatal care remained low.

Conclusions: The quality of first antenatal consultations in Malemba Nkulu is critically poor, reflecting broader systemic challenges in rural maternal health care. Strengthening provider training, improving infrastructure, and enhancing community engagement are essential to reduce maternal mortality and improve outcomes in resource-limited settings.

KEYWORDS

quality; antenatal; consultation; maternal health; Democratic Republic of Congo

Introduction

Background

Maternal mortality remains a major public health concern in low-resource settings, particularly in sub-Saharan Africa. According to the World Health Organization (WHO), nearly 99% of maternal deaths occur in countries with limited access to quality care [1]. In the Democratic Republic of Congo (DRC), the maternal mortality ratio is estimated at 473 deaths per

XSL•FO
RenderX

100,000 live births [2], a figure that reflects persistent gaps in the health system and the urgent need for targeted interventions.

Antenatal care (ANC) is widely recognized as a key strategy to reduce maternal and neonatal morbidity and mortality. The WHO recommends at least 8 prenatal visits, with the first ideally occurring before 12 weeks of gestation [3]. Early and high-quality ANC enables timely screening, prevention of complications, and health education. However, in the DRC, fewer than 8% of pregnant women initiate ANC in the first trimester [4], and many consultations are conducted by providers lacking formal medical training [5].

The Malemba Nkulu health zone, located in the rural province of Haut-Lomami, exemplifies these challenges. It was selected for this study due to its high maternal risk profile, limited access to qualified health personnel, and absence of recent data on ANC quality. Preliminary data from this region reveal that over half of pregnant women (52.4%) attend their first ANC visit in the third trimester, limiting the effectiveness of preventive measures. Additionally, nearly 43% of consultations are conducted by traditional birth attendants without advanced medical qualifications, and more than 60% of health facilities lack essential equipment for complete prenatal assessments, including tests for anemia and maternal infections [6]. These findings suggest that the quality of the first antenatal consultation (ANC1) may be a critical determinant of maternal outcomes. While previous studies in West Africa have linked ANC quality to provider training, infrastructure, and community engagement [7], few have examined this issue in depth within the DRC. Evidence from Rwanda and Ethiopia shows that integrating ANC into community health programs and investing in provider capacity can significantly improve maternal care [8].

Objective

This study aims to assess the quality of the first antenatal consultation in the Malemba Nkulu health zone using national and international standards as benchmarks. It seeks to identify structural, procedural, and contextual factors that influence care quality and to inform strategies for improving maternal health in rural Congolese settings.

Methods

Study Design and Setting

This study used a descriptive cross-sectional design to assess the quality of ANC1s in the Malemba Nkulu health zone. The study was conducted over a 2-month period from November to December 2023. This design was selected to provide a snapshot of service delivery and identify gaps in compliance with national and WHO standards.

Study Site

This study took place in the Malemba Nkulu health zone, located in the rural province of Haut-Lomami in southeastern DRC. The area is characterized by limited access to qualified health personnel, inadequate infrastructure, and high maternal risk indicators, making it a relevant setting for evaluating ANC quality.

Sampling and Methodological Justification

This study used a mixed sampling approach, combining probabilistic and nonprobabilistic techniques to ensure both representativeness and feasibility in a resource-limited rural context.

Health Facilities

Eight facilities were selected using simple random sampling from the official list of centers providing ANC services within the Malemba Nkulu health zone. This method ensured equal probability of selection and minimized selection bias.

Pregnant Women

A total of 248 pregnant women were recruited through consecutive sampling, including all eligible participants attending their ANC1 during the study period. This approach captured real-time practices without interruption or subjective filtering.

Health Care Providers

Fourteen providers were included through exhaustive sampling, meaning all active personnel involved in ANC1 services at the selected facilities were enrolled, provided they had at least 6 months of experience in antenatal care. This ensured a comprehensive representation of professional profiles and practices.

Methodological Rationale

This sampling strategy was chosen to maximize data representativeness in a heterogeneous rural environment, minimize bias related to participant availability and provider selection, and facilitate logistical implementation under field conditions.

Study Population and Eligibility Criteria

Pregnant Women

The inclusion criteria for pregnant women included those (1) attending their ANC1 during the study period, (2) receiving care in one of the selected facilities, and (3) providing informed consent after explanation of study objectives. Pregnant women were excluded if their ANC1 was previously conducted in another facility or if they refused to participate.

Health Care Providers

The inclusion criteria for health care providers included those (1) actively involved in delivering ANC services in the selected facilities and (2) with a minimum of 6 months' experience in antenatal care provision. Health care providers were excluded if they were absent during the study period due to leave or reassignment or refused to participate.

Sampling Strategy and Justification

Health facilities were selected using simple random sampling to ensure equal probability of inclusion and reduce selection bias. Pregnant women were recruited consecutively, including all eligible women presenting for ANC1 during the study period. Health care providers were included exhaustively from the selected facilities, based on availability and direct involvement in ANC.

XSL•FO
RenderX

This mixed sampling approach was chosen to maximize representativeness and feasibility. The final sample included 248 pregnant women and 14 health care providers, reflecting the diversity of practices and qualifications across the zone.

Data Collection Procedures

Data were collected using a standardized observation grid adapted from national guidelines and WHO recommendations. Ten key dimensions of ANC1 were assessed, as outlined in Table 1.

Each consultation was directly observed by trained data collectors. Medical records were reviewed to confirm procedures, and structured interviews were conducted with pregnant women to assess their perceptions of care.

Table 1. A summary for the measurement of the first antenatal consultation (ANC1) quality variable. The maximum total ANC1 quality score is 100, with each domain contributing up to 10 points.

Domains and their objects	Measure	Percentage rating per object
History of pregnant women		
Age of the pregnant woman	1=Requested, 0=No	2.5
Medications that the pregnant woman takes	1=Requested, 0=No	2.5
Date of start of the pregnant woman's last menstrual period	1=Requested, 0=No	2.5
Number of previous pregnancies the pregnant woman has had	1=Requested, 0=No	2.5
Aspects of previous pregnancies		
Previous stillbirth(s)	1=Requested, 0=No	1
Infant(s) who died during the first week of life	1=Requested, 0=No	1
Heavy bleeding during or after childbirth	1=Requested, 0=No	1
Previous assisted delivery (eg, cesarean, vacuum, or forceps)	1=Requested, 0=No	1
Previous spontaneous abortions	1=Requested, 0=No	1
Previous multiple pregnancies	1=Requested, 0=No	1
Previous prolonged work	1=Requested, 0=No	1
Hypertension induced by previous pregnancy	1=Requested, 0=No	1
Seizures related to a previous pregnancy	1=Requested, 0=No	1
High fever or infection in previous pregnancies	1=Requested, 0=No	1
Danger signs of ongoing pregnancy		
Vaginal bleeding	1=Requested, 0=No	1.43
Fever	1=Requested, 0=No	1.43
Headache or blurred vision	1=Requested, 0=No	1.43
Swollen face, hands, or extremities	1=Requested, 0=No	1.43
Fatigue or shortness of breath	1=Requested, 0=No	1.43
Cough or difficulty breathing for 3 weeks or more	1=Requested, 0=No	1.43
Any other symptoms or problems related to this pregnancy	1=Requested, 0=No	1.43
Physical examination		
Taking the pregnant woman's blood pressure	1=Executed, 0=No	1.25
Weighing the pregnant woman	1=Executed, 0=No	1.25
Examine the conjunctiva or palms for anemia	1=Executed, 0=No	1.25
Examine legs, feet, and hands for edema	1=Executed, 0=No	1.25
Examine any swollen lymph nodes or glands	1=Executed, 0=No	1.25
Palpate or measure the pregnant woman's abdomen for fundal height	1=Executed, 0=No	1.25
Examine the pregnant woman's breasts	1=Executed, 0=No	1.25
Perform a vaginal examination or perineal examination	1=Executed, 0=No	1.25
Routine examinations		
Hemoglobin test	1=Executed, 0=No	2.5
Blood typing	1=Executed, 0=No	2.5
Any urine test	1=Executed, 0=No	2.5
Syphilis test	1=Executed, 0=No	2.5
HIV testing and counseling		
Asked if the pregnant woman knew her HIV status	1=Requested, 0=No	2
Provide or refer for advice related to HIV testing	1=Executed, 0=No	2

XSL•FO

Domains and their objects	Measure	Percentage rating per object
Perform or refer for an HIV test	1=Executed, 0=No	2
Providing posttest counseling	1=Executed, 0=No	2
Discussion on partner testing	1=Discussed, 0=No	2
Maintaining a healthy pregnancy		
Discussed nutrition (ie, food to eat) during pregnancy	1=Discussed, 0=No	3.33
Informing the pregnant woman about the progress of the pregnancy	1=Executed, 0=No	3.33
Discussed the importance of at least 4 prenatal visits	1=Executed, 0=No	3.33
Iron and folate supplementation		
Prescribed or given iron or folic acid tablets or both	1=Executed, 0=No	2.5
Explained the purpose of iron or folic acid	1=Executed, 0=No	2.5
Explained how to take iron or folic acid tablets	1=Executed, 0=No	2.5
Explanation of the side effects of iron or folic acid tablets	1=Executed, 0=No	2.5
Tetanus toxoid injection		
Prescribed or administered a TAT[a] injection	1=Executed, 0=No	3.33
Explained the purpose of TAT injection	1=Executed, 0=No	3.33
TAT card verified or ANC[b] card	1=Executed, 0=No	3.33
Preparation for childbirth		
Asked the pregnant woman where she will deliver	1=Requested, 0=No	2
Advised the pregnant woman to prepare for delivery	1=Recommended, 0=No	2
Advised the pregnant woman to seek the assistance of a qualified health worker for delivery	1=Recommended, 0=No	2
Indicate what items to have on hand in case of emergency	1=Recommended, 0=No	2
Advised the pregnant woman to give birth in a health facility	1=Recommended, 0=No	2

[a]TAT: tetanus toxoid.

[b]ANC: antenatal care.

Variables

Independent variables included the following: (1) type of health facility (health center or general hospital), (2) provider profile (level of qualification and professional experience), (3) patient characteristics (age, education level, parity, and trimester of pregnancy at the time of ANC1), (4) availability of resources (medical equipment and access to laboratory tests), and (5) accessibility of care (distance from home to facility and consultation cost).

Dependent variables included the following: (1) overall conformity of the consultation (compliant or noncompliant), (2) completion of clinical and laboratory examinations, (3) quality of information provided to the patient (nutrition, danger signs, and birth planning), (4) preventive and curative interventions (prescription of iron or folic acid, tetanus vaccination, and malaria treatment), and (5) patient satisfaction (reception, waiting time, cost, and quality of counseling received).

Handling of Missing Data

Missing data were identified through systematic review of observation grids and medical records. Completely missing data were excluded from the analysis, and partially missing data were imputed using weighted averages and predictive modeling. Sensitivity analyses were conducted to assess the impact of missing data on key indicators.

Data Analysis

Data were entered and analyzed using SPSS version 25.0 (IBM Corporation). Descriptive statistics were used to calculate frequencies, proportions, means, and SDs. The results were stratified by facility type and provider qualification, and 95% CIs were calculated for key indicators. *P* values were reported where applicable, with statistical significance set at $P<.05$.

Ethical Considerations

This study was conducted in full compliance with the ethical principles outlined in the Declaration of Helsinki and the guidelines of the National Ethics Committee of the Democratic Republic of Congo. Ethical approval was obtained from the Ethics Committee of the School of Public Health at the University of Kinshasa, under reference number ESP/CE/099/2023, in accordance with institutional procedures.

Before any data collection, written informed consent was obtained from each pregnant woman included in the study,

XSL•FO
RenderX

following a clear explanation of the study's objectives and participation procedures. Participation was entirely voluntary, with no form of pressure or financial or material incentive.

Data confidentiality was ensured through anonymized records and the use of secure identification codes. All data were stored in protected files, accessible only to authorized members of the research team.

The authors declare no conflicts of interest related to this research. The study is part of a broader effort to strengthen local maternal public health capacities and to promote medical practices in rural settings.

Results

The distribution of pregnant women by the quality of the ANC1, according to the criteria defined by national and international standards, is shown in Table 2. It shows the percentage of consultations that meet quality standards and highlights gaps in care.

Table 2. Distribution of pregnant women according to the quality of the first prenatal consultation (ANC1) received (N=248).

Quality of ANC1	Pregnant women, n (%)	95% CI
Good quality	5 (2)	1.86-2.16
Poor quality	243 (98)	3.51-5.36

The study found that 61% (151/248) of health facilities lacked the necessary equipment to perform a comprehensive prenatal checkup. Essential laboratory tests such as syphilis screening and anemia assessment were systematically absent in 45% (112/248) of cases. Table 3 illustrates the availability and performance of essential laboratory tests at the first antenatal visit. It highlights gaps in screening, including the absence of hemoglobin tests, blood typing, and syphilis screening.

A significant proportion of consultations did not include all of the recommended examinations or adequate advice on pregnancy management.

Our analysis highlighted several constraints affecting the quality of ANC1. Among the limiting factors, 43% (107/248) of consultations were conducted by midwives without advanced medical training. Furthermore, 52% (129/248) of women had their first ANC in the third trimester, which significantly reduces the impact of preventive measures.

Table 4 describes the characteristics of the prenatal care providers who performed the consultations. It highlights their education level, average age, and sex distribution. Notably, a majority of providers did not have advanced medical training.

Table 3. Assessment of the quality of prenatal consultations according to laboratory tests.

Laboratory tests received	Pregnant women (N=248), n (%)
Hemoglobin test	
No	215 (86.7)
Yes	33 (13.3)
Blood typing	
No	240 (96.8)
Yes	7 (2.8)
Urine test	
No	218 (87.9)
Yes	30 (12.1)
Syphilis test	
No	243 (98)
Yes	5 (2)

XSL•FO
RenderX

Table 4. Distribution of prenatal care providers according to their sociodemographic characteristics.

Features	Providers (N=14)
Age (years), mean (SD)	49.3 (6)
Educational level, n (%)	
Nurse A2	8 (57.1)
None	6 (42.9)
Sex, n (%)	
Female	14 (100)
Male	0 (0)

Analysis of interactions between providers and pregnant women showed that only 37% (149/248) of consultations included in-depth education on nutrition, danger signs, and childbirth preparation. The average consultation duration was less than 15 (SD 3) minutes in 68% (169/248) of cases, limiting the quality of support.

Table 5 summarizes pregnant women's opinions on various aspects of their first prenatal visit, including cost, distance, reception by health workers, and waiting time. It provides insight into pregnant women's perceptions of the quality of care received.

Table 5. Assessment of the quality of prenatal consultation on the judgment of pregnant women.

Judgement	Pregnant women (N=248), n (%)
Cost	
Affordable	100 (40.3)
Pupil	114 (46)
Lower	22 (8.9)
Higher	12 (4.8)
Distance	
Short	59 (23.8)
Long	66 (26.6)
Normal	88 (35.5)
Too short	24 (9.7)
Too long	11 (4.4)
Welcoming health workers during ANC1 [a]	
Not satisfactory	40 (16.1)
Satisfying	158 (63.7)
Very satisfactory	50 (20.2)
Waiting times for prenatal consultations	
Long	138 (55.6)
Not long	97 (39.1)
Too long	13 (5.2)

[a]ANC1: first antenatal consultation.

Less than 50% (124/248) of women received necessary nutritional supplements, such as iron and folic acid. Vaccination coverage and the administration of antimalarial drugs were also limited, compromising the prevention of maternal and neonatal complications.

Table 6 details the elements covered during the prenatal consultation related to maternal and newborn health. It analyzes nutrition awareness, the importance of prenatal monitoring, the prescription of nutritional supplements and vaccines, as well as information on pregnancy management.

Discussion

Principal Findings

The findings of this study revealed that only 2% of ANC1s met minimum quality standards in the Malemba Nkulu health zone. This reflects broader systemic challenges in rural maternal health care, including limited provider training, lack of diagnostic tools, and delayed access to care.

Similar challenges have been documented in other Central and West African contexts. In Lubumbashi, DRC, a study found that only 0.2% of pregnant women initiated ANC in the first trimester, and most consultations were conducted by nurses with limited qualifications [9]. In Mali, research conducted in Sélingué highlighted gaps in counseling and continuity of care, despite satisfactory physical examinations and reception [10]. Another study in Bougouni emphasized the importance of integrating ANC into reproductive health programs and strengthening provider training [11].

These regional findings reinforce the relevance of our results and suggest that targeted interventions—such as community-based outreach, provider certification, and subsidized diagnostic services—could improve ANC quality across similar settings. They also support evidence from Rwanda and Ethiopia, where continuous training and integration of ANC into community health systems have led to measurable improvements in maternal outcomes [12,13].

The results obtained in this study are consistent with those reported in other research in sub-Saharan Africa. For example, a study conducted in Nigeria showed that more than 60% of antenatal consultations were carried out by unqualified personnel, leading to insufficient follow-up [14]. Research in Ghana has shown a direct link between the quality of antenatal consultations and obstetric complication rates [15]. Additionally, in Rwanda and Ethiopia, the quality of antenatal care has improved considerably thanks to policies targeting continuous training of providers and integration of antenatal services into community care [12,13]. These successes suggest that adapted strategies could be implemented in the DRC to improve the effectiveness of prenatal consultations and reduce maternal morbidity [16].

Factors Influencing the Quality of Care

Among the main causes of the insufficient quality of prenatal consultations in the health zone studied, the following elements stand out:

XSL•FO
RenderX

1. Training of providers: 43% (107/248) of consultations were carried out by midwives without advanced medical training, which limits the application of standardized protocols [17].
2. Late access to care: 52% (129/248) of women had their first prenatal consultation in the third trimester, thus reducing the impact of preventive interventions [18].
3. Lack of medical equipment: 61% (151/248) of health facilities did not have the necessary tools to carry out a complete prenatal assessment, compromising the quality of monitoring [19].
4. Cost of services: the high cost of consultations and additional examinations is a barrier to pregnant women's adherence to medical recommendations [16].

Implications for Health Policy

These results highlight the urgency of implementing strategies to strengthen the quality of prenatal care. Among the possible measures, several recommendations can be made, including:

1. Strengthening the training of providers, particularly through practical workshops and certifications in prenatal monitoring [12,13].
2. Subsidy of prenatal services to improve accessibility to care [14,15].
3. Community awareness to encourage pregnant women to consult from the first trimester [17].
4. Integration of prenatal care into maternal health programs to ensure comprehensive and effective monitoring [18,19].

Practical Implications of the Results

The study highlights several challenges related to the quality of antenatal consultations in the Malemba Nkulu health zone. These findings underscore the need for concrete interventions to improve the effectiveness of maternal care and reduce maternal and neonatal mortality. In particular, we highlight 4 measures that may contribute to a lasting improvement in the care of pregnant women and a significant reduction in maternal morbidity and mortality:

1. Capacity building for service providers: this involves organizing continuing education for prenatal care providers, with an emphasis on diagnostic examinations and management protocols, as well as establishing a skills assessment system, ensuring compliance with WHO recommendations.
2. Improving access to prenatal care: this involves developing community programs to raise awareness among pregnant women about the importance of early monitoring and reducing financial barriers by subsidizing essential medical consultations and examinations.
3. Strengthening medical infrastructure: this involves ensuring the availability of medical equipment in health facilities and implementing a policy for the distribution of essential medicines for the prevention and management of maternal complications.
4. Monitoring and evaluation of interventions: this involves integrating a monitoring system to measure the impact of improvements on prenatal consultations and encouraging further studies to refine strategies and adjust maternal health policies.

Limitations and Potential Sources of Bias

This study has several methodological limitations that must be taken into account.

Selection Bias

The sample studied is based on pregnant women who consulted in the 8 selected health structures, which may introduce a representativeness bias. In particular, this study could overestimate or underestimate the quality of prenatal care depending on the specific characteristics of the institutions selected. Notably, however, the magnitude of selection bias is low since there was no stratification that could have favored certain subgroups. This means that the results are generally representative of the study population, although random variations may remain.

Information Bias

Some variables, including the pregnant women's medical history and provider protocols, are based on medical records and self-reports from pregnant women; therefore, there is a risk of overestimating compliance with care, as some information may be incomplete or influenced by recall bias. We consider the magnitude of bias to be moderate because the data were collected by direct observation and validation of medical records, reducing potential errors.

Missing Data and Statistical Treatment

Although imputation methods were used, some missing data regarding laboratory tests and provider training could affect the accuracy of the results, leading to potential overestimation or underestimation of the quality of services based on missing data. We consider the magnitude of bias to be low to moderate as sensitivity analyses confirmed the robustness of the results.

Despite these limitations, this study provides a vital assessment of the quality of prenatal consultations and highlights priority areas for improvement. However, further research, particularly longitudinal, would be needed to refine the analysis and strengthen the generalizability of the results.

Generalizability of the Study Results

The study sample was selected by simple random sampling, ensuring an equal probability of inclusion for each patient. This methodological choice strengthens external validity, as it limits selection bias and improves the ability to generalize the results to all pregnant women attending health facilities in the Malemba Nkulu health zone. However, some constraints may affect generalizability. For example, the sample size, although statistically sufficient for analysis, might not capture all the nuances present in the entire target population. Additionally, women who did not attend the health facilities studied were excluded, which limits the applicability of the results to pregnant women who do not have access to prenatal care. The results obtained are consistent with similar studies conducted in sub-Saharan Africa, notably in Nigeria, Ghana, Rwanda, and Ethiopia, where comparable problems have been observed in terms of access to prenatal care and the training of providers.

Specific local factors may also limit the generalizability of the results, such as structural differences in the organization of care

XSL•FO
RenderX

(some countries have implemented targeted reforms, significantly improving access to prenatal care) and variability of prenatal monitoring protocols (national recommendations can influence the application of quality standards).

The issues identified in this study, notably, the limits of training providers in environments where traditional midwives play a dominant role and financial and geographical barriers that restrict access to early prenatal consultations, are broadly representative of the challenges encountered in several health zones in the DRC. However, local adaptations would be necessary to replicate these findings in urban contexts, where medical infrastructure is more developed and pregnant women have better access to specialized care.

The external validity of this study is moderately high, as simple random sampling enhances the representativeness of the results. However, certain contextual specificities must be taken into account before extrapolating these findings to other regions of the DRC or to other African countries.

Conclusions

This study reveals the poor quality of ANC1s in the Malemba Nkulu health zone, with only 2% meeting established standards. The findings underscore critical gaps in provider training, limited access to essential diagnostic tests, and insufficient awareness among pregnant women regarding the importance of early and comprehensive prenatal care. Addressing these deficiencies requires targeted interventions to strengthen health worker capacity, improve service availability, and enhance community engagement in maternal health.

Among the challenges identified, 43% of consultations were conducted by midwives without advanced medical qualifications, compromising the quality of follow-up. Furthermore, 52.4% of women had their ANC1 in the third trimester, limiting the impact of preventive measures.

To improve the quality of prenatal care, several recommendations can be made, including (1) strengthening the training of service providers through practical sessions and adapted certifications, (2) subsidy for prenatal services to ensure better access to care, (3) community awareness to encourage early consultations, and (4) integration of prenatal care into maternal health programs. These measures could contribute to a significant reduction in maternal morbidity and mortality. Further research is needed to evaluate the impact of the proposed interventions and ensure effective management.

Acknowledgments

All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Authors' Contributions

FIM conceived the study, supervised data analysis, and drafted the manuscript. PGM contributed to data collection and supported the interpretation of results. PKwI participated in field data collection and contributed to contextual analysis. IBK reviewed the scientific content and validated the consistency of the findings. DNM provided methodological corrections and ensured the scientific rigor of the study protocol. All authors reviewed and approved the final version of the manuscript and agree to be accountable for the integrity of the work.

Abstract

Background: Only 10% of Australian children meet the recommended daily physical activity guidelines. Augmented reality (AR) is increasingly being used in primary education and clinical rehabilitation, with high enjoyment and motivation to participate frequently reported. AR has increased physical activity participation in adult populations, but whether AR can increase physical activity in young children has yet to be investigated.

Objective: This study aimed to determine if an indoor AR-enhanced playground is enjoyed by young children and prompts physical activity in both low- and high-structured scavenger hunts.

Methods: Seventeen pairs of 5 - to 8-year-olds participated in 2 animal search tasks (ie, AR and non-AR) in 2 activity structure levels (ie, low-structured and high-structured) in a 2×2 repeated measures design in an indoor laboratory playground. Children searched for either AR animals (a custom AR app on a smartphone) or toy animals and followed a set obstacle course route (high-structured) or moved wherever they wished (low-structured). Questionnaires assessed child enjoyment, perceived physical activity, and caregiver perception of enjoyment. Thigh-worn accelerometers (SENS; SENS Innovation ApS) assessed postures and movements, and a video camera recorded engagement time.

Results: Children rated AR conditions (low-structured: mean 4.4, SD 1.0, and high-structured: mean 4.5, SD 0.9) as more enjoyable than high-structured non-AR (mean 4.1, SD 1.0; P=.03). When asked which condition was the most enjoyable, 15 chose the low-structured AR, followed by the high-structured AR (n=11) and low-structured non-AR (n=8). Caregiver perception of children's enjoyment ratings generally aligned. Ratings of perceived physical activity level were the same in all conditions (mean 4.3, SD 0.7; P>.05). Accelerometry showed that a greater percentage of time was spent in low-intensity postures and movements during AR conditions (AR: mean 50%, SD 13% vs non-AR: mean 35%, SD 14%; P<.001), namely in sitting and standing, and in high-intensity movements during non-AR (AR: mean 21%, SD 12% vs non-AR: mean 32%, SD 18%; P<.001). During low-structured conditions, engagement time was significantly longer with the AR animals compared to the toy animals (AR: mean 263.1, SD 65.7 seconds vs non-AR: mean 197.3, SD 76.5 seconds; P=.002).

Conclusions: While the intensity of physical activity was lower during AR, the greater enjoyment and longer engagement time may lead to greater overall accumulation of active play by motivating young children to go to and stay longer at playgrounds. The high-structured AR conditions resulted in higher-intensity physical activity compared to low-structured AR conditions; however, enjoyment ratings from children and caregivers were generally higher in the low-structured AR. Therefore, AR may be suitable to implement in both low- and high-structured play environments. Future research should investigate whether these findings hold true at outdoor playgrounds and examine the impact of novelty over time.

Introduction

Augmented reality (AR) digital technology is becoming increasingly available and promoted to children in both home and educational settings [1,2]. AR refers to the use of a smart device with an incorporated camera to present the user with an integrated, real-time view of the real world with superimposed digital information. This is commonly a smartphone or tablet, but headset technology is rapidly advancing, making it more affordable and available [3]. AR applications vary enormously, from static overlaid images to animated 3D creatures to semi-immersive 3D worlds. Not only can the appearance and fidelity of AR vary enormously, but so too can the way it is "activated." AR can be activated using a physical marker (eg, a QR code or image) or be markerless (eg, using GPS location or world tracking, where the device camera scans the environment for a flat surface to place the AR object upon). Despite its growing popularity, the implications of AR use by young children remain relatively unstudied. While there is often inherent skepticism and concern about potential risks with children engaging with digital technology [4], the potential benefits of AR should also be investigated.

Primary school education, particularly in science, technology, engineering, and mathematics subject areas, can benefit from AR by allowing teachers to extend learning into a 3D space and for children to visualize concepts that would not normally be accessible in real life [5]. Compared with traditional learning resources, children aged 8 - 10 years have reported a preference for AR games when learning about multiculturalism, solidarity, tolerance, and the water cycle [6,7]. AR has also been shown to increase motivation to learn [5] and knowledge retention [8] in areas such as mathematics [9], literacy, geography, biology [5], and recycling behavior [10]. The increased appeal and motivation that AR provides for children in educational settings could translate into other aspects of their daily lives, for example, motivating children to be physically active in leisure time.

Children's participation in physical activity in many countries is generally low. For example, in Australia, parent-reported data show that in 2020, only 10% of children aged 5 - 18 years participated in the recommended 60 minutes of moderate-to-vigorous physical activity daily [11]. Sufficient physical activity and avoiding excessive sedentary behavior are vital for child health and well-being by reducing obesity risk [12], improving mental health [13], and supporting muscle and bone development [14]. Enjoyment has been identified as a key factor in children's participation in physical activity in theoretical models such as the self-determination theory [15]. Intrinsic motivation and higher enjoyment of physical activity are related to increased physical activity levels [16-18]. Further, a randomized controlled trial of 2087 adolescent girls demonstrated that increasing enjoyment of physical activity resulted in increased voluntary participation in physical activity [19].

AR is effective in increasing physical activity levels in adults and adolescents [20,21]. For example, adolescents in a study of Pokémon Go (2016; Niantic Inc), an AR smartphone game that encourages users to move to different geographical locations to "catch" Pokémon, increased their participation in low, moderate, and vigorous physical activity by ~41 minutes per week [22] over 7 weeks. AR has also been shown to increase the motivation of adolescents to participate in physical education classes [23]. AR applications that encourage children to be physically active are becoming more prevalent [24,25]; however, very little research has been undertaken regarding the feasibility and effectiveness of AR to promote physical activity, motivation, and enjoyment among primary school–aged children. However, evidence shows that AR apps can improve motor function and increase participation in physical rehabilitation among pediatric clinical populations [26]. For example, in children with cerebral palsy, AR has been shown to improve upper limb muscle strength and range of motion [27] and to be an effective tool in improving gait speed [28]. In a review [29], the most frequently reported advantage of AR use in a clinical population was increased motivation leading to increased participation. If AR can effectively increase participation in physical rehabilitation in a clinical pediatric population, it remains possible that it could be an effective way to encourage increased physical activity in typically developing primary school–aged children; however, this has not been investigated.

AR as a tool to encourage physical activity in children is attractive due to its easy access and portability, being predominantly used on a smart device (eg, smartphone or tablet) already owned by many families, and its ability for use in both indoor and outdoor environments. Outdoor play not only provides children with the opportunity to practice and refine gross motor skills [30] but also reduces the risk of myopia [31] and vitamin D deficiency, which has been linked to poor bone development, cardiovascular disease, and diabetes [32]. This flexibility of use across multiple environments contrasts with many other digital devices aimed at eliciting active play in children, such as console-based active video games [33]. The versatility of AR applications, particularly marker-based AR, also allows for easy adaptation to different situations, such as different play styles. Physically active play can be broadly grouped into 2 overarching categories: high-structured and low-structured. High-structured physical play requires children to follow a set of rules or activities (eg, an obstacle course or football drills), while low-structured play is child-led free play. While both play types have overall benefits, highly structured play can emphasize motor skill development, while low-structured or free play can enhance imagination, autonomy, confidence, and self-esteem [34]. Marker-based AR could be adapted to both play styles, as the physical markers can, for example, be placed around an obstacle course by a parent, educator, or coach (high-structure play) or around a playground (low-structure play), prompting children to engage with the AR in diverse ways. However, how AR may encourage physical activity in children engaging in different play types remains unknown. This study aimed to explore whether marker-based AR digital technology could be a useful tool for engaging young children in physical activity during both high-structured and low-structured play, compared to a non-AR task. We hypothesized that children would enjoy AR more than non-AR conditions, and that their physical activity level (perceived and

XSL•FO
RenderX

measured) would be higher in both high-structured and low-structured play.

Methods

Study Design

This was a 2×2 repeated measures study (Animal Format: smartphone AR vs non-AR plastic toys × Activity Structure: low-structure vs high-structure) where children participated in 4 animal scavenger hunts in a laboratory playground setting. Outcome measures included enjoyment, time spent engaging, and level of physical activity. Pilot testing of the study protocol and AR app was conducted with 4 children (2 pairs, aged 5 - 8 years, male and female), and the protocol and app were refined before the commencement of participant data collection.

Laboratory Setup

The indoor laboratory was set up to simulate a playground, with the following equipment: a soft balance beam, wobble cushions, a see-saw plank, a hula-hoop tunnel, wooden boxes to climb, soft cushions to jump on, a mini trampoline, a climbing frame, a soft tunnel to walk through, hanging pillars to navigate, half Bosu balls, and wobble boards (Figure 1). Equipment setup was standardized for all participants and conditions.

Figure 1. Laboratory play equipment setup (all conditions) showing 2 participants in the low-structure non–augmented reality (non-AR) condition.

Participants

Thirty-four children aged 5 - 8 years and their caregivers volunteered to participate in the study. They were recruited from the local community and workplace networks in an Australian city via word of mouth and social media advertisements. Eligible children took part in the study in pairs, either a known friend or sibling (both henceforth termed “peer”). Parents and caregivers (henceforth termed “caregiver”) completed a screening questionnaire to determine if they and their children were eligible before being enrolled in the study. Participants were excluded if they did not speak fluent English (child and caregiver), had a physical injury (eg, sprained ankle) that limited their ability to move normally, a history of seizures or epilepsy, binocular vision abnormalities (eg, strabismus or amblyopia), frequent headaches or earaches, experienced severe motion sickness, had a known skin response to medical tape, or had any known or suspected psychological or physical clinical diagnosis that may influence their ability to understand and follow instructions or perform requested activities. The sample size was deemed appropriate based on previous accelerometer studies with children [35].

Protocol

Children and their caregivers visited the university laboratory for a single data collection session, approximately 60 minutes in duration. A standardized warm-up was completed, which involved a familiarization period with the AR technology, playground equipment, and obstacle course route. Children completed 4 conditions concurrently with their peers. Condition order was randomized (refer to Multimedia Appendix 1). Children were told they could work together with their peers but did not have to; it was their choice.

Animal Format: AR Versus Non-AR

A custom marker-based AR application (Animal Adventures; Curtin University) was developed for this study using Unity Vuforia Engine (Unity Technologies). Ten custom VuMarks (similar to a QR code but colorful images of the animal habitats; Figure 2) were designed, each linked to a different AR animal. VuMarks were 12×7.5 cm each. AR animals were virtual 3D low-poly animated animals (Unity Asset Store, Polyperfect) that appeared to be 30-100 cm in height, including a shark, elephant, panda, penguin, cat, rabbit, wolf, crocodile, seagull, and deer (Figure 2). AR animal size was adjusted to ensure they were visually impressive but not too large to be difficult to view on the smartphone. The distance the AR animal appeared relative to the VuMark was adjusted to ensure the children knew the animal had appeared (ie, close enough to the VuMark) but also far enough away to ensure the entire animal was visible. Once VuMarks were activated by holding them in the phone’s camera view for one second, the AR animal remained visible in that location for the remainder of the condition. The decision to use this setting was to prevent the animal from disappearing while children were viewing and interacting with it, which otherwise resulted in frustration. It also created the illusion of being surrounded by animals at the playground. Children were provided with an Apple iPhone 12 (Apple Inc) each to use

XSL•FO
RenderX

during the AR conditions. Children were given a demonstration and the opportunity to try using the AR app before commencing the first AR condition. For the non-AR conditions, plastic toy animals (Schleich Inc), the same as the AR animals, which ranged in size from 3 - 20 cm, were used (Figure 2).

Figure 2. Top shows children playing with the panda, elephant, and crocodile augmented reality (AR) animals during the AR conditions. The bottom left shows the VuMarks (marker-based AR) used in the AR conditions, including the penguin, deer, and panda. The bottom right shows the plastic toy animals used in the non-AR conditions.

Scavenger Hunt Activity Structure: Low-Structure Versus High-Structure

Conditions involved searching for 6 animals around the indoor play equipment, either AR animals or toy animals (non-AR), depending on the condition. Children were instructed that they could move wherever they wanted to find the animals during the low-structure conditions, or follow a set obstacle course route during the high-structure conditions. During the high-structure obstacle course conditions, children completed 2 laps of the circuit at the same time as their peers but in the opposite direction. They were not given any specific instructions on time, only that they should try to find the 6 animals while completing the 2 laps. During low-structure conditions, children were told there were 6 animals to find, after which they could play until they were told time was up. The low-structure conditions ended after a maximum of 5 minutes or earlier if the children lost interest in playing (total time). The time children stopped engaging with the AR or the non-AR animals during the low-structure conditions was noted and referred to as "engagement time."

Data Collection Tools

Questionnaires

Children completed a series of questionnaires for the outcomes of enjoyment and perceived physical activity. Children and caregivers were blinded to the hypotheses of the research in an attempt to avoid biases such as social desirability bias. Caregivers completed questionnaires regarding the outcomes of perceived enjoyment and their child's previous digital technology experience.

Child enjoyment and caregiver perception of their child's enjoyment were recorded following each condition and after the conclusion of all conditions using items from the Fun Toolkit [36], which have been frequently used with young children [37]. Specifically, children and caregivers were invited to circle the best response on a 5-item Smileyometer [37], a pictorial scale with round yellow faces ranging from awful (=1) to brilliant (=5) (refer to Multimedia Appendix 1) at the end of each condition. In addition, children and caregivers were invited to complete 3 variations of the fun sorter [37] following all 4 conditions. First, they were asked to rank which animal search condition they enjoyed more by placing cut-out images

XSL•FO
RenderX

representing the conditions (eg, AR or non-AR animals) into the appropriate box. Second, they were invited to rate whether they found the low-structure or high-structure conditions more enjoyable. Finally, they were asked to rank all 4 conditions from most enjoyable to least enjoyable. Caregivers were also provided with the option to complete a written open-ended question after each fun sorter task to elaborate on the reason for their answers.

Following each condition, children completed a 5-item pictorial Perceived Physical Activity Rating Scale, selecting how physically active they felt they were during the condition, from completely stationary (=1) to fast running (=5). This scale was adapted from the Children's Physical Activity Rating Scale (CARS) [38], a validated measure of observer-rated physical activity levels in young children. The adapted scale used the same 5 levels as the CARS but included illustrations, and children completed the scale themselves (refer to Multimedia Appendix 1). Caregivers were asked to complete a short questionnaire about their child's previous experience with digital technology.

Video

Total time and engagement time were calculated from accelerometer data and video footage. Video footage was captured from 2 video cameras (model A2403; Apple Inc; 30 Hz super wide lens) affixed to 1-meter-tall tripods and placed at opposite edges of the play area. Low structure condition total time (AR and non-AR conditions) commenced when the children started the condition and ended when either they lost interest in playing or after 5 minutes, whichever was sooner. Low structure condition engagement time (AR and non-AR) commenced when the child started the condition and ended when they lost interest in playing with the AR app or toys. In high-structure conditions, total time and engagement time were the same, commencing when the children started the obstacle course and ending when they completed their 2 circuits.

Accelerometer

The time children spent in different postures and movements was estimated from a thigh-worn accelerometer (SENS Innovation ApS) previously used in research with children of the same age [35]. The SENS motion PLUS (model number A01.6) accelerometer weighs 7 g and is 47×22×4.5 mm in size and was placed on the midline of the child's anterior right thigh halfway between the hip and knee. It was affixed using hypoallergenic double-sided tape underneath the accelerometer and hypoallergenic Fixomull stretch over the top. It was worn for the entire data collection. The accelerometer operated at 12.5 Hz and recorded accelerations in the x, y, and z axes with a range of +4 to −4 G.

Analysis

Accelerometer Analysis

Accelerometer data were cropped using a customized LabVIEW program (National Instruments). The Motus software, based on the Acti4 algorithm as developed and described in Skotte et al [39] and validated for use in school-aged children in a laboratory [35,40], was used to classify postures and movements. The software resamples the accelerometer data to 30 Hz in 2-second windows with a 50% overlap and uses both the inclinations and SDs of the thigh accelerations to classify different postures and movements using a rule-based algorithm [39]. The classified postures and movements are lying, sitting, standing, moving (stationary but with fidgeting legs), walking, running, stair climbing, cycling, or rowing (high-intensity movement that is not classified as running, stairs, or cycling). A customized R program (R Development Core Team) summarized these data into total and percentage of time spent in each movement and posture per condition. Due to the minimal incidences of movement coded as cycling and rowing (average total across all 4 conditions was 4.9, SD 10.1 seconds, and mean 4.6, SD 15.4 seconds, respectively, of a total average of 1200.4, SD 130.2 seconds), they were combined with the stair-climbing time to create a single stairs+ variable. Postures and movements were grouped as low intensity (lying, sitting, standing, and moving), moderate intensity (walking), and high intensity (running and stairs+).

Statistical Analysis

Questionnaire data from children and caregivers, along with pictorial scale numerical values, were transcribed into Microsoft Excel (Microsoft Corporation), and descriptive statistics were calculated. All other statistical analyses were performed in Jamovi (version 2.3.28; Jamovi). A critical alpha probability level was set at $P<.05$ for all analyses. Two-by-two (2×2) repeated-measures ANOVAs with post hoc pairwise comparisons without Bonferroni correction were run for all measures, except binomial fun sorter data, where a chi-square analysis was used. A thematic analysis of caregiver open-ended questionnaire responses was conducted.

Ethical Considerations

The study was approved by the Curtin University Human Research Ethics Committee (HRE2023-0323) before its commencement. An information sheet was provided to caregivers, and time was allowed for questions before the caregiver provided written consent. A simplified version of the information sheet was shown to children with their caregiver present. The study procedures were explained to children using visual illustrations and demonstrations of the study equipment, and time was allowed for questions. Children were invited to provide their verbal and written assent to participate. Three researchers were present for data collection, and all had current Working with Children Clearances. All data were deidentified for analysis when possible.

Results

Participants

All 34 children completed the study. Their average age was 6.2 (SD 1.2) years (range 5 - 8 years), 41% (n=14) were female, and all were currently in primary school education. The majority (n=20, 59%) attended with a friend of the same age and gender, while 41% (n=14) attended with a sibling (4 male-female sibling pairs, 2 brother pairs, and 1 sister pair). Parents reported that 47% (n=16) of children had previous experience with AR, most notably Pokémon Go, 59% (n=20) had active video game experience, and 94% (n=32) had previously played sedentary

XSL•FO
RenderX

games on a computer, tablet, or smartphone. There was no correlation between age and AR experience (r_{32}=0.165; P=.35).

Enjoyment in AR Versus Non-AR

Results from the children's ratings on the 5-item Smileyometer showed that AR was generally rated as more enjoyable than non-AR, and low-structure was sometimes rated as more enjoyable than high-structure. For child ratings of enjoyment, there was no overall main effect of Animal Format (AR: mean 4.5, SD 0.9 vs non-AR: mean 4.3, SD 1.0; $F_{1,33}$=3.79; P=.06) or Activity Structure (low-structure: mean 4.4, SD 0.9 vs high-structure: mean 4.3, SD 0.9; $F_{1,33}$=0.90; P=.35). However, pairwise comparisons revealed children rated low-structure AR and high-structure AR as more enjoyable than high-structure non-AR (t_{33}=2.26; P=.03; d=0.03 and t_{33}=2.26; P=.03; d=0.32, respectively; Table 1 and Figure 3). Caregivers' perception of their child's enjoyment was similar, though with a significant main effect of Animal Format showing AR rated as more enjoyable (AR: mean 4.2, SD 0.7 vs non-AR: mean 3.9, SD 0.6; $F_{1,33}$=6.81; P=.01; d=0.46), but no main effect of Activity Structure (low-structure: mean 4.1, SD 0.7 vs high-structure: mean 4.0, SD 0.7; $F_{1,33}$=0.66; P=.42). Pairwise analysis showed that caregivers rated low-structure AR as more enjoyable than low-structure non-AR and high-structure non-AR (t_{33}=2.54; P=.02; d=0.50 and t_{33}=2.73; P=.01; d=0.54; respectively; Table 1 and Figure 3). Multimedia Appendix 1 displays results based on the number of responses.

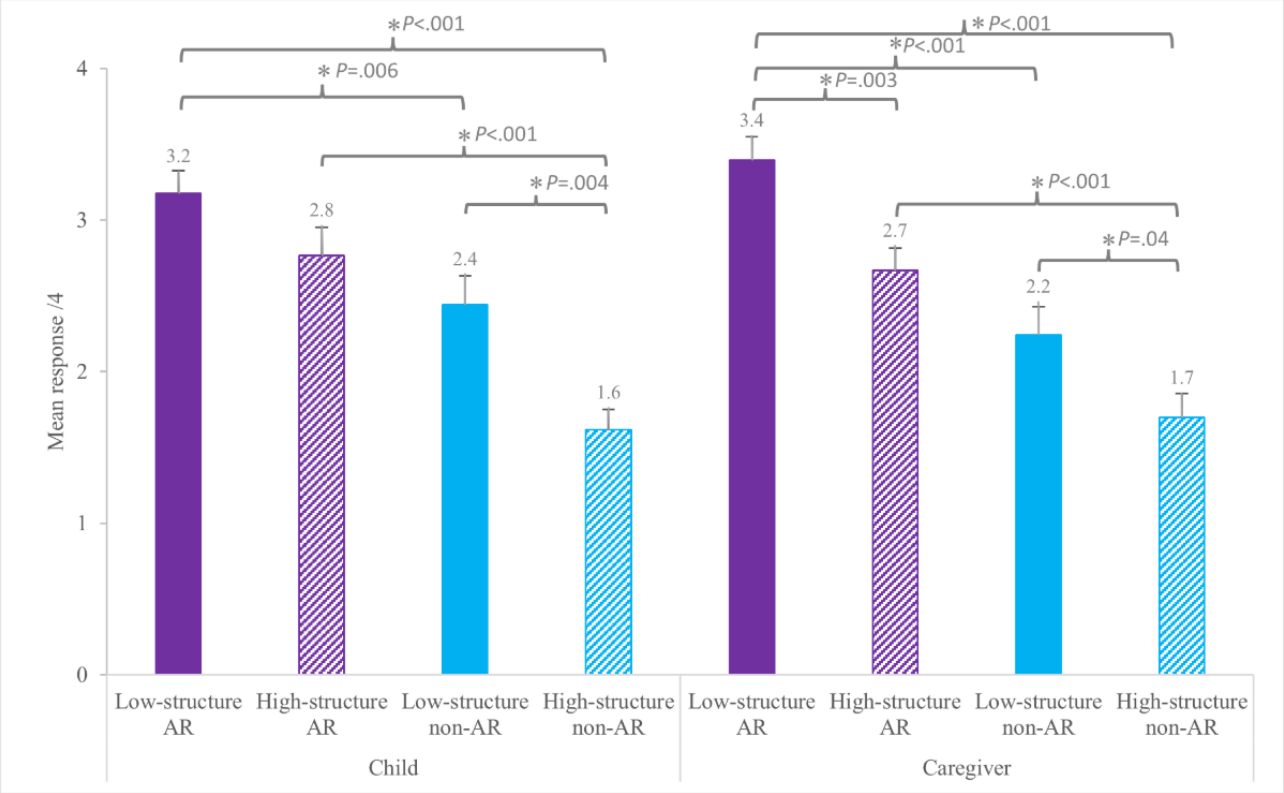
Figure 3. Group mean (SE) for child enjoyment and caregivers' perception of their child's enjoyment on the Smileyometer scale of 1 to 5, where 1 was "awful" and 5 was "brilliant." AR: augmented reality. *Indicates statistically significant differences in pairwise comparison (*P*<.05).

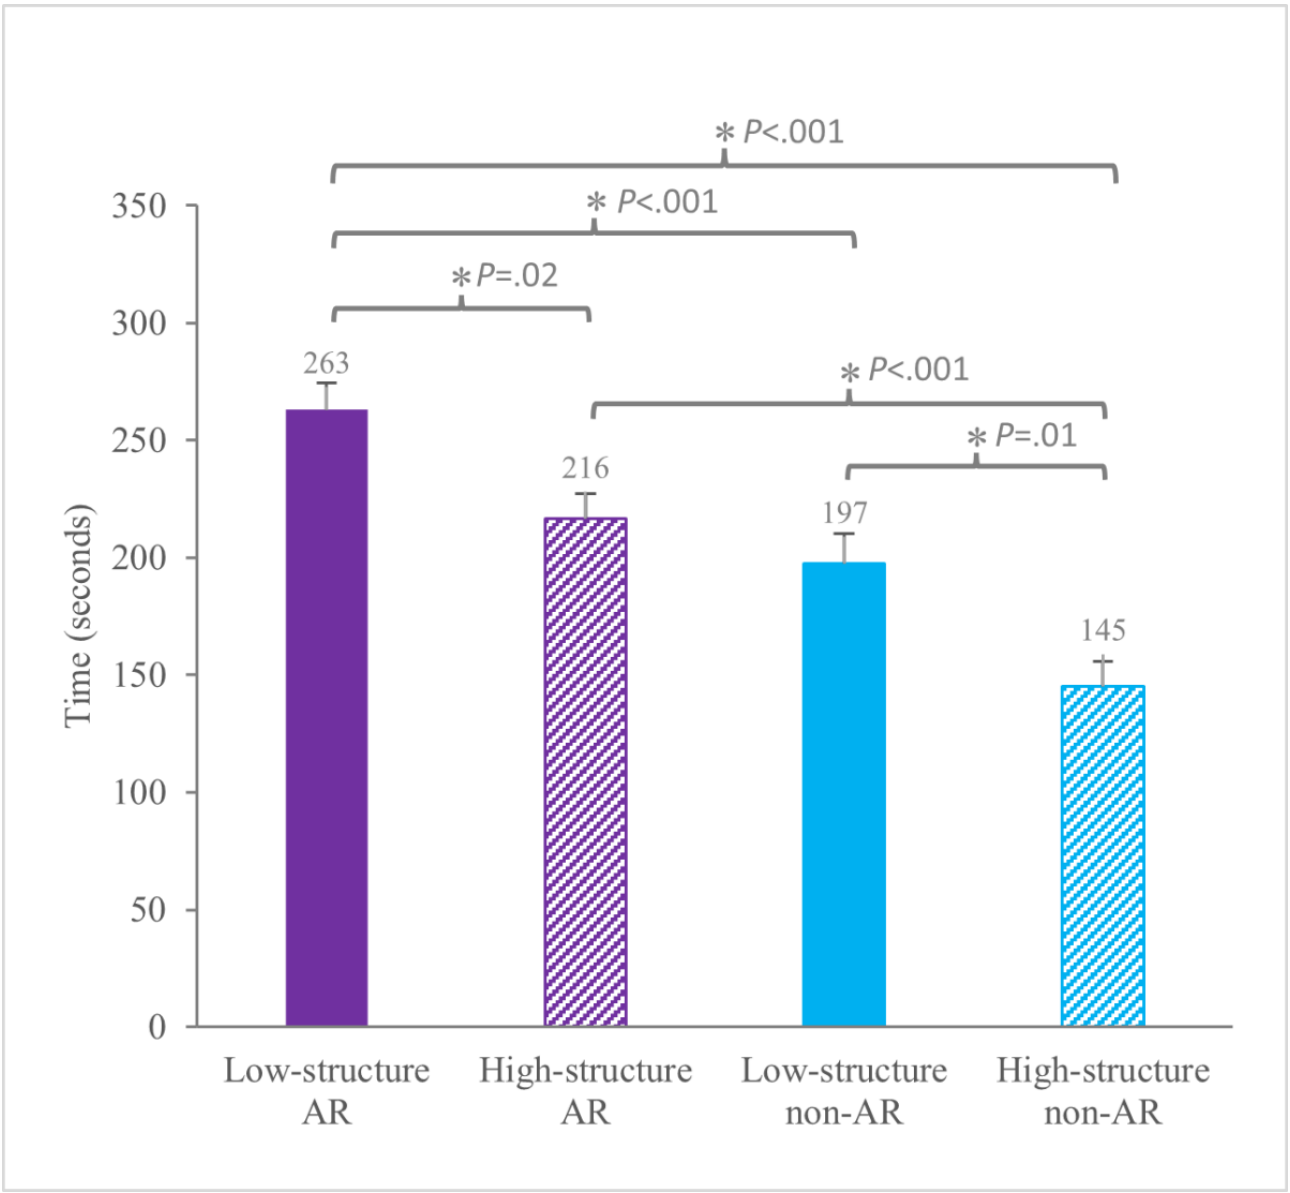


In the fun sorter questionnaire comparing enjoyment in AR and non-AR conditions (or caregivers' perception of their child's enjoyment), both children and caregivers ranked AR higher (children: 82%, n=28, $\chi^2_{1,34}$=15.1; *P*<.001 and caregivers: 91%, n=31, $\chi^2_{1,34}$=21.1; *P*<.001). When comparing enjoyment during low and high-structured conditions, both children and caregivers ranked low-structured conditions higher (children: 69%, $\chi^2_{1,34}$=4.5; *P*=.03 and caregivers: 69%, $\chi^2_{1,34}$=4.5; *P*=.03). There was a significant negative correlation between previous AR experience and AR enjoyment (r_{32}=−0.366; *P*=.03), with those who had not experienced AR previously more likely to rate it as the more enjoyable activity over the non-AR. Younger children (5 or 6 years old) were also more likely to rate the AR experience as more enjoyable (r_{32}=−0.366; *P*=.03) than older children (7 or 8 years old).

When children and caregivers were asked to rank the enjoyment of all 4 conditions individually, there were main effects of Animal Format and Activity Structure for both children ($F_{1,33}$=22.65; *P*<.001 and $F_{1,33}$=7.13; *P*=.01, respectively) and caregivers ($F_{1,33}$=33.21; *P*<.001 and $F_{1,33}$=7.61; *P*=.01, respectively). The majority of children and caregivers ranked low-structure AR as the most enjoyable condition (n=15 and n=21, respectively), followed by high-structure AR (n=11 and n=6, respectively; Table 1, Figure 4, and Multimedia Appendix 1).

XSL•FO
RenderX

Figure 4. Group mean (SE) for child enjoyment and caregivers' perception of their child's enjoyment on the fun sorter ranking scale of all 4 conditions, where 4 was the favorite condition and 1 was the least favorite. AR: augmented reality. *Indicates statistically significant differences in pairwise comparison (*P*<.05).



Of the 31 caregivers who rated AR as preferred, 25 chose to provide a written rationale for their rankings. Forty-eight percent (12/25) of caregivers wrote their child demonstrated more signs of excitement during the AR conditions, for example, stating, "More expressive, finding the AR animals 'argh, the shark is scary.'" Forty-eight percent (12/25) of caregivers who rated AR as preferred also referred to the novelty of the AR experience, making it more enjoyable, for example, stating, "[child] has never used AR, I think the novelty of it was a bit more enjoyable for him (new always better than old)." Caregivers also wrote that being able to use technology made the AR more appealing to their children (8/25, 32%), for example, "[child] hasn't used smartphone apps and it's extra exciting to have the technology and AR for the first time." Two caregivers mentioned that AR enhanced the social connection between their children, stating, "I think it added another dynamic to the play and added a social element." Of the 3 caregivers who felt their child preferred the non-AR conditions, all 3 believed this was because they were easier to find, stating, "quicker reward, easier to find." Regarding activity structure, 19 caregivers provided rationales for their responses. Of these, 42% (n=8) believed their child enjoyed the low-structure conditions more because they allowed more freedom and autonomy in play, for example, stating, "a bit more autonomy. They can create their own paths and adventures." Twenty-one percent (n=4) commented on the increased social aspects of low-structure, for example, stating, "We were able to concentrate on finding animals rather than completing the obstacle items and able to interact more with each other rather than being on their separate courses."

Time Spent in Each Condition (Engagement Time)

Time spent engaging with AR or non-AR animals differed significantly with main effects of both Animal Format (AR: mean 239.8, SD 68.3 seconds vs non-AR: mean 171.3, SD 73.9 seconds; $F_{1,33}$=39.17; *P*<.001) and Activity Structure (low-structure: mean 230.2, SD 78.2 seconds vs high-structure: mean 180.9, SD 71.8 seconds; $F_{1,33}$=14.14; *P*<.001). Low-structured AR engaged children for longer than all other conditions (mean 263.1, SD 65.7 seconds), followed by high-structured AR (mean 225.7, SD 69.4 seconds; Table 1 and Figure 5).

XSL•FO
RenderX

Figure 5. Group mean (SE) for engagement time in seconds. AR: augmented reality. *Indicates statistically significant differences in pairwise comparison (*P*<.05).

Physical Activity Intensity Across Conditions

Questionnaire: Perception

Child ratings of physical activity perception showed no main effect of Animal Format (AR: mean 4.3, SD 0.7 vs non-AR: mean 4.3, SD 0.8; $F_{1,33}$=0.03; *P*=.86) or Activity Structure (low-structure: mean 4.3, SD 0.7 vs high-structure: mean 4.3, SD 0.8; $F_{1,33}$=0.30; *P*=.59; Table 1) on perceived physical activity levels. Pairwise comparisons found no significant results. The majority of participants rated their perceived physical activity level as 5 out of 5 in all conditions, indicating they felt they spent the majority of their time running (refer to Multimedia Appendix 1 and Figure 3).

Accelerometer: Percentage of Time Spent in Postures and Movements

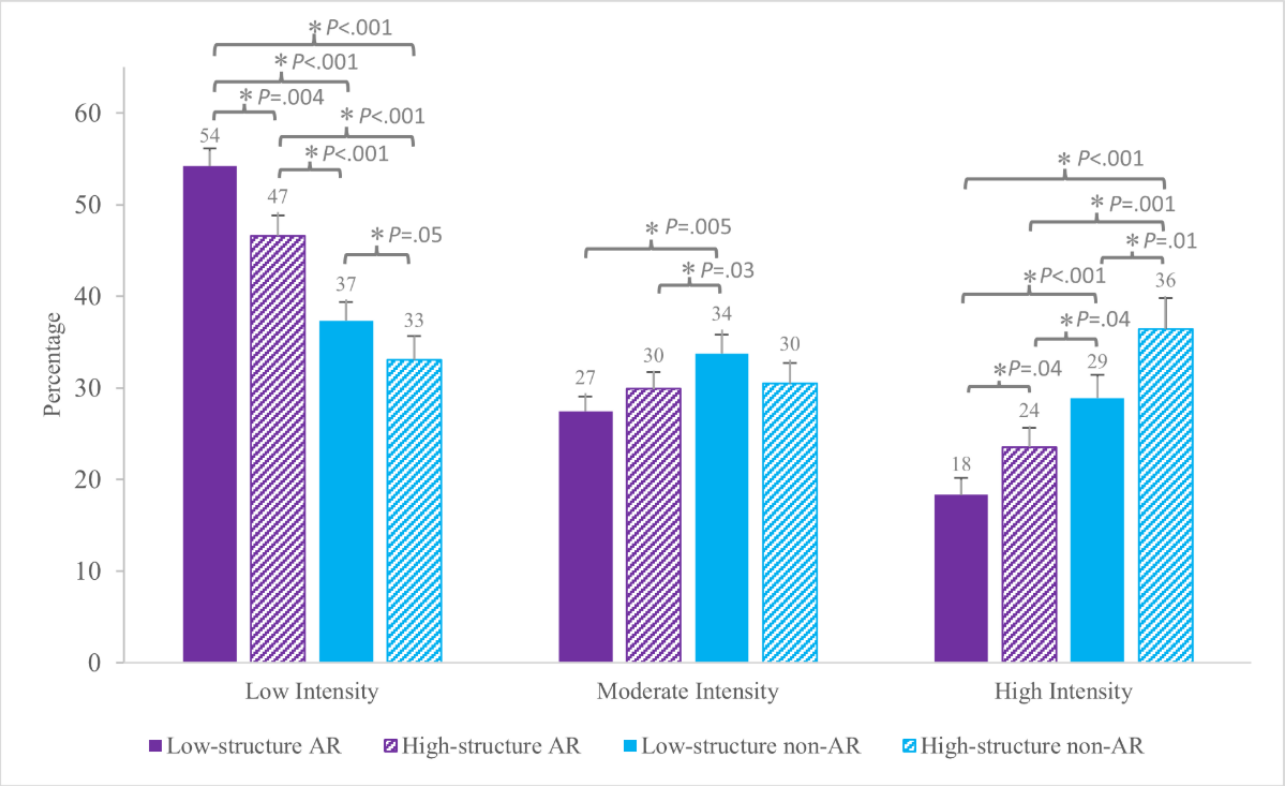
Low-Intensity Percentage

There were main effects of Animal Format (AR: mean 50%, SD 13% vs non-AR: mean 35%, SD 14%; $F_{1,33}$=68.13; *P*<.001) and Activity Structure (low-structure: mean 46%, SD 14% vs high-structure: mean 40%, SD 16%; $F_{1,33}$=13.15; *P*<.001) on the percentage of time spent in low-intensity postures and movements. During low-structure AR, the majority of time (54%) was spent in low-intensity postures and movements, a greater percentage than all other conditions (vs high-structure AR, *P*=.004; vs low-structure non-AR, *P*<.001; vs high-structure non-AR, *P*<.001). High-structure AR (47%) also differed from all other conditions (vs low-structure AR, *P*=.004; vs low-structure non-AR, *P*<.001; vs high-structure non-AR, *P*<.001; Figure 6). This was driven primarily by increased time spent standing (12% and 7%, respectively;) and sitting (11% and 8%, respectively; Table 1 and Figure 7). The lowest

XSL•FO
RenderX

percentage of time spent in low-intensity postures and movements was during high-structure non-AR (33%).

Figure 6. Group mean (SE) accelerometer results for the percentage of time spent in low-intensity postures and movements (lie, sit, stand, and move), moderate intensity (walking), and high intensity (run and stairs+) per condition. AR: augmented reality. *Indicates statistically significant differences in pairwise comparison (*P*<.05).



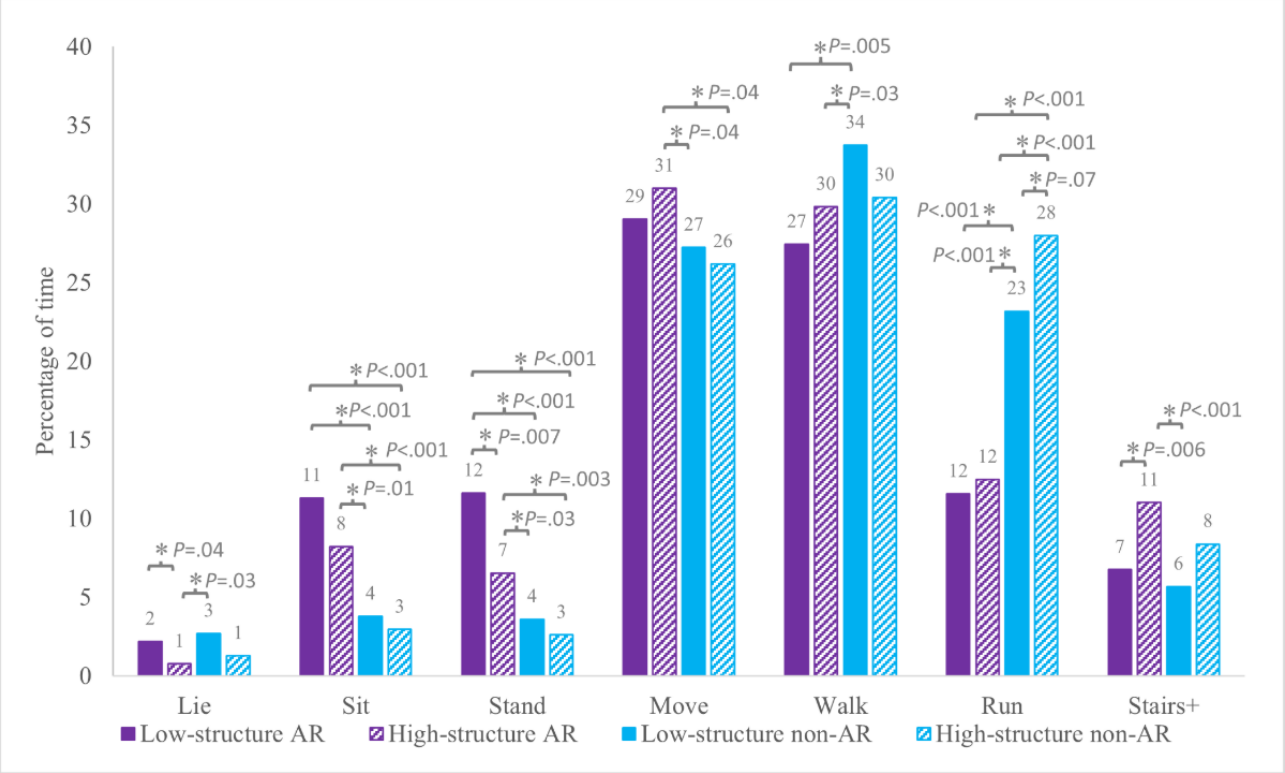


Figure 7. Group mean (SE) accelerometer results for the percentage of total time spent in each posture and movement per condition. AR: augmented reality. *Indicates statistically significant differences in pairwise comparison (*P*<.05).

XSL•FO
RenderX

Moderate-Intensity Percentage

There was a main effect of Animal Format (AR: mean 29%, SD 10% vs non-AR: mean 32%, SD 13%; $F_{1,33}$=6.61; P=.01) on the percentage of time spent in moderate-intensity movements, but no main effect of Activity Structure (low-structure: mean 31%, SD 11% vs high-structure: mean 30%, SD 12%; $F_{1,33}$=0.12; P=.73). A greater proportion of time (34%) was spent walking during low-structure non-AR compared to both AR conditions (low-structure AR: 27%; t_{33}=3.02; P=.005; d=0.60 and high-structure AR: 30%; t_{33}=2.32; P=.03; d=0.36) but did not differ from high-structure non-AR (30%; t_{33}=1.69; P=.10; Table 1; Figures 6 and 7).

High-Intensity Percentage

There were main effects of Animal Format (AR: mean 21%, SD 12% vs non-AR: mean 32%, SD 18%; $F_{1,33}$=37.87; P<.001) and Activity Structure (low-structure: mean 24%, SD 14% vs high-structure: mean 30%, SD 18%; $F_{1,33}$=9.84; P=.004) on the percentage of time spent in high-intensity movements. The greatest proportion of time in high-intensity movements was during non-AR conditions, with 36% of time during high-structure non-AR and 29% in low-structure non-AR (Figure 6). Both were due to an increased percentage of time spent in running (28% and 23%, respectively; Table 1 and Figure 7). The lowest proportion of time spent in high-intensity movements was during low-structure AR (18%; vs high-structure AR: 24%, P=.04; low-structure non-AR: 29%, P<.001; high-structure non-AR: 37%, P<.001). Accelerometer results in seconds are presented in Multimedia Appendix 1.

Discussion

Principal Findings

This study was the first to investigate the effect of a marker-based AR-enhanced versus traditional non-AR laboratory-based playground scavenger hunt on young children's enjoyment and physical activity during both low-structured and high-structured play. Our hypothesis that children would enjoy the AR was supported, with children rating AR in both low- and high-structured scavenger hunts as more enjoyable than non-AR, and they spent longer engaging with the AR. Caregivers' perceptions of their child's enjoyment showed a similar pattern. Physical activity was of a lower intensity during AR conditions; however, given the nature of AR interaction requiring children to be stationary to "activate" it, this is not surprising. Despite the lower intensity of activity, the longer engagement time during AR conditions may lead to greater accumulation of active play and, therefore, health and wellness benefits, although this warrants further investigation.

Enjoyment is reported to be a key factor in children's motivation to participate in physical activity from both theoretical models, such as self-determination theory [15], and research evidence [14,16,18,19,41,42]. In this study, children's enjoyment ratings across all tasks were high (range 4.1 - 4.5 out of 5), but when they were invited to rank conditions, there was a strong preference for AR, with 82% (n=28) of children and 91% (n=31) of caregivers ranking searching for AR animals as more enjoyable than searching for non-AR animals. Condition order was randomized, suggesting the preference for AR was unlikely to be a recency or order effect; however, it is possible there was a novelty effect. Children with no previous AR experience (59%, n=20) were more likely to rate the AR as more enjoyable. In addition, caregivers who ranked AR as more enjoyable commented on the novelty of the AR (48%, n=12) as a possible explanation. This is consistent with research in adults; for example, one study found that most adult participants increased physical activity for only the first 3 to 4 weeks of playing Pokémon Go [43]. How long the potential novelty effect of AR lasts in children is unknown, but could potentially be overcome by the design of the AR application (eg, changing challenges with increased play). Younger children in our study (aged 5-6 years) were more likely to rate the AR as more enjoyable than the non-AR condition in comparison to older children (aged 7-8 years). Given the lack of correlation between age and AR experience, this may be explained by the design of the AR—solo, low-fidelity, slightly animated animals—being too simple to hold the interest of some older children. The AR application used for this study was custom-built for this project by a single programmer and may not be as sophisticated as commercially available products. AR fidelity is an important consideration for future studies, particularly those aimed at an older age group. Caregivers (32%, n=8) also commented on the appeal of technology use as a possible explanation for their child's high enjoyment. The link between technology use, task enjoyment, and motivation to participate has been noted in children in clinical [29] and educational [5] settings and aligns with the self-determination theory and research by Sebire et al [18] that found young children's enjoyment was strongly linked with increased participation in physical activity.

While the enjoyment results suggest that AR may be a useful tool to motivate children to participate in physically active play, the physical activity intensity recorded in this study during AR was low. A greater percentage of time was spent in low-intensity postures and movements during AR, in particular low-structured AR, which saw 11% and 12% of time spent in sitting and standing, respectively, compared to 3% - 4% during non-AR conditions. In contrast, a greater percentage of time was spent in high-intensity movements during non-AR conditions, with 23% and 28% of time spent running in low- and high-structured non-AR conditions, respectively, compared to 12% - 13% during AR conditions. Despite the discrepancies in low- and high-intensity postures and movements, the greatest percentage of time in all conditions was spent moving (any instance when the child was stationary but not still, eg, fidgeting) or walking. Given the nature of the AR task, requiring children to stop and remain stationary to "activate" the AR and subsequently engage with it (eg, lying down to pretend the animal was standing on them), the accelerometer physical activity results are not surprising. It should also be noted that during AR conditions, children did participate in high-intensity movements, with a similar percentage of time spent running as they spent standing. While this particular AR experience may not have prompted as much high-intensity physical activity as non-AR play, it did engage children for 36% longer; if this were extrapolated out to a 1-hour playground visit, this could lead to an additional 22 minutes of play. However, future field-based studies with unrestricted time limits are needed to explore this further.

XSL•FO
RenderX

Interestingly, children perceived their physical activity level to be comparable across all conditions and felt they spent the majority of their time running. This discrepancy in reported versus recorded physical activity levels, possibly explained by social desirability bias, is common in research [44] and highlights the need for objective measures such as accelerometers to be used in children's physical activity research [35,40].

AR may be beneficial to implement in both low- and high-structured play environments. The level of activity structure affected physical activity levels, with a greater percentage of time spent in low-intensity postures and movements in low-structure AR conditions, and a greater percentage of time spent in high-intensity movements during the high-structure AR. This finding, however, may be offset by the generally greater enjoyment reported during the low-structured play, potentially leading to greater motivation to participate for longer. AR is versatile and can be adapted to different environments in comparison to many other digital technologies that encourage active play in children, such as game consoles. While these digital devices have been found to elicit low to moderate physical activity levels during gameplay [45], they are restricted to indoor use and require the purchase of expensive equipment. Marker-based AR, such as that used in this study (as opposed to markerless and GPS-based AR), may be particularly useful as it allows the greatest user control over AR location. For example, this study incorporated marker-based AR into laboratory play equipment, but this could easily be relocated to any other indoor or outdoor playground or obstacle course. AR applications may present a cost-effective way to enhance existing community playground infrastructure. Its simple and versatile application could be implemented by coaches and parents to encourage children to participate in certain movements; for example, AR markers could be placed along a beam to encourage balance, at the top of stairs to encourage climbing, or in a low-structured environment to encourage imagination. However, future research should investigate the potential risk to children colliding with objects and tripping over while moving around play equipment with a smartphone. Smartphone AR use by adults has been associated with poorer road-crossing behaviors [46], but whether the risk of miscoordination exists when children use a smartphone for AR remains unknown and warrants investigation before AR playgrounds can be considered in the community.

Limitations and Future Research

This study had several limitations. The use of subjective ratings in young children may be biased. For example, there were instances where the responses given by some of the children did not match what the researcher or caregiver perceived based on the child's behavior. These instances were not removed from the dataset and were instead considered a limitation of collecting subjective ratings in young children. Another potential limitation of subjective self-report measures completed in the presence of the researcher is the potential for social desirability bias. This may have impacted the perceived physical activity level and enjoyment outcomes; however, children were blinded to the hypotheses of the research in an attempt to reduce this. Future research should consider looking at evidence of children's enjoyment of AR playgrounds beyond self-rating scales and caregiver perspectives and using objective measures of physical activity such as accelerometers. This study was limited to a relatively small population in one geographical region and was conducted under controlled laboratory conditions. Whether these findings remain consistent in a community outdoor playground, where children may behave differently, and in different geographical regions, warrants investigation. It should also be acknowledged that the methods used to classify postures and movements from the accelerometer required the child to be performing the movement (ie, running) for at least one full second. Given the small indoor space and distances between play equipment, high-intensity movements may have been underestimated in all conditions. In an outdoor environment with more space to move, physical activity may be of higher intensity. AR experiences vary enormously, from a static generated image to completely immersive environments where the real-world visibility is minimal. Future research should investigate how children of different ages respond to different levels of AR immersion and whether there are added benefits to increased immersion, such as additional enjoyment or increased physical activity, or if it poses risks such as simulator sickness or falling. Simulator sickness is a common side effect in immersive virtual reality and headset AR [47], but little is known about whether handheld AR poses the same risk to children. An additional risk that should be investigated before smartphone AR games are used in community playgrounds is the distraction and social isolation that the presence of a smartphone may introduce. The potential effect that novelty may have on enjoyment, engagement time, and physical activity results should also be acknowledged. As this study was conducted in a single data collection session with a novel AR app, future longitudinal studies are needed to investigate how the novelty of AR-enhanced playgrounds changes over time. Future field-based studies are also needed to determine if unrestricted play time results in greater accumulated physical activity over time when using AR. Practical considerations for playground and AR designers that arose during this study include fidelity of the AR experience to appeal to a wide age range, the added flexibility and control of marker-based AR, and the potential need to maintain interest after initial novelty has worn off.

Conclusion

This study found that young children enjoyed participating in a search task for AR animals using a smartphone more than searching for traditional toy animals. Given that enjoyment is a key element in children's motivation to participate in tasks [5], including physical activity [41], AR may have the potential to encourage children to be physically active. While physical activity was of a lower intensity during the AR condition, which may be explained by the nature of the AR requiring children to stand to activate it, the engagement time was longer, potentially leading to an overall greater accumulation of active play if time was not restricted. This study cannot rule out the possibility that the novelty of AR may have produced the high enjoyment reported; therefore, future studies should explore the longer-term effects of AR on enjoyment and physical activity and whether these findings translate from the laboratory to a community

XSL•FO
RenderX

outdoor playground. However, these laboratory-based findings suggest that smartphone AR technology could be a novel method to encourage young children to participate in active play.

Acknowledgments

The authors would like to acknowledge Carley Tillett from the Curtin University Hub for Immersive Visualization and eResearch for her contribution to developing the augmented reality application used in this study. Abstract

Background: Medical resource allocation is important to ensure availability of care, especially in challenging circumstances like a pandemic. In fields of unpredictable care demand such as obstetrics, forecasting may help manage scarce resources.

Objective: The development, validation, and implementation of a regional birth forecasting tool to support obstetrical staff planning in the Utrecht region during the COVID-19 pandemic.

Methods: We combined predicted birth dates retrieved from Saltro, a large regional primary care laboratory, with data from the Dutch national perinatal registry (Perined) and Statistics Netherlands for model development. We created and implemented an HTML tool visualizing these forecasts, which were discussed during the regional acute obstetric health care network meetings. Six months after implementation, we assessed the impact of the tool using an evaluative stakeholder meeting.

Results: We achieved a performance accuracy (*R*) of 0.45, 0.61, and 0.67 (all actual number of births within 95% CI) forecasting the number of births in the region, pooled in 1-, 2-, and 3-weekly bins, respectively. After presenting these findings to stakeholders, we implemented a forecasting tool using the 2-week bin model. The evaluative stakeholder meeting proved that the tool improved communication, awareness of health care need, and collaborations among health care providers in the Utrecht region. Additionally, stakeholders identified additional applications, such as communication with patients and training of obstetric health care providers.

Conclusions: Implementation of a forecasting tool for the number of births based on available data across the health care system added value to obstetrical care by providing insight into care demand, and increasing communication, awareness, and collaboration between health care providers. Further research should aim at improving regional obstetric acute care by fostering data sharing in order to improve health care demand forecasts.

(JMIR Pediatr Parent 2025;8:e68284) doi:10.2196/68284

KEYWORDS

resource allocation; regional health planning; quality of care; routinely collected data; stakeholder participation

Introduction

Clinical care for patients in hospitals, and especially in the acute care chain, depends on the infrastructure and on careful planning of resources such as staff, equipment, and beds. The COVID-19 pandemic magnified this complexity as the combination of patients who were hospitalized with COVID-19 and frequent sick leave of already scarce medical personnel for clinical care posed a burden on hospital capacity. Even more complex is planning in acute care departments, including the emergency departments, the obstetrics ward, and the intensive care where medical personnel are not only scarce, but patients' needs are unpredictable [1,2]. The efficient allocation of resources is an important performance indicator of quality of care (QoC) according to the US Institute of Medicine [3]. The World Health Organization (WHO) identified the impairment of QoC in obstetrics as a major roadblock for ending preventable maternal and neonatal mortality and morbidity and called for skilled care

XSL•FO
RenderX

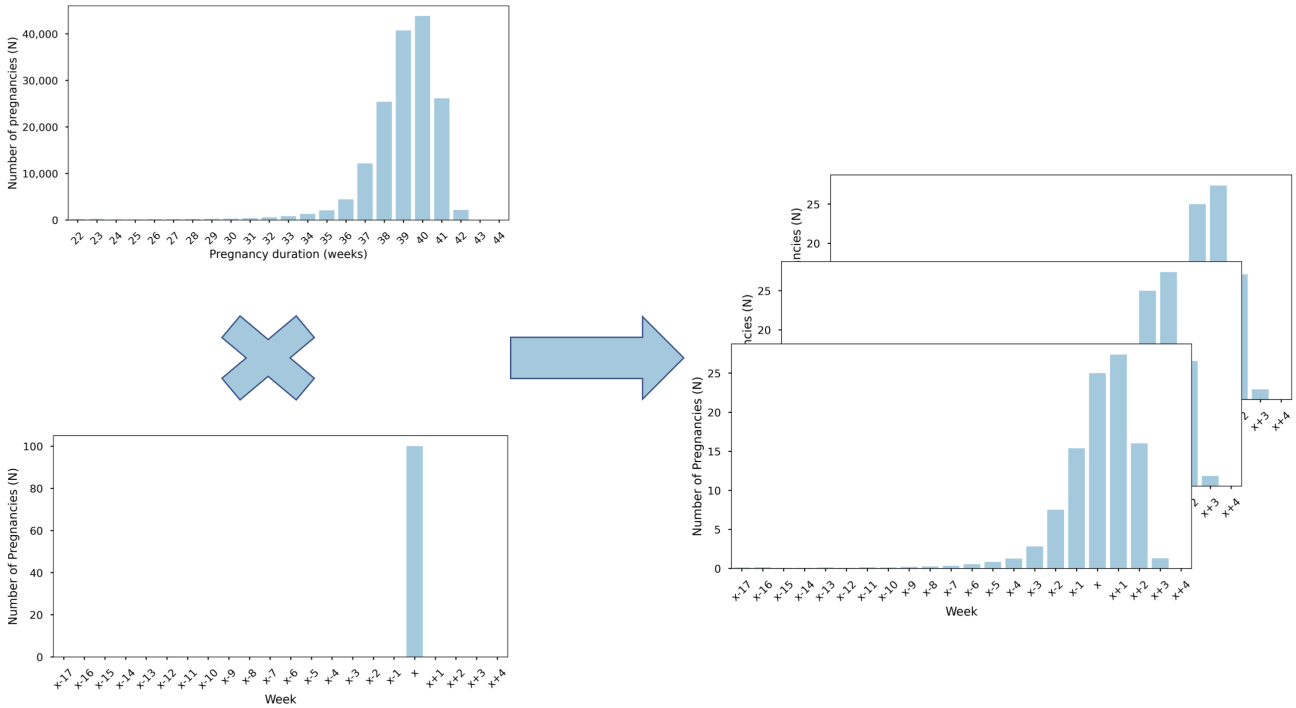
and evidence-based practices [4]. Managing resources such that high-quality obstetrical care delivery can be maintained is thus essential when hospital capacity is under pressure.

Contrary to acute care needs for emergency departments, the expected date of birth provides an opportunity to predict future average demand in obstetrics. Date of birth itself can be understood as a result of a prediction model, using first day of last menstruation date, and is in the Netherlands confirmed by the crown-rump length (CRL) at ultrasound around 11 weeks of pregnancy [5,6]. In addition, the Dutch health care system offers routine first-line obstetrical care around the eighth week of pregnancy. Around 11 weeks, women are invited to participate in a screening (booking blood) for infectious diseases (HIV, Hepatitis B, and Lues), anemia, and irregular erythrocyte antibodies (eg, Rhesus disease). A total of 99% of women take part in this screening program [7]. On the lab test order form, the calculated date of birth is listed. As such, these laboratories have access to data of expected birth dates. In the midst of regional (larger Utrecht area) capacity problems in acute obstetric care, there was a need within the network regional consultation acute care (ROAZ midden Nederland) to forecast the number of births in the region. Since we were not able to extract the estimated date of delivery from the existing perinatal health care systems, the idea came up to use the data registered during the booking bloods.

The goal of this study was to support obstetrical staff planning during the COVID-19 pandemic by using data from Saltro, a large primary care laboratory in the Utrecht region of the Netherlands and regional obstetrics outcomes to develop, validate, and implement a forecasting tool for the trend in number of births. Additionally, a qualitative stakeholder meeting was held 6 months after implementation in order to discuss the impact of the tool.

Methods

Data Sources



In order to model (trends in) the number of births in the population, we retrieved all historical data of expected birth dates from 2014 to 2019 of Saltro, as registered during the screening around 11th week of pregnancy, and linked them to a dataset of Statistics Netherlands with live births from 2015 - to 2017 as outcomes. To ensure a representative dataset, while also ensuring that data loss was minimized, we included only data from municipalities where Saltro had data on at least 55% of pregnancies. We aggregated the data to the number of births per week. We accounted for the uncertainty of the expected date of birth by using the national pregnancy length distribution (in weeks) of the Dutch national perinatal registry, Perined [8]. According to the Dutch legislation, this research did not fall under the Medical Research Involving Human Subjects Act (WMO). Only anonymized aggregated data were used for analysis. The research was conducted according to the declaration of Helsinki. Health care professionals provided verbal informed consent prior to the interviews.

Forecasting Tool and Model Development

To correctly forecast the number of births per week, we used the expected birth date as the base model. Consequently, we distributed the number of births for each week over the surrounding weeks according to the Perined distribution (Figure 1) and repeated this process 1000 times per week. This resulted in a calculated mean and SD per week. For a certain week, the number of expected date of births would actually be forecasted in the period between 17 weeks before and 5 weeks after the denoted week. When repeating this process for all weeks, the number in every week would become a sum of all these calculations.

XSL•FO
RenderX

Figure 1. Modeling approach. For a specific week (**X**), each expected birth date (left-bottom) was assigned to a specific week using the Perined distribution of pregnancy durations (left-top). By repeating this simulation 1000 times, we were able to calculate a mean estimate and SD assigned to each surrounding week (x-17 to x+4) (right). By repeating this for all weeks in our data, we were able to estimate a cumulative estimate per week.

To validate the modeling output on actual outcome data, we correlated the mean forecasted number of births for each week with the amount as reported by Statistics Netherlands. We combined the number per week to 2- and 3-weekly bins (ie, summing up the numbers for week 1 and 2, week 3 and 4, etc), and assessed whether this improved the correlation and thus predictive accuracy. Considering the potentially high variance of calculated number of births, binning the project number of births to 2- or 3-weekly bins may help smooth out large weekly differences. To compare the mean estimate and a 95% CI of our model to the actual number of births, we normalized the visualization of these two types of data, so that these two were comparable.

This work, and the development of the resulting tool, was performed using the Python programming language (version 3.8, Python Software Foundation) and the *pandas* (Version 1.1), *numpy* (version 1.19), and *scipy* (version 1.5) packages. We used the *plotly* package (version 4.14) for interactive visualization purposes.

Implementation Research Using Stakeholder Meetings

After the model for the tool was validated, we presented our findings to stakeholders in the obstetrics field, including future end-users of the tool, such as managers and obstetric care providers (n=13) during the weekly consultation of the regional obstetric acute care (ROAZ midden Nederland). After an introduction explaining the modeling and the visualization, we sent the forecast to this status meeting on a 2-week basis.

In order to assess the added value of the forecasting tool in the obstetrics care, we invited regional stakeholders (eg, gynecologists, midwives, and managers) from the network regional consultation acute obstetric care (ROAZ Midden Nederland) for an evaluative stakeholder meeting 6 months after implementation of the tool. To this purpose, we created a topic list to investigate the experiences with staff planning and resource management after implementation of the tool as compared to before this implementation, and the experience with use of the forecasting tool (Table S1 in Multimedia Appendix 1). We then analyzed this discussion using Nvivo (version 12.6.1.970; QSR International), and extracted information about the aforementioned topics, as well as remarks on the tool, including possible areas for further research and improvements of the tool.

Ethical Considerations

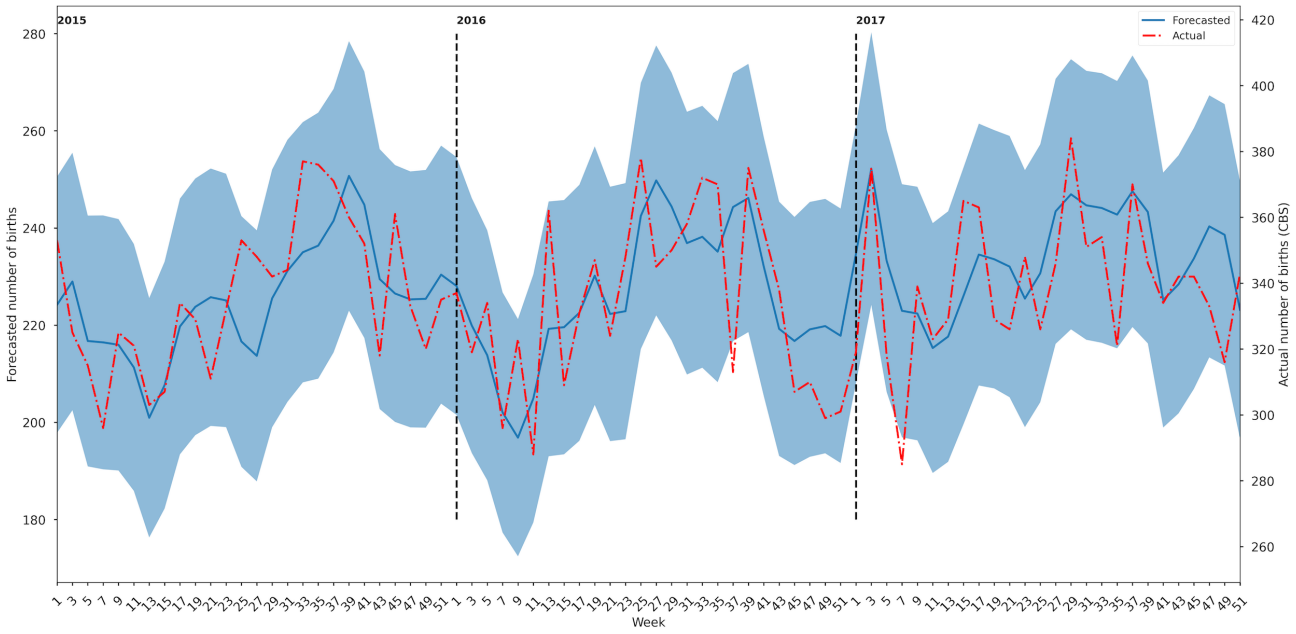
According to the Dutch legislation [9], this research did not fall under the Medical Research Involving Human Subjects Act (WMO). Only anonymized aggregated data were used for analysis. The research was conducted according to the Declaration of Helsinki. Health care professionals provided verbal informed consent prior to the interviews.

Results

Tool and Model Development

In total, Saltro screening data on 28,361 pregnancies were used from 23,778 patients with births per year ranging from 5052 in 2014 to 6047 in 2017 (mean 5681 per year). The Statistics Netherlands data from the included municipalities encompassed 35,394 births with births per year ranging from 8735 in 2016 to 9051 in 2014 (mean 8849 per year). The municipalities that were included in the development of the forecasting tool are given in Table 1, along with the number of pregnancies as reported by Saltro, and the actual number of births as reported by Statistics Netherlands.

XSL•FO
RenderX



The correlation between the modeling output and number of births as reported by Statistics Netherlands was 0.45 for weekly data. For the 2-weekly bins, we found that the correlation between the model output and the Statistics Netherlands increased to 0.61, and for 3-weekly bins, this was 0.67 (Figure 2; Figures S1 and S2 in Multimedia Appendix 2). All actual number of births were within the forecasted 95% CI, after normalization for differences in scale between modeling output and actual numbers (Figure 2).

Table . Included municipalities and included pregnancies from Saltro and reported births from Statistics Netherlands. Municipalities were included if more than 55% of reported births were found in the Saltro database.

Municipality	Expected date of births (Saltro), n	Date of births (Statistics Netherlands), n	Total births (Saltro data), (%)[a]
Bunnik	367	536	68
Bunschoten	819	1051	78
De Bilt	1148	1369	84
Houten	2011	1993	101
IJsselstein	991	1317	75
Leusden	828	1062	78
Nijkerk	1422	1784	80
Renswoude	231	305	76
Scherpenzeel	505	460	110
Stichtse Vecht	2460	2473	99
Utrecht	13,461	18,420	73
Utrechtse Heuvelrug	1239	1503	82
Woudenberg	566	590	96
Zeist	2313	2531	91

[a]The percentage can be more than 100%, as women can deliver in hospitals, therefore changing the municipality of birth in comparison to the municipality of the mother.

Figure 2. Forecast in 2-weekly bins in 2015, 2016, and 2017. The y-axis of the actual births (right-axis) is normalized on the forecast (left-axis), in order to compare the two data. The forecasted number of births is depicted in blue; the actual number of births is depicted in red.

Presentation to Stakeholders and Implementation

The stakeholders chose a 2-weekly bin for forecast-width as this was considered a good trade-off between actionability with regards to planning (smaller bins mean higher granularity), but also having good predictive power. Additionally, the numbers were presented with an overall average over the preceding years (2015 - 2020). From July 2021 onwards, we provided these forecasts every 4 weeks; in September, this interval was shortened to 2 weeks upon request. We performed forecasts

XSL•FO
RenderX

over 13 weeks in advance, as we observed that forecasts using this time window were most stable in comparison with follow-up forecasts, because of incomplete data in the later weeks.

Evaluative Stakeholder Meeting

In total, 4 stakeholders attended the evaluative stakeholder meeting, including 3 stakeholders that worked in hospitals and 1 stakeholder that worked as community midwife.

Insights Before Introduction of the Tool

The stakeholders noted that before the introduction of the tool, there was a sense of competitiveness between different health care providers, as there was little insight into the upcoming number of births (Textbox 1, quote 1A), and the general need of care in the region. This meant that health care providers tried to provide as much care as possible by themselves, rather than collaborating with other health care providers in the region. Additionally, stakeholders stated that when it came to planning, they only used their own data and experiences, and that sharing of information was not common practice (Textbox 1, quotes 1B and 1C).

Textbox 1. Quotes illustrating insights before the introduction of data from the Saltro and tool. Quotes are translations from original Dutch transcripts.

Quotes

- 1A: We came out of a situation where there was less trust and more competition.
- 1B: We just did something, especially forecasts. We didn't know a lot; we knew what we did ourselves.
- 1C: [We planned based] on our own numbers, not taking forecasts into account, because we didn't predict anything

Insights After Introduction of the Tool

Stakeholders did not use the forecasts for day-to-day staff planning, as the interval of the forecasts was still considered too wide, and the uncertainty around the forecasts was considered too large, as most women give birth in a period of 5 weeks around the predicted date of birth (Textbox 2, quote 2A). Interestingly, the application stressed the increasing sense of urgency of high health care demand and the communication of this urgency to the management and higher-up levels. Additionally, this sense of urgency also resulted in the regional collaborations and a lower sense of competitiveness (Textbox 2, quote 2B).

Textbox 2. Quotes illustrating further use of the tool and room for improvements and research with regards to the tool. Quotes are translations from original Dutch transcripts.

Quotes

- 2A: The problem is that the forecast is done with a period of 5 weeks where women give birth, and then not even all of them give birth [during that time]
- 2B: We dealt with each other in a very different way, because we were each other's competitors and we kept our cards to our chests. That's completely gone.
- 2C: Saying: don't take a holiday] is a difficult one, but we stopped schooling, training, several working groups, social activities, they were all canceled.
- 2D: On the one hand, you have the care demand with the forecasts, on the other hand, you have the care capacity, pretty high level, but it pretty well resembles the weekly reality. It made sure that we felt the urgency to have things together the first two weeks of December. So, canceling schooling, canceling all other stuff, make sure we are ready operationally.
- 2E: [We] have the sense of urgency to talk about this [timeliness], and it [the forecast] is a tool to get things rolling, which were otherwise ignored. Then everyone would have said: "We should look at it sometime." Now it is: "We should look at it now".

This sense of urgency also had implications for planning on the operational level. For example, during the summer and autumn of 2021, the number of births was relatively high, around 10% to 20% above average for that specific period. By using the forecasts, obstetricians were able to increase their number of regional escalation management meetings and subsequently de-escalate when the care demand decreased again in December. Additionally, the sense of urgency also resulted in the cancellation of schooling, working groups, and social activities. The tool helped gain insight into when education and holidays should be planned, moved, or canceled (Textbox 2, quotes 2C and 2D).

Finally, the tool created the insight and urgency to act on other markers for QoC. As the numbers of births increase over a time period, and the availability of resources decreases, the focus of care was not just on patient safety, but also on timeliness and availability of care (Textbox 2, quote 2E).

Other Means of Use

Another way in which the tool could be used and add value was in the communication of the available care toward clients and patients. The stakeholders indicated that, at present, prospective parents are selecting their preferred hospitals for childbirth. However, this preference cannot always be met, due to limited capacity of these hospitals (Textbox 3, quotes 3A and 3B), especially since total capacity of hospitals is based on regional instead of local demand. The stakeholders considered the tool as a helpful tool to discuss expectations of pregnant women and to manage their expectations and preferences. Stakeholders also

XSL•FO
RenderX

identified a current QoC issue in obstetrics, namely when pregnant women receiving extra obstetric care were not always able to deliver in that specific hospital, which was considered undesirable as stakeholders argued that these women should receive care from one single (specialized) hospital (Textbox 3, quote 3C).

Textbox 3. Quotes illustrating further use of the tool and room for improvements and research with regards to the tool. Quotes are translations from original Dutch transcripts.

Quotes

- 3A: The chance that a pregnant woman delivers in the hospital of their choice, let's be positive, is about 60%.
- 3B: We can't make that [choosing the hospital to deliver] happen anymore, we would want to, but we can't make it happen. Using these data, we can tell them why, … and first-line obstetrics care (i.e. community midwives and postpartum caregivers) can profit from this, because they end up telling parents that they can't deliver where they wanted to deliver, so that something that should be beautiful ends up being less beautiful.
- 3C: I think that we get to the point that we are going to talk to each other, that there are patients that we know and that should stay in our hospitals, because there is more at hand with these patients, and that there are patients that have an uncomplicated pregnancy, but develop something in the last weeks, that it doesn't matter where these [patients] end up.
- 3D: We here are 'believers', but there are people who are not used to think in this way, and by showing these numbers over and over again, we show what we can do using these numbers.
- 3E: We don't think together what we have available with regards to capacity, and we don't share [this information] in the first line care what we have filled up with care demand.
- 3F: You know how many pregnancies there are, which is nice, but we don't know where they will deliver, and how this relates to each midwifery practice.
- 3G: I think that postal code is the most important, the area of adherence, because that's where we eventually, if we manage it, can tune the data for the obstetrics and maternity care.
- 3H: Based on historical data you can determine for some group when they will deliver, as long as you have them well monitored.
- 3I: Can you say anything about the percentages of [caesarian sections]? Because then you can also account for length of stay and impact on admission and staffing.
- 3J: We have the opportunity now, because COVID gives us this opportunity. If you look at the [National Coordination Centre for Patient Allocation], data is used differently. We have the opportunity to design something like that, maybe we should start with that regionally.

Another possible application was seen in the education of (health care) professionals in obstetrics, as data on health care demand are not widely shared. Stakeholders argued that, although they themselves were used to these kinds of tools, this was not the case for other health care professionals (Textbox 3, quote 3D). To create more familiarity with these kinds of tools, the stakeholders identified important hurdles. An example of a hurdle was the implementation of data sharing and central data collection. The stakeholders were not used to collaborating and sharing their data, and it was stressed this needed improvement (Textbox 3, quote 3E).

Stakeholders also commented on issues that were not addressed in our study, that is, features that would increase the usability and information density of the tool. Primarily, the stakeholders stated that more information could be gained with regard to specific patient groups: on localization of the patients (Textbox 3, quotes 3F and 3G) or subgroups to be included, e.g., cesarean sections (Textbox 3, quotes 3H and 3I). Stakeholders identified that in order to implement some of these improvements for the tool, more data should be shared among stakeholders in the obstetrics field. For example, stakeholders proposed a centralized data collecting system, similar to the system as implemented in the Netherlands during the COVID-19 (Textbox 3, quote 3J).

Discussion

Main Findings

In this study, we developed, validated, and implemented a tool to forecast and visualize trends of births in the greater Utrecht region, using routinely measured and collected calculated date of births by a primary care laboratory, to support management of the regional acute obstetric care, including staff planning. We developed a forecasting model and found that a 2- and 3-weekly binned forecasting model provided good predictive power when it comes to forecasting trends within birth numbers. Subsequently, we presented our findings to stakeholders in obstetrics and then implemented a tool to visualize our forecasts using a 2-weekly binned forecast. Although 3-weekly binned forecasts showed slightly higher predictive power, the choice for 2-weekly binned forecast was made, as this provided a more granular view of obstetric care demand. After 6 months, using an evaluative stakeholder meeting, we found that, although our tool was not used in day-to-day staff planning but rather on a (global) operational level, we were able to add value to the obstetrics field by adding a sense of urgency, resulting in improved regional collaborations and operational actions and improving QoC in obstetrics.

QoC is multifaceted. According to stakeholders, the use of our tool in daily practice enabled the focus on timeliness. Simultaneously, the tool supported collaborations in obstetric care, leading to more efficient and available obstetric care. A

well-coordinated acute obstetric care chain is important, as impaired communication between health care providers is detrimental to patient safety and continuity of care [10].

We implemented the forecasting tool during the COVID-19 pandemic. This crisis sparked the demand for more insights into obstetric health care demand, especially since during the pandemic, births varied more than before the pandemic. Examples include a birth wave after lockdown and fewer preterm births during the first lockdown [11,12]. Similar to other literature, we found a decrease in birth numbers in 2020 and an increase in birth numbers in 2021. Additionally, the surge of COVID-19 required more flexible resource management, as resource requirements changed or were scarce [13]. Considering that our data are able to capture the true birth rate in the general population opens up additional angles for research. Further study could focus on the decline in birth rate as seen in Nordic countries and Germany after 2021 [14,15], by studying the trend in expected births in our data. The increase in care demand and need for flexible resource management due to the pandemic fueled the development and implementation of the tool, as regional resources had to be more efficiently allocated due to high demands. Stakeholders reported that our tool was helpful in achieving these aims, by offering concrete data that heightened the sense of urgency within the obstetric care.

The academic literature and practice alike highlight the challenges of forecasting acute care demand, as it is often driven by unforeseen events or factors that fall outside the scope of routine data collection [1,2]. Indeed, we observed in our data that it is very hard to forecast the weekly number of births, considering their weekly variance. However, widening the scope of the forecasting interval and retrieving information from these data, such as trends, are of added value to the obstetrics domain according to stakeholders in obstetric care.

Our research should be understood in the light of the following limitations. We have included only limited data, originating from municipalities for which data on at least 55% of pregnancies was available. The extent to which our study therefore suffers from selection bias remains unclear. As the obstetrics care in the Netherlands and the reporting of calculated date of births is standardized, we believe bias is limited. However, future studies could focus on combining data sources for the estimated dates of birth, in order to increase the data coverage, and to mitigate reliance on a single data source. Additionally, our dataset is relatively small. With larger numbers, the use of statistical models such as Autoregressive Integrated Moving Average, or machine learning models may be beneficial [16]. Considering we had data on the actual number of births for 3 years, the use of such models was currently infeasible. To the best of our knowledge, no other forecasting model for the number of births is currently used in the Netherlands.

As stakeholders have stated in the stakeholder meeting, there are several directions for further research. First of all, data should be shared between stakeholders to improve regional (acute) obstetric care. This could help further improve forecasts, as this can help identify subgroups of pregnancies, so that these groups and their health care demand can be further monitored. Additionally, data sharing could lead to further standardization of data collection, making data collection and research to improve obstetric care more feasible and impactful.

Conclusion

Implementation of a forecasting tool for number of births based on available data across the health care system during the COVID-19 pandemic led to increased communication, awareness, and collaboration between obstetric health care providers, showing that combining several sources of data within the routine acute care can add value to the routine acute care process. Providing visualizations of forecasted births created a sense of urgency about the high care demand situation and the impact of this demand on quality of care. Our tool thereby facilitated improved collaborations and cohesion between health care providers in the Utrecht region and aided further initiatives that can increase efficient use of resources in response to high care demand beyond pandemic situations. Further research should aim at improving regional obstetric acute care by fostering data sharing in order to improve health care demand forecasts.

Abstract
