Background: Mothers of sick and preterm infants need support to establish and maintain lactation. Although many health technologies on breastfeeding are available, most lack in evidence-based information and are therefore not appropriate for educating mothers. Furthermore, they do not focus on the special challenges of mother-infant separation during lactation in mothers of sick or preterm infants.

Objective: The aim of this study is to examine the usability and perceived usefulness of the evidence-based information about lactation and documentation tools contained in the Neo-MILK web app.

Methods: A cross-sectional online survey was conducted among mothers of sick and preterm infants admitted to a neonatal intensive care unit in Germany. Descriptive statistics were calculated for the System Usability Scale (SUS) and for self-developed items pertaining to overall satisfaction and perceived usefulness of the app. These included items on evidence-based information and the usability of tracking functions.

Results: Of 341 mothers who were contacted, 80 responded (response rate, 23.4%), and data from 63 mothers were analyzed. The mean SUS score was 76.4. The overall satisfaction rate was high, with 84% (n=53) of respondents indicating that they were either satisfied or very satisfied. Further, 82% (n=52) were inclined to recommend the web app to other parents. On average, the evidence-based information was perceived as helpful, more detailed, and not contradictory compared to information provided at the hospital. At the same time, most of the users reported that the Neo-MILK web app did not exert pressure to provide breast milk to their infants. Approximately 71% (n=45) of the mothers used the documentation tool in the web app several times per week to track their milk volumes.

Conclusions: By combining evidence-based information and useful tools to document milk volume, the Neo-MILK web app was high rated in usability and perceived usefulness. Considering the limitations of the study, this web app appears to be a valuable tool for educating and supporting pump-dependent mothers of sick and preterm infants during lactation.

Introduction

For all infants, mother's own milk (MOM) should be the first choice of nutrition and is, therefore, recommended by the World Health Organization [1,2]. Its health-promoting effects are evident and sick and preterm infants, in particular, benefit from the nutrition with MOM due to their high vulnerability [3]. However, achieving a sufficient milk volume has shown to be challenging for mothers of infants admitted to a neonatal intensive care unit (NICU) [4]. As many of these mothers are pump-dependent and cannot directly breastfeed, they require structured lactation support to facilitate MOM feeding in their sick and preterm infants [4,5]. This support enables timely communication about the importance of MOM, early initiation of lactation, and frequent pumping to establish a sufficient milk supply, thus ensuring the infants nutrition with MOM [4,6]. When providing lactation support to mothers, sensitive communication without distressing mothers should be facilitated, as stress may negatively affect lactation [7-9]. Indeed, perceived pressure to provide breast milk has been commonly reported among mothers, which may be associated with other mental health issues [10-12].

Mobile health (mHealth) apps and web app technologies are used in various settings such as disease management, medication reminders, and rehabilitation to promote and support a healthy lifestyle [13]. Several mHealth apps focused on breastfeeding already exist, which have shown to improve breastfeeding knowledge, attitudes, and self-efficacy [14-16]. However, mothers with infants admitted to a NICU require special tools and approaches from an app during lactation due to their unique situation. In general, NICU parents report a high demand for information and a willingness to use electronic devices for information and support [17,18]. This potential is further supported by studies which evaluated evidence-based education and information-sharing apps may promote parental mental health, parent-infant relationship, and family-centred care [19-21]. However, while many apps are already available for this target group, a systematic review showed that only a few of them are of good quality [22]. There is a notable lack of evidence-based and scientifically evaluated mHealth technologies focusing on combining evidence-based information sharing with valuable tools for NICU parents throughout the lactation process. The Neo-MILK web app aims to fill this gap for mothers with infants admitted in the NICU, by including both tools such as milk volume tracking and multimedia evidence-based information on several topics (eg, pumping, breastfeeding, or skin-to-skin contact). It was developed as part of the Neo-MILK project, which supports lactating mothers of infants admitted to a NICU [23]. Therefore, the intention of this web app was to complement rather than replace essential personal and direct lactation support provided within NICUs.

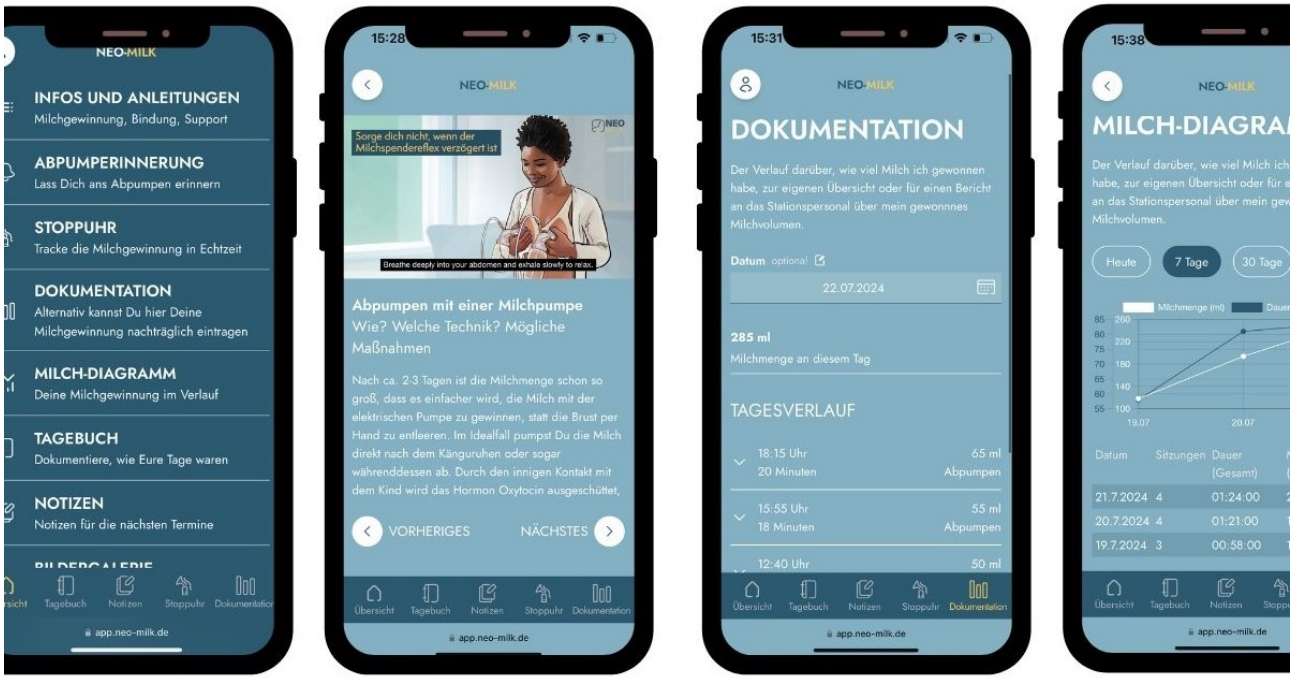
To measure the overall usability of mHealth technologies, the system usability scale (SUS) is a widely used instrument, which showed robust results in previous studies [24]. In addition, usability studies often report on ease of use, user experience, and user engagement, depending on the focus of the study [25]. Therefore, the objective of this study was to examine the usability and perceived usefulness of the evidence-based information about lactation and documentation tools contained in the Neo-MILK web app.

Methods

Research Design

A quantitative, prospective, and cross-sectional questionnaire was developed to evaluate the usability and perceived usefulness of the Neo-MILK web app.

Setting and Relevant Context



Participants in this study were mothers of preterm and sick infants admitted to a NICU. In Germany, initiation of lactation is often suboptimal [26]. This may be attributed to the often not implemented structured lactation support and lack of consistent information and personal support during lactation [27]. Mobile health technology may serve as a beneficial tool to help provide additional support to pump-dependent mothers.

Web App Development

In a participatory process involving mothers of very low birth weight (VLBW, <1500g) infants, features and content for the Neo-MILK web app were developed by a multidisciplinary team consisting of psychologists, economists, sociologists, neonatologists, neonatal nurses, and a web app developer. To determine the tools and features desired by mothers of VLBW infants, open questions were posted on Instagram. These questions were then ranked in an anonymous online survey completed by 138 mothers. Individual issues, such as the preferred type of communication, were also subject to direct voting via Instagram. Following this participatory process, the final design excluded photographs and instead featured animated parent-infant dyads and drawings. The illustrations were intentionally inclusive to reach a target group which is as diverse as possible. Therefore, the design includes people from different races and ethnicities. The illustrations and texts were developed through a process of various feedback rounds with the multidisciplinary team. As the Neo-MILK web app was part of the Neo-MILK project, the wording and presentation of the web app were aligned to the other materials developed within the project [23]. Finally, tools for recording the time, frequency, and volume of milk during expression, as well as a reminder for milk expression were included. Furthermore, evidence-based information on important topics related to lactation (eg skin-to-skin contact, bonding, milk expression, and hygienic handling of breast milk), along with answers to frequently asked questions regarding breastfeeding and pumping in the form of texts and videos are included in the web app to increase maternal knowledge. To reduce barriers to evidence-based information on pumping and breastfeeding, the videos were featured with subtitles in other languages. These were translated by native speakers working in the Neo-MILK team. Additionally, features such as a diary to document individual milestones of the child and the NICU-related reflections including the mother's mood and feelings were also provided. In cooperation with a media company (TAKEPART Media + Science GmbH), the app was designed as a browser-based web app (Figure 1).

XSL•FO

Measurements

The overall usability was measured using the SUS, which is a widely accepted tool to indicate usability, operability, and suitability for the use of digital health technologies [28]. Four slightly different translations of this scale are available in German. They were reviewed in a recent publication and revealed that the version by Rummel [29] described the developmental process and methodology most clearly. It was shown to be the best balance between methodologically clean development and wording and, therefore, was utilized in this study [29,30].

To measure the perceived usefulness of the information, videos and the documentation tools, self-developed items were assessed. Overall satisfaction was measured using a question: "How satisfied are you with the web app in general?" with a 4-point Likert scale ("very satisfied", "satisfied", "not satisfied", "not at all satisfied"). Moreover, participants were asked if they would recommend the web app to other parents with the following answering options: "yes", "rather yes", "rather no", and "no". Perceived usefulness of the information of videos was measured through a 4-point Likert scale of agreement ("agree", "rather agree", "rather disagree", "disagree") to three statements each for texts and videos which were as follows: (1) "The information I obtained from the texts (videos) were/are helpful for pumping and breastfeeding", (2) "The information I obtained from the texts (videos) were/are contradictory to those in the hospital," and (3) "The information I obtained from the texts (videos) were/are more detailed than those in the hospital."

To assess whether and how frequent mothers used the documentation tool for assessing their pumped milk volume using the following question "How frequently do you use the documentation tool?" which could be rated as: "several times a day", "daily", "several times a week", "several times a month", "less frequent", or "never." Moreover, they were asked whether they found the documentation tools easy to use in a 4-point Likert scale ("difficult", "rather difficult", "rather easy", or "easy"). Furthermore, to analyze whether the Neo-MILK web app caused negative feelings in mothers in terms of pressure to provide breast milk, the following statement was posed: "I felt pressured to provide breast milk by the Neo-MILK web-app" and could be rated on a six-point Likert scale ("totally disagree", "mostly disagree", "rather disagree", "rather agree", "mostly agree", "totally agree"). Data on feeding methods as well as previous experience with pumping or breastfeeding, and sociodemographic variables (eg, education, maternal age, infant's age) were collected. Due to small group sizes, the education level was dichotomized into lower education (lower secondary or secondary school) and higher education (higher education entrance qualification or university degree).

Data Collection

Data collection took place from September 2023 to May 2024 through the anonymous online survey tool Lime Survey (LimeSurvey GmbH). Data were collected and analyzed by researchers at the University of Cologne, who were also the principal investigators of the Neo-MILK project.

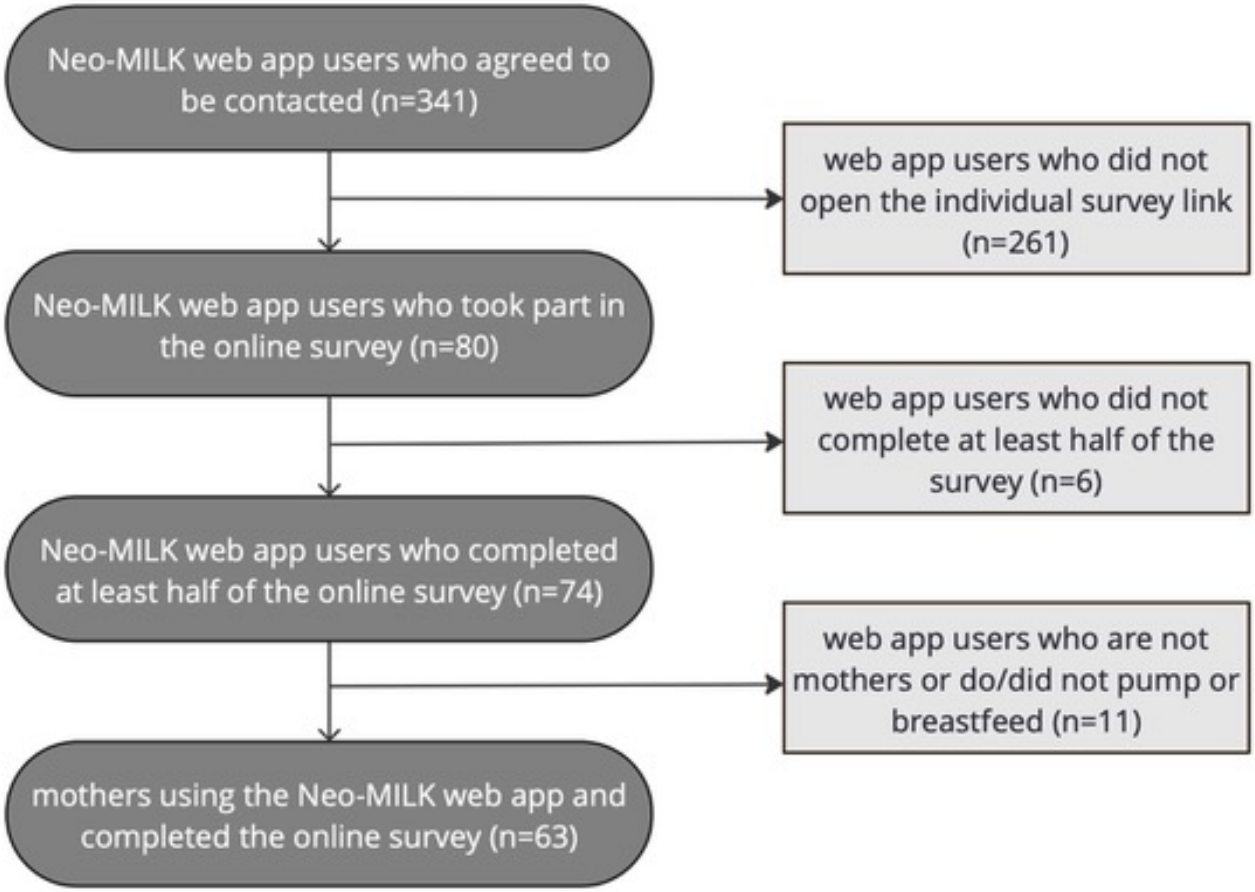
Data Analysis

Descriptive statistics including mean (SD), depending on the data distribution were calculated. Group comparisons between educational groups concerning the system usability were performed. Figures were used to visualize the data. Missing values were indicated in the description of the baseline characteristics and, in case of figures, in the figure legends. Data were analyzed using STATA (version 18; StataCorp).

Ethical Considerations

Ethical approval for this study was obtained from the ethics committee of the University of Wuppertal (SK/AE 230329).

XSL•FO
RenderX



All methods were performed in accordance with this approval. Before being permitted to complete the questionnaire, the participants were required to consent to the data protection regulations to realize informed consent. The resulting data was anonymous, as no personal data was collected. To compensate the time and effort of the participants, they were offered the opportunity to receive a €10b (US $11.60) voucher for a nationally represented drugstore.

Results

Sample

Four to eight weeks after registering in the web app, mothers of sick or VLBW infants were invited to participate in the survey. The requirement for registration was explicit consent to be contacted for scientific studies during the registration process. Therefore, 341 mothers received an email with individual tokens to participate in the survey and were reminded once via email if the questionnaire was not submitted within a two-week period. To further ensure correct sampling, all respondents were asked to indicate whether they were currently engaged in pumping or breastfeeding. Of the 341 mothers who were contacted, 80 responded, representing a response rate of 23.4%. Finally, data from 63 mothers were used for statistical analysis (Figure 2).

Figure 2. Flowchart of recruitment, inclusion, and exclusion of cases.

Sample Characteristics

Maternal sociodemographic characteristics (eg, age, educational level, native language), and whether reasons for expressing milk stem from maternal or child-related factors, as well as information about their infants (ie, past or current hospitalization, age, birth weight) are presented in Table 1.

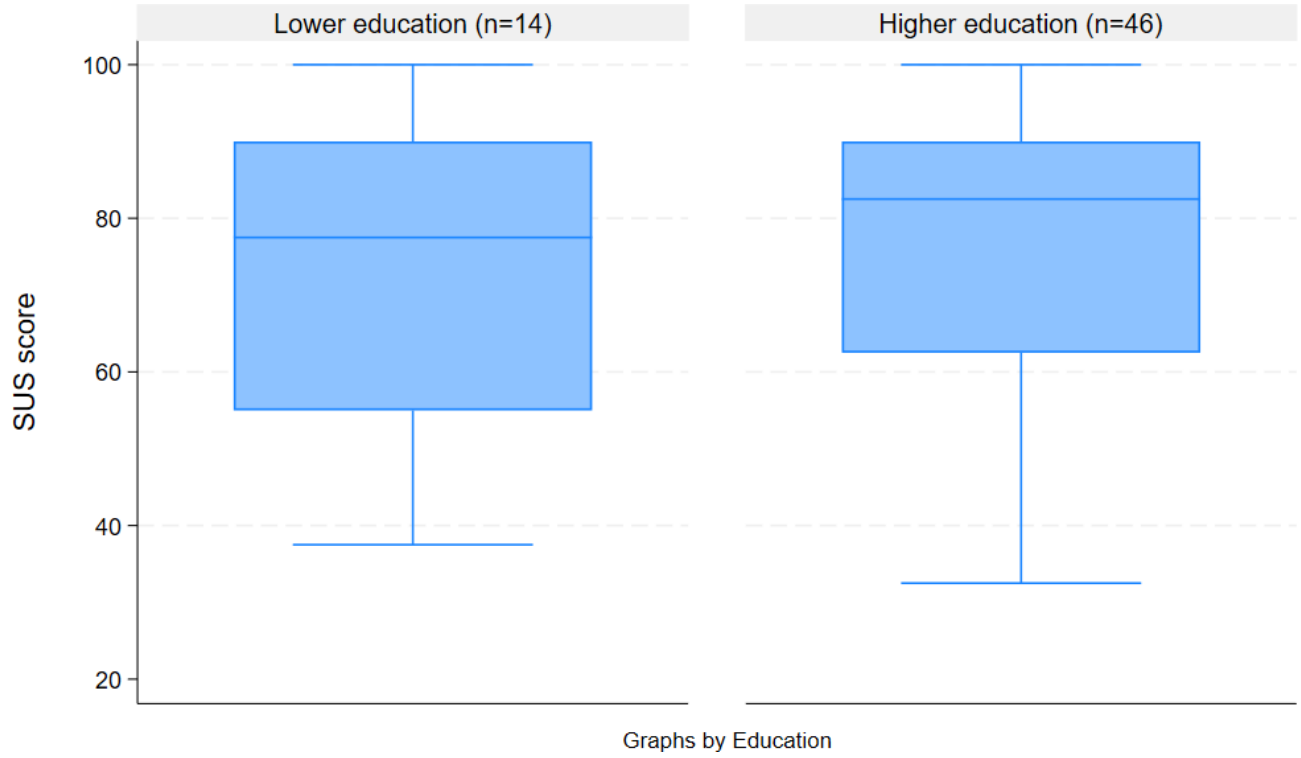
[a]There were 59 responses for this questions (ie, 4 did not response).



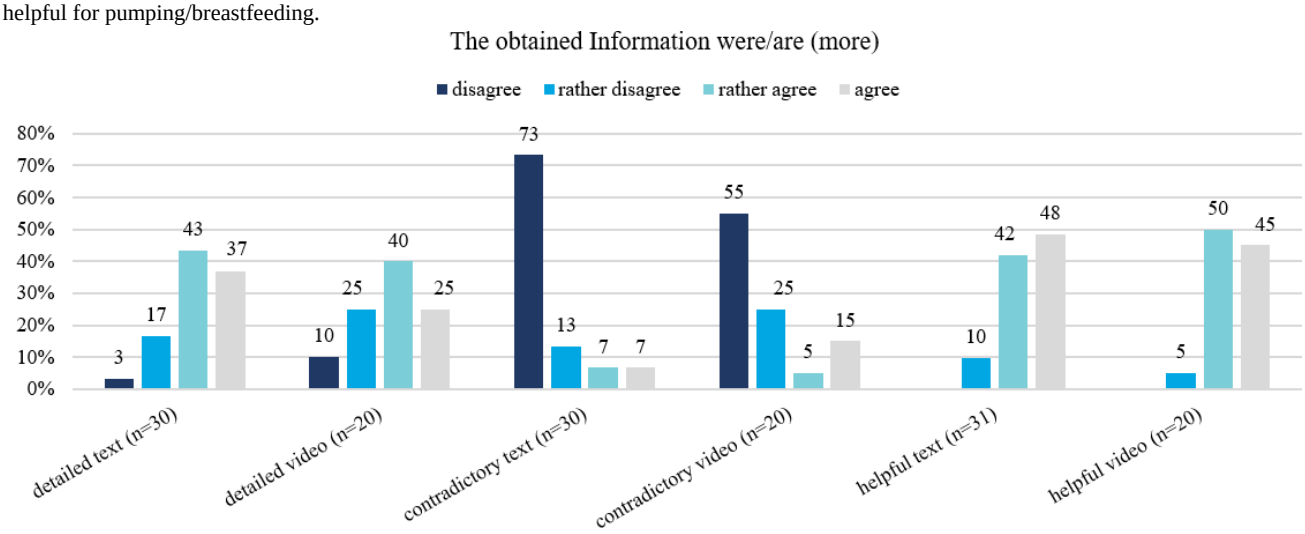
[b]There were 53 responses for this question (ie, 10 did not response).

Usability and Perceived Usefulness

The SUS score showed good usability of the Neo-MILK web app, with a mean score of 76.4 (n=61). The score only slightly differed between the lower and higher educational groups (Figure 3).

XSL•FO
RenderX

Figure 3. Boxplot of SUS score between the two educational groups. SUS: system usability scale.



Overall, 62 participants reported high satisfaction with the web app, with 53 (84%) participants being satisfied or very satisfied. Moreover, 52 (82%) would recommend the web app to other parents. The information provided in the web app via texts were accessed by 31 (49%) and videos by 20 (32%) of the participants. Most participants agreed that the information were more detailed than those provided in the hospital and that they were helpful for pumping and breastfeeding. The majority of participants disagreed that the content was contradictory (Figure 4).

Of the 63 participants, 45 (71%) used the pumping documentation tool of the web app (ie pumping timer or manual documentation of pumping) at least several times a week. Of the 54 participants who rated its ease of use, 46 (85%) found it "rather easy" or "easy to use."

Of 62 mothers, 56 (89%) indicated that they did not feel pressured by the Neo-MILK web app to provide breast milk, while only 6 (11%) reported experiencing such pressure.

Figure 4. Distribution of agreement whether information in the web app (texts/videos) were more detailed than or contradictory to those in the hospital, or helpful for pumping/breastfeeding.

Discussion

Principal Findings

This study showed that the Neo-MILK web app provides a suitable tool for mothers of VLBW and sick infants during lactation and pumping. The usability is good, as indicated by SUS scores being clearly over the widely accepted benchmark of 68 [24]. This is further supported by the positively rated overall satisfaction with the web app and the high number of participants who would recommend the app to other parents.

XSL•FO
RenderX

One main feature of the Neo-MILK web app is the provision of evidence-based information about central issues when pumping breast milk for a sick or preterm infant. These include bonding, breast milk expression, and solutions for problems with lactation. Recent studies showed that infant feeding applications are often of poor quality, with incomplete information and lacking in evidence-based content [13,22]. The information provided in the Neo-MILK web app was developed with a multidisciplinary expert team to ensure evidence-based content. Indeed, the results demonstrate that, on average, the information provided was helpful for mothers in their experience of pumping and breastfeeding. Furthermore, the information was more detailed than that provided in the hospital and not contradictory. It can therefore be assumed that the Neo-MILK web app is a suitable tool for informing mothers with an infant admitted to a NICU. However, it remains unknown, whether the mothers in our study received any personal lactation support or if the Neo-MILK web app was the only source of information and support available to them. It is important to emphasize that this web app should provide additional features and information for mothers. Personal and direct lactation support in the NICU, as part of a MOM-friendly hospital policy is crucial for ensuring nutrition with MOM [31,32].

Another central tool is the option to document the expressed milk volume. A recent study showed that tracking features lead to higher ratings of breastfeeding applications in general [33]. This indicates its importance for mothers and may be even more notable for pump-dependent mothers who are not able to feed their infant on demand. In our study, this assumption is strengthened, as most participants used the documentation tools to track their milk volume. In addition, the ranking of the ease of use indicates good usability of these features. This is particularly relevant, as usability has shown to be a crucial factor for the adoption of health technologies [34].

As elaborated before, stress and lactation are assumed to be associated [7,8]. This association is further assumed to be bidirectional, with stress leading to negative breastfeeding outcomes and impaired lactation increasing stress [35]. Due to the high levels of stress NICU mothers perceive, it is of paramount importance to minimize stress rather than triggering further distress [9]. Recent studies showed that mothers feel specific pressure to breastfeed or provide breast milk, which can stem from internal or external factors, for example, from their social environment or health care providers [11,12,36]. However, even though the Neo-MILK web app contains a lot of information about the importance of MOM, as well as tracking options for milk supply, users do not perceive these features as triggering such feelings.

Limitations

This study has some limitations. The SUS is available in four German translations, all of which have different deficiencies, for example, in methodology or wording. Although there is a validated version available, it lacks in terms of translation, leading to unnatural wording. In this analysis, we used the recommended translation, which is regarded as the best compromise between methodologically rigour and comprehensibility [30]. This might have had an impact on the validity of the measurement and therefore influenced the results. The response rate of this study is low. It may be the case that the users were no longer using the web app at the time of the survey. This may particularly apply to mothers who have transitioned from pumping to breastfeeding after a few weeks, and therefore no longer require the tools of the Neo-MILK web app. Another reason for the low response rate could be that registered web app users who were unsatisfied or were not frequent users did not respond due to their dissatisfaction. Furthermore, it can be suggested that the utilization of mHealth technologies is determined by the educational level and age of users, which may indicate a healthy bias among its users [37]. This is reflected by the broad number of participants with a high educational level in this sample. However, the Neo-MILK web app utilization and its ratings might not be biased by educational level, as indicated by only slight differences in the SUS score between these groups. Nevertheless, the information should be accessible for all groups to reduce communication difficulties, including those due to language barriers, which are a common problem in health services [38]. To reduce these barriers, the videos in the Neo-MILK web app are available with subtitles in other languages, including Russian, French, English, and Turkish. In addition, the videos are composed of easily understandable images and keywords. However, the provision of a translated version of the entire web app when necessary would further facilitate the accessibility of the web app to all relevant target groups.

Conclusions

The combination of evidence-based information about lactation and useful tools for tracking was identified as being of particular importance for this special group of mothers, with both elements rated highly in terms of usability and usefulness. Therefore, it can be concluded, that in our study, the Neo-MILK web app serves as a useful tool to complement personal support for pump-dependent mothers during lactation.

Abstract

Background: Preteen girls of lower socioeconomic position are at increased risk of physical inactivity. Parental support, particularly from mothers, is positively correlated with girls' physical activity levels. Consequently, family-based interventions are recognized as a promising approach to improve young people's physical activity. However, the effects of these interventions on girls' physical activity are often inconsistent, with calls for more rigorous, theory-informed, and co-designed family-based interventions to promote physical activity in this cohort.

Objective: This study aimed to use co-design methods to develop an evidence- and theory-informed mother-daughter mobile health intervention prototype targeting physical activity in preteen girls.

Methods: The intervention prototype was developed in accordance with the United Kingdom Medical Research Council framework, the Behaviour Change Wheel, the Theoretical Domains Framework, and the Behaviour Change Techniques Ontology. The Behaviour Change Intervention Ontology was also used to annotate the intervention characteristics. The co-design process incorporated three phases: (1) behavioral analysis, (2) the selection of intervention components, and (3) refinement of the intervention prototype. Throughout these phases, workshops were conducted with preteen girls (n=10), mothers of preteen girls (n=9), and primary school teachers (n=6), with additional input from an academic advisory panel.

Results: This 3-phase co-design process resulted in the development of a theory-informed intervention that targeted two behaviors: (1) mothers' engagement in a range of supportive behaviors for their daughters' physical activity and (2) daughters' physical activity behavior. Formative research identified 11 theoretical domains to be targeted as part of the intervention (eg, knowledge, skills, and beliefs about capabilities). These were to be targeted by 6 intervention functions (eg, education, persuasion, and modeling) and 27 behavior change techniques (eg, goal setting and self-monitoring). The co-design process resulted in a mobile app being chosen as the mode of delivery for the intervention.

Conclusions: This paper offers a comprehensive description and analysis of using co-design methods to develop a mother-daughter mobile health intervention prototype that is ready for feasibility and acceptability testing. The Behaviour Change Wheel, Theoretical Domains Framework, and Behaviour Change Techniques Ontology provided a systematic and transparent theoretical foundation for developing the prototype by enabling the identification of potential pathways for behavior change. Annotating the Behaviour Change Intervention Ontology entities represents the intervention characteristics in a detailed and structured way that supports improved communication, replication, and implementation of interventions.

Introduction

Background

Globally, 81% of adolescents are not meeting the recommended physical activity (PA) guidelines [1], with PA levels regressing annually throughout adolescence [2,3]. This rate of decline is more pronounced in girls than boys [1,4] and is most apparent during the transition period from primary to secondary school [5,6]. Studies also indicate that children of lower socioeconomic position (SEP) are less likely to be physically active than those of higher SEP [7-9]. Indeed, this is noteworthy in girls of low SEP, as evidence indicates that this cohort experiences a steeper decline in PA than their more advantaged peers at the transition to adolescence [4,9], putting them at a greater risk of obesity, type 2 diabetes, and cardiovascular disease [8,10]. Most interventions targeting children's daily PA levels have taken place during school hours [11]; however, children are reported to be less active during time spent outside of school, such as at weekends or holidays [12]. Thus, there is a need to also promote PA outside of the school context [13].

Families are a central foundation of support and guidance for children and adolescents in shaping healthy PA behaviors particularly outside of school [14]. Parental support is an umbrella term used to represent numerous support behaviors for PA such as encouragement, logistical support, or coactivity [14,15]. This type of parental support is positively correlated with child PA [16,17], with some evidence for stronger effects for girls when they are supported by their mothers rather than by other family members [18,19]. While there has been a growing interest in family-based PA interventions to promote girls' PA, the evidence for such interventions is mixed [20-22]. These inconclusive findings may be due to factors such as poor study design, small sample sizes, the use of self-report measures, the lack of theory to underpin interventions, the absence of the participant voice in the intervention development process [20,23], and differences between modes of delivery (eg, face-to-face vs eHealth or mobile health [mHealth]) [22,23]. Rapid developments in technology in recent decades have seen an increased use of eHealth and mHealth as modes of delivery for promoting PA in preschoolers [24], children and adolescents [25-27], families [22], and individuals of low SEP [28]. Meta-analyses of eHealth and mHealth PA interventions have reported positive effects for PA-related outcomes in children and adolescents, such as steps per day [25,26] and total PA [26,29], with a lack of improvement in moderate to vigorous PA stated as a limitation [25,29]. Considering the prevalence of smartphone phone use across children, adolescents, and adults [30,31] and the cost-effectiveness, reach, and scalability of mHealth interventions [25,26], there is a pressing need for more robust theory-based mHealth interventions to harness the potential of digital platforms for enhancing PA [22,24,25], particularly for individuals of low SEP [28].

Intervention Development

There is increasing recognition of the need for guidance to support the robust design of interventions targeting health behaviors such as PA. Specifically, the United Kingdom Medical Research Council (MRC) has developed a framework for complex interventions that provides a systematic process for developing and evaluating interventions across 4 interacting stages [32]. Within this process the importance of using theory, considering context, developing and refining a program theory and related logic model, and engaging with stakeholders is emphasized [32]. Theory offers a valuable organizing framework for the development of effective interventions and is necessary to test hypothesis, identify constructs that effect behavior, and enable study replication and generalization [33,34]. There have been mixed findings reported regarding the effectiveness of interventions that are underpinned by theory [35,36], predominantly explained by a lack of clarity as to how a particular theory's constructs (ie, mechanisms of action) are targeted and measured within interventions [33,35]. The Behaviour Change Wheel (BCW) builds on MRC guidance and offers a practical guide for how to develop theory- and evidence-based interventions [37]. The BCW is a synthesis of 19 frameworks for classifying behavior change and facilitates the mapping of intervention targets (ie, the behavior, the population, and the context) to specific mechanisms of action (ie, the processes through which behavior change occurs) [38]. At the core of the BCW is the Capability, Opportunity, and Motivation–Behavior (COM-B) model, which proposes that Capability, Opportunity, and Motivation interact to influence behavior. *Capability* refers to the individual's physical and psychological ability to enact the behavior. *Opportunity* denotes the social and physical resources that facilitate or hinder the behavior. Finally, *Motivation* is defined as the reflective or automatic processes that enable the behavior [37]. The BCW contains 9 different intervention functions that can be applied to target the desired behavior and 7 categories of policy that can be used to deliver these intervention functions. The BCW and associated elements have been successfully used in different contexts to develop interventions promoting PA [39-41]. For example, while using the BCW as part of the development process for a PA app, Truelove et al [39] targeted individuals' physical and psychological capabilities, physical and social opportunities, and reflective and automatic motivation to increase PA levels in Canadian adults. To achieve this, the intervention functions of education, persuasion, incentivization, training, environmental restructuring and enablement were chosen from the BCW to be included in the app, alongside 2 policy categories (communication and marketing, and environment and social planning) to support the delivery of the intervention functions [39]. One study has used the BCW to develop a mother-daughter PA intervention for adolescent girls [41] by selecting 6 intervention functions (education, persuasion, incentivization, training, modeling, and enablement).

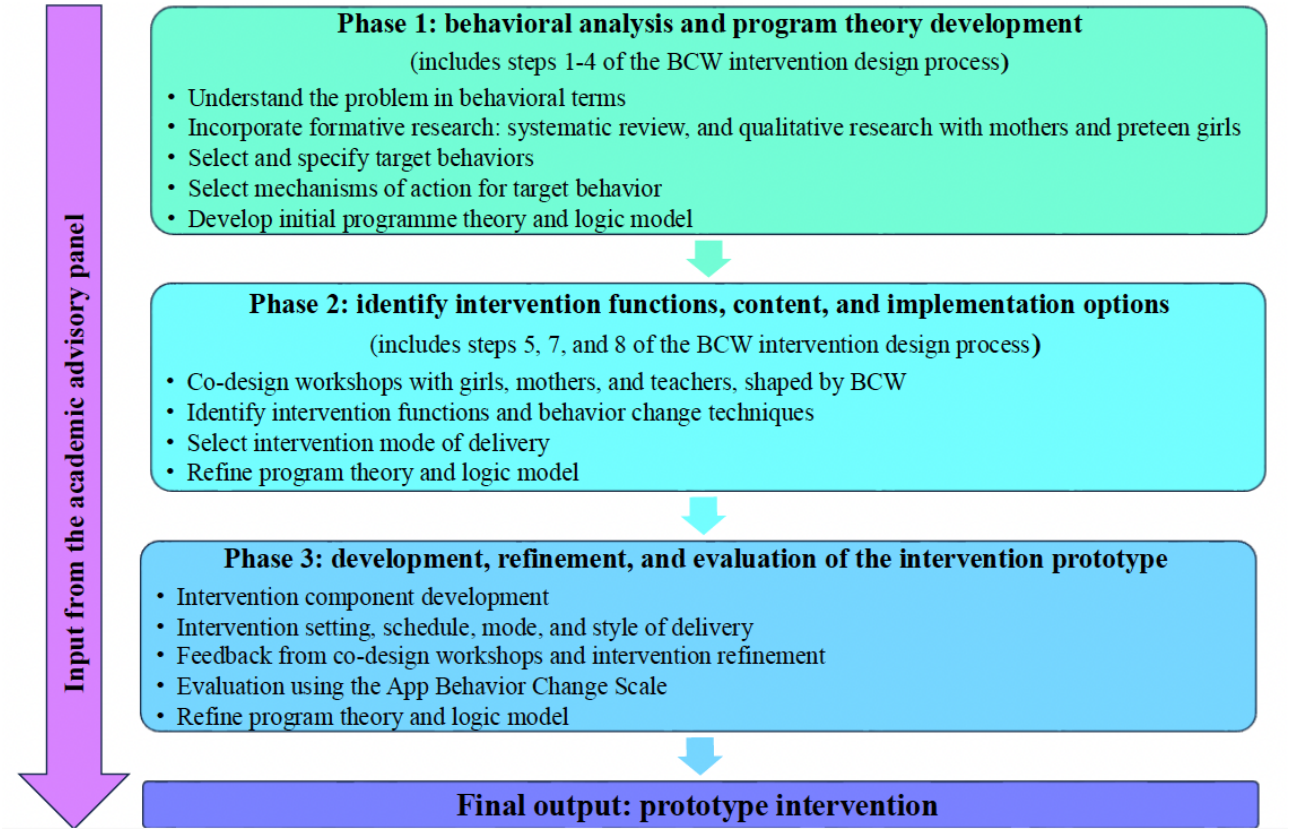
XSL•FO
RenderX

The COM-B components of the BCW can be further understood by using the Theoretical Domains Framework (TDF) [42]. The TDF is a validated integrative framework of 14 theoretical domains synthesized from 128 theoretical constructs and 33 behavioral change theories [42]. Additionally, the TDF presents a comprehensive grouping of the overlapping constructs within behavioral theories and supports the identification and selection of relevant mechanisms of action (eg, knowledge and beliefs about capabilities) for targeting within interventions [37,43]. The TDF has been applied across a variety of settings to inform the development of PA interventions [44,45]. For example, a study by McQuinn et al [45] identified the TDF domains of social influences, environmental context and resources, behavioral regulation, beliefs about capabilities, goals, and reinforcement as target mechanisms of action for a co-designed school-based intervention promoting PA in adolescent girls. However, to date, no intervention has used the TDF to identify mechanisms of action for an intervention promoting PA in preteen girls and maternal PA support behaviors.

An intervention achieves its functions through the use of behavior change techniques (BCTs), which are "the smallest part of the behaviour change intervention content that are that are observable, replicable and on their own have the potential to bring about behavior change" (eg, self-monitoring of behavior and problem-solving) [46]. The Behaviour Change Techniques Ontology (BCTO) offers a reliable and extensive classification system for behavior change intervention content. Using the BCTO is considered best practice, as it contains considerably more BCTs than the original BCT Taxonomy version 1 (BCTTv1), has more precise and clear groupings, labels and definitions, and links to other characteristics of an intervention, such as mechanisms of action [47]. The influence of intervention content (eg, BCTs) on behavior can differ depending on how it is delivered to participants, and therefore vary its effectiveness [48]. The recently developed Behaviour Change Intervention Ontology (BCIO) assists researchers to fully specify and classify intervention characteristics (eg, delivery) in a way that supports improved communication, replication, and implementation of effective interventions [46]. Within the BCIO, the delivery of an intervention is divided into the following components: (1) mode of delivery (ie, the medium through which an intervention is provided) [49], (2) intervention setting (ie, the setting where an intervention takes place) [50], (3) intervention schedule (ie, the timing of intervention components), and (4) intervention style of delivery (ie, the manner in which the intervention is delivered) [48]. Using the BCIO entities to annotate the delivery of an intervention increases our understanding of how the effect of intervention content differs according to the mode and style within which it is delivered [48]. While using the BCIO may be time consuming for researchers, it is increasingly used for evidence synthesis [51,52] and intervention development [53,54]. The BCIO has not yet been applied in PA interventions as it is a new development and is only recently available. To our knowledge, this is the first study to use the BCIO entities to annotate the characteristics of an intervention targeting PA in children.

Objectives

Alongside this increased emphasis on a systematic theory-informed intervention development, a collaborative approach to intervention design involving the end users of research is essential. Co-design methods ensure meaningful involvement of the end user in the research process [55] by enabling the specific needs and preferences of the target population to be recognized and allowing for the identification of potential implementation challenges early in the intervention development process [56]. Indeed, research that involves end users in the design process leads to interventions that are more contextually relevant and thus more effective [57]. However, while there is a continued call for greater involvement of young people in the research process through participatory methods such as co-design [58,59], only a few studies on family-based interventions targeting girls' PA [41] or on PA in teenage girls from lower SEP have applied such methods [45,60]. Therefore, the purpose of this study was to provide a detailed outline of the systematic process undertaken to using the BCW and TDF to develop an evidence-based and theoretically informed behavior change intervention, using co-design methods, to promote PA in preteen girls incorporating maternal support behaviors, before preliminary testing for feasibility and efficacy.



Methods

Overview

This study was informed by the initial development stage of the MRC framework for complex interventions [32]. In line with MRC guidelines, a program theory and logic model were developed and refined throughout the intervention development process. A program theory is a tool that can be used to unpack the relationship between the intervention activities and intended outcomes [61]. Logic models can assist in visually representing the program theory to effectively communicate with research team members and stakeholders [61]. The intervention prototype developed across 3 phases (Figure 1). Phase 1 was guided by the steps in the BCW process [37] and also incorporated the TDF to identify more specific mechanisms of action [42]. Phase 2 involved co-design workshops with stakeholders (ie, mothers, preteen girls, and primary school teachers) to identify potential intervention components and mode of delivery. In phase 3, the prototype was refined through an iterative and dynamic process based on evidence, theory, and input from additional co-design workshops with stakeholders (ie, mothers, preteen girls, and primary school teachers). An academic advisory panel provided guidance throughout the process. The BCIO entities were annotated to report the intervention characteristics; some of the BCIO unique identifiers are provided in the manuscript, with a full list available in Multimedia Appendix 1.

Ethical Considerations

Ethics approval was obtained by the University College Dublin's Human Research Ethics Committee (LS-22-62) before study commencement. No payments or incentives were offered for participation. Information packs containing information sheets and consent and assent forms were distributed to mothers, children, and teachers alike.

Recruitment

Co-Design Participants

A suburban primary school identified by the Department of Education's Delivering Equality of Opportunity in Schools (DEIS) program was identified as suitable for this study. The Department of Education uses the DEIS classification system to support students attending schools situated in communities at risk of social and economic disadvantage [62]. To classify schools as meeting the DEIS criteria, data from the Department of Education's online database and the HP Deprivation Index for Small Areas (HP Index) are used [62]. The HP Index is a process that measures the relative affluence or disadvantage of small geographical areas using categories such as demographic growth, dependency ratios, education levels, single parent rate, overcrowding, social class, occupation, and unemployment rates [62]. The school in this study is a mixed primary school based in a suburban town located 10 km from Dublin city center, Ireland, with approximately 520 pupils and 33 teachers. After discussions between the lead author (CB) and the school principal, the school principal invited mothers and female guardians of girls aged 10 to 12 years, girls aged 10 to 12 years, and teachers to take part in the study. All girls who were aged between 10 and 12 years and from fourth, fifth, or sixth class were eligible to take part.

Academic Advisory Panel

As part of the research process, an academic advisory panel was established to discuss the findings from the co-design workshops, the use of theory, and support the research team (CB and JM). This panel consisted of 3 academics (GO'D, AK, and RER) with expertise in PA, sedentary behavior, and the development of complex interventions and co-design methodologies. Both GO'D and AK are experienced qualitative researchers and have conducted previous studies exploring PA and sedentary behavior using the TDF, and RER is an experienced researcher with an applied focus on PA during life transitions.

Intervention Prototype Development Process

Phase 1: Behavioral Analysis and Program Theory Development

Phase 1 included steps 1 to 4 of the BCW intervention design process [37]. In line with this approach, the definition of the problem in behavioral terms (step 1) was based on findings from previous literature (ie, preteen girls are not active enough) [1,4]. A systematic review of mother-daughter interventions and formative qualitative research (ie, interviews with 29 mothers of preteen girls and 19 focus groups with 107 low-SEP preteen girls) was then conducted to further understand the problem and the related factors. This was followed by selection and specification of the intervention target behaviors (steps 2 and 3 of the BCW process). After these steps, CB and JM used the TDF to identify the barriers and enablers of the target

XSL•FO
RenderX

behaviors. These were presented to the academic advisory panel (GO'D, AK, and RER) to establish what needs to change to achieve the target behaviors (step 4; Multimedia Appendix 2 [6,14,63-76]). This led to the selection of specific mechanisms of action to be targeted within the proposed intervention. An initial program theory and related logic model for the intervention were then developed.

Phase 2: Identify Intervention Functions, Content, and Implementation Options

This phase includes steps 5, 7, and 8 of the BCW intervention design process [37]. Three co-design workshops took place at the school premises during school hours and were facilitated by CB and JM. Three separate groups took part in a co-design workshop: (1) mothers of preteen daughters (n=9), (2) preteen girls (n=10), and (3) teachers (n=6). The workshops took place in April 2023, with a mean duration of 52 (SD 1.9) minutes. The aim of these workshops was to identify potential intervention functions, BCTs, and modes of delivery to target the proposed mechanisms of action identified in phase 1. A range of age-appropriate and interactive methods were used in these co-design sessions (Multimedia Appendix 3). For example, to encourage participants to think about the practical application of their suggestions to a wide variety of mothers and girls, personas of mothers and girls who were individually, socially, and geographically diverse were provided [77]. Using the information gathered from these co-design sessions, along with findings from phase 1 and further consultation with the academic advisory panel (GO'D, AK, and RER), intervention functions (step 5), BCTs (step 6), and a proposed mode of delivery (step 8) were selected by the research team (CB and JM). The program theory and logic model were also refined.

Phase 3: Development, Refinement, and Evaluation of the Intervention Prototype

This phase involved incorporating the findings from phase 2 into the development of the intervention components. A second series of co-design workshops (n=3) took place in the school premises during school hours and were facilitated by CB and JM. The same participants as phase 1 took part. The three separate workshop groups were (1) mothers of preteen daughters (n=6), (2) preteen girls (n=10), and (3) teachers (n=3). The workshops took place in June 2023, with a mean duration of 44 (SD 5) minutes. The aim of the workshops was to obtain participants' feedback on the acceptability of the proposed intervention components (Multimedia Appendix 4). Following these workshops, the research team (CB and JM) discussed the findings from the workshops, the proposed intervention components, and the use of theory with the academic advisory panel (GO'D, AK, and RER). The 21-item App Behavior Change Scale [78] was also used by the research team to ensure that relevant behavior change components were appropriately included. This scale has been used in several studies targeting PA to assess intervention effectiveness [39,79]. The program theory and logic model were refined for the final time.

Results

Phase 1: Behavioral Analysis and Program Theory Development

As described in the Introduction section, the identified problem behavior was the decline in PA as children transition to adolescence, with this decrease in activity levels particularly prevalent for girls of lower SEP [1,4]. Children whose parents support PA are likely to have higher overall levels of activity than children whose parents do not support their PA, with stronger effects when that support is provided by a parent of the same gender [80,81]. The formative research related to this study is described in previous studies, [82-84] therefore a brief description of it is provided here. A review of behavior change theories and techniques used in mother and daughter PA interventions highlighted a lack of clarity as to why interventions were effective or not and the increased need for a stronger theoretical basis for future interventions as well as enhanced reporting of how these interventions are developed [82]. Qualitative formative work with mothers of preteen girls highlighted barriers and enablers related to engaging in PA-supportive behaviors with their daughters [83]. These ranged from individual-level factors such as their PA-related identity and their confidence to engage in supportive behaviors to social and environmental factors such as the role of other family members and the infrastructure within their communities and their daughters' schools [83]. Finally, qualitative work was conducted with preteen girls who discussed barriers and enablers to their PA, such as the importance of skills and confidence to support their engagement in PA and strengthen their self-identity for PA alongside the important role of family members, friends, teachers, and coaches [84]. On the basis of this formative work, 2 related behaviors were deemed appropriate to target as part of the intervention. The first behavior was to improve mothers' support for their preteen daughters' PA and, in doing so, indirectly increase the likelihood of preteen girls engaging in PA. The second behavior being targeted was to increase preteen girls' PA. These behaviors are presented in Table 1 in terms of who needs to perform the behavior, when, where, and with whom.

The academic advisory panel then reviewed the analysis of the barriers and enablers to the target behaviors. Following discussion with the advisory panel, the research team then chose 11 of the 14 TDF domains as proposed mechanisms of action for enabling these target behaviors (Table 2).

Table 2. Mechanisms of action, intervention functions and behaviour change techniques for mother-daughter intervention.

Mechanisms of action and what needs to happen for behavior change to occur	Intervention functions for improving maternal PA[a] support and promoting PA in preteen girls	BCTs[b] from BCTO[c] for improving maternal PA support and promoting PA in preteen girls
Knowledge Develop mothers' and daughters' understanding of the following: • The rationale and purpose of the program • The types and benefits of PA and PA guidelines • How to be physically active • The types and benefits of maternal PA support behaviors • How to perform maternal PA support • Typical challenges experienced by mothers while engaging in PA support (eg, pushback from daughter) • Typical challenges experienced by preteen girls while engaging in PA support (eg, friends not active) • Available resources to facilitate engagement in PA and PA support	*Education* • About the rationale and purpose of the program • About ways of enacting desired behavior and avoiding undesirable ones • Provide credible, appealing information that can be used to enact target behavior • Provide clear, consistent, and standardized messages about maternal PA support and PA • Provide information to address prevalent misconceptions about maternal PA support and PA behaviors	• Instruct how to perform behavior BCT (BCIOd:007058) • Inform about health consequences BCT (BCIO:007063) • Inform about social consequences BCT (BCIO:007064) • Inform about environmental consequences BCT (BCIO:007176) • Present information from credible influence BCT (BCIO:007075)
Skills Develop skills to do the following: • Select and engage in PA and PA-supportive behaviors • Apply problem-solving and set and review personalized goals for PA and PA support behaviors • Monitor progress of physical activity behaviors • Monitor progress in supporting daughter to be active; overcome the challenges encountered while engaging in selected PA and PA support behaviors	*Training* • Practice and engage in PA support and PA behaviors • Engage in problem-solving and select and review goals related to target behavior • Monitor progress when engaging in PA support and PA behaviors • Engage in behavioral strategies to overcome challenges associated with providing support or being active	• Goal strategizing BCT (BCIO:007008) • Provide feedback on behavior BCT (BCIO:007023) • Self-monitor of behavior BCT (BCIO:007024) • Instruct how to perform behavior BCT (BCIO:007058) • Demonstrate the behavior BCT (BCIO:007055) • Practice behavior BCT (BCIO:007094) • Context-specific repetition of behavior BCT (BCIO:007096) • Set graded tasks BCT (BCIO:007100)
Social role and identity • Develop mothers' identity as a person who provides support for their daughters' PA • Develop mothers' and daughters' identity as a person who is physically active	*Education* • About how to link supportive and PA behaviors to other intrinsic goals • Provide information about positive experiences when supporting their daughter to be active or being active and how to overcome associated challenges • Provide information about extra resources available to help mothers provide support or preteen daughters be active when program ends *Persuasion* • Highlight compatibility with current identity, but expand it to include maternal PA identity or PA behaviors and social identities • Emphasize the role of mother as change agent for daughter and in family	• Social support BCT (BCIO:007028) • Inform about social consequences BCT (BCIO:007064) • Prompt social comparison BCT (BCIO:007073) • Practice behavior BCT (BCIO:007094) • Present information from credible influence BCT (BCIO:007075) • Identify self as role model BCT (BCIO:007158) • Reframe past behavior BCT (BCIO:007056) • Adopt changed self-identity BCT (BCIO:007160)

XSL•FO
RenderX

Mechanisms of action and what needs to happen for behavior change to occur	Intervention functions for improving maternal PA[a] support and promoting PA in preteen girls	BCTs[b] from BCTO[c] for improving maternal PA support and promoting PA in preteen girls
Beliefs about capabilities Improve perceived competence in ability to do the following: • Perform selected PA and PA support behaviors • Use problem-solving, goal setting, and action planning to engage in PA and PA support • Ability to monitor progress • Overcome challenges encountered while enacting PA and PA support • Engage in long-term PA and PA support behaviors	*Persuasion* • Enhance perceived competence to problem solve, actions plan, select and monitor goals, and self-monitor PA support and PA behaviors • Encourage mothers to believe that providing support is possible or daughters to believe that being active is possible, even given constraints of their circumstances *Enablement* • Assist mothers or daughters in problem-solving and action planning to overcome barriers to providing support or being active *Modeling* • Present real-life examples of mothers or preteen girls in similar circumstances	• Goal strategizing BCT (BCIO:007008) • Social support BCT (BCIO:007028) • Instruct how to perform behavior BCT (BCIO:007058) • Demonstrate the behavior BCT (BCIO:007055) • Practice behavior BCT (BCIO:007055) • Set graded tasks BCT (BCIO:007100) • Advise how to reduce negative emotions BCT (BCIO:050344) • Persuade about personal capability (BCIO:007137) • Prompt focus on past success BCT (BCIO:007139) • Prompt self-talk BCT (BCIO:007140)
Beliefs about consequences • Enhance mothers' expectations related to the positive consequences of engaging in selected PA support • Enhance mothers' and daughters' expectations related to the positive consequences of engaging in selected PA behaviors	*Education* • Explore beliefs and attitudes related to PA and the associated health benefits • Explore beliefs and attitudes between providing PA support and expected outcomes *Persuasion* • Enhance beliefs that being physically active has positive health benefits in the short and long term • Provide expert information about how, where, and why to be active • Enhance beliefs that providing support for daughters' PA would be beneficial • Provide expert information about the short- and long-term benefits of providing PA support *Modeling* • Provide demonstrations of mothers of teen girls or preteen girls to show the benefits they received as a result of providing support or being active	• Inform about health consequences BCT (BCIO:007063) • Inform about social consequences BCT (BCIO:007064) • Inform about environmental consequences BCT (BCIO:007176) • Monitor emotional consequences BCT • (BCIO:007066) • Demonstrate the behavior BCT (BCIO:007055) • Prompt social comparison BCT (BCIO:007073) • Present information from credible influence BCT (BCIO:007075)
Intentions • Increase mothers' and daughters' autonomous motivation to • Engage in and maintain selected PA or PA support behaviors • Engage in problem-solving and setting and reviewing goals to facilitate engagement in selected PA and PA support behavior • Engage with tools to monitor progress	*Education* • Inform about importance of formulating intentions of how and where to provide support or be active *Persuasion* • Encourage mothers and daughters to consider why being active might be important to them and the benefits they will receive • Encourage mothers to consider why providing PA support may be important to them and how it would benefit their daughter and other family members *Modeling* • Provide demonstrations of mothers and preteen girls describing their experiences of setting short- and long-term intentions to be provide support or be active and the associated benefits	• Set behavior goal BCT (BCIO:007003) • Inform about health consequences BCT (BCIO:007063) • Inform about social consequences BCT (BCIO:007064) • Inform about environmental consequences BCT (BCIO:007176) • Instruct how to perform behavior BCT (BCIO:007058) • Demonstrate the behavior BCT (BCIO:007055) • Prompt social comparison BCT (BCIO:007073) • Present information from credible influence BCT (BCIO:007075)

XSL•FO
RenderX

Mechanisms of action and what needs to happen for behavior change to occur	Intervention functions for improving maternal PA[a] support and promoting PA in preteen girls	BCTs[b] from BCTO[c] for improving maternal PA support and promoting PA in preteen girls
Goals • Support mothers and daughters to • Use action planning, problem-solving, and goal setting to facilitate engagement in selected PA and PA support behaviors • Use tools to monitor progress • Overcome challenges encountered while setting and reviewing goals	*Training* • Select and review personalized goals related to the target behavior *Enablement* • Provide support and guidance for setting realistic goals for mothers to provide support or to preteen girls to be physically active • Affirm small achievable and interim goals and successes • Prompt planning to provide PA support or be active during and after the intervention	• Set behavior goal BCT (BCIO:007003) • Goal strategizing BCT (BCIO:007008) • Action planning BCT • (BCIO:007010) • Provide feedback on behavior BCT (BCIO:007023) • Self-monitor behavior BCT (BCIO:007024) • Instruct how to perform behavior BCT (BCIO:007058) • Demonstrate the behavior BCT (BCIO:007055) • Practice behavior BCT (BCIO:007055) • Set graded tasks BCT (BCIO:007100)
Environmental context and resources • Provide knowledge of and access to a variety of PA opportunities available so that mothers can support daughters' PA and daughters can engage in PA • Provide materials or equipment so that mothers can support their daughters PA or daughters can be active	*Environmental restructuring* • Provide mothers or preteen daughters with practical equipment that can enable them to be active, for example, skipping ropes and balls • Provide mothers and daughters with access to feasible and realistic options that enable them to be active during and after the intervention *Enablement* • Provide practical support for mothers and daughters to action plan and problem solve to engage in PA support and PA behaviors	• Goal strategizing BCT (BCIO:007008) • Action planning BCT (BCIO:007010) • Social support BCT (BCIO:007028) • Present information from credible influence BCT (BCIO:007075) • Add objects to the environment BCT (BCIO:007156)
Social influences • Develop mothers' and daughters' understanding of the type of support available to them regarding supporting their daughters' PA and being active • Develop mothers' and daughters' ability to engage with the social support available to them	*Modeling* • Provide demonstrations of other mothers and girls describing their experiences for seeking and receiving social support and the benefits they received as a result *Enablement* • Prompt mothers and preteen daughters to seek social support and provide examples of types of social support available to them	• Social support BCT (BCIO:007028) • Advise to seek instrumental support BCT (BCIO:007030) • Demonstrate the behavior BCT (BCIO:007055) • Prompt social comparison BCT (BCIO:007073) • Present information from credible influence BCT (BCIO:007075) • Provide positive social consequence for behavior BCT (BCIO:007265) • Persuade about personal capability BCT (BCIO:007137)
Emotion • Promote positive and reduce unpleasant emotions associated with providing PA support (eg, embarrassment while being active with daughter) and being active (eg, enjoyment in activities)	*Persuasion* • Help mothers and daughters recognize the positive feelings associated with providing support or being active *Enablement* • Provide safe and nonjudgmental environment for mothers or daughters to explore emotions around providing support or being active • Provide opportunities for mothers or daughters to evaluate their emotional state after providing support or being active	• Goal strategizing BCT (BCIO:007008) • Social support BCT (BCIO:007028) • Monitor emotional consequences BCT (BCIO:007066) • Present information from credible influence BCT (BCIO:007075) • Advise how to reduce negative emotions BCT (BCIO:050344) • Reframe past behavior BCT (BCIO:007056)
Behavioral regulation Develop mothers' and daughters' ability to do the following: • Select and apply PA or PA support behaviors into their daily life • Implement tools to monitor PA or PA support progress	*Training* • Provide means so that mothers and daughters can assess their progress during the intervention and in the future *Enablement* • Provide opportunity, support, and tools to self-monitor PA support or PA behaviors and related habits

RenderX

Mechanisms of action and what needs to happen for behavior change to occur	Intervention functions for improving maternal PA[a] support and promoting PA in preteen girls	BCTs[b] from BCTO[c] for improving maternal PA support and promoting PA in preteen girls
		• Goal strategizing BCT (BCIO:007008) • Action planning BCT (BCIO:007010) • Self-monitor behavior BCT (BCIO:007024) • Instruct how to perform behavior BCT (BCIO:007058) • Demonstrate the behavior BCT (BCIO:007055) • Practice behavior BCT (BCIO:007055) • Substitute behavior BCT (BCIO:007095) • Context-specific repetition of behavior BCT (BCIO:007096) • Provide positive social consequence for behavior BCT (BCIO:007265) • Advise how to reduce negative emotions BCT (BCIO:050344) • Prompt self-talk BCT (BCIO:007140)

Phase 2: Identify Intervention Functions, Content, and Implementation Options

The co-design workshops led to a number of recommendations from preteen girls, mothers, and teachers. These recommendations are illustrated in Table 3 using exemplar quotes and were categorized under a range of intervention functions as per the BCW intervention design process [37]. The intervention functions included education, training, persuasion, modeling, enablement, incentivization, and environmental restructuring. Potential modes of delivery discussed included face-to-face delivery, remote synchronous delivery (eg, Zoom Communications, Inc), or the use of a mHealth application. The mothers' group recommended the use of a mHealth application as a potential mode of delivery. These recommendations informed the selection of potential intervention functions, BCTs, and a proposed mode of delivery (ie, mHealth application) for each target behavior by the research team and were presented to the academic advisory panel for review. The final listing of intervention functions and BCTs for each mechanism of action are presented in Table 2. The academic advisory panel suggested applying of the principles of self-determination theory (SDT) [85] to the mHealth application content to enhance the communication style within which it is delivered [48].

XSL•FO
RenderX

Table 3. Summary table of the co-design workshops.

	Summary of the recommendations from workshops	Example quotes	Related intervention functions
Improving mothers' knowledge and understanding of PA[a] and PA support	• Provide mothers with information about the different types of PA, the benefits of PA, how to be active, and how much PA is recommended for daughters and themselves • Provide mothers with information and instruction about how to support their daughters, particularly as they transition into teenage years • Provide mothers with more information about what is available to them in their local area for their daughters to be active or for them to be active with their daughters • Information could be provided through videos, social media, websites, an app, parent-teachers association, and word of mouth	• "Maybe something about their mental and physical development, psychosocial development at this age that would help mothers understand what they're going through." [Imelda, daughter in fifth class] • "Making sure mothers know how often children, girls at that age should be exercising each week. Maybe if they're not conscious that they're doing their weekly exercise, how are they supposed to pass it on to their children." [Kate, primary school teacher] • "if you were thinking of an app and giving people ideas, could add the likes of yoga and stuff." [Susan, daughter in sixth class]	• Education • Training
Persuading mothers to support their daughters to be active	• Present mothers with examples of other mothers, coaches, teachers, and local sports partnership representatives explaining how, where, and the benefits of supporting daughters to be active • Provide examples of other mothers supporting their daughters to be active, how they overcame challenges, and being active themselves or with their daughters or family members • Use mainstream media, social media, videos, websites, apps, and word of mouth to promote positive messages	• "Or other mammies probably. I think other mammies would be good to see. Well, if they can balance it, I'm sure there's ways around that we can balance it." [Niamh, daughter in fourth class] • "Someone giving them their personal story" [Sharon, primary school teacher] • "an app would be great because the kids are on it...you can challenge your friends or family members and track what you have done." [Sinead, daughter in sixth class]	• Persuasion • Modeling
Practical help for mothers to engage in support behaviors	• Assistance with cost of activities, thus provide opportunities to try out in school or community for free first • Provide materials for mothers to plan, record, and monitor their PA support behaviors at their own time and pace • Feedback on behavior, in particular, if they engage in activities with daughters, either through technology or in person	• "And the cost of living at the moment is crazy as well. Like you should be really dropping. If the cost of it came down a bit, I think a lot more people would do it, absolutely." [Michelle, daughter in fourth class] • "If you're doing that at your own pace, in your own time. There was ideas on of, you can do this today, tomorrow, next week, or whatever, but also a blank space that you could fill in what you've done. I wasn't able to do this, but I did this, or we done that." [Sinead, daughter in sixth class] • "You can break it into profiles like you can have yours, your partners, your daughters, whatever. It's under the one branch, basically. But you have your own little sections as well, where there's probably things tailor-made for you for that age group. You put in your age, you put in your interest or something...Like Netflix." [Imelda, daughter in fifth class]	• Incentivization • Environmental restructuring

XSL•FO
RenderX

	Summary of the recommendations from workshops	Example quotes	Related intervention functions
Social support for mothers	• Provide opportunities for mothers to get support from other mothers of preteen daughters, for example, Facebook group • Opportunities to get to know other mothers at daughters' activities	• "every club should have a mammies group." [Niamh, daughter in fourth class] • "then you could have like a chat group for them (mothers) on the app." [Susan, daughter in sixth class] • "Yeah, support network through your app, through your group or whatever. Just like, oh, I've done this week, you might like it or I found this video, you might like it whatever." [Anna, primary school teacher] • "Because some of the other parents have groups themselves where they can keep in contact. If one parent doesn't want to do it, the second parent may motivate them to do it. While we're all doing this together." [Joe, primary school teacher]	• Enablement
Improving daughters' knowledge and understanding of PA	• Provide daughters with information and instructions about the different types of PA, the benefits of PA, how to be active in their leisure time, and how much PA is recommended • Provide daughters with information about what is available to them in their local area to be active. Information could be provided through videos, social media, websites, an app, and word of mouth	• "tips on how to play a game or rules of the game." [Emily, fifth class] • "we could have like speakers, people going into the classroom and talking to girls to join sports." [Sophie, sixth class] • "Some people post on YouTube how to do skills. If you're a beginner and you want to learn some skills, you could just look at some YouTube videos and then that would do it." [Robyn, sixth class] • "But the danger is that there are parents who don't know and don't care, and they probably won't look at an app. I would be afraid of that happening...let the child have their own profile." [Jennifer, daughter in sixth class]	• Education • Training
Persuading daughters to be active	• Provide encouragement for daughters with examples of coaches, teachers, and local sports partnership representatives explaining how, where, and the benefits of being active • Provide examples of other preteen girls and older adolescent girls being active and how they overcame challenges • Use mainstream media, social media, videos, websites, apps, and word of mouth to promote positive messages	• "You could tell them how worth it will be when they get stronger and healthier and they can run more. Basically, classes, carrying, and shopping, you'll just get quicker and it'll become easier." [Emily, fifth class] • "They might because they are their own age feel like they are like them." [Aisling, fifth class] • "Probably get girls that do sports, like making ads or something. If girls are watching their phones and you could do that." [Evie, sixth class] • "Like that, if there were videos that they (girls) could click into." [Sharon, primary school teacher]	• Persuasion • Modeling
Practical help for daughters to engage in leisure time PA	• Cost of activities is a barrier, so provide opportunities to try them out in school or community for free first (initial cost) • Provide materials for daughters to plan, record, and monitor their PA behaviors, including opportunity to arrange a reward of their choice for themselves • Feedback on behavior if they engage in activities • Provide equipment and merchandise for daughters to practice with at home, for example, footballs, basketballs, skipping ropes, T-shirts, jerseys, hoodies, water bottles, and merchandise	• "You can write a to-do list, so that way you can be more motivated to keep on schedule."[Emily fifth class] • "They could lend them a ball to practice." [Maisie, fifth class] • "Something like if you have all the jumpers and the jersey's, it makes you feel a part of the team, so you want to go again because you are part of this team." [Evie, sixth class] • "If you could practice it at home to see if you like it." [Sarah fourth class]	• Incentivization • Environmental restructuring
Social support for daughters			• Enablement

XSL•FO
RenderX

	Summary of the recommendations from workshops	Example quotes	Related intervention functions
	• Provide opportunities for daughters to get support from other preteen girls, for example, bringing friends to activities and opportunities to ask girls their own age about certain activities • Opportunities to get to know other girls at activities. Can be organized by coaches, teachers, and other club members	• "They could get a friend to join with them so that they have someone to talk to." [Aisling, fifth class] • "Maybe if one of your friends was not on the team can now join the sport, you could even ask them if they wanted to come down to maybe one of your matches so they could have a look and see what the sport is all about and that might make them want to join." [Sophie sixth class]	

[a]PA: physical activity.

Phase 3: Development, Refinement, and Evaluation of the Intervention Prototype

Intervention Component Development

The research team developed separate mobile apps for each target behavior (ie, mothers' support behaviors and preteen daughters' PA) using the *Pathverse* app design platform for mHealth research [86]. This platform enables researchers to develop mobile apps for testing without the requirement of software developers. It is a "no-code" development platform, which allows researchers to create a mobile app with "drag and drop" features instead of coding [87]. The *Pathverse* platform includes features such as the design of customized multimedia content, implementation of participant surveys, provision of self-monitoring tools, setting of personalized goals, the customization of app notifications, digital badges, and a community group chat option [86]. Intervention components were developed within this platform to ensure that the relevant mechanisms of action were targeted and the related BCTs were enacted. Examples of how the intervention components relate to the targeted mechanisms of action are provided in Tables 4 and 5 for mothers and preteen daughters, respectively. For example, for the mothers' intervention, app module 3 titled "What does supporting your daughter involve?" includes infographics about the benefits of and the different ways for mothers to support their daughter to be active. It also includes videos of mothers describing their experiences of engaging in different supportive behaviors. Similarly, in the daughters' intervention, app module 3 titled "Why should you be active?" includes infographics and a video about the benefits of being active as well as a video of a preteen girl describing her experiences of engaging in PA. The mechanisms of action that these modules target are "knowledge," "beliefs about consequences," and "social influences."

XSL•FO
RenderX

Table 4. Intervention components mapped to the mechanisms of action in the mothers' intervention.

	Intervention components, activities, and resources	Mechanisms of action
Week 1: introduction to the study and group meeting (included after feedback from the co-design workshops, session 2)	• Face-to-face meeting with the mothers who are taking part in the study and introducing them to the research team and providing information about the study and consent forms, equipment and merchandise that are part of study (eg, footballs, skipping rope, yoga mat, T-shirts, and water bottles), demonstration of how to download the app and navigate the modules and features of the app, and inform mothers that they will receive certificate for taking part at the end of the study.	• Knowledge • Beliefs about consequences • Environmental context and resources
App module 1: getting started	• Includes a video with a welcome message and brief description about the study; a video demonstrating how to use the app and answer survey questions; and a survey with questions about demographics, PAa levels, and providing support for daughter's activities	• Knowledge
App module 2: what is PA and why is it important?	• Includes infographics about the module objectives, PA and benefits of being active, how active adults should be, how active children and teenagers should be, the benefits of PA for children and adolescents, and how active our teenage girls currently are • A multiple-choice challenge question about how active children should be and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences
App module 3: what does supporting your daughter to be active involve?	• Includes infographics about the module objectives; why mothers were chosen for the study; the benefits of and ways to support their daughter to be active, for example, providing transportation to their daughter's activities; spectating at daughter's activities; and how and where mothers can be active with their daughters • A video with a mother of preteen girls describing her experience of spectating at her daughter's activities • A multiple-choice challenge question about what a mother can do to help support their daughter to be active and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Social influences
App module 4: who can help you support your daughter?	• Infographics about the module objectives, the benefits of social support, having families as a source of support, how friends can support, how neighbors and people in the local community can support, how a daughter's friends can facilitate providing support, how coaches and teachers can support, and how support groups both web-based and in the local community can help mothers • A video of mothers of preteen girls describing how they avail the social support available to them • A multiple-choice question about who can help mothers with the day-to-day challenges of supporting their daughter to be active and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Intentions • Social influences

XSL•FO
RenderX

	Intervention components, activities, and resources	Mechanisms of action
App module 5: tips to help you support your daughter	• Infographics about the module objectives, the challenges mothers face when supporting their daughter and how to overcome them, to remember why supporting their daughter can help do what is important to them, tips for how to get started when feeling overwhelmed, details about shared decision-making and how it could be helpful, and how to manage a lapse in behavior • A video with tips and advice from a role model, for example, mother of an athlete and how they support their daughter • A multiple-choice questions about the types of support messages mothers would like to receive throughout the study as push notifications (eg, reminders, encouragement, praise, affirmations, or inspirational) and a digital badge of congratulations for reaching the end of the module	• Knowledge • Skills • Identity • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion
App module 6: next steps: planning to support your daughter	• Includes infographics about the module objectives, what is goal setting, why and how to set goals, challenges associated with goal setting and how to overcome them, and showing mothers how they can self-monitor their progress in the app • Provide selection goals related to maternal PA support (eg, spectate at daughter's activity and mother and daughter coactivity) • Mothers select and set a PA support goal of their choice, including when and where and how often the support behavior would be enacted, and a digital badge wishing mothers "good luck" with their chosen goal	• Knowledge • Skills • Beliefs about capabilities • Beliefs about consequences • Intentions • Goals • Behavioral regulation
App module 7: booster module (included after feedback from co-design workshops, session 2)	• Includes infographics about the module objectives; recap on maternal PA support behaviors; how to overcome potential barriers to providing support, for example, using if...then statements; and how lapses in behaviors are normal • A video with messages of encouragement and support from other mothers of teenage girls and a digital badge of congratulations for reaching the end of the module	• Knowledge • Identity • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion • Behavioral regulation
App module 8: final module	• Includes infographics with a summary of the study, recap on maternal PA support behaviors, goal setting, how to overcome challenges, where to look for social support, and what to do next • A survey with questions about PA levels for mothers and daughters and regarding providing support for daughter's activities • A survey providing feedback about acceptability and feasibility of the study and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Intentions • Social influences • Behavioral regulation
App icon: resources	• Links to external websites providing information on local resources, family support services, and community events. Includes podcasts about parenting for PA with a focus on mothers and girls, videos of skills or activities that mothers can practice with daughter (eg, yoga, exercises, and football skills), and videos of other mothers of preteen girls discussing and sharing their experiences	• Knowledge • Skills • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion
App icon: goals	• Summary of goals set for the duration of the study • Mothers can review progress of goals set in the module, for example, spectate at daughter's activity or walk to school with daughter twice a week. Mothers can manually set and record additional goals of their choice	• Intentions • Goals • Behavioral regulation

XSL•FO
RenderX

	Intervention components, activities, and resources	Mechanisms of action
App icon: trackers history	• Option available for mothers to self-monitor their progress of goals set that are paired with a smartwatch that is synced with the app, for example, step count and exercise minutes. Mothers can self-monitor their daily steps and exercise minutes manually. Mothers manually self-monitor an activity (eg, walked to school with daughter), rate their enjoyment factor, and record any notes or points of interest	• Intentions • Goals • Behavioral regulation
App icon: chat	• A feature that enables mothers to join a community forum to send and receive messages to and from the research team; an interactive forum where mothers share their experiences and strategies with other mothers who are partaking in the study; and avail of opportunities to meet other mother and daughter participants for group activities, as per information provided by the research team or as suggested by other participants	• Social influences • Emotion
Intervention feature: motivational messages	• Tailored prompts or cues sent as push notifications to mothers that are relative to their chosen goals and generic messages of encouragement, praise, or inspiration that change each day	• Beliefs about capabilities • Identity • Social influences • Emotion
Week 8: conclusion of study and group meeting (included after feedback from co-design workshops, session 2)	• Face-to-face group meeting with mothers to award mothers with a certificate of completion, receive feedback on the intervention, and answer any questions	• Social influences

[a]PA: physical activity.

XSL•FO
RenderX

Table 5. Intervention components mapped to the mechanisms of action in the preteen girls' intervention.

	Intervention components, activities, and resources	Mechanisms of action
Week 1: introduction to the study and group meeting (included after feedback from the co-design workshops, session 2)	• Face-to-face meeting with the girls who are taking part in the study and introducing them to the research team and providing information about the study and consent forms, equipment and merchandise that are part of study (eg, footballs, skipping rope, yoga mat, T-shirts, and water bottles), demonstration how to download the app and navigate the modules and features of the app, and answers to queries or concerns girls may have • Inform girls that they will receive a certificate for taking part at the end of the study	• Knowledge • Beliefs about consequences • Environmental context and resources
App module 1: welcome to our study	• Includes a video with a welcome message and a brief description about the study; a video demonstrating how to use the app and answer survey questions; a survey with questions about demographics, PAa levels, and being active, and a digital badge of congratulations for reaching the end of the module	• Knowledge
App module 2: what is PA?	• Includes infographics about the module contents, what is PA, how active preteen girls need to be, and different ways to be active • A multiple-choice challenge question about how many minutes per day should preteen girls be active for and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences
App module 3: why should you be active?	• Infographics about the module objectives and the benefits of being active • Videos about the benefits of being active, with a preteen girl describing her experiences of being active and the associated benefits • A multiple-choice challenge question about the benefits of being physically active and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Social influences
App module 4: how can you be active?	• Includes infographics about the module objectives; walking or wheeling to school; outdoor play in the neighborhood with friends; going to local parks, woods, and playgrounds with family members; walking the dog as a way to be active; and yoga as a way to be active • Videos about ways in which preteen girls can be active, of interview with famous female sports stars describing their experiences of playing sport and being active, with mothers and daughters dancing together as a way to be active, and of exercises that can be implemented at home as a way to be active • A question about favorite way to be active and a digital badge of congratulations for reaching the end of the module	• Knowledge • Skills • Beliefs about consequences • Intentions • Social influences
App module 5: who can you be active with?	• Includes infographics about the module objectives, who can support girls to be active and the benefits of social support, having fun with friends at school, playing with children in the neighborhood, and being active with family members • Video of other preteen girls sharing their experiences of who they are active with • A multiple-choice question about who girls can be active with and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Intentions • Social influences

XSL•FO
RenderX

	Intervention components, activities, and resources	Mechanisms of action
App module 6: tips to help you be active	• Includes infographics about the module's objectives; why some girls do not want to be active; about how family members or friends can support you to be active; and remembering why you chose to be active, with a support message about what to do when feeling overwhelmed and with a support message about staying positive in times of self-doubt and how to manage a lapse in behavior • A video of preteen and teenage girls sharing their experiences and how they overcame challenges with being active. A video of a famous female sports star discussing their role models, how they overcame challenges related to staying active, and who supported them along the way. A video demonstrating ways to stay active at home • An infographic with a question about tips to help girls be active • A digital badge of congratulations for reaching the end of the module	• Knowledge • Skills • Identity • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion
App module 7: let us get moving	• Includes infographics about the module's objectives, goal setting what is it, why and how to set goals, the challenges associated with goal setting and how to overcome them, and showing girls how they can monitor their progress in the app • Provide a selection of goals related to leisure time PA for girls to choose from • Girls select a goal of their choice, including when and where the activity would be enacted and with whom, and a digital badge wishing girls "good luck" with their chosen goal	• Knowledge • Skills • Beliefs about capabilities • Beliefs about consequences • Intentions • Goals • Behavioral regulation
App module 8: booster module (included after feedback from the co-design workshops, session 2)	• Includes infographics about the module's objectives; revision of PA behaviors; revision of benefits of being active; how to overcome potential barriers to providing support, for example, using if...then statements; and how lapses in behaviors are normal • A video with support messages from other teenage girls and a digital badge of congratulations for reaching the end of the module	• Knowledge • Identity • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion • Behavioral regulation
App module 9: final module	• Infographics about the module's objective; recap on PA and benefits of PA; recap on goal setting; and recap on how to overcome challenges, where to look for social support, and what to do next • A survey with questions about PA levels and being active. A survey providing feedback about acceptability and feasibility of the study and a digital badge of congratulations for reaching the end of the module	• Knowledge • Beliefs about consequences • Intentions • Behavioral regulation
App icon: resources	• Links to websites of resources available to them in their local area • Podcasts about PA, with a focus on girls • Videos of other preteen girls and their experiences	• Knowledge • Skills • Beliefs about capabilities • Beliefs about consequences • Intentions • Social influences • Emotion
App icon: goals	• Summary of goals set for the duration of the study • Girls can review progress of goals set in the module (eg, walk or wheel to school with mother twice a week and practice skills at home) • Girls can manually set and record additional goals of their choice	• Intentions • Goals • Behavioral regulation

XSL•FO
RenderX

	Intervention components, activities, and resources	Mechanisms of action
App icon: trackers	• Option available for girls to self-monitor their progress of goals set that are paired with a smartwatch that is synced with the app (eg, step count and exercise minutes) • Girls can self-monitor their daily steps and exercise minutes manually • Girls manually self-monitor an activity (eg, practiced skills), rate their enjoyment factor, and record any notes or points of interest	• Intentions • Goals • Behavioral regulation
App feature: motivational messages	• Tailored prompts or cues sent as push notifications to girls that are age appropriate and relative to their chosen goals. Generic messages of encouragement, praise, or inspiration that change each day	• Beliefs about capabilities • Identity • Social influences • Emotion
Week 8: conclusion of study and group meeting (included after feedback from the co-design workshops, session 2)	• Face-to-face group meeting with girls to award girls with a certificate of completion, receive feedback on the intervention, and answer any questions	• Social influences

Intervention Delivery

Intervention delivery was considered from 4 perspectives: mode of delivery, intervention setting, schedule, and delivery style in line with the BCIO [49]. As described in Phase 2: Identify Intervention Functions, Content, and Implementation Options section, the intervention's mode of delivery is primarily through a mobile app with a face-to-face component at the start and end of the intervention. The settings where the intervention takes place for mothers and daughters are at their household residences, local sport and exercise facilities, or in outdoor environments (ie, local parks, greens, forests, or beaches). The time frame chosen for the intervention schedule is based on the findings from formative research, which suggested that mother-daughter interventions lasting <12 weeks were likely to be more effective [82], and from engagement with participants in the co-design sessions and the academic advisory panel. The 8-week intervention schedule starts with face-to-face sessions for both mother and daughter participants. Over the course of the first 2 weeks of the intervention, 5 short modules are released for the participants to complete. Following completion of the modules, both mothers and daughters are then required to select and set a goal of their choice related to the target behavior (module 6). They then self-monitor their progress for 6 weeks. A booster module summarizing the intervention content is released during week 5 of the intervention, and there is a final module to be completed at the end of the intervention. To conclude the intervention and answer any questions, a second face-to-face session is held with the mothers and daughters. Figure 2 provides an overview of the intervention schedule and details of the core learning outcomes of the modules for both apps.

To ensure the communication style in which the intervention content (ie, BCTs) is delivered is collaborative, autonomy supportive, and person centered [48], the principles of SDT [85] were applied. According to SDT, autonomous motivation for a behavior is developed through the satisfaction of the basic psychological needs of autonomy, competence, and relatedness [85]. The need for autonomy refers to a mother's or daughter's desire to have choice and to feel empowered in directing their own behavior [85]. For example, in the app, the goal-setting feature supports the basic need of autonomy by providing mothers and daughters with choices and options, enabling them to make decisions and take responsibility about how they chose to support their daughter or be active. The need for competence relates to a mother's or daughter's need to feel capable of achieving a desired outcome [85]. To illustrate, whenever mothers or daughters log activities on the app, it represents a confirmation that they sustained the behavior and thus enhances their feelings of competence. The need for relatedness denotes an individual's aspirations to feel a sense of belonging and connectedness with others [85]. For instance, the messaging feature enables mothers to connect with others who face the same challenges or achieve the same goals, thus promoting a sense of belonging and providing an opportunity to develop meaningful relations with other participants (Table 6).

Table 6. Intervention delivery style, illustrating how app features align with the principles of self-determination theory.

App features	Description	Expected benefit
Autonomy-supportive features		
Goal setting	• This feature provides mothers and daughters with the option to choose from a set of predefined activities or exercises they wish to perform • Mothers and daughters have the option to proactively set a goal they will perform, which is related to either maternal support for PAa or daughters' leisure time activity	• The goal-setting feature supports the basic need of autonomy and promotes autonomous motivation by providing mothers and daughters with choices and options, enabling them to make decisions and take responsibility about how they choose to support their daughter and be active
Reminders	• The app will provide a reminder that is delivered as a push notification around the time the mothers and daughters should perform a specific activity • The reminders are set by the mothers and daughters while they are selecting their goals and are optional	• This feature helps mothers and daughters stay organized and on track with regard to the target behaviors • To reduce the feeling of acting out of pressure or control, this is an optional feature and can only be activated by the mothers and daughters
Motivational messages	• Feature with preset messages delivered as push notifications that provide encouragement, praise, and inspiration to perform target behaviors • Messages are not task inherent and are provided to mothers and daughters at specified time intervals regardless of performance or completion of target behaviors • A feature that allows mothers and daughters to write a brief message about why it is important for them to continue engaging in the target behavior. This self-directed message is available whenever needed and can be delivered as a push notification at chosen time intervals	• Mothers and daughters provided feedback regarding the time and type of messages they would like to receive in an earlier module; the messages are tailored to suit their preferences • The messages provide a meaningful rationale for engaging in the target behaviors • The self-directed messages enable mothers and daughters to reflect on why they want to engage and sustain the behaviors
Competence-supportive features		
Self-monitoring	• Provides mothers and daughters with option to self-record the accomplishment of a goal or the completion of a task related to the target behaviors • Mothers and daughters can record information about what happened on specific days (eg, bad weather, lots of homework, and stress at work) and rate their enjoyment factor while partaking	• Whenever mothers or daughters log an activity, it represents a confirmation that they sustained the behavior and thus enhances their feelings of competence • The information entered helps mothers and daughters know themselves and understand their personal circumstances that influence the target behavior • By entering data into the app, mothers and daughters express their interest in maintaining the behaviors
Activity feedback	• Provides mothers and daughters with information about how the task that was performed and provides them with details of their overall progress toward completing a predefined set of activities or goal. The information might be accompanied by a score (eg, step count) or encouragement message or badge (well done for completing the module) • Timing of feedback is important to avoid unsatisfactory results such as underachievement; therefore, mothers and daughters choose to view their own feedback rather than receiving it unexpectedly • The activity feedback needs to be personal, nonevaluative and specific to the task performed.	• Positive feedback shows growth or improvement trends and enhance mothers' and daughters' sense of competence • Activity feedback in the form of encouragement messages or badges can foster positive emotions toward the target behavior
Relatedness-supportive features		
Community forum	• Enables mothers and daughters to connect with other participants where they have the opportunity to interact and connect with others • The research team will also facilitate opportunities for participants to meet and participate in activities through the group chat feature	• Messaging enables mothers and daughters to connect with other participants who face the same challenges • They can share experiences, provide and receive support, and experience a sense of belonging and relatedness

XSL•FO
RenderX

App features	Description	Expected benefit
Modeling videos or podcasts	• Videos or podcasts of other mothers of preteen daughters and preteen girls sharing their experiences are embedded throughout the app's modules and in the resources icon	• These videos or podcasts provide mothers and girls with information and advice from other mothers and daughters who face similar challenges, which can help satisfy their need for relatedness and support their autonomous motivation to perform the target behavior over time

[a]PA: physical activity.

Feedback From Co-Design Workshops and Intervention Refinement

After the development of the intervention content and delivery (with separate mobile apps for mothers and daughters), a second series of workshops was held to present the mobile apps to mothers, preteen girls, and teachers. All groups acknowledged how the intervention content was informative and persuasive, as shared by Sadie, fifth class:

> *Instead of just getting girls to join sports, giving good reasons as well. Instead of saying like, do you want to try this and try this? It was giving good reasons.*

The girls found the videos of other girls' experiences regarding being active useful and inspiring, particularly those with girls their own age and a little older than them, as described by Sophie, sixth class:

> *Because if they're girls older, like what Evie said, they can be like role models. If they're the same age as you, then they could inspire you to join a team as well.*

This was a similar finding for the mothers and teachers, who recognized how videos demonstrating experiences of "other mothers and girls they can relate to" (Kate, primary school teacher) would encourage maternal PA support and girls to be active. The mothers' and teachers' groups provided positive feedback when exploring the resources feature, which presented what was available to them in their local community for supporting their daughter to be active, as described by Susan, who has a daughter in sixth class:

> *That's brilliant. Little bits like that on it, You just let people know (about the resources feature) and you just click the link then and pick it up.*

Several amendments were suggested at these workshops, which were then included in the final version of the intervention. For example, the mothers and teachers' groups suggested that it would be important to have an initial and final group-based face-to-face session as part of the intervention, as shared by Emer, a primary school teacher:

> *I think at the start, if you get them in like...that first meeting and first introduction thing is crucial. They feel invested in it.*

As a result of this feedback, we introduced both an initial and final group-based face-to-face intervention sessions. Specifically, the initial session will enable mothers and preteen daughters to meet other users of the smartphone app and develop social connections, which can then be reinforced through using some of the social support features on the app. It would also allow mothers and preteen daughters to get instruction from the research team as to how to use the features of the smartphone app. The final face-to-face session will allow mothers and preteen daughters to share their experiences and provide an opportunity to sustain their social network developed as part of the intervention. It was also suggested to avoid providing all the modules on the app at once, instead phasing them in over a few weeks to prevent mothers and daughters from feeling overwhelmed by the information. This recommendation was shared by Michelle, whose daughter was in fourth class:

> *I'd phase it in, different bits of information every couple of weeks...I think if you throw too much at people, they won't bother looking at it. It's just too much information...People don't like too much information at once. It just bugs them.*

Further suggestions were for a booster module to be added to the app to provide a reminder of the key features of the intervention content and for a podcast with parenting tips for teenage daughters to be added to the resources feature as "there's a lot of challenges out there. People are looking for...Looking for help and guidance." (Jennifer, daughter in sixth class).

Evaluation of the Intervention Prototype and Logic Model

The App Behavior Change Scale [78] was used as a checklist by the research team to assess the behavior change elements of the apps. Both proposed mobile apps included 18 items on the scale, indicating a high number of BCTs embedded in the apps and strong behavior change potential (Multimedia Appendix 5 [78]). The academic advisory panel reviewed and agreed on the final intervention prototype as well as the refined program theory. Figure 3 is a logic model that represents the program theory of the mother-daughter intervention. It depicts the flow of the intervention from (1) the identification of the problem (ie, preteen girls are not active enough) to (2) the inputs (ie, target behaviors of maternal PA support and preteen girls' PA), to (3) the mechanisms of action (ie, Table 1), to (4) the intervention components (ie, Tables 4 and 5), to (5) outputs (ie, mothers and daughters develop knowledge and understanding and improve motivation to enact target behaviors), to (6) short-term outcomes (ie, mothers and daughters enact target behaviors), to (7) long-term outcomes (ie, mothers and daughters maintain target behaviors), and finally (8) overall outcomes of the intervention (ie, improved PA levels in preteen girls). The app targeting mothers will be called the Physical Activity Virtual Assistant for Mothers (PAVA-M), whereas the app targeting their preteen daughters will be called Physical Activity Virtual Assistant for Daughters (PAVA-D) (Figures 4 and 5).

Discussion

Principal Findings

This paper describes the systematic process to develop an evidence- and theory-informed intervention, using co-design methods, to increase PA in preteen girls of low SEP by incorporating maternal supportive behaviors. This is noteworthy given that levels of PA decline with age in preteen girls of low SEP [4,9], placing them at elevated risk of obesity, type 2 diabetes, and cardiovascular disease [8,10]. In keeping with MRC guidance, the intervention was refined through an iterative and dynamic process based on evidence, theory, feedback from co-design workshops with mothers of preteen daughters, preteen girls, and primary school teachers and input from a multidisciplinary academic advisory panel. This process resulted in the development of an intervention with 2 target behaviors, one targeting mothers' supportive behaviors for their daughters' PA and the other targeting preteen daughters' PA directly, which is ready for feasibility and acceptability testing.

The systematic approach applied in this study was guided by the BCW framework for developing interventions [37]. Using the BCW facilitated a rigorous analysis of the problem and how it could be potentially addressed. It also enabled the consideration and incorporation of evidence from several sources: the extant research literature, formative research [82-84], as well as the judgments of the academic advisory panel. We followed a step-by-step process that involved the following: identifying and specifying the target behaviors; conducting a thorough analysis of the barriers and enablers to these behaviors; using the TDF to identify the proposed mechanisms of action; and selecting feasible intervention functions, BCTs, and delivery methods. One study has used the BCW to develop a mother-daughter PA intervention for adolescent girls [41], but to our knowledge, this is the first study to use the BCW and TDF in conjunction with the BCIO to target children's PA through a theory-informed family-based intervention.

The intervention prototype incorporates 27 BCTs, which is greater than the average of 8 to 10 BCTs per intervention reported in recent systematic reviews of family-based interventions targeting health behaviors such as PA [82,88]. There is some evidence to suggest that more effective interventions include a greater number of BCTs [89]. Furthermore, interventions that include a greater number of BCT clusters, with a threshold of at least 3 clusters, increase the likelihood of intervention effectiveness [90]. There were 13 BCTs clusters within the intervention prototype, and we incorporated particular clusters and specific techniques that have shown promise in theory-based interventions. For example, identity is an important mechanism of action for the promotion and maintenance of PA in adults and young people [63,91] and for providing parental PA support [64]. Our intervention is one of the few to include BCTs, which strengthen maternal identity for PA support and mother and daughter PA identity such as "reframe past behaviour BCT," "identify self as role model BCT," and "adopt changed self-identity BCT" [64]. In addition, this study incorporates BCTs that have proven effective in mother-daughter PA interventions and more broadly in health behavior change research. These include selecting a relevant behavioral goal, self-monitoring progress toward that goal, and developing problem-solving skills to address potential challenges [82,92-94].

This study engaged with end users (eg, mothers and preteen girls) and other relevant stakeholders (eg, primary school teachers) in the intervention development process using co-design methods. Despite continued advocacy for engaging children and adolescents in co-design methods, there is a paucity of studies targeting family-based PA that have applied such methods, in particular when it comes to children aged 10 to 12 years [59]. To the best of our knowledge, this is the first intervention prototype that meaningfully engaged with girls aged 10 to 12 years throughout the entire development process. The girls provided information into the selection of intervention components and towards the acceptability of intervention

XSL•FO
RenderX

materials and resources [95]. Interestingly, the girls in the study suggested that a video of teenage girls slightly older than they were (ie, aged 13-14 years) describing how they overcame challenges to PA would be relatable and helpful for promoting PA in their cohort, an approach that the research team had not considered. Therefore, by including girls aged 10 to 12 years in the co-design process, this study increased the likelihood of acceptability and implementation at the intervention testing stage [56,96]. Furthermore, there is a lack of resources dedicated to detailing and evaluating the process of engaging with participants using co-design methods in the development of interventions [55,97]. As a result, there may be a need to develop guidance as to how to report the use of co-design principles in studies similar to the Template for Intervention Description and Replication (TIDieR) checklist [98] or the BCIO [46].

The mode of delivery of the intervention was another important intervention component. The selection of the mobile app was driven by the end users who wanted flexibility in how they engaged with the intervention. Indeed, mothers in the study highlighted the importance of being able to complete the intervention at their own pace, thus recommending a mobile app as the primary mode of delivery. Mothers often describe barriers to engaging in PA related to household, family, and occupational responsibilities [83]. Thus, the mobile app may allow individuals to complete intervention content at their own pace and facilitate adherence to the intervention. There is increased use of mobile apps as a mode of delivery for PA interventions [22,99,100]. However, research to date in children and adolescent populations is less frequent and is typically poorly designed [100]. Consequently, there is a need for further systematic theoretically informed research on the use of mobile apps with this population, a need which this study attempts to address. One of the challenges in using mobile apps as the mode of delivery for interventions is the cost of development of such apps, which can be prohibitive [101]. This study used the Pathverse platform to address this issue, as it provided our team with a rapid and cost-effective tool for creating and refining the intervention content [86,102]. Alongside the use of the BCW and related elements, we used the App Behavior Change Scale as a checklist during the development of the intervention to maximize the behavior change potential of the applications. However, it is important to note that the App Behavior Change Scale only measures the theoretical behavior change potential of the application, and it does not attempt to investigate the relationship between the actual features of application and behavioral outcomes [39]. Future work should consider the uptake, engagement, and user retention of the app by following frameworks such as the Reach, Effectiveness, Adoption, Implementation, and Maintenance framework [103].

An important component within intervention development is how an intervention is delivered, including the style of delivery of the intervention [48]. Typically, this focuses on human to human interaction; however, there is an increasing realization of the importance of considering a person-centered intervention delivery style, which is reflective and empathetic when designing applications and their related content [104]. Consequently, the principles of SDT [85] were applied to the intervention, ensuring that BCTs and specific features used in the intervention mapped to the basic psychological needs of autonomy, competence, and relatedness proposed by SDT [105-107]. Indeed, there is a growing body of work highlighting how applications underpinned by the SDT principles can strengthen digital therapeutic alliance and increase engagement in behaviors such as PA [107,108].

Future Directions

This study took place within the intervention development phase of the MRC framework [32]. Future research would involve using a no-code development app [102] to assess the feasibility of the intervention and inform decisions about how to progress to the following phases of intervention evaluation and implementation [32]. After engagement with the co-design participants, it was suggested that it was most feasible to promote this intervention via the school environment although it is targeting girls' PA outside of school hours. The school setting can reach children and adolescents of diverse racial and socioeconomic backgrounds and provides a ready-made social network for both mothers and daughters to engage with when undertaking the intervention [109,110]. Furthermore, it would allow for tailoring of the intervention resources within the school and local community that could support increased leisure time PA [109,110]. This is in line with research by Pfledderer et al [111] and van Sluijs et al [23] who recommend that interventions consider both family and community engagement (eg, family based and linked to school) to promote children's and adolescents' PA, particularly for underserved populations such as children and adolescents of low SEP. Although our preference is for mothers and daughters to take part in the intervention, the separate mobile app mode of delivery allows preteen girls to partake in the intervention regardless of their mothers' participation. This is an important feature, given that reaching parents of low SEP is often a challenge for interventions [112].

A limited number of these interventions are scaled-up and applied in real-world settings, identifying a significant research practice gap [113,114]. A recent review by Crane et al [115] found that health interventions (including PA interventions) that followed a research pathway were approximately 3 times more likely to have a positive effect on population health. Therefore, in line with recommendations by McKay et al [113], our future research would involve continuous planning for scaling-up, developing scale-up pathways, and evaluation of the scale-up throughout the duration of the intervention. Schools serving children with low SEP are frequently underresourced and often need more support to reach the same outcomes as their more advantaged counterparts [109,113]. To this end, maintaining relationships with schools and local community partners is essential in the scaling-up process to establish trust and identify potential implementation barriers [113,114]. This would involve hosting meetings with principals, teachers, and administrators to understand the pressing issues in their school environment; engaging with teachers, coaches, and local community partners to overcome implementation barriers; and developing collaborative strategies to encourage mothers and daughters to be physically active and sustain activity levels after the intervention [116]. Finally, based on the findings from this study, potential avenues for future research could be additional studies to evaluate the long-term effectiveness and sustainability

XSL•FO
RenderX

of the intervention, research exploring the factors influencing parental engagement in family-based mHealth interventions, and investigation into the impact of mobile app on PA behavior change in children and adolescents.

Strengths and Limitations

This study used a systematic, evidence- and theory-based approach to integrate a body of evidence from a systematic review, 2 qualitative studies, an academic advisory panel, and end users' knowledge to co-design and develop a novel intervention to promote PA in preteen girls of low SEP. The uniqueness of this study lies in following the first phase of the MRC framework, while using the BCW, the TDF, BCTO, and input from co-design workshops, which offered procedural direction, structure, and transparency. Annotating the BCIO entities enabled us to represent the intervention characteristics in a detailed and structured way, which can be used across contexts and disciplines. In addition, the entities' unique identifiers will facilitate the use of artificial intelligence including machine learning–based methods in data extraction and evidence synthesis [46]. Family-based PA interventions have been the focus of previous research [21,117]. However, no digital intervention to date has specifically focused in promoting PA in preteen girls of low SEP complemented by maternal support behaviors. Thus, this work fills an important gap by seeking to support an at-risk group. Furthermore, the involvement of key stakeholders in the development process is a key strength of this study. It ensures that the content of the intervention was adapted to accommodate the users' needs, making it useful and relevant, thus increasing the likelihood of a more feasible, acceptable, and ultimately effective intervention [56,118].

Our work has some limitations. First, the highly structured and systematic approach used to develop this intervention prototype takes a significant amount of time and resources. For example, using the BCW, the TDF, and the BCTO requires considerable skills and training. Second, the process of converting BCTs into intervention content can be open to interpretation, and the research team had to make subjective and pragmatic decisions regarding intervention content throughout the process [119,120]. Third, we did not collect additional information regarding mothers' backgrounds such as their educational levels and PA experience as part of the co-design workshops. Finally, similar to other research [45], we used DEIS schools to recruit low-SEP preteen girls and their mothers. However, the data might not be fully representative of the target population, as DEIS schools are categorized by district, and it is possible that some girls or mothers in the school might not be of low SEP. Continued efforts should be made to target this cohort, for example, using household income or area level socioeconomic status.

Conclusions

In conclusion, this study uses a systematic evidence- and theory-based approach incorporating findings from a systematic review, formative qualitative research with mothers and preteen girls, input from an academic advisory panel, and knowledge from end users. This process was used to co-design an mHealth intervention prototype aimed at promoting PA in preteen girls, with a focus on maternal support behaviors, and is now ready for feasibility and acceptability testing. The novel contribution of this study lies in the use of theory and the meaningful involvement of key stakeholders throughout the development process. In addition, this study offers a practical example of how to integrate evidence, theory, and stakeholder engagement, which can be adjusted and tailored to fit different contexts and populations. Finally, the comprehensive annotation of the BCIO entities denotes the intervention characteristics in a structured manner that enables improved communication, replication, and implementation of interventions.

Acknowledgments

The authors would like to thank the school principal, teachers, mothers, and girls for taking part in the co-design workshops. The authors would also like to thank Amanda Wilms from Pathverse for her help and guidance with using the no-code app development platform.

Authors' Contributions

CB and JM conceptualized and led on the idea of Physical Activity Virtual Assistant for Mothers (PAVA-M) and Physical Activity Virtual Assistant for Daughters (PAVA-D). GO'D, AK, and RER helped develop the idea of PAVA-M and PAVA-D and provided guidance based on their expertise, including the section of mechanisms of action, behavior change techniques, and intervention components. CB and JM led on the co-design workshops and development and adaptation of the intervention content. CB and JM drafted the original manuscript. GO'D, AK, and RER reviewed the initial content and structure of the manuscript. All authors have read, revised, and approved the final manuscript.

Abstract

Background: Parenting programs are the recommended treatment for common mental health problems of childhood such as conduct disorder. In the United Kingdom, local authorities have responsibility for providing or commissioning these programs through face-to-face and video call weekly groups and e-learning style asynchronous offerings. However, there has been a shortage of research into the potential of digital resources to augment and enhance parenting groups.

Objective: This pilot study aimed to explore whether providing digital microinterventions in a mobile app (Pause) to augment parenting programs is a feasible strategy. Pause fits into parenting programs and prompts and supports parents to use each week's new parenting skill at home. Specifically, we want to understand (1) whether parents use Pause, (2) what type of features or tools in Pause are most frequently used for support, and (3) what are the perceived strengths and weaknesses of Pause.

Methods: Pause was provided to parents attending 3 of the most common parenting programs delivered across 3 local authorities in the United Kingdom. During weekly sessions, parents were supported to add "tools" in the app, which mapped onto the training in their session, for example, distracting their child, setting age-appropriate consequences, and using praise. Preprogram surveys were obtained at the first session. After programs were completed, postprogram surveys were administered to measure app use, gather which tools parents used, and explore the strengths and weaknesses of the app. Participants and practitioners were invited for interviews, where the strengths and weaknesses of augmenting parenting programs with Pause were discussed in more detail.

Results: In total, 53 parents were recruited from groups. A total of 25 of 53 (47%) parents completed postsurveys distributed at their final parenting group session, in keeping with typical rates of attrition in parenting programs. In addition, 7 parents and 3 practitioners agreed to interviews after the program. Most of the parents (23/25, 92%) had used Pause. Other than the journal, used by 17 parents, the most popular tools were the relax tool and praise tool, each used by 10 parents. Survey data revealed specific strengths and weaknesses of the tools in Pause, particularly highlighting that parents wanted Pause to provide more ideas for distraction or relaxation activities. Interviews revealed the challenges parents attending programs face, the range of family members using Pause, and the diverse settings where it was used. Interviews also revealed specific opportunities for improving the user interface and for addressing challenges in the journaling function.

Conclusions: This pilot study found good acceptability and engagement with Pause. Interviews revealed promising evidence, suggesting that Pause may improve family life and aid child behavior change. Future research should evaluate whether adding Pause to parenting programs increases their positive effects on children's behavior and mental health.

Introduction

Background

Parenting programs are recommended as the first-line treatment for common mental health problems of childhood such as disruptive behavior disorders and attention-deficit/hyperactivity disorder [1-3]. In the United Kingdom, such parenting programs are predominantly commissioned or delivered through local government [4]. Provision tends to include groups (whether face-to-face or via video call) and e-learning style asynchronous offerings [4,5]. However, there has been a shortage of research into the potential of digital resources and mobile technology to augment parenting groups and enhance change in parenting style to better match evidence-based approaches [6,7].

Poor parent engagement is an ongoing challenge in these programs, stopping families from receiving the full benefit of programs, so it is important to evaluate means of augmenting programs to maximize engagement and therefore increase impact. One systematic review found that only around half of parents who start a parenting program finish it [8]. A large study of a web-based parenting intervention found that, in practice, as few as 7% of referred parents complete the program [9]. This problem may arise in part due to the didactic delivery of programs, which is not well-suited to all parents [10]. Moreover, education is not always sufficient for behavior change. Insights from behavioral economics can ensure that interventions to encourage health-promoting behaviors achieve their potential [11,12]. For example, social norm insights can help avoid situations, where interventions aimed at reducing harmful behaviors in fact normalize and increase them [13].

Digital microinterventions provide one potential means of promoting parenting style change due to the focus on optimizing engagement. Digital microinterventions involve a trigger situation prompting a decision rule process, which is mediated by an app but situated within a wider therapeutic process [14].

Pause (Pause Ltd) is a digital platform that was developed to provide parents with a selection of digital microinterventions to augment parenting programs [6]. The digital microinterventions in Pause—called "tools"—each corresponds to one of the skills parents are taught during parenting programs, such as praise, time together, or distract. As the parenting program proceeds and new skills are taught, group leaders support parents to add the corresponding tool to their toolkit on Pause [10]. In between group sessions, they can use those tools to help them increase the frequency and quality of their use of that particular skill. For example, parents can use the "distract tool" to help them think about how to distract their child from emotions or from unwanted behavior. The distract tool includes 4 age-appropriate distraction ideas and includes space for parents to add ideas for ways to distract their particular child. Another tool, the relax zone, guides parents through teaching their child grounding activities, which they can use to manage anxiety or overwhelming emotions. Finally, the consequences tool suggests age- and neurodevelopmentally appropriate consequences and guides parents through the process of setting short feasible consequences and getting back on good terms immediately after. The wide range of tools is designed either to be used in the heat of the moment when parents face a challenge or to structure a planned interaction. Previous papers describe the development of the app [6,7].

Best practice software development is iterative and user-centered. It is therefore important to find out whether the approach taken in Pause is acceptable and engaging to parents, whether any tools are not engaging, and what are the strengths and limitations of this approach.

Aims

This pilot study aimed to explore whether providing digital microinterventions in a mobile app (Pause) to augment parenting programs is a feasible strategy. Specifically, we want to understand (1) whether parents use Pause, (2) what type of features or tools in Pause are most frequently used for support, and (3) what are the strengths and weaknesses of Pause.

Methods

Participants

Participants were recruited through 3 local authorities in the United Kingdom: Wiltshire Council, Leicestershire Council, and Buckinghamshire Council. To accurately draw from Pause's population of interest, inclusion criteria were pragmatic. Included participants were attendees at a parenting program run by a local authority whether or not they had legal parenthood. People younger than 18 years of age were excluded, and people who did not have a mobile phone were unable to participate.

Seven weekly groups were selected for inclusion based on practical considerations at local authorities. All attendees of these groups running between January and June 2024 were invited to participate in the study. Recruitment was conducted directly by parenting practitioners who offered participants QR codes to complete pre- and posttest surveys on Qualtrics (Lake Technology Management, LLC) and to download Pause.

Parenting practitioners' leading groups received 2 personalized training sessions from researchers, where they were shown the relevant tools in Pause. They also had access to ongoing technical and practical support from the research team throughout the study.

Procedures

Practitioners' leading participating groups had 2 training sessions to show them how to add the Pause app to their programs. This training was different for the 3 groups, which were running different programs (Wiltshire Council used a Care for the Family program, Buckinghamshire Council used a Family Links program, and Leicestershire Council used a Triple P program). There was no control group. In the first session, participants were given a chance to download the Pause app, consent to participation, and complete the preintervention surveys. These surveys included demographic information (sex,

XSL•FO
RenderX

decade of age, language spoken, and whether they had a degree), the Parenting Sense of Competence Scale (PSOC), Warwick Edinburgh Well-Being Scale, and the Strengths and Difficulties Questionnaire Conduct Subscale (SDQ-c) [15-17]. At every subsequent session, the practitioner advised participants which "tool" from the Pause app would complement the topic of the session. In every respect aside from the use of the app, practitioners completed the programs as usual. At the end of the study, parents received a second survey, which repeated the consent process and the rest of the preintervention survey as well as including questions about their use of the Pause app and their experience. Specifically, participants were asked which tools on the Pause app had been used. For each tool they had used, they were asked how many times it was used, what was good about it, and what could be improved. All parents who completed these surveys were invited to attend a video call interview with a researcher to explain on how Pause fits into their experience of the parenting program. Finally, parenting practitioners who had led groups using Pause were invited to be interviewed. Interview topic guides are included in Multimedia Appendix 1. Children were not directly involved in this study.

Ethical Considerations

All participants provided informed consent. Participants received a US $13.38 voucher for each survey and a US $26.76 voucher for the interview, up to a maximum of US $53.52. Ethics approval was provided by the Biomedical Sciences Research Ethics Committee at the University of Warwick (BSREC 14/23-24).

Analysis

Demographics

Demographics were described using descriptive statistics, including SDs for continuous measures and percentages for binary measures. The characteristics of those who dropped out were compared with those who completed both surveys using 2-tailed *t* tests and chi-square tests using Stata (version 17; StataCorp LLC).

RQ 1: Did Parents Use Pause?

This research question (RQ) was assessed in 2 ways using data from surveys. First, on the basis that there were no systematic differences between those who completed the postintervention survey and those who were lost to follow-up, we assumed that rates of using the Pause app were the same among those who completed the second survey and those who did not. To measure this, we divided the number who used Pause by the number who completed both surveys.

Second, we calculated the worst-case scenario engagement rate by assuming that none of those who failed to complete the second survey downloaded and used Pause. To measure this, we divided the number who used Pause by the number who completed at least 1 survey.

RQ 2: Which Tools Did Parents Use Pause to Support?

This RQ was assessed using a survey self-report of which tools within Pause were used. Descriptive statistics were used to present how many people used each tool and how many times. These results were presented in a stacked bar chart constructed using Microsoft Excel (version 365). Practitioner interviews were used to evaluate the validity of these findings.

RQ3: What Are the Strengths and Weaknesses of Pause?

This RQ was assessed using thematic analysis based on 3 data sources, free-text data from all postintervention surveys, parent interviews, and practitioner interviews. Surveys were reported using illustrative quotes from each question. Interviews were analyzed using thematic analysis using Taguette qualitative software, conducted following Braun and Clarke's 6 stages, and within a philosophical framework informed by user-centered design [18-20]. Specifically, following familiarization with the data (stage 1), the researchers generated initial codes (stage 2) and searched for themes (stage 3) while remaining attentive to the context of users, their journey through parenting support, the usability of the technology, and opportunities for further refinement—rather than viewing the app as a finished product that either "worked" or "did not." Following these stages, the themes were refined (stage 4), defined and named (stage 5), before being written up (stage 6). Within this framework, the researchers distinguished parents' experience of existing parenting courses from the technology. The technology is added to augment the courses so both are reported because (1) understanding the use of Pause entails a rich understanding of the experience of people in courses and (2) explicitly reporting both reduces the risk of wrongly eliding the course and the app. The resulting coding frame was reported with illustrative quotes.

Results

Participants

In total, 53 parents completed preintervention surveys. Among them, 25 completed the postintervention surveys, 3 of whom had failed to complete preintervention surveys.

The 25 of those who completed the postintervention survey included 22 (88%) female participants, and 3 others were male participants. In total, 3 were in their 20s, 15 were in their 30s, 6 were in their 40s, and 1 was 50 years and older of age. None were in their teenage years. Most of them (n=23, 92%) reported that English was the main language they spoke at home. Only 6 (24%) had a bachelor degree or higher. The mean age of the child they were primarily concerned about was 6.7 (range 3-13) years. A total of 20 were from the Wiltshire site, 3 from Buckinghamshire, and 2 from Leicestershire.

The 22 completers had a mean PSOC score of 55.2 (SD 2.09). In total, 8 (37%) parents scored below the cutoff for low confidence of 58 [21]. The 22 completers had a mean SDQ-c score of 5.5 (SD 2.24), and 18 (82%) scored above the cutoff of 4 for abnormal conduct problems [22]. The 22 completers had a mean adjusted Short Warwick Edinburgh Mental Well-Being Scale (SWEMWBS) score of 18.9 (SD 2.96), and 14 (64%) scored below the cutoff for the lowest 15% of the population (cutoff=19.5) [23].

There were no significant differences between the 22 who completed both surveys and the 29 who only completed the baseline surveys with respect to demographics (sex, age, language spoken at home, educational level, and child age) or

XSL•FO
RenderX

survey responses (PSOC, SDQ-c, and SWEMWBS). Table 1 compares those who completed both surveys with those who only completed one.

Seven participants agreed to interviews. All had completed baseline measures. A total of 4 were from Wiltshire, 1 from Buckinghamshire, and 2 from Leicestershire. They were all female participants, all spoke English at home, and 2 had bachelor degrees. In total, 1 was in her 20s, 5 were in their 30s, and 1 was in her 40s. The mean age of the child they were primarily concerned about was 7.4 (range 4-13) years. Compared with all participants, interviewees had slightly higher confidence (PSOC=58.4; t_{51}=0.943; P=.35), slightly lower conduct problems (SDQ-c=5.0; t_{51}=–1.19; P=.24), and slightly higher well-being (adjusted SWEMWBS=19.8; t_{51}=1.14; P=.26). None of these differences were significant at the .05 level. In addition, we interviewed 3 parenting practitioners who had delivered the Pause program. They were all female, and all from Wiltshire Council.

Table 1. Comparing those who completed only the preintervention survey with those who completed pre- and postintervention surveys.

	Only preintervention survey	Both pre- and postintervention surveys	Statistical tests	
			Statistics	*P* value
PSOC[a], mean (SD)	55.1 (1.87)	55.2 (2.09)	t_{49}=–0.044	.96
SDQ-c[b], mean (SD)	6.14 (1.81)	5.46 (2.24)	t_{49}=1.21	.23
WEMWBS[c] (adjusted), mean (SD)	18.6 (2.36)	18.9 (2.96)	t_{49}=–0.454	.65
Decade of age, mean (SD)	3.1 (0.62)	3.2 (0.81)	t_{49}=–0.62	.54
Child age, mean (SD)	5.9 (2.1)	6.5 (2.5)	t_{49}=–0.93	.36
Female, n (%)	25 (86)	22 (86)	χ^2_1=0.0003	.99
Speaks English at home, n (%)	25 (86)	20 (91)	χ^2_1=0.3	.61
Bachelor degree, n (%)	7 (24)	8 (36)	χ^2_1=0.9	.34

[a]PSOC: Parenting Sense of Competence Scale.

[b]SDQ-c: Strengths and Difficulties Questionnaire Conduct Subscale.

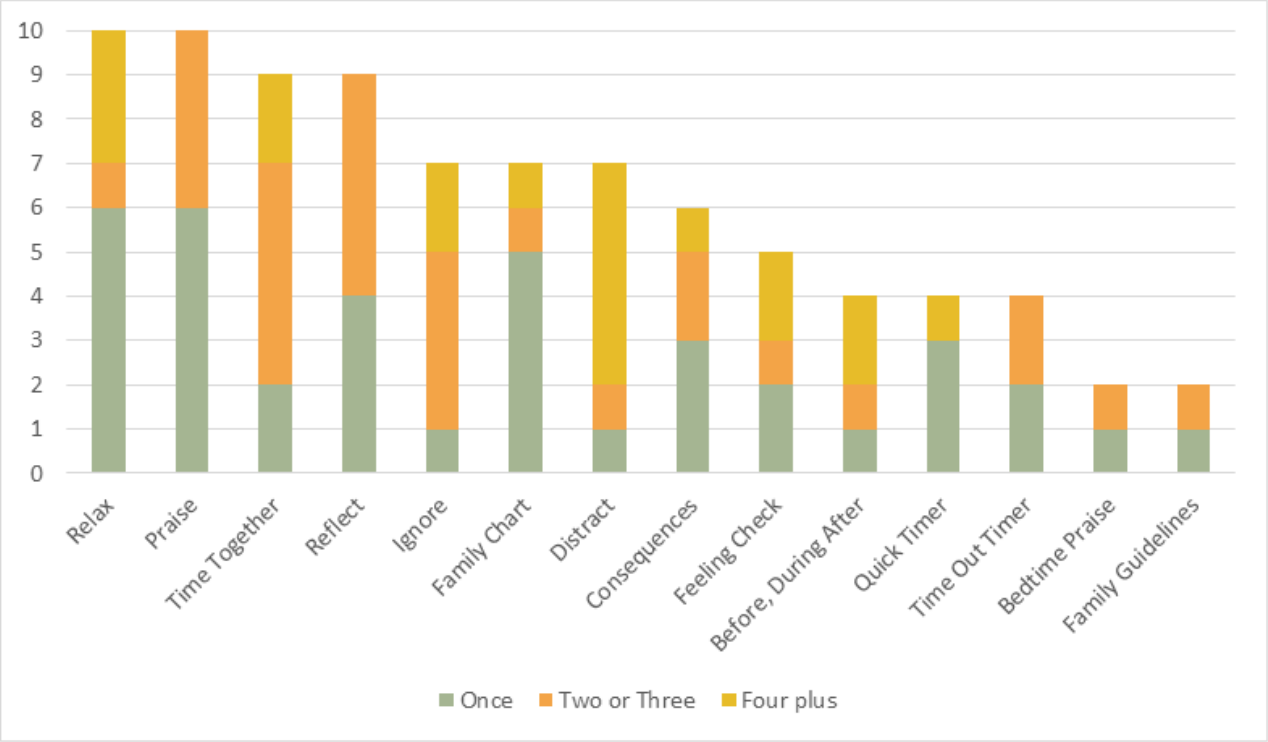
[c]WEMWBS: Warwick Edinburgh Well-Being Scale.

RQ 1: Did Parents Use Pause?

In total, 23 of 25 (92%) parents had downloaded and used the Pause app, and 2 (8%) did not. Both cited concerns about personal data, and 1 reported thinking that using an app to support parenting was inappropriate. They were 1 male and 1 female participant, both in their 30s, both spoke English at home, neither had bachelor degrees, and both from the Wiltshire site.

Given the absence of systematic differences between those who did not complete the postintervention survey and those who completed both surveys, we could assume that the app uptake rate of 92% (23/25) held across the whole sample. However, it is also possible that an unmeasured factor linked both engagement and completion of the second survey. A worst-case scenario estimate is that none of the 29 who dropped out used the app so only 23 of 53 (43%) downloaded and used the Pause app.

RQ 2: Which Skills Did Parents Use Pause to Support?



The core components of the Pause app are the child and parent profiles and the journals; in addition to which, there were 15 digital “tools” available to parents. In total, 20 (87%) parents completed the one-off reflective exercise to create a profile for their children, and 15 (65%) completed the one-off reflective activity to create their own parent profile. Only 12 (52%) reported that this was a positive experience, but 2 said that there were too many questions.

In total, 17 (74%) parents had used the journal. Among them, 6 (26%) only used it once, 7 (30%) used it 2 or 3 times, and 4 (17%) used it more than 4 times. A total of 6 (26%) never used it (3 were unaware of the journal, 1 found it confusing, 1 did not think journaling would be helpful, and 1 did not explain why). Among those who used it, for 6 of 17, their favorite feature was writing down thoughts, and for 6 (26%), it was reading it later and noticing their progress. However, when asked about problems with the journal, 7 (30%) reported that they found journaling time-consuming, 3 (313%) reported that they struggled to put thoughts into words, and 2 (9%) reported that they were worried about privacy.

In total, 15 digital “tools” were available for parents through the Pause app. Participating parents were in 3 different parenting programs so they were supported to use different tools. The relax and praise tools were used by 10 (40%) parents each. Both the relax and praise tools were used only once by 6 parents, perhaps because they contain learnable reminders. By contrast, the time together and ignore tools were used more than twice by 7 (28%) and 6 (24%) parents, respectively, only 2 or 1 used the tool only once. Similarly, the distract module was only used by 7 (28%) overall, but 5 of those used it 4 or more times. Figure 1 shows how many parents used each tool and how many times.

XSL•FO
RenderX

Figure 1. How many parents used each tool and how many times?

RQ 3: What Are the Strengths and Limitations of Pause?

Part A: Survey Results

Surveyed parents gave 157 comments about what the "best things" about tools were and also suggested changes. Strengths of the tools included providing a good reminder and a useful distraction, children liking the tools, and creating a helpful structure. Proposed changes included requests for more examples and recommendations, more customization, and simplification. Table 2 describes representative survey results as they relate to each tool.

XSL•FO
RenderX

Table 2. Illustrative quotes of best things and suggested changes to Pause tools.

	Best thing	Suggested changes
Relax	"Daughter found it good when she started struggling she would ask for it as said it helped her" and "It created a distraction when my child's meltdown was about to escalate" [Leicestershire].	"To have more ideas" [Wiltshire].
Praise	"It helps break things down" and "reminder how important it is" [Leicestershire].	"Quite limited, with only a few options" [Wiltshire].
Time together	"It gave us time together and daughter would ask for it" and "The short timers making it easier to show them how long we have" [Leicestershire].	"To add ideas of an activity" [Leicestershire].
Reflect	"Being made aware of how you're feeling as the parent and how it can affect how we parent, it certainly makes you think about what you can do to change your mood in order to be better for your children and in supporting your children through their emotions and difficulties" [Leicestershire].	"Include 'sad' into the emotions" [Leicestershire].
Ignore	"Was a good distraction whilst trying to ignore daughter when she was saying silly/rude words" and "suggestion to distract and timer to help"; "Asks for the reason as to what the need was that caused the behaviour which needed ignoring" [Leicestershire].	"Be able to customise how to ignore not just present one" [Wiltshire].
Family chart	"Being able to set targets for her to follow, and tracking the stars" [Leicestershire].	—[a]
Distract	"Daughter really liked this one, especially if she felt like she was struggling in a situation this would give her something else to focus on and would stop a meltdown" and "Having something to use when out and about" [Leicestershire].	"Add more distract examples" and "be able to customise options" [Wiltshire].
Consequences	"Little games in natural consequences section" [Leicestershire].	"Need to remember to actually look at it. Also didn't look in the moment" [Leicestershire].
Feeling check	"Making them aware of how they're feeling at different times" [Leicestershire].	"Suggestions as to what could be making them feel that way" [Leicestershire].
Before, during, and after	"It was a good way to unpick incidents" and "Breaks it down so you can see what happens during a meltdown and what could have triggered it!" [Leicestershire].	"Option to edit which child as I posted to the wrong child and could not change" and "Be able to voice note it would make it easier to document the event" [Leicestershire].
Quick timer	"Handy and the children can see the timer" [Leicestershire].	—
Time-out	"Handy to have easily accessible" [Buckinghamshire].	"Descriptive example of how to use the option" [Wiltshire].
Bedtime praise	"Prompts" [Buckinghamshire].	—
Family guidelines	—	"Long winded" [Wiltshire].
My body	"It gives you prompts on what to discuss with your child when talking about body" [Wiltshire].	—

[a]Not available.

Part B: Interview Results

Overview

Three themes emerged from these interviews: (1) features of programs without Pause; (2) the interface between parent, child, and Pause app; and (3) the outcomes and effects of the Pause app. The themes are outlined in Table 3.

Table 3. Macro- and microlevel themes.

Macrolevel themes	Microlevel themes
Theme 1: features of programs without Pause	• Theme 1.1: what made programs effective? • Theme 1.2: what made programs difficult?
Theme 2: the interface between parent, child, and app	• Theme 2.1: how Pause was used? • Theme 2.2: interaction with the app
Theme 3: the outcomes and effects of Pause	• Theme 3.1: Pause enhances parenting programs • Theme 3.2: Pause improves behavior and enhances family life

XSL•FO
RenderX

Theme 1: Features of Programs Without Pause (Overview)

Rather than solely discussing Pause, we also explored parents' experience of the program in order to ensure that the strengths and weaknesses of programs in general were not elided with the strengths and weaknesses of Pause. We report these below to illustrate the context in which Pause is being used.

Theme 1.1: What Made Programs Effective?

Participants talked about how their groups were useful because of program content, other parents, and effective practitioners. Nine commented on the content of the program, always positively.

> *I really enjoyed it. I found out a lot of helpful information, so it was really good.* [Participant 2, parent]

The composition of the group, other parents facing similar challenges at home, also added value to the group experience for 4 parents.

> *I'm going through all the things with my child by myself. It kind of makes you feel isolated, so hearing from other parents that they're having the same or similar issues, I think that was the most helpful because it made me feel like it wasn't just me.* [Participant 1, parent]

The careful and inclusive didactic approach of practitioners was also highlighted as a key feature of what made groups useful. Three practitioners specifically mentioned the quality of the explanations.

> *they made sure everyone understood each week what we were doing and made sure by the end of it, everyone was clear of what it was.* [Participant 5, parent]

Theme 1.2: What Made Programs Difficult?

The reasons parents were attending groups also made programs difficult. Specifically, family life was already very difficult due to their children's challenges, and many demands on their time and attention could also lead to attendance problems. Four parents described the problems that had motivated them to seek help for their family, which were primarily due to externalizing behaviors such as meltdowns, anger, violence, and shouting.

> *My son is quite angry and has a lot of angry outbursts. For a long time, I thought he was just being boisterous, but when the same problems started happening at school, I realized there might be something else going on.* [Participant 1, parent]

Six participants commented on the children's neurodevelopmental differences, special educational needs, or subclinical behavior problems, as well as the challenges of long waiting lists and parents' own problems. They did not mention anxiety or low mood among their children.

> *Three out of my four (are) diagnosed autistic and ADHD. My 4 year old is ... he's on waiting lists but he's not quite being diagnosed yet, but he has got traits. I've looked back into my past and things like that and I'm now on waiting lists for an ASD and ADHD diagnosis for myself.* [Participant 6, parent]

All parents were asked about their attendance. Parents and practitioners identified that it is hard for single parents to attend, especially when they have several children with neurodevelopmental disorders, but parents also reported that events come up. Video call sessions were thought to have made it easier to attend.

> *It's rare that you'll get a parent that will attend every single week, because there may be something that's come up, you know, like, obviously, the parents are there and the children have got disabilities.* [Participant 8, practitioner]

All 3 practitioners, but no parents, also gave examples of reasons parents struggle to engage such as circumstances or demographics. For example, unwilling to change parenting style, feeling overwhelmed in groups, or requiring translation.

> *Another barrier is if parents are not willing to make changes but blame everything onto the child.* [Participant 8, practitioner]

Theme 2: The Interface Between Parent, Child, and App (Overview)

Participants reported how Pause was used, noting which people used it, where they used, and which parts of the app they used. They also commented on their experience of interacting with the app, including the user interface and the idea databases.

Theme 2.1: How Pause Was Used

Participants commented on who, where, and when Pause was used and which parts of Pause were used. Nine participants mentioned who used Pause. Pause was used by parents and children. Sometimes it was used by parents and children together, sometimes by parents without their children, and occasionally by children alone. Sometimes it was only used with 1 child, sometimes it was used with all children, and sometimes it was used by the extended family.

> *I've got two children. The oldest is nearly 15, so he wasn't really involved that much. But the youngest is 4, and it was very age-appropriate.* [Participant 1, parent]

Five participants mentioned the settings or scenarios where Pause was used. Parents used the app at relatives' houses, in shops and restaurants, and in their bedrooms alone. They used it during the day, with their children, and also at night alone.

> *It's that big time reassurance that we're going out. We've just been to my nan's and we've had meltdown after meltdown. So I said to her, do you want to do the breathing? And she said yeah, and she sat there with it for a good five minutes, like going through them all. So yeah, it's a great reassurance knowing it's just there and it's a click of a button away.* [Participant 5, parent]

Eight participants commented on specific modules. In total, 11 different modules were mentioned as particularly useful, particularly relax and distract, which were mentioned favorably by 3 parents.

XSL•FO
RenderX

> *We also used the "distract" function a lot. If something was brewing, I'd quickly check for an idea, and now I have a few ideas in my head. It's hard to think on the spot when everything is going on, so it was helpful to have ideas that worked, and it could shift their thought process for a minute.* [Participant 3, parent]

Five participants commented specifically on the function of Pause as a reminder. Parents appreciate Pause providing reminders of when and how to use evidence-based skills.

> *it's been quite helpful as, like, reminders to do things. I've always felt like I'm quite good at praise, but actually having that reminder there, because things can get quite negative quite quickly when you've got behaviors that are quite unwanted. But it's quite good as a reminder.* [Participant 7, parent]

Five participants commented on the good fit between the modules of the Pause app and the content of the parenting programs.

> *I liked, as the course was going on, you could add the modules that you were talking about.*
>
> *Or, you know, so you didn't have everything all in one go. So, as you were going on in the course, they were like, "oh, you can add this module now to your app." I liked that feature because then ... You haven't got everything in one go.* [Participant 6, parent]

Theme 2.2: Interaction With the App

Participants commented freely on the strengths and weaknesses of the user interface, offering ideas for additional features of Pause and particularly requesting additional personalized ideas added to the app.

Nine participants commented on the user interface. Overall, and in general, parents found it easy to use the app. When assigned tasks during the interview, they were almost always able to find things immediately, and all succeeded in the tasks. There were instances of bugs where text entry boxes and buttons did not display properly because the app remains in its infancy.

> *It's really easy to use. So it's fairly self-explanatory. So as you go on to it, you've got your homepage with different sections. Obviously, you can add the sections you want. And it has come in really handy.* [Participant 5, parent]

Parents engaged with the app and had suggestions about potential features that could be added to the app or ideas for improvements to the app. Seven participants offered ideas for additional features. These suggestions related to both interaction with the app and the functions of the app.

> *I wish there was a branch-off for a child version, so he could have it on his iPad. Then he would know when he's starting to feel frustrated. I've implemented a "busy bag" for him, so he might say, "Mum, I think I need 5 minutes quiet time, I'm going to take my busy bag." So maybe there could be a child version of the Pause app, where he could blow out the candles on his iPad or something like that.* [Participant 4, parent]
>
> *Is there a thing in the app where they can request help or ask questions if they're not sure about something?* [Participant 8, practitioner]

Five participants indicated that Pause was particularly useful in providing a database of ideas, which added value for parents.

> *If he's escalating, I can use the app to prompt him, like "How many colors can you name?" I've even sent him to quiet time with a task like, "Can you name as many animals as you can think of?" He's only there for 3 minutes, but it helps.* [Participant 4, parent]

Journaling is a central component of the app so parents were specifically asked about any difficulties with reflection. Several people found reflection hard despite the prompts in Pause, and there is more work to do to ensure everybody gets to reflect on their parenting using Pause.

> *It's just sometimes finding the time to go on your phone to do those things. A lot of the time, things are going on in my head, if you know what I mean, but aren't necessarily on paper or on my phone.* [Participant 7, parent]

Theme 3: The Outcomes and Effects of Pause (Overview)

Parents and practitioners reported that Pause was useful during parenting programs, and parents continued to use it after their programs had finished. Parents reported that Pause had improved their children's behavior and their family life as a whole, linking this to the convenience of using an app. They also reported improved insight into their child's behavior and their own behavior, linking this to the reflection encouraged in Pause.

Theme 3.1: Pause Enhances Parenting Programs

All participants reported that the app helped them. Describing it as "brilliant" (Participant 4, parent) or "really useful" (Participant 2, parent) and explaining that they use it "regularly" (Participant 3, parent).

> *I would say life-changing, really, because before, in a blink of an eye, she could run. And she's fast. Now she will ask for it and it will calm her. So, it has for us made it slightly better going out. Even going to a restaurant now, she will sit with it and she will get the app up and get it up herself. If she's doing the five senses one, she'll walk around the restaurant looking for different stuff and smells. So it has changed a lot for us and it has really helped.* [Participant 5, parent]

Seven participants noted that the app remains useful after the sessions have finished, including all 3 practitioners.

> *I really liked it, and I still use it now. Even though the course has finished, I still use it.* [Participant 2, parent]
>
> *Once they've done the program and they've got the app, they've got it forever. So there'd be no need to come back through the program.* [Participant 10, practitioner]

XSL•FO
RenderX

Theme 3.2: Pause Improves Behavior and Enhances Family Life

Three parents attributed improvements in their child's behavior to Pause.

> *We're out and about and then we feel it's coming, it just, I mean, it works for minutes with her. Once she starts doing it, she's like, I'm calm.* [Participant 5, parent]

> *Now, he's starting to tell me, "I feel a bit fidgety, I need to do something." It would help him take control and gain more independence in regulating himself.* [Participant 4, parent]

Four attributed improvements in their family life to Pause. Parents described how Pause improved life for the whole family, the child who was referred, plus other children and parents.

> *Having the use of the Pause app, where I've been able to take things like consequences and reward systems with me easily, rather than carrying a jar of buttons or a sticker chart—it's enabled me to put other things in place to make life a bit more manageable. Like, when I know there's going to be a meltdown, I can use techniques like "blow out your candles" to stop things before they escalate. So yeah, it's been a really, really good learning curve, and it's been brilliant to be able to apply it to all my children, not just the one who was referred.* [Participant 4, parent]

Five participants commented that the effectiveness of Pause came from it being a mobile app. Specifically, Pause is with parents in their pockets all the time wherever they need it, and parents and children enjoy the interactive nature of sharing the app.

> *They found it useful to be able to refer back to it, because obviously their mobiles are around all the time rather than have, you know, like paperwork.* [Participant 8, practitioner]

Six participants commented on the improvements in insight into children's behavior and what drives them.

> *She said, I'm so glad I've got a Pause app because I used it the whole time through halftime when I felt like I was just losing the plot. And she kept saying that she kept going back to the pause app and it really helped to support her child to know like how he was feeling and to be able to do the before, during and after so she could pick up the patterns and work out why her child was finding, I don't know, doing the particular activity or anything challenging.* [Participant 10, practitioner]

Four participants commented on how parents had also gained insights into their own behavior.

> *It's about taking a step back. We don't need to shout and yell; we can deal with it calmly. It's about making people aware of how to deal with that child and what works.* [Participant 4, parent]

Six participants suggested that reflection had improved due to the Pause app.

> *Especially when I was doing the "before, during, and after," I'd do that on my own and write it down, which I liked because it made me realize, "actually, this happened before," whereas previously, I wouldn't pay attention to that. You'd just think, "what's going on now?" But looking back, I could see it was a trigger.* [Participant 3, parent]

Discussion

Summary of the Results

This pilot study aimed to explore whether providing digital microinterventions to augment parenting programs via the Pause app was feasible. We explored (1) whether parents used Pause, (2) which tools parents used, and (3) what the strengths and weaknesses of the app were. We addressed questions (1) and (2) using a survey of parents who attended groups where Pause was offered. We addressed question (3) by combining survey data with interviews. In total, 25 of 53 (47%) parents completed postsurveys. Only 7 parents and 3 practitioners completed interviews. A total of 23 of 53 (43%) parents who completed presurveys had downloaded and used the Pause app (ie, 92% of those who completed postsurveys used the Pause app). Other than the journal, used by 17 parents, the most popular tools were the relax tool and praise tool, each used by 10 parents. The survey data revealed specific strengths and weaknesses of the tools in the Pause app. Interviews revealed the challenges existing in programs without Pause, the way Pause was used by many family members in diverse settings, and how Pause enhanced parenting programs and improved outcomes for families. Interviews also revealed specific opportunities for improving the user interface and for addressing challenges in the journaling function.

Comparison With the Literature

The main digital alternatives to parenting digital microinterventions are e-learning programs. This study has shown that Pause can offer a different approach. The key limitations of e-learning programs are "providing a 'one size fits all' program with no adaptation or tailoring to the user's state" and "lack of referrals to in-person treatment in relevant cases" [24]. The biggest studies indicate that only around 7% of referred parents complete these interventions [9]. By using Pause to enhance, rather than replace, parenting groups, we ensured that parents received the benefits of tailoring and personalization, which come from group work with a facilitator. This approach is in line with a growing body of research in digital mental health, which highlights the need for human support to ensure long-term engagement and effectiveness of digital tools [25].

In this study, we estimated that 92% of parents used the Pause app sometimes, but acknowledged that it could be as low as 43%, if none of the survey nonresponders downloaded the app. Either way, this figure is difficult to compare with e-learning style programs where sessions are concurrent and so a completion rate can be calculated [26-28]. Patchy engagement

XSL•FO
RenderX

is the norm in digital mental health interventions, and the most important factor is whether parents use evidence-based skills at the appropriate time or whether they do not. Nevertheless, the results of this study indicate that further research to evaluate the effect of the app on parent and child outcomes is appropriate.

Strengths and Limitations

This study tested Pause in a natural setting rather than a laboratory or staged parenting program; this evaluated both the practitioners' engagement with distributing Pause themselves and parents' engagement with the app within the context of the parenting program. Similarly, there were no clinical exclusion criteria so the participants were representative of parenting group attendees in the United Kingdom.

Retention was good within the context of parenting programs. We obtained postprogram surveys from 25 of 53 (47%) parents. Systematic review evidence suggests that 51% of parents disengage before or during long parenting programs such as these, so the proportion of postprogram surveys obtained is likely to represent a large proportion of retained parents [8]. Moreover, 2 parents who did not use Pause completed postprogram surveys, reassuring us that those who did not engage with the intervention were not excluded from data collection. In addition, even after inevitable attrition, the number of included parents was typical for a pilot study of a digital parenting intervention [29-32].

Finally, this paper was strengthened by the use of 4 sources of data: pre- and postprogram surveys, interviews with parents, and interviews with practitioners. These different forms of data collection allowed a rich understanding of how Pause was used within groups.

The main limitation of this study was the self-reported use data. We asked parents to refer to their app to report which "tools" they had added on the app, but it is possible that errors could be made in this process and social desirability bias could have an effect. Although our study design did not include a formal analysis of how frequently tools were used, the self-report data are in keeping with the app feedback, providing some reassurance regarding this potential limitation.

Implications for Research and Practice

Altogether, this pilot study provides preliminary evidence that Pause can be incorporated into parenting programs with positive effects for many parents and no evidence of adverse effects. These findings suggest that it is appropriate to continue honing the Pause app and exploring its short-term and long-term effects on parenting style. Future research should explore whether incorporating Pause into parenting programs leads to greater change in child behavior outcomes such as the Strengths and Difficulties Questionnaire compared with treatment as usual [17]. We used Pause alongside 3 parenting programs in this study, Triple P Primary, Family Links Nurture, and Care for the Family's Time Out for Parents. Future research should explore whether the results are the same with other programs.

In their paper, outlining the basis of digital microinterventions, Baumel et al [14] imagined a "hub" bringing together a suite of digital microinterventions. Pause provides that function for the suite of "tools" in the app. They outlined three areas for research: (1) microrandomized trials, (2) optimizing microintervention suites, and (3) understanding for whom digital microintervention care is suitable for. This paper shines light on (2) and (3) by interrogating the strengths and weaknesses of these microinterventions (allowing optimization) and revealing who uses them (at least 43% of parents who start programs in the included UK local authorities). It also provides proof of concept for augmenting parenting programs with mobile technology, similar to other research in digital mental health [33,34]. We plan to further contribute to research on microinterventions in parenting by exploring options to use microrandomized trials for engagement with Pause [35,36].

Conclusions

The Pause app can be combined with commonly used parenting programs and is well-received by parents. Parents and practitioners identified that Pause enhanced programs and could provide lasting support after programs had finished, with the potential to enhance family life and improve child behavior. Further research is required to evaluate the effect of adding Pause above and beyond treatment as usual, but results indicate that adding digital microinterventions alongside a face-to-face parenting program is a promising, feasible, and acceptable approach at least for some of the parents.

Acknowledgments

The authors would like to thank the local authority teams who supported this project.

Conflicts of Interest

The Pause app is owned by the University of Warwick, and under a division of proceeds agreement, NH and PIW would theoretically be paid from any licensing, but no licensing arrangement is currently underway. PIW is the co-inventor of the Pause Mobile App.

Abstract

Background: The postpartum period represents a critical period for both birthing and nonbirthing parents due to mental health concerns and new caregiving demands. Collaborative care models aim to address these needs, but postpartum care remains fragmented, lacking continuity and holistic support. Baby2Home (B2H) is a digital intervention rooted in the collaborative care model, specifically designed to support parents through their transition into parenthood by addressing their physical, emotional, and psychosocial needs. This intervention seeks to close the gaps left by traditional care models by providing continuous, organized, and accessible support throughout the postpartum period. In our qualitative study of the B2H intervention, we reference the parallel journeys framework and use it as a part of our analysis to evaluate whether mobile health (mHealth) technology addresses the holistic needs (postpartum and psychosocial) of new parents.

Objective: We aimed to assess how the B2H app supports the holistic needs of new parents and addresses care gaps identified in traditional postpartum services.

Methods: We conducted semistructured interviews with 20 birthing and nonbirthing parents selected through purposive sampling based on their app use. Data were analyzed using the postpartum parallel journeys framework and inductive coding.

Results: Our findings demonstrate the comprehensive impact of the B2H intervention in addressing both the physical and psychosocial needs of new parents. B2H supported postpartum care by helping parents navigate uncertainties, enhancing health care provider–parent communication, promoting self-care, and increasing parental self-efficacy. Psychosocial support included symptom identification, timely care manager assessments, coordinated treatment, and transition resources. The app also addressed care gaps by promoting inclusivity for nonbirthing parents, bridging screening and treatment, supporting real-time treatment navigation, and ensuring continuity of care.

Conclusions: We demonstrate that the use of mHealth technology such as the B2H app can effectively support the multifaceted needs of new parents during their postpartum care period. By applying the parallel journeys framework, the research also identifies gaps in care that are addressed by the B2H app, presenting unique opportunities for future development and research.

Introduction

Background

The postpartum period is a critical phase for both birthing and nonbirthing parents as they adjust to the emotional, physical, and lifestyle demands of caring for a newborn [1,2]. Postpartum depression (PPD) is incredibly common among birthing parents, with a prevalence of 10% to 15% [3], and affects about 10% of nonbirthing parents within 3 to 6 months after childbirth [4]. Existing studies on PPD typically focus on birthing parents within the first 2 months post partum. However, a Swedish study [5] extended the time frame to 25 months after childbirth and reported depressive symptoms in 11.3% of birthing parents and 4.9% of nonbirthing parents. Beyond depression, parents face anxiety and psychological distress tied to caregiving responsibilities, which can affect marital quality and parenting behaviors [6,7].

Despite growing recognition of these challenges, postpartum care remains fragmented, often split across multiple care providers, leading to communication gaps and inconsistent support [8]. The COVID-19 pandemic further highlighted the need for scalable, patient-centered care models. In response, collaborative care programs (CCPs) have emerged as a strategic approach to address these gaps in postpartum care, aiming to provide holistic support for new parents [9]. CCPs aim to foster interdisciplinary collaboration by bringing together obstetricians, pediatricians, mental health professionals (care managers [CMs] and psychiatrists) to address the diverse needs of parents and newborns [9]. Health information technologies significantly contribute to the success of these programs by enhancing communication, coordination, and engagement between health care providers and patients. To date, these technologies have primarily included clinician-facing tools [10]. Because collaborative care is a patient-centered approach that seeks to inform and empower patients for improved self-management, incorporating a patient-facing mobile health (mHealth) tool is a logical extension of the collaborative care model (CCM) [11].

Despite the potential of mHealth technology in postpartum care and CCPs, it is crucial to note that the current body of research has primarily focused on designing technologies that support patients in managing their perinatal and postpartum mental health in day-to-day contexts [12]. The key lies in a comprehensive understanding of how mHealth interventions impact the dynamics of CCPs and the extent to which they contribute to the overall success of these programs [13].

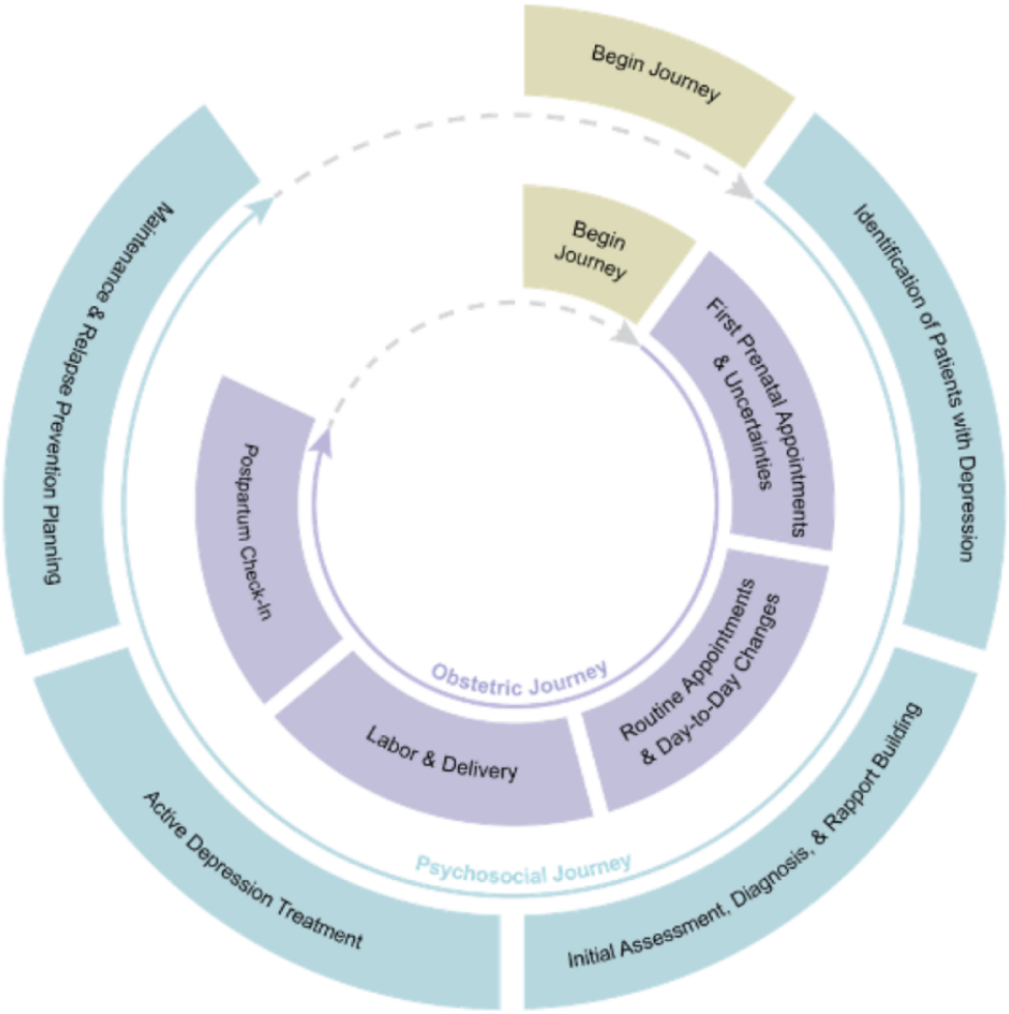
Embracing a Holistic Approach: Our Rationale for Developing the Baby2Home Intervention and the Need for Qualitative Inquiry

Previous studies on technology in CCPs have mainly addressed specific aspects of the postpartum experience. Some focused on mobile technologies delivering educational resources to birthing parents [14,15], while others designed interventions targeting their mental health [16-18]. Research also emphasizes that birthing parents' support needs evolve throughout pregnancy and parenthood [19,20]. However, these studies often overlook integrated solutions that address the full postpartum care journey, leaving gaps in how parental mental health, infant care, and overall well-being intersect. In addition, most interventions prioritize birthing parents, often neglecting the significant role of nonbirthing parents in postpartum care [21]. The lack of inclusive, comprehensive programs limits support for families and hinders optimal outcomes for both caregivers and infants [22].

To address this gap, we developed Baby2Home (B2H), an mHealth intervention, based on the CCM, designed to support families holistically by meeting both physical and psychosocial postpartum needs. Unlike existing studies that focus on isolated interventions, B2H is designed to encapsulate the full spectrum of postpartum care for both birthing and nonbirthing parents.

Understanding how such an intervention fits into the broader care experience requires a qualitative approach. A qualitative study enables a deeper exploration of parents' lived experiences, especially around how mHealth technologies influence emotional well-being, engagement with care teams, and adaptation to caregiving roles—dimensions that are not easily captured through quantitative measures.

To guide this inquiry, we applied the parallel journeys framework (PJF). Unlike most frameworks that are primarily designed for health care practitioners, the PJF is distinctive in offering a comprehensive perspective that encompasses the entire postpartum experience from the parent's point of view. This framework uniquely integrates all facets of the postpartum journey, ensuring that the physical and psychosocial needs of parents are thoroughly addressed.



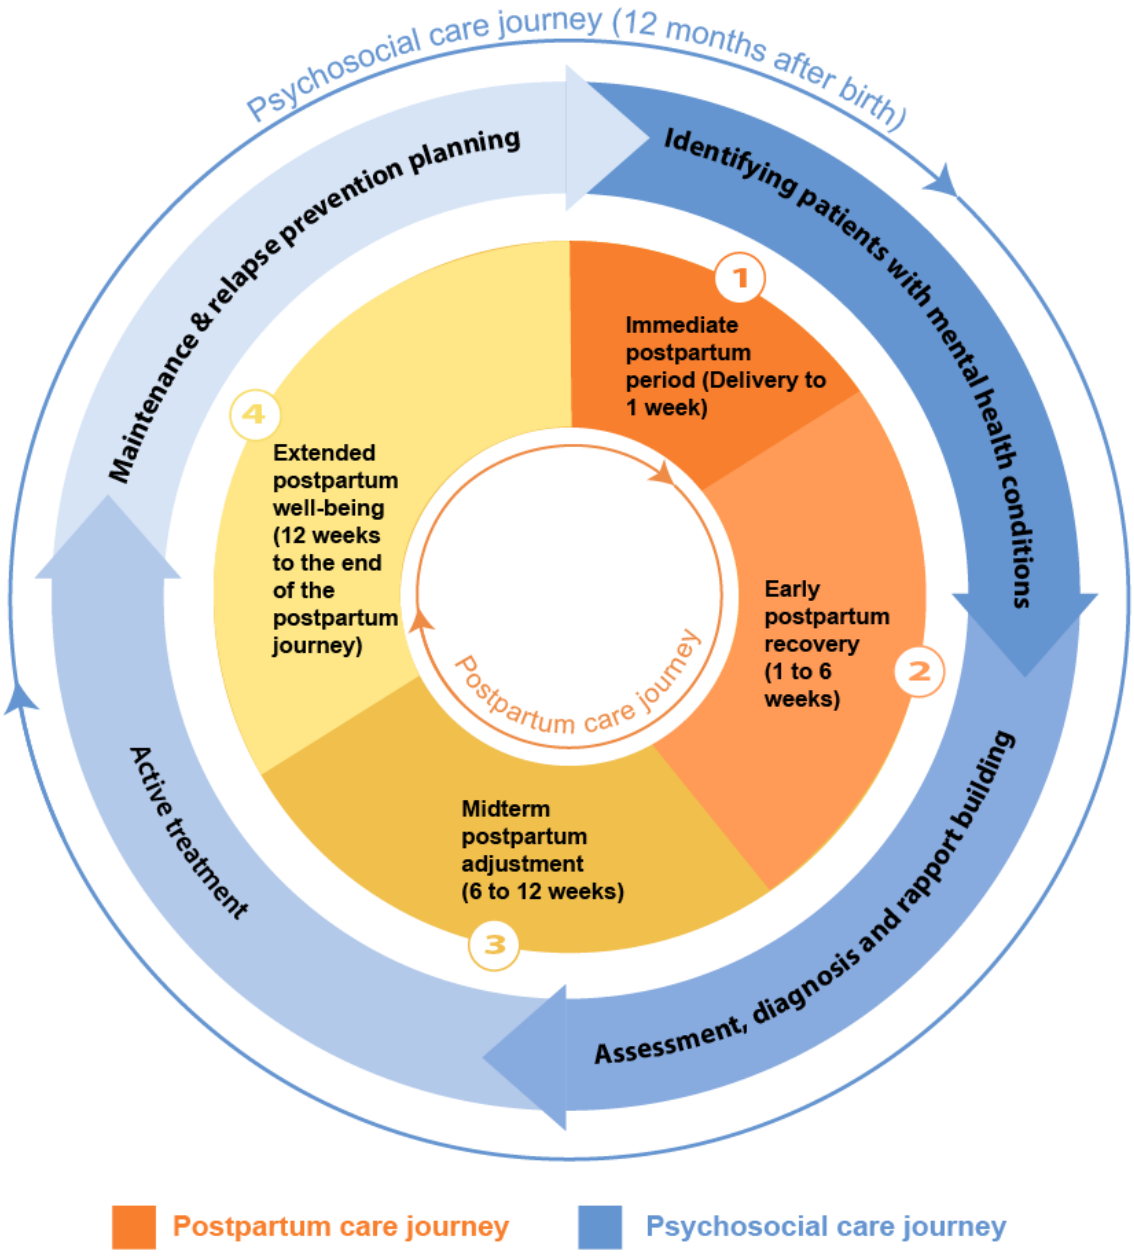
The PJF

Overview

The PJF, conceived by Suh et al [23], offers a lens through which the concurrent and intertwined paths of 2 distinct health care journeys can be examined, especially within collaborative care. Originally developed for collaborative cancer care, this framework sheds light on the intersecting challenges of psychosocial and cancer care journeys. Haldar et al [12] later adapted this framework for perinatal CCPs to delineate the challenges parents face at the intersection of obstetric care and psychosocial care journeys (Figure 1 [12]).

XSL•FO
RenderX

Figure 1. Expansion by Haldar et al [12] of the parallel journeys framework for perinatal care, representing cyclical journeys in obstetric care and psychosocial care.



In our study, we have modified the PJF to develop the postpartum PJF (PPJF) (Figure 2) to address the specific needs of postpartum care, which was not emphasized in the framework used by Haldar et al [12]. This adaptation was guided by a theory-driven process, drawing on the structural design by Suh et al [23] and Haldar et al [12] while integrating empirical data from our qualitative interviews. Specifically, each phase of the postpartum and psychosocial care journeys was refined through an iterative coding process informed by participant narratives and validated against existing literature. Feedback from CMs and behavioral health care providers (BHPs; therapists, counselors, and psychiatrists) in perinatal mental health and collaborative care further informed the refinement of stages to ensure clinical and experiential relevance.

The resulting PPJF captures the multifaceted progression of postpartum and psychosocial care by outlining distinct stages of transition, each marked by specific parent needs and challenges. This expanded framework offers a more holistic perspective on postpartum care and serves as the foundation for analyzing how digital interventions, specifically the B2H app, support the evolving needs of both birthing and nonbirthing parents during this critical period.

XSL•FO
RenderX

Figure 2. Our expansion of the parallel journeys framework highlighting the phases of postpartum care and psychosocial care.

Phases in the Postpartum Care Journey

The PPJF delineates the postpartum care journey into 4 phases, each marked by unique challenges, needs, and transitions. These phases are derived from both the interview data and relevant literature, framing the comprehensive journey from immediate postdelivery care to long-term postpartum adjustment.

Immediate Postpartum Care and Transitioning Home (Delivery to 1 Week)

This phase is also known as the initial or acute period, which refers to the time following childbirth and the first few days post partum [24]. The immediate postpartum care phase is characterized by care provided to birthing parents and newborns within 24 hours after delivery. During this time, health care providers closely monitor birthing parents and infants for potential complications and offer support for breastfeeding initiation, bonding, and emotional well-being [25]. The health care team assesses uterine involution, monitors vital signs, addresses any postpartum discomfort or complications, and provides guidance on postpartum care, such as proper hygiene, pain management, and contraception options [26]. Regarding the care provided to the newborn, the postnatal check involves evaluating vital signs, conducting a physical examination, and assessing feeding patterns and weight. Health care providers offer guidance on newborn care, including feeding techniques, diapering, and safe sleep practices [26].

Transitioning home from the hospital marks a significant shift as the family assumes greater responsibility for caring for the newborn. This period involves adapting to the challenges of

XSL•FO
RenderX

parenthood, establishing feeding routines, and managing the physical and emotional changes that accompany childbirth [27]. Overall, the immediate postpartum period and transition home represent a dynamic and emotionally charged time, wherein the integration of medical care, emotional support, and practical guidance sets the foundation for a healthy start to the new family's journey.

Early Postpartum Recovery (2 to 6 Weeks)

The early postpartum recovery phase, also referred to as the subacute postpartum period, spans the first 6 weeks after childbirth and encompasses the initial weeks of physical and emotional adjustment for new birthing parents [24]. Physically, this phase involves the body's gradual recovery from the demands of childbirth. Birthing parents may experience uterine contractions, vaginal healing, and hormonal fluctuations during this time [24]. Emotionally, the postpartum period can bring about a range of feelings, from joy to potential mood fluctuations. In this context, the preparation for the first postpartum visit gains significance.

The first postpartum visit marks an important phase in the continuum of care for both the birthing parent and the newborn. Typically occurring within the first 2 to 4 weeks postpartum, this visit acts as a pivotal touchpoint for health care providers to assess the physical and emotional well-being of the birthing parent [24]. During this phase, the obstetric care provider conducts a physical examination and administers mental health symptom screening to assess health concerns that might have emerged during delivery [10]. The physical examination includes a pelvic examination and checking the birthing parent's blood pressure, weight, and temperature. In case of a vaginal tear or c-section incision, the obstetrician checks to ensure that the stitches are healing [28]. A breast examination is also conducted to assess for engorgement or any changes that can occur with breastfeeding and pumping [29]. As part of the mental assessment, the obstetric care provider uses a paper-based screening tool to assess the risk for PPD. By addressing the physical and emotional aspects of postpartum recovery, the first postnatal visit lays the foundation for ongoing support, promoting the well-being of both birthing parents and the infant.

Midterm Postpartum Adjustment (6 to 12 Weeks)

The midterm postpartum phase, spanning from 6 to 12 weeks after childbirth, is a pivotal period for new parents as they further adapt to the responsibilities of parenthood. This phase is characterized by continued physical recovery from childbirth and deeper emotional adjustments as parents settle into their new roles [30]. During this time, the initial intensity of postpartum recovery begins to wane, and parents may start to feel more physically comfortable [26]. However, this period also brings its own set of challenges and adjustments. Physical recovery may still be underway, with some women experiencing lingering postpartum symptoms, such as pelvic floor issues, hormonal changes, and fatigue [31]. Emotionally, this period can be intense, with new parents grappling with feelings of anxiety, and in some cases, signs of postpartum mood or anxiety disorders [3]. While parents may start to feel more confident in their caregiving abilities, the reality of ongoing sleep deprivation, hormonal adjustments, and the challenges of balancing personal and professional responsibilities can contribute to feelings of fatigue.

As parents approach the end of the midterm postpartum phase, a comprehensive postpartum checkup is recommended [32]. This comprehensive evaluation aims to provide a detailed review of the birthing parent's physical, emotional, and psychosocial health, covering critical areas, such as emotional well-being, care and feeding of the infant, sexual health, contraception, and planning for future pregnancies, as well as management of sleep, fatigue, physical recovery, chronic conditions, and overall health maintenance. For most patients, the comprehensive postpartum appointment is their final touchpoint with their obstetric care provider.

Extended Postpartum Well-Being and Long-Term Adjustment: (3 Months and Beyond)

The extended postpartum well-being phase, also known as the delayed postpartum period, emphasizes a comprehensive and ongoing approach to health for both the birthing parent and infant [24]. As this phase unfolds, the needs of parents evolve while they adapt to more settled routines and face the sustained elements of postpartum care.

Birthing parents experience a multifaceted mix of physical and emotional adjustments during this stage, especially as they transition back to work or adjust to their partners doing so. Physical recovery from childbirth may still be underway, with women navigating changes in skin and hair, hormonal fluctuations that can impact mood and physical well-being, the gradual return of menstruation, and efforts toward weight management [33]. Changes during this phase are extremely gradual. Although change is subtle during this phase, it is important to remember that a birthing parent's body is not fully restored to its prepregnant state until about 6 months after delivery.

Furthermore, the challenges of balancing professional responsibilities with the demands of parenthood and the added stress of securing suitable daycare arrangements can further contribute to elevated stress levels. This period marks a critical juncture where ongoing monitoring of mental health becomes essential as parents navigate through the complexities of returning to work and maintaining the well-being of their expanding family.

Phases in the Psychosocial Care Journey

For new parents, psychosocial well-being encompasses a broad range of factors that contribute to mental, emotional, and social health. Here is a detailed overview of how the psychosocial care journey unfolds within the context of postpartum care.

Identification of Patients With Mental Health Conditions

This phase acknowledges that while it is common for new parents to experience a broad range of emotions, such as periods of sadness, known colloquially as "baby blues," there's a crucial distinction to be made when these feelings persist or intensify, potentially indicating PPD, a more serious condition [32]. Typically occurring at the 2- to 4-week mark, this phase represents a birthing parent's first postpartum encounter with their obstetrician. During this initial postpartum visit, the

XSL•FO
RenderX

obstetric care provider uses standardized paper-based measures, such as the Edinburgh Postnatal Depression Scale [34] or the Patient Health Questionnaire [35], to screen patients for symptoms of PPD. If a parent exhibits symptoms or has a known history of mental health issues, the health care provider introduces CCM as a valuable resource. The health care provider discusses the potential benefits of connecting with CCP and gauges the patient's interest in a referral. However, it is important to note that most perinatal care offices do not have a CCM available on-site and often refer parents to external mental health support.

The significance of this stage lies in its emphasis on timely intervention and the establishment of a supportive care environment that prioritizes mental health. Early identification allows for the timely implementation of support systems and interventions helps promote the overall well-being of both the parent and the newborn [36].

Initial Psychosocial Assessment, Diagnosis, and Rapport Building

Following the detection of symptoms of PPD, birthing parents who screen positive and have a clinical assessment congruent with PPD are referred to a BHP by their obstetric care providers. This process is designed to gather detailed information about the patient's symptom severity. The BHP conducts a thorough psychosocial assessment using standardized tools to establish baseline symptom severity (eg, 9-item Patient Health Questionnaire [PHQ-9] and 7-item Generalized Anxiety Disorder [GAD-7]) [35,37]. In addition to these quantitative measures, the BHP also dives deeper into the patient's personal history, gathering information on a range of factors that could influence their mental health. This includes exploring the patient's family and medical history, which can reveal genetic predispositions or health conditions that may impact mental well-being [38]. Psychiatric and substance use history is also reviewed, as previous or current issues can significantly affect treatment planning and outcomes. In addition, understanding the patient's financial background and social support systems is crucial, as financial stressors and isolation can exacerbate mental health problems [38]. However, it is important to note that despite the critical importance of the referrals provided by the obstetrician, recent data suggest that fewer than 1 in 10 people referred to BHP actually engage with behavioral health services. While an obstetrician may refer a patient to a BHP, this transition often does not occur as intended. Patients frequently face challenges navigating the process, such as identifying the right contact, scheduling an appointment, finding health care providers who accept their insurance, and securing timely appointments close to home. This represents a significant barrier and highlights a substantial gap in the current health care system.

This phase sets the stage for a personalized treatment approach, which is essential for successful outcomes in mental health care. The assessment conducted by the BHP ensures that the subsequent steps in the treatment process are based on a solid understanding of the patient's psychosocial context, facilitating targeted interventions and individualized care plans.

Active Depression Treatment

The active treatment phase for PPD involves a targeted and evidence-based approach [23]. The treatment plan administered during this phase is highly individualized, considering the patient's unique circumstances, preferences, and needs to ensure personalized care [36]. In most clinical settings, when a birthing parent screens positive for depression during their 6-week postpartum visit, the obstetrician prescribes medication. If the patient is receiving mental health care, such as therapy, the clinician will monitor their progress and intervene as necessary. In some instances, insurance providers employ care coordinators who contact postpartum parents at some point after birth to assess for PPD and connect them to appropriate support services.

In the context of PPD, active treatment may involve various therapeutic approaches, including supportive counseling, psychotherapy, and medication management. For parents experiencing mild to moderate depression, psychological interventions, such as cognitive behavioral therapy or interpersonal therapy, are recommended [33]. These therapies aim to enhance coping strategies, address interpersonal issues, and modify negative thought patterns that contribute to depressive symptoms. For those with moderate to severe depression, a combination of psychotherapy and antidepressant medications may be advised [39]. Medications are chosen with care, considering the patient's breastfeeding status and personal preferences to ensure both safety and effectiveness.

The goal of the active depression treatment phase is not only to reduce symptoms of depression but also to empower parents to manage mental health effectively. This process is dynamic and responsive, characterized by a collaborative partnership between the patient and their health care team. Such an approach ensures that treatment aligns with the patient's recovery goals and adapts to their changing needs, ultimately paving the way for a successful recovery from PPD.

Maintenance and Relapse Prevention Planning

The final phase of the psychosocial care journey plays a crucial role in sustaining the well-being of new parents after active treatment has concluded [39]. This phase is designed to equip patients with the resources needed to maintain their mental health and prevent the recurrence of depressive episodes. It acknowledges the reality that the journey through PPD is not solely about overcoming the immediate symptoms but also about building a resilient foundation for long-term mental health [40].

In this phase, BHPs work closely with parents to develop a comprehensive maintenance plan (eg, identifying early warning signs or establishing effective coping strategies) that addresses each individual's unique needs and circumstances [23]. Ideally, postpartum care should extend up to 1 year after birth, as postpartum-related mental health symptoms can often persist throughout this period [12]. However, most clinical settings lack CCMs, with obstetric care typically concluding within 6 to 8 weeks post partum, leaving a gap in ongoing support. Toward the end of obstetric care, BHPs proactively engage with individuals to discuss the end point of their program involvement. In cases where additional support is needed, BHPs

XSL•FO
RenderX

provide external referrals, ensuring that patients can access longer-term therapy or treatment in locations convenient to them [39]. BHPs also encourage parents to engage in self-care practices, such as regular physical activity, healthy eating, and mindfulness exercises, which can contribute to overall well-being and resilience.

In conclusion, the fourth phase helps secure the progress made during the active treatment of PPD and lays the groundwork for sustained mental health. It represents a transition from intensive care to a more self-directed approach, with continued professional support tailored to prevent relapses and promote long-term recovery. Although perinatal care concludes at the 1-year postpartum mark, a patient's mental health treatment may continue beyond this end point outside the postpartum context.

The B2H Intervention

B2H is an mHealth intervention built on the CCM designed to support families during their transition to parenthood. Upon being allocated to the intervention arm, families are introduced to the B2H services through a mandatory download and use of the B2H smartphone app, compatible with both iOS and Android platforms. The app incorporates features designed to support both parent wellness and infant care. These features cover essential postnatal care practices, including, but not limited to, tracking mechanisms for feeding, sleeping patterns, growth milestones, diaper changes, and vaccination schedules. Moreover, the app engages parents with educational content on infant developmental milestones, conducts monthly mental health assessments, and supports adherence to preventive health care schedules for both the parents and their newborns.

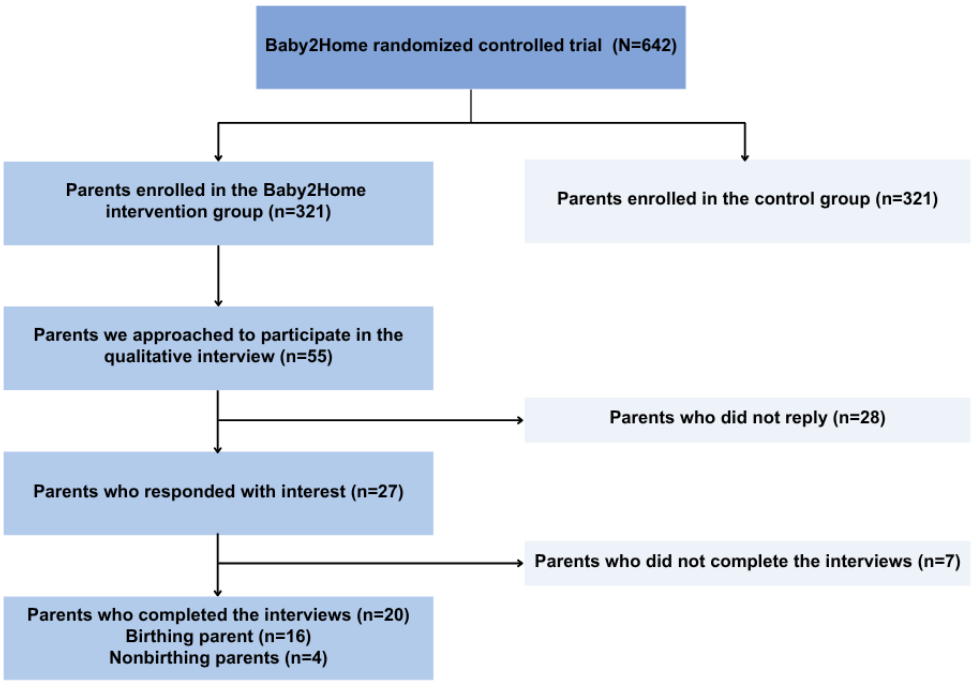
The B2H intervention is structured to offer a holistic suite of services aimed at reinforcing the well-being of both parents and infants (Multimedia Appendix 1 [41]). If a parent screens positive for moderate stress (eg, a Perceived Stress Scale [PSS] score of 14-26), the CM reaches out to the parent via chat to assess the parent's stress situation and recommends stress management resources, such as the Stress Management and Resiliency Training module, that teaches self-care practices to manage daily stress and regain a sense of emotional control. If severe stress is identified (eg, PSS≥27), the CM contacts the parent directly to assess the source of stress and provides psychoeducation on stress management techniques.

On the other hand, if a parent screens positive for depression or anxiety (PHQ-9≥10; GAD-7≥10), the CM will contact the patient to facilitate a clinical assessment and initial treatment planning. For individuals who desire psychotherapy, brief behavioral care (8 sessions of behavioral activation) will be initiated, led by the CM via phone. For individuals who desire pharmacotherapy, the CM will refer the participant to a primary care physician or a psychiatrist, with the decision regarding the type of referral informed by the clinical context.

If the assessment scores indicate a level of concern, the CM consults with a clinical psychologist to discuss recommendations for supporting the patient in accessing the appropriate care. This may involve assisting the parents in developing a safety plan and connecting them with the necessary behavioral health services. In more severe cases, this could include contacting the OB or an emergency contact if needed. Once the recommendations are agreed upon, the CM follows up with the parent to ensure that the proposed plan is acceptable and discusses next steps. Through this personalized and supportive approach, B2H aims to enhance the user experience, providing guidance and resources to ensure the parent receives the care they need throughout their postpartum journey.

Methods

Study Design



This research is carried out in parallel with a National Institutes of Health–funded (grant #1R01HD105499-01) randomized controlled trial (RCT; NCT05595486) [42] that attempts to investigate the efficacy of mHealth apps (in particular B2H) on preventive health care use for the family unit and patient-reported outcomes trajectories with a focus on mental health. As part of the RCT, 642 diverse families have been randomly assigned to either usual care or the innovative B2H intervention to evaluate the efficacy of B2H health services use and patient-reported outcomes.

This paper, while part of a larger study, specifically focuses on the intervention group. In this group, families (n=321) received the specialized services offered by the B2H app (see Figure 3). In this qualitative study, we aimed to explore the engagement and experiences of both birthing and nonbirthing parents within the intervention group as they interact with the B2H app.

Importantly, this qualitative component offers critical context to the broader findings of the RCT by helping to explain potential mechanisms behind intervention efficacy. While the RCT will evaluate user engagement quantitatively through backend app analytics and assess perceived app efficacy using the User Version of the Mobile Application Rating Scale, this study provides insight into the "why" behind the use patterns, such as the multifaceted needs of new parents during the postpartum period and how these evolving needs influence app engagement. These qualitative findings help contextualize quantitative trends in use, satisfaction, and outcomes, offering actionable design recommendations to enhance intervention effectiveness and inform future iterations of the B2H app.

XSL•FO
RenderX

Figure 3. Flow diagram of the qualitative study participants in the intervention group.

Participant Recruitment and Interviews

A purposive sampling technique was used to select a diverse group of participants from the B2H intervention arm, specifically targeting parents in the 4- to 8-month postpartum period with varying levels of app engagement, categorized based on cumulative time spent on the app. App use was calculated by taking the average of the total number of sessions (number of times the app was opened) and dividing it by the number of participants in the intervention group. Participants were then classified into 2 groups: those with fewer than 175 total sessions were categorized as low use and those with more than 175 sessions as high use (Multimedia Appendix 2). However, it is essential to note that some individuals classified as low app use users demonstrated substantial engagement in specific features of the app, including baby tracking, chat functionality, content consumption, and participation in mental health assessments.

Semistructured interviews facilitated the collection of detailed narratives concerning the participants' use of the B2H app and its impact on their postpartum experience. These interviews, lasting between 45 and 60 minutes, were conducted by the first author via videoconferencing software (Zoom Communications Inc). The semistructured interview schedule was developed by the research team and informed by the objectives of the larger RCT, as well as existing literature on postpartum care, digital health engagement, and CCMs. The interview questions (Multimedia Appendix 3) sought to uncover patterns of app use; impacts on health care accessibility; engagement with the app's specific features (eg, baby tracking, mental health assessments, and educational resources); perceived impacts on postpartum experiences; and areas for improvement. To ensure clarity and relevance, the guide was pilot-tested with 2 participants and refined based on team discussion and feedback from early interviews.

The recruitment process involved systematically disseminating email invitations and providing potential participants with comprehensive details about the study, including its objectives, procedures, and potential benefits. A notable proportion of parents who were initially contacted did not respond, as many of them had recently returned to work and reported difficulty balancing work responsibilities with the demands of caring for a newborn, making it challenging to find time for an interview. In some cases, parents expressed interest but ultimately could not commit due to time constraints. To mitigate this, we followed up with additional emails and initiated phone calls to encourage participation. This iterative recruitment strategy aimed to maximize participant involvement and ensure the diversity of perspectives within the study cohort.

Sample Size and Data Saturation

A subset of 20 parents, exhibiting both low and high app use based on the cumulative time spent on the B2H app in the 4- to 8-month postpartum period, consented to participate in the semistructured qualitative interviews. The participants selected for qualitative interviews exhibited a diverse range of demographic characteristics. The demographic composition included 15% (3/20) of the participants identifying as Hispanic or Latinx, 10% (2/20) as Black or African American, and 75% (15/20) as European or White. Notably, the study cohort reported various postpartum challenges, such as neonatal intensive care unit admissions, PPD, preeclampsia, a fourth-degree tear during childbirth, and previous complications such as miscarriage. A subset of participants (7/20, 35%) had a history of managing one or more pre-existing mental health conditions, including depression, anxiety, bipolar disorder, and attention deficit hyperactivity disorder, before giving birth. These diverse characteristics enrich the qualitative exploration of the B2H app's impact on postpartum care experiences within this unique participant cohort.

XSL•FO
RenderX

Data saturation was reached during the interview process. This was determined when no new themes or patterns emerged from the data, and additional interviews yielded redundancy in responses. The research team monitored for saturation iteratively, and once the analysis of the last few transcripts confirmed that further interviews were unlikely to generate new insights, data collection was concluded.

Data Analysis

We adopted a mixed methodology for our data analysis. The PPJF was used as a guiding lens to organize and interpret our analyses. The phases of the PPJF were first created, after which we adopted an inductive, open-coding methodology for our data analysis. A total of 21 codes were generated, and the identified themes were subsequently organized into different phases of postpartum care and psychosocial care. This process involved multiple team members to ensure a comprehensive and reliable coding framework. The research team applied the coding framework to all transcripts using qualitative data analysis software (ATLAS.ti; Lumivero, LLC). At least 2 team members coded each transcript to ensure reliability and consistency in coding. Any discrepancies or disagreements in coding were resolved through discussion and consensus among team members.

Following the completion of the data analysis, the PPJF was used to organize and interpret the results. Gaps identified in each phase were noted and informed by the qualitative codes generated during the analysis. We also made modifications to the framework proposed by Haldar et al [12] to better align it with the intricacies of the postpartum experience, offering a deeper, more nuanced perspective on the participants' experiences and the role of mHealth technology in navigating the complexities of collaborative care settings.

Rigor and Trustworthiness

To strengthen the trustworthiness of our qualitative findings, we incorporated several strategies throughout the data collection and analysis process by adhering to the guidelines proposed by Lincoln and Guba, as reported in the study by Thomas [43]. Credibility was ensured through triangulation, involving multiple coders who independently analyzed transcripts and resolved discrepancies through discussion and consensus. This meticulous approach ensured that various perspectives were considered, enhancing the reliability and validity of the data analysis. Dependability was enhanced by maintaining a detailed audit trail of coding decisions, analytic memos, and theme development. Confirmability was supported through regular debriefings among the research team to reflect on biases and maintain analytic neutrality. Finally, transferability was addressed by providing rich descriptions of the study's themes and supporting them with direct quotes, all of which helped to support the validity of our analysis and contribute to the study's trustworthiness.

Ethical Considerations

The research protocol adhered to the ethical standards set forth by the institutional review board of DePaul University (research protocol #RB-2024-1203), ensuring compliance with the established guidelines. Informed consent was obtained from all study participants prior to data collection, and participation was voluntary. To safeguard participant privacy, all identifying information was removed, and data were deidentified before analysis. To acknowledge participants' time and effort, compensation was provided in the form of $50 for participation in the interviews, along with additional payments for completion of assessments: $20 for the baseline, 1-month, 2-month, 4-month, and 6-month assessments, and $30 for the 12-month assessment.

Results

To provide a comprehensive analysis of the B2H app's impact, our findings are organized into 2 main areas: postpartum care outcomes (see Figure 4) and psychosocial care outcomes (see Figure 5). This structure not only highlights the multifaceted role of the app in addressing the diverse needs of new parents but also underscores the potential of mHealth technology to bridge gaps in traditional care practices.

Parent-Reported Outcomes Indicating App Support During the Postpartum Care Journey

Theme 1: Helping Parents Navigate Uncertainties During the Immediate Postpartum Phase

Parents in the intervention group reported that the educational articles and the baby tracking features in the B2H app played an essential role in guiding new parents through the multifaceted challenges of this period. Birthing parents, in particular, found solace in the app's extensive library of educational content aimed at easing the transition after childbirth.

One parent explained as follows:

> *5 months into postpartum, I definitely feel better mostly, because I have had a lot of time to just read articles on self-care and de-stressing. As a new parent you tend to prepare a lot for everything surrounding baby care. Everyone tells you that you need this or that but no one really tells you how you're gonna be. I don't think you could really prepare for how you will be doing mentally after giving birth. B2H has been helpful in assisting me navigate those uncharted waters in those earlier weeks.* [P7; birthing parent; low app use]

Other parents reported that the targeted educational content provided within the app on postpartum discomfort and recovery offers essential support for new parents during the critical initial weeks following childbirth. These resources were especially valuable for parents who were uncertain about the postpartum health conditions they could encounter.

One parent reflected as follows:

> *I read the article on B2H about the signs and symptoms of preeclampsia and how you can get it up to six weeks postpartum. And guess what, I had six of the seven symptoms that were listed in that article. This prompted me to call my physician and I went in for an appointment that day, ended up being admitted and was on a magnesium drip for 24 hours. It was pure hell! But that article really helped me solidify that yes, I am definitely not going crazy and this isn't just postpartum psychosis, which I was feeling at that point. I was valid in my reasoning and needed to ask for help.* [P10; birthing parent; low app use]

In the realm of newborn care, parents reported a heightened reliance on the B2H app's baby tracking feature within the app during the initial weeks following childbirth. This heightened engagement with the app can be attributed to the myriad changes and challenges associated with the transition to parenthood.

One participant shared their experience, stating the following:

> *Our daughter was born a little underweight than most babies, and the immediate concern for us was feeding. Just because it was difficult in the hospital, to get her to latch. Being new parents, the scariest thing in the world is the thought that maybe you're doing something that might not be leading to the right type of nourishment. To be able to get some answers on the app on what's normal as far as breast milk production, which is what the article covered, was very useful. The app was helpful to keep track of the feedings and have a timestamp of when you last fed so that you can make sure that you're staying on a feeding schedule.* [P2; nonbirthing parent; high app use]

Another parent reflected on their breastfeeding challenges and the role that B2H played in supporting them:

> *As a new parent, you tend to question every decision made and often underestimate mom guilt. Breastfeeding was not the easiest thing in the world at the start. The article from September 28th, regarding breast milk regulation, which I was able to discuss with my wife, was very useful. To be able to get some answers on what's normal as far as breast milk production which is what the article covered was really helpful. It gave me the confidence to manage breastfeeding on my own terms without going through the hassle of finding and contacting a lactation consultant.* [P20; birthing parent; high app use]

Theme 2: Enhancing Communication and Collaboration With Health Care Providers and Partners During the Postpartum Recovery Phase

The early postpartum recovery phase spans the first 6 weeks after childbirth, encompassing the initial weeks of physical and emotional adjustment for new parents. During this phase, most participants reported an increased engagement and reliance on the baby tracking feature and the library of evidence-based resources on postpartum care and newborn health. According to the feedback provided by the parents, the educational articles and the tracking features served as a key preparatory step for their upcoming postpartum visit and well-child checkup.

In the days leading up to the postpartum visits and the well-child visit, the parents described how the app acted as a valuable preparatory tool, ensuring that they felt confident in discussing their own progress with the obstetricians during the postpartum visit and their newborn's progress during the well-child visit.

One parent reported the following:

> *I do love that there's an option for tracking and added notation. We were able to have a well laid out list or any notes that we had about certain things. This made it easy for me to give detailed responses to the obstetrician's questions about breastfeeding, latching, or ask the pediatrician any specific questions about our baby.* [P1; birthing parent; low app use]

Another parent explained as follows:

> *I struggled for the longest to remember every single thing associated with baby care such as time spent breastfeeding, diapers changed etc. Having to remember all these small details got me stressed out even more. The articles on the app helped shed light on our baby's nutrition. I am now more aware of my baby milestones and what to expect specifically in terms of growth. I see a dip in his weight and the app*

XSL•FO
RenderX

> *helps alert me and allows me to reach out to the pediatrician and get the help needed. This helps reduce any anxieties or uncertainties. Just seeing my baby's weight and height increase on the growth chart within the app gives me this sense of relief because at one point my baby did lose weight which was concerning.* [P6; birthing parent; high app use]

In addition to improving communication with health care providers, birthing parents also mentioned how the app enhanced communication and collaboration with their partners during the early postpartum recovery phase. Birthing parents recovering from the physical demands of childbirth emphasized their reliance on the baby tracking feature as a means of distributing caregiving responsibilities effectively. This feature allowed them to share the workload and ensure that both parents were equally involved in the care of their newborn, fostering a more balanced and supportive environment during this critical period.

One participant recounted as follows:

> *B2H really helps take out all the guesswork in parenting. Before having our baby, my husband and I were actually looking for apps that we could both use simultaneously to input the baby's information. There were other apps that we downloaded but I could only see my entries and my husband couldn't see how many times I had fed the baby or how many times the diapers had been changed or when she last slept. With the B2H app we could see each other's entries which allowed us to be on the same page. We would take turns feeding and used the app as a reference tool to track when the baby was last fed and how much the baby had eaten. I was able to look at the app and say that the baby ate half an hour ago, and my partner would get the bottle prepared when she was ready to eat again within the next 30 minutes.* [P9; birthing parent; high app use]

Theme 3: Facilitating Midterm Postpartum Adjustment by Promoting Self-Care Practices

Parents progressing through the midterm postpartum period reported a noticeable shift in their app use behavior, with a growing reliance on educational content within the B2H app. According to their feedback, this evolution reflects their increasing comfort and confidence in addressing their baby's basic needs, prompting a broader exploration of topics, such as self-care, postpartum well-being, hormonal adjustments, and fatigue management strategies.

One parent reported the following:

> *The baby tracking feature was useful during those initial checkups, allowing me to answer very specific questions about the frequency of feeding and diaper changes. However, in subsequent checkups, I noticed a decrease in the request for such information. Initially, my primary concern centered around my baby's weight, leading to extensive use of the baby tracking feature. However, during subsequent visits, the pediatrician gave me some confidence by saying that as long as my baby stays on her weight curve, there is no reason to be concerned and we can now start feeding on demand. This allowed me to move away from being metric centered and take some time and prioritize my own wellbeing.* [P8; birthing parent; low app use]

As parents become more adept in recognizing their baby's cues and patterns, their transition from heavy use of tracking features to increased focus on educational content signifies a positive evolution in their parenting journey. This shift in app use reflects a natural progression from the intensive tracking required in the immediate postpartum period to a more holistic approach that encompasses a broader understanding of self-care and infant care. Birthing parents, in particular, mentioned how the app addressed this need by providing them with a rich repository of evidence-based information and resources, including articles and educational resources that guide physical recovery, hormonal balance, and improved rest and energy.

One parent shared the following:

> *As new parents, your needs are constantly changing almost every other month. In my case, the need for documentation and tracking was a lot higher during those earlier weeks, gradually transitioning as time passed. I really enjoyed the articles on postpartum recovery. I thought that they were incredibly helpful and gave me some useful tips to manage my fatigue and adjust to the hormonal changes. This made me feel more in control of my recovery and less overwhelmed.* [P12; birthing parent; high app use]

Another parent emphasized how the app supported their self-care routine:

> *The educational content surrounding self care was great. After you have a baby you forget about yourself. Having that content is a nice reminder to check in on yourself. I feel like it gave me a second to breathe and understand what I should be doing. It gave me a different perspective and resources on things to do. I needed to hear that from an outside source, especially when I was having a really bad day. The content made me feel like it was okay to leave my baby in the crib if I needed to. It gave me different avenues to alleviate my stress and know that this stress is just temporary and it will pass.* [P10; birthing parent; low app use]

As parents approach the end of the midterm postpartum phase, a comprehensive postpartum checkup is recommended. This evaluation aims to provide a detailed review of the birthing parent's physical, emotional, and psychosocial health. Birthing parents who attended their comprehensive postpartum checkup reported ways in which the app helped them prepare for this critical consultation:

> *The app allows for the tracking of physical symptoms, emotional states, and key milestones, all of which are useful when talking to my provider. B2H does a good job providing parents with checklists and question prompts which in my case helped me articulate concerns and queries regarding self care and coping*

XSL•FO
RenderX

> *with any lingering postpartum challenges. In a way it helped me have a thorough and productive checkup.* [P16; birthing parent; high app use]

On the other hand, parents who failed to attend their comprehensive postpartum visit mentioned how the educational articles within the app effectively covered any critical areas they might have missed during the comprehensive visit.

One parent remarked as follows:

> *I attended my first postpartum visit and was scheduled for a follow up visit which I ended up skipping as I felt fine for the most part. That being said I don't think I missed out on much as the app's articles pretty much made up for it. They had detailed information on everything from mood and emotional well-being to contraception and planning for future pregnancies. It pretty much covered everything I needed to know about my own recovery.* [P14; birthing parent; high app use]

Theme 4: Ensuring Long-Term Well-Being Through Parental Self-Efficacy

Another significant theme that emerged from the qualitative interviews was the pivotal role that the B2H app played in facilitating long-term adjustment and well-being for new parents as they transitioned from intensive postpartum care to more self-directed management of their physical and mental health. Parents noted that the timely articles and targeted educational content within the app offered them a comprehensive suite of tools designed to enhance their self-efficacy.

In terms of maternal care, birthing parents reported that the weekly articles encouraged them to engage in regular physical activity, healthy eating, and mindfulness exercises, all tailored to fit into their busy schedules. Parents also reported that the app provided them with educational content focused on identifying triggers, managing stressors, enhancing self-efficacy, and empowering parents with the knowledge and skills to navigate future challenges independently.

One parent expressed the following:

> *The articles helped me think and reflect on what I am feeling. They help normalize aspects of my mental health. For instance the article shared with me yesterday by my care manager on grounding and de-stressing techniques reminded me to take some time for self-reflection whenever I feel anxious or stressed. It's helpful to have these resources to refer back to and allows me to practice different ways of coping with stress such as breathing and meditation exercises.* [P6; birthing parent; high app use]

Parents in the extended postpartum phase who were navigating the challenges of returning to work mentioned how the personalized content that was tailored to their baby's age and parenting journey addressed their evolving needs during the postpartum period.

A birthing parent noted as follows:

> *While many online resources cover postpartum care, few actually do a good job preparing you for transitioning back to work and not having the rest you previously did. Because you go from work to having to take care of your child so it's like work and then a different type of work that is full of warmth and fuzzies, but can be exhausting. I remembered coming across some articles on B2H which in a way helped me mentally prepare for this shift and helped me realize that it would be helpful to track my stress levels during this period. Both my wife's and my anxiety levels were slightly elevated compared to our General Anxiety Disorder scores before we resumed work. I checked in with my care manager around this time and she assisted me with daycare options and told me that she can help me find a therapist in my neighborhood to ensure that my new routine did not come in the way of my personal wellbeing.* [P17; birthing parent; high app use]

Another nonbirthing parent mentioned the following:

> *The educational content is laid out where it kind of feels like it's growing with our daughter. The content is targeted towards us during the six to twelve week period which is huge. If this continues with this app, that's gonna make me keep opening the app because there is nothing better than having information that is timed for when you need it or when you start looking for it. It's almost like a reassurance that if I'm going through something at a certain time period, it's probably going to be in that educational center at the time that I need it.* [P2; nonbirthing parent; low app use]

In terms of baby care, parents explained how the targeted content provided within the app helped them navigate the often overwhelming journey of early parenthood, fostering a sense of competence and security as they adapt to their new roles.

One participant reported the following:

> *The app in a way provided me with assurance that my baby is doing okay or that I am doing the right thing as a new parent. Sometimes I just want to know what to expect in terms of my child's developmental milestones. The app works great because it shows you 6-9 months milestones and things to watch out for. I like reading ahead, because I'm a person that likes to plan. For example, after reading an article in the app about visual development and sleep regression, I contacted my pediatrician to discuss these stages in more detail and clarify any questions I had about this.* [P8; birthing parent; low app use]

Another parent commented the following:

> *There are times you go to Google to search for something and are overwhelmed with hundreds of articles where everyone says something different. All the articles on the B2H app are relevant, and I feel safe to follow the information provided by the app because I noticed that all the articles list out the*

XSL•FO
RenderX

source they are coming from at the bottom which makes it trustworthy. [P7; birthing parent; low app use]

Parent-Reported Outcomes Indicating App Support During the Psychosocial Care Journey

Theme 1: Supporting Parents in Proactively Identifying Mental Health Symptoms Through Self-Monitoring

Subtheme 1: Enhancing Health-Promoting Behavior Through the Integration of Multiple Touchpoints and Reminders With Mental Health Screenings

Participants reported an increased engagement and involvement with their mental health care due to the integration of B2H. According to them, this was a direct result of ongoing assessment and the integration of multiple touchpoints with mental health screenings, which played a crucial role in encouraging and sustaining positive health behaviors.

Participants reported that, unlike clinical settings where birthing parents typically have just one touchpoint for mental health screening during the 6-week postpartum visit, the B2H app provided parents with a continuous and proactive method for managing their mental health. The monthly mental health surveys, which are a part of the B2H intervention, encouraged ongoing self-monitoring and reflection, allowing parents to maintain a consistent awareness of their mental well-being.

One parent shared as follows:

> *There are times when I feel deeply connected and engaged with my mental health, but other times I find myself rushing through the monthly surveys, reassuring myself that everything is okay or dismissing any concerns. Yet, there are moments when certain questions prompt me to pause and reflect, often bringing me to tears and making me realize that I may indeed feel a certain way or need to pay closer attention to my mental well-being. These moments underscore the importance and value of consistently taking these surveys.* [P19; nonbirthing parent; high app use]

In addition, parents in the intervention group reported that the app's reminders and prompts for regular check-ins contributed to a more structured and disciplined approach to mental health care.

One parent noted the following:

> *I am a big believer in staying on top of my mental health; however, there were times when I did not remember to open the app on my own. The in-app notifications, text reminders and care manager follow-ups, helped me ensure that I didn't miss any screenings. There were certain times when the reminders were very helpful in reminding me to carve some time for myself and reflect on my mental health. It gave me the space to think rationally about whether I needed to have a conversation with my partner or make an appointment with a therapist.* [P10; birthing parent; low app use]

Subtheme 2: Improving Symptom Awareness as an Outcome of Remote Screening and Comprehensive Mental Health Assessments

Enhanced symptom awareness emerged as another theme in the qualitative interviews. According to the participants, this was a direct outcome of the integration of comprehensive mental health assessments (PHQ-9, GAD-7, and PSS) and remote screening.

Parents reported that the use of comprehensive, evidence-based screening tools enabled them to identify symptoms of anxiety or stress that they might have otherwise overlooked, especially if their initial screenings for PPD during their postpartum visits were negative.

One parent shared the following:

> *There have been stressful moments, certainly, but I haven't felt like I had depression or anything along those lines, so I haven't been actively seeking out help. However, seeing my screening results was truly eye-opening. Although my scores for PhQ9 were moderate, I had no idea that I was experiencing such high levels of stress and anxiety.* [P5; birthing parent; low app use]

In addition, parents who completed paper-based screenings during their postpartum visit reported that they often rush through the assessment, potentially overlooking critical questions about their own mental health as they prioritize asking questions about their infants during their postpartum visit.

One participant noted the following:

> *I felt like I was navigating this complex web of decisions on my own, without consistent guidance or support from my healthcare providers. I attended my 6-week postpartum visit and was scheduled for a 12-week one, but I did not attend it. I feel that the care offered to parents during pregnancy is much better than the postpartum care, which often feels neglected and rushed. In reality, all the support I received during my postpartum visit was mostly centered around caring for the newborns.* [P16; birthing parent; high app use]

On the other hand, parents who engaged with the B2H screenings reported that the transition from paper-based screening to using mHealth tools for mental health assessments provided them with the flexibility needed to manage their mental health more effectively and proactively. A substantial number

of parents reported that the flexibility and privacy of completing these assessments remotely at their convenience enabled them to take more time for self-reflection, which is often not possible in clinical settings.

One parent remarked as follows:

> *The mental health surveys provided by B2H are a nice way for me to reflect upon certain things at my own pace, allowing me to think more deeply about my feelings and recognize symptoms I might have previously missed. The digital surveys are also quick,*

XSL•FO
RenderX

> *like they only take about like five minutes or so. So it's just those five to ten min where I get to focus on my own mental health. Outside of these surveys, I haven't had much time to really worry much about my own well-being at this point.* [P3; nonbirthing parent; high app use]

Subtheme 3: Empowering Birthing Parents to Recognize and Respond to Mental Health Symptoms in Partners Through App Support

The qualitative study findings revealed that by providing a more inclusive approach that screens both birthing and nonbirthing parents, the app not only helped facilitate early detection of mental health issues but also created awareness among birthing parents on the potential mental health challenges their partners might face, which often go unrecognized:

> *For me and my husband, the ability to see our test scores and keep taking those surveys is valuable. Instead of having a pen and paper and having to calculate our scores, the app does a good job tracking our scores for us and is right there at your fingertips. When my husband or I get the survey reminders, we remind each other to take the survey and read the resources provided within the app. We would not compare our scores but discuss them and collectively reflect on the moments that may have resulted in elevated scores. When both you and your partner feel like you are at 25% and need to be there at 100% for the sake of the baby, having these surveys reminds us that we need to talk to each other about this and take time for ourselves or together or as a family if we're both feeling stressed.* [P12; birthing parent; high app use]

Parents reported that the educational content provided on the B2H app equipped them with the knowledge needed to notice symptoms or signs of depression or anxiety in their partners. In addition, the articles helped parents support their partners by sharing useful strategies for managing symptoms and seeking professional help if needed, allowing for equitable mental health care for all parents, regardless of their role in birthing.

One birthing parent reported the following:

> *I specifically enjoyed reading the articles on how to communicate with your partner regarding fatigue and taking some time for yourself. There were times when the article would tell us what to look out for, what to avoid doing, and make suggestions for suitable alternatives, which were pretty helpful. Since my wife and I work in the mental health profession, we often tend to rationalize our mental health. So the articles are a great reminder for us to dedicate time for our self-care and check in on each other's mental health.* [P17; birthing parent; high app use]

Another parent shared as follows:

> *I often felt reassured by my own screening results, but seeing my husband's results was truly eye-opening. I had no idea he was experiencing such high levels of stress and anxiety, as he hides it so well. Without the monthly assessments, I would never have known about his struggles. Seeing his scores made me start checking in on him more frequently to see how he is doing and encourage him to actively seek out mental health support if needed.* [P5; birthing parent; low app use]

Theme 2: Timely Assessment and Rapport Building Through Care Manager Support

The qualitative study revealed that the presence of a CM to monitor scores made a significant difference in the experiences of parents. A significant number of participants reported that having a CM to monitor their scores and provide timely feedback markedly improved their overall experience and outcomes.

One parent reported the following:

> *Although I did not communicate with my care manager frequently. I appreciate that the option was given to me. The care manager reached out to me in those early weeks to let me know that she was available and was there to monitor our mental health scores based on the assessments. It was almost as if there was someone paying close attention to your mental health and even though our communication has not been frequent or consistent, I do know that they're available, which is reassuring.* [P15; birthing parent; low app use]

Feedback from parents underscores the value of having a dedicated CM monitor their scores, compared to an app that lacks human oversight. Parents expressed that knowing there is a person on the other end tracking their progress makes them feel reassured that their mental health is being actively monitored by a professional, thereby strengthening their engagement and confidence in the care process. This human element offered parents a reliable touchpoint for ongoing support, contributing to a more personalized and effective care approach.

One participant reported as follows:

> *To me, having a care manager and monthly mental health surveys within the app goes above and beyond any other baby tracking apps. My care manager did a great job of reaching out to me and checking in with me regularly. She was very responsive and knew when to push and when to pull back. This way I could utilize her in a manner that worked well for me.* [P4; birthing parent; high app use]

Theme 3: Supporting Mental Health Treatment Through Care Coordination and Engagement With Mental Health Modules

When asked how the app supported treatment, many parents highlighted the crucial role of CMs in helping them navigate their treatment plans and the significant impact of the mental health modules in providing effective coping strategies. The combination of these elements fostered a sense of support and empowerment among parents, ensuring that they felt confident and prepared in managing their mental health.

XSL•FO
RenderX

One parent stated the following:

> *A few days after taking my assessment, a care manager reached out to me and offered to do the Behavioral Activation (BA) sessions with me. These sessions were easy to follow, providing tips and methods on how to effectively handle stress. This was incredibly helpful, allowing me to practice different ways of coping with anxiety and stress. The care manager also shared some articles in the chat feature of the app, which gave me something to go back and look into every time I feel anxious.* [P7; birthing parent; low app use]

Another parent emphasized the role of CMs in helping them feel supported with their treatment decision:

> *Having a care manager to discuss the risks and benefits of treatment options made me feel prepared and a bit more confident in my decisions. The conversations we had allowed me to dig deeper into the root causes of what was going on. The care manager would provide resources to support me and schedule check-ins with me. She would follow up kind of in between the survey periods to check and see if the resource she sent worked or if I needed additional support. I think just having that kind of ongoing support made me feel empowered and more likely to engage in my care. Plus the ability to reach out to her at any time gives me this added sense of security and makes me feel less isolated in my treatment journey.* [P14; birthing parent; high app use]

Parents also appreciated the CMs' follow-ups to ensure that they remained connected to care and helped them find therapists covered under their insurance. One parent reported as follows:

> *While the app did not directly influence my treatment decisions, the follow-ups provided by care managers played a crucial role in helping me connect with a therapist. The care manager followed up with me regularly to check on my progress and make sure I was connected to the right care. The care manager even helped me find a therapist covered by my insurance, which was a huge relief.* [P19; birthing parent; high app use]

Theme 4: Empowering Parents With the Resources and Support Needed to Ensure a Smooth Transition Out of the CCP

Parents nearing the end of their postpartum care journey reported that the B2H intervention's approach of integrating continuous support, educational resources, and follow-up care has empowered them to manage their mental health effectively, ensuring a smooth transition out of the CCP. This holistic support system has fostered a sense of confidence and preparedness among parents, allowing them to maintain their well-being independently.

The transition out of the CCP often presents challenges for parents. As parents draw near to the end of their postpartum care journey (12-month postpartum milestone), they usually find themselves needing to connect with external psychosocial care providers to ensure continuity of care. This transition can be fraught with difficulties, such as connecting with new therapists or finding a therapist covered by their insurance. The support provided by the CMs during this transition was particularly appreciated by parents, as it ensured that they remained connected to care resources and felt supported in their mental wellness journey.

One parent shared their experience, stating as follows:

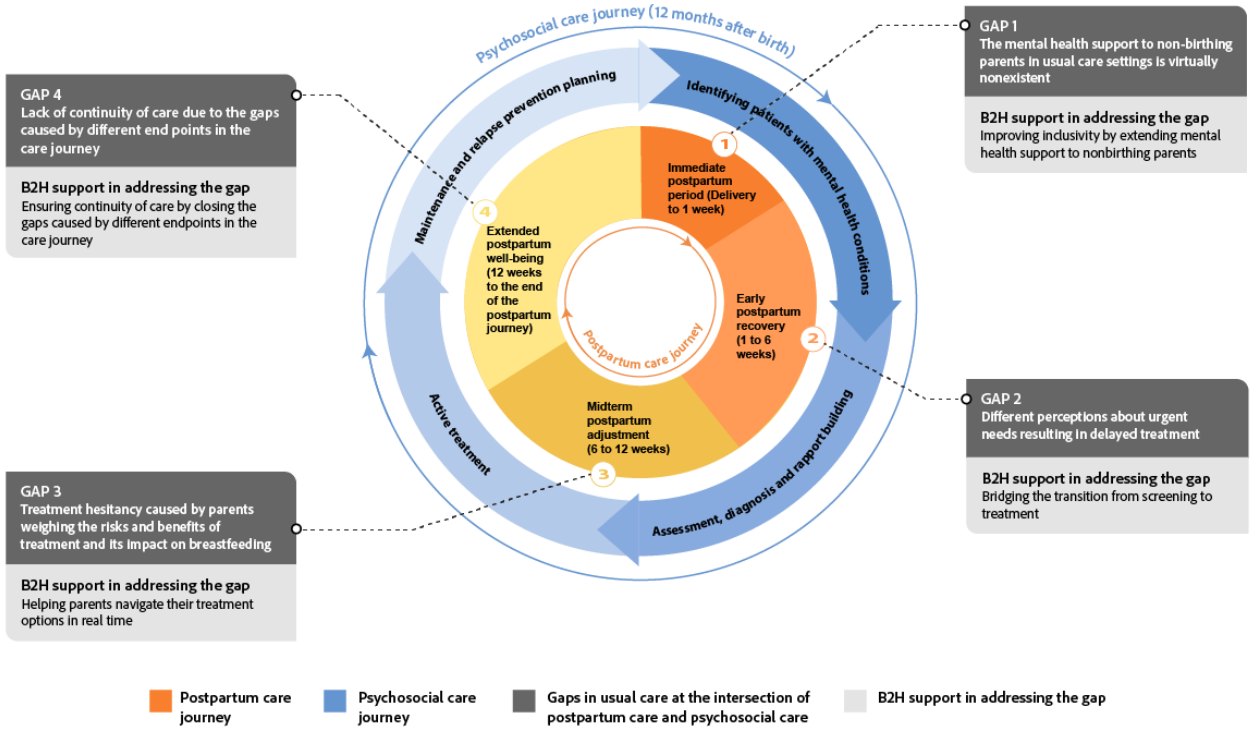
> *I recently moved to a new state and have been struggling to find a therapist that is covered by my healthcare plan. I reached out to the care manager through chat hoping to seek recommendations for a therapist and a new primary care provider. The care manager not only provided me with several options but also followed up to ensure I had all the resources necessary to support the continuity of my care. Having the care manager check in regularly gave me a sense of continuity. I didn't feel like I was being left on my own.* [P17; birthing parent; high app use]

Parents also shared the importance of the guidance and support provided by the educational articles, which helped them maintain the progress they had made during the program.

One parent highlighted how the knowledge gained from the app's educational content prepared them for life after the CCP:

> *The articles and mental health modules on the app taught me so much about recognizing and managing my symptoms. The articles on identifying potential triggers and the ones on stress management techniques gave me the tools needed to confidently handle any future challenges. I now feel equipped with resources needed to help me keep up with my mental health, making it less intimidating to handle things on my own once my postpartum journey ends.* [P9; birthing parent; high app use]

B2H's Role in Addressing Gaps in Usual Care at the Intersection of the 2 Journeys



Overview

In addition to demonstrating how the B2H app effectively supports the comprehensive needs of parents in their postpartum care journey, our findings also illuminate several critical gaps in usual care as reported by the parents. By applying the PJF to our analysis, we were able to uncover how these gaps manifest in the real-world experiences of parents and explore the potential of mHealth technology to address these deficiencies.

At the intersection of the 2 journeys, we provide the gaps identified by our data, noting that additional unobserved gaps may exist. Figure 6 demonstrates these gaps and highlights the role of mHealth technology in closing these gaps.

XSL•FO
RenderX

Figure 6. Gaps at the intersections between the psychosocial care journey and the postpartum care journey.

Improving Inclusivity by Extending Mental Health Support to Nonbirthing Parents

The interview findings revealed that the mental health support provided for nonbirthing parents in usual care settings is virtually nonexistent.

One parent reported the following:

> *When I first logged into the app, I just assumed that the app was mainly for baby tracking. That's kind of the only way I was thinking about it. I think as new dads you often get conditioned to thinking that most of the resources and support out there are mainly for the moms or the baby. Sadly dads often get overlooked when it comes to mental health support. Besides the mental health surveys on the apps I don't think I have had any other encounter with mental support in the real world.* [P2; nonbirthing parent; high app use]

This finding supports the existing literature, which indicates that the current system lacks any framework to support screening or treatment for nonbirthing parents, highlighting a significant oversight in the existing approach to care [44]. Unlike routine assessments for depression and anxiety symptoms in new birthing parents during postpartum visits, there is a notable absence of similar checkups for nonbirthing parents. This exclusion often hinders nonbirthing parents from actively participating in postnatal care and fully understanding their role in supporting both the birthing parent and the newborn.

Nonbirthing parents in the intervention group reported positive experiences with the B2H intervention, noting how the tools and resources provided within the app empowered them to take charge of their own mental health and actively participate in the care of their partners. This involvement not only enhanced their own well-being but also contributed to a more supportive and collaborative postpartum care environment.

A nonbirthing parent stated as follows:

> *My wife was dealing with some health stuff before this. So every time she fills out the survey, the care managers in the app check in with her which is nice because there is someone besides me looking out for her. That being said, we are now a little bit aware of our scores due to the assessments and try to track and manage each other's mental health.* [P13; nonbirthing parent; low app use]

In addition, the app also enabled nonbirthing parents to take a proactive role in supporting their partner's mental health journey. It provided them with the tools to regularly check in on their partner's mental well-being, engage in shared decision-making, and offer timely encouragement for seeking professional help when necessary.

One parent recounted the following:

> *Four months into having the baby my husband and I were having a lot of stress mainly because of him working late hours and my health. We did not know how to communicate what we were feeling. Taking the surveys in a way helped us communicate better about our scores and my partner suggested for us to go back to therapy as a way of dealing with our frustrations.* [P10; birthing parent; low app use]

XSL•FO
RenderX

The findings of this study also underscore the role of mHealth technology in facilitating communication and engagement within the family unit. Nonbirthing parents reported that using the B2H app helped them become more informed on critical aspects of postpartum care, including postpartum visits, contraception, and breastfeeding. This increased knowledge significantly enhanced their involvement in their partner's postpartum care journey, enabling them to effectively communicate the importance of attending postpartum visits, encourage continued breastfeeding, and provide both emotional and practical support.

One parent explained as follows:

> *My husband reads more of the articles that I do and informs me on what he reads which in turn helps me stay informed. If my partner comes across an interesting article on the app he shares it with me and after we talk about it for a bit I use Google to dig deeper and get more information surrounding the topic. Like the other day he read something about questions to ask during the postpartum visit and shared the article with me.* [P6; birthing parent; high app use]

However, it is important to note that although nonbirthing parents in the intervention group regularly engaged in the monthly assessments, their app use indicated limited interaction with the mental health modules and low chat use. Further research needs to be conducted to identify ways to enhance the engagement of nonbirthing parents with the CM and the mental health modules.

One parent reported the following:

> *I do not think I reached out to the care manager as much as she reached out to me to check in with me and see how I am doing. She reached out to me based on my scores and shared articles with me. I feel like, just because I read all the articles shared by my care manager I do not really feel like I need to approach her. We would chat like once in a while, especially in the beginning. I do not really need to go to my care manager just because I feel like the app offers a lot of support already.* [P3; nonbirthing parent; high app use]

Another parent reported the following:

> *I personally have not engaged with the mental health content. There've been stressful moments, certainly, but I haven't felt any sort of depression or anything along those lines. I see therapists on the side so I didn't use the app for any mental health content. I actually do teletherapy through zoom but occasionally meet in person. But you know, because I see a therapist monthly I don't normally seek things like this on an app.* [P19; nonbirthing parent; high app use]

Bridging the Transition From Screening to Treatment

Another gap identified by parents in our study was the difference in perceptions between health care providers and parents regarding what constitutes urgent needs, particularly in the context of mental health.

One parent explained as follows:

> *I have a history of depression and anxiety, I was really hoping my postpartum visit would address my mental health more seriously. Instead, I felt like my concerns were kind of brushed off by my provider. The OB told me it was just the typical stress and anxiety that new moms experience. It didn't feel like my needs were prioritized at all, and I left feeling like I wasn't really heard or understood.* [P7; birthing parent; low app use]

This gap often exacerbates challenges, especially during the critical transition from screening to treatment. While national guidelines emphasize the importance of screening for conditions such as PPD and anxiety, the actual follow-through from an elevated screening result to a formal diagnosis and subsequent treatment is often faced with obstacles. These challenges arise because the importance of addressing mental health concerns is not always uniformly recognized by all key informants in usual care settings. Obstetric clinicians, who do not have specialized training in mental health, might underestimate the urgency of the patient's mental health needs. In contrast, parents experiencing significant distress may perceive their needs as urgent but find that the health care system's response does not align with this urgency. This misalignment can lead to delays in care, underdiagnosis, and, ultimately, untreated mental health conditions.

mHealth technology offers a promising solution to bridge this perception gap and facilitate a smoother transition from screening to treatment. Parents reported that the ability of mHealth technologies to track and monitor real-time data allows both parents and CMs to identify any changes in the mental health status and alert them if a situation requires immediate attention. Parents in the study also mentioned that the use of standardized screening tools, such as the PHQ-9, GAD-7, and PSS, empowered them to regularly assess their mental health and communicate their needs and concerns more effectively, making it less likely that their symptoms would be overlooked.

One parent reported the following:

> *Everyone should be screened for depression and anxiety during the postpartum visit. However, what actually occurs can be quite different. While many screen for postpartum depression, only a few are beginning to screen for anxiety, despite the fact that perinatal anxiety is incredibly common. Having these monthly reminders and surveys supported me by highlighting any red flags or providing resources to help me or like point me in the right direction. Although some of the questions in the survey were not necessarily applicable for me, I still think it's important for people who may have a change in their relationship status or might not have the support system that I have. For parents who respond to surveys indicating a change in their relationship or health with the app I would assume that the app would*

XSL•FO
RenderX

> *then allow the care manager to reach out, check in with them and make sure they have additional support.* [P17; birthing parent; high app use]

Moreover, mHealth apps, such as B2H, can streamline the transition from screening to treatment by automatically flagging positive screening results for further evaluation by dedicated CMs. These CMs, trained specifically to identify and respond to symptoms of mental health issues, use a triage model to assess the severity and urgency of the cases. This approach ensures that parents with urgent needs receive immediate attention, reducing their reliance on obstetric clinicians to make diagnostic decisions outside their expertise and ensuring timely and appropriate referrals for those at elevated risk.

Another parent stated as follows:

> *Having a care manager was reassuring during my early days as a parent. It made me feel less alone, knowing there was someone there to check in on me and track my progress. As a new parent, you're always questioning yourself: Am I doing this right? Is this experience normal? Everyone's journey is different, so having a care manager to reassure me that I was on the right track made a huge difference. I think my care manager reached out to me right after my first mental health survey when we were in the NICU, and my stress levels were high as we tried to navigate everything. In a way the care manager made me feel validated, and validated my feelings more than anything.* [P4; birthing parent; high app use]

These findings underscore the benefit of integrating mHealth technology into the postpartum care process, particularly in enhancing the triage system and enabling CMs to track symptom scores in real time. However, the success of this approach relies on the presence of trained collaborative care coordinators within the mHealth framework, who are essential for monitoring changes in parents' mental health status as they occur. By combining real-time data collection with expert analysis, CMs can respond swiftly and accurately to emerging needs. This synergy between technology and specialized care ensures that timely interventions are delivered, effectively bridging the gap between screening and treatment and providing parents with the support they need exactly when they need it most.

Helping Parents Navigate Their Treatment Options in Real Time

Our findings indicated that parents who engaged in mental health treatment often had to consider not only their psychosocial well-being but also their obstetric and infant care journeys. This multifaceted decision-making process involved weighing advice from multiple health care providers and evaluating the potential impacts of treatment—especially medication—on breastfeeding and overall infant health. For some parents, this created a significant source of anxiety, often delaying treatment decisions or causing parents to question the appropriateness of certain interventions.

A major concern expressed by parents was the potential impact of treatment, particularly medication, on breastfeeding.

One parent shared the following:

> *I have a history of ADHD [attention deficit hyperactivity disorder] and was taking medication prior to my pregnancy. But ever since I had the baby, I stopped and haven't been actively seeking out medication since I was still breastfeeding and wasn't sure if it would affect my baby and whether it was safe.* [P7; birthing parent; low app use]

This uncertainty reflects the lack of preparation and support provided to parents once they leave the hospital after delivery. While health care providers typically offer some guidance on postpartum care during the hospital stay, this support is often minimal, leaving parents to navigate the complexities of postpartum care on their own.

One parent noted as follows:

> *There was so much information given to me at the time of delivery, but as soon as I got home, I realized how little I actually knew about managing postpartum care, especially when it came to breastfeeding while considering treatment for my mental health. It felt like I was on my own.* [P9; birthing parent; high app use]

Parents in this study recounted how the abundance of online resources, while well-intentioned, often became overwhelming. The sheer volume of information left many feeling more confused and anxious than reassured.

One parent described as follows:

> *I spent hours researching what is safe during breastfeeding. We have a pile of books in my house that we've tried to make our way through, but have been looking for quick little snippets or tidbits of valuable information that you can quickly read and digest in comparison to reading 300-400 pages. I tried googling this information but every website seemed to have conflicting advice, and I wasn't sure who to trust.* [P5; birthing parent; low app use]

This overwhelming influx of information further highlighted the gap in accessible, timely support during the postpartum period. Without clear, reliable guidance from health care professionals, parents were left navigating complex decisions about their mental and physical health alone, often unsure of the best course of action for their postpartum journey.

The findings from this study underscore the critical role that CMs can play in helping parents make these complex decisions. Care managers, by providing personalized support and guidance, could alleviate much of the confusion and anxiety of parents that stems from the sheer volume of information they encounter. Parents reported how CMs serve as a reliable, accessible resource for answering questions and helping parents navigate their treatment options in real time. This proactive approach to addressing concerns about breastfeeding and mental health treatment can help parents feel more confident in their decision-making.

One parent reflected on how having a CM made a difference in her postpartum care journey:

XSL•FO
RenderX

> *I was unsure about starting medication while breastfeeding. My care manager was the one who really took the time to answer all my questions and made sure I had the latest information from trustworthy sources. It felt reassuring to have like a medical professional guide me through the process, and I didn't feel as anxious about making the decision anymore. Without her, I would have been lost in all the information I found online.* [P9; birthing parent; high app use]

These findings highlight the complex decision-making process parents face when managing their postpartum mental health. The lack of consistent, accessible support after hospital discharge leaves parents vulnerable to confusion and anxiety, often causing treatment hesitancy. The inclusion of a CM within the app provided parents with an additional layer of support, offering personalized, timely support needed to make informed decisions about their mental health and breastfeeding, ultimately promoting more effective treatment engagement. This organized and responsive system of care ensures that parents are not left to troubleshoot issues on their own but are supported in a way that is both comprehensive and accessible. By doing so, mHealth transforms the experience of postpartum care from one associated with feelings of uncertainty and being overwhelmed to one that fosters empowerment and encourages proactive self-care.

Ensuring Continuity of Care by Closing the Gaps Caused by Different End Points in the Care Journey

In most usual care settings, the obstetric care journey comes to an end with the postpartum visit that is usually scheduled during the early postpartum recovery phase (approximately 6 weeks after birth). However, the psychosocial care journey extends 12 months after birth. This disjointed timeline creates challenges for psychosocial care providers and impedes the patient's ability to receive continuous and appropriate care during a critical period when they may still be experiencing or developing mental health issues, such as PPD.

As regular contact with obstetric care providers diminishes after the 6-week postpartum visit, the window for ongoing monitoring and early intervention for issues such as depression and anxiety narrows significantly. This gap creates a vulnerability in the health care system, where the absence of sustained medical oversight may allow psychosocial challenges to go undetected and untreated. The mismatch between the end point of the obstetric care journey and the continued need for psychosocial support highlights the need for more integrated and continuous care pathways that extend beyond the initial postpartum period.

One parent highlighted this gap and reflected on her postpartum journey, stating as follows:

> *It's kind of sad to think about the existing state of postpartum care. I definitely feel like there is so much more that can be done to support new birthing parents with their postpartum journey. There's a striking gap in the time and resources allocated towards pregnancy versus the postpartum period. While a woman might visit her OBGYN multiple times during pregnancy, she'll typically only visit the OB once or twice during the postpartum period. And while it's common for an expectant birthing parent to take a birth education class, it is virtually unheard of for her to receive postpartum education.* [P20; birthing parent; high app use]

mHealth technology offers a promising solution to bridge this care gap by providing continuous, accessible support throughout the extended postpartum period. Through mHealth apps such as B2H, new parents can maintain regular engagement with CMs even after the formal end of their obstetric care. The findings of our study indicate that integrating a CM within mHealth technologies helps facilitate ongoing monitoring of mental health through self-assessments and screening tools that can be administered at intervals well beyond the 6-week mark, ensuring that symptoms of depression or anxiety are not overlooked as time passes.

One parent explained as follows:

> *I really assumed postpartum was only like the first few months after having a baby and I'm learning that that's not the case at all. Now I understand that postpartum doesn't necessarily have a finite time. The surveys kind of prompted me to reconsider what I thought the timeline was for postpartum. What I found most helpful was the care manager check-ins from time to time. I liked bouncing ideas off the care manager. Just having a conversation with the care manager solidified what I was thinking. What I liked about the chat feature was the ability to touch base with someone because you can feel very isolated when you're home with the baby all day.* [P11; birthing parent; low app use]

In addition to facilitating continuous monitoring, integrating various support resources, such as educational content, mental health assessments, and a chat functionality, helps maintain a connection between the patient and their care coordinator, promoting a more seamless transition from obstetric care to comprehensive psychosocial support.

Another parent compared the B2H app to other existing apps, stating the following:

> *There are a lot of apps that once you sign up, they'll send you emails or reminders about upcoming milestones and things like that. However B2H has a lot more daily education that keeps you engaged for the entirety of the postpartum journey. I think with this app there's a lot of information there about things like, mindfulness resources. Just taking those surveys and knowing my scores were a great indicator of my mental health. As a new parent you assume that after six weeks or twelve weeks things are supposed to get better and your scores should be improving but that is always not the case. I did feel that especially after the last survey which prompted me to reflect on the month that I had and what I need to do differently in the next month so that my scores are lower such as looking for a postnatal counseling services.* [P13; birthing parent; low app use]

XSL•FO
RenderX

By leveraging mHealth technology, health care providers can ensure that the psychosocial care journey is not abruptly interrupted by the end of the obstetric journey. Instead, these tools create a continuum of care that supports new parents throughout the first year after birth. This approach not only enhances the ability to monitor and manage mental health concerns but also ensures that the support offered is consistent, responsive, and aligned with the evolving needs of the patient.

Discussion

Principal Findings

Evolving Postpartum Needs and the Role of mHealth

Summary of Key Findings

A summary of key findings about evolving postpartum needs and the role of the mHealth app examined in this study is provided in Table 1.

Table 1. Key findings about the evolving postpartum needs and the role of the mobile health (mHealth) app.

Phases in postpartum care	Emerging needs	App features used	Role of mHealth app (B2H)
Immediate postpartum phase	Navigating uncertainties related to their recovery and newborn care	Heavy reliance on the baby tracking feature (feeding, pumping, diaper, and sleep tracking)	Helped parents monitor newborn activities, support daily caregiving decisions, and reduce anxiety in early care routines
Recovery phase	Establishing routines, enhancing communication with health care providers, and sharing caregiving responsibilities with partners	Continued use of shared baby tracking and educational content (eg, breastfeeding and infant safety)	Facilitated partner collaboration, supported routine formation, and prepared parents for well-child visits and postpartum visits
Midterm postpartum phase	Shifting focus to parental well-being and self-care	Educational content on self-care and monthly mental health assessments	Supported fatigue management, hormonal balance, and mental and emotional health through timely, relevant guidance
Extended postpartum phase	Supporting the baby's developmental milestones	Educational content on baby development	Helped parents track developmental progress and provided age-specific guidance to support caregiving decisions

Implications for mHealth Design

The findings of our study underscore the importance of designing mHealth interventions that can dynamically adapt to the evolving needs of parents across the postpartum journey. In the early and recovery phases, parents exhibited heavy reliance on the baby tracking features (feeding, pumping, and diapering). However, usability issues such as inability to save entries due to app session timeouts, laggy response times when inputting data, and lack of visual clarity in the time tracking interface resulted in decreased app use, prompting parents to switch to alternative apps that provided similar tracking functionalities. Parents also expressed a desire for more personalized visualizations of daily activities and trends across days and weeks to help make sense of their baby's patterns—features available in competing apps. These specific pain points influenced app switching behavior not because users found the app irrelevant, but because they perceived the core tracking functions as unreliable or inefficient. This highlights the importance of seamless design and usability to maintain engagement, particularly when parents need reliable tools the most. In mHealth apps, where user engagement is tied directly to the ability of the app to meet evolving and time-sensitive needs, a frictionless experience is essential. Frustration with core features can lead to disengagement, reduced intervention effectiveness, and fragmented care, limiting opportunities for holistic support such as mental health check-ins and educational content.

As parents progressed into the midterm and extended postpartum phases, their needs shifted toward self-care, mental well-being, and baby developmental milestones. The B2H app's integration of educational content on postpartum recovery and mental health proved particularly valuable during this transition. To better meet these changing needs, future mHealth interventions should consider incorporating modular designs that adjust based on the stage of parenthood. In addition, personalized content recommendations based on the baby's developmental stage and parental mental health screening results could help ensure that mHealth tools remain relevant and engaging throughout the postpartum journey.

Addressing Psychosocial Needs With mHealth Support

Summary of Key Findings

A summary of key findings about addressing psychosocial needs with mHealth support is provided in Table 2.

XSL•FO
RenderX

Table 2. Key findings about addressing psychosocial needs with mobile health (mHealth) support.

Phases in psychosocial care	Emerging needs	App features used	Role of mHealth app (B2H)
Identification of patients with mental health conditions	The need to enhance health-promoting behavior, improve symptom awareness, and empower birthing parents to recognize symptoms in their partner	Monthly mental health assessments using PHQ-9[a], GAD-7[b], and PSS[c]	• Helping parents manage their mental health by offering multiple assessment touchpoints throughout the postpartum journey • Enabling early detection through the use of comprehensive, evidence-based screening tools • Providing remote, self-paced screening, giving parents more time and comfort to reflect on their mental health • Enhancing symptom awareness, including recognition of mental health challenges in their partners
Initial psychosocial assessment, diagnosis, and rapport building	Timely assessment and rapport building through care manager support	In-app chat functionality	• Enabling parents to receive timely support and personalized guidance in managing their mental health by assigning them a dedicated care manager
Active depression treatment	Supporting mental health treatment through care coordination and engagement with mental health modules	Mental health education modules (such as behavioral activation module and stress module); follow-up from care managers	• Helping parents actively manage depression, anxiety, and stress by tracking their mental health score progression and providing them ongoing access to mental health modules and resources • Facilitating informed decision-making by allowing parents to discuss treatment options with a care manager • Offering care manager support to help parents connect with therapists or additional services, improving access to professional care
Maintenance and relapse prevention planning	Empowering parents with resources and support for a smooth transition out of the collaborative care program	Long-term postpartum care resources; care manager–supported transition guidance; reminders and check-ins on relapse indicators	• Helping parents sustain the progress made during the program and prevent relapses through educational resources and articles • Supporting continuity of care by helping parents connect with external psychosocial health care providers as they approached the 12-month postpartum milestone • Providing care manager guidance during the transition period to ensure that parents remained supported and aware of available resources beyond the conclusion of the collaborative care program

[a]PHQ-9: 9-item Patient Health Questionnaire.

[b]GAD-7: 7-item Generalized Anxiety Disorder.

[c]PSS: Perceived Stress Scale.

Implications for mHealth Design

The B2H intervention's success in addressing psychosocial needs demonstrates the ability of mHealth tools to enhance postpartum care. The continuous touchpoints for mental health assessments, combined with CM support, played a crucial role in fostering health-promoting behaviors and ensuring timely mental health interventions. Furthermore, the combination of automated features, such as reminders and surveys, with personalized CM support highlights the importance of integrating both digital and human elements in mHealth solutions. This hybrid approach creates a balanced system where technology facilitates self-monitoring while CMs provide tailored support, ensuring a more holistic and personalized experience.

However, the findings also highlight the need for more targeted efforts to engage nonbirthing parents and address the unique psychosocial challenges they face. This study revealed

XSL•FO
RenderX

disparities in CM engagement between birthing and nonbirthing parents. Nonbirthing parents reported lower interaction levels, which may have limited the intervention's effectiveness for them. Although less involved in physical recovery, nonbirthing parents face significant psychosocial challenges and report elevated stress and anxiety. Their reduced engagement suggests that they may not be receiving adequate support to manage these challenges. This gap highlights a key area for improvement in future iterations of B2H. Increasing outreach and tailored support for nonbirthing parents could enhance the app's impact. Because birthing parents often influence their partners' treatment decisions, educating them to recognize mental health symptoms in their partners and encouraging CM engagement could promote a more collaborative approach, ensuring both parents receive the support they need.

This calls for more equitable support across all users, regardless of their role in caregiving. Future mHealth interventions should consider developing targeted strategies to increase the engagement of nonbirthing parents. This could include personalized check-ins, more targeted reminders, a gamified approach, and additional resources focused on the unique psychosocial stressors nonbirthing parents face. In addition, providing educational content that encourages birthing parents to monitor and support their partners' mental health could foster a more collaborative and inclusive approach to postpartum care.

Contribution of the PPJF in Highlighting the Holistic Needs of New Parents

The application of the PJF in this study provided a comprehensive approach to understanding the distinct yet interconnected experiences of both birthing and nonbirthing parents during the postpartum period. By mapping the postpartum and psychosocial care journeys of each parent and identifying the unique challenges they face, this framework allowed for a more nuanced understanding of how mHealth interventions, such as B2H, can support different roles within the caregiving unit.

CCPs have made significant progress in acknowledging the association between psychological and physiological challenges encountered by birthing parents, highlighting the growing awareness and importance of holistic care. Despite the increased attention to comprehensive patient care, 78% of women who screen positive for PPD do not receive mental health treatment, while nonbirthing parents receive little to no support when it comes to psychosocial care [4]. By applying our modified version of the PPJF to our study, we highlight several missed opportunities or gaps in usual care settings that resulted in parents receiving less-than-ideal care. Through the lens of the parallel journey, our work exposes many of these gaps at the intersection of postpartum and psychosocial care while drawing focus on technological opportunities to ensure that new parents receive adequate support and care.

One of the key contributions of this framework is the ability to draw attention to the often-overlooked psychosocial challenges that affect both birthing and nonbirthing parents. Our findings illuminated the gaps in usual care, particularly in how mental health support is disproportionately provided to birthing parents, while nonbirthing parents are left without adequate resources to manage their own mental health. As revealed in the interviews, nonbirthing parents frequently assumed their role was limited to supporting the birthing parent and the newborn, overlooking their own need for psychosocial support. This study showed how an mHealth intervention, such as B2H, can fill this gap by extending mental health resources to nonbirthing parents, encouraging their active involvement in caregiving and in their own well-being. The inclusion of nonbirthing parents in mental health support systems reflects a more inclusive approach to postpartum care.

In addition, the PPJF exposed several systemic issues that result in less-than-ideal care for parents. First, the findings revealed that health care providers and parents often have differing perceptions of what constitutes urgent mental health needs. This misalignment frequently results in delayed treatment, as mental health concerns raised by parents are sometimes dismissed or minimized by obstetric clinicians who may lack specialized training in mental health. By identifying this gap, the framework highlights the need for better alignment between parent-reported mental health concerns and health care provider responses, an area where mHealth technologies such as B2H can help by flagging urgent needs based on real-time assessments. Second, the framework also illuminated the issue of treatment hesitancy, particularly among birthing parents who face the challenge of weighing the risks and benefits of mental health treatment in the context of breastfeeding. Parents often hesitate to seek treatment, concerned about the potential impact on their infant's health. The PPJF underscores the importance of providing clear, reliable guidance on how to balance mental health needs with infant care. mHealth interventions play a critical role here by offering educational tools and CM support to guide parents through these decisions, thus reducing anxiety and improving treatment engagement. Third, one of the most significant gaps identified through this study is the lack of continuity of care due to the different end points in obstetric and psychosocial care. While postpartum visits typically conclude around 6 weeks after birth, psychosocial care needs often extend much longer, leaving many parents without adequate support during a critical period of their mental health journey. The framework allowed us to highlight how mHealth technologies such as B2H can bridge this gap, providing continuous engagement and monitoring well beyond the obstetric care. This ongoing support ensures that mental health concerns, such as PPD or anxiety, are not overlooked as time passes.

Using the PPJF, we were able to illustrate the experiences of both birthing and nonbirthing parents as part of an interconnected system of care, where psychosocial and physical needs must be addressed simultaneously. It highlights the importance of integrating mental health screening and support into the postpartum journey as a continuous, rather than episodic, process.

Limitations of This Study

While our findings provide valuable insights into postpartum care and have the potential to inform future interventions, several limitations should be acknowledged.

Selection bias is a notable limitation, as the experiences and engagement levels of participants who chose to enroll in the

XSL•FO
RenderX

study might differ from those who declined participation. This could influence the generalizability of our findings, as those who opted in may have had a greater interest in or need for the support provided by the B2H app.

Another limitation is the relatively small number of nonbirthing parents (4/20, 20%) who participated in the study. This smaller sample size may not fully represent the diverse needs and feedback of all nonbirthing parents, which could lead to an incomplete understanding of how the app addresses their specific concerns during the postpartum period. Further research focusing specifically on nonbirthing parents is crucial to better understand their unique challenges and engagement with mHealth tools. By exploring their experiences in greater depth, future studies can identify opportunities to enhance app features and address any unmet needs, ultimately improving support for nonbirthing parents during postpartum care.

Furthermore, our study did not fully address the needs of postpartum parents without smartphones or those who may face barriers to accessing digital health interventions. To ensure greater inclusivity, our next steps include conducting a study in Kenya to explore how B2H can become more equity focused. This study will investigate modifications to the app that make mHealth tools accessible to parents across different socioeconomic and technological divides, ensuring that the benefits of digital health interventions reach a broader and more diverse population of postpartum parents.

Finally, the qualitative nature of this study, while providing in-depth insights, may limit the ability to generalize findings across larger populations. Future research could benefit from a mixed methods approach that combines qualitative insights with quantitative data to validate and expand upon these findings. By acknowledging these limitations, we hope to encourage further exploration and refinement of mHealth technologies, ensuring that they are inclusive, accessible, and capable of addressing the diverse needs of all postpartum parents.

Conclusions

The implications of applying the PPJF to mHealth interventions are significant for both the design and evaluation of postpartum care technologies. This framework provides a structured way to understand how mHealth solutions can support multiple stakeholders within the caregiving unit, ensuring that both birthing and nonbirthing parents are engaged and supported throughout their postpartum journey.

From a design perspective, mHealth technologies should be developed with the recognition that postpartum care is not a singular experience but a set of parallel journeys that intersect and influence one another. This means that features such as mental health screening tools, educational resources, and CM support should be tailored to address the needs of both parents, with attention to how their roles and experiences differ and overlap. For nonbirthing parents, interventions should prioritize increasing their engagement with psychosocial care, helping them to navigate their role in both their own well-being and that of their partner.

In terms of evaluation, the PPJF offers a method for analyzing the success of mHealth technologies by examining their impact on the holistic care experience. It allows researchers and developers to measure not only the physical health outcomes of birthing parents but also the psychosocial outcomes for both parents. This approach can provide a more comprehensive understanding of how mHealth interventions improve care coordination, communication, and mental health outcomes for the entire family unit. By identifying gaps in the usual care settings and showing how mHealth technologies can address these gaps, this framework can be used by other researchers in the future design and evaluation of technologies for postpartum care as a way of ensuring that parents receive the comprehensive, continuous support they need during one of the most critical periods of their lives.

Abstract

Background: Parent-child communication about sexuality education is critical for safe adolescent sexual development and well-being. Yet, there is evidence that these conversations are often ineffective. Digital tools have therefore emerged as promising interventions that may assist parents in addressing sensitive or difficult topics. However, our understanding of the factors that may motivate parental adoption of these technologies remains limited.

Objective: This study aimed to explore factors associated with European parents' intentions to use a digital tool designed to support parent-child sexual communication and complement school-based sexuality education. The study was conducted across the United Kingdom, Belgium, and Italy.

Methods: Using the technology acceptance model, we applied structural equation modeling to identify motivators of parents' *intention to use* the hypothetical app. This included *perceived usefulness* and *perceived ease of use*. *Perceived usefulness* was further analyzed by its subcomponents—*relevance to parenting* and *quality of technology*—through an alternative 3-construct model. Additionally, the associations between demographic characteristics (age, gender, country of residence, and education level) and the latent constructs were assessed.

Results: The study sample included 1296 parents. The explanatory power of the model was R^2=0.47. *Perceived usefulness* was significantly associated with *intention to use* (β=0.67, *P*<.001), while *perceived ease of use* showed no significant association with either *intention to use* (β=–0.01, *P*>.05) or *perceived usefulness* (β=0.10, *P*>.05). An alternative 3-construct analysis revealed that *relevance to parenting* and *quality of technology* were both independently significantly associated with *intention to use* (β=0.09, *P*<.001 and β=0.59, *P*<.001, respectively). Demographic characteristics were also significantly related to the technology acceptance model constructs in the model.

Conclusions: These findings highlight the critical role of perceived usefulness, specifically relevance to parenting needs and the perceived quality of technology, in shaping parental intentions to use digital parent-child sexual communication tools. Developers of educational digital technologies should therefore prioritize high-quality design features to inspire usage. Future research should evaluate real-world digital tools to assess actual usage, long-term engagement, and their effectiveness in enhancing parent-child sexual communication.

Introduction

Background

Sexual health encompasses more than the absence of disease; it includes physical, emotional, psychological, and social well-being [1]. As such, sexuality education must go beyond teaching on anatomy, physiology, and the prevention of sexually transmitted infections and unintended pregnancies. Rather, it should also foster positive self-esteem, the ability to engage in healthy relationships, and the skills needed to navigate adult social and sexual experiences safely and confidently [2]. Effective sexuality education must therefore transcend basic and didactic teaching to engage young people in discussions on diverse attitudes, cultural perspectives, and relationship dynamics [3,4]. This should empower young people to explore their emerging identities and meaningfully engage with the world around them [5].

The role of the sexual health educator may be assumed by different figures in a young person's life: family members, peers, teachers, as well as the wider social and cultural context the child exists within [6-8]. These all act in a network of influence on an adolescent's sexual development [9]. Here, we explore parents' perspectives on a hypothetical intergenerational app designed to support parent-child sexual communication. We proposed an app that would be endorsed by schools and align with regional or national school sexuality education curricula. This app would thus serve as both an educational resource for parents and a prompt to initiating parent-child sexual communication [10]. The app's aim was to enhance young people's sexual development through parental education, as well as ensure close collaboration between the timing and content of parent and teacher sexuality education. Thus, the app would be integrated into the school curriculum and would unlock access to sexuality education content at appropriate times in the child's development, aligned with the timing and topics being covered in school.

Parent-Child Sexuality Communication

Parents are key agents of sexual socialization [8,11]. Recognized as some of the most significant sexual educators, they provide essential information and instill their children with basic values regarding sexual health and well-being [12]. Previous research has examined what constitutes positive and effective parent-child sexual communication. It has been identified that optimal parent-child sexual communication should involve open, supportive, and reciprocal communication [13-15]. Such high-quality parent-child sexual communication appears to support children's safe sexual development [16,17], reduce their sexual risk-taking [18,19], increase their testing for sexually transmitted infections [20], and improve psychological sexual well-being [21]. This provides evidence that parent-child sexual communication can have a significant positive impact on young people.

There are, however, several barriers to effective parent-child sexual communication. First, it appears that parents often initiate discussions after their child's sexual debut [22]. This reduces their ability to influence the young person's behavior. This delay may be because parents perceive their children as too young for sexuality education [23]. Alternatively, it may stem from a desire to protect their child's perceived innocence by avoiding topics deemed too mature or sexual [24]. Parents may also feel unsure how to initiate parent-child sexual communication and therefore not be able to overcome this initial hurdle [25].

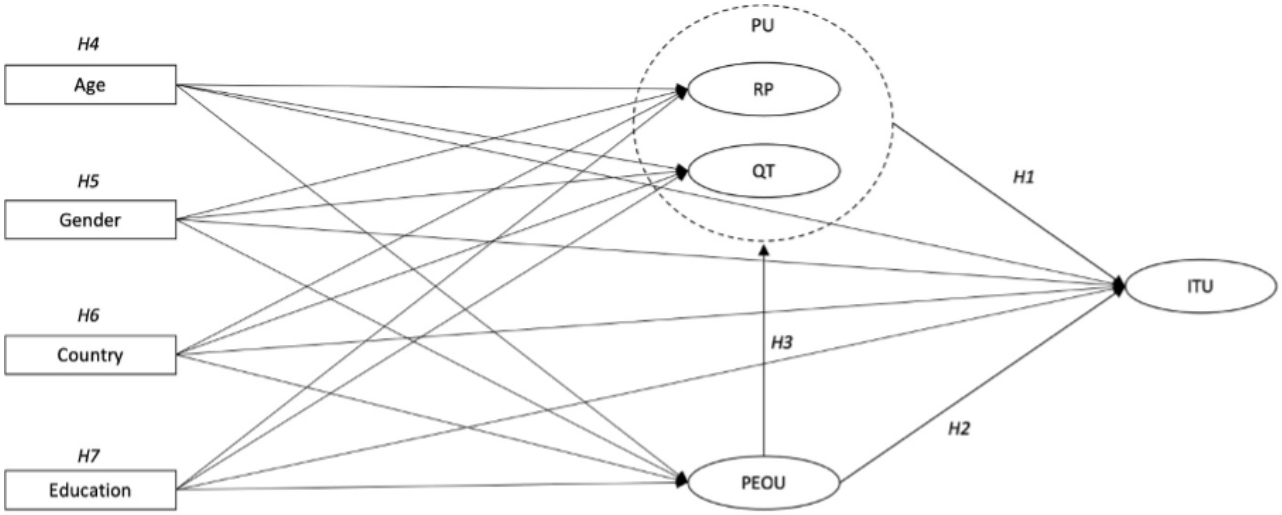
Second, parents appear to overestimate the frequency of their parent-child sexual communication. They report more frequent communication episodes than their child counterparts [26]. This is problematic because effective parent-child sexual communication has been shown to involve regular dialogue rather than one-off discussions [26,27]. This implies that parents may need prompting to remember to engage in regular open communication on sexual health topics with their children.

Finally, the quality of parent-child sexual communication may be low. This may be because of parental discomfort, low self-efficacy, or limited sexual health knowledge [23,28-31]. If parents are misinformed, they may engage in conversations that are inaccurate or inappropriate. This includes conducting inappropriately gendered parent-child sexual communication, such as providing insufficient information on sociosexual issues [32] or reinforcing archaic or negative gender stereotypes [33]. The risk of this appears to be amplified when parent-child sexual communication involves sexual or gender minority children [34]. In these circumstances, parents have been observed to conduct inappropriately heteronormative parent-child sexual communication or overly prioritize discussions on the risk of HIV and other sexually transmitted infections over other aspects of sexuality education [35].

For these reasons, there are ongoing attempts to support parents to engage in better parent-child sexual communication. This has included in-person workshops [36], web-based learning [37-39], as well as intergenerational activities for parents and children to engage in together such as joint homework [40] and online games [41]. Yet, despite these efforts, parental engagement with parent-child sexual communication educational resources remained low [42]. It is therefore crucial to identify what motivates parents to adopt tools that may improve parent-child sexual communication.

Technology Acceptance Model

To examine the factors that are associated with parents' intention to use an app to support parent-child sexual communication, we used a modified version of the technology acceptance model (TAM) [43]. Davis developed the TAM as an extension of Ajzen and Fishbein's theory of reasoned action (TRA) [44]. The TRA predicts human behavior as determined by different cognitions including attitudes toward the behavior and subjective norms. Attitudes toward the behavior were defined as an individual's feelings toward performing the behavior, whether negative or positive [44]. The TRA was thus used as a conceptual



XSL•FO
RenderX

framework for modeling intention to perform voluntary behaviors. The TRA was then adapted in the form of the TAM to apply theories of voluntary behavior to user acceptance and utilization of computer technologies.

The TAM has been previously used as a conceptual framework to assess parental acceptance of educational digital tools [45]. This study is, however, the first to apply the TAM to understand parental intentions to use technology to improve their parent-child sexual communication. According to the TAM, *intention to use* predicts actual system usage. The attitudes that determine *intention to use* are defined as the technology's *perceived usefulness* and *perceived ease of use*.

Perceived usefulness reflects the degree to which a person believes the technology will enhance their job performance. According to the TAM, perceived usefulness has a positive association with intention to use. Thus, individuals should be more likely to adopt technologies that they perceive as beneficial and aligned with their goals. In the context of this study, we hypothesize that parents will be more inclined to use the app if they perceive the digital tool as useful in supporting their parent-child sexual communication (Figure 1).

Figure 1. Technology acceptance model (TAM) framework. Rectangles represent observed (measured) variables, and ellipses indicate latent constructs. The dotted circle denotes a second-order latent construct, where *perceived usefulness* is composed of *relevance to parenting* and *quality of technology*. Arrows indicate hypothesized relationships between variables. ITU: intention to use; PEOU: *perceived ease of use*; PU: *perceived usefulness*; QT: *quality of technology*; RP: *relevance to parenting*.

We adapted the TAM to fit our study's context by inputting elements of the TAM2, in which additional measured factors were added to shape *perceived usefulness* [46]. In our framework, *perceived usefulness* is conceptualized as a second-order latent variable determined by the *quality of technology* and *relevance to parenting*. This decision reflects a theoretical alignment with later iterations of the TAM, in which job relevance (*relevance to parenting*) and output quality (*quality of technology*) are recognized subcomponents of *perceived usefulness* [46]. By embedding *relevance to parenting* and *quality of technology* as dimensions of *perceived usefulness*, our framework acknowledges that parents' perceptions of usefulness are inherently multidimensional. We do, however, adapt the TAM such that *quality of technology* and *relevance to parenting* do not only influence *perceived usefulness* but instead act as its subcomponents.

> Hypothesis: *Perceived usefulness* has a direct and positive association with *intention to use* (H1).

Perceived ease of use may be defined as the extent to which a person believes that using the technology will be free of effort. Perceived ease of use is expected to be positively associated with *intention to use*. If a user finds a technology intuitive and accessible, they are anticipated to be more likely to engage with it [47]. Thus, an app that is easy to navigate should be more appealing to parents and encourage usage (Figure 1).

In our study, we examined parents' *perceived ease of use* of an intergenerational app. We considered that parents might inherently find digital tools difficult to use but may perceive this technology as easier due to its intergenerational design. Specifically, knowing their digitally native children could assist them may positively influence their overall perception of the app's ease of use [48]. Thus, our assessment of *perceived ease of use* incorporated both parents' own perceptions and their views regarding their children's digital fluency.

> Hypothesis: *Perceived ease of use* has a direct and positive association with *intention to use* (H2).

Perceived ease of use is also hypothesized to be positively associated with perceived usefulness, forming an indirect pathway to intention to use [47]. This hypothesis identifies the interplay between the cognitive effort to use a technology and the perception of its functional benefits. Thus, if parents find an app easier to use, they may be more likely to recognize its utility in enhancing parent-child sexual communication. This may then mean that they are more likely to intend to adopt its usage (Figure 1).

> Hypothesis: *Perceived ease of use* has a direct and positive association with *perceived usefulness* (H3).

We hypothesized that parents' sociodemographic factors would be associated with the latent constructs measured in our model (*relevance to parenting*, *quality of technology*, *perceived ease*

XSL•FO
RenderX

of use, and *intention to use*; Figure 1). These factors included age, gender, country of residence, and education level.

We based the relevance of age in our model on previous research identifying the digital divide between adults of different ages [49]. Thus, older generations may feel that they lack the confidence or skills required to effectively engage with an intergenerational app. We anticipated that younger parents may be more accustomed with digital tools and therefore find them easier to use, more useful, and be more willing to engage in technology usage.

We anticipated that parents' gender would also be significantly associated with our first-order latent constructs. Previous research has identified that fathers engage in parent-child sexual communication less frequently than mothers [50]. When fathers educate their daughters on sexual health, they also discuss fewer topics with a more narrowed focus [29]. We therefore predicted that fathers would be less likely to see the app as relevant to their parenting, thus seeing the app as less useful and having reduced intention to use the digital tool.

Parents' *perceived usefulness*, *perceived ease of use*, and their *intention to use* may also be influenced by their perceived social norms. Social norms refer to collective beliefs about typical and appropriate beliefs, behaviors, and actions within a group [51]. These norms are internalized during the socialization process and shaped by cultural and educational contexts [52]. Consequently, our study also examined the influence of the parents' country of residence and education level on the latent constructs. We hypothesized that parents residing in more liberal countries within Europe would be more inclined to engage with parent-child sexual communication digital technologies, whereas parents from more conservative regions would be less willing. Furthermore, consistent with prior research on in-person school-based sexuality education [53], we anticipated that higher parental educational attainment would be associated with greater parental support of sexuality education and thus a higher intention to use a parent-child sexual communication app.

Hypotheses: Age (H4), gender (H5), country of residence (H6), and education level (H7) may be associated with *relevance to parenting*, *quality of technology*, *perceived ease of use*, and *intention to use*.

Methods

Recruitment

This work represents the second phase of a multifaceted survey on parental attitudes toward digital sexuality education [54]. In the first phase, we examined parental views on the age at which adolescents should receive sexuality education topics via a digital app. The present study builds on this by focusing not on the age-appropriateness of content but on parents' intention to use multigenerational digital tools to improve parent-child sexual communication. Data collection occurred between May and June 2022 across 3 regions: Belgium (the Flemish area), the United Kingdom, and Italy. These locations were selected to capture a diverse spectrum of perspectives on sexual and gender diversity within Europe, as reflected by ILGA-Europe rankings. ILGA-Europe assesses the legal and policy landscape for gender and sexual minority people across European countries. It calculates an index score based on the country's laws on equality, gender recognition, family rights, and hate crimes, as well as their tolerance toward freedom of expression. In the 2022 survey, Belgium ranked highly, the United Kingdom received an intermediate ranking, and Italy scored relatively poorly for their lack of inclusive laws and policies [55].

Data were gathered through an anonymous online survey administered by the official polling agency iVOX [56]. iVOX is a Belgian company that holds the largest consumer panel in Belgium. It has been incorporated by the Bilendi research marketing agency, which enables access to panels across European countries. A total of 1500 individuals were recruited from iVOX's closed survey online panels, which comprise between 30,000 and 250,000 members per region. Members voluntarily participated in the surveys and were compensated with gift vouchers upon completion. Members were provided with an informed consent form to complete prior to enrollment. Data were pseudoanonymized at the point of collection.

Eligible participants were adult parents of children aged 9-18 years. The lower age threshold of 9 years was chosen to reflect the age at which many children start to engage with more complex sexuality education in schools [1]. Inclusion criteria required participants to provide essential demographic details such as ethnicity, gender, and sexual identity, as well as complete key sections of the survey (Multimedia Appendix 1). Participants were excluded if they failed to meet these criteria or if their engagement with the survey was deemed insufficient. Insufficient engagement was determined by low or absent variability in response to Likert scale questions, which was presumed to indicate poor attention to the survey content.

Survey Instrument

The survey was administered in English, Dutch, and Italian. The survey was developed in English, and back-translation was performed by native Dutch and Italian speakers (JT and LC, respectively) to ensure linguistic consistency. Before completing the survey, participants were briefed on the hypothetical app. The app was described as a complement to school sexuality education, which would release material in accordance with the school curriculum. It would be available in parent and child versions to download onto their smartphones. To minimize response errors, the questionnaire included working definitions of sexuality education and parent-child sexual communication [57].

Participants reported on individual and family characteristics. Individual characteristics included age, which was nonparametric and presented as median (IQR). Categorical individual characteristics included gender, ethnicity, education level, sexuality, relationship status, and religion. Religiosity was evaluated on a 5-point Likert scale ("I am a religious person"; 1=strongly disagree to 5=strongly agree) and reported as mean (SD). Sociosexual attitude was assessed using items from the Sociosexual Orientation Inventory [58]. Participants rated 3 statements on a 5-point Likert scale (1=strongly disagree to 5=strongly agree): "sex without love is okay," "I can imagine myself being comfortable and enjoying 'casual' sex with different partners," and "I do not want to have sex with a person

XSL•FO
RenderX

unless I am sure that we will have a long-term serious relationship" (reverse coded). Sociosexual attitude was expressed as a composite mean (SD).

Family characteristics included the number of children in the family and the age of the oldest child. These items were nonparametric and expressed as median (IQR). Parents also provided their perceptions of their children's gender and sexual identities. As their children were not surveyed in parallel, we could not confirm the veracity of the perceived identities.

The latent constructs *intention to use*, *perceived ease of use*, *quality of technology*, and *relevance to parenting* were measured using a minimum of two items each (Table 1) [59]. The items for *relevance to parenting* were directly obtained from Pariera [23]. In contrast, the measured items for the other constructs were not previously validated, and their development was informed by prior research instead [23,38,41,60]. To ensure content validity, a panel of 7 European experts in sexuality education and child development reviewed all items. The panel recommended minor adjustments, which were enacted prior to study commencement. All items were rated on a 5-point Likert scale (1=strongly disagree to 5=strongly agree).

Table 1. First-order latent constructs.

Item	Item question
Intention to use (ITU)	
ITU1	I would like my child or children to use the app.
ITU2	I would like to use the app to aid communication with my child about sexual health.
ITU3	I think that the app would improve my child's sexuality education.
Perceived ease of use (PEOU)	
PEOU1	I find apps easy to use.
PEOU2	My child or children find apps easy to use.
Quality of technology (QT)	
QT1	As a parent, I should be able to have my own profile on the app.
QT2	The app should include information sections for me to learn from.
QT3	The app should include example scripts on difficult topics for me to use when talking to my child about sexual health.
QT4	The app should include mock scenarios that I can discuss with my child.
QT5	The app should include educational games for me to play with my child.
QT6	The app should allow my child to flag topics to me that they would like to discuss in person.
QT7	The app should be able to send me alerts to encourage me to broach important or relevant topics with my child.
Relevance to parenting (RP)	
RP1	I think it is important for parents to talk to their children about sex.
RP2	I think parent-child communication about sex has a positive effect on young people.

Statistical Analysis

Demographic data were presented as frequencies for the total sample and stratified by region.

Exploratory factor analysis (EFA) was conducted to identify the dimensionality of the survey instrument. Analysis was performed using maximum likelihood extraction with oblique rotation (oblimin). Confirmatory factor analysis (CFA) was then performed using maximum likelihood with robust standard errors. This was because items were not normally distributed, as determined by the Andersen-Darling tests (P<.001) [61]. Internal consistency was evaluated using composite reliability. Convergent validity was assessed using average variance extracted (AVE), and discriminant validity was evaluated with the Fornell-Larcker criterion [62]. Harman's single-factor test was used to assess for common method bias [63]. Structural equation modeling (SEM) was then applied to test the study hypotheses. Model fits were assessed using multiple commonly used indices—comparative fit index (CFI), Tucker-Lewis Index (TLI), root-mean-square of residuals (RMSR), and root-mean-square error of approximation (RMSEA)—to provide a robust and well-rounded evaluation of fit [64].

Initially, *perceived usefulness* was conceptualized as a latent variable with its own measurement items. However, preliminary analysis revealed that the items developed for *perceived usefulness* did not consistently load onto a factor. To address this, *perceived usefulness* was respecified as a second-order latent variable determined by *quality of technology* and

XSL•FO
RenderX

relevance to parenting. Such higher-order modeling within SEM has been previously performed in other contexts [65]. Thus, in our model, parents' perceived usefulness of a hypothetical parent-child sexual communication app was composed of the quality of the technology and how relevant they deemed the app to their parenting. This adjustment deviates from the TAM but was deemed theoretically plausible and empirically necessary to ensure good alignment between measurement items and their latent constructs. A CFA was performed to assess the loading of *quality of technology* and *relevance to parenting* on the second-order construct *perceived usefulness*. This identified good CFI (0.95) and TLI (0.93), and acceptable RMSEA (0.08). Thus, the adjustment from the original model was empirically justified. Our approach also aligns with prior extensions of TAM in educational contexts, where the original variables of the TAM have been modeled as higher-order constructs to capture multiple elements [45]. Indeed, a recent meta-analysis on the modern use of TAM emphasized the importance of improving the predictive power of technology adoption models by tailoring the TAM to the specific context of the study [47].

The observed constructs—age, gender, country of residence, and education level—were added to the SEM in accordance with our TAM framework. Age was a scale variable. Gender, country of residence, and education level were categorical and therefore inputted with dummy variables. The reference groups for the categorical variables included in the SEM were female, the United Kingdom, and primary education level.

All analyses considered a 2-tailed *P* value of <.05 as statistically significant. This study has been reported in adherence with the Checklist for Reporting Results of Internet e-Surveys (CHERRIES) [66].

Ethical Considerations

Ethics approval was granted on May 25, 2022, by the KU Leuven Social and Societal Ethics Committee (SMEC reference: G-2022-5160). Informed consent was obtained from all participants before survey engagement. Data were anonymized and required and stored securely to ensure confidentiality and compliance with ethical standards. Participants were compensated with gift vouchers through the online platform.

Results

Sample Characteristics

Demographic data are summarized in Table 2. A total of 1296 participants were included in the analysis. The median age of the participants was 46 (IQR 40-51) years. Most participants reached either college-level education (aged 16-18 years) or tertiary education (aged >18 years). The frequencies of gender, ethnic, religious, and sexual minority groups in the sample were low. Only 3.2% (n=42) of study participants identified as noncisgender, 3.9% (n=51) as not heterosexual, and 4.7% (n=61) considered themselves of non-European ethnicity. Similarly, most individuals (n=785, 60.6%) considered themselves Christian. There were, however, a sizeable minority of individuals who identified as not having a religion (n=459, 35.4%). This likely impacted religiosity, where most participants across the 3 regions gave intermediate scores (Table 2). Nearly 89% (n=1150) of participants considered themselves to be in a committed relationship, and the sociosexual attitude scores were intermediate (composite mean 2.89 on a Likert scale from 1 to 5; Table 2). With respect to family characteristics, the median number of children per family was 2 (IQR 1-2). This approximates the total fertility rate across countries in the European Union [67]. The median age of the eldest child of parents surveyed in our sample was 15 (IQR 12-17) years. Across all regions, fewer than 10% of parents perceived their children to identify as a minority gender or sexuality group (n=30 [2.3%] and n=67 [5.2%], respectively).

Sexuality, n (%)				
Heterosexual	1245 (96.1)	438 (94.6)	413 (96.9)	394 (96.8)
Any other sexuality	51 (3.9)	25 (5.4)	13 (3.1)	13 (3.2)
Relationship status, n (%)				
In a committed relationship	1150 (88.7)	411 (88.8)	364 (85.4)	375 (92.1)
In a casual relationship	28 (2.2)	8 (1.7)	11 (2.6)	9 (2.2)
Single	118 (9.1)	44 (9.5)	51 (12.0)	23 (5.7)
Sociosexual attitude[b], mean aggregate value (SD)	2.89 (1.0)	2.9 (1.0)	3.0 (1.0)	2.8 (1.0)
Family characteristics , median (IQR)				
Number of children	2 (1-2)	2 (1-3)	2 (1-3)	2 (1-2)
Age of the oldest child (years)	15 (12-17)	15 (12-17)	15 (12-17)	14 (11-16)
Parental perception of their children's gender, n (%)				
Cisgender female	315 (24.3)	110 (23.8)	106 (24.9)	99 (24.3)
Cisgender male	387 (29.9)	122 (26.3)	114 (26.8)	151 (37.1)
Cisgender female and male	540 (41.7)	213 (46.0)	187 (43.9)	140 (34.4)
One or more transgender, gender fluid, or nonbinary child	30 (2.3)	7 (1.5)	15 (3.5)	8 (2.0)
Their parent does not know	24 (1.0)	11 (2.4)	4 (0.9)	9 (2.2)
Parental perception of their children's sexuality, n (%)				
Heterosexual	1036 (79.9)	336 (72.6)	331 (77.7)	369 (90.7)
One or more homosexual, bisexual, or any other sexuality child	67 (5.2)	30 (6.5)	31 (7.3)	6 (1.5)
Their parent does not know	193 (14.9)	97 (21.0)	64 (15.0)	32 (7.9)

XSL•FO
RenderX

[a]Data were measured on a 5-point Likert scale ("I am a religious person"; 1=strongly disagree to 5=strongly agree).

[b]Data were measured on a 5-point Likert scale reflecting (1=strongly disagree to 5=strongly agree) increasing sexual liberalism.

Measurement Model

The item-level correlation matrix alongside the items' means (SD) is presented in Multimedia Appendix 2. EFA identified 4 factors with eigenvalues >0.5 (Table 3). These factors were assigned based on item loadings ≥0.4, consistent with the recommendations of Stevens [68]. This threshold ensured robust item-factor associations, with all items aligning well with the model's theorized latent constructs. Sample adequacy was confirmed by a Kaiser-Meyer-Olkin statistic of 0.83 [69]. This provided a strong basis for factor analysis. The EFA model demonstrated excellent fit indices: TLI=0.95, RMSEA=0.06, and RMSR=0.02 [70]. The highest interfactor correlation was 0.54, which was below the recommended upper threshold of 0.7 [71]. This supported our assumption of factor independence.

Table 3. Exploratory factor analysis.

	Intention to use (ITU)	Perceived ease of use (PEOU)	Quality of technology (QT)	Relevance to parenting (RP)
ITU1	0.86	—[a]	—	—
ITU2	0.75	—	—	—
ITU3	0.79	—	—	—
PEOU1	—	0.88	—	—
PEOU2	—	0.95	—	—
QT1	—	—	0.57	—
QT2	—	—	0.75	—
QT3	—	—	0.81	—
QT4	—	—	0.73	—
QT5	—	—	0.48	—

RP2	—	—	—	0.90

[a]Not applicable.

To validate the factor structure identified in the EFA, CFA was used (Table 4). The 4-factor CFA model demonstrated similarly excellent fit indices: CFI=0.96, TLI=0.95, and RMSEA=0.06. These values met or exceeded benchmark standards for model fit (CFI>0.9, TLI>0.9, and RMSEA<0.08) [70]. All standardized factor loadings were greater than 0.4, further reinforcing the validity of the associations between items and their respective factors (Multimedia Appendix 3) [68]. Measurement reliability analyses using composite reliability provided additional support as they identified excellent internal consistency (Table 4).

Table 4. Confirmatory factor analysis for first-order latent constructs.

Items	Composite reliability	Average variance extracted
Intention to use	0.86	0.67
Perceived ease of use	0.91	0.84
Quality of technology	0.86	0.48
Relevance to parenting	0.83	0.71

Convergent validity was evaluated using AVE. Three constructs (*intention to use*, *perceived ease of use*, and *relevance to parenting*) achieved AVE values above the recommended threshold of 0.5, reflecting strong convergent validity (Table 4). While the AVE for the *quality of technology* construct was slightly below this threshold at 0.48, it was deemed acceptable given its proximity to the cutoff and the exploratory nature of the study. This was considered appropriate given the overall robustness of the CFA results. Discriminant validity was confirmed using the Fornell-Larcker criterion. Furthermore, Harman's single-factor test revealed that less than 50% of the variance was explained by a single construct model (32%). This alleviated concerns regarding common method bias. Together, these findings confirmed the appropriateness of the model for capturing the intended constructs.

Structural Model

The SEM is presented in Table 5. The SEM demonstrated good fit indices (CFI=0.94, TLI=0.93, and RMSEA=0.05),

XSL•FO
RenderX

demonstrating that the model adequately represented the data. The explanatory power of the model was R^2=0.47.

Perceived usefulness emerged as a dominant determinant of intention to use, demonstrating a strong and statistically significant direct association (β=0.67, *P*<.001). This supports hypothesis H1. However, perceived ease of use did not show a significant relationship with either intention to use (β=–0.01, *P*>.05) or perceived usefulness (β=0.10, *P*>.05). These findings suggested that perceived ease of use, which we had anticipated was a key component of our TAM, did not influence participants' perception of usefulness or their intention to use the parent-child sexual communication app. We therefore rejected hypotheses H2 and H3.

Age was significantly negatively associated with *intention to use* (β=–0.06, *P*=.05). This implied that younger parents were significantly more likely to intend to use the tool to assist with their parent-child sexual communication. Yet surprisingly, this was not explained by any significant relationship between age and the other latent constructs. This included *perceived ease of use*.

Our model identified that male gender had a significant negative association with *relevance to parenting* (β=–0.15, *P*<.001). This indicated that male parents considered the tool less relevant for parent-child sexual communication than their female counterparts. Conversely, male gender was positively associated with *intention to use* (β=0.08, *P*=.01). This suggested that despite its decreased relevance to parenting, men expressed a higher intention to use the digital tool overall. Participants of gender minority groups similarly displayed a significant positive association with *intention to use* (β=0.06, *P*=.05) when compared with their female counterparts. They however had a significant negative association with *perceived ease of use* (β=–0.09, *P*=.05). Thus, compared to female parents, they were less likely to perceive apps as easy to use. However, due to the small sample size of gender minority parents (42/1296, 3.2%), these results should be interpreted cautiously and considered exploratory.

Parents' country of residence also demonstrated significant associations with several constructs. Compared with respondents from the United Kingdom, Belgians demonstrated significant negative associations with *quality of technology* (β=–0.12, *P*=.001), *perceived ease of use* (β=–0.07, *P*=.004), and *intention to use* (β=–0.14, *P*<.001). Thus, the only construct that was not significantly associated with was *relevance to parenting*. This suggests significant cultural differences in technology acceptance between the United Kingdom and Belgium. Conversely, parents from Italy voted similarly to parents from the United Kingdom, except they were significantly less likely to perceive the technology as easy to use (β=–0.79, *P*<.001).

College-educated participants exhibited significant positive associations with *relevance to parenting* (β=0.25, *P*=.05), suggesting increased perceived relevance for parenting among more educated parents. Similarly, those with tertiary or higher education also showed significant positive associations with *relevance to parenting* (β=0.27, *P*=.04). No significant relationships emerged between secondary education level and any of the latent constructs.

Given that *perceived usefulness* was the only observed significant latent construct associated with *intention to use*, we sought to further understand the relative contributions of its subcomponents—*relevance to parenting* and *quality of technology*. A secondary analysis was therefore conducted by constructing an alternative 3-latent-construct model (Figure 2).

This 3-latent-construct model retained good fit indices (CFI=0.91, TLI=0.89, and RMSEA=0.06). The explanatory power of the model was, however, reduced to R^2=0.38. Within this model, both *relevance to parenting* and *quality of technology* had a significant positive association with *intention to use* (β=0.09, *P*=.002 and β=0.59, *P*<.001, respectively). The altered estimates and *P* values for the measured variables are presented in Multimedia Appendix 4 and show equivalent results to the full TAM framework.

Discussion

Principal Findings and Comparison With Previous Works

This work examined the potential for a hypothetical intergenerational app designed to enhance parent-child sexual communication and align parental efforts with school-based sexuality education. Using a modified TAM [43], we explored factors that may relate to parents' intention to use the proposed digital tool. We sampled across 3 distinct regions in an attempt to obtain perspectives of parents across the spectrum of European opinion. Belgium, the United Kingdom, and Italy were selected because they differ in sociopolitical contexts: Belgium has progressive sexuality education policies, the United Kingdom is in an intermediate position, and Italy lacks a national mandate for sexuality education and holds more conservative social norms [55]. These contextual contrasts were mirrored in our descriptive statistics: Italian parents reported higher religiosity and fewer nonheterosexual identities, while parents from Belgium and the United Kingdom were more open to their children having alternative gender and sexual identities. Together, these findings suggest that both sociopolitical climate and demographic composition shaped parents' responses to the hypothetical technology.

We identified that *perceived usefulness* is significantly associated with participants' *intention to use* the app. This aligns with one of the foundational premises of the TAM, which posits that *perceived usefulness*—the degree to which an individual believes that using the technology will enhance their performance—is a critical driver of technology adoption [43]. The importance of *perceived usefulness* has been observed in previous studies on user adoption of new educational information technologies, including multimedia learning environments [72,73]. The dominance of *perceived usefulness* underscores that, in our context, parents' intentions are primarily related to their perception of the app's utility in addressing their parent-child sexual communication needs.

To further investigate the relative contributions of the first-order constructs, which comprised *perceived usefulness*, *relevance to parenting*, and *quality of technology*, we proposed an alternative 3-latent-construct model. While both models demonstrated good fit indices, the TAM-based model explained a greater proportion of variance in *intention to use* (R^2=0.47) compared to the 3-latent-construct model (R^2=0.38). In the 3-latent-construct model, both *relevance to parenting* and *quality of technology* significantly influenced *intention to use*. These findings align with prior studies on intergenerational sexuality education tools. Parents who ascribe value to sexuality education were more likely to be motivated to engage in new technologies to improve their parent-child sexual communication [42]. Furthermore, we identified the critical role of reliable, engaging, and content-rich technologies in facilitating parental adoption of digital tools [41]. In this work, features deemed attractive by parents included example scripts, interactive games, mock scenarios, and alert features. Similarly, surveys of children and adolescents have emphasized the importance of high-quality

XSL•FO
RenderX

app features in driving user adoption of sexuality education technologies [60,74].

Alongside identifying the significant positive association of *perceived usefulness* with *intention to use*, we also identified that sociodemographic factors were significantly associated with parents' intention to use the digital technology. Younger parents were more likely to intend to use the sexuality education app, which is in keeping with their comfort with digital educational adjuncts [75]. Furthermore, parents who did not identify as female were also more likely to intend to use the app. This may be because mothers feel more self-efficacy and confidence engaging in parent-child sexual communication and therefore do not see the same utility [18]. Notably, the country of residence was also an important determinant of survey responses. Belgian parents reported lower perceived ease of use, technology quality, and intention to use compared with British parents, despite broadly similar demographic profiles. This may reflect differences in cultural expectations around school-parent collaboration, with Belgium's comprehensive sexuality education perhaps reducing the perceived need for supplementary tools [76]. Conversely, in Italy, lower ease of use ratings may be linked to the more limited digital literacy when compared to its European neighbors [77]. These differences suggest parents across Europe will interact differently with virtual sexuality education technologies, and that national policies, sociocultural norms, and digital confidence must be considered when adapting such tools. Finally, we identified that the relative importance ascribed to parent-child sexual communication increased among parents who had higher educational attainment. This has been previously identified in other settings [78,79].

Unlike *perceived usefulness* or sociodemographic factors, *perceived ease of use* was not significantly associated with the other constructs in the model. This diverged from the classical TAM and contrasts with prior research on education technologies, which found that poor usability negatively affected parental engagement in their children's digital education [45]. In those cases, parents were less engaged in their child's online learning when they perceived the technology as difficult to use. However, our findings suggest that parents' intention to use an intergenerational app to support parent-child sexual communication was independent of its usability. Instead, parents were willing to engage with educational technology they found useful, regardless of how easy it was for them or their children to navigate. This discrepancy may be because our study only examined parents' theoretical intention to use, rather than their actual usage behaviors. Alternatively, it may reflect contextual differences, as the referenced study examined parents' technology usage to facilitate children's home-based learning during the global COVID-19 pandemic [45]. Given the heightened parental stress during this period, which negatively impacted children's learning outcomes [80], parents may have had reduced emotional and cognitive capacities to engage effectively with new or challenging educational technologies.

Our work is also not the first study to observe a diminished role for *perceived ease of use* within the TAM. Several studies on online educational platforms have similarly found that *perceived ease of use* does not significantly predict *intention to use* [81,82]. However, unlike our study, these works primarily sampled Generation Z students (born between 1995 and 2012) [83]. As "digital natives" who grew up with internet and mobile phone technologies [84], Generation Z may be less concerned with ease of use due to their familiarity and adaptability with new digital tools. In contrast, our study population consisted of parents with a minimum survey age of 18 years and a median age of 46 (IQR 40-51) years. It may therefore be that parents are willing to overlook usability challenges if they perceive the technology as highly useful or important, such as in the context of parent-child sexual communication. Yet, we also observed that lower parental ages were associated with greater intention to use the technology. This implies that younger parents may have the additional benefit of feeling comfortable tackling new technology challenges, independent of their current perceived ease of use.

Limitations

There are several limitations to the study that warrant discussion. First, the study relied on an online polling agency and a closed survey panel for recruitment, which may have introduced sampling bias. This may have introduced a self-selection bias, where only individuals motivated and interested in the topic with sufficient free time took part in the survey. To reduce the risk of this and increase overall motivation to engage with the project, we ensured that participants were adequately compensated for their involvement. Yet, there remained a predominance of cisgender, heterosexual, Christian, and European ethnicity participants in the sample. This limited diversity constrains the extent to which our findings can be applied to broader and more diverse parent populations. However, this demographic composition aligns with region-specific census data in the United Kingdom, which is the only region studied here with detailed census records available [85]. Nevertheless, it would be important to survey parents and children from backgrounds underrepresented here, who may have different attitudes toward digital parent-child sexual communication tools [13,34]. Future work should therefore use inclusive recruitment strategies to capture the parental attitudes among minority groups, such as community partnerships and targeted oversampling of underrepresented groups. Qualitative approaches such as focus groups or in-depth interviews may also provide richer insights from parents underrepresented in online survey panels.

Second, the hypothetical nature of the app may have constrained participants' engagement with the survey items. Unlike studies evaluating real-world interventions [42], our work relied on participants' imagination to envision the app's features, utility, and their intention to use it. This reliance on the hypothetical may have reduced the real-world applicability of our findings, as stated intention may not translate to actual adoption and engagement in the technology. There is a potential gap between an individual's intent to use and actual usage behaviors, as has been observed among consumers in other settings [86]. Furthermore, causality could not be established due to the cross-sectional nature of the study. While our model provides insights into relationships between constructs, future longitudinal or experimental studies with app prototypes are necessary to determine causal effects and understand how parental

XSL•FO
RenderX

engagement evolves over time in real-world settings. This evaluation may also include objective usage data, for example, in-app analytics.

Third, there are limitations related to our construction of the specific TAM model. Our *perceived ease of use* construct was also measured using only 2 items (capturing parents' ease and their perception of their children's ease). This was to avoid an excessively long and tiring survey, which may have reduced respondent attention and answer quality. Yet while reliability was high, the reduced breadth of our measure may have limited its sensitivity and contributed to the lack of significant associations observed. Future work may therefore expand on our measurement to assess whether these influence parental intent. Furthermore, we modified *perceived usefulness* to a second-order latent construct comprising *quality of technology* and *relevance to parenting*. While this approach was empirically justified, it deviated from the traditional TAM framework [43]. This modification prevented us from evaluating *perceived usefulness* as an original construct. This may limit the comparability of our findings with studies that operationalized *perceived usefulness* as a single first-order construct. However, our decision reflects known extensions of TAM and was therefore both justified. Our decision was in keeping with previous research in educational and e-learning settings, which have adjusted the TAM and its constructs to specific contexts [46]. Furthermore, as the purpose of the TAM is to provide a theoretical springboard for understanding the psychology of technology acceptance, it is necessary to tailor the foundational model to the specific context in which the research is performed. If this is not performed, the predictive capability of the TAM may be limited [47].

Implications of Study Findings

This study provides insights for researchers, educators, and app developers aiming to enhance parent-child sexual communication through digital interventions.

From a theoretical perspective, our findings add to a growing body of evidence that suggests that *perceived ease of use*—a previously core tenet of the TAM—plays a diminishing role in technology adoptions as digital literacy becomes ubiquitous among younger generations [87]. This shift calls for a re-evaluation of traditional TAM constructs when applied to "digital native" groups who feel comfortable with trialing new technologies. Future studies should investigate whether this trend persists across different cultural and technological settings.

From a practical standpoint, the overarching importance of *perceived usefulness* to parents' intention to engage in parent-child sexual communication apps should be central to any future app development. We identified that parents who perceive sexuality education as relevant and important were more likely to be motivated to use an app to assist and guide their parent-child sexual communication. Future work should consider how to encourage and inspire less motivated parents to engage in parent-child sexual communication. Our findings directly inform this, as they highlight which sociodemographic groups may be less likely to adopt the technology and why. Tailored information campaigns may then be developed to build trust and highlight the apps' utility for these groups, as well as explain the benefits of comprehensive sexuality education. For example, our identification of education level as significantly associated with perceived relevance to parenting should be useful to future researchers in this area. Care should be taken to engage parents with lower levels of educational attainment to emphasize the importance of parent-child sexual communication on their children's development. It is, however, noteworthy that this reduction in perceived relevance to parenting did not affect parents' overall intention to use the technology.

Our work also underscores the importance of prioritizing high-quality features in app development to improve parent-child sexual communication. The parents surveyed in this study prioritized the quality of technology as a critical determinant of intention to use. This encompassed app content reliability, functionality, multimedia options, and user engagement features. Educators should therefore focus on developing apps that are functional and high specification. However, balancing these desirable features against the associated development and operational costs of such complex app functionalities is essential [88]. Cost-benefit analyses may therefore be helpful to identify the most impactful features to prioritize in resource-constrained settings [89]. Collaboration between developers, schools, and policymakers could also help distribute costs to ensure high-quality tools are equitably accessible to families. Engaging parents through qualitative work in the design process may yield further insights into their preferences and priorities, ensuring that the most desirable app features are incorporated. Additionally, the recent advent of large language models and artificial intelligence technologies offers promising avenues to enhance content customization to the learning needs of the parent-child dyad with the aim to maximize user interaction [90]. Future work may also explore the role of cost-sharing models, such as government subsidies or collaborations between schools, to make development of high-quality parent-child sexual communication tools feasible and the apps freely accessible to families. When a suitable app prototype has been developed, longitudinal studies will be needed to assess how parental engagement evolves as they interact with a parent-child sexual communication app over time. Understanding these dynamics could inform strategies to sustain long-term adoption and maximize the app's effectiveness. For example, periodic app updates based on user feedback may improve satisfaction and retention [91].

Finally, children's engagement is integral to the success of any intergenerational interventions [26]. It is therefore imperative to include children in future evaluations of parent-child sexual communication apps. The maturity of the educational content they receive on the app and discuss with their parents [1], as well as their preferences for different app features [92], will evolve as they develop. Sampling across diverse age groups will be helpful to ensure apps resonate with children's evolving needs and preferences.

Conclusions

This study contributes novel insights into digital sexuality education technologies aiming to enhance parent-child sexual communication. We identified that *relevance to parenting* and

XSL•FO
RenderX

quality of technology were the critical determinants of parental intention to use hypothetical sexuality education apps. Our findings contribute to the theoretical advancement of the TAM in the context of parent-child sexual communication and provide actionable recommendations for app developers, researchers, and educators. Future research should involve real-world evaluations of intergenerational sexuality education apps to further refine our understanding and improve communication tools available for parents and their children. This is with the overall aim of ensuring parents can engage in high-quality, unprejudicial, and open communication with their children on sexual health topics.

Acknowledgments

We would like to thank the panel of European experts who assisted in modifying and improving the survey instrument.

Abstract

Background: Chatbots are increasingly accepted in public health for their ability to replicate human-like communication and provide scalable, 24/7 services. The high prevalence of dental caries in children underscores the need for early and effective intervention.

Objective: This study aimed to develop the 30-Day FunDee chatbot and evaluate its effectiveness, usability, and acceptability in delivering oral health education to caregivers of children aged 6 to 36 months.

Methods: The chatbot was created using the artificial intelligence (AI) chatbot behavior change model, integrating behavioral change theories into content designed for 3 - 5 minutes of daily use over 30 days. A pre-post experimental study was conducted from December 2021 to February 2022 in Hat Yai District, Songkhla Province, and Maelan District, Pattani Province, Thailand. Fifty-eight caregivers completed a web-based structured questionnaire at baseline and 2 months post baseline to evaluate knowledge, protection motivation theory-based perceptions, and tooth-brushing practices. Usability was assessed via chatbot logfiles and a web-based questionnaire at 2 months post baseline. Acceptability was evaluated through three methods: (1) open-ended chatbot interactions on day 30, (2) a web-based structured questionnaire at 2 months post baseline, and (3) semistructured telephone interviews with 15 participants 2 weeks post intervention. Participants for interviews were stratified by adherence levels and randomly selected from Hatyai and Maelan districts. All self-reported variables were measured on a 5-point Likert scale (1=lowest, 5=highest).

Results: The chatbot was successfully developed based on the 4 components of the AI chatbot behavior change model. Participants had a mean age of 34.5 (SD 8.6) years. The frequency of tooth brushing among caregivers significantly improved, increasing from 72.4% at baseline to 93.1% two months post baseline (P=.006). Protection motivation theory-based perceptions also showed significant improvement, with mean scores rising from 4.0 (SD 0.6) at baseline to 4.5 (SD 0.6) two months post baseline (P<.001). The chatbot received high ratings for satisfaction (4.7/5, SD 0.6) and usability (4.7/5, SD 0.5). Participants engaged with the chatbot for an average of 24.7 (SD 7.2) days out of 30. Caregivers praised the chatbot's content quality, empathetic communication, and multimedia design, but noted the intervention's lengthy duration and messaging system as limitations.

Conclusions: The 30-Day FunDee chatbot effectively enhanced caregivers' perceptions of oral health care and improved tooth-brushing practices for children aged 6 - 36 months. High user satisfaction and engagement demonstrate its potential as an innovative tool for oral health education. These findings warrant further validation through large-scale, randomized controlled trials.

Introduction

Chatbots have emerged as a socially responsible technology to bridge socioeconomic disparities and promote equitable access to high-quality health care [1,2]. Chatbots are digital tools that emulate human conversation and have the potential to promote health education, support behavior changes, and deliver health care, especially for clinical or vulnerable populations. Their adaptability also makes them suitable for deployment in a variety of sizeable and diverse samples [3]. Chatbots provide flexible, on-demand support, offering personalized assistance and content with continuous availability, helping to mitigate the limitations of traditional telehealth services [4]. Overall, chatbots offer a humanized interaction that can support health care professionals in managing and preventing conditions on a societal scale [5].

Multiple studies attest to the effectiveness of incorporating chatbots in health care, illustrating their role in facilitating a modification of health-related behaviors [3,6-8]. However, the existing literature on the use of chatbots for dental health purposes is limited [9,10], and few studies have explored the complicated process of constructing chatbots with oral health goals in detail.

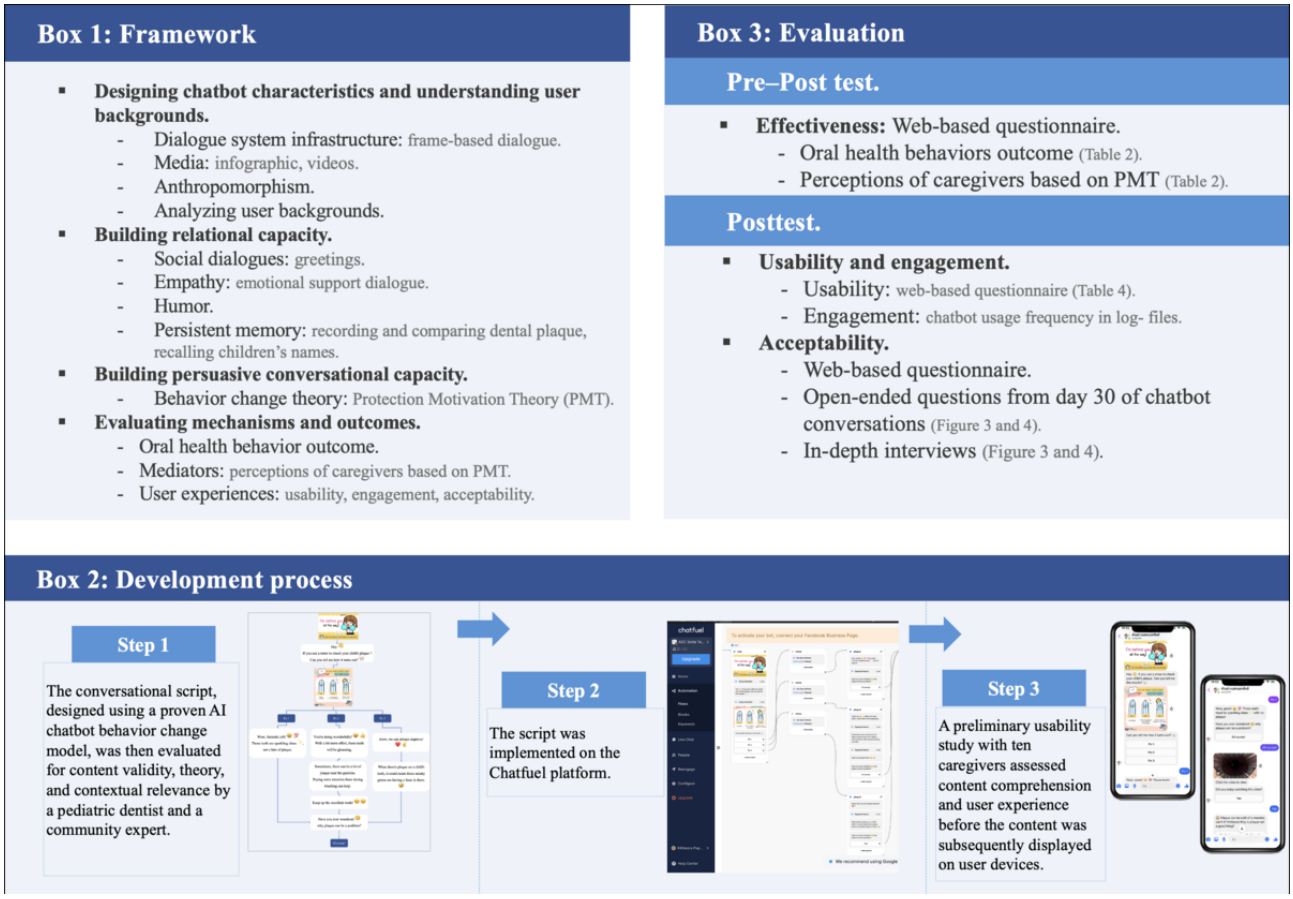
Zhang et al [11] suggested some guidelines for the development of an artificial intelligence (AI) chatbot for behavior modification with the formulation of a theoretical framework that consists of four essential components: (1) specifying chatbot characteristics and understanding user backgrounds, (2) establishing relational capacity, (3) establishing persuasive capacity using behavioral-based theory, and (4) implementing an evaluation mechanism to assess outcomes.

Early childhood caries (ECC), identified as a significant chronic disease, emerges from the dynamic interplay of various risk and protective factors over time [12]. In Thailand, the earliest detection of noncavitated caries occurred at 9 months of age, while cavitation was first identified at 10 months of age [13]. In this context, parental tooth brushing, conducted twice daily with a rice-sized amount of fluoridated toothpaste, has been proven to be a pivotal strategy for reducing dental caries in children [12], whereas systematic reviews revealed that the effectiveness of simple health education in preventing ECC is restricted [14]. In line with a review regarding oral health promotion for ECC, home visits, and hands-on techniques for dental health education substantially enhance habit formation and effectiveness [15]. In addition, caregivers should receive practical training and empowerment from oral health professionals [16]. However, these interventions must be tailored to each individual, requiring not only highly skilled dental personnel but also considerable time and financial resources [17]. Chatbots have the potential to serve as a scalable model for skill development, motivation, problem-solving, and continuous follow-up, replicating the advantages of home visits.

Habits emerge as a consequence of acquiring repeated patterns of behavior, originating from consistent contextual stimuli, and they are formed through automated responses to the conditions in which they happen [18]. The research findings revealed that the time required to form habits varied, with values ranging from 18 to 254 days, depending on the level of complexity or challenge associated with a particular behavior [19]. Monitoring and reinforcement are effective ways to develop healthy habits [19,20] toward caries prevention in children [15], however, interaction with health professionals often requires traditional onsite visits, substantial time, and financial cost [21,22].

The protection motivation theory (PMT), a key theory in health psychology, explains how people change their behavior based on their evaluation of threats and their ability to cope with them [23,24]. The threat appraisal component of the PMT comprises 2 key elements: the individual's assessment of the disease's severity (perceived severity) and the probability of developing the disease (perceived vulnerability). The PMT additionally specifies that attitudes and behavior modification are indirectly influenced by the emotional state of fear arousal, which occurs through the evaluation of the danger's severity. The coping appraisal of the model comprises the individual's response efficacy, which is the expectation that implementing the recommendations will eliminate the threat, and self-efficacy, which is the belief in one's own ability to effectively execute the recommended course of action. Behavior performance should be significantly influenced by the intentions that are mediated by the cognitive predictors of threat and coping appraisals [25,26]. Kimhasawad et al [27] used a PMT-based education program to guide caregivers of 9 - to 12-month-old infants in adopting proper tooth brushing techniques, revealing that this approach effectively motivated and increased awareness, leading to a positive change in the oral health behavior of caregivers.

Currently, there is no standard evaluation method for a health care chatbot [28,29]. The concepts of usability and acceptability were identified as important factors for evaluating the use of chatbots [17]. However, there are differing definitions and some overlap between these terms [29,30]. Our study adopted broad interpretations of these concepts: usability as use, engagement, and ease of use; acceptability as satisfaction; continued use intention; and appropriateness. In addition, the frameworks of Zhang et al [11] and Denecke et al [31] were applied for content evaluation integrating usability and acceptability. This comprehensive evaluation provides a holistic assessment of the factors influencing chatbot adoption [32].



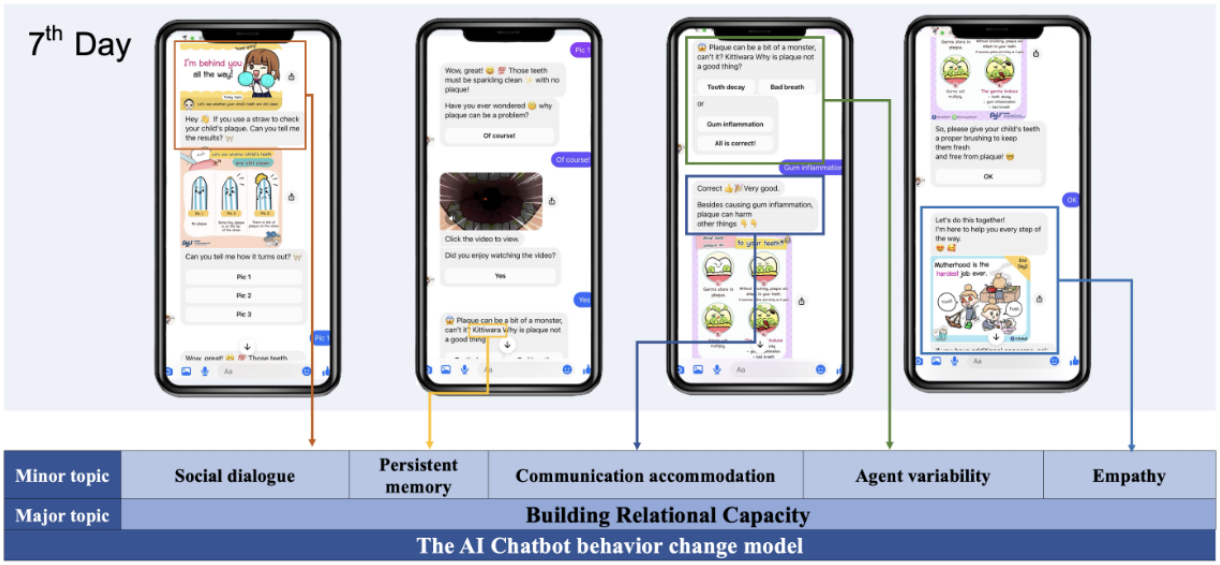
Therefore, the study aimed to elucidate the chatbot development process using PMT and Zhang's model. In addition, the pre-post study sought to assess the effectiveness, usability, and acceptability of a developed chatbot, the "30-Day FunDee," which was intended to educate caregivers of children between 6 and 36 months regarding oral health.

Methods

Figure 1 illustrates the comprehensive process involved in the defining framework, development, and evaluation of the 30-Day FunDee oral health promotion chatbot.

XSL•FO
RenderX

Figure 1. Framework, development, and evaluation of the 30-day FunDee chatbot. AI: artificial intelligence.



Defining a Framework for the 30-Day FunDee Chatbot

Designing Chatbot Characteristics and Understanding User Background

The objectives and target audience were specified for educating and assisting Thai caregivers with oral hygiene care for children aged 0 to 3 years. Designing chatbot characteristics encompassed dialogue system infrastructure, media, and anthropomorphism [11] as shown in Figure 2. The chatbot's dialogue system infrastructure is frame-based, enabling users to select their responses. The chatbot created a variety of media, including simple and clear language, illustrations, written text, audio components, conversational dialogue, infographics, animations, animated songs, and videos with authentic and animated content. Moreover, within the anthropomorphic realm, "Dr. Pin" the chatbot's dentist avatar, was depicted as a kind, charming, empathetic, and attentive caregiver for children's oral health.

XSL•FO
RenderX

Figure 2. Screen example of the chatbot translated from Thai to English, showing dialogues that incorporate the design characteristics of the AI behavior change model on the seventh day. AI: artificial intelligence.

Understanding the user's background is critical in designing chatbots for behavior change [11,33]. Based on previous studies [34-36], the majority of caregivers were 20- to 40-year-old mothers with low to middle socioeconomic status who were responsible for nurturing their children, especially in relation to their children's tooth brushing. The chatbot's role was to assist users in overcoming obstacles and offering emotional support in childcare. Due to internet availability, both urban and rural caregivers could access the chatbot.

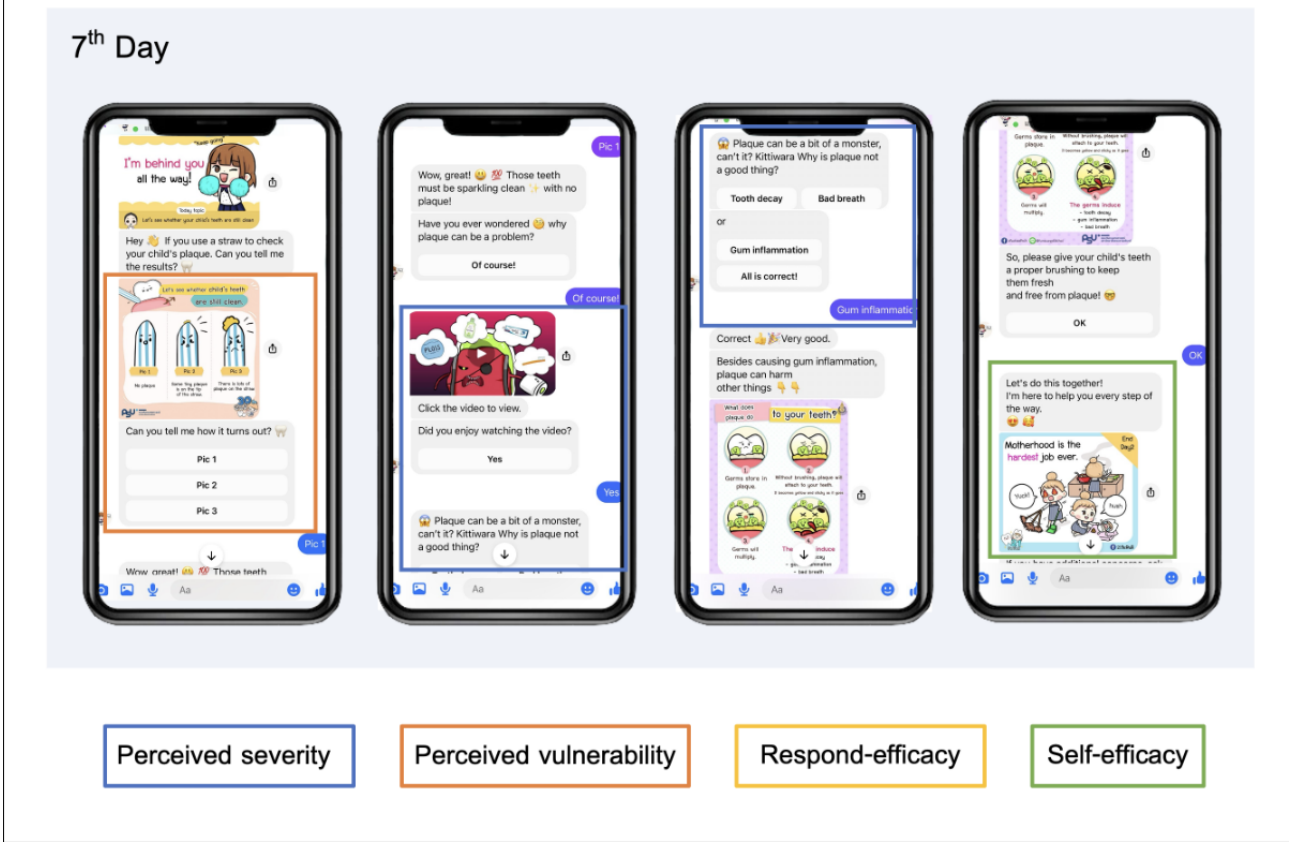
The content of the 30-Day FunDee chatbot was influenced by pediatric and community dentistry experts' recommendations and qualitative research insights on Thai caregivers' experiences with children's tooth-brushing behaviors [35,36], insights from community caregivers, inquiries from dental clinics, and knowledge gained from the earlier 21-Day FunDee chatbot, which is mentioned elsewhere [9]. Therefore, the updated chatbot was extended from 21 to 30 days, including more various media and dialogues, especially focusing on tooth-brushing practices.

Building Relational Capacity

Building relational capacity involves using elements such as social dialogues, empathy, relationship discussion, humor, self-disclosure, persistent memory, and agent variability [11,29]. Daily, the chatbot initiated conversations with charming greetings and concluded with farewell messages (Figure 2) that conveyed understanding and encouraged parents or caregivers in childcare [11]. For goal setting [37], daily welcome cards were designed with topics to be discussed.

The chatbot was designed to consistently display comprehension, empathy, and emotional support during interactions, especially when users encountered obstacles.

XSL•FO
RenderX



Emojis and animated GIFs conveying positive feedback and emotions were incorporated to increase engagement. Progress tracking enabled self-comparison and confidence-building over time. Periodic child dental plaque assessments prompted reflection on tooth-brushing techniques. Positive reinforcement was provided when plaque decreased, while setbacks received encouragement without punishment. Conversation features like remembering children's names, revisiting prior discussions, and using age-appropriate informal language aimed to simulate natural human-to-human dialogues. These elements enhanced the user experience and facilitated task completion [37,38] (Figure 2).

Building Persuasive Conversational Capacity

Overview

The 30-Day FunDee chatbot, meticulously designed, provided oral health education to caregivers based on PMT (Figure 3) for behavior modification by systematically sequencing threats and coping topics. Examples of chatbot topics are shown in the following sections.

Figure 3. Screen examples of chatbot dialogues translated from Thai to English, incorporating protection motivation theory (PMT) on the seventh day.

Perceived Severity

The importance of primary teeth, the consequences of dental infections, and anticipating problems from poor oral health care were discussed.

Perceived Vulnerability

The chatbot instructed caregivers on the child's dental plaque assessment and provided animation and infographics explaining plaque. Periodic plaque checks were encouraged, and an API enabled tracking of plaque levels over time.

Belief in Response Efficacy

Benefits and instructions, especially for tooth brushing, were incorporated into a variety of videos, infographics, and games. The chatbot also asked caregivers about children's sugar intake and diet to discuss potential health impacts.

Belief in Self-Efficacy

The chatbot was designed to increase caregiver self-efficacy for children's oral health management through motivational techniques and daily emotional support. At the end of each conversation, it expressed empathy for mothers' exhaustion and encouraged overcoming obstacles.

Chatbot Development Process

The development of chatbots followed a systematic, 3-phase process, as illustrated in Figure 1. The first step involved designing the conversational flow, which included scripts, infographics, videos, and other content. This step was crucial to ensure that the chatbot can engage effectively with users. This phase followed an established AI chatbot behavior change model and PMT, which guided the creation of responsive conversations tailored to encourage specific behavioral outcomes. The next step involved implementing the conversational flow using the Chatfuel platform, which enabled the transformation of the predesigned scripts into interactive

XSL•FO
RenderX

conversations accessible on users' devices. The Chatfuel platform facilitated the efficient deployment of the chatbot design, ensuring seamless operation and scalability to accommodate the intended target audience, without advanced programming skills and includes push message functionality [39]. Given that over 80% of Thailand's population uses Facebook [40], Facebook Messenger was chosen as the delivery platform using Chatfuel.

The final step involved presenting the chatbot's content on user devices. After implementation, the chatbot became accessible, with its content displayed across various devices. This stage completed the chatbot's development, enabling it to interact with users as intended and deliver the conversations crafted during the initial phase. The chatbot used persuasive communication, including comprehension, empathy, and suggestions, to address the child's oral health challenges. It used a decision tree with recommended responses along with natural language understanding [37]. A pediatric dentist and a community expert evaluated the content validity, theoretical basis, and contextual appropriateness. A preliminary usability study with 10 caregivers evaluated content understanding and user experience.

Chatbot Evaluation

Chatbot evaluation should assess user patterns, user experience, conversation quality, perceived relational ability, and behavior outcomes [11,31]. This chatbot was evaluated on all aspects with the exception of oral health examinations due to COVID-19 pandemic operation limitations.

Participants and Recruitment

From December 2021 to February 2022, a total of 66 caregivers were recruited using convenience sampling including 29 caregivers from the Early Childhood Development Center at the Faculty of Medicine, Prince of Songkla University, Hat Yai District, Songkhla Province, and 37 caregivers from the Early Childhood Development Center in Maelan District, Pattani Province, Thailand. The inclusion criteria for caregivers were as follows: (1) currently caring for children aged 6 to 36 months with at least 1 tooth; (2) their children had no disabilities or significant underlying medical conditions that could have affected their oral health; and (3) equipped with electronic devices such as computers, tablets, or mobile phones, allowing for daily internet access and a propensity to interact via Facebook Messenger. The exclusion criteria were (1) caregivers who could not speak, read, or write Thai and (2) caregivers who were opposed to the data collection.

The sample size was calculated using G*Power software (version 3.1; Heinrich Heine University Dusseldorf) to determine the mean difference in the frequency of tooth brushing per day between pre- and postintervention time points. An effect size of 0.4283, derived from unpublished data of a previous multicenter study conducted across 6 provinces in southern Thailand that evaluated the effectiveness of a chatbot in promoting tooth-brushing behaviors among 398 children aged 6 months to 2 years [41], was used. Additional parameters included a correlation coefficient of 0.5, an α level of .05, and a power of 0.8. The calculation indicated a minimum of 60 participants was required. To account for a 10% dropout rate, the target sample size was increased to 66 participants to ensure sufficient data for analysis.

Initial contact involved outreach at childcare centers and communication with caregivers via Line or phone calls to assess eligibility and interest in participation. After identifying eligible caregivers, researchers scheduled appointments to provide detailed study information. Invitation letters were distributed by the research team (Multimedia Appendices 1 and 2).

Data Collection

Self-Reported Oral Health Behavior, Usability, and Acceptability

At baseline and 2 months later, a structured self-administered questionnaire (Multimedia Appendices 3 and 4) via Google Forms gathered information regarding participant characteristics and the effectiveness of chatbot use in terms of tooth-brushing behaviors and PMT-based oral health perceptions. At 2 months, usability and overall user satisfaction measures were added.

Oral hygiene behaviors were assessed using categorical questions on tooth cleaning methods, fluoride toothpaste use, and toothpaste amount.

Oral health perceptions were assessed using 14 items based on PMT including perceived severity (5 items), vulnerability (1 item), response efficacy (4 items), and self-efficacy (4 items), measured on a 5-point Likert scale.

A 5-point Likert scale, ranging from 1 (lowest) to 5 (highest), was used for all variables. The mean (SD) for each group was calculated by averaging the total items in each category. Negative items were reverse-scored before calculating the mean. The mean scores were interpreted as follows: 1.0 - 1.79 were the lowest perceptions, 1.8 - 2.59 were low, 2.6 - 3.39 were moderate, 3.4 - 4.19 were high, and 4.2 - 5.0 were highest.

The usability test was designed in relation to models of Denecke et al [31] and Zhang et al [11], consisting of 15 items. This measured user experience (3 items), conversation quality (4 items), perception of relation and capacity (2 items), self-esteem (4 items), and usefulness (2 items) on a 5-point Likert scale with the same calculation and interpretation methods as shown above. In addition, the engagement was quantified by analyzing use days from chatbot logfiles.

The assessment of acceptability was conducted using 3 different methodologies. First, on day 30, participants interacted with the chatbot, responding to open-ended prompts designed to elicit both positive and negative use experiences. Second, a structured questionnaire was administered 2 months post baseline. It consisted of 1 item evaluating overall user satisfaction using a 5-point Likert scale, ranging from 1 (lowest) to 5 (highest).

Two weeks post intervention, semistructured in-depth telephone interviews were conducted. Participants (n=15) were stratified into 4 groups based on adherence levels and were randomly selected from the Hatyai and Maelan districts with equal distribution: 100% adherence (30 d, n=4), 80% - 99% adherence

XSL•FO
RenderX

(24 - 29 d, n=4), 50% - 79% adherence (15 - 23 d, n=4), and <50% adherence (<15 d, n=3).

Participants were contacted to schedule interviews. Nonresponders were replaced through random selection until quotas were met, except in group 4, where participants were unreachable. Interviews, lasting 10 - 15 minutes, covered the study's objectives; interview methods; and explored satisfaction, dissatisfaction, feedback, and suggestions. Field notes were recorded during each interview.

Quality Control of Questionnaire and In-Depth Interview

The content and construct validity of the questionnaires and guiding questions for in-depth interviews were evaluated by 3 experts: a community dentist, a pediatric dentist, and a dentist from a public hospital. The usability test, adapted from Denecke et al [31] and Zhang model frameworks [11], was validated by the same 3 experts. Reliability for PMT-based perceptions was determined using Cronbach α (α=0.85). Face validity of the overall questionnaire was established through pilot telephone interviews with 10 caregivers. The in-depth interview guidelines were validated by 3 experts. To ensure triangulation, 2 additional independent researchers conducted content analysis. Multiple data collection methods were used to assess acceptability.

Statistical Analysis

Descriptive statistics were presented as means (SD) for continuous variables, and frequency (percentage) for categorical variables. Within-group comparisons were used for the nominal/categorical data, and chi-square or Fisher exact tests were used. For continuous data, paired *t* tests were used. Satisfaction scores were reported as the mean (SD) on a 5-point scale. IBM SPSS Statistics for Windows (version 29.0.0.0 (241); IBM Corp) was used.

Analysis of Qualitative Data

The responses of the participants from in-depth interviews were analyzed thematically using an inductive method guided by the procedure outlined by Jang et al [42] and Fitzpatrick et al [37]. Data from in-depth interviews and open-ended queries were analyzed using thematic analysis [43,44] and reported in terms of frequency.

Ethical Considerations

Adhering to social distancing measures recommended during the COVID-19 pandemic, participants attended group Zoom information sessions where researchers explained the study comprehensively. To ensure privacy, attendees could use pseudonyms and disable cameras. The researcher outlined the following: (1) study purpose; (2) data handling procedures; (3) privacy measures; and (4) participant rights, including voluntary participation, and withdrawal options. Questions could be asked during the session or privately via Zoom chat. Verbal consent was obtained during the session, with the completion of the web-based questionnaire (Google Forms) serving as additional confirmation. Participants could withdraw by not completing the questionnaire. Privacy measures included guidelines against sharing others' identities or comments outside the session, and secure data storage with restricted access to research team members only. The protocol was registered to the Thai Clinical Trials Registry (TCTR20210927004) and approved by the Institutional Review Board of the Faculty of Dentistry at Prince of Songkla University (EC6407-053).

Results

Characteristics of Participants at the Baseline

Initially, 66 individuals were enrolled in the study, but following the 30-day postintervention period, 8 enrollees were excluded due to loss of follow-up.

The demographic and socioeconomic status of participants (n=58) were presented below (Table 1). The mean participant age was 34.5 (SD 8.6) years, and 87.9% (n=51) were mothers. The mean child age was 20.9 (SD 7.9) months. Of the participants, 55.2% (n=32) participants obtained oral hygiene advice via the web. Most web-based use was 51.7% (n=30) of the participants for between 3 and 5 hours per day, then >6 hours per day (15/58, 25.9%) and followed by 1 - 2 hours per day (13/58, 22.4%). Daily internet use was 72.4% (n=42) during the week.

XSL•FO
RenderX

Table . Demographic and socioeconomic characteristics of study participants (N=58).

Demographic characteristics	Values, n (%)
Caregiver's education level	
Lower than Bachelor degree	26 (44.8)
Bachelor degree or higher	32 (55.2)
Religion	
Buddhism	26 (44.8)
Islam	32 (55.2)
Caregiver's occupation	
Stay-at-home parent	18 (31)
Civil servant	23 (39.7)
Employee	8 (13.8)
Private sector employee	4 (6.9)
Farmer	2 (3.4)
Business owner	3 (5.2)
Family income	
Not enough	5 (8.6)
Enough	53 (91.4)

Oral Health Behaviors

Results from the posttest showed that tooth brushing by caregivers and the use of fluoride toothpaste and smear-sized toothpaste improved significantly (Table 2).

Table . Oral health behaviors among study participants at baseline and after 2 months from the first day of intervention (N=58). Fisher exact test significance level: $P<.05$.

Behaviors	Preintervention, n (%)	Postintervention, n (%)	*P* value
Teeth cleaning method			.006
Improper or no tooth brushing[a]	16 (27.6)	4 (6.9)	
Tooth brushing by caregiver	42 (72.4)	54 (93.1)	
Frequency of tooth brushing			<.001
<1 time/day	21 (36.2)	8 (13.8)	
≥2 times/day	37 (63.8)	50 (86.2)	
Use of Fluoride toothpaste (Yes)	31 (53.4)	49 (84.5)	.001
Smear-sized toothpaste used	34 (58.6)	48 (82.8)	.008

[a]Improper tooth brushing is defined as insufficient cleaning, rinsing with water only, using a cloth for cleaning, or allowing the child to brush independently.

Perceptions of Caregivers Based on PMT

All perceptions of caregivers based on PMT showed significant improvement from high to highest perceptions, except for perceived vulnerability, which improved but without a statistically significant difference (Table 3).

XSL•FO
RenderX

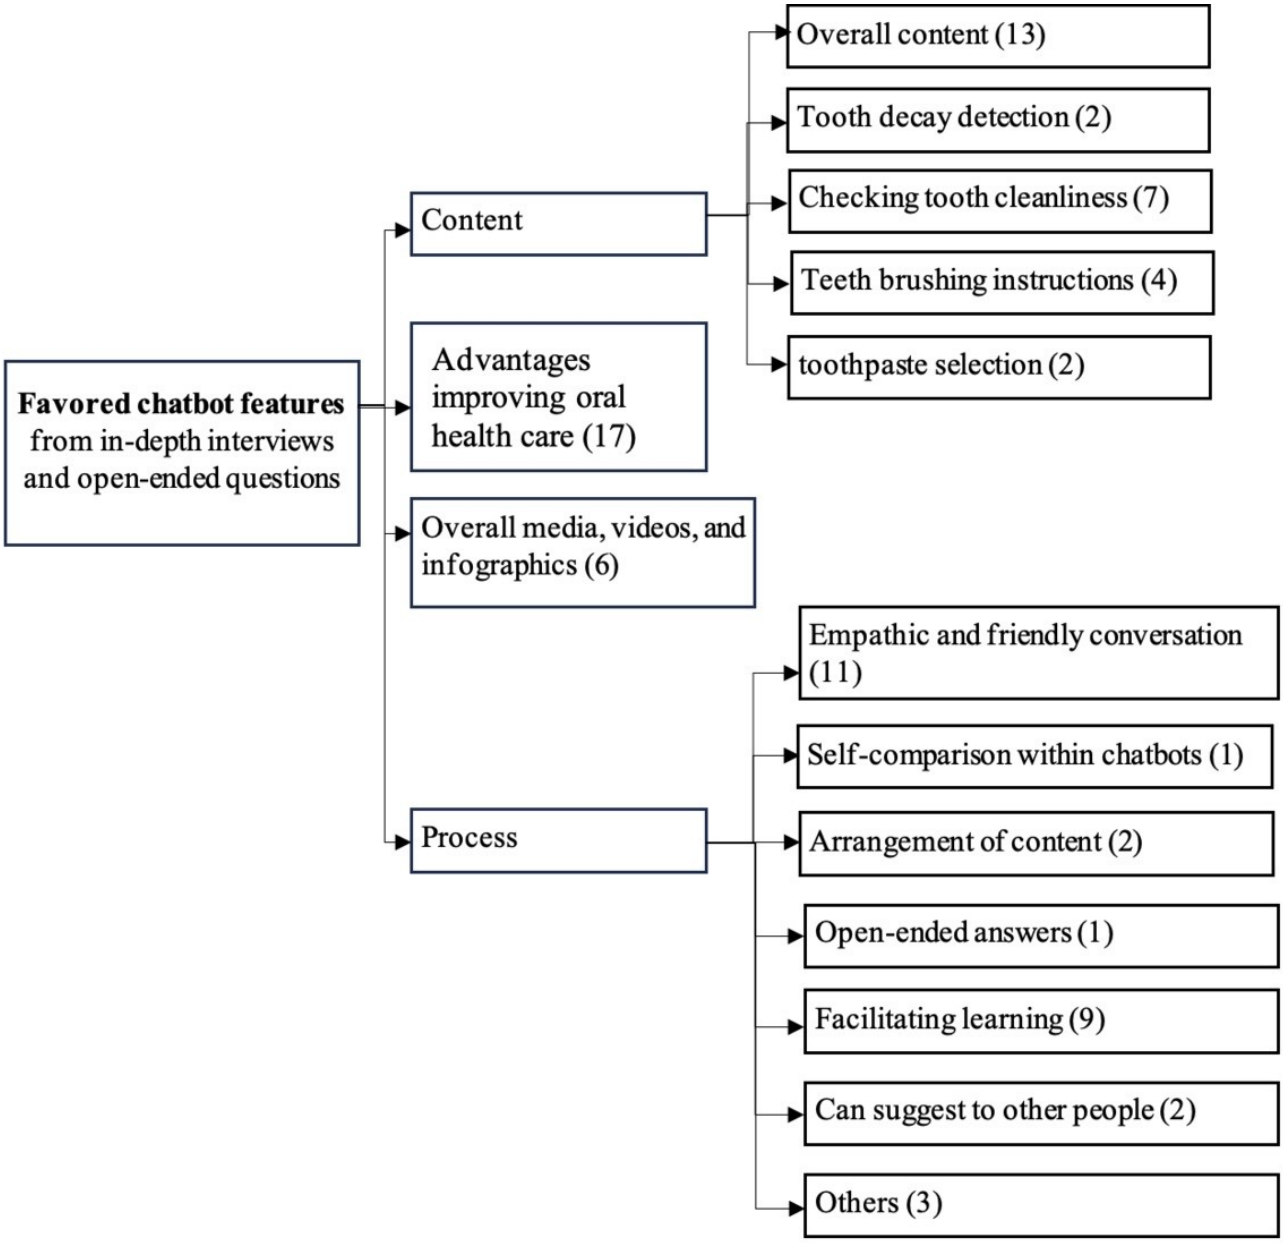
Table . Perceptions of caregivers based on protection motivation theory (PMT) toward oral health behavior (total score=5). Paired *t* test significance level: *P*<.05.

	Preintervention, mean (SD)	Postintervention, mean (SD)	*P* value
PMT parameters			
Perceived severity	4.0 (0.9)	4.5 (0.7)	<.001
Perceived vulnerability	4.3 (1.1)	4.6 (0.9)	.56
Response-efficacy	3.9 (0.8)	4.4 (0.8)	.04
Self-efficacy	3.9 (0.9)	4.3 (0.7)	.001
Overall	4.0 (0.6)	4.5 (0.6)	<.001

Usability and Engagement

The usability levels were highest in every category (Table 4). Of those who completed the program, 32.8% of the study participants were fully engaged in using the chatbot. The average chatbot user engagement was 24.7 days (SD 7.2), with an additional insight into weekly engagement of 5.8 days (SD 1.7).

Table . Usability on the chatbot (N=58).



Usability items (total score=5)	Values, mean (SD)
User experiences	4.6 (0.6)
Convenience	4.6 (0.7)
Acceptable performance and acceptance	4.6 (0.7)
Conversational quality	4.7 (0.6)
Understandable media	4.7 (0.6)
Reliable content	4.8 (0.7)
Appropriate content order	4.6 (0.8)
Linguistic features, naturalness, and fluency conversational quality	4.8 (0.6)
Perception of relational and capacity	4.7 (0.6)
Rapport perception of relation and capacity	4.6 (0.8)
Self-efficacy and perceived social support	4.8 (0.6)
Increased self-esteem	4.6 (0.6)
Usefulness of chatbot	4.8 (0.5)
Overall average score	4.7 (0.5)

Acceptability

In the structured questionnaire, overall satisfaction was rated 4.7 out of 5 (SD 0.6). Open-ended questions from day 30 of chatbot conversations (42 users) and in-depth interviews (15 users) revealed 4 major themes through thematic analysis: content, user learning, media, and process (Figure 4). Most users expressed positive feedback on the value of the content and the engagement methods, particularly empathetic communication and media. However, the duration of chatbot interactions and issues with the messaging system were identified as key barriers to sustained engagement (Figure 5).

Discussion

Principal Findings

The study indicates that using the "30-Day FunDee" chatbot significantly improved PMT-related perceptions and tooth-brushing behavior for young children. High levels of acceptability and usability were reported for the chatbot acceptability and usability were reported.

Several studies supported that knowledge and attitudes regarding tooth brushing can evolve and that alterations in tooth-brushing practices are influenced by or linked to this factor [45,46]. Caregiver-led tooth brushing for children twice daily with a rice-sized amount of fluoridated toothpaste has been proven to be a key strategy for preventing dental caries in children younger than 3 years [12]. In the study, tooth brushing by caregivers increased significantly from 72.4% to 93.1% (a significant increase of approximately 22%). The dedication of caregivers to twice-daily brushing and the use of fluoride toothpaste for children significantly grew, with an increase of approximately 22.4% (from 63.8% to 86.2%) and 31.1% (from 53.4% to 84.5%), respectively. These results go beyond those of other studies involving similar age groups, whether they used traditional oral health education with or without in-person tooth-brushing training [22,47].

Oral health professionals should provide caregivers with practical training and empowerment regarding the prevention of tooth decay in young children [15,16,48]. Within the framework of this chatbot interface, caregivers are expected to autonomously acquire the skill of proper tooth brushing through the use of educational content, encompassing videos, images, and textual information. The resultant feedback on this intervention demonstrated noteworthy effectiveness, reflecting an elevated tooth-brushing behavior and satisfaction level, quantified with a score of 4.7 out of 5. Additionally, media preferences were thoroughly explored through in-depth interviews and open-ended questions within the chatbot interface.

Meta-analyses indicate that 4 key factors within the PMT including perceived severity, perceived vulnerability, response efficacy, and self-efficacy contribute significantly to changes in health behaviors [49]. Perceived severity significantly increased, likely due to integrating PMT principles into the chatbot design and content structure. As in prior research, the perceived severity of the condition (cancer) impacted intentions to prevent disease, suggesting fear appeals influenced the perceived threat of disease [50]. In addition, the systematic review identified self-efficacy within the PMT's coping appraisal construct as the most effective predictor and promoter of physical activity participation [51]. Our findings align with these studies, demonstrating improvements in perceived severity, response efficacy, and self-efficacy.

In this chatbot on perceived vulnerability, we requested caregivers evaluate their children's dental plaque to determine their abilities in tooth brushing. We hypothesized that there would be a significant difference in perceived vulnerability, however this was not supported. Nevertheless, such interactions still improve oral health behaviors in children [27]. Caregivers, with a strong belief in response efficacy, are more likely to change their behavior to take care of their children [27,52]. In this study, we aimed to share tooth-brushing techniques using various media such as conversational text, infographics, both real-life and animated images, and videos. This finding is consistent with the excellent level of user satisfaction observed regarding the understandable media and reliable content

XSL•FO
RenderX

displayed. Self-efficacy is a significant component that plays a critical role in influencing the improvement of health behavior [27,45,46,53].

Consistently maintaining oral health behaviors, crucial for the success of preventing caries, should be upheld over an extended period [54]. As habit formation typically takes place within a range of 18 to 254 days [19], we anticipate that the 30-day exposure to the intervention and the subsequent 60 days from the first day of intervention to the evaluation day will sufficiently ensure a lasting behavioral change.

Behavior change theories were recommended in interventions promoting change, including in-person and digital formats. These approaches emphasized goal-setting, self-monitoring, reviewing goals, addressing obstacles, providing motivation, feedback, social support, and individualized guidance and education [21,55,56]. The 30-Day FunDee chatbot study incorporated these techniques.

Integrating behavior change methods into chatbot interventions likely improved targeted behaviors and overcame limitations of conventional in-person interventions, including restricted health care professional interaction, declining motivation over time, and insufficient access to education. Thus, chatbots may elicit positive behavior changes by addressing the restrictions of traditional approaches [3].

The research involves designing a satisfaction assessment using a web-based questionnaire that was applied to evaluate the design of the AI behavior change model [11]. The evaluation focused on user experiences, conversational quality, perception of relational capacity, self-esteem enhancement, and chatbot usefulness. The results indicate the highest satisfaction across all evaluated criteria and that it was effective enough to increase tooth brushing behavior. Powerful chatbots, such as the 30-Day FunDee chatbot, are not only capable of simple conversation, but also of oral health education and self-training.

The average duration of chatbot engagement, which was 5.8 days per week in this study, is a salient feature. Due to the increased level of satisfaction, this duration is especially noteworthy; it exceeds Todaki's 5.1 days-per-week engagement during a similar 4-week study period [42], but is inferior to Woebot's 6.1 days-per-week engagement in a shorter 2-week study period [37]. Observations from both our own investigations and other research [42] indicate that the chatbot exhibited notable use during the initial week, followed by a decline in use from the second to the fourth week. User feedback revealed 3 key reasons: excessive workload strain, preference for shorter programs, and reliance on chatbot notifications. These findings indicate a misalignment between chatbot functionality and user needs, consistent with previous research highlighting drawbacks such as extended training programs and technical errors [37,42]. Future iterations will prioritize content condensation, enhanced user engagement, and potential platform optimization or replacement to address these challenges and improve overall chatbot efficacy.

According to the challenges of chatbot development in public health, establishing rapport and cultivating relationships with users through compassionate and personalized interactions is critical for a sustained and engaging intervention [3,4,57]. This study aligns with previous research findings, where the term "empathic and friendly conversation" emerged during in-depth interviews and open-ended questions. Similarly, studies on other chatbots corroborated these benefits [37,42,58].

The strengths of this study focus on systematically planning, developing, analyzing, and assessing the chatbot. It was meticulously designed based on behavior modification theory and principles of AI chatbot behavior change. This resulted in profound understanding, facilitating improvement, development, testing, and evaluation of interactive programs to align with the goals. This included the capacity to discuss, summarize outcomes, and conduct extensive comparative analyses with other study findings. The ultimate goal is to formulate guidelines for the next phase of chatbot development.

Our research possesses limitations due to a pre-post design, potentially introducing a maturity bias and consequently, possibly overestimating the chatbot's effectiveness in enhancing oral health behavior. In the research methodology, a self-administered web-based questionnaire was used, raising concerns about compromised validity.

In order to improve the applicability of our results, we recommend that future research use randomized trials involving a wide range of demographic groups and conduct a more extensive evaluation of caries prevention. Furthermore, to enhance the effectiveness, user-friendliness, and acceptance of chatbots, efforts should be made to incorporate adaptive learning and AI-driven conversational methods.

Conclusion

In summary, this research suggests that the 30-Day FunDee chatbot can be an effective, highly usable, and acceptable resource for individuals seeking oral health information and children's caries prevention. Such a tool could be developed in the next phase of chatbots to serve as a scalable complement to conventional treatment approaches.

Acknowledgments

The study was funded by the Faculty of Dentistry, Prince of Songkla University. The researchers express their sincere gratitude to Mrs Thiraporn Auechuchit, Dr Rohannee Yalaeka, and the dedicated staff from the Early Childhood Development Center at the Faculty of Medicine, Prince of Songkla University, Hat Yai District, Songkhla Province, as well as the Maelan hospitals in Pattani Province, for their tremendous support. The researchers would like to extend their heartfelt appreciation to the caregivers who actively participated in this study.

Abstract

Background: Dental phobia (DP) and injection phobia (IP) are common in pediatric populations, resulting in inability to receive dental care. Internet-based cognitive behavioral therapy (ICBT) has demonstrated efficacy, but its long-term effects are unexplored.

Objective: This study aimed to evaluate the long-term effects of ICBT on DP and IP in children and adolescents.

Methods: In total, 49 participants (mean age 11.1 years, SD 2.1) with DP, IP, or both underwent a 12-week, parent-guided, exposure-based ICBT, supplemented by visits at local dental clinics and weekly psychologist correspondence. Assessments occurred at baseline, posttreatment, and 1-year follow-up. Primary outcomes included diagnostic status (clinical interview) and ability to receive dental procedures. Secondary outcomes included measures of dental anxiety, injection anxiety, negative cognitions, and self-efficacy. The study was conducted in Sweden.

Results: Of the 49 participants, 42 (86%) completed the 1-year follow-up. At 1-year follow-up, 19 (53%) of 36 (86%) participants who initially met the criteria for DP no longer did (P<.001), and 17 (46%) of 37 (88%) participants who initially met the criteria for IP did not fulfill the IP diagnosis (P<.001). Repeated-measures ANOVA showed significant improvements, with large effect sizes for self-reported ability to undergo dental procedures (d=1.1, P<.001), dental fear (d=1.0, P<.001), negative cognitions (d=0.9, P<.001), injection fear (d=0.7, P<.001), and self-efficacy (d=1.1, P<.001). Predictor analysis showed greater improvements in older participants and males.

Conclusions: This study discussed the clinical implications of and approaches to ICBT implementation. ICBT for children and adolescents with DP and IP maintains its effects over a 1-year follow-up period, facilitating improved self-reported willingness to undergo dental treatment. Given its accessibility and sustained efficacy, ICBT should be considered for managing severe dental fear in pediatric dentistry.

Trial Registration: ClinicalTrials.gov NCT02588079; https://clinicaltrials.gov/study/NCT02588079

KEYWORDS

adolescents; CBT; cognitive behavioral therapy; ICBT: internet-based cognitive behavioral therapy; dental fear and anxiety; children; dental anxiety; dental fear; dental phobia; injection phobia; internet; specific phobia

Introduction

Dental fear and anxiety (DFA) is widespread, affecting approximately 24% of all children and adolescents [1]. When fear becomes so intense that it significantly disrupts an individual's functioning, it can be classified as a specific phobia according to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) [2]. A phobic response involves avoiding the feared object; in the context of dental phobia (DP), this often results in patients greatly delaying or being unable to seek dental care [3]. Failing to attend or delaying visits to the dentist is associated with poor oral health [4], making DP a serious health concern for those affected.

Pediatric dentistry has methods for preventing fears and providing children with DFA treatment, including pharmacological treatments and dental behavior support (DBS) [5]. However, the DBS conventionally used has not proven to be as effective in treating children with DP [6]. Similarly, the evidence regarding pharmacological sedation to reduce anxiety is conflicting and inconclusive, with no reports on the long-term effects of reduced anxiety [7].

In contrast, cognitive behavioral therapy (CBT) has been shown to be effective in both children [8] and adults with high DFA or DP [9]. CBT in this context is based on learning theory and uses exposure-based techniques to modify maladaptive responses to negatively valenced stimuli. However, the application of CBT in pediatric dentistry is currently limited in most countries due to constraints in availability, trained personnel, and successful implementation [10].

Internet-based cognitive behavioral therapy (ICBT) was partially developed to address some of the challenges associated with traditional CBT treatments, such as high costs and limited access to trained therapists. Research has previously indicated that ICBT is effective for children with DP [11]. However, the long-term effects of the treatment remain unknown. If ICBT demonstrates positive long-term effects, it has significant potential to enhance availability and cost-effectively assist children and adolescents with dental anxiety in reducing their anxiety and more willingly accepting dental treatment.

The purpose of the study was to assess the long-term efficacy of ICBT on DP, as well as injection phobia (IP), in children and adolescents assessed 1 year after the completion of treatment. The hypothesis was that the effects of ICBT will be maintained at the follow-up assessment.

Methods

Study Design

This study was a long-term follow-up, pooling participants from the research group's pilot study [12] and randomized controlled trial (RCT) [11], which focused on an ICBT for DP and IP. Both studies used the same recruitment strategies, treatment program, and measurements; however, the RCT implemented a randomization process to assign participants to either direct treatment or a waiting list control group after their inclusion and pretreatment measurements. The waiting list control group received the treatment after the 12-week posttreatment measurement. The follow-up assessment was administered 1 year after the completion of treatment.

Study Setting and Participants

The study was conducted in Sweden, and the intervention was delivered as therapist-guided ICBT via an online platform, with concurrent visits to participants' regular dental clinics. In Sweden, both general and specialist pediatric dental services are publicly funded and made available at no cost to all children. Routine dental examinations for children and adolescents are scheduled on an annual or a biennial basis. The intervention was delivered independently without direct collaboration with the children's dental care providers. A central component was parental involvement, wherein parents assumed the role of a coach to support and guide their child or adolescent throughout the treatment. The intervention was therefore designed and targeted for children and adolescents with DP and IP aged 8-15 years. Participants who met the inclusion criteria (Textbox 1) were invited to join the study, and those who met any of the exclusion criteria (Textbox 2) were excluded.

XSL•FO
RenderX

Textbox 1. Inclusion criteria for internet-based cognitive behavioral therapy (ICBT).

Inclusion criteria:

- The child's age is from 8 to 15 years.
- The child and parents sign informed consent forms.
- A psychologist establishes a diagnosis of dental phobia (DP) or injection phobia (IP) according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-4) based on the results of the internet parent version of the Development and Well-Being Assessment (DAWBA) in the initial screening and of the Kiddie Schedule for Affective Disorders and Schizophrenia for School-Age Children – Present and Lifetime (K-SADS-PL) in the semistructured diagnostic interview.
- The child's and parents' Swedish language skills are sufficient to manage treatment and the questionnaires.
- Access to a computer and the internet is readily available.
- The child and parents have sufficient time and motivation to work with ICBT 3 hours each week for 12 weeks.
- The parents agree to book at least three visits at the dental clinic during the 12 weeks of treatment.
- If a child is diagnosed with IP, the parents agree to exposure training for intraoral injections at the dental clinic, even if the child does not require dental treatment.

Textbox 2. Exclusion criteria for internet-based cognitive behavioral therapy (ICBT).

Exclusion criteria:

- The child and parents obtain full points on the child and parent versions of the Picture-Guided Behavioral Avoidance Test (PG-BAT). The maximum score of 17 means that the child and the parent assess that the child can already manage the most challenging dental situations.
- The child and parents obtain a score of 31 or less on the child and parent versions of the Children's Fear Survey Schedule – Dental Subscale (CFSS-DS), and there is no diagnosis of injection phobia (IP) by the psychologist during screening.
- There is a previously established diagnosis of a neurodevelopmental disorder or a likely diagnosis of a neurodevelopmental disorder according to the results of the Development and Well-Being Assessment (DAWBA) or the psychologist during screening.
- Other psychiatric disorders, such as severe depression, eating disorders, or self-harming behaviors, should be treated before addressing specific dental phobia (DP).
- Psychiatric/psychological examination is ongoing or planned.
- Psychological treatment is ongoing or planned.
- The child has had stressful life experiences over the past 12 months, such as parental divorce or physical illness, that the parent or psychologist views as obstacles to treatment.
- The child has undergone cognitive behavioral treatment for dental fear and anxiety (DFA) or DP/IP in the past 3 years.

Recruitment Process

Participants were recruited through dental clinics and Facebook advertisements, targeting parents of children in the appropriate age range and dental professionals. Information was also shared in Facebook groups directed at dental professionals and psychologists. Dental clinics throughout Sweden were informed about the study and encouraged to promote participation in their waiting areas using posters. The dentists, especially specialists in pediatric dentistry, were asked to recommend patients with severe dental or injection fears that hindered their dental treatment to apply for the study. Interested families were directed to an online platform hosted by the Department of Dental Medicine at Karolinska Institutet. The study's website offered information about the research and its target population. Interested parents or caregivers could apply directly through the website, after which they would receive login credentials for online screening.

The recruitment period for the pilot were from August 2014 to February 2015 [12], while the recruitment for the RCT spanned from October 2015 to December 2019 [11]. The RCT's recruitment timeline had to be extended due to slower-than-expected participant enrollment. Please refer to Schibbye et al [11] and Shahnavaz et al [12] for more specific information about each process.

Screening Procedure

The first stage of the online screening provided detailed information about the study and included a study participation approval form for informed consent for caregivers (hereafter referred to as "parents"). After obtaining informed consent, one parent (designated to complete the questionnaires and participate in the telephone interview) and the child provided basic background information through an online questionnaire. Subsequently, they completed four standardized assessments online: the Picture-Guided Behavioral Avoidance Test (PG-BAT) [12], the Children's Fear Survey Schedule – Dental Subscale (CFSS-DS) [13], the Children's Negative Cognitions in Dentistry (CNCD) scale [12], and the Injection Phobia Scale for Children (IPSC) [14].

After evaluating the initial stage of screening, parents of eligible participants were asked to complete the Development and

XSL•FO
RenderX

Well-Being Assessment (DAWBA) [15] and were provided with new login credentials to access the assessment on a different platform. A clinical psychologist conducted a telephone interview with the parent using a semistructured diagnostic interview based on the specific phobia section of the Kiddie Schedule for Affective Disorders and Schizophrenia for School-Age Children – Present and Lifetime (K-SADS-PL) [16] to determine whether the child met the criteria for a diagnosis of DP or IP. The psychologist also reviewed the DAWBA results with the parent to identify potential exclusion criteria, which were addressed during the interview.

Allocation Process

The study began by establishing baseline outcome measurements. In the pilot study, all participants could then start their treatment immediately, while in the RCT, they were randomized to either begin treatment directly or be placed on a 12-week waiting list. After 12 weeks on the waiting list, participants completed the outcome measurements again and were then offered an opportunity to start treatment; thus, the follow-up measurement in the RCT served as the baseline measurement for this group in this study.

The Treatment

The ICBT implemented in the study was based on a previously published manual [17]. The primary component of the treatment was exposure therapy, delivered through video and audio recordings, a home-based toolkit, and in vivo exposure sessions at a dental clinic. Additional treatment components included psychoeducation, behavioral analysis, controlled breathing techniques, and parental education (Textbox 3). Parents were encouraged to determine who among them would take on the role of coach, responsible for guiding and supporting the child or adolescent throughout the treatment process. A specific treatment module was designed for the coach (week 2) to provide information about effectively supporting, motivating, and assisting the children or adolescents with their assigned tasks. One of the coach's responsibilities included contacting each participant's local dental care provider to arrange at least three in vivo exposure sessions conducted by the clinic's regular dental staff. Participants downloaded instructions for exposure exercises from the platform and either mailed or submitted digital copies to the clinic. In the second week of treatment, participants also received a toolkit containing dental instruments and a Visual Analogue Scale (VAS) designed to facilitate home-based exposure exercises for the children, adolescents, and their coaches.

Textbox 3. Outline of the 12 internet-based cognitive behavioral therapy (ICBT) modules, with 1 module for each week.

ICBT modules:

- Introduction to cognitive behavioral therapy (CBT) and the online treatment
- For the coach only: psychoeducation, practical arrangements, home assignments, how to guide a child to elicit and reinforce behavioral change, reward strategies, and enhancing the child's self-efficacy
- Behavioral analyses, child psychoeducation and treatment rationale, and goal setting
- Constructing an exposure list and beginning exposure
- Continued exposure (films, training package) and controlled breathing
- Dentistry-related communication training and preparation for the first dental visit
- Evaluation of the dental visit and cognitive restructuring
- Midterm evaluation of ICBT and of exposure at the dentist's, and relaxation techniques
- Pain and pain management education; fear, thoughts, and pain; and focus shift and acceptance training
- Problem solving and mindfulness training
- Repetition, strategies for maintaining change and relapse prevention, and letter to yourself
- Relapse prevention plan, enhancing self-efficacy, and diploma

The intervention consisted of 12 online treatment modules (Textbox 3), provided to participants at a pace of 1 module per week. Each module included written content, with most containing images, animations, and videos or audio recordings of dental procedures to enhance exposure therapy. Each participant was paired with a specific psychologist for support during the treatment process. In total, 3 psychologists were involved to support the online therapy, all of whom held at least a master's level (5-year) degree in clinical psychology. Additionally, all had face-to-face clinical experience in CBT for DP and IP in children and adolescents.

Each week, participants and their coaches completed a new module that ended with an assignment made up of knowledge-based questions and practical exercises. After finishing the assignment, participants submitted their answers and a log of their completed tasks to their assigned psychologist. The psychologist provided feedback and granted access to the next module within 2 business days. Participants could also message their psychologist directly via the platform, with responses typically given within 2 business days. In cases of inactivity, psychologists would send reminders through SMS or email to encourage the continuation of the modules. If a participant remained inactive for more than 10 days, the psychologist would attempt to reach out to them by phone.

XSL•FO
RenderX

The intervention and all related data collection took place on a secure online platform under the supervision of the Internetpsykiatri (the Internet Psychiatry Clinic), Stockholm Health Care Services, Region Stockholm, Sweden. Both the coach and the participants used the same login credentials to access the platform. After 12 weeks, all treatment modules were made accessible to participants on the platform, regardless of whether they had completed them. The accounts for the child or adolescent and their coach, along with their login credentials, remained active for an additional 12 months. However, participants could no longer communicate with their psychologist once the treatment period concluded.

Primary Outcome Measurements

The study used two primary outcome measures. The first was a diagnosis of DP and IP, which was assessed using the specific phobia section of the K-SADS-PL. A clinical psychologist administered this assessment during a semistructured telephone interview with the parent. The K-SADS-PL is a well-established instrument with demonstrated reliability and validity in assessing psychiatric diagnoses [16].

Since it is preferable to use the child as the informant for DFA [18], an additional self-assessed primary outcome was also included, which was the PG-BAT [12]. The PG-BAT was rated independently by both the child and the parent. The PG-BAT assesses the number of dental procedures (n=17; response options: yes=1, no=0) that participants or their parents believe the child can accept and handle voluntarily (Textbox 4). The test features images of 17 dental procedures arranged in a sequence that increases anxiety-provoking potential. Each image includes a written description of the procedure and its context. Scoring ranges from 0 (unable to even enter the dentist's office) to 17 (capable of managing all dental treatment steps). The two outcomes were both considered primary, reflecting their importance in addressing the participants' central clinical issue: the ability to accept dental treatment and the functional impairment resulting from the inability to access dental care. Because of this, the designation of primary outcomes from the pre-registration was revised to include the clinician-rated diagnosis originally listed as a secondary outcome, as this collectively offers a more comprehensive assessment of the same underlying construct. This approach incorporates multiple perspectives and informants—including those of the clinician—and better captures the core dimension of the participants' clinical presentation and functional impairment.

Textbox 4. Dental procedures included in the Picture-Guided Behavioral Avoidance Test (PG-BAT) used in internet-based cognitive behavioral therapy (ICBT).

Dental procedures in the PG-BAT:

- Enter the treatment room.
- Sit in the treatment chair, with a paper bib around the neck.
- Sit in the treatment chair while the chair is lowered.
- Lie in the dental chair, with the lamp turned on and the dental tools close by on a tray.
- Open the mouth and let the dentist look into the mouth.
- Let the dentist use a small saliva ejector in the mouth.
- Let the dentist blow air and water in the mouth.
- Undergo a clinical examination with a dental mirror.
- Undergo a clinical examination with a mirror and a dental probe.
- Let the dentist take an X-ray in the back of the mouth.
- Receive topical anesthesia.
- Receive an injection of a local anesthetic.
- Let the dentist use a large saliva ejector in the mouth.
- Let the dentist attach composite filling to the surface of a tooth.
- Let the dentist drill with a high-speed drill.
- Let the dentist polish a filling with a low-speed drill.
- Let the dentist extract a tooth.

Secondary Outcome Measurements

The CFSS-DS is a widely used tool for assessing DFA. It consists of 15 items rated on a 5-point Likert scale ranging from 1 (no fear) to 5 (high fear). These items evaluate various situations related to dental and medical care, and ratings are provided separately by both the child and the parent. The Swedish version of the CFSS-DS has shown strong psychometric properties [13].

Children also assessed the 5-item CNCD scale using a 10-point VAS. The endpoints of the scale were 0 (no negative thoughts whatsoever) and 10 (some negative thoughts). These endpoints were visually represented by happy and sad figures, respectively. The CNCD measures the presence and intensity of five common

XSL•FO
RenderX

negative thoughts associated with dentistry: feelings of uncontrollability, distrust in dentists, unpredictability, perceived danger, and pain related to dental procedures [12].

The IPSC, completed by the child, consists of 18 items, each assessed on a 5-point Likert scale ranging from 1 (no fear) to 5 (high fear). The items evaluate fear associated with various injection-related situations and procedures. The IPSC has demonstrated strong psychometric properties [14].

Participants also completed the Swedish version of the 14-item Self-Efficacy Questionnaire for Phobic Situations (SEQ-SP), which is evaluated on a 5-point scale ranging from 1 (low self-efficacy) to 5 (high self-efficacy) [19].

Additionally, parents completed the Swedish version of the 12-item Parental Self-Efficacy Questionnaire for Dental Anxiety (P-SEQ-DA) [12], which is assessed on a 10-point scale ranging from 0 (no parental self-efficacy) to 10 (very high parental self-efficacy).

Assessment Schedule

Pretreatment baseline outcome measurements were collected, which included the PG-BAT and the CFSS-DS, rated separately by both the child and the parent. Additionally, the child completed the CNCD scale, the IPSC, and the SEQ-SP. The parent also filled out the P-SEQ-DA.

The posttreatment measurement was conducted 12 weeks after the treatment start and included all baseline outcome measures and a semistructured diagnostic telephone interview by a clinical psychologist using the specific phobia section of the K-SADS-PL. Additional questionnaires gathered qualitative insights into the child's current dental anxiety and experiences with ICBT, using a combination of free text, multiple-choice questions, and the VAS. These included questions about adverse events or unintended treatment effects, which were also addressed during the psychologist's interview.

A follow-up was conducted 1 year after the posttreatment measurement and included all baseline outcome measurements, including the diagnostic telephone interview by a clinical psychologist.

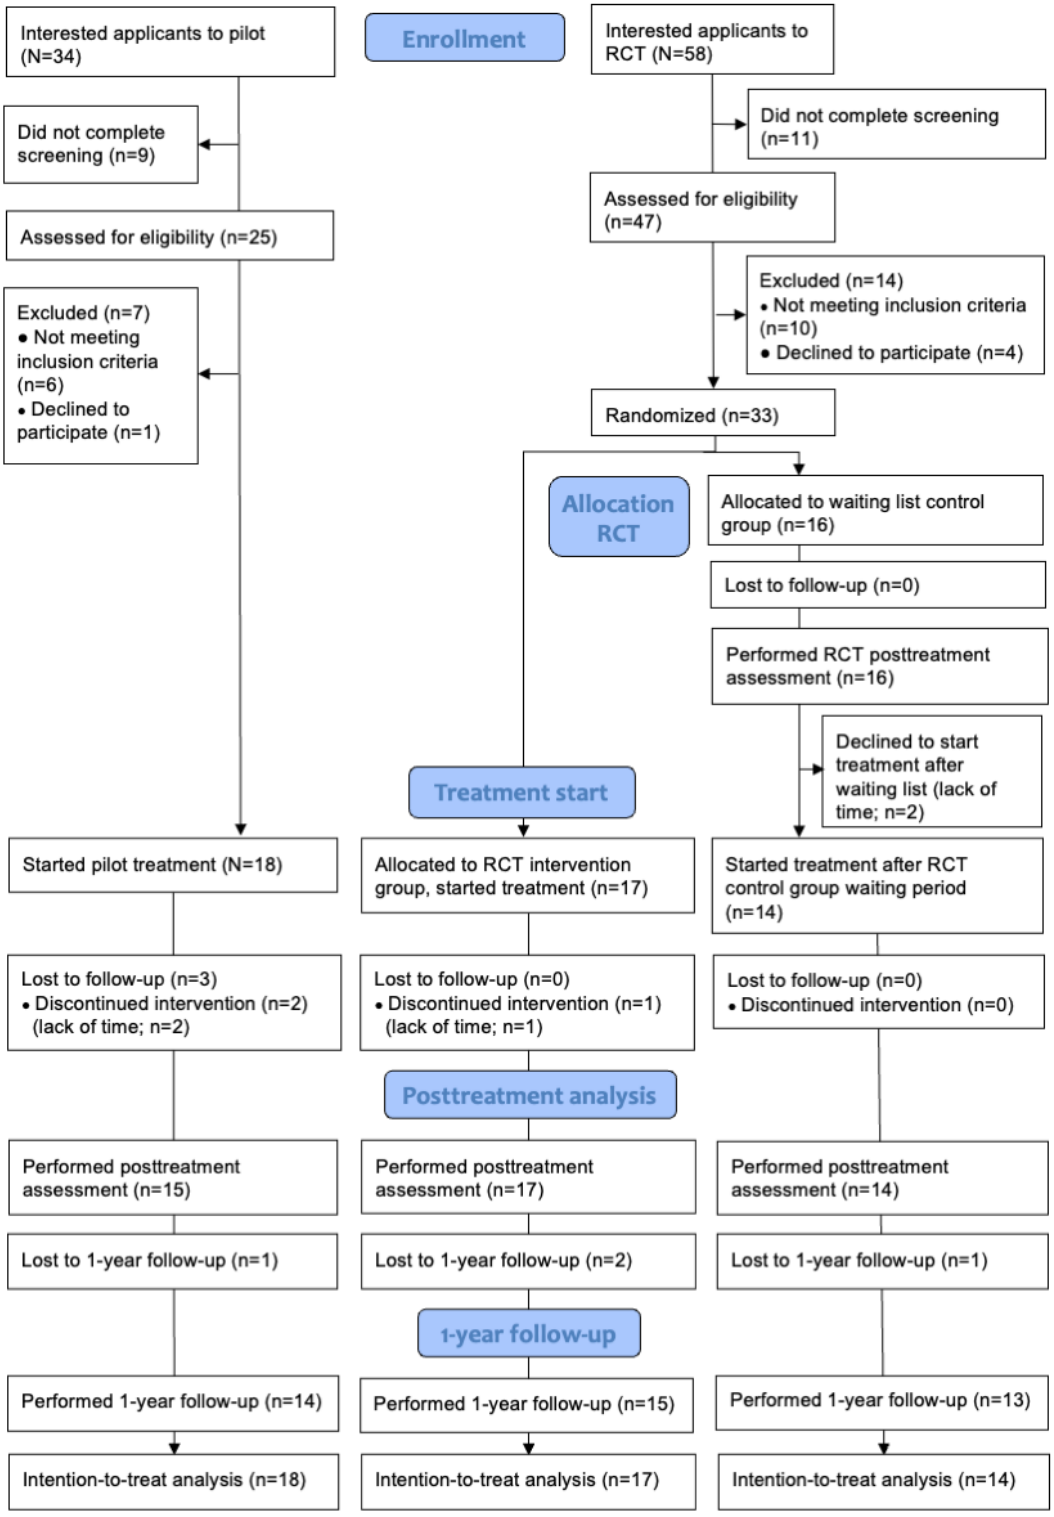
Statistical Analysis

All statistical analyses were conducted using R version 4.3.2 (R Foundation for Statistical Computing) [20]. A type I error rate of 5% was accepted for all analyses. Before conducting the analyses, the data were assessed for normality. The McNemar test was conducted to analyze the differences in diagnosis (yes or no) between paired observations. ANOVA was performed to evaluate potential differences between baseline, posttreatment (12 weeks), and the 1-year follow-up on continuous outcome measurements. A post hoc analysis using a generalized linear model (GLM) with repeated measures and pairwise comparisons was conducted to estimate effect sizes using Cohen d, which represents the standardized mean difference [21]. A GLM with repeated measures, along with Bonferroni correction for multiple comparisons, was used to analyze predictor effects.

The analysis used an intention-to-treat approach, meaning that all participants who started the treatment were included regardless of the degree to which they completed it. Sensitivity analyses were performed by using maximum likelihood estimation to impute missing values into the dataset.

Ethical Considerations

The study received approval from the regional ethics review board in Stockholm (ID 2014/633-31/5) and was pre-registered at ClinicalTrials.gov (NCT02588079). Informed consent was obtained before participant enrollment in the study and screening process completion. Study information and consent forms were provided in Swedish, and consent included authorization for the secondary data analysis without needing additional approval. For participants with two caregivers, consent was required from each caregiver separately. No financial compensation was offered to participants, and the intervention was provided at no cost, consistent with the provision of dental care for children and adolescents in Sweden.



Results

Participant Details

Of the 16 participants in the ICBT control group, 14 (88%) began the treatment after the 12-week waiting period. Those who did not start treatment reported that a lack of time was the reason for their decision. As a result, a total of 31 (94%) participants from the RCT and 18 (100%) participants from the pilot study started ICBT. Consequently, a combined total of 49 participants was included in the long-term analysis of ICBT. For a flowchart of the participants in the ICBT, see Figure 1.

XSL•FO
RenderX

Figure 1. Flowchart of participants in the pilot study and the RCT of ICBT. ICBT: internet-based cognitive behavioral therapy; RCT: randomized controlled trail.

Of the 49 participants who began the treatment, 39 (80%) indicated that their main fear related to dentistry was injections. The majority had experiences with sedation and restraint during previous dental treatments. The most reported specific phobias other than DP and IP among the participants were blood and bee/wasp phobias. For a complete overview of the characteristics of the participants, see Table 1.

[b]RCT: randomized controlled trial.

[c]DP: dental phobia.

[d]IP: injection phobia.

[e]Diagnosis of a specific phobia besides DP or IP.

Treatment Adherence and Dropout Frequency

After the initial 3 weeks, 3 (6%) of 49 participants did not continue due to time constraints and were classified as dropouts. The remaining 46 (94%) participants completed at least the first 5 modules of the treatment and had started the exposure training, while 40 (82%) progressed to at least module 8 and were identified as treatment completers, having finished the home exposure exercises and conducted in vivo exposure at their local dental clinics by the end of the 12-week period. The average number of modules completed was 9.6 (SD 2.7) of 12.

Of the 49 participants who began the treatment, 47 (96%) completed the posttreatment measurement. At the 1-year follow-up, the parents of 42 (86%) participants and 40 (82%) of the children completed follow-up measurements; the parents who completed the measurements also partook in a clinical phone interview. No participants reported any adverse events of the treatment in the follow-up questionnaires or during the clinical phone interviews.

Main Outcome Measurements

At the 1-year follow-up, 18 (43%) of 42 participants no longer met the diagnostic criteria for either DP or IP, whereas at the posttreatment measurement, 16 (35%) of 46 participants did not fulfill the criteria for either DP or IP. The McNemar test revealed a significant difference compared to before treatment for both groups ($P<.001$); however, the difference was not significant when comparing posttreatment with the 1-year follow-up ($P=.77$). Table 2 presents the intervention results stratified by diagnosis. A statistical difference from before treatment to posttreatment was observed at the 1-year follow-up in all the analyses. However, as seen in Table 2, the proportion of participants meeting the criteria for the respective disorders, any disorder, or both remained stable from posttreatment to the 1-year follow-up. Among the participants who met the diagnostic criteria for DP at baseline, 8 (32%) no longer met the criteria, while 3 (12%) developed a new diagnosis of DP between the posttreatment and 1-year follow-up measurements. Similarly, of those initially diagnosed with IP, 7 (28%) remitted, whereas 5 (20%) developed IP at the 1-year follow-up compared to posttreatment.

XSL•FO
RenderX

Table 2. Participants meeting the criteria for diagnoses of DP[a], IP[b], either DP or IP, or DP and IP before treatment, posttreatment, and at 1-year follow-up in ICBT[c].

Diagnosis	Participants, n/N (%)			*P* value (McNemar test)		
	Before treatment	Posttreatment	1-year Follow-up	Before treatment to posttreatment	Before treatment to 1-year follow-up	Posttreatment to 1-year follow-up
DP	42/42 (100)	25/40 (63)	17/36 (47)	<.001[d]	<.001[d]	.23
IP	44/44 (100)	25/41 (61)	20/37 (54)	<.001[d]	<.001[d]	.77
DP or IP	49/49 (100)	30/46 (65)	25/42 (60)	<.001[d]	<.001[d]	.77
DP and IP	37/37 (100)	19/35 (54)	11/31 (35)	<.001[d]	<.001[d]	.23

[a]DP: dental phobia.

[b]IP: injection phobia.

[c]ICBT: internet-based cognitive behavioral therapy.

[d]Significant *P* values.

A repeated-measures ANOVA was conducted to examine changes in the number of dental procedures managed by the participants (self-assessed through the PG-BAT) before treatment, posttreatment, and at the 1-year follow-up. The analysis revealed a significant main effect of time, as assessed by both the child and the parent (see Table 3). The effect size of the post hoc pairwise comparisons was then calculated, which showed large effects (Cohen d≥1.1) at the 1-year follow-up. There was no significant difference between the children from posttreatment to the 1-year follow-up; however, parents reported more dental procedures managed at the 1-year follow-up than posttreatment (Cohen d=0.3, *P*=.04). The pre- to posttreatment measurements were also significant, showing large effect sizes, as rated both by the child and the parent.

XSL•FO
RenderX

Secondary Outcome Measurements

A repeated-measures ANOVA was conducted, and the effect size of the post hoc pairwise comparisons for the secondary outcome measurements was calculated (see Table 3). The analysis revealed a significant effect of time at the 1-year follow-up on all the secondary outcomes. The effect size was large (Cohen d≥0.8) for most outcomes, except for injection fear (Cohen d=0.7) and parental self-efficacy (Cohen d=0.3). For most outcomes, there was no significant difference between posttreatment and the 1-year follow-up, except for negative cognitions, which increased for the children (indicating that they had more negative cognitions about dentistry) at the 1-year follow-up (Cohen d=–0.4, *P*=.006). A sensitivity analysis was conducted, which showed no change in the statistical significance of any of the main analyses after imputing missing data to the dataset.

Predictor Analysis

Finally, a predictor analysis was conducted to determine whether background variables (participants' age and sex) or the number of modules completed influenced the outcome measures. The results revealed that age influenced the clinical diagnosis outcomes, with older participants being less likely to meet the criteria for a clinical diagnosis at later time points (see Table 4). Additionally, an effect for the participants' sex was found, revealing more favorable results for male participants, particularly at the posttreatment time point, on all measurements. However, only the effects on self-rated injection fear, self-efficacy, and parental-rated DFA were statistically

XSL•FO
RenderX

significant. A separate analysis that included both age and sex was also performed, where all the results from the previous analyses remained significant. Furthermore, more completed treatment modules demonstrated a significant association with more favorable scores of self-rated DFA, negative cognitions, and increased self-efficacy.

Table 4. Predictor effects on the outcome measurements of ICBT[a].

Discussion

Principal Findings

At the 1-year follow-up, participants who received ICBT demonstrated significant improvements relative to their pretreatment baseline. Furthermore, the results observed posttreatment were maintained over the follow-up period. After 1 year, 49% of participants no longer met the diagnostic criteria for either DP or IP. Specifically, 53% of participants who initially met the criteria for DP no longer did, and 46% of those who initially met the criteria for IP no longer met the criteria for an IP diagnosis. Additionally, participants self-assessed their ability to manage dental procedure steps at the dentist's significantly higher, showing a large effect size (Cohen d=1.1). They also, compared to baseline, significantly reduced their fear and anxiety, again with a large effect size (Cohen d=1.0), and exhibited improvements across all outcomes, as reported by both the children and their parents. The treatment appeared to be more beneficial for male participants than females and for older individuals, although these findings reflect associations rather than causal relationships. Additionally, a higher number of completed treatment modules was associated with more favorable outcomes of ICBT.

Comparison With Previous Research

The long-term effects of ICBT are comparable to that of face-to-face CBT, further supporting the notion that exposure-based CBT treatments are an effective long-term intervention in pediatric dentistry. An RCT of face-to-face CBT conducted by a clinical psychologist revealed within-group effects comparable to this study on the Behavioral Avoidance Test (BAT) and the CFSS-DS [17]. However, at posttreatment and the 1-year follow-up, 64% and 91%, respectively, of the participants in that study no longer met the diagnostic criteria for DP, while 38% and 53%, respectively, did not meet the diagnostic criteria for DP at the different time points in this study. This discrepancy might be attributed to a higher level of engagement in treatment due to the direct interaction with participants or the advantage of using trained personnel delivering the in vivo exposures. Additionally, it may also indicate that the structures surrounding the CBT, such as

XSL•FO
RenderX

integration with continued dental care, play a crucial role in achieving favorable long-term results from exposure-based CBT in dentistry. The clinic in the face-to-face CBT RCT had trained personnel (clinical psychologists), established routines, and collaborations for referrals back to local clinics that continued the treatment for the participants, whereas the ICBT lacked all these features. In another RCT [22] where specially trained dentists conducted CBT for intraoral IP, the posttreatment effects on their BAT, CFSS-DS, and an injection phobia scale were comparable to the effects observed in this trial. At the 1-year follow-up, 69% of participants were able to receive intraoral injections at the dentist's, indicating that they likely would not meet the diagnostic criteria for intraoral IP. In this study, 46% of participants lost their initial diagnosis of IP at the 1-year follow-up. This difference may once again be attributed to not only the specifically trained personnel delivering the exposure but also the stricter focus on intraoral injection exposure treatment and diagnosis in that study [22], while this study also examined participants' ability to receive injections in health care when establishing the diagnosis of general IP. Finally, a systematic review of the long-term effects of ICBT showed an average long-term symptom improvement of 50% across studies of different conditions [23], consistent with the results of this 1-year follow-up of ICBT for DP and IP, showing that ICBT can provide meaningful long-term effects and should be considered in dentistry. Although research on the stability of diagnosed DP and IP in children and adolescents is limited and needs to be better understood, one study found that stability is lower in younger children under 12 years of age [24]. Notably, the sample in this study had an average duration of 46 months for dentist fear and 70 months for injection fear, and the majority had undergone various prior treatment modalities (76% had received sedation, 20% had received general anesthesia), indicating that ICBT is effective for the group that has stable fears and where conventional methods within pediatric dentistry have been unsuccessful.

Interesting predictor effects of ICBT were observed; however, these results should be interpreted with caution due to the relatively small sample size. Older participants more frequently lost their clinical diagnosis of DP or IP during ICBT. Additionally, although not statistically significant, the trend of the CFSS-DS and the number of dental procedures managed also favored older children. Previous findings on age as a predictor of treatment results for anxiety disorders have been conflicting [25]. However, some suggest that children over 12 years respond better to these treatments [26]. A trend, with some results reaching statistical significance, was observed, indicating that males had a better treatment effect than females, especially at the posttreatment time point. This represents a new finding that has not been reported in previous research on ICBT or psychological anxiety treatments for children and adolescents. Future research is needed to determine whether this is related to the specific conditions of DP and IP or whether these effects are seen in combination with this specific treatment. Nevertheless, DFA and DP have been shown to be more common in females than in males [1], indicating that there could be underlying sex differences affecting both the condition itself and, therefore, possibly its treatment.

Clinical Implications

This study, along with other research on other psychiatric conditions, indicates that ICBT has robust long-term effects for patients who are willing to receive an internet-based intervention and, in many instances, is comparable to in-person CBT. Given the current lack of availability of evidence-based treatment options for children and adolescents with DP and IP, ICBT should be seriously considered for integration into dental practice. However, the methods for effectively incorporating ICBT into standard dental care remain unexplored. This study shows that ICBT can eliminate the need for specialized staff onsite and can be implemented with minimal training of personnel at regular dental clinics. However, further research on the effects of ICBT with better-trained personnel delivering the in vivo exposure is needed since there is a possibility that this could increase its effect. Moreover, the treatment must be presented in such a way that both personnel and patients recognize its benefits; considering the slow recruitment for this study, ICBT needs to be integrated into local practices. Therefore, trained dental personnel aiding in both treatment delivery and its incorporation into ongoing patient care seems imperative. Finally, it is important also to note that efficacy studies on ICBT are based on participants who actively seek this type of treatment or exhibit strong motivation when invited to participate, which may also disproportionately include individuals with higher socioeconomic resources. This distinction must be carefully considered during implementation to ensure the treatment remains both effective and appropriate. ICBT should not be administered to individuals lacking motivation to engage with the treatment or the resources necessary to complete it.

The participants in this ICBT study can be considered selected due to the screening process and inclusion criteria for research participation, as well as the thoroughness of the treatment provided. Those who withdrew or declined to participate indicated that time constraints were the barrier, suggesting that a less intensive treatment could serve patients with limited time and resources, potentially enhancing its use. In addition, in the posttreatment qualitative evaluation, some participants described the intervention as overly extensive and suggested that it could be delivered in a more condensed format. For example, the RCT conducted on children with intraoral IP achieved comparable results using only five sessions. The number of completed modules in the treatment was primarily linked to the cognitive aspects of dental fear, possibly further indicating that a less extensive treatment could still help with the functional aspects of overcoming the challenge of receiving dental care. In the cases of DP and IP, the impaired oral and general health they cause could arguably be the most important aspect to address, aiming to enable the person to receive needed care willingly. Less extensive ICBTs combined with in vivo exposure provided by trained dental personnel, such as dental assistants or hygienists, seem to be a plausible way to implement a treatment that could reach larger patient groups and maintain efficacy. Importantly, they may also be more feasible for implementation in groups with fewer resources, as they place lower demands on the participants and structures around them. The dental staff delivering the treatment would benefit from training in exposure

XSL•FO
RenderX

methods to better assist patients through the ICBT process and serve as a bridge to their ongoing dental care at the clinic. Future research is necessary to establish such treatments' efficacy and effectiveness and determine which patient groups would benefit most from them. A favorable solution would involve establishing an initial assessment that directs the patient to the appropriate level of treatment. This could include a less extensive ICBT that is standardized and focuses more on exposure to a specific stimulus (primarily injections but also aspects such as the drill, gag reflex, or other physiological sensations that might be the main fear) offered at local dental clinics by trained personnel to help patients overcome their hurdles in receiving dental care. When necessary, a more comprehensive ICBT that also emphasizes cognitive aspects, such as the one used in this study, could be provided to those patients who might require it and are interested. Additionally, the option to consult with a clinical psychologist face-to-face is essential for certain groups, such as individuals with comorbid posttraumatic stress disorder (PTSD), other severe psychiatric conditions, or neuropsychological conditions.

The novel findings indicating that age and sex may influence treatment outcomes are intriguing; however, replication in future studies is necessary to substantiate these effects. Given that DFA and DP have been shown to be more prevalent among females, it is possible that sex-specific adaptations to an intervention may be warranted. Future research should establish whether treatment responses for DP, IP, and intraoral IP differ systematically based on sex. If such differences are confirmed, further investigation into potential variations in the etiology of these phobias could inform the development of tailored treatment approaches that address these sex-specific mechanisms.

Moreover, the predicting effect of age on treatment outcomes further underscores the need to explore the efficacy of a more condensed ICBT protocol. A shorter intervention primarily centered on exposures may be a more pragmatic and effective alternative for younger individuals, minimizing the burden of unnecessarily prolonged treatment, while maintaining therapeutic efficacy. This consideration aligns with evidence suggesting that the stability of blood-injection-injury (BII) phobia diagnoses increases significantly after the age of 12 years [24] and that psychological treatments for anxiety disorders might have a better effect on children aged 12 years and above. Consequently, comprehensive CBT interventions for DP and IP should likely be prioritized for older children and adolescents, where the risk of long-term symptom stabilization and treatment efficacy may be greater.

A final consideration concerns how the delivery and organizational responsibility for exposure-based CBT in dentistry should be strategically addressed in policy planning. In most countries, pediatric dentistry and general pediatric health care are administratively and financially separate, often resulting in higher out-of-pocket costs for dental care. Given that DP and IP are psychiatric conditions with a significant impact on overall health, exposure-based CBT should be integrated into the publicly funded health care systems to enhance accessibility and reduce financial barriers. For ICBT, existing national digital health platforms, where available, offer a scalable and cost-effective avenue for dissemination. However, effective implementation into existing dental care structures requires close collaboration with dental services, where the treatment, with its in vivo exposures, is ultimately to be delivered. This underscores the need for coordinated policy efforts across both general health care and dentistry to address the care of patients with a phobia hindering their dental treatment.

Strengths and Limitations

A key strength of this study is the inclusion of a clinically relevant sample, with a substantial proportion of participants experiencing persistent functional impairment due to their severe fear. Notably, the vast majority had previously required sedation and physical restraint during dental procedures, underscoring the long-term efficacy of ICBT in enabling these individuals to undergo dental treatment voluntarily. Furthermore, the study used multiple outcome measures assessed by the children themselves, as well as by independent observers, allowing for a comprehensive evaluation of treatment effects across various dimensions of phobic impairment. The strong concordance among these measures further reinforces the effectiveness of ICBT. Additionally, as the intervention was delivered in routine clinical settings by personnel without extensive formal training in CBT, the findings suggest robust external validity and feasibility for implementation in general dental practice. However, careful considerations regarding implementation and how trained personnel could possibly potentiate the effect of the treatment need to be done.

However, certain methodological limitations must also be acknowledged. The clinical interviews conducted to establish the posttreatment and 1-year follow-up diagnoses were not blinded, which may introduce potential bias. Nevertheless, given the consistency of treatment effects across all outcome measures, this limitation is unlikely to have significantly influenced the overall findings. Another limitation is that rather than assessing intraoral IP specifically, this study classified participants based on the broader diagnosis of a general IP in the posttreatment and 1-year follow-up assessments. However, this only attenuated the results, showing the robustness of the treatment effects.

Additionally, the generalizability of the results to populations excluded from this study remains uncertain, potentially limiting the external validity of the findings for certain clinical subgroups and those with limited socioeconomic resources. Furthermore, unmeasured confounding variables could have influenced the predictor analyses, as the study was not originally designed to systematically investigate these aspects. The relatively small sample size may also have constrained statistical power in these analyses, potentially obscuring significant associations where trends toward significance were observed. Despite these limitations, the findings suggest clinically interesting effects that warrant further investigation in future research.

Conclusion

ICBT for children and adolescents with DP and IP appears to maintain its effects over a 1-year follow-up period. ICBT is associated with long-term reductions in fear and allows the child to willingly accept dental treatment, thus leading to improved dental and general health. This study further supports that ICBT

XSL•FO
RenderX

is a method that enhances accessibility to evidence-based, long-term, effective treatment for fear and anxiety in pediatric dentistry.

Abstract

Background: Approximately 1 in 6 US children has a developmental disability. Early detection is crucial but often delayed, especially in families with limited access to resources. Current paper-based screening methods, such as the Ages and Stages Questionnaire, face challenges such as cultural barriers and timing issues. Digital tools can improve parent engagement and screening accuracy. This research explores new technologies to enhance long-term parent involvement in developmental screening.

Objective: The study aims to understand whether features of a digital intervention specifically designed to engage parents in developmental screening are effective over a long-term period.

Methods: Parents of children between 7 and 12 months old were recruited through flyers at clinics and libraries, mailing lists, and social media, and then they self-enrolled after eligibility screening. We conducted a randomized controlled trial with 139 families over 20 months, along with follow-up interviews and surveys. The intervention consisted of an interactive web portal that combined developmental and sentimental record-keeping, family-friendly visualizations, and the ability to answer screening questions via multiple modalities (eg, text messaging and web), without involvement of health care providers. The control condition consisted of a web-based portal with no specific engagement features, modeled after standard web-based developmental screening tools.

Results: Overall, we enrolled 67 parents in the control group and 72 parents in the experimental group, for a total of 139 enrolled participants. Several parent engagement strategies we deployed in the experimental group were effective in increasing milestone questionnaire completion, with text messaging standing out as the most impactful and efficient, offering the highest return relative to the effort required for its development and implementation. Overall, the experimental group demonstrated a 44% higher average response rate compared to controls (t_{125}=−3.32, P<.01). Participants in the experimental group submitted significantly more timely and valid responses, after text messaging was introduced (phase 2: 95% vs phase 1: 71%; t_{107}=−4.44, P<.01), which is a critical factor for effective and timely tracking of child development. The experimental group participants responded to more questions on average (mean 127.60, SD 49.01) than those in the control group (t_{70}=−7.23, P<.01) in phase 2 as well. In addition, study completion rates were significantly higher in the experimental group (83% vs 30%; t_{119}=−8.40, P<.01), indicating greater long-term engagement. Sentimental record-keeping features showed promise but limited use, suggesting the need for integration with tools parents already use.

Conclusions: This study demonstrates that a human-centered design approach for technology-based interventions can significantly enhance parent engagement and completion rates of developmental screening questionnaires. However, further research is needed with a larger sample to determine whether such features effectively prompt parents to seek early intervention services. Future studies should focus on engaging more diverse and underserved populations to validate these findings.

Introduction

Background

Approximately 1 in 6 children between the ages of 3 and 17 in the United States are diagnosed with a developmental disability, such as autism, attention-deficit hyperactivity disorder, or intellectual disabilities [1]. The earlier developmental delays are detected, the sooner early interventions can start, which can result in better outcomes for these children [2]. Unfortunately, approximately half of the children who eventually receive a diagnosis of developmental delay are not identified until they reach kindergarten in the United States [3], with lower-income populations being missed at a higher rate [4]. Regular screening of child development is one of the primary mechanisms for early detection of many types of developmental disabilities.

The current approach for screening for developmental progress asks parents or primary caregivers a series of questions about a child's abilities in areas such as gross motor, communication, and problem-solving. For example, "does your baby say two-syllable sounds, such as 'da-da' or 'ga-ga'?" or "can your child walk upstairs while holding onto a railing?" A popular screener tool, the Ages and Stages Questionnaire (ASQ), consists of 22 questionnaires with 30 questions each across the child's first 5 years [5]. The screener is administered via paper or through a website, often at Well-Child Visits with the child health care providers, by childcare providers, through community-based services, or by parents self-monitoring their child's development. There are some limitations to using milestone questionnaires for screening, such as questions not being culturally competent, language or literacy barriers, or the potential for parent anxiety when tracking their child's development [6]. However, developmental questionnaires are currently the most effective method for screening according to the American Academy of Pediatrics [7].

A major challenge with paper-based or even web-based screener surveys is that it is often difficult to ensure that parents complete each survey, especially if families are not regularly attending Well-Child Visits or are not yet connected to a Medical Home [7]. Given that Well-Child Visits are months to up to a year apart depending on the child's age, these visits may not be the best timing for conducting timely screens. In addition, when parents answer screener questions in a single sitting in a time- and resource-constrained setting, such as in their child health care provider's waiting room, they may not have the opportunity to try each activity with their child, such as drawing shapes on a piece of paper or interacting with a mirror. Also, busy or overwhelmed parents may just not have the time or available cognitive load to use paper- and web-based systems [8].

Digital interventions that can help prompt parents to answer questions at more regular intervals have the potential to encourage more complete and accurate responses, better patient engagement [9], and parent awareness of their child's activities. Because child development takes place in daily life outside of traditional clinical settings, parents' and caregivers' reports of the early signs of developmental delay are the most reliable way to track them [10]. Therefore, it is important to engage, inform, educate, and empower parents to track and assess their child's development in easier ways to make developmental screening more accessible, accurate, and meaningful. Human-centered design researchers have designed interactive digital tools that can promote this engagement [11-16]. However, there are limitations with standalone software or mobile apps, such as requiring the parent to remember to open the app to answer questions or device compatibility. Even with proactive notifications or email reminders, parents may still not engage as easily and as often as they might otherwise. Because these screening tools are intended to be used over a long period (eg, up to 5 years), they require specifically considered methods to maintain parent engagement over the long term.

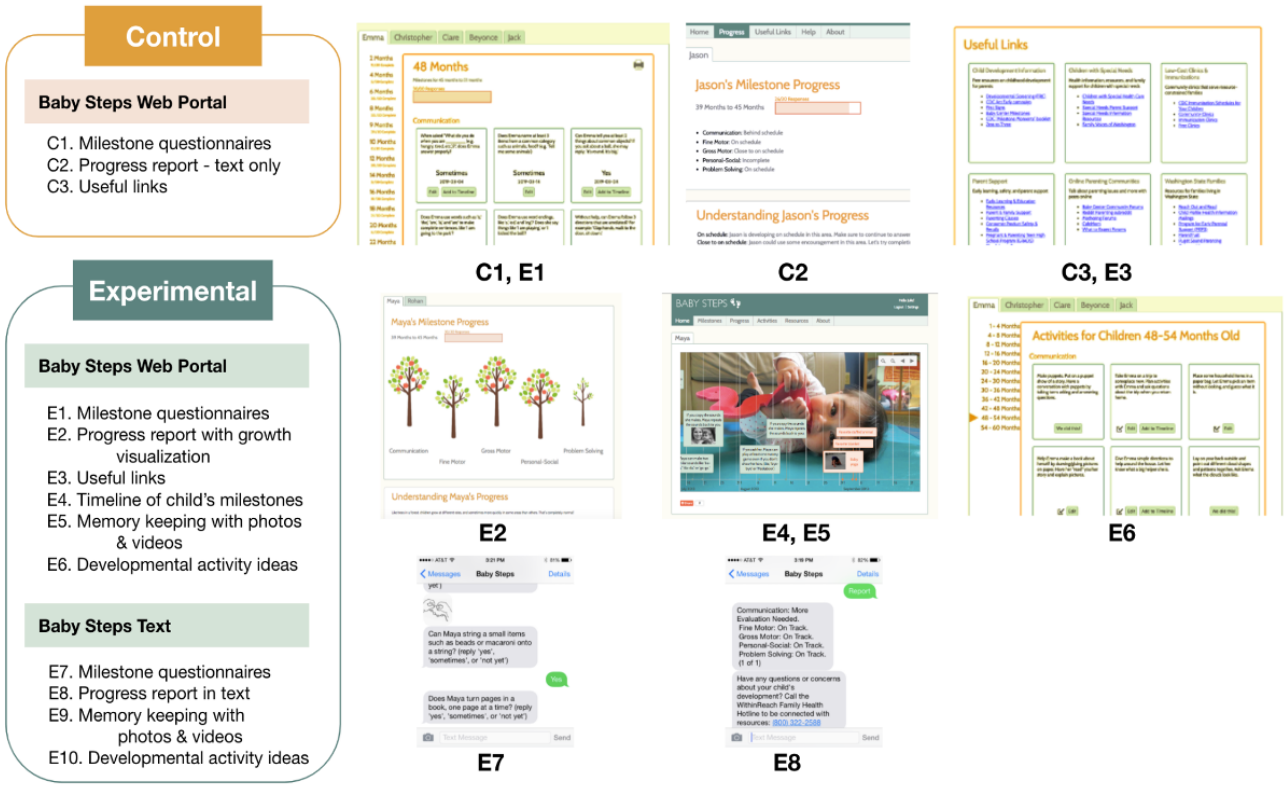
Researchers in the computing, health informatics, and medical fields have focused on the usability and feasibility of technology-based interventions designed for use between and outside of clinic visits. Mobile health (mHealth) interventions, in particular, have been introduced to support various health domains for children [15], such as:

1. Providing pregnant mothers with information about pregnancy and newborns [17-19]
2. Promoting healthy infant feeding for obesity prevention [20]
3. Sending infant vaccine reminders [21]
4. Delivering speech developmental education [22]
5. Developmental monitoring and screening [23,24]

However, the long-term impact of mHealth interventions is not well understood due to the limited study periods of deployment studies, and further research is needed to establish long-term effectiveness. For example, Stowell et al [25] highlighted that engaging in extended interactions with participants through formative work can prevent researchers from making premature judgments and conclusions. This approach allows for a deeper understanding of the populations and their contexts. They also emphasized that without prolonged and thorough formative work, researchers might design evaluations based on a superficial understanding of the community's challenges, attitudes, and resources, which can impact health inequities.

In this research, we aimed to (1) develop and evaluate novel techniques for leveraging interactive technology to engage parents in the developmental screening process and (2) assess the immediate and long-term effects of the designed systems in fostering family engagement with early childhood developmental screening.

Design of Baby Steps Web Portal and Text Messaging Intervention



Based on preliminary research with key stakeholders [8,11,23], we identified potential methods for engaging families in the developmental screening process that would be combined in a new digital intervention called Baby Steps. We hypothesized that 3 key design features would help increase parent engagement in the screening process: (1) engaging visualizations to help families interpret results and guide them to appropriate actions, such as completing developmental activities or connecting with early intervention for evaluations; (2) combining developmental screening with sentimental record-keeping, such as keeping track of memories and fun

XSL•FO
RenderX

activities; and (3) multiple, integrated ways to complete screening questionnaires (eg, via web or text messaging). Our goal was to understand whether these engagement features would lead to increased screening completion rates and thus ultimately lead to more connections to early support services if needed.

We designed and implemented 2 versions of Baby Steps that would allow us to test these design features. We designed the control version of Baby Steps to be as close as possible to the current standard of care, which consists of neutral, web-based developmental screening questionnaires with text-based feedback on child progress. The experimental version of Baby Steps included additional features that tested our design hypotheses, such as tracking sentimental information and photos on the baby's timeline, suggestions for activities that parents can do with their child to promote development, family-friendly visualizations of child's progress that promote a growth mindset of development, and integration of text messaging prompts to complete milestone questionnaires that would synchronize with data on the web portal. Figure 1 shows the differences in features between the 2 versions, along with screenshots of those particular features. (The baby photo on the website screenshot was used with parental consent.)

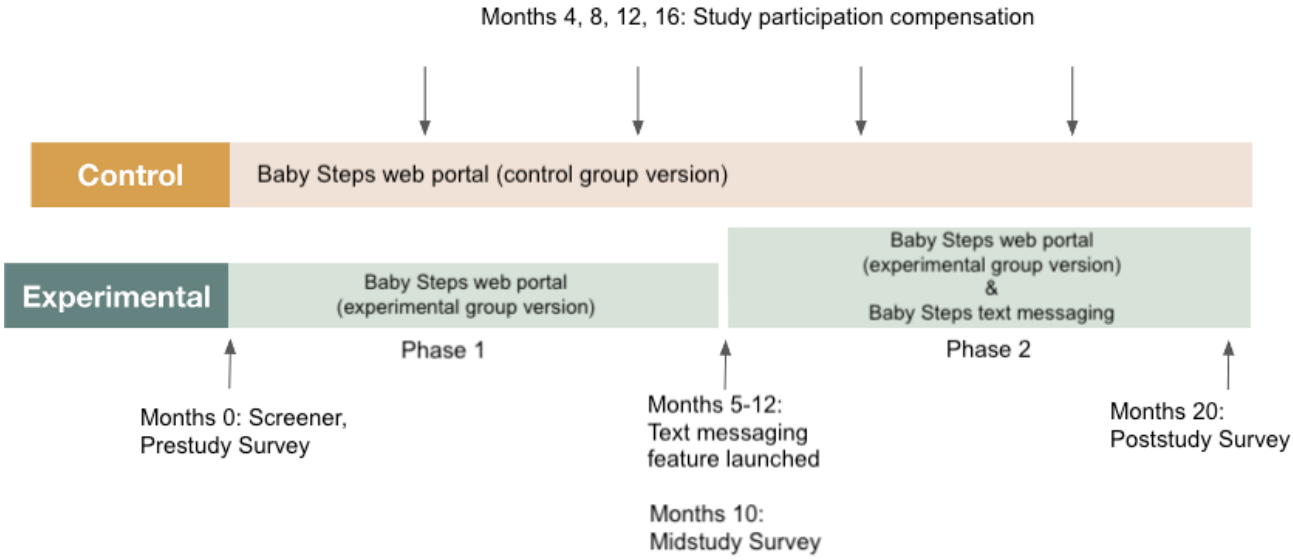
Figure 1. Baby Steps feature differences between control and experimental groups with screenshots. Photo of child included with parents' consent.

Methods

Recruitment and Participants

We recruited parent participants via mailing lists, flyers posted in family-centered locations such as libraries, advertisements on social network services targeting parents of young children in Washington State, postings on local parenting lists, flyers at state-wide Women, Infants, and Children (WIC) clinics, and the University of Washington Communication Studies Participant Pool. We aimed to recruit parents who had a child between 7 and 12 months old, lived in Washington state, and were proficient in English to read and respond to milestone questions on the web portal. To ensure all participants meet the criteria, potential participants completed a screener survey. We recruited on a rolling basis, with the entire recruitment period taking about 7 months. To examine how specific design elements of the intervention affected self-monitoring behavior, we used a between-subjects design. A total of 180 participants completed the screener survey, and 139 were deemed eligible to enroll based on the age of the child and residing within Washington State. The first author used a random number generator to randomly assign participants to each group—if the generated number was odd, participants were assigned to the control group; if it was even, they were assigned to the experimental group. We then invited them to enroll in the study. Overall, we enrolled 67 parents in the control group and 72 parents in the experimental group, for a total of 139 enrolled participants.

Study Procedure



Upon enrollment in the study, participants signed a web consent form and completed a prestudy survey on family demographics, child demographics, current parenting experience, and technology use. We then sent an invitation email to participants to create accounts and register on the Baby Steps web portal. The invitation email contained a brief introduction to the Baby Steps system, information about child development, and details on the study procedure, including the compensation plan. It also included an invitation code to use for portal registration, which

XSL•FO
RenderX

was different for the control group and the experimental group. Depending on which invitation code was entered during registration, participants were exposed to 2 different web portal features as laid out in Figure 1. To study natural and realistic usage, we told our participants they could use Baby Steps as much or as little as they wanted, and we minimized interactions with the research team to allow for naturalistic use. Parents used Baby Steps to answer child developmental questionnaires, without involvement of health care providers. To encourage regular developmental screening, we included a paragraph noting to participants that if they did not interact with the Baby Steps system for more than 60 consecutive days, we might consider them to have withdrawn from the study and would send the exit package with a prorated incentive up to that point. However, we did not drop any participants until they reached the 12-month participation mark.

To track Baby Steps usage, we instrumented the Baby Steps website with timestamped logging that allowed us to see which features were accessed by which participants and when. Due to some technical difficulties initially in the system development, the text messaging option for the experimental group could not be launched at the start of the study. Depending on when a participant started their participation, text messaging was introduced between 5 and 12 months into the study (Figure 2). When text messaging became available, the research team emailed the experimental group to introduce it and provided an instruction sheet. In total, 52 of the 72 experimental group participants registered their mobile phone numbers and began receiving milestone questions via text messages. This enabled us to also collect within-subjects data points from the experimental group and compare specific design characteristics of the web portal and text messaging. We will refer to the experimental group before text messaging as phase 1 and after text messaging as phase 2.

Figure 2. Overview and timeline of Baby Steps study.

During the study, researchers only interacted with participants: (1) to send periodic compensations, (2) to introduce the text messaging option when it became available for the experimental group, and (3) to send a midstudy survey at 10 months. The midstudy survey was designed to receive participant feedback on their experience with Baby Steps, and 118 participants (54 in the control group and 64 in the experimental group) out of 139 enrolled participants completed the survey. At the end of the 20 months, we sent a poststudy survey to all 139 enrolled participants, regardless of how much of the study they had completed and received overall 87 responses (30 from the control group and 57 from the experimental group). Participants received a $20 Amazon.com gift card each at 4-, 8-, 12, 16-, and 20-month completion and a $10 Amazon.com gift card for each survey completion. In addition, participants who completed the entire 20-month study received a $20 Amazon.com gift card completion bonus. Participants who participated in a poststudy interview also received a $20 Amazon.com gift card.

We also partnered with WithinReach Washington [26], a local nonprofit organization and statewide Help Me Grow affiliate [27] that serves many low-income families and maintains a toll-free parent hotline number for parents to answer questions or address concerns about child development. The web portal's progress report page directed parent participants to contact their child's health care provider or the Help Me Grow Washington parent hotline for both the experimental and control conditions, as did the text message progress report in the experimental condition. We worked with WithinReach to cross-reference the names of study participants with parents who had registered with their system to analyze whether parents had reached out as a result of using either version of Baby Steps.

Analysis

Data analysis focused on evaluating the impact of the Baby Steps intervention on parent engagement and the completion of developmental screening questionnaires over a long-term period. We used system usage logs and a survey to assess these. Given the importance of timely tracking of child development, we first separated responses based on whether parents completed milestone questions within the appropriate age range (responses within the valid time window vs those outside it). We then separated sources of response (website vs text messaging). Because the text messaging option was introduced later in the

XSL•FO
RenderX

study, we were able to collect within-subjects data points for the experimental group (phase 1 vs phase 2) as well as between-subjects data (control group vs experimental group; and experimental group who used text messaging in phase 2 vs those who did not use). Descriptive analyses were used to analyze quantitative systems. Where appropriate, quantitative analysis was performed using *t* tests to compare the groups. For qualitative data from 3 surveys (intro, midstudy, and exit) and interviews, we conducted rapid qualitative analysis to identify key themes. These analyses aimed to determine the effectiveness of the design intervention in enhancing engagement and adherence to developmental screening protocols over the long term.

Ethical Considerations

This study was reviewed and approved by the Institutional Review Board of the University of Washington (IRB 49545). All participants gave informed electronic consent before enrolling in the study and were informed about their right to opt out at any time. Participants received a US $20 Amazon.com gift card each at 4-, 8-, 12, 16-, and 20-month completion and a US $10 Amazon.com gift card for each survey completion. In addition, participants who completed the entire 20-month study received a US $20 Amazon.com gift card completion bonus. Participants who participated in a poststudy interview also received a US $20 Amazon.com gift card.

Results

Participant Demographics

Table 1 shows primary parent participant demographics across both groups. Despite our statewide recruitment efforts, the majority of the participants were from the greater Seattle, Washington metropolitan area. Our sample also overrepresents mothers and individuals from higher socioeconomic status compared to the general Washington State population (eg, education and income) [28], though it is closer to the average demographics for Seattle, WA, where the median household income is $118,745 and 38.1% have bachelor's degrees and 31.9% have graduate degrees [29]. The sample does underrepresent the racial and ethnic diversity of the state as well as Seattle, especially that of Black, Hispanic, American Indian or Alaska Native, and Native Hawaiian or Pacific Islander families. This may have been a result of our lack of resources to provide the intervention and study materials in languages other than English. The complete participant flowchart is depicted in Figure 3.

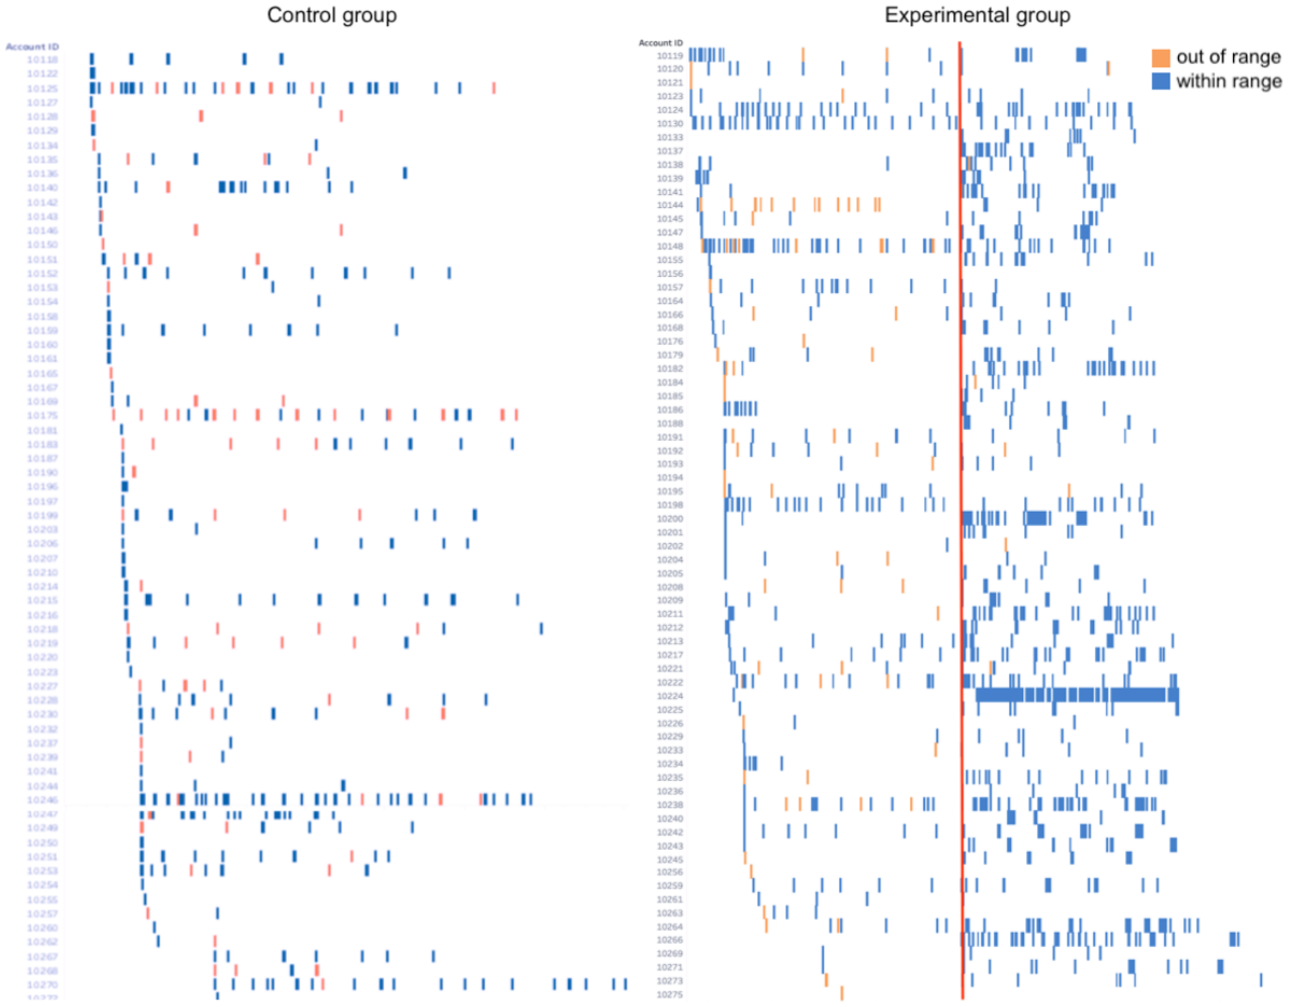
Figure 3. CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the study.



Developmental Screening Questionnaire Responses

There was a statistically significant difference between 2 groups in terms of screening questionnaire response rates (t_{125}=−3.32, P<.01, 2-tailed). The experiment group yielded a total of 15,619 responses (mean 216.93, SD 102.42, median 205, [IQR] 145.75-306) compared to the control group's 10,075 responses (mean 150.37, SD 130.95, median 90, [IQR] = 30-240), resulting in 44% more responses per participant on average. In addition, while there was no control group participant who updated their answers to questions (eg, changing "not yet" to "sometimes" or "yes") when their child became able to meet the milestone, 20/72 (28%) experimental group participants updated their answers to questions, and 95% of those updates were made within the valid time range, indicating the experimental group participants were more engaged in monitoring their child's development beyond answering milestone questions just once.

Figure 4 shows chromograms of responses to developmental questionnaires over the study period. Chromograms are a visualization technique used to detect and present patterns in large datasets [30]. This allows us to show the milestone response patterns of participants in each group over 20 months in one figure. In the figure, the left side represents the control group, and the right side represents the experimental group. Within each side, each participant is a row, and each column represents a day of the study. Because each questionnaire of ASQ is designed for a specific age range, answering outside of the valid age range may not accurately reflect a child's development. We used blue to indicate responses recorded within the valid time range and orange to indicate responses recorded outside the valid time range (eg, the 9-month-old questionnaire was completed after the child was already 12 months old). The date at which text messaging was introduced for the experimental group is highlighted with a red line.

XSL•FO
RenderX

Figure 4. Chromograms of responses to developmental questionnaires over the entire study period. Blue lines indicate questions completed within the correct time range; orange lines indicate questionnaires completed outside of the recommended time range.

Follow-Up With Providers Based on Screening Results

Another goal of this longitudinal study was to determine whether the experimental version of Baby Steps could nudge parents to follow up with child health care providers or early intervention services when the progress report indicated that more evaluation may be needed. The experimental group checked the web-based progress report 1.3 times more often than the control group (8.14 times per participant for the control group vs 10.46 times per participant in the experimental group) but this difference was not statistically significant. In addition, when we cross-referenced the list of study participants with the names of parents who had contacted WithinReach, there were only 6 total study participants that matched names with the WithinReach database (3 from the control group and 3 from the experimental group), and their contact had happened prior to the study, indicating that there was no participant who contacted WithinReach with concerns as a result of using Baby Steps. However, we did learn from our qualitative survey and interview responses that several participants in the experimental group contacted their child's health care providers after reviewing the progress reports in Baby Steps.

> *"Used this data to discuss delays with pediatrician, got referrals to early intervention services for therapy and other developmental delays and child will be starting developmental preschool next month with an IEP."* [(E20)]

> *"On one occasion, he was delayed in his development (based on the progressreport) and at his doctor's well check appointment I brought it up and after some tests, it was discovered that my child had iron deficiency. He was prescribed a supplement and right after, my son's condition improved, and he eventually caught up to his development milestone. I would not have discovered or noticed the iron deficiency if not for the app"* [(E34)]

Engagement With Sentimental Memory Tracking and Timeline

We hypothesized that adding sentimental memory keeping to developmental tracking would help engage parents in a strength-based approach [31] to development rather than a deficit-focused one by allowing them to celebrate meaningful events in their child's development (eg, first steps, first zoo visit, etc), which could help reduce emotional burden and promote positivity and resilience. However, memory keeping was not frequently used by the participants. Only 44/72 (61%) experimental group parents logged memories at least once, and of those, 23 (32%) used this feature 3 times or fewer. In the poststudy survey and interview, participants expressed

XSL•FO
RenderX

uncertainty about keeping their memory logging data in the long term as a barrier to the usage of the feature.

> *"I was not clear on how the information was going to be retained. At first, I was using the site every few days to track new developments, but then I realized that I probably wasn't going to be able to keep the data. There was no option for printing it or saving it, so I ended up transitioning to a paper baby book instead."* [(E27)]

However, several participants in the control group suggested adding a memory-keeping feature to the Baby Steps system, implying a desire for combining developmental tracking with sentimental memory keeping.

> *"(I want a) place to save photos of them [a child] attempting the tasks"* [(C26)]

> *"It would be nice to have a record of when my child was able to do some of the tasks at each milestone"* [(C3)]

Engagement With Web Portal Versus Text Messaging for Questionnaire Completion

Between-Subject Comparisons: Control Group Versus Experimental Group

While there was no statistically significant difference in the milestone question response rate between the control group and experimental group rate in phase 1, there was a statistically significant difference between the groups in phase 2, when 88% of the experimental group responses were from text messaging (t_{136}=−7.71, P<.01). Five experimental group participants who answered fewer than 5 milestone questions via the website over 10 months of participation answered over 100 milestone questions respectively after text messaging was added in (in less than 10 months). This indicates that the introduction of text messaging significantly increased long-term participant engagement in the experimental group.

Also, before the text messaging option was introduced, the experimental group answered more questions within the valid time window than the control group (86% of the experimental group's responses vs 72% of the control group's responses) but the difference between the groups was not statistically significant. However, since the introduction of the text messaging option, the experimental group responses were statistically significantly more within a valid range (t_{135}=−7.90, P<.01). Thus, the addition of text messaging improved the timeliness and validity of responses in the experimental group.

Between-Subjects Comparison: Experimental Group With Text Messaging Versus Without

The positive effect of using text messaging was evident again when we compared the experimental group who used text messaging in phase 2 (n=52) versus the experimental group who did not use text messaging in phase 2 (n=20). There was a statistically significant difference between the 2 groups (t_{70}=−7.23, P<.01). The group that used text messaging answered 127.60 questions on average (SD 49.01, median 120 (IQR) 90.75-150), while the group that did not use text messaging answered 36.85 questions on average (SD 44.07, median 15.5 (IQR) 0-67.25), resulting in 246.27% more responses per participant on average. These findings underscore the substantial impact of text messaging on increasing participant response rates over time.

Within-Subjects Comparison (Phase 1 vs Phase 2)

In addition to between-subjects differences, when we compared within-subjects data of experimental group participants in phase 1 versus phase 2, the experimental group participants answered more milestone questions within the valid range in phase 2 (95%, 7279/7639) compared to phase 1 (71%, 5691/7980); t_{107}=−4.44, P<.01. This within-subjects comparison further confirms the effectiveness of text messaging in enhancing response validity over time.

Overall, these findings demonstrate that the introduction of the text messaging option significantly enhanced long-term adherence among participants. This method not only increased the number of milestone questions answered but also improved the timeliness and validity of responses. Consequently, text messaging proved to be an effective tool for more accurate and timely tracking of child development, as reconfirmed by the positive feedback in the survey responses.

> *"LOVED the text portion. It's so easy to get side tracked with kids and constantly forget. I needed to text prompts and it made it easy to participate."* [(E23)]

> *"Text was much much better, so easy to use and good for on the go. Gave me fun ideas to try in the moment as well."* [(E45)]

Overall Engagement and Completion of the Study

Finally, we ran descriptive statistics and compared general usage patterns between the 2 groups, and there was a significant difference in study completion rates. While only 30% (20/67) of the control group finished the entire 20-month study, 83% (60/72) of the experimental group remained enrolled in the study through the end (t_{119}=−8.40, P<.01, 2-tailed), suggesting the experimental group study design was successful in engaging parents over a long period of time.

Discussion

Principal Findings

In this research, we aimed to (1) design and evaluate new approaches that use interactive technology to involve parents in the developmental screening process and (2) examine long-term impacts of these systems on promoting family engagement with early childhood developmental screening. Overall, design features to explicitly engage parents over time implemented in Baby Steps increased engagement and screening questionnaire completion rates. As early child developmental screening requires continuous monitoring over the first 5 years of a child's life, it is promising that a large number of the experimental group participants were able to complete the 20-month study. However, the study was inconclusive regarding whether greater engagement led to connections to early intervention resources, and thus more research may be needed

XSL•FO
RenderX

to understand what design features, if any, might prompt parents to follow up on making those connections. Because there were a very small number of cases, it is premature to conclude whether the differences in progress reports (text vs visualization) made a difference in follow-ups, but it is promising to know the progress reports were successful in triggering follow-up actions with their child's health care providers for several parents.

The introduction of text messaging seemed to be a clearer success. We acknowledge that the proactive notifications that drew people to engage with the system were a big part of this, which prior research has also identified as important [32,33], and we also believe this success is due to the integration into a communication mechanism that is frequently used by parents already, which has been advocated for as a way to lower barriers to access [34] and can increase accessibility for lower-income populations without access to higher-end digital devices and data plans [35,36]. We believe that being able to answer milestone questions directly via text message, as opposed to just text-based reminders to log into the website, was a useful implementation of this feature that would benefit from further exploration.

More research is also needed to better understand the role that combining developmental screening with sentimental memory keeping can play in parent engagement. Although we saw low use of this feature overall, numerous parents reported finding the idea to be promising. However, because Baby Steps was separate from other ways that they tracked their baby's sentimental milestones in baby books or using social media, the feature could be improved to better integrate with families' needs. Adding the option to print information as physical books or integrate with Facebook or Instagram, which parents already frequently use to share information about their child with others [37] and benefit from [38,39], could be a promising next step.

Limitations

Our study shows promising results for improving parent engagement with developmental screening, but this study is not without its limitations. Despite our best efforts for a broad recruitment approach, most of our study's participants were of a higher socioeconomic status and less racially or ethnically diverse than the general population of Washington State [28]. It is known that many resource-constrained populations, such as low-income or immigrant families, lack the insurance to cover Well-Child Visits, frequently move, or face language barriers that make it difficult to access information about normal child development, and they often struggle because they may not be aware of what to monitor [40,41]. Therefore, further research is needed to examine the efficacy of interventions and monitor outcomes in larger, more diverse populations. As a follow-up to this work, the research team has started work via a community-based participatory research approach [42] to ensure that both technology designs and study designs better fit the needs of people from marginalized communities and to better understand how systems such as Baby Steps can fit into a broader macrosystem of care [43], including pediatric practices, community organizations, childcare providers, and public health organizations. Another limitation is that the ASQ currently has a cost per screen associated with it that we paid as part of our study's grant. Future work could use an open-source screening tool, such as the Survey of Wellbeing in Young Children [44].

Conclusions

This paper describes the findings from a long-term, randomized controlled trial of a novel technology-based intervention aimed to engage parents of children aged 0 - 5 in the process of developmental screening. We enrolled 139 parent participants over a 20-month period and randomly assigned parents to use one of 2 versions of the system: one being a neutral, web-based screening questionnaire tool that mimics current standards for web-based developmental screening, and one that followed a human-centered design process to develop features aimed to engage parents in developmental screening over the long term. Our study determined that the version of the system designed via a human-centered process resulted in twice as many people completing the full study and engaged parents significantly more in completing timely developmental screening questionnaires. However, it was inconclusive whether the designed features would prompt parents to take actions such as engaging in activities to promote development or engaging with early intervention services if needed, as the overall number of children in the study who fell below the cutoff for developmental concerns was small. This study provides evidence that human-centered design methods for designing technology-based interventions can lead to systems that are engaging and improve the completion of developmental screening questionnaires. More community-based design research is needed to understand how to better engage families from more underserved communities.

Acknowledgments

This work was primarily funded by the National Science Foundation (Award no. 0952623) with supplemental funding from the University of Washington Innovation Fund and Provost's Bridge Funding. The authors have no competing interests to declare. We acknowledge Alexis Hiniker, John Porter, Robert Racadio, and Yi-Chen Sung for their contributions to the design and development of the Baby Steps web portal and text messaging system. We also acknowledge Within Reach for assisting us with data collection from participants who reached out to their Help Me Grow hotline. This work was reviewed and approved by the University of Washington Human Subjects Division.

Abstract

Background: Young survivors of childhood cancer diagnosed and treated before the age of 7 years are at heightened risk of developmental difficulties. As a result, their caregivers may experience stress as they navigate various educational and health care systems while advocating for their child's needs. To our knowledge, there are no tailored early interventions or support programs to address the unique and multifaceted needs of young survivors of childhood cancer and their caregivers. Digital platforms can provide anticipatory guidance and developmental resources, which may be especially impactful for families at increased risk for health and educational disparities, particularly in underserved rural and Appalachian areas.

Objective: This mixed methods study describes the usability testing of an internet-based responsive parenting program for caregivers of young survivors of childhood cancer, called the Preparing for Life and Academics for Young Survivors (PLAY) program.

Methods: Twelve caregivers of young survivors of childhood cancer (9 biological parents, 2 grandfathers, and 1 legal guardian; 33% rural, 33% Appalachian, and 83% White) participated in an online usability session with a task-based, think-aloud method. This session was followed by completion of the System Usability Scale (SUS), responses to reaction cards to describe their experiences with the platform, and a semistructured interview. Two trained coders used rapid analysis and consensus methods to identify themes.

Results: Overall, caregivers found the platform easy to use (92% SUS >68; mean 82.2, SD 14.45). Most caregivers provided positive feedback in response to reaction cards (eg, useful, appealing, and valuable) to describe the platform. Qualitative findings highlighted that most caregivers perceived the platform as "easy to use," and several participants described it as a helpful educational tool. Participants noted that potential platform improvements should include accessibility features (eg, closed captioning for videos), more tailored content, and usability on mobile devices.

Conclusions: With further improvements, digital platforms such as PLAY may be a promising avenue to bridge access to care for high-need groups and ultimately improve child neurodevelopmental outcomes.

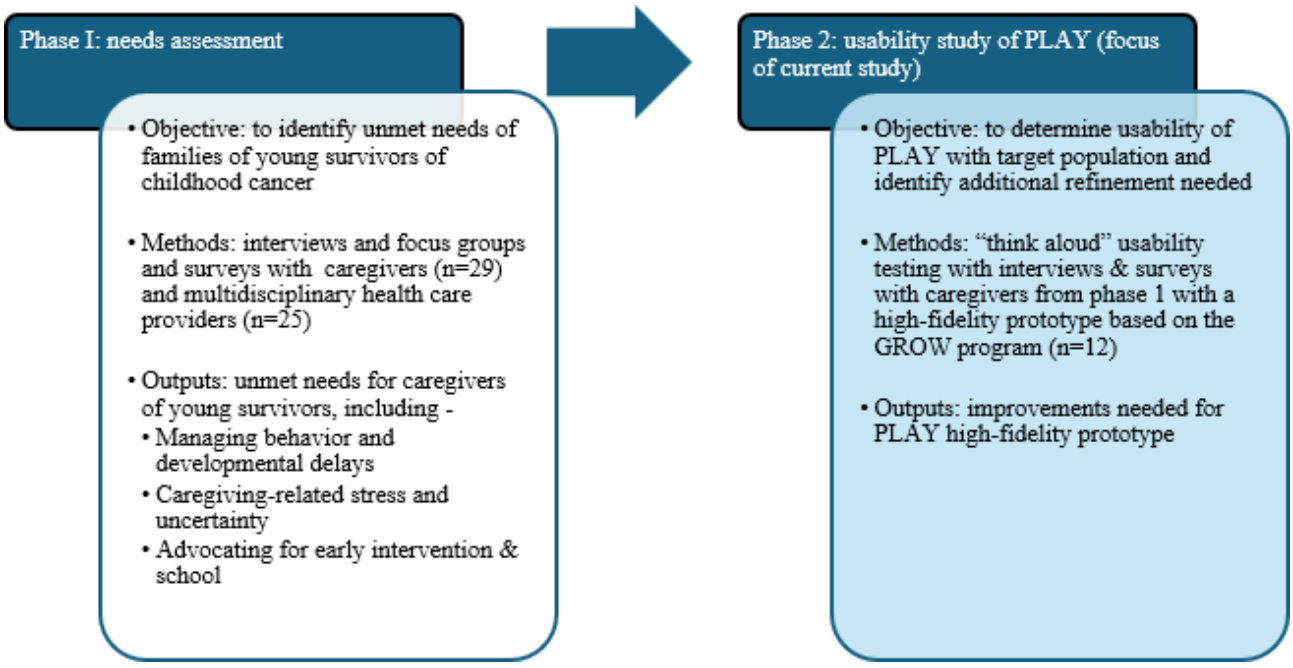
Introduction

Survival rates for most types of childhood cancers have fortunately risen to over 80%, resulting in a growing cohort of nearly half a million childhood cancer survivors in the United States [1]. However, life-saving cancer treatments, such as chemotherapy and radiation, can be detrimental to a child's development and lead to a host of chronic health needs for up to two-thirds of survivors, termed late effects [1]. Late effects from cancer treatment can vary and include impacts on physical, cognitive, social, and emotional development that may impair long-term academic functioning and quality of life [1-4]. Cancer treatment is particularly disruptive to early development, with young survivors of childhood cancer who are diagnosed and treated before the age of 7 years at heightened risk for chronic late effects [5-7].

The emotional toll of cancer extends to caregivers, who are faced with the daily realities of caring for a young child with cancer [8]. Even after cancer, caregivers may need to manage chronic medical needs and heightened anxiety about recurrence, with up to 40% of caregivers having clinically significant levels of post-traumatic stress symptoms [9]. Caregivers have reported a high need for information about their child's medical condition and future late effects [10]. Parenting stress has also been linked with poorer developmental outcomes for young survivors of childhood cancer [11], further exacerbating the detrimental impact of cancer treatment. In other neurologically vulnerable populations, such as those with traumatic brain injury (TBI) and preterm birth, responsive parenting programs that teach parents how to increase warmth and cognitive stimulation and take care of themselves may lead to improvements in child developmental outcomes [12,13], suggesting potential intervention opportunities for young survivors of childhood cancer.



Still, young survivors of childhood cancer and their families living in underserved rural or Appalachian areas have barriers to survivorship care. Appalachia is a 250,000-square-mile region extending from New York to Mississippi and includes over 25.7 million residents [14]. This region has been plagued by economic distress, often resulting in residents with limited access to specialty health care due to financial barriers and distance [15]. Access to mental health care is further limited by stigma and misperceptions of the potential benefits of these services [16,17]. Although research is scarce in young survivors of childhood cancer, older CCS in rural regions have demonstrated deficits in social competence as compared to their nonrural counterparts [18,19]. Thus, to improve health equity, it is essential to identify accessible, evidence-based early interventions and psychosocial supports for young survivors of childhood cancer and their caregivers to mitigate disparities in outcomes.

Digital health interventions may be a potential solution to increase access to specialized care for underserved populations [20], such as rural and Appalachian young survivors of childhood cancer and their caregivers. Recent systematic reviews have identified over 30 studies (N=32) focused on digital health interventions for families of children with special health care needs [21]. A few of these studies identified additional barriers to care for rural pediatric populations, including poor internet connectivity, leading to poor video quality and interruptions to care [21,22]. Thus, to facilitate future implementation and uptake, and to promote health equity, user-centered design methods that begin at the earliest stages of intervention development are needed [23]. The Consolidated Framework for Implementation Research (CFIR) has identified innovation design, or the extent to which an intervention is accessible and easy to use, as a key component of uptake and implementation [24]. Furthermore, interventions that have included user-centered design have also demonstrated greater effectiveness [25,26].

To our knowledge, there are no tailored early intervention or support programs to address the unique and multifaceted needs of young survivors of childhood cancer and their caregivers, especially for those living in underserved rural or Appalachian areas. Therefore, we sought to develop a responsive parenting program for this population. Figure 1 provides an overview of this work. The findings from the needs assessment (phase 1; Darow et al, report in preparation; Kaufman et al, report under review; and Moscato et al; report in preparation) suggested several unmet psychosocial needs for young survivors of childhood cancer (eg, behavioral dysregulation, developmental delays, and impaired quality of life), as well as their caregivers (eg, caregiving-related stress, managing uncertainty, and advocacy related to early intervention services and school). Given that the unmet needs endorsed by caregivers of young survivors of childhood cancer were similar to those identified by caregivers of other neurologically vulnerable populations, such as individuals with TBI, we opted to tailor a previously developed internet-based intervention called the Gaining Real Life Skills Over the Web (GROW) program. The GROW program was designed for caregivers of young children after TBI (ages 0 - 4 years) [27] and targeted responsive parenting and caregiver distress through psychoeducation and individualized coaching [28].

XSL•FO
RenderX

Figure 1. Overview of the development of the Preparing for Life and Academics for Young Survivors program, including the previous phase of research (phase 1 [Darow et al, report in preparation; Kaufman et al, report under review; and Moscato et al; report in preparation] and phase 2 [focus of this paper]). GROW: Gaining Real Life Skills Over the Web program; PLAY: Preparing for Life and Academics for Young Survivors.

Following the needs assessment, our team tailored the wording of the content in GROW to fit the population-specific needs of young survivors of childhood cancer (eg, changing "brain injury" to "cancer experience") in the adapted intervention, now called the Preparing for Life and Academics for Young Survivors (PLAY) program. We also opted to focus on young survivors of childhood cancer aged 3 - 6 years for the PLAY program, given that state-based early intervention programs focus on 0 - 3 years, and caregivers in phase 1 identified an unmet need related to the transition to preschool and kindergarten. The focus of this study (Figure 1, phase 2) is a preimplementation, mixed methods usability testing study [24] involving interviews and standardized measures with 12 caregivers of young survivors of childhood cancer using a high-fidelity prototype of the PLAY program. The purpose of this phase of the study is to inform the refinement of PLAY based on usability metrics, including both standardized measures (ie, the System Usability Scale [SUS] and acceptable usability indicated by scores >68) [29,30] and qualitative feedback from caregivers. The ultimate goal of this program of research is to develop an accessible program that will improve parenting stress and child outcomes for this vulnerable group of young survivors of childhood cancer, especially those in underserved rural and Appalachian areas.

Methods

Overview

We used a mixed methods research design with a sample of caregivers (n=12) to examine the usability of the PLAY high-fidelity prototype. A high-fidelity prototype is a simplified version representing the skeletal framework of a website or application's interface [31]. Specifically, we used an expedited iterative design process to advance the study timeline. Rapid usability analysis has been used to speed the interpretation of user feedback and maximize identified codes and themes via reviewing conversations (ie, audio and video recording) instead of transcriptions [32-34]. This approach is known for its efficiency in distilling user feedback, accelerating the identification of codes and themes by analyzing audio and video recordings directly, thereby bypassing the labor-intensive transcription process. This method ensures swift progression from user feedback to design iteration, aligning with user-centered design principles [23]. By engaging a diverse cross-section of caregivers, including a significant representation from underserved rural or Appalachian regions (over 30%), we aimed to rapidly pinpoint and implement essential modifications to tailor the platform to the needs of these communities.

PLAY High-Fidelity Prototype

A high-fidelity prototype of the PLAY website, based on GROW (Figure 1), was developed and shared with caregivers in this study to (1) determine usability among caregivers of young survivors of childhood cancer and (2) identify recommendations for tailoring the program to their unique needs. The PLAY website was based on the GROW website, a fully developed digital health intervention program originally designed for caregivers of young children ages 0 - 4 years following TBI, to improve responsive parenting skills and cognitive stimulation [27,28]. Participants were instructed to review the content, as generally about having a child with a chronic medical condition. The GROW intervention involves internet-based learning modules (ie, GROW platform), as well as live one-on-one coaching via videoconferencing and weekly homework. GROW was based on a previously developed and tested responsive parenting program called PLAY and Learning Strategies (PALS) [35] and informed by caregivers and experts in special education and TBI. All 3 programs (ie, PALS, GROW, and PLAY) are rooted in attachment theory [36] and sociocultural models of child development [37]. The core treatment target is responsive

XSL•FO
RenderX

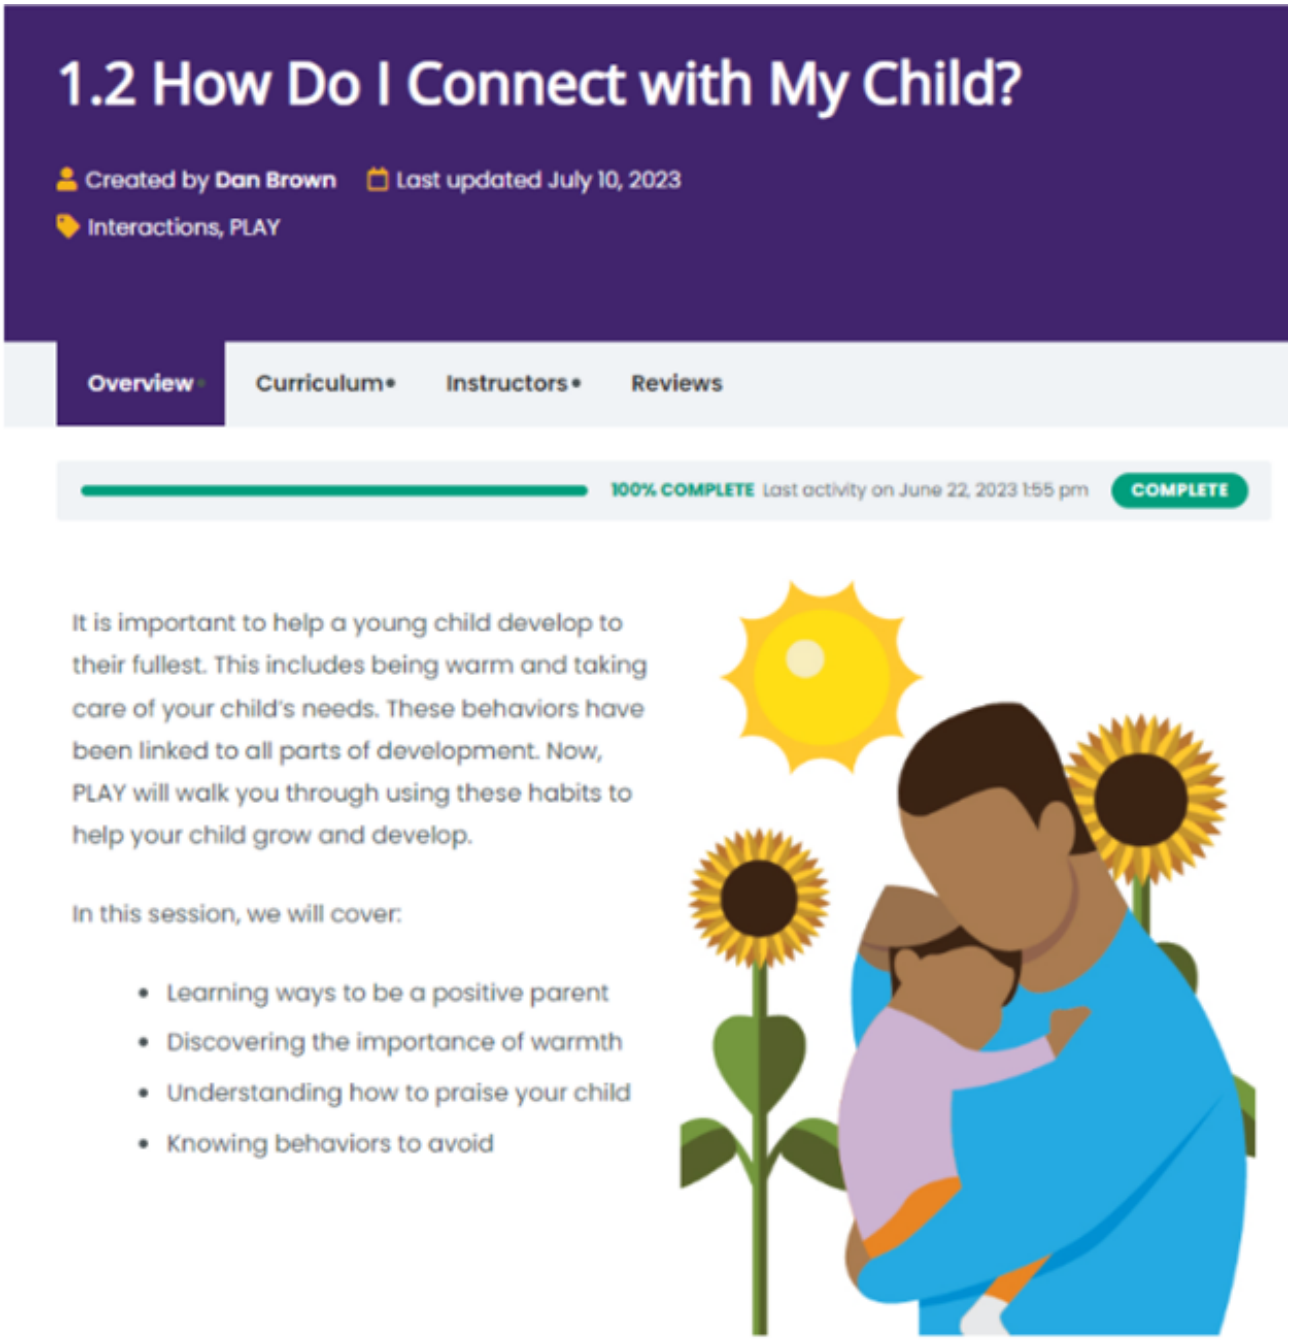
parenting, which involves increasing caregiver warmth and contingent reactions to their child's cues, while also providing verbal stimulation that enriches development.

The PLAY website, such as GROW, has six learning modules: (1) interactions, (2) language development, (3) attention/play, (4) parent self-care, (5) relationships, and (6) working with schools. Each module includes brief text content on the topic area, videos highlighting examples of caregivers interacting with their children and practicing the skills, and exercises to apply learned information, such as matching and quizzes (refer to previous publications) [27]. The interface was built using the popular content management platform WordPress (Automattic, Inc), augmented with the LearnDash plugin to provide learning management system functionality. This system is compatible with PC, mobile (Android and iOS), and tablet browsing due to an inbuilt responsive design.

Procedure

Purposive sampling was used to identify potentially eligible caregivers of young survivors of childhood cancer from the cancer registry of a Midwest pediatric academic medical center. Inclusion criteria for eligible participants included caregivers of a child who (1) was diagnosed with cancer before the age of 7 years, (2) was between the ages of 3 - 12 years at the time of study participation, (3) did not have a history of a neurodevelopmental disorder prior to their cancer diagnosis (eg, neurofibromatosis, tuberous sclerosis, Down syndrome, and autism), (4) had completed treatment for cancer at least 6 months prior or was on maintenance oral chemotherapy only, without evidence of recurrent disease or current hospitalization. Caregivers also were required to be (1) the child's legal guardians, (2) living with the identified child at least 50% of the time, (3) fluent in English, and (4) residing in the state of the institution or surrounding states (ie, Ohio, Kentucky, Pennsylvania, or West Virginia). Note that families at different time points post treatment were recruited to provide a range of perspectives, and that caregivers of children currently aged 7 - 12 years were asked to retrospectively consider unmet needs and the use of the PLAY program during the planned target age range of 3 - 6 years.

Stratified purposive sampling was conducted by using random sampling within subgroups to ensure representation by diagnosis type (ie, brain tumor, leukemia/lymphoma, and solid tumor), geographic location (ie, rural, nonrural, Appalachian, and non-Appalachian as defined by the Rural Urban Commuting Codes [38] and Appalachian Regional Commission [14]), and age of the young survivors of childhood cancer (ie, either 3 - 6 or 7 - 12 years; to include those at various time points postcancer diagnosis/treatment). We also intentionally oversampled individuals from racial and ethnic minority groups to increase representation in our sample and reflect the institutional cancer registry (ie, 9% Black and 6% Latinx).



Caregivers were invited to participate with a mailed letter from their oncologist or neurosurgeon, which was followed by attempts to contact the caregiver by phone. Caregivers could opt out of future contact with the research team. In phase 1 of this study, caregivers were initially invited to participate in a mixed methods assessment of their unmet psychosocial and educational needs involving internet-based REDCap (Research Electronic Data Capture; Vanderbilt University) surveys and an interview conducted by phone or secure videoconferencing. Caregivers could also elect to participate in a monthly Community Advisory Board (CAB) and future research. Research staff discussed the CAB and usability testing with potentially interested members during their scheduled phone/videoconference interview until the desired sample size for planned usability testing was acquired (n of at least 10) [39] and saturation in rapid data analysis was attained.

Usability testing visits were scheduled at the convenience of caregivers on a secure videoconferencing platform with screen sharing and recording capabilities. All visits were recorded and transcribed automatically by the secure videoconferencing platform for cross-referencing during the coding process. During the usability testing visit, a trained research staff member who conducted phase 1 with the caregiver provided brief context on the platform (ie, currently designed for families of young children following TBI). Next, caregivers were provided with the link to the platform and were instructed to engage in unstructured navigation of the platform on their own for 5 minutes while sharing their screen (ie, hereafter "unguided use"). Caregivers were encouraged to "think aloud" about any of their feedback. Pages accessed and verbal comments were noted for analysis.

Following this, caregivers were instructed to perform a series of structured, task-based scenarios involving one specific module of the platform (refer to Figure 2; minimodule: "How Do I Connect with My Child?" and File S1 in Multimedia Appendix 1) for standardization across caregivers. This minimodule introduced the key concept of warmth, including how to use specific, labeled praises and the skill of diaphragmatic breathing for caregiver stress management. On each page of this module, research staff members provided standardized prompts (eg, "start the module," "go to the next page," "watch the video," and "complete the exercise") and encouraged caregivers to continue to "think aloud." Total time to complete the scenario, navigation challenges, and verbal comments were noted for analysis. Following the completion of the scenario, caregivers completed brief online surveys (refer to the "Measures" section below) to indicate the device used (ie, mobile, tablet, or PC) and to provide feedback about the platform. Caregivers also engaged in a semistructured interview based on the technology acceptance model [40] about their overall impressions of the platform, other potential components of the intervention (ie, coaching by videoconferencing and text messaging), and suggestions for improvement. A copy of the semistructured interview guide is included in File S2 in Multimedia Appendix 1.

Figure 2. Sample module web page from the high-fidelity prototype of the responsive parenting platform for usability testing.

Measures

Background Characteristics

In phase 1 of the study, caregivers completed a brief demographic survey including their relationship status, family income, employment status, race, ethnicity, and self-identification as Appalachian/non-Appalachian. The institutional cancer registry was also used to obtain information about the cancer diagnosis of young survivors of childhood cancer and to code for geographic region based on the family's current address.

Device Usage

Caregivers completed a brief survey on the type of device used to access the platform (ie, smartphone, laptop/desktop computer, iPad/tablet, and other), the type of device they believed would be most useful for the platform (repeated options), and the selection of all devices available in their household.

System Usability Scale

Caregivers completed the 10-item SUS [30] to quantitatively assess usability. The SUS is a widely used, validated, and reliable measure of the acceptability and comprehensibility of the online program, ranging from 1 to 100, with higher scores indicating higher usability. A score more than 68 is considered acceptable/above average usability [29,41].

Reaction Cards

Caregivers selected words from an abbreviated list of 55 adjectives based on the Microsoft reaction cards [42] to describe

XSL•FO
RenderX

their feelings and reactions toward the platform, providing qualitative insights into desirability and aesthetic design.

Data Analysis Plan

Descriptive statistics (means and SDs) and frequency counts were calculated for demographic and medical variables, device usage, SUS scores, reaction cards, and documented data from the sessions (ie, pages accessed and length of time for scenario). For the qualitative data, a rapid analysis approach [32-34] was implemented with 2 trained research staff members, who served as interviewers and coders (EM, a postdoctoral fellow and licensed clinical psychologist, and ED, a clinical research coordinator). They attended usability testing sessions live and took detailed field notes. Recordings and field notes were reviewed a second time, with general codes extracted into summary templates organized by interview question in Microsoft Excel spreadsheets. Double coding was conducted for 25% of the interviews, with consensus reached prior to independent coding for the remainder of the data. A second consensus meeting was held to identify themes endorsed by a majority of participants across interviews using a matrix. Member checking was conducted with Caregiver Advisory Board members, who confirmed the findings and coding themes.

Ethical Considerations

This study was reviewed and approved by the Nationwide Children's Hospital's institutional review board (00002939). As a minimal risk study, participants verbally agreed to participate after reviewing a written information sheet detailing risks and potential benefits. Participants also had an opportunity to ask questions of the study staff.

Results

Participants

Of 524 families in the cancer registry, 137 families were randomly selected as part of the stratification process in the "Procedure" section and were attempted to be contacted. Of those, 84 caregivers were reached by phone, and 32 caregivers agreed to participate in phase 1. A total of 25 agreed to be recontacted to participate in the CAB and other future studies, and the first 12 caregivers were sequentially invited for usability testing. There were no significant differences in demographic characteristics of the caregiver or child with cancer (ie, geographic region, sex, income, race, ethnicity, and diagnostic type) between the subsample of 12 participants who completed usability testing and the 32 participants from phase 1 (Fisher exact tests; $P>.05$), except that caregivers who completed usability testing were slightly older (mean 42.67 and SD 6.5 years) than those who did not participate in the usability phase (mean 36.8 and SD 6.8 years; $t_{30}=-2.41$, $P=.02$).

A total of 12 usability sessions were conducted by videoconference. However, there was 1 technical difficulty in saving the video for 1 father, and thus, only audio was available for that visit. Detailed field notes were also documented for each visit by 2 staff members in attendance. The sample of caregivers who participated was mostly White (n=10, 83%) and married (n=8, 67%). They were equally dispersed amongst metropolitan, rural, and Appalachian areas (n=4 each, 33% each). Although most caregivers were biological parents (n=9, 75%), there were 2 grandfathers and 1 legal guardian/adoptive parent. At the time of the interview, young survivors of childhood cancer were between the ages of 3 and 9 years. Demographic characteristics are presented in Tables 1 and 2.

Preliminary Impressions

Passive Use Feedback

During the 5 minutes of unguided use of the platform, the top viewed pages included: “What changes to expect” (module 1 landing page, n=9), “telling my child” (n=6), “growth of my child” (n=5), and “effects of health condition” (n=5; refer to File S3 in Multimedia Appendix 1 for heatmap of engagement). Given that these were several of the first pages of the first module, it seemed that most caregivers preferred to review the content in chronological order. Notably, some caregivers explored the module overview page and selected topics based on title (n=4), while fewer reviewed the resources page (n=3), and only 1 caregiver watched the tutorial video. Caregivers noted positive initial impressions of the platform, including that it was user-friendly and liked the overall design. For example, one mother of a 7-year-old described: “Anyone with young children would probably want to go through it and play around.” Similarly, a grandfather of a 7-year-old reported: “I think this is a wonderful program, and would be very beneficial for families going through this with their child.” Caregivers also made suggestions for improvement, including greater accessibility (eg, captioning on video and audio versions of content) and tailoring of content for this population. For example, related to the integration of audio content, one mother of a 7-year-old described: “Some parents are just so tired, they don’t wanna sit there, and their eyes just look at a screen. They just want to sort of listen.”

Scenario-Based Feedback

Caregivers spent an average of 17.83 (SD 6.28; range 8 - 31) minutes completing the scenario (module 1.2: How do I connect with my child?). They made several positive comments about the videos, design, and relatability of the content. For example, one mother described: “It’s easy to read, not too many words, which is nice, because I feel like when you wanna learn information…you wanna get to what’s important.” Caregivers also made suggestions for improvements, including the mobile navigation and ease of starting the modules.

Summative Feedback

SUS Results

All but one mother, who used PLAY on a smartphone, found the platform easy to navigate and usable (92% SUS score>68, indicating acceptable usability; total mean 82.2). Both men and women caregivers reported similar levels of overall usability (men: mean 82.50, SD 6.85; 100% SUS score>68 and women: mean 83.21, SD 18.75; 86% SUS score>68).

Device Usage

Half of the caregivers used a laptop or desktop PC to access the platform (n=6, 50%), while 5 (42%) used a smartphone, and 1 used an iPad. Caregiver responses for their preferred device to access the platform mirrored their usage for the usability testing. However, all caregivers reported that they had access to a smartphone, while 11 (92%) reported having a laptop or desktop PC, and 9 reported having an iPad/tablet (75%). Usability scores were lower and more variable for caregivers who used a smartphone as compared to those who used a PC (smartphone user: mean 79.50, SD 20.95; PC user: mean 84.16, SD 8.76).

XSL•FO
RenderX

However, these group differences were not statistically significant (t_9=−0.50; P=.63), nor were the scores below the SUS threshold (<68) for acceptable usability.

Reaction Cards

Caregivers used primarily positively valenced adjectives to describe their impressions of the platform, including useful, valuable, easy to use, accessible, and appealing. A heatmap displaying the frequency of adjectives selected is presented in Figure 3.

Figure 3. Heatmap of reaction cards following usability testing regarding the website. The numbers in parentheses indicate the number of participants who selected the adjective, with the most highly endorsed adjectives in the top right corner.

Useful (10)	Easy to use (10)	Organized (9)	Inviting (7)	Empowering (6)	Desirable (4)	Stimulating (4)	Trustworthy (2)
Valuable (10)	Accessible (9)	Consistent (7)	Straight forward (6)	Simplistic (4)	Exciting (3)	Reliable (2)	Sophisticated (0)
Appealing (9)	Usable (7)	Attractive (5)	Connected (4)	Fast (3)	Timesaving (2)	Intimidating (0)	Too technical (0)
Motivating (7)	Comprehensive (5)	Personal (4)	Collaborative (3)	Complex (1)	Inconsistent (0)	Patronizing (0)	Overbearing (0)
High quality (5)	Efficient (5)	Flexible (3)	Fresh (1)	Rigid (0)	Confusing (0)	Time-consuming (0)	
Fun (3)	Relevant (3)	Hard to use (1)	Gets in the way (0)	Frustrating (0)	Familiar (0)		
Busy (1)	Customizable (1)	Unpredictable (0)	Predictable (0)	Stressful (0)			
Slow (1)	Unconventional (0)	Uncontrollable (0)	Not valuable (0)				

Rapid Analysis

The summative interview data yielded several themes, which are displayed in Table 3 and throughout the “Results” section.

XSL•FO
RenderX

Table . Rapid analysis themes on the innovation design based on Preparing for Life and Academics for Young Survivors program prototype.

Themes	Enablers	Overarching suggestions for improvement
Overall impressions	• Easy-to-use interface • Positive toward the platform • Simple/straightforward design (M)[a]	• Reduce/reformat text • Changes to videos • Message boards with caregivers • Chat feature with professionals • Other websites/resources to learn about specific tumor types and treatments • Links to local support groups • Directory for resources • Discounts for parents to destress (eg, spa/massages) • Link to electronic medical record
Perceived usefulness	• Found to be useful for supporting and teaching responsive parenting skills	• Add more realistic scenarios dealing with stress • Use "coach" vs "therapist" • Add more real-life examples of dealing with stress as a parent • List of questions to ask at follow-up appointments • Ways to destress before scans/follow-up appointments • More information about feeling misunderstood by friends • Improvements to videos, including a greater variety of ages, closed captioning, and video testimonials about the program
Design and layout	• Favorable design	• Reduce text: more images and graphic representation of concepts • Visual progress bar • Bold key points • More accessible "take-away points" • More concise instructions on exercises • More layman's terms • Option to have text read aloud
Navigation	• Easy-to-use interface	• Improved mobile menu and mobile accessibility • Linkages between modules
Preferred format and timing	• Internet-based and easily accessible format	• Offer a platform to women caregivers shortly after diagnosis (W)[b] • Offer a platform to men caregivers on the transition off treatment (M)

[a]M indicates theme for men caregivers only.

[b]W indicates theme for women caregivers only.

Overall Impressions

Overall, most caregivers noted that they found the platform "easy to use," including comments that the platform was "simple," "straightforward," and "user-friendly." A few caregivers made suggestions about "reducing and reformatting text" to make it easier to digest, such as including more comics and images to "break up the text," bolding key points, and including key takeaways that are easily accessible for future reference in bullet point format. Specific enablers and suggestions for improvement are presented in Table 3. Caregivers also recommended "improvements to the videos," such as closed captioning and showing a greater variety of age groups and developmental periods. One mother of a 7-year-old survivor noted that she would prefer if the videos were "more fun" and "less forced." Caregivers "denied concerns about privacy" while using the platform, with a few noting that it seemed "trustworthy" with the ability for an individual log in.

Perceived Usefulness

Most caregivers described that the platform "could be useful." One father of a 3-year-old survivor described that he liked that the platform showed: "the various challenges that you're about to embark upon and puts them into nice boxes...modules that are easily digestible." Several caregivers noted that some of the content was familiar to them. On the other hand, caregivers described that they may benefit from learning how to "be more specific with praise" in interacting with their children. One

XSL•FO
RenderX

grandfather of an 8-year-old survivor noted that presenting this information in this online format reduces defensiveness, as compared to having someone else tell you what to do. Specifically, he described:

> *I think it's (platform) better than hearing their parents tell them how to do it or having another person tell them how to do it directly...because then they…kind of have some more time to process what they're seeing and viewing...I think that it's good because it gives them an opportunity to process versus having just people saying it to their face and then being defensive. With a module like this, they can…be defensive to the module, but nothing is going to talk back to them.* [Grandfather of an 8-year-old survivor]

One suggestion for improvement included more "real life examples" of caregivers managing stress in the moment, such as taking a break or a walk. One mother of an 8-year-old survivor suggested that it would be important to incorporate relatable examples:

> *Real-life scenarios, real-life practice, and examples that we (caregivers) can do with our child that are just kind of practical, like even if it's not traditional. Just a reminder that when you go out to a park with your child today, why not ask them about the colors they see or count how many swings are at the swing set? Just a reminder of simple things we (caregivers) can do.* [Mother of an 8-year-old survivor]

Caregivers also described that the platform may be useful for "enhancing teachers' understanding" of cancer, as well as caregivers' understanding of late effects of cancer treatment and the impact of cancer on siblings. They also noted that the platform would, in the words of a mother of a 6-year-old survivor, help caregivers be "more empowered to be advocates for their child."

Design and Layout

In relation to the design and navigation, most caregivers commented "positively," describing the platform as "pleasant," "relatable," and saying that the "preschool" designs are fitting for the age group.

Navigation

Consistent with the reduced SUS scores for the mobile version, a few caregivers suggested improvements for mobile usability, including expanding the mobile menu and navigating to start the modules.

Preferred Format

Most caregivers (9/12) described that individual coaching in a future intervention program "could be helpful" and should be offered as "an option" for families to provide "another level of support." Still, one grandfather of a 5-year-old survivor noted that it is important that caregivers do not feel "graded" or "judged." Caregivers also emphasized the need for ease of scheduling these appointments, such as evenings, weekends, and flexibility with appointments (eg, last-minute cancellations).

With respect to offering text messaging as a supplement to the internet-based modules, caregivers described that they could be helpful as reminders of skills learned on the platform. Caregivers noted that it would be important to ask about preferences for frequency (eg, weekly and monthly) to prevent these reminders from becoming overwhelming.

Preferred Timing

Regarding the timing of a responsive parenting program, caregivers expressed a variety of opinions, which differed by the gender of the caregiver. Most women caregivers described desiring this type of support within a few months of diagnosis. One mother of an 8-year-old survivor described:

> *Definitely not the first month…we were in the hospital for two weeks. It was a whirlwind. Parents were taking time off work. The family's coming to town. No one knows what's going on...and then you're sort of in denial for the first month, and you're in fight or flight mode. So, I would say probably month two or three would be a good time, because now you're sort of learning, learning how your kid responds to some of the treatment.* [Mother of an 8-year-old survivor]

Another mother of a 6-year-old survivor commented about feeling somewhat helpless at the beginning and that there is "not much action you can take right away, except for learning how to help your child." In contrast, most men caregivers reported that they would prefer to receive this support after the conclusion of treatment. For instance, one grandfather of a 5-year-old survivor described the intensity of the acute treatment period as: "It's like you're hit with a sledgehammer."

Discussion

Principal Findings

This mixed methods study involved initial usability testing of a high-fidelity prototype of an internet-based responsive parenting intervention program called PLAY, designed to support caregivers of young survivors of childhood cancer. Overall, all but one caregiver found PLAY usable (92% reported SUS scores ≥68). Acknowledging the limitations of the SUS as a summative measure, we supplemented this analysis with qualitative feedback and the use of reaction cards [42,43]. Caregivers primarily selected positively balanced adjectives (eg, useful, valuable, easy to use, accessible, and appealing) to describe the program. These results are promising and comparable to other internet-based support and educational resources for caregivers of children with various chronic and developmental conditions and for those from rural and remote areas (eg, autism and asthma) [44-48]. Similarly, in the previous pilot of the 6-session intervention with caregivers of young children with TBI, all 11 families who completed the full 6-session intervention reported high satisfaction with the program [27].

This study, strengthened by a mixed methods approach to usability testing, yielded valuable and detailed information related to the innovation design (ie, CFIR) [24] of PLAY. Caregivers identified key aspects to tailor the program for the unique needs of the young survivors of childhood cancer, such

XSL•FO
RenderX

as resources specific to cancer and late effects, examples and resources related to advocacy for their child in health care and school settings, and the importance of the caregiver managing their own stress and uncertainty (eg, "scanxiety") in their capacity to implement responsive parenting skills. Other general suggestions included increasing usability, offering coaching and texting as optional supports, and considering intervention timing, which differed by gender of the caregiver. With respect to usability, caregivers repeatedly underscored the necessity of PLAY being highly mobile-friendly, practical, and brief, given multiple competing demands on caregivers' time and attention. Most caregivers agreed that the length of the module was appropriate (approximately 15 - 20 minutes), and all caregivers reported having access to a smartphone and a preference for mobile usability. This is comparable to other studies with caregivers of young children with autism, in which mobile usability was a top priority [45]. The Pew Center also highlights that most adults living in both metropolitan (89%) and rural (80%) areas own a smartphone [49]. Still, both quantitative (ie, SUS) and qualitative data indicated that improvements were needed in the mobile usability and design of the platform, such as easier navigation to the main menu on the mobile version. Other suggestions to improve accessibility included closed captioning on videos and options for the text to be read aloud on each module page. These suggestions are in line with similar studies of digital health interventions (DHI) for caregivers [50,51]. Furthermore, these adaptations would assist in bridging the "disability digital divide" [52].

Most caregivers described receptiveness to coaching from a trained professional and occasional text message reminder, in addition to the self-guided platform resource. Caregivers emphasized that these supports should be optional and individually tailored in terms of frequency. They also recommended that coaching should be flexibly scheduled to increase accessibility for busy families with young children (ie, evenings and weekends). In studies of telehealth interventions for caregivers of children with autism [46], caregiver retention and positive outcomes were superior following weekly contact with a therapist, as compared to self-guided. Multimodal interventions may be especially needed, given the documented decline in caregiver participation over the course of internet-based positive parenting programs [53]. One consideration for future intervention development is that videoconference coaching may require high-speed broadband coverage, which may reduce accessibility for this benefit for rural families, as approximately 73% of rural households have home subscriptions [49].

Unexpectedly, there were some gender differences in the preferred modality and timing of this type of responsive parenting resource. Specifically, women caregivers preferred resources in the immediate period after diagnosis, while men caregivers preferred resources after cancer treatment had concluded. Although not universal even amongst our participants, this may be attributed to the common division of responsibility and typical gender roles after a child is diagnosed with cancer. Mothers often directly support the child in the hospital, while fathers and grandfathers often maintain their work schedule and household responsibilities [54,55]. Fathers may prefer to wait until after treatment is concluded when they feel more involved and included in care. Furthermore, there may be gender differences in how caregivers cope and adjust to the diagnosis and treatment [56], which may affect readiness for intervention. Still, this difference in preferred timing of resources may also be attributed to the difference in mean age and caregiver type, such that there were two grandfathers but no grandmothers in our small sample. At least one grandfather reported that he preferred to receive information about responsive parenting through the self-guided platform as opposed to coaching due to feeling defensive or "judged." This aligns with previous work suggesting that fathers and other caregivers who are men may face unique barriers in help-seeking [57] and are often excluded from parenting intervention research [58]. Given that preferences in timing and modality may differ across family members, DHI such as PLAY might be offered to families earlier and more periodically throughout the illness trajectory, with careful framing of the parenting intervention to encourage father engagement.

Limitations

Although this usability testing study offers several insights for the refinement of digital health platforms for caregivers of young children with chronic health conditions, several limitations should be considered. First, although we attempted to conduct stratified sampling, our post hoc testing indicated possible ascertainment bias with our subsample, including slightly older caregivers, who may have differing usability and information preferences than younger caregivers. Similarly, our recruitment rate of approximately 40% was relatively low, yet higher than a similar study with caregivers of young children following TBI (25%) [27]. This highlights the inherent challenges of engaging with caregivers of young children with complex medical needs, requiring future work to identify additional ways to engage and provide accessible psychosocial care to this underserved and sometimes hard-to-reach group. Second, although our sample size was sufficient to assess usability experience [39], we were not powered to examine subgroup differences based on type of caregiver or diagnostic group. Third, we used a rapid analysis approach [34], in which we were unable to calculate interrater reliability between coders. The interviewers and coders were part of the study team and, thus, their probing during interviews and observations in rapid analysis may have been biased. Still, the usability was assessed with multiple methods (ie, standardized measures, reaction cards, and "think aloud" procedures), in line with current research recommendations [43]. Finally, the single-session usability testing limited the review of only one module in detail (ie, responsive parenting). Future work will need to obtain perspectives of the PLAY intervention comprehensively (ie, other modules listed in File S3 in Multimedia Appendix 1).

Future Study Plans

Overall, internet-based responsive parenting interventions to support caregivers of young children may have promising transdiagnostic applications. However, creative problem-solving may be needed to improve future engagement, uptake, and implementation. Guided by the CFIR framework and designing with implementation in mind, our next step (ie, phase 3) will

XSL•FO
RenderX

involve an iterative co-design process [59] with a CAB (n=13) and a multidisciplinary Healthcare Provider Advisory Board (HPAB; n=11). Co-design involves close collaboration between researchers, designers, and users, who serve as the experts due to their experiences [59]. For our proposed study, the research study team will partner with both the CAB and HPAB during monthly meetings held via videoconference to review and discuss feedback on each module of the PLAY program to allow for in-depth feedback and tailoring of each page of the intervention. For example, the self-care and relationships (refer to File S3 in Multimedia Appendix 1) modules focus on how the caregiver and their relationships have been affected, as well as strategies that may help (eg, relaxation strategies, and "I statements"). Both advisory boards will collaborate with the study team to develop and iteratively refine the graphics, videos, exercises, and text-based content to reflect their lived experiences and clinical expertise. Additional single-session user-experience testing with another group of caregivers will be conducted to ensure adequate usability (SUS ≥68) with the refined and tailored PLAY program. A pilot of the PLAY intervention will test feasibility and acceptability with caregivers of young survivors of childhood cancer, with a small randomized controlled trial to follow. A future larger randomized controlled trial will determine whether the program improves responsive parenting behaviors over several months and leads to downstream effects on neurodevelopmental outcomes for young survivors of childhood cancer. Future work will also identify barriers and facilitators in the inner and outer settings from the CFIR framework to support the adoption of the PLAY intervention in clinical practice.

Conclusion

Designing equitable digital health interventions demands the active and ongoing engagement of individuals with lived experience across all stages of design, particularly ensuring the inclusion of underrepresented groups to optimize success.

Acknowledgments

The authors would like to acknowledge and thank the funding and support of The Ohio State University Presidential Postdoctoral Scholars program and the American Psychological Association Division 54 Drotar-Crawford Postdoctoral Fellowship Research Grant in Pediatric Psychology, which were each awarded to Emily Moscato, PhD, and her mentor, Cynthia A. Gerhardt, PhD. Abstract

Background: Pediatric and adolescent firearm injuries and fatalities in the United States have surged to levels not seen since the mid-1990s, marking a critical public health inflection point. Young Black males (ages 15 - 24) experience firearm-related fatality rates 24 times higher than their White peers. Despite this disproportionate risk, they are less likely to participate in traditional firearm violence prevention programs. This disparity highlights the urgent need for innovative, culturally responsive approaches that address the emotional, behavioral, and social determinants of violence.

Objective: This pilot study aims to evaluate the preliminary effects of BrotherlyACT, a culturally responsive, trauma-informed, multicomponent mobile and web-based intervention designed to support young Black males (ages 15 - 24) in navigating and preventing community violence, substance use, and mental health challenges. The intervention aims to increase access to precrisis support and mental health resources for youth living in low-resource, high-violence settings.

Methods: Seventy young Black males with Serious Fighting, Friend Weapon Carrying, Community Environment, and Firearm Threats (SaFETy) scores between 1 and 5 (indicating low-to-moderate firearm violence risk) were enrolled in this prospective pretest-posttest study. Participants completed a psychoeducational component of the BrotherlyACT intervention, consisting of 7 video-based modules. Surveys were administered at baseline and again 4 weeks later to assess changes in attitudes toward guns and violence (Attitudes Toward Guns and Violence Questionnaire), reactive and proactive aggression (Reactive-Proactive Aggression Questionnaire), psychological distress (Kessler Psychological Distress Scale), and depressive symptoms (8-item Patient Health Questionnaire). Paired *t* tests were conducted to analyze pre-post differences.

Results: A total of 70 young Black males (mean age 20.97 years, SD 2.44 years) participated in the study. Nearly half reported recent physical fights (48/70, 69%), gun threats (39/70, 56%), or hearing gunshots in their neighborhood (63/70, 90%). More than 50% (39/70, 56%) reported illicit drug use, and 32 out of 70 (46%) reported substance-related violence. SaFETy scores revealed heterogeneous but elevated exposure to firearm risk factors, particularly in community violence and firearm threats. Postintervention, participants demonstrated a statistically significant reduction in attitudes toward guns and violence (Attitudes Toward Guns and Violence Questionnaire; mean 29.8-26.1, $P<.001$, $d=0.53$), with the largest shift observed in "Aggressive Response to Shame" (28% reduction). Reactive aggression significantly declined (mean 10.48-8.67, $P=.008$, $d=0.37$), whereas proactive aggression remained stable. Psychological distress and depressive symptoms remained stable. Nearly all participants (68/70, 97%) completed all modules in a single session, with 47 out of 70 (67%) finishing within an hour, suggesting high feasibility and user engagement.

Conclusions: Preliminary findings indicate that BrotherlyACT may reduce proviolence attitudes and reactive aggression among young Black males. These results underscore the feasibility and potential impact of culturally responsive digital interventions as a strategy to prevent firearm violence among underserved youth populations.

KEYWORDS

mental health; youth violence; substance use; digital intervention; prevention

Introduction

Firearm injuries and homicides constitute a national public health crisis in the United States, representing the leading cause of death among children and youth aged 0‐24 years [1,2]. This epidemic, including firearm homicides, suicides, incidental shootings, and nonfatal incidents, disproportionately affects children and adolescents in low-income urban and rural communities. Young Black males aged 15–24 experience the highest firearm homicide burden in the United States, with rates reaching 52.9 per 100,000 [2-4], more than 18 to 24 times higher than those of their White male peers, particularly in the aftermath of the COVID-19 pandemic [3,5-9].

Black youth remain historically underserved in mental health and early violence prevention systems (ie, primary prevention). Barriers to accessing trauma-informed care include stigma, institutional mistrust, racialized criminalization, and systemic underinvestment in their communities [10]. Even after injury, long wait times, limited follow-up, cold referrals, and provider mistrust deter intervention and engagement with follow-up services [11-16]. Critically, a major limitation of existing pediatric firearm injury prevention programs is their focus on postviolence contexts, typically after youth present in emergency departments (EDs) [17-19] or at advanced stages of violence involvement, such as during adjudication or institutionalization [16,17,20]. While ED-based programs show promising effects in reducing aggression and trauma [17,18,21-23], they face challenges such as staffing shortages, reimbursement issues, and difficulties with postdischarge follow-up [18]. These systemic and structural barriers continue to discourage young male engagement in interventions and contribute to service avoidance or early dropouts from programs.

Before an injury or ED contact, psychosocial and behavioral risk factors, such as aggression, emerge as modifiable determinants of firearm violence that can be addressed early in life [3,7,24-28]. Within this context, 2 subtypes of aggression are noteworthy: reactive and proactive aggression. Reactive aggression is characterized by impulsive responses to perceived threats and emotional dysregulation [29-32], whereas proactive aggression is calculated, planned, and self-serving, often associated with status and protection [33,34]. These aggression subtypes predict firearm risk more reliably than household firearm access alone [35], yet they are rarely targeted in primary prevention efforts aimed at reducing pediatric firearm injuries and homicides.

Recent evidence indicates that digital mental health interventions can effectively improve mental and behavioral health outcomes among children and adolescents, including those from high-risk or marginalized backgrounds with limited access to existing and traditional resources. In a systematic review focused on low- and middle-income settings, Lehtimaki et al [36] found that digital interventions produced promising reductions in adolescent depression and anxiety. Similarly, self-guided digital interventions have been shown to reduce suicidal ideation among youth [37]. In high-income contexts, Lattie et al [38] emphasized the importance of user-centered design in mobile and web-based tools targeting depression and anxiety among young adults. Additionally, Ranney et al [39,40] demonstrated that app-based tools used in ED settings can reduce aggressive behaviors in urban adolescents. These findings highlight the potential of digital health interventions as scalable and accessible tools for youth mental health and violence prevention.

Building on this evidence, we developed *BrotherlyACT*, a culturally responsive, trauma-informed, multicomponent mobile and online intervention designed to support young Black males (aged 15‐24 years) in navigating and preventing community violence, substance use, and mental health challenges. The app aims to improve access to precrisis support and mental health resources for youth living in low-resource, high-violence environments. We conducted a single-group, prospective pre-post pilot study to evaluate the preliminary effects of BrotherlyACT's video-based psychoeducational modules. Primary outcomes were changes in reactive and proactive aggression, firearm-related attitudes, and mental health indicators.

Methods

Study Design

This prospective pretest/posttest pilot study was conducted from June to July 2024. It adheres to the guidelines for nonrandomized pilot and feasibility studies, as well as the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines. A comprehensive description of the study protocol is provided elsewhere [41].

In addition, prior usability testing and heuristic evaluation of the BrotherlyACT intervention involving young Black males and mobile health (mHealth) specialists have been documented elsewhere [42]. The app received an average System Usability Scale score of 79, equivalent to an A-minus grade and placing it in the 85th percentile, indicating near-excellent usability [42]. Similarly, heuristic evaluation by mHealth experts identified only minor and cosmetic usability issues, with a median severity score of 1 across various heuristics (on a scale of 0‐3), indicating minimal impact on user experience. Overall, minor adjustments were recommended to improve navigation, customization, and user guidance, while the app's visual and functional design was generally well received [42].

Ethical Considerations

This study was reviewed and approved by the Rush University Institutional Review Board (approval number 21122902), and the protocol was registered on ClinicalTrials.gov (NCT06359990). Informed e-consent was obtained from all participants. For those under 18 years of age, parental or guardian consent and participant assent were obtained before enrollment. Participants were informed of the voluntary nature of their involvement, their right to withdraw at any time without

XSL•FO
RenderX

penalty, and measures to protect their confidentiality and data privacy. All data were deidentified, coded using unique participant IDs, and stored in encrypted, password-protected databases accessible only to authorized study staff. No identifiable information was linked to survey responses or intervention data. Given the vulnerability of this population, additional safeguards were implemented, including private consent procedures, information on local support services, and on-call support for participants reporting distress or imminent risk. To compensate participants for their time and contribution, US $50 was provided after completing the pretest survey and intervention, and an additional US $50 (Target or Amazon e-gift card) was distributed 4 weeks later following completion of the posttest questionnaires.

Study Procedures

Participants: Inclusion and Eligibility Criteria

Eligible participants met the following criteria: (1) male-identifying; (2) Black/African American; (3) aged 15 - 24 years; (4) a score >1 on the 4-item Serious Fighting, Friend Weapon Carrying, Community Environment, and Firearm Threats (SaFETy) clinical screening tool, indicating elevated risk for future firearm violence based on 4 domains: Serious Fighting, Friends' Weapon Carrying, Community Environment, and Firearm Threats [43,44]; (5) English literate; and (6) able to assent/consent (with parental consent if under 18).

Exclusion criteria were (1) being detained or incarcerated; (2) inability to complete assent/consent and assessment forms due to language barriers, cognitive dysfunction, or injury; (3) presenting with an acute psychotic disorder, a suicide attempt as the mechanism of firearm injury, or a recent sexual assault requiring intensive psychosocial support; and (4) a score ≥6 on the SaFETy tool, as such individuals were referred to more intensive programs, as recommended by Goyal et al [45]. Recruitment was successfully conducted in collaboration with community partners, including local organizations, school-based health centers, and social media, with minimal loss to follow-up due to the intervention's brief and single-session format.

Upon expressing interest in the study, participants completed a sociodemographic enrollment form on Research Electronic Data Capture (REDCap; Vanderbilt University), adapted from the biennial cross-sectional Youth Risk Behavior Surveillance System (YRBS) survey. All study procedures were reviewed and approved by the Rush University Institutional Review Board. Informed e-consent was obtained in accordance with federal and institutional guidelines for research involving minors using REDCap. Consent and assent forms were written in age-appropriate and culturally sensitive language, and all participants were informed of their right to decline or withdraw at any time without penalty.

Participants then completed a pretest survey battery comprising 63 questions assessing psychological distress (Kessler Psychological Distress Scale [K10]), depression (8-item Patient Health Questionnaire [PHQ-8]), attitudes toward guns and violence (Attitudes Toward Guns and Violence Questionnaire [AGVQ]), and aggression (Reactive-Proactive Aggression Questionnaire [RPQ]). All survey questions remained unchanged, as these instruments have been previously validated for use with children and adolescents. To ensure greater control over participant access, engagement tracking, and data capture during the pilot phase, the intervention was delivered via REDCap, with embedded YouTube-hosted videos simulating the app's video modules. This approach enabled secure and streamlined testing of the core acceptance and commitment therapy (ACT)–based video modules before full app deployment, allowing us to evaluate the acceptability and preliminary effects of the behavioral modules while testing fidelity to content delivery and use styles, and engagement tracking.

Immediately following baseline survey completion, participants were given access to the BrotherlyACT modules and instructed to complete all video-based modules and in-app content either in 1 sitting or at their own pace within a 48-hour window. The posttest survey was administered electronically exactly 4 weeks (28 days) after the pretest, regardless of when participants completed the intervention content.

Additionally, we tracked the amount of time participants spent on the REDCap page and their engagement with the videos (ie, in-app quiz completion, likes and comments). Participants who completed the video content prematurely, either by not viewing all the materials or by skipping through them rapidly, were encouraged to reengage through various means, including indicating approval, providing comments, or submitting a summary of the knowledge acquired from the video content via email. Incentives for participating in the study were distributed after completion of the pretest and video modules (US $50) and again 4 weeks later, following completion of the posttest questionnaires (US $50 in the form of Target and Amazon e-gift cards).

Intervention: BrotherlyACT's Video-Based Psychoeducational Modules

Drawing from evidence-based behavior change models and community insights, the app incorporated elements that address the personal, social, and environmental factors contributing to youth firearm-related violence. Its development involved collaborative design with young Black males from the target age group, ensuring that the app's content, imagery, language, and delivery methods were culturally attuned to their real-life experiences.

As at testing, the app comprised a set of 8 concise, video-based psychoeducational modules that depict realistic situations. These modules address topics such as refusing guns, resisting gang involvement, practicing gun safety, saying no to alcohol and drugs, resolving conflicts, avoiding retaliation, recognizing healthy and unhealthy relationships, practicing mindfulness, cultivating a positive outlook on the future, and using adaptive coping strategies. They incorporate behavioral skills training, emotional regulation techniques, and decision-making strategies to help reduce youth violence and risky firearm behavior. The app's video modules are primarily based on ACT [46-49], a third-wave cognitive behavioral therapy that emphasizes accepting and navigating difficult thoughts and emotions rather than attempting to persistently change or avoid them [50-54]. ACT has demonstrated efficacy in improving emotional

XSL•FO
RenderX

regulation and reducing aggression among trauma-exposed youth, who often cannot control their environments but can control how they respond to and navigate these chronic and intersecting issues [55]. Utilizing a micro-learning approach, complex topics were broken down into smaller, ready-to-use and life skill-based components to enhance comprehension, application, and retention, particularly for youth with various attention spans [56,57].

A Black male narrator presents the modules with multimedia and interactive heuristics, offering skills for navigating and preventing firearm-related scenarios such as peer pressure to carry weapons, retaliatory violence, and rejecting gang involvement. The modules use culturally familiar language and visuals, with a tone that emphasizes respect, empowerment, motivational enhancement, and nonpunitive language to avoid pathologizing young people's behavior. Table 1 summarizes the behavioral skill objectives and theoretical frameworks underpinning each BrotherlyACT module.

Table . BrotherlyACT module overview: focus areas, behavioral skills, and theoretical underpinnings.

Module title	Module target	Behavioral skills taught	Theoretical underpinning
Gun Safety 101	Firearm safety and harm reduction	Safe storage awareness and noncarry decision-making	Harm reduction theory and social cognitive theory
Gun Refusal Skills 101	Peer pressure and firearm refusal	Assertive communication and verbal refusal strategies	Social norms theory and motivational interviewing
Healthy Relationship Skills	Intimate partner and peer conflict	Emotional literacy, boundary-setting, and consent communication	Attachment theory and acceptance and commitment therapy
Gang Resistance Skills	Gang avoidance and safety navigation	Risk recognition, exit planning, and identity affirmation	Strength-based approach and narrative therapy
Coping Skills	Managing stress, trauma, and emotion	Emotion regulation, distress tolerance, and adaptive self-talk	Acceptance and commitment therapy and cognitive behavioral theory
Mindfulness for Black Boys	Emotional regulation and trauma recovery	Grounding, breathwork, and body scanning	Acceptance and commitment therapy and mindfulness-based stress reduction
Alcohol and Drug Refusal Skills	Substance use prevention	Refusal techniques and decision-making	Social learning theory and motivational interviewing
Conflict Resolution Skills	De-escalation and self-regulation	"Cool down" tools, perspective-taking, and problem-solving	Acceptance and commitment therapy and problem-solving therapy

The broader BrotherlyACT app also includes additional features such as (1) a safety planning toolkit with interactive tools for mood tracking, risk assessment, mindfulness exercises, goal setting, and a zip code–enabled directory of local mental health services, community support resources, and violence prevention programs within a 50-mile (80.47 km) radius; and (2) service engagement and talk therapy via an artificial intelligence–powered chatbot named DEVON, a confidential and programmed resource for discussing stressors, emotional triggers, and challenges related to violence and substance use. DEVON was designed as a trauma-informed conversational agent to simulate peer dialogue and support help-seeking behaviors. Embedded within the app interface, the chatbot provides confidential, just-in-time emotional support accessible outside structured intervention sessions. Conversations with DEVON are anonymous, with user input logged only as anonymized session data. Participants are advised not to enter personal identifiers. App access was password-protected and intended for use on personal or study devices in private settings. These additional features were not evaluated in this study.

Sociodemographic Measures

Overview

We adapted items from the Centers for Disease Control and Prevention's biennial YRBS, which assesses health-related behaviors among a nationally representative sample of US students in grades 9‐12. Our analysis included sociodemographic variables such as age, gender, race/ethnicity, socioeconomic status (ie, household income), school and employment status, zip code or address, dating relationship status, and smartphone ownership. The questionnaire also assessed violence (physical and psychological violence toward a partner, 30-day weapon carriage, and community violence) and substance use experiences (ie, 30-day adolescent binge drinking, nonmedical drug use, and substance-related violence perpetration). Substance use behaviors were assessed due to their known association with youth aggression, trauma exposure, and risky weapon-related behaviors [8,27,58]. These variables were included to examine participants' broader behavioral profiles and identify overlapping intervention targets. Table 2 summarizes the sociodemographic characteristics of participants who completed the pretest and posttest questionnaires and received the intervention (ie, the analytic sample).

[a]Age missing for 1 participant; percentages calculated among respondents to this item (n=69).

[b]Employment status categories are not mutually exclusive; respondents could select more than 1 type (eg, part-time worker and student). Counts therefore exceed N. Percentages are calculated using the total sample size (N=70).

[c]Item nonresponse for 1 participant; percentages calculated among respondents to this item (n=69).

[d]Item nonresponse for 2 participants; percentages calculated among respondents to this item (n=68).

The SaFETy Score

The SaFETy score, a 4-item firearm risk assessment questionnaire included in our enrollment survey, was used to categorize participants into low-risk (0), medium-risk (1-5), and high-risk (≥6) groups for firearm violence based on weighted item responses. The questionnaire inquired about the frequency of serious physical fights, friends carrying weapons, hearing gunshots, and having guns pulled on them in the past 6 months. This clinically feasible tool has been shown to correlate with firearm violence, although further validation is needed [43]. The SaFETy score demonstrates potential in predicting future firearm violence risk, with each point increase associated with a 1.5-fold higher likelihood of firearm violence within 2 years (odds ratio 1.5), underscoring its value as a clinical screening instrument [44,59]. Administration of the tool takes less than 1 minute, and Goldstick et al [44] suggested referring patients with scores ≥6 to more intensive programs.

Attitudes Toward Guns and Violence

The 23-item AGVQ assesses individual attitudes toward using guns and violence for conflict resolution, power assertion, or safety across 4 scales: Aggressive Response to Shame (disrespect sensitivity; items 1, 2, 5, 10, 15, 16, 18, and 20), Comfort With Aggression (violence acceptance; items 8, 12, 13, 17, 21, and 22), Excitement (gun-related excitement; items 6, 7, 9, 11, and 14), and Power/Safety (power and safety from guns; items 3, 4, 19, and 23). Cronbach α coefficients were 0.83, 0.81, 0.79, and 0.72, respectively. Respondents rated their agreement on a scale from 0 (disagree) to 2 (agree). The summed scores for the AGVQ subscales ranged from 0 to 46, with higher scores indicating more favorable attitudes toward guns and violence. Juvenile firearm possession is linked to violence lethality and may reflect risky exposure to firearms or a proviolence viewpoint. Although the correlation between attitude and behavior change varies, modifying attitudes is crucial for changing behavior [60]. Youth typically complete the AGVQ in 5 - 10 minutes. The AGVQ correlates with handgun ownership [31] and with various psychological and behavioral assessment instruments, supporting its construct validity and helping to understand how attitudes toward guns and violence relate to broader patterns of violent behavior, cognitions, and emotions. Although the AGVQ remains an insufficiently addressed aspect of pediatric firearm violence prevention, interventions such as the "Cradle to Grave" program have shown potential in reducing AGVQ scores, particularly among students with higher baseline tendencies toward violence [61].

The Reactive-Proactive Aggression Questionnaire

The RPQ is a 23-item validated self-report instrument designed to differentiate between reactive aggression (11 items; eg, "Reacted angrily when provoked by others") and proactive aggression (12 items; eg, "Had fights to show who was on top"). Respondents reflect on these behaviors over the past 30 days, rating each item on a 3-point Likert scale (0=never, 1=sometimes, and 2=often). Subscale scores were summed to generate separate reactive and proactive aggression scores, as well as a combined total aggression score. Higher scores indicate a greater frequency of aggressive behaviors [29,62]. The RPQ has demonstrated good reliability and construct validity in adolescent populations and has been extensively used in research on aggression, violence, and trauma exposure. Reactive aggression is more strongly linked to internalizing symptoms, such as anxiety and depression, whereas proactive aggression is associated with externalizing and antisocial traits [29,62].

Kessler Psychological Distress Scale

The K10 [63] is a widely used self-report diagnostic tool for identifying individuals who may require further evaluation for anxiety and depression. It is applicable in both the general population and clinical settings. The K10 comprises 10 questions rated on a 5-point scale (5=all the time to 1=none of the time), reflecting experiences over the past 4 weeks. Scores range from 10 (no distress) to 50 (severe distress), with lower scores indicating less distress. The scale includes 2 subscales: depression (items 1, 4, 7, 8, 9, and 10) and anxiety (items 2, 3, 5, and 6). Items 3 and 6 are omitted if the previous response is "none of the time" [64].

Patient Health Questionnaire-8

The PHQ-8 is extensively used to evaluate depression severity in clinical and research settings [65,66]. It comprises 8 items aligned with the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition criteria for major depressive disorder and serves as a reliable tool for screening and monitoring depressive symptoms. The PHQ-8 is a shortened version of the PHQ-9, omitting the item on suicidal ideation. It assesses mood and feelings over the past 2 weeks on a 4-point scale from 0 (not at all) to 3 (nearly every day), with total scores ranging from 0 to 24. Scores above 10 indicate moderate depression, while scores above 20 indicate severe major depression.

Data Analysis

All analyses were conducted using the JASP software system (version 0.18.3 for Windows) and Microsoft Excel, with results subsequently verified using STATA (version 18; StataCorp LLC). Participant characteristics are presented as means with SDs for continuous variables, and as frequencies and percentages (%) for categorical variables.

All surveys were scored to calculate total and subscale raw scores. Higher scores indicated a proclivity toward violence or

XSL•FO
RenderX

aggression (AGVQ and RPQ) or poorer mental health status (K10 and PHQ-8). Paired-sample *t* tests and Wilcoxon signed rank test (a nonparametric measure) were used to detect differences in scores across all validated instruments, with *P* values <.05 (2-tailed hypothesis) considered statistically significant.

Initial data analysis focused on ensuring data quality by checking for allowable ranges, errors, and patterns of missing data, as well as examining outliers and variable distributions to confirm alignment with the assumptions underlying the planned analyses. Missing data were observed in 6 out of 70 (9%) cases and ≤3-4 out of 70 (<5%) variables. This missingness was addressed using listwise deletion, which may have introduced bias if the data were not missing completely at random. While this approach preserved the internal consistency of the paired analyses, it may limit the generalizability of the findings and reduce statistical power.

Owing to limited prior effect size estimates, we conducted an a priori power analysis using G*Power 3.1.9.7 to determine the minimum sample size required to detect a medium effect (*dz*=0.5) in a paired-sample *t* test comparing pre- and postintervention scores on the AGVQ. Assuming α=.05 and 95% power, the minimum required sample size was 54 participants. To account for potential attrition and up to 20% missing posttest data, we oversampled and enrolled 70 young Black males (aged 15 - 24 years) from a larger multiphase study (N=312). Pre- and postintervention data were analyzed to evaluate statistically significant changes and effect sizes across key outcomes.

Results

Participant Characteristics

Our sample consisted of 70 young Black men aged 15 - 24 years (mean age 20.97, SD 2.44 years). All participants identified as African American, and 7 (10%) also identified as Hispanic or Latinx. Educational attainment varied, with 18 (26%) having less than or equal to a high school diploma, and 22 (31%) reporting a college or university education. Nearly half of the participants (34/70, 49%) worked part-time (<35 hours per week). Over half were single (39/70, 56%) or dating (30/70, 43%). Smartphone ownership was nearly universal (68/70, 97%), highlighting access to digital intervention. Regarding annual household income, 46 (66%) reported between US $40,000 and US $59,999. Most participants were recruited from Illinois (47/70, 67%), followed by Florida (6/70, 9%), New York (4/70, 5%), Texas (3/70, 4%), and Pennsylvania (3/70, 4%). Other participants were recruited from Alabama, Georgia, Michigan, New Jersey, Louisiana, and Wisconsin.

Firearm Violence Profile

To characterize the participants' violence exposure and firearm risk, we collated both descriptive data (ie, YBRS survey questions) and domain-specific scores (ie, SaFETy screening tool).

Descriptive Profile of Violence Exposure

Community Violence and Interpersonal Aggression: Participant Experiences

Nearly half of the participants (32/70, 46%) reported engaging in a serious physical fight within the past 6 months. During the same period, 31 (44%) indicated that a friend had carried a weapon (knife, razor, or gun), and 31 (44%) reported having been directly threatened with a gun at least once. Additionally, 41 (59%) had heard gunshots in their neighborhood in the previous 6 months. Exposure to community violence was highly prevalent, with 49 (70%) participants endorsing direct or indirect involvement in violence (eg, fighting, threats, or gang activity) in the past year. Furthermore, 53 (76%) respondents reported witnessing someone being attacked, beaten, stabbed, or shot in their neighborhood. Regarding relationship aggression, 41 (59%) reported psychological aggression toward a romantic or dating partner, and 31 (44%) disclosed having engaged in physical aggression in the past year. Notably, 31 (44%) reported carrying a weapon at least once in the past 30 days.

SaFETy Score Breakdown

Table 3 presents item-level responses and scoring contributions for each domain of the SaFETy score: Serious Fighting, Friend Carrying Weapons, Community Environment, and Firearm Threats. The most commonly endorsed level for Serious Fighting was "3 - 5 times in the past 6 months," reported by 19 of 70 (27%) participants, contributing 2 points to the SaFETy score. In the Friend Carrying Weapons domain, 38 (54%) participants reported that at least some of their friends had carried a weapon in the past 6 months, with 7 (10%) participants reporting that many, most, or all of their friends had done so, contributing 1 point.

XSL•FO
RenderX

Table . Breakdown of SaFETy[a] score distribution.

Category and question/scale levels	Values, n (%)	SaFETy contribution
Serious Fighting		
In the past 6 months, including today, how often did you get into a serious physical fight?		
0 (never)	22 (31)	0
1 (once)	11 (16)	1
2 (twice)	17 (24)	1
3 (3 - 5 times)	19 (27)	1
4+ (6 or more times)	1 (1)	4
Friend Carrying Weapons		
In the past 6 months, including today, how many of your friends have carried a knife, razor, or gun?		
1 (none)	31 (44)	0
2 (some)	31 (44)	0
3+ (many, most, or all)	7 (10)	1
Community Environment		
In the past 6 months, how often have you heard guns being shot?		
0 (never)	5 (7)	0
1 (once or twice)	8 (11)	0
2 (a few times)	30 (43)	0
3 (many times)	25 (36)	1
Firearm Threats		
How often, in the past 6 months, including today, has someone pulled a gun on you?		
0 (never)	31 (44)	0
1 (once)	22 (31)	3
2+ (twice or more)	17 (24)	4

[a]SaFETy: Serious Fighting, Friend Weapon Carrying, Community Environment, and Firearm Threats.

Community environment exposure was notably high: 57 (81%) participants reported hearing gunshots at least “a few times” in the past 6 months, with 26 (37%) hearing them “many times,” contributing 3 points. The highest-weighted item was Firearm Threats: 17 (24%) participants reported being threatened with a gun 2 or more times, contributing 4 points. Notably, 22 (31%) respondents scored 0 across all categories of firearm threat. These distributions reflect a high prevalence of direct and indirect exposure to firearm violence in this sample, contributing to higher cumulative SaFETy scores and elevated future firearm violence risk.

The distribution of total SaFETy scores among participants reveals a wide range of firearm risk exposure. While a notable portion of the sample scored 0, indicating minimal or no reported exposure to serious fighting, weapon-carrying peers, gunfire in the community, or direct firearm threats, the majority reported at least one source of exposure. A significant subset scored between 4 and 7, reflecting high cumulative exposure, particularly in the domains of community gun violence and direct firearm threats. This right-skewed distribution suggests heterogeneity in risk profiles, with a sizable group facing elevated vulnerability to firearm-related harm, an important consideration for intervention targeting and future risk stratification.

Substance Use Profile

We measured 30-day adolescent binge drinking, nonmedical drug use, and substance-related violence perpetration. Nearly one-fourth of the participants (17/70, 24%) had engaged in binge alcohol consumption, defined as more than 5 drinks in a single sitting within the past 30 days. Over half reported illicit use of pharmaceuticals or narcotics for nonmedical purposes, impacting 39 (56%) participants. Finally, 32 (46%) participants reported perpetrating substance-related violence.

Intervention Preliminary Effects

Overview

We assessed multiple outcomes (summarized in Table 4), such as attitudes toward guns and violence, reactive and proactive aggression, and mental health outcomes (eg, psychological distress).

XSL•FO
RenderX

Table . Pretest and posttest changes in the study outcomes.[a]

Outcome	Test used	Pretest, mean (SD)	Posttest mean (SD)	*t* test (*df*) or *z* value	*P* value	Effect size (Cohen *d*)
Attitudes toward guns and violence	Paired *t* test	29.8 (8.7)	26.1 (9.0)	3.52 (44)	<.001	0.53
Reactive aggression	Paired *t* test	10.48 (5.39)	8.67 (4.92)	2.74 (53)	.008	0.37
Proactive aggression	Paired *t* test	6.89 (4.95)	6.70 (5.01)	0.82 (53)	.42	0.11
Psychological distress (Kessler Psychological Distress Scale)	Paired *t* test	18.2 (6.3)	18.1 (6.2)	0.20 (58)	.84	0.03
Depressive symptoms (8-item Patient Health Questionnaire)	Wilcoxon signed rank test	9.82 (6.41)	9.33 (6.26)	0.90[b]	.37	N/A

[a]*P*<.05 considered statistically significant. Paired *t* tests were used for normally distributed outcomes, and the Wilcoxon signed rank test was used for nonnormally distributed data (8-item Patient and Health Questionnaire).

[b]*z* value.

Attitudes Toward Guns and Violence

A significant reduction in AGVQ scores was observed among participants (n=43) from pretest (mean 29.8, SD 8.7) to posttest (mean 26.1, SD 9.0), with a mean difference of 3.69 (SE 1.05, t_{42}=3.522, *P*<.001), and a moderate effect size (Cohen *d*=0.53). Subscale analysis revealed the most considerable improvement in the "Aggressive Response to Shame" subscale (28% reduction), followed by the "Excitement Toward Guns and Violence" subscale (14.8%), the "Feelings of Power/Safety" subscale (8%), and the "Comfort with Aggression" subscale (2.3%). These crucial findings indicate that participants experienced reduced emotional reactivity to perceived threats and decreased excitement and reliance on firearms for power and safety. For example, Goldberg et al [61] found that small but statistically significant decreases in AGVQ scores were predictive of lower intentions to carry firearms and decreased willingness to use violence in future peer conflict situations.

Reactive and Proactive Aggression

Mean scores indicated that reactive aggression significantly decreased from 10.48 (SD 5.39) preintervention to 8.67 (SD 4.92) postintervention (mean difference 1.82, SE 0.66, t_{53}=2.74, *P*=.008), with a small-to-moderate effect size (Cohen *d*=0.37), suggesting a notable improvement in managing impulsive, emotionally driven responses to perceived threats following exposure to the intervention. By contrast, no significant change was detected in proactive aggression scores between the pre- and posttest (t_{53}=0.82, *P*=.42), with a small effect size (Cohen *d*=0.11), indicating the need for longer-term or more intensive and targeted interventions to address the underlying cognitive patterns and motivations associated with planned aggression.

Psychological Distress

A paired-samples *t* test was used to evaluate changes in psychological distress, focusing on subscales (depression and anxiety) and overall psychological distress (ie, total scores) from pre- to posttest. No significant changes were found in depression symptoms from pretest (mean 15.85, SD 6.28) to posttest (mean 15.97, SD 5.85, t_{58}=–0.20, *P*=.84, Cohen *d*=0.03). Likewise, anxiety scores did not significantly differ between pretest (mean 10.32, SD 3.93) and posttest (mean 10.02, SD 3.88, t_{58}=0.76, *P*=.45, *d*=0.10). In addition, overall psychological distress scores remained stable from pretest (mean 26.17, SD 10.02) to posttest (mean 25.98, SD 9.54, t_{58}=0.20, *P*=.84), with a negligible effect size (*d*=0.03). At baseline, 21 of 70 (30%) respondents reported potentially moderate to severe psychological distress (K10 scores>16), highlighting a substantial mental health burden within this sample.

A change of 5 points or more on the K10 is considered clinically meaningful for psychological distress [67,68]. Based on our sample mean difference (mean difference 0.186), the absence of both statistically and clinically significant changes suggests that the intervention may have had a limited short-term impact on psychological distress, underscoring the need for enhanced or sustained mental health support in the long term.

Depression (PHQ-8)

The Shapiro-Wilk test revealed a significant deviation from normality in the pretest scores (*W*=0.939, *P*=.008), indicating a need for a nonparametric approach. A Wilcoxon signed-rank test was conducted to compare pretest (mean 9.82, SD 6.41) and posttest (mean 9.33, SD 6.26) scores. The results showed no statistically significant difference (*W*=597.50, *z*=0.903, *P*=.37) in depression, corroborating earlier findings. Although descriptive statistics suggested a slight reduction in the mean PHQ-8 scores, this change was not significant. For the PHQ-8, a reduction of 5 points or more is widely accepted as the minimal clinically important difference in both primary care and research settings [66].

XSL•FO
RenderX

Intervention Engagement Outcomes

Backend analytics from REDCap were used to monitor time stamps and session durations. Almost all participants (68/70, 97%) completed the video modules in a single session, with 47 (67%) finishing within an hour, suggesting high feasibility of BrotherlyACT as a digital intervention. Participants were advised to complete 1-2 modules daily, with no upper limit per session. This flexible approach accommodated varying schedules and comfort levels while ensuring consistent content delivery. Future iterations will aim to explore sustained engagement and assess feasibility in school and clinical settings.

Discussion

Principal Findings

This study evaluated the preliminary effects of BrotherlyACT, a culturally responsive, trauma-informed, multicomponent mobile and online intervention designed to support young Black males (aged 15 - 24) in navigating and preventing community violence, substance use, and mental health challenges. The app aims to improve access to precrisis support and mental health resources for youth living in low-resource, high-violence environments. BrotherlyACT builds on promising ED-based models, such as that by Carter et al [17], by expanding intervention reach beyond clinical settings. Its mobile delivery, cultural relevance, and trauma-informed framework address key barriers to care—namely, limited access to early interventions, lack of continuity, and low trust in traditional systems.

Our findings demonstrated a significant reduction in overall attitudes toward guns and violence, with the most considerable reduction occurring in the "Aggressive Response to Shame" subscale (a 28% decrease). This result aligns with research linking shame and emotional dysregulation to aggression, particularly in populations exposed to high levels of systemic inequities and chronic community violence [55,69,70]. Shame proneness during adolescence is a significant psychological construct linked to aggressive behavior, often mediated by hostility and externalization of blame [71].

Additionally, notable reductions in "Excitement Toward Guns and Violence" (14.8%) and "Feelings of Power/Safety" (8%) suggest meaningful shifts in attitudes associated with the perceived role of firearms in self-protection, empowerment, and identity formation among adolescents. These changes reflect progress in addressing key psychosocial drivers of risky firearm behavior. The medium effect size for the overall AGVQ outcome (d=0.53) also suggests that the observed difference was not only statistically significant but also practically notable. We posit that the intervention effectively shifted attitudes toward firearms and violence by challenging norms that reinforce gun carrying and retaliation, and by altering cognitive frameworks around violence, likely through the promotion of nonviolent problem-solving and prosocial coping strategies. These attitudinal changes may reflect the malleability of belief systems when disrupted by relatable, peer-aligned narratives. The app's nondidactic tone and culturally resonant scenarios may have reduced defensiveness and increased engagement, particularly among youth resistant to adult-led violence messaging.

In terms of aggressive behavior, the intervention's differential impact on the *reactive aggression* subtype underscores its potential to mitigate impulsive, emotionally driven aggression, a key contributor to firearm injuries and homicides in urban settings [72]. Several mechanisms may explain these shifts. First, the app's video content was designed to engage users through culturally salient and emotionally resonant messaging, aligning with principles of social learning theory and narrative persuasion frameworks. Youth may have identified with the characters and scenarios presented, leading to emotional mirroring and internalization of the modeled prosocial behaviors. Notably, reactive aggression, typically driven by perceived threat and emotional dysregulation, may have been mitigated through the vicarious modeling of alternative conflict resolution strategies presented in the modules.

Conversely, we observed a nonsignificant decline in proactive aggression, which prior studies suggest may be more responsive to interventions that explicitly target cognitive processes such as empathy and moral reasoning [73,74]. Addressing proactive aggression may also require longer-term interventions, such as dialectic behavioral therapy, in combination with content that affirms identity, fosters critical consciousness, challenges harmful masculinity norms, and promotes consequential thinking and value realignment. Importantly, interventions targeting proactive aggression must also address the broader social determinants of health that shape youth behavior.

Similarly, no significant changes were observed in psychological distress (depression or anxiety), aligning with prior research in the neuroscience of aggression that underscores the importance of trauma-informed or mental health–focused components—approaches shown to be effective in analogous nondigital contexts [75]. This finding was anticipated, as key mental health features of BrotherlyACT, including the safety planning toolkit and artificial intelligence–powered talk therapy chatbot, were not fully implemented or tested at this stage. Additionally, it remains unclear whether the minimal changes observed in depression were cognitive, affective, or somatic in nature, an area that will be explored in the larger planned study.

The absence of change in psychological distress supports the notion that distress may not be the primary mechanism through which video-based interventions reduce aggression. However, we are investigating a hypothesized pathway of effects in supplemental analysis. Nonetheless, these findings provide a robust foundation for refining intervention strategies aimed at improving both aggression-related outcomes and mental health outcomes.

Lastly, the significant rate of substance misuse in this group emphasizes the critical need to cotarget drug and alcohol use as a concurrent risk factor within this population. Over half of the participants (39/70, 56%) reported illicit drug use, and substance-related violence perpetration (32/70, 46%). These findings are consistent with other studies linking substance use to elevated risks of both perpetrating and experiencing firearm violence [58,76]. Future interventions may benefit from expanding current modules that directly address substance misuse, given its interplay with firearm violence.

Implications for Practice and Prevention

Traditional firearm safety interventions for youth often emphasize parent-focused messaging and home-based storage practices. However, these strategies may not align with how at-risk older adolescents, particularly young Black males, access and engage with firearms. Such approaches frequently overlook structural realities, such as neighborhood-level firearm acquisition, systemic mistrust of support systems, and limited access to secure and inexpensive storage options. BrotherlyACT addresses these gaps by directly engaging high-risk youth through developmentally appropriate, culturally grounded modules focused on gun safety, nonretaliation, and coping within violence-impacted environments.

Critically, the intervention is grounded in trauma-informed design and rooted in evidence-based behavioral frameworks, including ACT and motivational interviewing. These frameworks promote emotional regulation, values-driven decision-making, and self-reflection, offering a nonstigmatizing, empowering alternative to punitive behavior change models. Given that 97% of US adolescents own smartphones [77], BrotherlyACT offers a scalable and discreet solution for reaching youth who may avoid traditional services. The high levels of engagement observed in this study underscore its feasibility; however, variability in module completion points to the need for additional engagement strategies, such as personalized incentives or enhanced interactive features to improve module completion and reuse.

Reducing firearm-related injuries and deaths among young Black males requires a multilevel public health strategy. This includes individual behavioral interventions, community-level engagement, and systemic policy changes, all underpinned by trauma-informed, culturally sensitive approaches, including direct-to-youth interventions that address care barriers and societal drivers of firearm violence [3,78]. Ultimately, BrotherlyACT contributes a novel, culturally responsive tool to this effort. Future research should explore how digital tools such as BrotherlyACT can integrate with broader structural and environmental interventions to produce sustainable, equity-centered outcomes.

Because of its modular design and digital delivery, BrotherlyACT is particularly well-suited for integration into school-based health centers, community mental health clinics, after-school programs, and youth-serving community-based organizations. Importantly, the intervention is consistent with both citywide and national priorities that emphasize trauma-informed, equity-centered approaches to the prevention of youth gun violence. For instance, in Chicago, we are investigating opportunities to align BrotherlyACT with the city's *Office of Gun Violence Prevention* and its trauma recovery ecosystem, as well as with initiatives funded under the Chicago Youth Service Corps.

At the policy level, this study provides preliminary evidence to inform future digital health innovation grants, Medicaid reimbursable pilots for technology-based behavioral health tools, and public health department efforts aimed at expanding digital care access for underserved youth. Our proposed scale-up model includes collaboration with public school systems, local Federally Qualified Health Centers, and youth justice diversion programs, guided by implementation science frameworks and equity-based partnership principles. Future research will focus on formalizing these implementation pathways, evaluating institutional readiness, and identifying sustainable policy mechanisms for long-term adoption.

Limitations and Strengths

A central strength of this study is its focus on an urban, high-risk sample of young Black males most impacted by firearm violence. The utilization of validated self-report instruments, namely, the AGVQ and RPQ, facilitated a direct assessment of attitudes and behaviors related to aggression, specifically in the context of gun violence. Previous research corroborates the reliability of these measures within similar populations [79]. Furthermore, the confidential and computerized format of our survey likely mitigated response bias concerning sensitive topics such as gun use and substance involvement, particularly in a population that exhibits a high level of mistrust regarding the disclosure of personal information and details.

However, some limitations are worth noting. Self-report data remain vulnerable to social desirability bias, which may have influenced participants' disclosures. While this could inflate observed changes, it is a common limitation in violence prevention research. Additionally, the RPQ and AGVQ may oversimplify the complex and context-dependent nature of youth attitudes toward firearms and aggression. Although we reported subscale results where appropriate, aggregating scores can obscure important variability. In addition, the pilot design was not powered to detect subgroup differences or interaction effects. While missing data were minimal, our use of listwise deletion may have reduced power and introduced bias. Future studies will need to incorporate more robust missing data techniques, such as multiple imputation.

Critically, participants only engaged with the video-based module component of BrotherlyACT via REDCap, rather than the full app interface. This limited exposure may have underestimated the intervention's true engagement potential. Moreover, we did not capture objective metrics of video engagement (eg, watch time or skipping behavior), limiting interpretation of intervention dose effects. We also did not collect data on firearm use motivations, such as distinctions between recreational, protective, or aggressive carrying, which bear implications for study interpretation. Despite these limitations, module completion rates remained high and nearly all participants completed the content in a single sitting, supporting the feasibility and acceptability of brief digital violence prevention tools. These early findings reinforce the promise of BrotherlyACT as a scalable, youth-centered intervention.

Conclusions

This study demonstrates the promise of BrotherlyACT as a culturally responsive, trauma-informed tool for addressing both attitudinal and behavioral risk factors linked to firearm violence among young Black males. By targeting reactive aggression and shifting norms around violence, BrotherlyACT offers a novel, scalable approach to primary prevention in medium- to

XSL•FO
RenderX

high-risk groups. These findings lay important groundwork for future strategies aimed at reducing dynamic and context-dependent risks, such as seasonal or escalating violence, through brief, targeted interventions. However, given the multifaceted nature of aggression and the systemic barriers faced by this population, further refinement of intervention components and deeper engagement with structural determinants will be critical. Sustained progress in firearm violence prevention will require integrative solutions that blend individual-level change with community and policy-level action to promote long-term safety and well-being.

Acknowledgments

We express our gratitude to the Urban Male Network, from which most of our study participants were recruited, for their assistance in youth consultations and coordination of recruitment efforts. We also thank Hekademeia Research Solutions (Blake Anderson and Shana Permenter) for their contributions to the design and programming of BrotherlyACT. We are deeply grateful to the young Black male participants who participated in this pilot study, and the Rush-BMO Institute for Health Equity Scholars Program at Rush University.

Our research was made possible through funding from various sources: the Chicago Chronic Condition Equity Network via the National Institute on Minority Health and Health Disparities (grant 5P50MD017349-02), the Institute for Translational Medicine through the National Institutes of Health/National Center for Advancing Translational Sciences (grants UL1TR002389, KL2TR002387, and TL1TR00238), and the Rush-BMO Institute for Health Equity Scholars Program at Rush University.

Data Availability

Study data can be obtained by contacting the corresponding author with a valid request. Access to the data is limited to safeguard participant anonymity, given the small number of subjects and identifiable institutional connections. Any data access inquiries will be evaluated in accordance with organizational and funder protocols regarding data distribution and subject privacy.

Authors' Contributions

CE, the principal investigator, conceptualized the study and played a pivotal role in its design, supervision, and manuscript editing. Statistical analyses were conducted collaboratively by CE and JBR. The entire research team, comprising CE, JBR, AF, TW, WAJ, and NSK, contributed to the study's conceptualization, design, oversight, and manuscript revision. CE and JBR were responsible for data preparation, validation, and analysis. The initial manuscript draft was authored by CE, with subsequent versions incorporating feedback from all the coauthors. The final manuscript was reviewed and approved by the entire research team.

Conflicts of Interest

None declared.

Abstract

Background: The pain resulting from venipuncture is one of the primary sources of stress during childhood and can have adverse effects on children. The Buzzy device can play an important role in alleviating the pain of venipuncture in children.

Objective: The aim of this study is to investigate the independent and combined effects of cold and vibration in reducing venipuncture pain and resistance behavior in children aged 2-7 years.

Methods: A total of 130 children who underwent venipuncture were randomly assigned to 4 groups: 32 in the control group, 30 in the external cold group, 37 in the vibration group, and 31 in the cold combined with vibration group. The cold, vibration, and cold combined with vibration interventions used the Buzzy device. Nurses used the Face, Legs, Activity, Cry, Consolability Pain Behavior Scale and the Children's Behavior Scale to assess pain and resistance behaviors before and during the venipuncture.

Results: Compared with the control group, the cold group, vibration group, and cold combined with vibration group experienced milder pain and demonstrated weaker resistance behavior (P<.05). Pairwise comparison results showed that the combination group was superior to the vibration group (P<.05).

Conclusions: External cold and vibration are effective in reducing procedural pain and improving compliance in children aged 2-7 years undergoing venipuncture. The cold combined with vibration has a synergistic effect, and the effect is better than vibration only.

Introduction

Background

Venipuncture is a common medical procedure, with moderate to severe pain stimulation [1]. Needle pricks are a significant part of early pain experiences [2]. Needle-related procedural pain is one of the primary sources of stress in childhood, causing fear in children [3]. Early pain experiences can affect physiological indicators and hormonal changes in children, potentially leading to reduced immunity and disrupted pain thresholds in the long term, which is detrimental to the development of the nervous system [4]. Furthermore, Cuenca-Martínez et al [5] suggest that children are more likely to develop a bias in pain memory toward acute pain. Therefore, improper pain management can lead to negative pain memories and needle phobia in children, which may not only increase pain but also trigger it [6]. However, many children do not receive adequate pain prevention and management during venipuncture [7].

The Buzzy device is a widely used nonpharmacological method for alleviating venipuncture pain in children. It is a bee-shaped tool that combines ice pack cooling and vibration. The device includes a vibration-generating engine powered by batteries, with a detachable ice pack as its wings. Compared to other nonpharmacological methods like virtual reality [8] and distraction interventions [9], it is simple to operate: you only

XSL•FO
RenderX

need to place it approximately 5 centimeters above the puncture site and activate the device a few minutes before venipuncture. The Buzzy device's soothing effect combines cold and vibration, two common and effective methods for reducing pain in children [10]. The individual use of cold or vibration has been well-validated in pediatric pain management [11]. Among nonpharmacologic strategies, the use of cold and vibration is a common and effective method for pain reduction in children [12]. Cold packs work by applying cold to a specific body area, which slows or inhibits pain transmission via peripheral nerves and induces vasoconstriction, thus raising the pain threshold [13]. Vibration stimulates tactile receptors in the skin, which localizes the sensation of pain and, when applied repetitively, reduces its intensity. This vibratory stimulation activates pain-blocking mechanisms and increases the release of β-endorphins, which raise the pain threshold and diminish the perception of pain [14,15]. The Buzzy device has been widely used to reduce pain during venipuncture in children [16].

However, researchers found that the combined use of cold and vibration with the Buzzy device did not seem as effective as imagined. Semerci et al [17] discovered that in school-aged children, using cold spray alone was more effective in relieving pain compared to the combined use of cold and vibration with the Buzzy device. Similarly, Ueki et al [18] found that for children under 6 years old, there was no difference in pain relief whether or not the vibration feature of the Buzzy device was activated when using an ice pack. Moreover, the pain relief effect of the Buzzy device might be due to the distraction caused by its bee-like appearance, which diminishes in older children [19]. Therefore, it seems there is a debate on whether the pain relief effect of the Buzzy device in children is due to the cold, the vibration, or the combination of both; current studies compare the Buzzy device with other pain management methods (such as cold spray) while neglecting the effects of the device itself. Compared to other nonpharmacological approaches, the Buzzy device is more cost-effective and easier to operate. If we can demonstrate that either cold application or vibration alone is effective, the Buzzy device could still be a viable option for pain relief—even if cold spray proves more effective.

According to a paper titled "A practical guide to acute pain management in children" [20], most pain assessment tools define age 7 as the threshold at which children can accurately self-report. Furthermore, Hedén et al [21] believe that children over the age of 7 are better able to distinguish between fear and pain. Younger children may develop a psychological and behavioral resistance to injections due to fear, increasing the risk of unsafe venipuncture [22]. For children under 2 years old, incomplete skin barrier function and thermoregulatory capabilities make them susceptible to skin damage, so cold is not recommended [23]. Therefore, this study selected children aged 2-7 as subjects to explore the independent effects and interactions of cold and vibration during the venipuncture process using the Buzzy device. The aim is to reduce pain and resistance behavior during venipuncture, enhance children's adherence to treatments, and ultimately improve pain management in children.

Objective

This study aims to investigate the independent and combined effects of cold and vibration in reducing venipuncture pain in children aged 2-7 years. The research hypothesis is that there are independent and interactive effects between vibration and external cold in solving procedural pain in children.

Methods

Participants

A randomized controlled trial was conducted to select children aged 2-7 years requiring venipuncture between May 2023 and November 2023 in the Department of Pediatrics of a tertiary hospital in Changsha City, Hunan Province, including the pediatric emergency department and pediatric ward, and the main reason for venipuncture was blood sampling, requiring peripheral intravenous access. This trial was reported using CONSORT (Consolidated Standards of Reporting Trials) guidelines. Informed consent was obtained from parents, and verbal assent was acquired from the children prior to their participation.

The inclusion criteria were (1) no history of cognitive or neurodevelopmental delay and (2) informed consent/assent obtained from both the children and their parents. The exclusion criteria were as follows: (1) difficulty in cooperation (ie, the child's strong resistance to venipuncture, continuous struggle throughout the entire venipuncture process, and inability to cooperate with the use of the Buzzy device); (2) use of sedative drugs or treatments prior to venipuncture; (3) broken skin at the needle puncture site; (4) extreme sensitivity to cold (Raynaud's syndrome or sickle cell disease); (5) experience with external cold or vibration within the past week; and (6) withdrawal of consent during venipuncture process.

While the child was waiting for the venipuncture, the researchers explained the purpose and methods of the study to the parents and obtained written consent from them. In addition, the researchers would explain the study to the child in simple and understandable language. If the child refused to participate, we would exclude the child from the study even if the parents agreed.

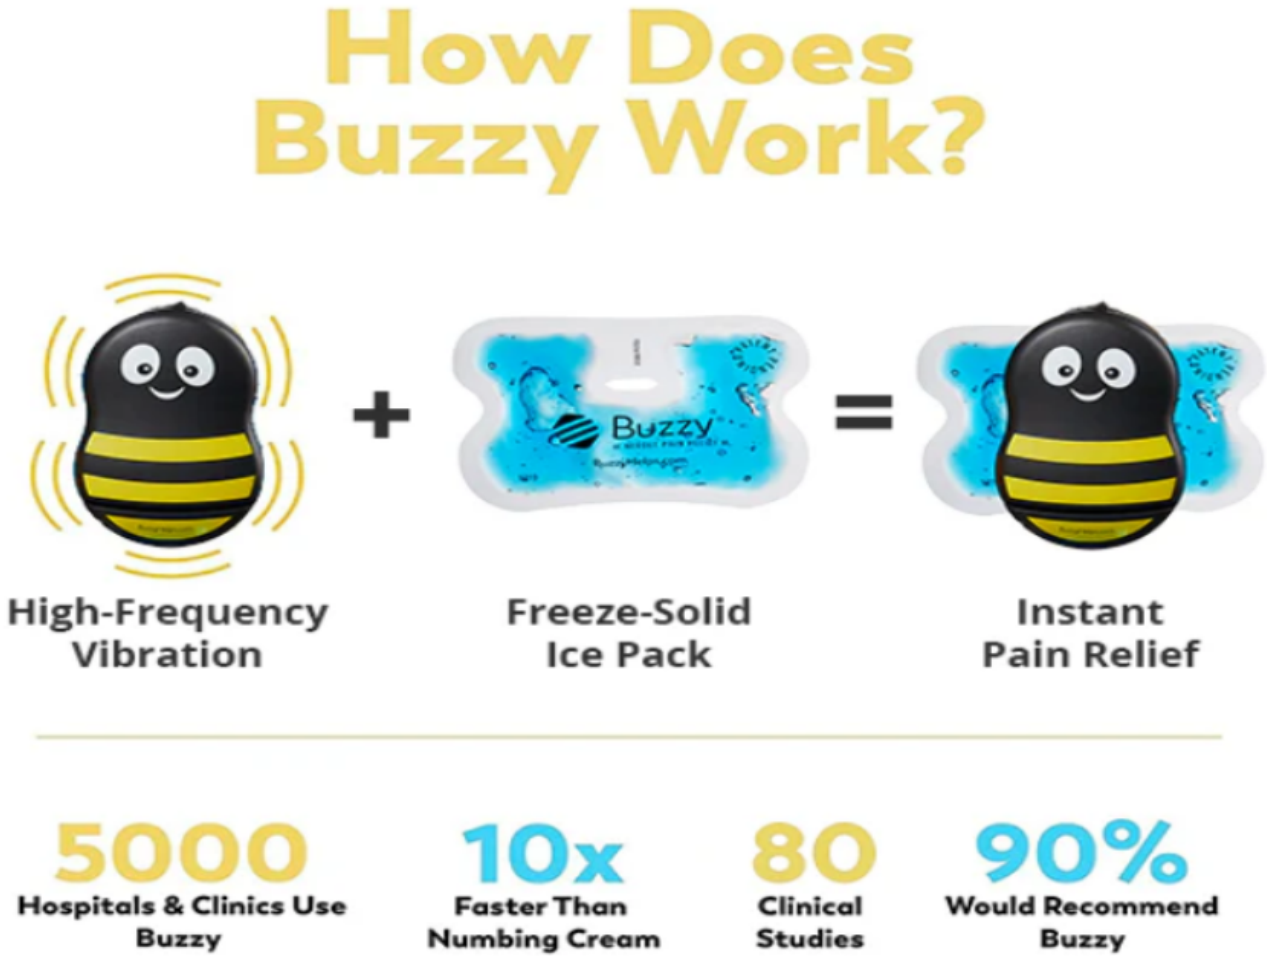
Sample Size Calculation

The efficacy analysis of a 2-factor, 2-level ANOVA was performed using G*Power with settings of 1-β=.80, effect size=0.40, α=.05 according to the preexperimental results, a degree of freedom of 3, and 4 groups. Considering a 15% sample attrition rate, it was determined that each group should include at least 21 participants, requiring a total of 84 participants across the 4 groups.

A total of 145 children, aged 2-7 years and meeting the inclusion and exclusion criteria, were enrolled in the study. Participants were randomized into 4 treatment groups using IBM SPSS software (version 24.0; IBM Corp) based on the random number table method. Of the original cohort, 15 participants withdrew their consent by refusing to use the Buzzy tool during the venipuncture phase, leaving 130 participants for the final analysis.

XSL•FO
RenderX

Ethical Considerations



The study was approved by the Ethics Review Committee of Xiangya School of Nursing, Central South University (E2023149) on June 23, 2023, and registered with the Clinical Trials Register (ChiCTR2400079536) on January 5, 2024. All participants were informed of the study's purpose and the venipuncture process. Informed consent was obtained from parents, and verbal assent was acquired from the children prior to their participation. Participants did not receive any compensation. To protect the privacy of participants, we numbered them and did not retain any identifying information.

Setting

Before starting the venipuncture, the researcher introduced the study to the children and their families. Due to the characteristics of the Buzzy device and the principle of informed consent, it was not possible to blind the children and their families. The nurses performing the venipuncture had all been working in pediatrics for over 5 years, held the title of "nurse-in-charge," and had all undergone standardized pediatric venipuncture training, obtaining the necessary qualifications for conducting venipuncture.

The Buzzy device (MMJ Labs) is a bee-shaped tool, measuring 8 × 5 × 2.5 cm, that integrates both vibration (the body of the bee) and cold (a removable ice pack). The ice pack is stored in the freezer and inserted into the device before the venipuncture. After use, it is returned to the freezer to maintain its cooling effect (Figure 1).

Figure 1. Buzzy device (image by MMJ Labs).

Preparation for Venipuncture

The pediatric outpatient emergency injection room is designed to accommodate the needs of children, featuring decorations such as cartoon characters and warm colors. The room maintains appropriate levels of natural light, temperature, and humidity. Nurses ensure they are properly prepared, organize the necessary injection supplies and emergency equipment, and perform double-checks on medications to ensure accuracy.

Venipuncture

For the control group, routine nursing care was implemented. The children's and their families' basic information was verified, and the purpose of the venipuncture was explained. According to the recommended usage of the Buzzy device [24], 1 minute before the injection, the Buzzy device was placed 5 centimeters above the puncture site before tightening the tourniquet. The cold pack and the vibration switch were not activated. An appropriate injection site and vessel were chosen, the area was disinfected twice, and the needle was positioned at a 15 - 30° angle with the skin, bevel up, and advanced slightly after seeing

XSL•FO
RenderX

blood return. Blood return was checked before advancing the needle slightly for fixation. The needle was secured and the Buzzy device was removed after securing the pillow. During the injection, the child was encouraged, engaged in conversation, and provided with timely feedback and praise. Postinjection, instructions on precautions were given, and the child was monitored for any discomfort or adverse reactions.

For the observation group, the other conditions were the same as the control group, but for one group, the vibration switch was activated, for another, an ice pack was applied for cold therapy, and the final group received both vibration and cold therapy.

Data Collection

Before puncture (denoted as T_0, no venipuncture or movement within the injection room) and during the puncture process (denoted as T_1, from the application of the tourniquet to confirmation of successful puncture and fixation), two time periods were observed. Based on the scale, one research team member assessed the patient's resistance behaviors while another evaluated the level of pain and recorded it.

General Information

The child-specific information collected included gender, age, height, weight, punctured vein, whether it is the first intravenous injection, the time of the most recent injection, how many puncture attempts were needed for success, any hospitalization experience, presence of needle phobia, type of disease, and typical sensitivity to pain. This information was provided by the parents.

Children's Pain (Primary Outcome Measure)

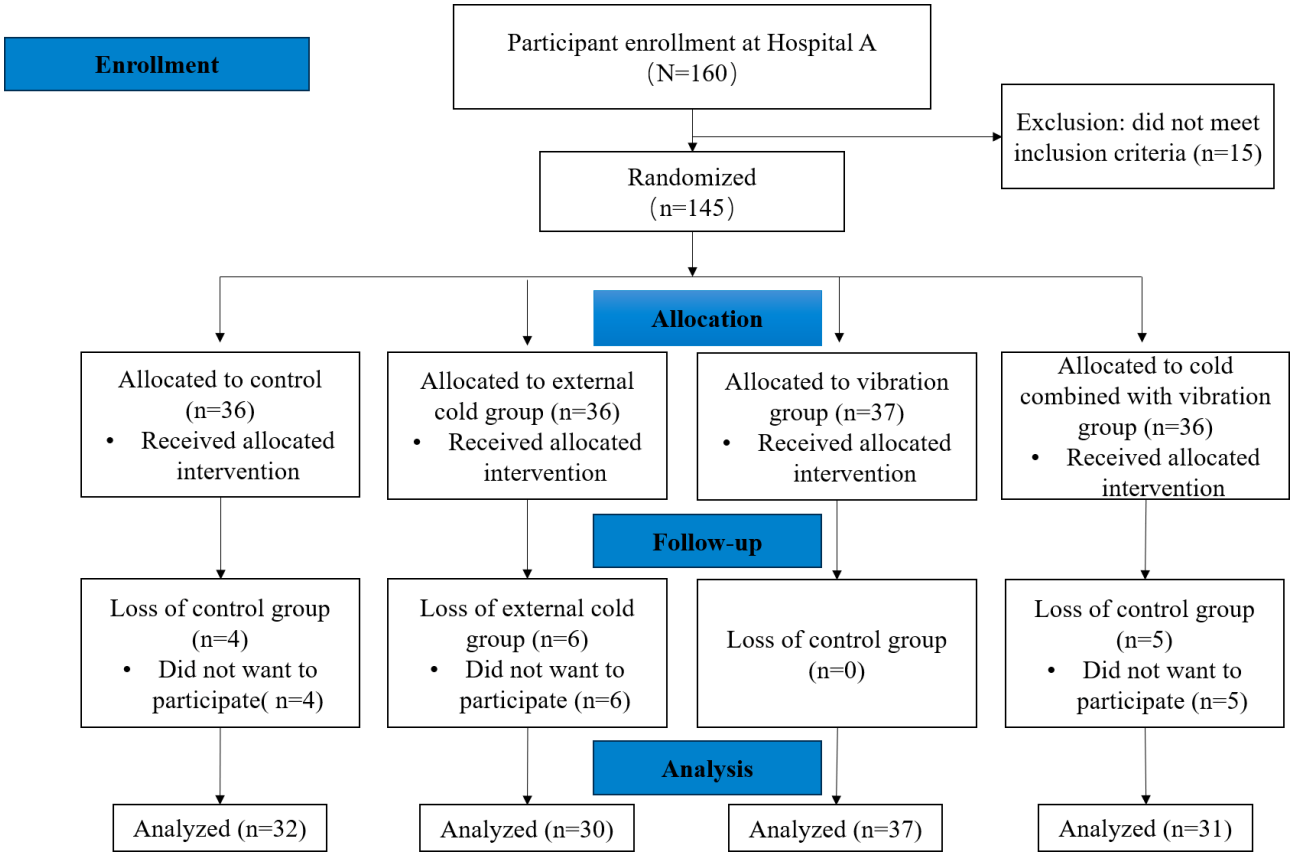
The Face, Legs, Activity, Cry, Consolability (FLACC) Pain Behavior Scale is used to assess pain in children aged 2 months to 7 years or in individuals unable to communicate their pain. Each category is scored from 0 to 2, with a total score of 0 to 10. A score of 0 indicates no pain; 1 - 3 indicates mild pain; 4 - 6 indicates moderate pain; and 7 - 10 indicates severe pain. Liu et al [25] translated it into Chinese, and it has demonstrated reliability and validity, with a Cronbach α of 0.88.

Behavioral State

A compliance and resistance behavior assessment was conducted for each child. This involved evaluating the child's behavior during the injection, including crying, screaming, agitation, struggling, and avoidance. A scoring system of 0-3 was used, with 5 items in total and a maximum score of 15. The higher the score, the poorer the compliance and the stronger the resistance behavior [22].

Statistical Analysis

Statistical analysis was conducted using SPSS software (version 24.0; IBM Corp). Measurement data were described as mean (SD), and ANOVA was used for comparisons between groups. Categorical data were described using frequency and composition ratios, and comparisons were made using the chi-square test and Fisher exact test. The significance level was set at 0.05. For measurement data that did not follow a normal distribution or exhibited heterogeneity of variance, the median (percentile) was used for description, and intergroup differences were analyzed using nonparametric rank-sum tests (Kruskal-Wallis rank-sum test). In cases of homogeneity of variance, post hoc multiple comparisons were performed using the Bonferroni test.



Results

Demographic Information

A total of 145 children were enrolled in the study and randomized into 4 treatment groups. Of these, 15 participants withdrew their consent, leaving 130 participants for the final analysis. The flowchart of participant allocation is shown in Figure 2.

XSL•FO
RenderX

Figure 2. Flow diagram.

A total of 130 sets of data on children aged 2-7 years were collected, including 32 in the control group, 30 in the external cold group, 37 in the vibration group, and 31 in the combined cold and vibration group. The results showed that the average age of patients in the control group, external cold group, vibration group, and combined cold and vibration group was 3.97, 4.03, 4.00, and 3.77 years, respectively. There were no statistically significant differences in demographic variables between control, vibration, cold, and combined treatment groups (P>.05), indicating a general comparability, as shown in Table 1.

Impact of External Cold and Vibration on Pain and Resistance Behavior

After comparing pain (*P*=.26) and compliance resistance behavior scores (*P*=.31) among the groups of children at the T_0 stage, the differences were not statistically significant. The differences at the T_1 stage were statistically significant (*P*<.001). Pairwise comparison results showed that at T_1, the pain scores of the control group were higher than those of the external cold, vibration, and combination group (*P*<.001), and the vibration group had higher pain scores than the combination group (*P*=.03). Furthermore, the mean pain scores from highest to

XSL•FO
RenderX

lowest were as follows: control group (4.38, SD 2.25), vibration group (1.81, SD 1.4), external cold group (1.10, SD 1.77), and combination group (0.65, SD 1.20). At T_1, the resistance behavior of the control group was higher than that of the external cold, vibration, and combination group (P<.001), and the vibration group exhibited higher resistance behavior than the combination group (P=.01), with the differences before and after decreasing in the following order: control group (mean 2.97, SD 2.39), vibration group (mean 1.08, SD 1.23), external cold group (mean 0.57, SD 1.89), and combination group (mean 0.26, SD 0.93) (Table 2).

The Independent and Combined Effects of External Cold and Vibration Intervention

Both external cold and vibration had statistically significant main effects on reducing pain and compliance-resistance behaviors in children (P<.001), and there was a statistically significant interaction between external cold and vibration (FLACC scores: F=12.469, P=.001; resistance behavior: F=7.025, P=.009), as shown in Table 3 and Figures 3 and 4.

Discussion

Main Finding

The main finding of this study is that cold and vibration methods can effectively reduce resistance behavior and increase compliance, while decreasing pain in children aged 2-7 years during venipuncture. The cold combined with vibration is superior to external cold or vibration alone.

Impact of External Cold and Vibration on Pain and Resistance Behavior

The findings of this study are consistent with previous research [26-28]. Ballard et al [24] suggested the Buzzy device works through gate control theory. According to this theory, nonpainful stimuli (like touch, pressure, and temperature) carried by large nerve fibers can inhibit pain signals transmitted by smaller A-δ and C fibers. Applying external cold and vibration before venipuncture generates nonpainful sensory signals that activate inhibitory functions in neural transmission, causing the gate that regulates pain signals entering the brain to close, blocking pain signal transmission and thereby reducing pain [29]. The cold and vibration also trigger β-endorphin release, raising pain thresholds. Additionally, external cold causes vasoconstriction, increasing the pain threshold and reducing pain perception [12], while vibration stimulates skin tactile receptors, such as Pacinian and Meissner's corpuscles, confining pain to a local area [30]. Furthermore, these stimuli distract children from pain, increasing their comfort [31].

Current research mostly focuses on the effect of reducing pain in children during venipuncture, neglecting the assessment of behavioral state effects [12,32]. Our research explores this. On the one hand, by effectively reducing venipuncture pain, the child's resistance to the venipuncture is diminished; on the other hand, it serves as an effective distraction, lowering the child's anticipatory anxiety about the venipuncture, thereby reducing irritability and restlessness [33]. Cold and vibration can decrease discomfort and uneasiness in children during venipuncture, helping them to overcome negative perceptions and responses, increasing compliance, and improving the success rate of venipuncture [34].

The Independent and Combined Effects of External Cold and Vibration Intervention

The study results indicate that during venipuncture in children aged 2-7 years, cold and vibration interventions have both independent effects and interaction effects on reducing resistance behavior and pain. That is, the effects of cold or vibration can change with the level of either intervention, with a synergistic interaction between them, enhancing the effects when combined. The group receiving both external cold and vibration showed a better effect in reducing resistance behavior and alleviating venipuncture pain than the groups receiving only external cold or only vibration. This suggests that the cold combined with vibration is more beneficial, as demonstrated by Faghihian et al's results [35], which indicated that combining external cold with vibration was more effective in alleviating anesthesia injection pain in children aged 6-12 compared to using only an

XSL•FO
RenderX

ice bag to apply external cold. External cold and vibration can each play a role by blocking pain signal transmission and affecting neurotransmitter secretion mechanisms, respectively, reducing pain perception and increasing pain thresholds [36], thereby minimizing the children's resistance behavior due to pain.

There was no difference in reduced pain results when using vibration with cold. Ueki et al [18] also found that when children's pain was assessed by researchers, there was no significant difference in pain relief from vaccination when using only cold or a combination of both cold and vibration. However, they did not further explore the difference between using the Buzzy device and not. This "1+1<2" result may be related to the limited interception of pain signals by nonpain sensory signals provided by cold application and vibration. The specific reasons require further investigation. The individual use of cold and vibration is more convenient, and future studies could conduct a cost-effectiveness analysis of using the Buzzy device to apply cold, vibration, and cold combined with vibration.

Clinical Implication

This study demonstrated the effectiveness of the Buzzy device for pain management in children aged 2 - 7 years, providing a theoretical basis for clinical practice in pediatric pain management.

Limitations

The participants in this study all came from the same hospital and only included children aged 2 - 7 years, which limits its representativeness. Future studies could implement multicenter research and include all age groups. The effect of external cold in this experiment may vary with different seasons and temperatures, and this study did not compare the minimal clinically important difference, which could be further explored in future research.

Conclusion

The application of cold and vibration methods has been shown to significantly mitigate resistance and enhance compliance, concurrently diminishing pain in children aged 2-7 years undergoing venipuncture. The combined effect of cold and vibration was superior to vibration alone, but no different from cold compress alone. Future research could focus on the cost-effectiveness analysis of using the Buzzy device for cold, vibration, and both interventions.

Abstract

Background: The use of extended reality (XR), including virtual reality (VR) and augmented reality (AR), for treating pain has accelerated in the last 10 years. XR is an attractive biobehavioral intervention that may support management of pain or pain-related disability. Reviews of the literature pertaining to adults report promising results, particularly for acute procedural pain.

Objective: This study aimed to (1) summarize the available evidence with respect to feasibility, safety, and effectiveness (pain intensity) of XR for pediatric acute and chronic pain; (2) summarize assessment tools used to measure study outcomes; and (3) identify gaps in evidence to guide future research efforts.

Methods: This study is a systematic review of the literature. Multiple databases (CINAHL, Cochrane Central, Embase, MEDLINE, PsycINFO) were searched from inception until March 2023. Titles, abstracts, and full-text articles were reviewed by 2 team members to determine eligibility. Articles were included if the (1) participants were aged 0 to 18 years; (2) study intervention was VR or AR; (3) study outcomes included safety, feasibility, acceptability, or effectiveness on the outcome of pain; and (4) study design was observational or interventional. Data were collected on bibliographic information; study characteristics; XR characteristics; outcome domains; outcome measures; and study findings pertaining to safety, feasibility, and effectiveness.

Results: We included 90 articles in the review. All included studies used VR, and 93% (84/90) studied VR in the context of acute pain. Of the 90 studies, 74 studies were randomized trials, and 15 studies were observational. Safety was assessed in 23 studies of acute pain, with 13 studies reporting no adverse events and 10 studies reporting events of low concern. Feasibility was

XSL•FO
RenderX

assessed in 27 studies. Of the 84 studies of acute pain, 62% (52/84) reported a positive effect on pain intensity, 21% (18/84) reported no effect, and 13% (11/84) reported mixed effects. All 6 studies of chronic pain reported a positive effect on pain intensity. An evidence gap map was used to illuminate gaps in specific research areas stratified by subtypes of pain. Risk of bias assessment revealed 67 studies had a moderate risk of bias, 17 studies had a high risk, and 5 studies were deemed to be low risk.

Conclusions: The current body of literature around XR for pediatric pain is focused on acute pain with promising results of safety and effectiveness on pain intensity. The literature pertaining to chronic pain lags behind, limiting our ability to draw conclusions. The risk of bias in studies is problematic in this field, with the inherent challenge of blinding participants and researchers to the intervention. Future research should aim to measure effectiveness beyond pain intensity with a consistent approach to measuring key outcome domains and measures. Current efforts are underway to establish expert consensus on best research practices in this field.

KEYWORDS

virtual reality; augmented reality; extended reality; acute pain; chronic pain; pediatrics; adolescents; safety; feasibility; effectiveness; evidence gap map; child; children; VR; XR; biobehavioral; intervention; systematic review

Introduction

Acute and chronic pain are common among children [1-3] and can result in negative short and long-term health and mental health consequences. Within pediatric populations, acute pain can negatively impact treatment adherence such as vaccination schedules [4] and routine port access [5] and can worsen outcomes in the context of surgery and rehabilitation [6,7]. Additionally, acute pain can transition into chronic pain if not adequately assessed, managed, and treated [8]. If not addressed in childhood, these pain and other health-related problems often continue into adulthood and therein increase risk for functional disability and mental health challenges including depression, suicidality, and substance use, with particular concern for opioid use or misuse [9-12].

Technologies have been emerging to support the management of pain for both acute and chronic pain, including the integration of extended reality (XR) into clinical care. XR is most often inclusive of virtual reality (VR) and augmented reality (AR), which aim to immerse a person or patient in a simulated environment that they perceive to be real [13]. In the context of VR, youth are transported to a new or alternative environment, while AR alters or enhances the environment in which the youth is already existing [14].

The integration of XR into health care has been a rapidly growing area of clinical research and treatment, with promise surrounding the management of pain across a variety of acute and chronic conditions for youth and adults [15-17]. Much research has been conducted in the acute pain management context and specifically surrounding wound care, venipuncture ("needle pokes"), and minor procedures (eg, dental fluoride therapy, orthopedic pin removal). Among adults, XR has also been used commonly to manage chronic pain such as low back pain or fibromyalgia [18,19]. Together, results to date indicate that XR holds great promise for supporting biopsychosocial treatment for pain management for youth and adults; however, consistency in measurement as well as defined outcomes for assessing the effectiveness of XR research are missing, thereby limiting the ability to coordinate research efforts and examine effectiveness on a large scale.

One reason for the variability and the lack of consensus in technology and outcomes in XR research is related to the rapid adoption and evolution of technology (ie, hardware and software). Since the initial studies of XR for pain began in the 1980s, the rate at which XR is being evaluated and integrated into clinical care for pain management has sharply increased, with over 250 PubMed-indexed studies published since 2020 alone compared with the total 78 studies published in the 20 years preceding. Identifying a core outcome set for XR trials in pain is needed given the rapid adoption and evolution of this technology into clinical research and the potential for XR to provide breakthroughs in the treatment and management of acute and chronic pain. We undertook this task and, as a part of this effort, conducted a systematic review to summarize the current state of the literature with a specific aim toward understanding how researchers are currently assessing XR effectiveness.

Therefore, the purpose of this systematic review was to describe the feasibility, safety, and effectiveness of XR for pediatric acute and chronic pain. Moreover, this review collated current research to establish an evidence and gap map for guiding future research efforts. Finally, given the variability in XR study treatment outcomes, this review also assessed the measurement tools that have been used to measure outcomes in XR research. Together, these findings provide an updated description of the state of the field and highlight a path forward for improving the application, feasibility, and effectiveness of XR research in the context of pediatric acute and chronic pain.

Methods

Search Strategy

The systematic review protocol was registered on PROSPERO (#CRD42022307153). The literature search strategy was developed in consultation with a medical librarian who executed the searches. Examples of search terms (including MeSH terms) included "virtual reality," "pain," "treatment outcome," "safety," and "feasibility studies." A randomized controlled trial (RCT)

XSL•FO
RenderX

hedge or study-type filter was not applied as it was considered too limiting for the overall search. Major electronic databases (CINAHL, Cochrane Central, Embase, MEDLINE, PsycINFO) were searched from database inception to March 2023. The full search strategy is included in Multimedia Appendix 1.

Selection Criteria

The inclusion criteria for the current review included (1) participants aged 0 to 18 years; (2) study intervention of XR (VR or AR); (3) study outcomes of safety, feasibility, acceptability, or effectiveness on the outcome of pain; and (4) observational or interventional study design. For this review, XR was defined as "technology that blurs the lines between the physical and virtual worlds, creating a sense of immersion and enhancing the realism of virtual experiences" [20-22]. Additionally, the age criterion was not applied until screening to allow for a comprehensive search of the literature.

Studies were excluded from the review if they were reviews, opinion papers, case studies with ≤4 participants, or conference proceedings. Studies in which the participant sample was exclusively adults (>18 years old) were excluded as well as studies in which the intervention was not deemed to align with the definition of XR (eg, intervention delivered on a computer screen or flat board display panel) or where there was insufficient description of the hardware to determine whether the intervention met the definition of XR. Although no uniform definition nor criterion exists for defining XR as immersive or not immersive, through group discussion and guided by existing definitions [23], we excluded technology where the user only existed in the real world (eg, looking at a 2D image on a computer). If a reviewer was uncertain about whether the XR trial was immersive, additional review of the study and group discussion were used to determine whether the paper was included in the review. Papers that were not available in the English language were also excluded from the review.

Study Selection

Following completion of each of the systematic literature searches, 2 reviewers independently screened titles and abstracts for inclusion following established PICO (Population, Intervention, Comparison, Outcome) strategies. Disagreements between raters were resolved by a third reviewer. Following initial review of title and abstracts, a subsequent review of retained studies was completed, reviewing complete texts to evaluate for inclusion. Disagreements between raters were resolved by the same third reviewer. All screening was completed through Covidence [24], a web-based collaboration software platform that streamlines systematic review management and allows for blinded, independent review of included studies.

Assessment of Study Quality

Assessment Tools

For studies that assessed the effectiveness of the XR intervention, a study risk of bias assessment was conducted. For RCTs, the Cochrane Risk of Bias Tool (RoB-2) was used, and for nonrandomized studies, the Methodological Index for Non-Randomized Studies (MINORS) was used. The risk of bias assessment was completed by 2 separate groups with one group conducting risk of bias for the RCTs and the other group conducting risk of bias for the nonrandomized trials. Given the distinct tools used for each group, it was deemed appropriate to allow for 2 separate coding groups.

Risk of Bias in RCTs

To assess the RCTs, the 2 reviewers used and adhered to the RoB-2 protocol [25]. RoB-2 serves as an algorithmic framework for considering the risk of bias in the outcomes of RCTs [26]. The tool asks reviewers to rate the bias in RCT protocols among 5 domains: (1) randomization process, (2) deviations from intended interventions, (3) missing outcome data, (4) measurement of the outcome, and (5) selection. Reviewers evaluated the studies independently then met to discuss agreement on rating. If the raters disagreed on a rating, a third rater resolved the disagreement. Each domain was assigned an algorithm result and an assessor's judgement of Low, Some Concerns, or High. The overall bias followed the same 3 outcomes.

Risk of Bias in Nonrandomized Studies

To assess the nonrandomized studies (eg, observational, interventional without control), the reviewers used MINORS [27]. MINORS consists of 12 method-oriented items (eg, "A clearly stated aim") to assess quality and risk of bias in nonrandomized studies. Each item is rated on a scale from 0 to 2, with 0 indicating that the item was not reported, 1 indicating that the item was reported but inadequate, and 2 indicating the item was reported and adequate. MINORS can be used for studies with or without a comparator group, with the first 8 items applying to all studies and the final 4 items specific to comparative studies. Total scores for noncomparative studies range from 0 to 16, and total scores for comparative studies range from 0 to 24, with higher scores indicating more methodological integrity. For this review, 2 raters independently rated each of the nonrandomized studies then met to compare. Each of the 12 items as well as the total scores were compared between raters. Any disagreements were resolved through discussion and, if needed, through consultation with a third rater.

Data Extraction

A data extraction form was created and pilot tested to ensure relevant data were pulled based on the form directions. A team of research assistants was trained on the data extraction form, and each research assistant independently extracted data for their assigned studies. Data extracted included study characteristics (participants, design, setting, control group), intervention characteristics (hardware, software, intervention protocols), outcome domains (safety, feasibility, effectiveness), outcome measures used, and a summary of study findings.

Data Coding (Evidence Gap Map)

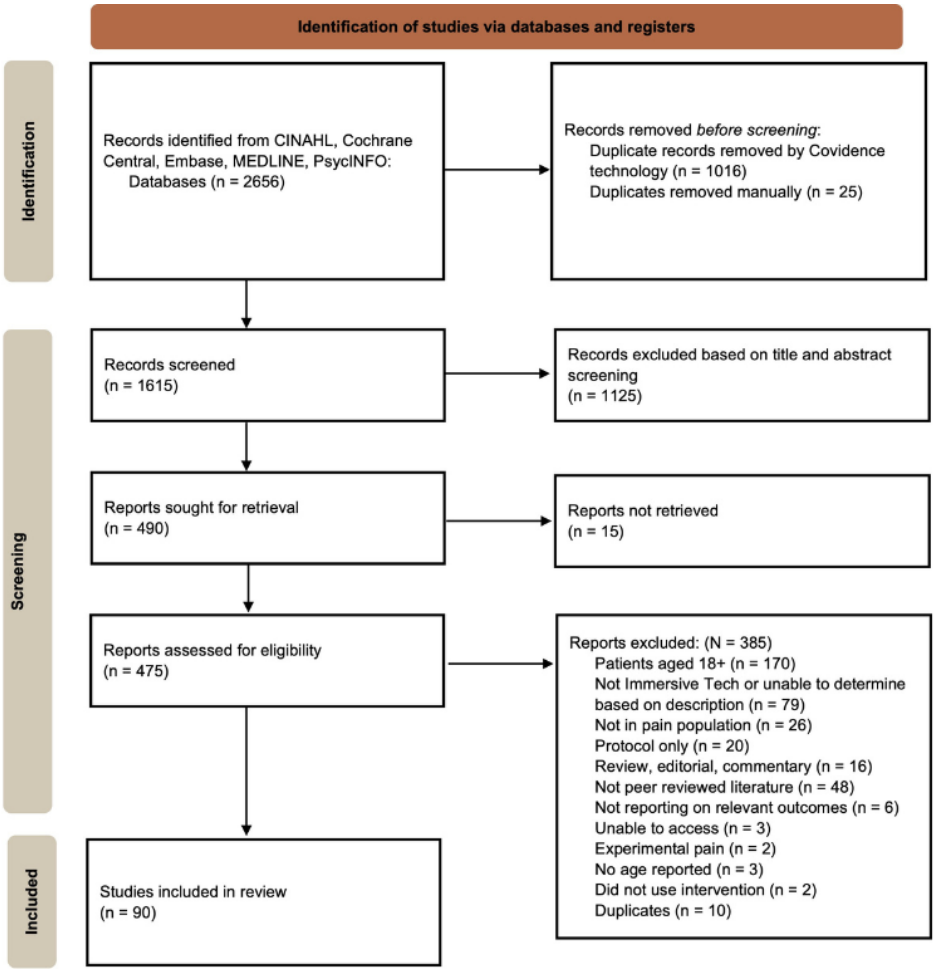
All included studies were uploaded to EPPI Reviewer, software designed for systematic reviews and in support of developing evidence and gap maps. Using existing literature, authors CWH and GM developed operational definitions for each of the pain populations and target outcomes, which were reviewed by the larger author group and iterated until a final draft was created

XSL•FO
RenderX

then used to guide coding of the studies. To code studies for the evidence and gap map, reviewers were assigned a series of studies in EPPI Reviewer and were asked to review the manuscript and code each article for the patient population (adult or pediatrics), pain population, and outcomes targeted by VR. Two training meetings were held with all reviewers to provide operational definitions, and they were asked to code a single article. A subsequent meeting was held to provide feedback and answer questions to increase consistency across coding. Once all articles were coded, any articles identified as unclear were reviewed again by a single author. Operational definitions are provided in Multimedia Appendix 2.

Data Synthesis

Included studies were summarized, and fulsome details of all included studies are provided in Multimedia Appendix 3. Additionally, descriptive statistics were used to synthesize study characteristics and aims as well as intervention characteristics. To synthesize data pertaining to outcome domains, an evidence and gap map was created. To create the evidence and gap map, 7 reviewers independently coded each study according to the study population including age (pediatric, adult) and pain type (acute pain-venipuncture, acute pain-wound care, acute pain-procedural, acute pain-other, chronic pain-cancer related, chronic pain-postsurgical/trauma, chronic pain-headache/migraine, chronic pain-musculoskeletal, chronic pain-neuropathic, chronic pain-other), as well as the pain-related outcomes targeted by the XR intervention (user experiences, participation/engagement, cognitive, behavioral, physical functioning, pain intensity, quality of life, health care utilization, safety, feasibility). Each study was also coded according to its established risk of bias (low, moderate, high). Coding was conducted through EPPI Reviewer [28], a collaborative web-based research synthesis software that supports study classification, and EPPI Mapper, a web-based program that generates evidence and gap maps based on coding conducted in EPPI Reviewer. Finally, for each of the identified pain treatment targets, the measures used to assess those targets were extracted by 2 authors and summarized to indicate the number of unique measures reported for each treatment target, and the number of studies that used the measure.



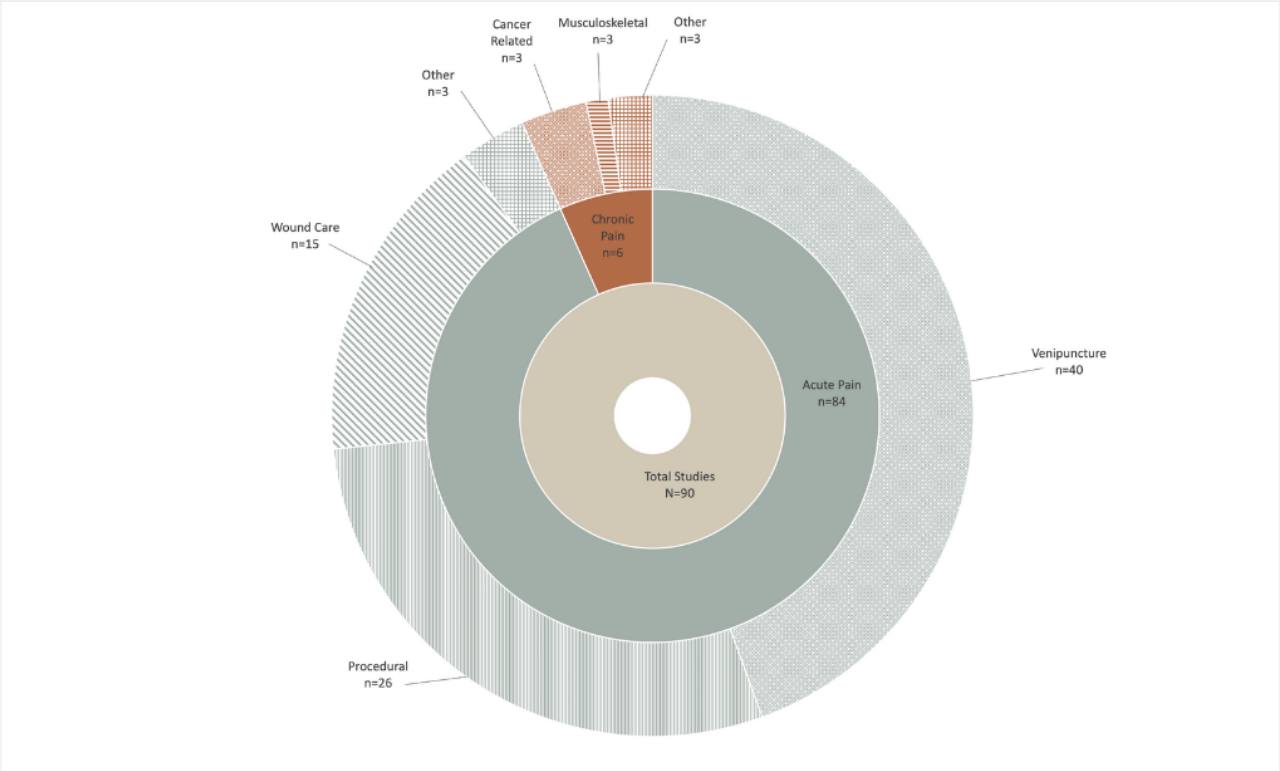
Results

Article Identification

The search identified 2656 articles across the 5 identified databases. Of the articles identified, 1041 duplicates were identified and removed prior to abstract and title screening. We screened 1615 articles for inclusion based on abstract and title, and 1125 were removed based on relevancy to the review. Of the remaining 490 studies, 15 could not be located, so 475 full-text articles were screened for inclusion. Of those, 90 studies were included in the review. The most common reason for exclusion was that the study sample was exclusively adult (170 studies) followed by determination that the XR technology was not immersive (79 studies). See Figure 1 for additional information related to the screening process.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Study Characteristics

Of the included articles, all 90 studies used VR technology, and no studies reported the use of AR technology. As such, when discussing XR for pediatric pain management, currently this is exclusively VR technology. Additionally, the majority of studies focused on assessment of VR in pediatric acute pain (84/90, 93%), specifically venipuncture (40/90, 48%) [29-68], burn dressing and wound care (15/90, 18%) [69-83], and minor procedures (26/90, 31%) [31,84-108], as well as other acute pain (3/90, 3%; ie, acute pain in emergency department, acute upper limb rehabilitation, vaso-occlusive crisis) [109-111]. A much smaller number of studies (n=6) examined the utility of VR in chronic pain populations including intensive pain rehabilitation (n=1) [112], chronic burn dressing (n=1) [113], chronic musculoskeletal pain (n=1) [114], chronic cancer-related pain (n=2) [115,116], and chronic abdominal pain (n=1) [117]. See Figure 2 for the summary of pain populations included across the studies. Within the 90 included studies, there were a total of 6596 participants enrolled, including 3615 enrolled in intervention arms and 2981 enrolled in control arms. Study sample sizes ranged from 5 to 254. Across studies, 3631 participants were male, while 2929 were female. The age of the participants ranged from 3 years to 18 years. Among participants enrolled in the intervention group, the mean age was 11.07 (SD 2.64) years, and in the control groups, the mean age was 10.38 (SD 2.37) years. Most studies (84/90, 93%) evaluated the use of XR in the context of pediatric acute pain management, while 7% (6/90) of the studies focused on XR in the context of pediatric chronic pain. Most studies took place in a hospital setting (63/90, 70%), and interventions were most often delivered by a researcher (36/90, 40%) or nurse (19/90, 21%). Regarding intervention design, an RCT was used 82% (74/90) of the time. See Table 1 for a full description of the study characteristics.

Study Quality Assessment

Where possible, studies were examined for risk of bias based on study design. Of the 90 studies, 74 studies were evaluated using the RoB-2 assessment for randomized trials and 15 studies were evaluated using the MINORS assessment for nonrandomized interventional and observational studies. We could not assess 1 study due to the study design (ie, case series: Birnie et al [34]). Results of the risk of bias assessment revealed that most included studies (67/90, 74%) had a moderate risk of bias, while 17 studies (17/90, 19%) had a high risk of bias, and 5 studies (5/90, 6%) were deemed to have a low risk of bias. To see the summary of risk of bias ratings for each study, please see Figure 3. Although sources indicating risk of bias were variable across studies, most included studies were identified as moderate or high risk of bias due to their failure to blind study participants to the intervention and researchers to who was in the intervention arm (69 studies). Increased risk of bias was also commonly identified in the randomization procedures, although to a much lesser degree (19 studies).

XSL•FO
RenderX

Figure 3. Risk of bias for included studies (N=89). MINORS: Methodological Index for Non-Randomized Studies; RoB-2: Cochrane Risk of Bias Tool.

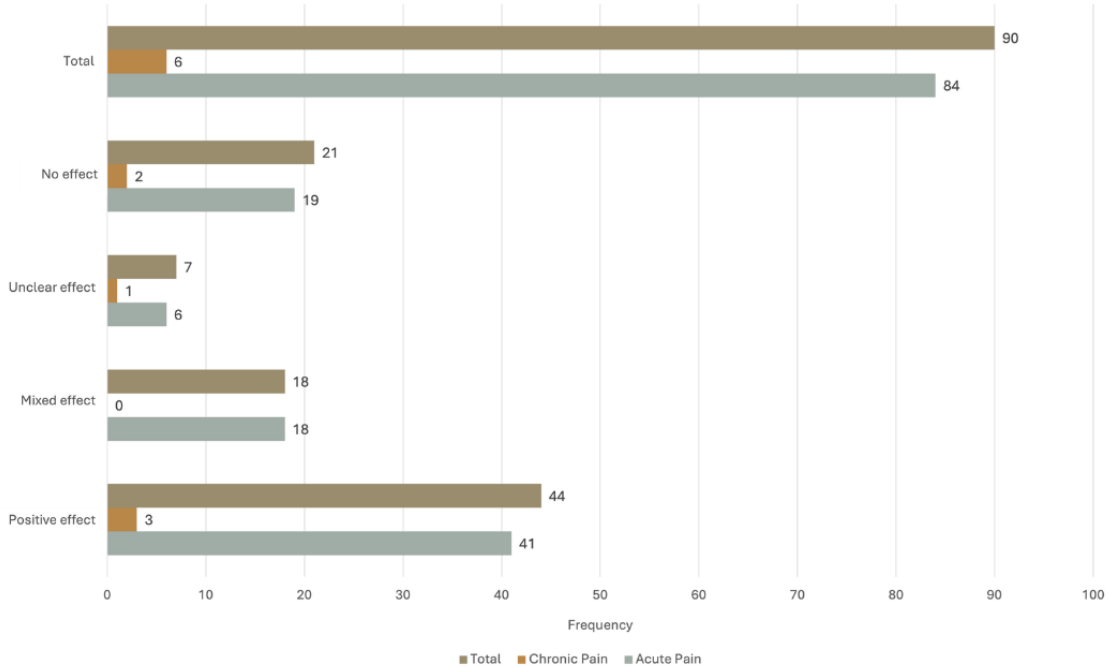
XR Feasibility

Across all included studies, feasibility was evaluated 43% (39/90) of the time. Within chronic pain studies, 50% (3/6) of the studies assessed the feasibility of VR. Although limited in scope, of the 3 studies that examined feasibility, results did indicate VR to be a positive experience that supported their management of pain. Within the acute pain studies (n=84), feasibility was assessed in 35 studies. When evaluated, feasibility of VR appears to be high according to patients, caregivers, and health care staff. Feasibility was assessed in several different ways including but not limited to recruitment and withdrawal rates, satisfaction surveys, patient-reported "fun," and provider-reported disruption in clinical flow. Recruitment rates varied but indicated moderate (40/65, 62%) to high (66/71, 93%) levels of interest in VR use, and dropout rates were reported to be low. Health care professionals also indicated good feasibility. VR was perceived to not interfere with procedure time, decrease the perceived difficulty of procedures, and be easily implementable in the clinic setting, and health care staff expressed interest in repeated use. Patients and caregivers reported ease of use, high levels of satisfaction with VR, preference for VR over alternate distraction methods, and interest in repeated use in future procedures. As such, although more consistent assessment of VR feasibility is needed, the available data from the pediatric acute pain management setting suggest that VR is acceptable and feasible across stakeholders.

XR Safety

Across included studies, safety, often measured through the presence of adverse events, was measured or reported 49% (44/90) of the time. Within the chronic pain studies, only 2 studies examined the safety of the VR intervention, so conclusions regarding the safety of VR for chronic pain populations cannot be made. Among the pediatric acute pain studies, 44 studies examined safety, limiting our ability to draw robust conclusions for safety. However, when safety or adverse events were reported, most studies (31/44, 70%) reported no adverse events or no differences between their control and VR intervention groups. When adverse events were reported, they were most often mild in nature and occurred in a minority of the participants. Rates of adverse events varied, occurring in <1% to 17% of participants, with intensity and severity of the concern low (eg, nausea rating of 4/100). Two studies reported that at least 1 participant withdrew from the intervention due to reported adverse events.

XR Effectiveness



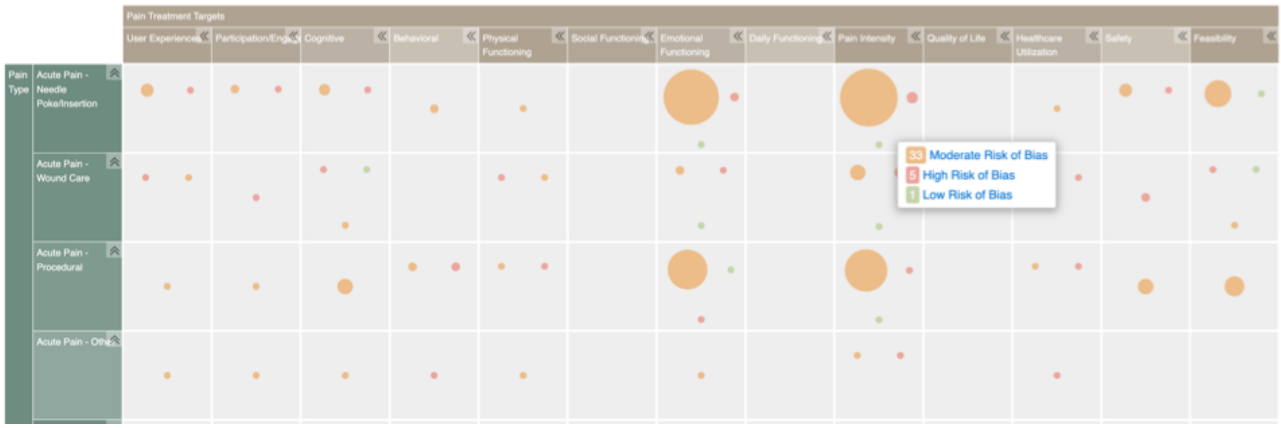
Several treatment targets emerged through the review as relevant to the effectiveness of VR for pain management. That is, targets of VR interventions for acute and chronic pain often went beyond pain intensity itself, as measures of effectiveness spanned several domains (eg, pain intensity, physical functioning, fear, anxiety). Given the wide variety of targeted outcomes, we summarized the findings across the identified target domains for acute and chronic pain. The variability in targets highlights several areas where additional research is needed to adequately examine the effectiveness of VR for pediatric pain.

Pain intensity was examined across all included studies (n=90), and overall, VR interventions demonstrated good effectiveness for reducing pain intensity (see Figure 4). Among the acute pain studies, 63% (53/84) demonstrated a positive effect (statistically significant reduction in pain) of VR on pain intensity, 21% (18/84) demonstrated no effect (nonsignificant reduction in pain or no change in pain), and 12% (10/84) demonstrated a mixed effect (different results across pain measures, pain reporter, or

XSL•FO
RenderX

at different time points in the intervention) on pain intensity. Mixed effect findings were often due to a variable impact of VR on pain across a procedure (eg, positive impact on postprocedural pain but no effect on pain during the procedure) or variable impact of VR on pain across informants (eg, child reported improved pain, no improvement in pain reported by health care provider). No studies reported worse pain than the control or following the VR intervention. Among the chronic pain studies, 100% (6/6) of the studies demonstrated improved pain intensity in the context of the VR intervention.

Figure 4. Effects of virtual reality on pain across pediatric acute and chronic pain.



Evidence and Gap Map

There was a wide range of outcome targets across studies. We created an evidence and gap map to collate current targets of VR in pain management as well as illuminate gaps (Figure 5). Guided by the conceptual model described by Trost et al [118], we categorized studies according to their target population as well as measured outcome targets. Additionally, the risk of bias results were integrated into the evidence and gap map. Therefore, the map illustrates, across the 90 included studies, the populations and pain targets with greater amounts of research evidence and those with missing or scant research evidence as well as the quality of evidence at various intersections (eg, pediatric venipuncture research targeting anxiety and pain intensity). Specifically, for XR research, the gap map illuminated significant gaps in research using XR to support pain management in pediatric chronic pain populations. Within the chronic pain populations, no research exists related to postsurgical or trauma-related pain, headaches, or neuropathic pain. Additionally, the risk of bias across all studies was moderate to high, prompting the need for more sophisticated research designs to reduce the risk of bias, particularly as it relates to blinding the research team and study participants. Within the acute pain setting, the most studied patient populations were children undergoing venipunctures and minor procedures. Primary targets of XR intervention for acute pain include pain intensity and emotional functioning. Across acute and chronic pain, measuring the effectiveness of XR on other important outcomes such as user experience, social functioning, and quality of life are important gaps that emerged from this review.

XSL•FO
RenderX

Figure 5. Snapshot of the evidence and gap map for virtual reality trials in pediatric acute and chronic pain [118]. The interactive evidence and gap map can be found in [119].

Measures in XR Research

Across all study outcomes (feasibility, safety, effectiveness targets), there was tremendous variability in the outcome measures used. As such, we identified the number of distinct measures and the frequency of measures used across each outcome, which are summarized in Table 2. Full details of the measures used within each outcome domain can be found in Multimedia Appendix 4. Measures in XR research include validated, study-specific, researcher-developed and researcher-adapted tools. Additionally, similar measures are often used in distinct ways to measure different outcomes. For example, some researchers used heart rate as a measure of physical functioning, while others used heart rate as a measure of anxiety. The outcome target with the highest number of measures was psychological constructs, which contained 31 distinct measures across 67 studies. This is unsurprising as psychological construct is a broad outcome inclusive of multiple psychological and emotional states including but not limited to anxiety, mood, fear of pain, and pain catastrophizing. The outcome target with the second highest number of measures was feasibility, which contained 14 distinct measures across 28 studies, followed by user experience, which contained 13 distinct measures across 18 studies. The number of measures used across studies for each outcome domain is summarized in Table 2. This review highlighted that there is little agreement regarding how best to measure outcomes in XR research, an important area for future study, particularly given the high number of researcher-developed or researcher-adapted measures currently being used.

Table 2. The number of measures used within each outcome domain across pediatric acute and chronic pain studies.

Outcome domain	Measures, n
Pain intensity	21
Adverse events	8
User experience	13
Psychological constructs	31
Pain interference	8
Feasibility	14

Discussion

Principal Findings

Overall, in the context of pediatric acute pain, specifically venipuncture and minor procedural pain, good evidence exists to support continued use of XR, as it is effective for the management of pain and emotional functioning and demonstrates good feasibility and safety. Limited evidence exists, however, to guide the use of XR research in chronic pain populations. Although initial evidence does appear promising for the utility of XR to support pain management in several chronic pain populations (eg, cancer-related pain, abdominal pain, diffuse musculoskeletal pain), more robust examination is needed as is research that assesses the safety and feasibility of implementing XR into the flow of clinical care. Another area requiring more research in pediatric populations is the subacute period (ie, up to 3 months after injury, trauma, or surgery). Research has demonstrated this period to be a vulnerable time for the development of fear avoidance related to pain and movement, which increases the risk for the transition of acute pain to chronic pain [8]. XR interventions would likely be useful during this period as both a form of distraction and to support confrontation of feared movements.

XSL•FO
RenderX

This review indicates that most studies to date have been implemented within the context of a children's hospital, which is unsurprising given the preponderance of research focused on acute pain management. However, there is limited research to guide the implementation of XR research outside the context of a hospital setting, which may be particularly important for chronic pain patients who may be receiving care across a variety of treatment settings (eg, home, outpatient clinic, physical therapy clinic). In the adult literature, XR has been successfully implemented into community care for chronic pain management [120,121]; however, this is unstudied in pediatric populations. The use of implementation science frameworks (eg, Consolidated Framework for Implementation Research) [122] to evaluate contextual and personnel differences as they relate to technology integration in settings outside of a hospital can support these efforts.

This review also demonstrated that research to date has been exclusively on the use of VR in pediatric pain management, and, as such, little is known about the potential for AR to support acute and chronic pain. Exploration of the utility of AR is particularly relevant in the context of chronic pain where exposure to painful movements may benefit from gradation such that a young person is first fully distracted by immersion into a VR world then gradually progressed toward exposure of their environment using an AR system to continue to support distraction while increasing exposure to their lived environment [123-125].

Another finding of this review is the significant variability in the way outcomes are being measured across XR studies. That is, measurement remains an area for needed consensus to support a better ability to compare effectiveness of XR across studies. Moreover, efforts are needed and indeed underway to better define both process (eg, immersion) [23] and outcome (eg, pain intensity) variables in XR trials, which will facilitate better reporting and thus improved ability to effectively compare XR across studies. Moreover, definitions of emotional functioning were also quite varied across studies, even when similar constructs were being targeted (ie, anxiety, fear, mood). Different definitions of anxiety and fear emerged across studies as well as how they were operationalized and assessed. For example, some studies assessed anxiety vis-à-vis heart rate variability and oxygen saturation, while other studies completed self-report assessments, proxy reports, and behavioral observations. Although all approaches to assessing anxiety may be valid, it limits the comparability of anxiety as an outcome across studies. Additionally, mood was examined to a much lesser degree in the reviewed studies and warrants increased attention, particularly in the context of chronic pain or acute-to-chronic pain transition. Another challenge with comparing XR effectiveness across studies is inconsistent reporting of study protocols. In this review, several studies were excluded because of an insufficient description of the XR technology. Creation of standards for reporting for XR studies, including how to describe the technology used (eg, hardware and software) and intervention protocol (eg, number of sessions, duration of intervention), is needed to increase the ability to replicate studies and compare outcomes across studies, thereby improving our ability to understand which XR approaches are most effective, when they are most effective, and for whom they are most effective.

There are also potential outcomes or targets of XR research that warrant attention, namely social and academic functioning alongside quality of life. Given the growing feasibility of real-time social interactions in the context of XR alongside established challenges for youth with pain to engage socially with peers [126], examination of the potential for XR research to improve or support social functioning is an important area for future work. Building from existing literature that has demonstrated the effectiveness of virtual peer-to-peer pain groups [127-130], development of virtual pain groups that can target multiple domains of functioning (eg, physical functioning, social functioning) is an untapped and potentially high-yield target for XR research. Similarly, academic functioning is commonly cited as a challenge for youth with chronic pain [131,132], and although research is emerging in this domain [133], more is needed to evaluate the potential for XR research to support academic engagement and facilitate a return to school learning for youth with pain. Finally, quality of life was minimally examined in the included studies (n=2). This is likely due to the overwhelming number of studies focused on acute pain where quality of life measures may be less relevant; however, development of quality of care measures or consideration for implementation of quality of care measures that are relevant to the acute pain context may be important to truly capture the impact of XR on patients. Moreover, as additional research is conducted in the chronic pain population, where pain and anxiety may become less of an emphasis, quality of life measures will be important markers of improvement.

Finally, decreasing the risk of bias in XR studies also emerged as an important priority for future research. That is, most studies had a moderate to high risk of bias according to the RoB-2 assessment, prompting the need for more sophisticated research designs. Specific areas where innovation is needed are addressing participant blinding to the intervention and the development of prespecified analysis plans. Given the nature of XR interventions, innovation for blinding participants to their assigned group, such as the development and use of sham XR software, is needed to decrease the risk of bias. Prepublished analysis plans and transparency surrounding blinding of the analyses are also needed.

Limitations

This systematic review has some limitations that are important to note. First, the search for this systematic review was completed in March 2023 and likely omits several manuscripts published since then. Given the rapidity of XR research in pediatrics, it was not feasible for this research group to keep pace with the rate of publication. Moreover, this review was conducted with the aim of supporting the consensus conference surrounding outcomes for pediatric XR research. Future updates to this review are needed to support ongoing identification of gaps in research and inform clinical practice. Additionally, although a strength of this review is the breadth of studies included, future research could be conducted to allow for more focused assessment of efficacy, particularly as it relates to specific patient populations and XR configurations. To this end,

XSL•FO
RenderX

future research should consider the interaction of XR interventions and child development to assess whether developmental stage or chronological age impact XR feasibility, safety, or effectiveness and guide precision medicine to match the XR intervention or configuration to best meet the needs of youth across diverse developmental stages. This review assessed the risk of bias for all included studies; however, this is not synonymous with quality and should be interpreted with caution. That is, studies may have been of high quality yet received high risk of bias scores due to their lack of blinding, a common challenge faced by XR researchers. Finally, studies were limited to the English language and excluded gray literature and conference papers, which may limit the inclusion of important research published in languages other than English and could reinforce publication bias such that studies in which XR was unhelpful or not feasible are not well represented.

Conclusion

This systematic review provides an important update regarding the state of XR research for pediatric acute and chronic pain. Review of XR feasibility, safety, and effectiveness solidified the significant potential of XR for pain management across a variety of pain presentations and for a range of diverse outcomes. Moreover, the developed evidence and gap map illuminated important gaps in the current research base that warrant attention. Finally, limitations identified in the research studies reviewed also highlight the need for innovative research designs, establishment of measurement consensus, and improved reporting standards for XR studies to more effectively establish best practices in XR intervention research and improve clinical translation of the evidence base.

Acknowledgments

The authors thank medical librarian Jessie Cunningham at The Hospital for Sick Children for their assistance with development and execution of the literature search strategy. The authors would also like to thank all the research coordinators and research assistants in the Biobehavioral Pediatric Pain Lab (principal investigator [PI]: LES), Nicole Jehl, Ellison Choate, Amanda VanOrden, Hannah Nguyen, and Yerin Yang for your support in extracting data and formatting Table 1. Thank you also to the research coordinator and summer students in the Improving Outcomes in Child Health (iOUCH) lab (PI: JNS), Prabdeep Panesar, Ariane Isaac-Bertrand, and Sandy Luu, for your support in extracting data.

The authors recognize the funding from Canadian Institutes of Health Research (CIHR) for the planning and dissemination grant (Co-PIs: JNS and Fahad Alam) and MayDay fund (PI: DL). Additionally, BNR conducted this work during her postdoctoral fellowship at The Hospital for Sick Children and was funded by a CIHR Banting Fellowship. Across the duration of this study, authors CWH and LES were funded by the National Institutes of Health under NIAMS R21 grant AR079140. Author GM is funded by a CIHR Canada Graduate Scholarship (Doctoral) and SickKids Clinician Scientist Training Program (CSTP) scholarship.

Authors declare that there was no use of GenAI in the production of the described research, analysis or interpretation of data, or in the writing of the submitted manuscript.

Data Availability

All data from the systematic review are available upon request from primary or senior authors.

Authors' Contributions

JNS, LES, DL, and JIG were involved in the conceptualization of the study, funding acquisition, and supervision as well as data analysis and review and editing of the drafted manuscript. CWH, BNR, and GM were involved in the conceptualization of the study, data curation, formal analysis, data visualization, and writing of the manuscript. CO was involved in the data curation and offered her expertise as a person with lived experience. EC was responsible for project administration and data visualization. All authors made substantial contributions to the study and provided approval of the submitted manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Children's screen time has substantially increased worldwide, including in Bangladesh, especially since the pandemic, which is raising concern about its potential adverse effects on their physical, mental, and social health. Parental supervision may play a crucial role in mitigating these negative impacts. However, there is a lack of empirical evidence assessing the relationship between parental screen time supervision and health outcomes among school children in Dhaka, Bangladesh.

Objective: We aimed to explore the association between supervised and unsupervised screen time on the physical, mental, and social health of school-going children in Dhaka, Bangladesh.

Methods: We conducted a cross-sectional descriptive study between July 2022 and June 2024. A total of 420 children, aged 6 - 14 years, were enrolled via the stratified random sampling method across three English medium and three Bangla medium schools in Dhaka. Data were collected through a semistructured questionnaire; anthropometry measurements; and the Bangla-validated Strength and Difficulties Questionnaire (SDQ), Pittsburgh Sleep Quality Index (PSQI) Scale, and Spencer Children Anxiety Scale (SCAS).

Results: A total of 234 out of 420 students (56%) used digital screen devices without parental supervision. We did not find a substantial difference in the duration of the daily mean use of digital devices among the supervised students (4.5 hours, SD 2.2 hours) and the unsupervised students (4.6 hours, SD 2.4 hours). According to the type of school, English medium school children had a mean higher screen time (5.46 hours, SD 2.32 hours) compared to Bangla medium school children (3.67 hours, SD 2.00 hours). Headache was significantly higher among the unsupervised digital screen users compared to those who used digital screens with parental supervision (175/336 students, 52.1% versus 161/336 students, 47.9%; P<.003). Moreover, students who used digital screens without parental supervision had poor quality of sleep. Behavioral problems such as conduct issues (119/420 students, 28.3%) and peer difficulties (121/420 students, 28.8%) were observed among the participants. However, when comparing supervised and unsupervised students, we found no statistically significant differences in the prevalence of these issues.

Conclusions: The findings of the study showed that the lack of screen time supervision is associated with negative health effects in children. The roles of various stakeholders, including schools, parents, policy makers, and students themselves, are crucial in developing effective guidelines for managing screen use among students. Further research is needed to demonstrate causal mechanisms; identify the best interventions; and determine the role of mediators and moderators in households, surroundings, and schools.

Introduction

To what extent can parental supervision mitigate the effects of excessive digital screens in school-going adolescents? This is becoming an increasingly common concern of parents and researchers, as digital screens fill our living spaces and take up our quality time. A recent study showed that daily screen time for users aged 16 - 64 years has increased to 6 hours 37 minutes worldwide [1]. Across age groups, 44% of all waking hours are spent on screens [1]. In 2020, the World Health Organization released a milestone report with detailed guidelines on sedentary behavior including screen time for children under the age of 5 years, defining screen time as time spent passively watching screen-based entertainment (TV, computer, or mobile devices) [2]. The American Academy of Child and Adolescent Psychiatry agreed with the findings, recommending less than 2 hours of daily screen time for children aged under 5 years, but for children aged 6 years and older, recommending "healthy habits" and to "limit activities that include screens" [3]. At present, no concrete guidelines have been presented for adolescents, although health concerns are just as pressing for them [4].

Higher sedentary behavior such as screen time is associated with a range of physical and mental health issues, including headaches, myopia, obesity, sleep disorders, behavioral disorders, and anxiety [4-8]. A study of 5844 children around the world found that children averaged 8.6 hours of daily sedentary time, associated with poor weight status and physical inactivity [9]. Lauricella and Cingel [10] found one of the most reliable predictors of higher screen time among adolescents to be parental media use, along with weaker associations with parental attitudes to technology and screen time rules.

In Asia, higher incomes and a rising middle class have led to longer exposure to screen time (>2 h a day) for children and adolescents [11,12]. Without parental intervention, excessive screen time exposure has been associated with less sleep duration among Asian preschoolers, but Lin et al [13] found parental education and awareness, among best practices, to be an effective intervention against these effects.

Bangladesh's rising socioeconomic status has contributed to an explosion in digital device access and usage across demographics [14]. Khan and Burton [15] found that almost 80% of Bangladeshi adolescents have high recreational screen time, reported at 4.0 (SD 2.2) hours per day on average, with the mean values of 4.3 (SD 2.4) hours for boys and 3.6 (SD 2.3) hours for girls. High screen time was associated with sleep disturbance and higher family income, among other factors [15]. Anjum et al [16] found a higher incidence of depressive symptoms in adolescents with higher screen time exposure (>2 h per day), alongside other physical and mental health concerns including sleep disturbance and mood disorders prior to the COVID-19 pandemic.

During the COVID-19 lockdown, Bangladeshi children began to spend much more time on the internet, for entertainment, communication, and education [17-19]. Koly and colleagues [20] noted worsening psycho-social health of school-going students in this period, associated with quarantine adaptations and difficulties with online learning. Simultaneously, Rashid and colleagues [21] found physical and mental health deterioration among secondary school students, with symptoms including headaches, backaches, visual and sleep disturbance, and depression. During the pandemic, online learning became a necessity, leading to a significant increase in children's digital screen use. While it ensured educational continuity, this shift also contributed to extended screen time, potentially indicating the physical, mental, and emotional health risks associated with excessive screen exposure [4,22].

Following the pandemic, increased digital screen time did not lessen, leading to significant adverse consequences on adolescent health [23,24]. For instance, Shuvo and Biswas [25] note that when electronic device exposure overlaps with eating times and habits, there is an increased likelihood of obesity. Meanwhile, heavier reliance on technology for education, entertainment, and socialization after COVID is associated with increased anxiety, difficulty sleeping, addiction, and various sociobehavioral difficulties [23,24,26].

In Bangladesh, there is a dearth of comprehensive academic research on the effects of screen time on adolescents, despite the fact that there is a substantial amount of empirical evidence around the world [4,22,27-34]. Furthermore, as the results are utilized to create thorough screen-use guidelines, these studies have significant policy ramifications. Furthermore, while parental supervision is crucial in preventing excessive screen time, researchers found that inappropriate methods to discipline children and adolescents may increase long-term screen use and exaggerate other adverse psychosocial effects [24,35]. Therefore, this study aimed to distinguish between the effects of supervised and unsupervised screen time on the physical, mental, and social health of Bangladeshi schoolchildren.

Methods

Study Setting, Participants, and Sampling

This was a cross-sectional descriptive study and adopted a quantitative approach. The survey was conducted between July 2022 to June 2024. We purposively selected 6 schools from the list of all schools in Dhaka North and South city corporations to ensure the equal distribution of the Bangla and English medium schools. Moreover, we considered the socioeconomic, geographic, and feasibility of data collection. During the school selection, with the approval of the school authorities, we considered children aged between 6 to 14 years who were in class 2 to class 8 and who had more than 2 hours of screen time each day as the qualifying criteria for sample inclusion. Smartphones, tablets, laptops, personal computers, gaming consoles, televisions, and portable gaming devices were among the acceptable gadgets. Children with preexisting conditions, such as physical or psychological impairment, were excluded from the study, as this might have influenced the results. We used a stratified random sampling method to recruit a total of 420 students, by including 70 students from each school (ie, 10 students from each grade from grades 2 to 8).

Data Collection Procedure

We collected data through face-to-face interviews with parents and students on school grounds. The day prior to the interview,

XSL•FO
RenderX

study staff scheduled the appointment time with parents, and the class teacher brought the students during the lunch break. A half-hour interview period was allotted for students and an hour for parents. To check for differences in accuracy between staff and trainers (ie, psychologists who trained all the staff on each of the psychometric tools used in this study), 30 pilot tests were performed prior to the start of data collection. Interrater reliability was measured using the Cohen kappa coefficient to quantify the level of agreement between each of the three staff and trainers (n=30 nonstudy participants/staff) for all the Bangla-validated scales. On average, the calculated Cohen kappa values ranged between 0.84 and 0.89 (scores for 30 nonstudy participants/staff-trainer pairs), indicating strong agreement among the staff.

All data collection forms were checked at the field site for completeness, accuracy, and consistency. The quality control team was responsible for regular observations at school, and identical forms and tools were used across the duration of the study. Investigators personally traveled to the sites weekly to ensure proper field implementation.

Study Instruments

Screen Time

A semistructured questionnaire was developed to collect information about screen time from both parents and students. The parents' questionnaires included socioeconomic factors, pattern and quantity of child screen time usage, gadget-using behavior of the children, and parents' mediating role in screen time exposure (supervised vs unsupervised). The student's questionnaire included the type of device use, time and pattern of use, and purpose of device use. Screen time was considered to be any time spent engaging with content in front of a digital device with an electronic screen, including but not limited to iPads, gaming consoles, laptops, smartphones, tablets, and desktop devices. Students were categorized into supervised versus unsupervised based on the self-reporting information regarding the supervision. In this study, supervised screen time is defined as when parents are aware of their child's digital device usage, including what they are doing, how much time they spend, and the type of content they consume. In contrast, unsupervised screen time occurs when parents lack awareness of their child's activities, duration of use, and the content they engage with on digital devices. Similar definitions have been used in other studies [36,37].

Physical Health

Anthropometric measurements (weight and height) were collected from students on school premises during data collection. Measurements were calibrated daily before data collection to ensure standardization. The BMI (kg/m^2) was calculated and converted to z-scores, then categorized according to cut-off points given by the World Health Organization BMI-for-age growth chart for ages 5 to 19 years: underweight (<15 kg/m^2, −1 SD), normal weight (15 - 25 kg/m^2), overweight (25 - 30 kg/m^2, +1 SD), obese (30 - 40 kg/m^2, +2 SD), and morbidly obese (>40 kg/m^2, +4 SD) [38]. Additional physical health issues, such as blurred vision, headaches, indigestion, backache, and neck pain, were also asked of the students via a questionnaire. The students' physical health responses were initially categorized into four groups: "No," "Sometimes," "Often," and "Most of the time." These categories were then consolidated into two broader groups: "No" and "Yes," with "Yes" encompassing the responses "Sometimes," "Often," and "Most of the time."

Mental and Social Health

Age-appropriate Bangla-validated versions of the following scales were used to find well-being indicators for children's mental and social health.

Strength and Difficulties Questionnaire

This is a behavioral questionnaire (25 questions) designed to identify a combination of positive and negative attributes across 5 dimensions–emotional symptoms, conduct problems, hyperactivity or attention deficit, peer relationship problems, and prosocial behavior. The sum of the scores of the four negative behavior subscales represents the children's general difficult behavior with a maximum score of 40, whereas the maximum score for prosocial behavior is 10. Gustin and colleagues have verified the Strength and Difficulties Questionnaire (SDQ) against independent clinical diagnoses of Bangladeshi children [39,40].

Spencer Children Anxiety Scale

This scale is used to evaluate symptoms relating to separation anxiety, social phobia, obsessive-compulsive disorder, panic, agoraphobia, generalized anxiety, and fear of injury. Goodman et al have validated the Spencer Children Anxiety Scale (SCAS) as a reliable instrument for Bangla-speaking communities [41].

Pittsburgh Sleep Quality Index

This questionnaire has components spanning several subcategories such as subjective sleep quality, latency, duration, habitual efficiency, disturbances, sleeping medication, and daytime dysfunction. Mamun et al [42] have successfully used the Pittsburgh Sleep Quality Index (PSQI) to identify sleep-related concerns among Bangladeshi students.

Statistical Analysis

Data were entered via IBM SPSS version 20.0 (IBM Corp) and analyzed on Stata version 15.1 (StataCorp LLC). Categorical data were represented as frequency numbers and percentages, while continuous data with reasonably normal distributions were summarized as means and SDs. Nonnormal continuous data were instead summarized as medians and IQRs. Participants were categorized into two main subgroups, supervised and unsupervised. Subsequently, a comparative analysis was performed across various factors, including demographic characteristics, amount of screen time, and health metrics. To assess differences across groups, the chi-squared test for independence was employed for categorical data, and the 2-tailed unpaired *t* test for differences between proportions was used for continuous data with nearly normal distributions. A significance threshold of $P<.05$ was used to assess statistical significance.

Ethical Considerations

This study was approved by the Institutional Review Board of icddr,b (protocol number: PR-22002). Written informed consent was obtained from all parents, and confidentiality and anonymity were maintained throughout the study. Children aged above 11 years provided assent in addition to their parents' consent. All the respondents were informed in Bengali about their rights related to their voluntary participation in the study as well as their right to withdraw from the interview at any time during the interview.

Results

A total of 420 students were enrolled based on the screening criteria. Of them, 186 (44%) children were supervised and 234 (56%) children were unsupervised. Table 1 represents the demographic summary statistics of the population. The students were between 6 and 14 years, with a mean age of 10.9 (SD 1.9) years; 207 out of the 420 children (49.3%) were girls. Of the 420 children, 292 (69.5%) belonged to single-family households. In families with 1 - 2 children, 161 out of 288 children (55.9%) were unsupervised, while for families with more than 3 children, 73 out of 132 children (55.3%) were unsupervised.

Table . Demographic and socioeconomic information of study participants.

Characteristics	Overall (N=420)	Supervised (n=186)	Unsupervised (n=234)
Child's age (years)			
Mean (SD)	10.9 (1.9)	11.0 (1.9)	10.8 (1.9)
Child's sex, n (%)			
Male	213 (50.7)	101 (47.4)	112 (52.6)
Female	207 (49.3)	85 (41.1)	122 (58.9)
Family type, n (%)			
Single	292 (69.5)	132 (45.2)	160 (54.8)
Joint	128 (30.5)	54 (42.2)	74 (57.8)
Number of children in the family, n (%)			
1 - 2	288 (68.6)	127 (44.1)	161 (55.9)
≥3	132 (31.4)	59 (44.7)	73 (55.3)
Average monthly income, n (%)			
<BDT[a] 50,000 (<US$ 420)	137 (32.6)	57 (41.6)	80 (58.4)
BDT 50,000 - 100,000 (>US$ 420 to <US$ 840)	144 (34.3)	63 (43.8)	81 (56.2)
>BDT 100,000 (>US$ 840)	139 (33.1)	66 (47.5)	73 (52.5)

[a]BDT: Bangladeshi taka.

The mean total daily screen time for the entire population was 4.6 (SD 2.3) hours. The large SD relative to the mean indicates widely varying screen habits among the study population. The range of screen time for the unsupervised group was 0.3 - 15 hours and that for the supervised group was 0 - 12 hours. The mean total daily screen time for the unsupervised group was 4.6 (SD 2.4) hours, slightly higher than the supervised group's mean of 4.5 (SD 2.2) hours. These large deviations imply factors other than supervision contribute more to total screen time.

Multimedia Appendix 1 shows the mean daily screen time spent by children categorized by age, sex, and type of school. No significant difference was observed in the mean daily screen time between different age groups (6 - 10 years vs 11 - 14 years) or between male and female participants. However, children attending English medium schools had a significantly higher average daily screen time (5.4 hours) compared to those attending Bangla medium schools (3.6 hours).

Table 2 shows the prevalence of physical symptoms among students with supervised and unsupervised use of digital devices. Overall, out of 420 students, 391 (93.1%) students experienced blurred vision, 341 (81.2%) reported abdominal pain, 336 (80%) had headaches, and 327 (77.9%) experienced dry eyes or soreness. Considering all the health issues, a higher proportion of unsupervised students experienced these problems compared to supervised students. Headaches were significantly more prevalent among the unsupervised group (175/336 children, 52.1%) than the supervised group (161/336 children, 47.9%; P<.003). All the data are shown in Table 2.

XSL•FO
RenderX

Table . Prevalence of physical symptoms among study participants with supervised and unsupervised use of digital screens and devices.

Physical symptoms	Frequency (N=420), n (%)	Supervised (n=186), n (%)	Unsupervised (n=234), n (%)	*P* value
Eye problems	150 (35.7)	64 (42.7)	86 (57.3)	.62
Dry eye or soreness	327 (77.9)	150 (45.9)	177 (54.1)	.22
Blurred vision	391 (93.1)	177 (45.3)	214 (54.7)	.14
Hearing difficulty	14 (3.3)	6 (42.9)	8 (57.1)	.91
Indigestion or gas	276 (65.7)	118 (42.8)	158 (57.2)	.38
Headache	336 (80.0)	161 (47.9)	175 (52.1)	.003
Neck pain	192 (45.7)	86 (44.8)	106 (55.2)	.85
Abdominal pain	341 (81.2)	150 (44.0)	191 (56.0)	.80
Back or any other musculoskeletal problem	134 (31.9)	63 (47.0)	71 (53.0)	.44
Diabetes	4 (1.0)	0 (0.0)	4 (100.0)	.07
Change in appetite	204 (48.6)	86 (42.2)	118 (57.8)	.39
Sleep issues	82 (19.5)	32 (39.0)	50 (61.0)	.29

Table 3 shows a mean BMI of 19.3 (SD 4.7) kg/m^2 for the study population. There was a slight difference in the mean BMI between the supervised (mean 19.6 kg/m^2, SD 4.9 kg/m^2) and unsupervised (mean 19.1 kg/m^2, SD 4.4 kg/m^2) groups (*P*=.26 indicates statistical insignificance). Overall, out of 420 children, 335 (80.1%) children were healthy, 21 (5%) were underweight, and 42 (10.1%) were overweight/obese. No statistically significant differences were observed in the distribution of BMI between the supervised and unsupervised categories.

Table . Association of BMI with supervised and unsupervised digital screen use.

Characteristics	Overall (N=420)	Supervised (n=186)	Unsupervised (n=234)	*P* value
BMI, kg/m^2				.26
Mean (SD)	19.3 (4.7)	19.6 (4.9)	19.1 (4.4)	
BMI category, n (%)				.50
Underweight	21 (5.0)	9 (42.9)	12 (57.1)	
Healthy weight	335 (80.1)	143 (42.7)	192 (57.3)	
Overweight	42 (10.1)	21 (50.0)	21 (50.0)	
Obesity	16 (3.8)	9 (56.2)	7 (43.8)	
Severe obesity	4 (1.0)	3 (75.0)	1 (25.0)	

Table 4 shows the association of anxiety with supervised and unsupervised digital screen use. Out of 420 children, 414 (98.6%) children were identified within the normal range. Just 1 of the 6 children fell into the high anxiety range; only 1 was left unsupervised and the other 5 were in the supervised group. Despite the fact that there was a significant difference (*P*<.05), the small number of individuals in this group could provide an inaccurate correlation. It is recommended to conduct additional research before drawing any conclusions. There were no discernible variations between the supervised and unsupervised proportions for any specific anxiety subcategory on the SCAS.

Multimedia Appendix 2 shows the results of the SDQ scale in the 420 students; of the 420 students, 119 students (28.3%) had conduct problems, 121 students (28.8%) had peer problems, 66 students (15.7%) reported emotional problems, 73 students (17.4%) experienced hyperactivity, and 28 students (6.7%) reported prosocial behaviors. Based on the borderline/abnormal results shown in Multimedia Appendix 2, Table 5 was prepared, and it shows the distribution of supervised and unsupervised children categorized as having borderline/abnormal results for digital screen use based on the SDQ subcategories (emotional symptoms, conduct problems, hyperactivity or attention deficit, peer relationship problems, and prosocial behavior).

The percentage of unsupervised children was greater than that of supervised children among those classified as having borderline or abnormal results. The most common abnormality was peer relationship problems among the children. Of the 420 students, 121 (28.8%) had peer relationship problems: 55 students (45.38%) were supervised and 66 students (55.6%) were unsupervised. Less borderline/abnormal results were found considering prosocial behavior. Of the 420 students, 28 (6.7%) were identified with abnormal/borderline results: 11 (39.29%) were supervised and 17 (60.71%) were unsupervised.

XSL•FO
RenderX

Table . Association of anxiety with supervised and unsupervised digital screen use by using the Spencer Children Anxiety Scale (SCAS).

SCAS	Overall (N=420), n (%)	Supervised (n=186), n (%)	Unsupervised (n=234), n (%)	*P* value
Overall				.05
Normal range	414 (98.6)	181 (43.7)	233 (56.3)	
Elevated range	6 (1.4)	5 (83.3)	1 (16.7)	

Table . Distribution of supervised and unsupervised children categorized as borderline/abnormal for digital screen use based on the Strength and Difficulties Questionnaire subcategories (emotional symptoms, conduct problems, hyperactivity, peer relationship problems, and prosocial behavior).

Category	Supervised (%)	Unsupervised (%)
Emotional symptoms	43.94	56.66
Conduct problems	45.38	54.62
Hyperactivity	47.95	52.05
Peer relationship problems	45.45	54.55
Prosocial behavior	39.29	60.71

Table 6 shows that a majority of children reported good quality of sleep on the PSQI (358/420, 85.2%). Of those who reported bad sleep, the proportions were similar between supervised and unsupervised children (14% of supervised children vs 15.4% of unsupervised children). Nonetheless, a potentially significant result was found on comparing the mean total sleeping durations: supervised children sleep on average for 7.7 (SD 1.5) hours, compared to 7.4 (SD 1.6) hours for unsupervised children (against an overall mean of 7.6, SD 1.6). However, the *P* value showed borderline significance; furthermore, if the children were subcategorized by the average hours of sleep (>7, 6 - 7, 5 - 6, and <5 hours), no significant difference was found across any subgroup between supervised and unsupervised children.

Discussion

Principal Results and Comparison With Prior Works

This study enrolled a total of 420 children, with 186 (44%) supervised and 234 (56%) unsupervised children. Unsupervised children had a slightly higher mean screen time of 4.6 (SD 2.4) hours compared to supervised children who had a mean screen time of 4.5 (SD 2.2) hours. Additionally, the study found a higher prevalence of physical symptoms and slightly different BMI distributions among unsupervised children. No significant differences in sleep quality were observed between supervised and unsupervised children, although supervised children slept slightly longer. A greater percentage of unsupervised children were categorized as having borderline or abnormal findings based on the SDQ subcategories (emotional symptoms, conduct problems, hyperactivity or attention deficit, peer relationship problems, and prosocial behavior).

Significant variations depending on the type of education were found in this study, which examined key facets of the role of parental supervision in digital screen use among students in Dhaka city. Although teenagers attending school spent a mean of 4.6 (SD 2.3) hours a day on screens, there was no discernible difference in the amount of time spent on screens between students who were under supervision and those who were not. Nevertheless, when stratified by the type of education, students in Bengali medium schools had screen time of 3.67 hours, while students in English medium schools showed considerably higher screen time (5.46 hours). This discrepancy could have several causes. In Bangladesh, English medium students often come from higher-income households that can afford the higher costs of English medium education, making them more likely to have access to personal digital devices. A similar indication was provided in an article published by The Daily Star [43]. Additionally, English medium students are typically Ordinary level (O level) or Advanced Level (A level) candidates, an internationally recognized qualification that is considered to be the equivalent of Cambridge IGCSE and UK General Certificate of Secondary Education; the preparation for these international-standard examinations necessitates greater screen exposure as part of their learning process [44]. Despite the differences in total screen time, the study did not find any correlations between parental education or income level and screen time supervision. Another study also showed the same findings that no significant association was observed between parental education or income level and screen time supervision [45].

Such trends are concerning given the established negative effects of excessive screen time on adolescent health, including obesity, diabetes, poor sleep, and increased risks of depression and anxiety [5-9]. Effective parental supervision is known to reduce screen time and mitigate these adverse effects. Parent-child interaction improved prosocial behavior and reduced psychosocial difficulties while contributing to healthier body mass indices and better sleep [11]. Furthermore, the findings of this study align with the results from previous studies [7, 9]. The empirical evidence found that parental mediation and active participation are associated with improved physical health outcomes, including BMI and sleep duration [7,9]. School-going participants in this study also reported a range of health concerns, with blurred vision, abdominal pain, headaches, dry or sore eyes, and indigestion being the most commonly noted. Such impacts are also reported by several previous studies [46-48]. A notable difference was observed between supervised and unsupervised groups specifically for headaches, with a higher proportion of unsupervised students reporting this issue. A previous study also reported that unsupervised children are more vulnerable to associated health issues [49]. Although supervision did not significantly impact other physical indicators, the findings suggested a potential association with blurred vision and diabetes. However, the small number of patients with diabetes limits the interpretability of these findings. Therefore, further research is needed to explore the effects of different supervision methods on these health concerns and to identify any potential correlations.

In contrast, the statistical significance indicates that factors other than supervision, such as lifestyle, might have a greater impact on other physical issues. For instance, a sizable percentage (28.3%) of kids showed conduct and peer relationship problems when they had results in the borderline or abnormal range on the SDQ. Despite these findings, no significant differences were observed between supervised and unsupervised groups across the SDQ subcategories, suggesting that these behavioral issues may be influenced by factors beyond supervision, including lifestyle and home or school conditions.

Furthermore, we identified a concern that supervision might exacerbate anxiety. This is because, among the 6 children who reported overall anxiety, only 1 was unsupervised. Although the result is statistically significant, this finding should be interpreted with caution due to the small sample size. Collectively, these observations highlight a significant deficiency in effective parental guidance and supervision methods among contemporary urban families in Dhaka. Therefore, further research is needed to explore the specific supervision strategies employed by parents and their impact, with the aim of developing guidelines for healthy technology use.

Finally, we explored a potential correlation between parental supervision of digital screen use and the mean total bedtime based on PSQI data, with the supervised group having slightly more sleep on average compared to their counterpart. However,

XSL•FO
RenderX

when analyzing total sleep duration and examining differences related to supervision across various subgroups, the significance diminished, indicating that the observed differences were not conclusive. Specifically, the proportions of children who slept more than 7 hours were similar between the supervised and unsupervised groups, and these proportions did not differ meaningfully from the overall study sample. Given these borderline findings, further investigation is warranted to explore the potential associations between supervision and sleep patterns.

Limitations

This study has several limitations. First, inconsistencies emerged between the parents' and children's reports, as many parents used a broad definition of "supervised," such as occasional checks or limited awareness of the child's activities on the device. As the children's reports were found to be more reliable predictors, final supervision categorization was based on the children's statements. A similar approach has been followed previously [44]. Second, the study's scope was limited to 6 schools (3 Bangla and 3 English medium schools), which may not be representative of the broader variation between urban and rural settings or differing school resources. Third, data on technological interactions and parental mediation were collected via face-to-face interviews, which may have introduced recall bias. Finally, discrepancies between parent and child reports could not be independently verified. Future research should include diverse populations and settings to provide a more comprehensive understanding of screen time impacts.

Strengths

Despite these limitations, the strength of this study lies in its pioneering exploration of the association of parental supervision with the physical, mental, and social well-being of students in Bangladesh. Additionally, by including students from both Bangla and English medium schools, the study provides valuable comparative insights. The findings are expected to motivate and inform parents, policy makers, and educational authorities, highlighting the need for enhanced supervision and education to promote healthier and more balanced lifestyles for students. Further research is required that may explore causal relationships through experimental or longitudinal designs.

Conclusions

The results of this study enhance our understanding of how to mitigate the negative impacts of unsupervised screen time on students' well-being. Effective guidelines for managing screen use require the involvement of multiple stakeholders: schools, parents, policy makers, and the students themselves. Schools can play a crucial role in educating students about safe screen use and enforcing balanced screen time through workshops and seminars. Parents need to be informed about the risks of excessive screen time and the benefits of active supervision, adopting strategies to enhance their children's well-being. Additionally, accessible mental health services, including counseling and support groups, can help students manage stress and anxiety related to screen time. Conducting further research to develop comprehensive screen time guidelines is essential for promoting the health and well-being of future generations.

Acknowledgments

The authors would like to acknowledge their affiliation, with the icddr,b and its core donors who provide unrestricted support to icddr,b for its operations and research, including the governments of Bangladesh and Canada. We gratefully acknowledge our core donors for their support and commitment to the research efforts at icddr,b. The authors are also grateful to the school authorities for their unconditional support. The current study was financially supported by the Bangladesh government's Mujib100 Research Grant for Women award, in collaboration with icddr,b, grant no. 1945. Abstract

Background: Recent advancements in digital technologies hold promise for psychological interventions. Virtual reality (VR) has emerged as a particularly innovative tool, and its application expanded during the COVID-19 pandemic period. A recent study combining material and psychological rewards within a VR platform showed that this approach effectively improves attention-deficit behaviors in children with attention-deficit/hyperactivity disorder (ADHD), enhancing their inhibitory control abilities.

Objective: This study aimed to evaluate the effectiveness of a newly developed VR-based cognitive control training game for children with ADHD symptoms. Specifically, it examined the sustainability of the training effects through a 3-month follow-up assessment. In addition, the study analyzed training response patterns and influential factors using a clustering method.

Method: A total of 29 children and adolescents (21 males and 8 females) aged 10-14 years participated in the study, with a mean IQ of 94 (SD 16.53). For 20 consecutive days, participants self-administered the training on a daily basis using the VR app. The following assessments were administered face-to-face: the Korean Wechsler Intelligence Scale for Children, Fourth Edition; the Stroop test; the Color Trails test; and the Flanker test from the National Institutes of Health toolbox. In addition, the parent-completed Korean Child Behavior Checklist was used to identify behavioral problems in the children. Participants engaged in at least 20 minutes of daily training for 20 consecutive days, with assessments conducted at baseline, posttraining, and follow-up.

Results: Repeated measures ANOVA revealed significant main effects in the Stroop Color-Word test ($F_{2,56}$=4.97; P=.001; ηp^2=0.151), Child Behavior Checklist (CBCL) Total Problems ($F_{2,56}$=21.0; P<.001; ηp^2=0.429), CBCL Attention Problems ($F_{2,56}$=11.7; P<.001; ηp^2=0.294), and CBCL ADHD ($F_{2,56}$=3.46; P=.004; ηp^2=0.110). K-means clustering identified 2 distinct clusters that did not differ significantly in IQ variables but showed significant differences in game-related behavioral variables, including mean correct response time (t_{27}=−2.56; P=.02) and the correct response ratio (t_{27}=2.60; P=.02).

Conclusions: The findings indicate that the VR-based training effectively improved cognitive control on the Stroop test and ADHD-related symptoms as measured by the CBCL. However, no significant training effects were observed on other attentional measures, namely the Color Trails test and the Flanker test from the National Institutes of Health toolbox. This VR-based approach shows promise as a potential therapeutic intervention for children with ADHD symptoms.

Introduction

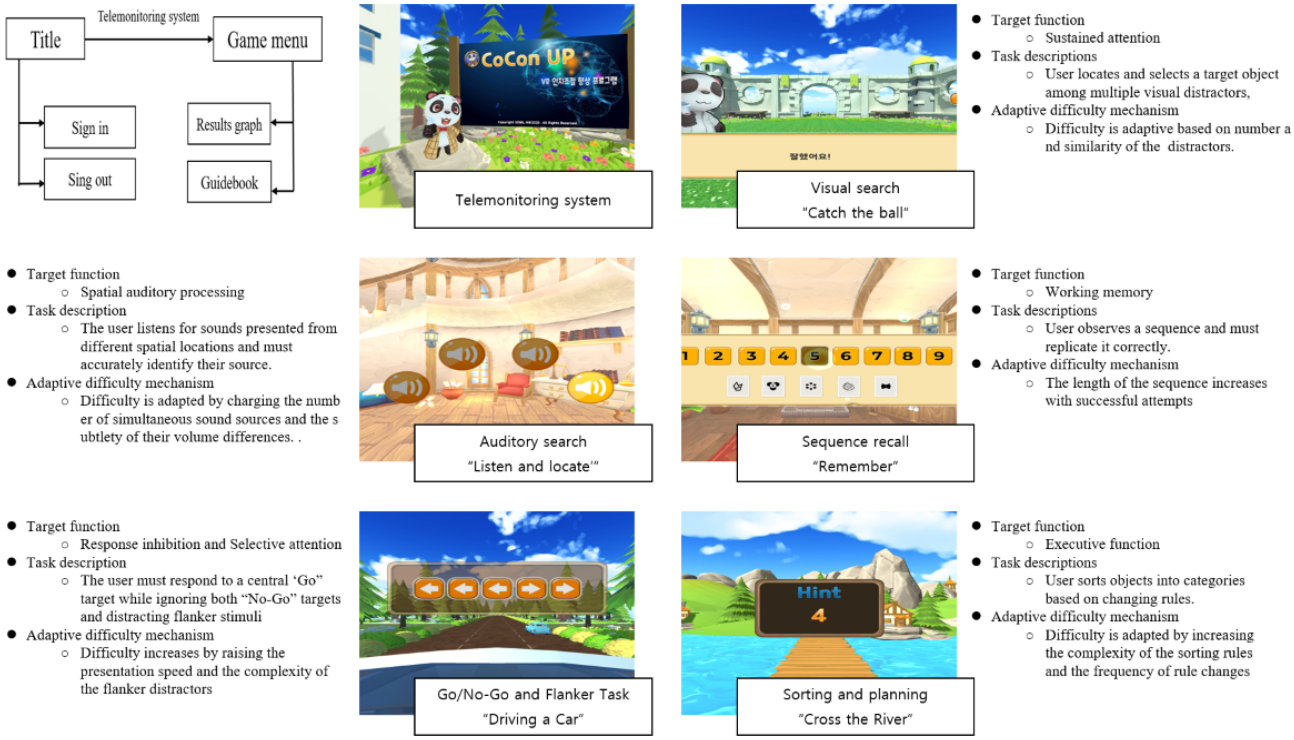
Technological advancements have significantly transformed psychological interventions, particularly through digital therapeutics and personalized treatment strategies. The concept of "enhanced psychotherapy" has been introduced, which builds on traditional psychotherapy by integrating innovative treatment modules, approaches, or techniques [1]. A distinctive feature of this enhanced psychotherapy is the use of personalized treatment strategies, incorporating digital technologies, wearable devices, and computerized cognitive behavioral therapy. Recent advancements in digital technologies hold significant promise for psychological interventions. For instance, the integration of formally recognized treatment options, such as EndeavorRX (Akili Interactive; AKL-T01), which has received approval from the Food and Drug Administration, has enhanced both the feasibility and applicability of digital therapeutics in clinical practice [2]. It has been argued that current technologies could transform cognitive interventions, allowing for better targeting of individuals in need of specific treatments [3]. In addition, it has been emphasized that the ability to dynamically tailor treatments in real-time through data processing technologies marks the dawn of a new era in psychiatry [4].

Virtual reality (VR) has emerged as a particularly innovative tool [5]. It has revolutionized psychotherapy and psychological assessment [6,7], and its application significantly expanded during the COVID-19 pandemic, including in sensitive contexts [8-10]. VR interventions have been explored in the treatment of anxiety disorders, pain management, eating disorders, psychosis, autism, and addiction. Research suggests that VR-based interventions can be as effective as, or even more beneficial than, traditional treatment methods [11]. Several recent studies have highlighted the potential of VR in cognitive intervention. For instance, attention training using VR has been reported to be effective in patients with acquired brain injuries [12]. Research has demonstrated that VR technology provides significant benefits in mental health management for adolescents experiencing various challenges, including emotional, cognitive, and social difficulties [13,14].

Although treatments for attention-deficit/hyperactivity disorder (ADHD) have been rigorously documented [15], therapies focusing on enhancing cognitive control lack systematic validation regarding both efficacy and long-term treatment effects [16]. In addition, there is a notable shortfall in ecologically valid treatment outcomes. Basically, treatment benefits should translate into improvements in real-world functioning. Spooner and Pachana [17] stressed that neuropsychological assessment should correlate closely with daily functioning outcomes. However, a recent meta-analysis reflecting on 2 decades of research identified only 7 studies that included parental reporting on ADHD symptoms and behaviors in daily life [18].

Cognitive control is a foundational concept in modern cognitive neuroscience, encompassing decision-making, goal-directed behavior, response inhibition, and attention allocation [19]. Deficits in cognitive control have been closely linked to childhood and adolescent behavioral problems, including ADHD [20-22], autism spectrum disorder [23], conduct disorder, and various impulsive behaviors [24]. ADHD is notably associated with deficits in cognitive control, which can be identified through behavioral assessments and neuroimaging measures [25]. The prefrontal cortex, with its extensive interconnectivity with sensory, motor, and subcortical structures, serves as a hub for cognitive control [19,20,26].

One study illustrated VR's potential in treating ADHD, showing results comparable to those achieved with methylphenidate treatment [14]. In addition, a recent study combining material and psychological rewards within a VR platform showed that this approach effectively improves attention-deficit behaviors in children with ADHD, enhancing their inhibitory control abilities [26]. Furthermore, research has demonstrated that older adults experiencing cognitive and functional decline benefit from VR game interventions, with particularly pronounced effects observed in self-adaptive VR interventions [27]. This highlights the importance of participant-centered approaches in optimizing both cognitive and motor outcomes while prioritizing the enhancement of user experiences. The recent review exploring VR and exercise simulator intervention in patients with ADHD emphasized the need for a comprehensive approach to interventions and advocated improving technological interventions to address the varied needs of individuals with ADHD [28,29].



We hypothesized that the immersive experience of VR could offer an optimal training environment for children with ADHD symptoms, particularly those who struggle to maintain focus due to difficulties in filtering irrelevant stimuli. In addition to the immersive experience, the newly developed VR game encompasses 3 core aspects. First, the intervention is built on rigorous cognitive neuroscience principles. This VR game was designed based on carefully selected games from the cognitive control training app, CoCon (Huno [30]). CoCon, a previously validated 2D mobile app, has shown promising results in improving cognitive control in children, thus providing a strong foundation for this VR-based extension. Each game was designed based on a cognitive experimental paradigm relevant to cognitive control functions, such as visual and auditory search, working memory, response inhibition, and executive function [30]. Second, this VR game uses an adaptive difficulty algorithm, ensuring that participants benefit from the training regardless of their baseline attention capabilities. The game difficulty progressively increases as users advance, pausing when users reach their cognitive capacity limits. Task difficulty is regulated using algorithms derived from an adaptive staircase approach. The adaptive staircase algorithm, originally developed based on established psychophysical methods and now patented (10-2019-0125031), enables real-time adjustment of task difficulty to individual cognitive thresholds. Third, this VR game incorporates a remote monitoring system, encouraging consistent engagement in the training program. Research assistants track participants' progress through server data and provide feedback via phone, engaging primary caregivers when necessary. This integrated approach of at-home training, combined with direct support, has been designed to optimize treatment outcomes. The overall structure and primary cognitive functions of each VR game are depicted in Figure 1. This figure

XSL•FO
RenderX

shows the main modules of the game system, including the user interface, the core gameplay loop, the data management module, and their interconnections.

This study aims to examine the efficacy of the VR-based cognitive training through a structured 20-day intervention program, followed by a 3-month follow-up assessment to evaluate the durability of training effects. We hypothesize that the intervention will yield significant and sustained improvements in key domains of cognitive control, including attention regulation, inhibitory control, and executive functioning.

Figure 1. Key components of the game's architecture.

Methods

Participants

A total of 32 children aged 10-14 years participated in this study. This age range was selected to ensure participants had the developmental capacity to understand instructions, operate the VR equipment, and adhere to the training protocol. A total of 22 participants were recruited from the Department of Psychiatry at a general hospital in Seoul, where they were diagnosed with ADHD by a child psychiatrist. None had comorbidities. Notably, 18 participants were medicated with varying types and dosages, while 4 were medication-naive. An additional 10 participants were recruited from the community via social networks and community boards. Inclusion criteria for community participants were based on the mobile-based cognitive control assessment app, CoCon. To be included, candidates had to score below a T-score of 40 on at least one of 4 indices: sustained attention, working memory, cognitive control, and cognitive execution. A T-score of 40 on the CoCon app represents a mean score 50 (1 SD) below the mean. There were no significant differences between the clinical and community participants in the basic variables (Table S1 in Multimedia Appendix 1).

Sample size calculation was performed using G*Power version 3.1 software (Heinrich-Heine-Universität Düsseldorf [31]). Initially, the study was designed as a between-subjects repeated measures ANOVA, and a sample size of 86 was recommended, assuming a medium effect size (Cohen *f*=0.25), an α level of .05, and a statistical power of 0.80. However, due to uncontrollable circumstances, such as the COVID-19 pandemic, it was not feasible to recruit enough participants for the between-subjects design. Therefore, the study design was changed to a within-subjects repeated measures ANOVA. Based on this revised design, a sample size of 28 was recommended under the same parameters (Cohen *f*=0.25; α=.05; power=0.80), assuming a medium effect size for a within-subjects context. To account for an estimated dropout rate of 20%, the final target sample size was increased to 32 participants. Overall, 3 participants dropped out during training, resulting in a final count of 29 participants. In addition, 1 participant who reported red-green color blindness after the pretraining test had their Stroop test data replaced with mean values from corresponding variables for analysis. For the 29 participants who completed all study assessments, all of them also completed the full 20-day training protocol, demonstrating 100% adherence among this group.

Study Design

This VR game was developed using the Unity (Unity Technologies) game engine and is compatible with the Oculus Quest 2 (Meta) VR device. The VR game app was designed for home-based cognitive control training, with each participant expected to engage in at least 20 minutes of training daily for 20 days. Research assistants monitored training data and proactively addressed difficulties over the phone each day, conducting in-home visits as needed for technical challenges.

XSL•FO
RenderX

This study included 3 assessment phases comprising a pretest for initial assessment, a posttest after 20 days of training, and a follow-up test conducted 3 months later. To evaluate the retest effect specifically, 14 participants underwent an additional test (retest) without training. Participants, including those in the no training retest group, were alternately allocated based on enrollment order with randomization. After evaluations, this group participated in training sessions, followed by subsequent posttests and follow-up assessments.

The pretest included the Korean Wechsler Intelligence Scale for Children-Fourth Edition (K-WISC-IV) [32], the Korean Color Trails test (CTT) 1 and 2 [33], the Korean Stroop test [34], the NIH toolbox [35], and the Korean Child Behavioral Checklist (K-CBCL) [36], lasting approximately 90 minutes excluding the parent-completed K-CBCL. The posttest and follow-up tests included CTT 1 and 2 [33], Stroop test, Flanker test from the NIH toolbox [35], and the K-CBCL [36], each taking about 30 minutes, excluding the parent-completed K-CBCL [36]. Training monitoring and assessments were conducted by research assistants who had graduated from master's programs specializing in clinical psychology.

Measurements

K-WISC-IV Assessment

The K-WISC-IV [32] uses 10 core subtests to measure intelligence. The subtests yield scaled scores (mean 10, SD 3) and 4 composite indices, such as verbal comprehension index (VCI), perceptual reasoning index (PRI), working memory index (WMI), and processing speed index (PSI), presented as standard scores (mean 100, SD 15).

Korean Version of the Color Trails Test 1 and 2

The Color Trails test [33] comprises 2 parts. The first (CTT1) part assesses attention sustainability, and the second (CTT2) part assesses the ability to shift attention. Converted T-scores based on the completion time for both assessment parts were used for analysis.

Korean Version of the Stroop Color-Word Test for Children

The Stroop Color-Word test [34] evaluates the ability to inhibit irrelevant information and select relevant responses. The Korean version, which demonstrated reliability (Cronbach α=0.72 for the normative population and 0.73 for the clinical population), was administered. Normative data are available for children aged 5-14 years. In this study, the number of correctly reported color words within 45 seconds served as the measurement.

NIH Toolbox Flanker Test

The Flanker Inhibitory Control test from the National Institutes of Health (NIH) toolbox [35] was used to evaluate executive function. This task assesses a participant's ability to inhibit irrelevant visual information while maintaining attention on a target. The age-corrected standard scores (range 59 - 140) were used for analysis.

K-CBCL Assessment

The K-CBCL [36] was used to identify behavioral problems in children, adapted from the Achenbach [37] Child Behavioral Checklist (CBCL). Raw scores were converted to T-scores (mean 50, SD 10). The analysis focused on the total problem score, attention problem score, and ADHD score.

Mobile-Based Cognitive Control Assessment App (CoCon)

CoCon [30] served to screen high-risk groups in the community. Its concurrent validity was established through comparisons with traditional neuropsychological tests, including the Stroop test and the CTT. Four composite indices were produced, converted into T-scores (mean 50, SD 10): sustained attention, working memory, cognitive control, and cognitive execution. A T-score of 40 was used as the cutoff for high-risk group selection (higher scores indicating better function).

Statistical Analysis

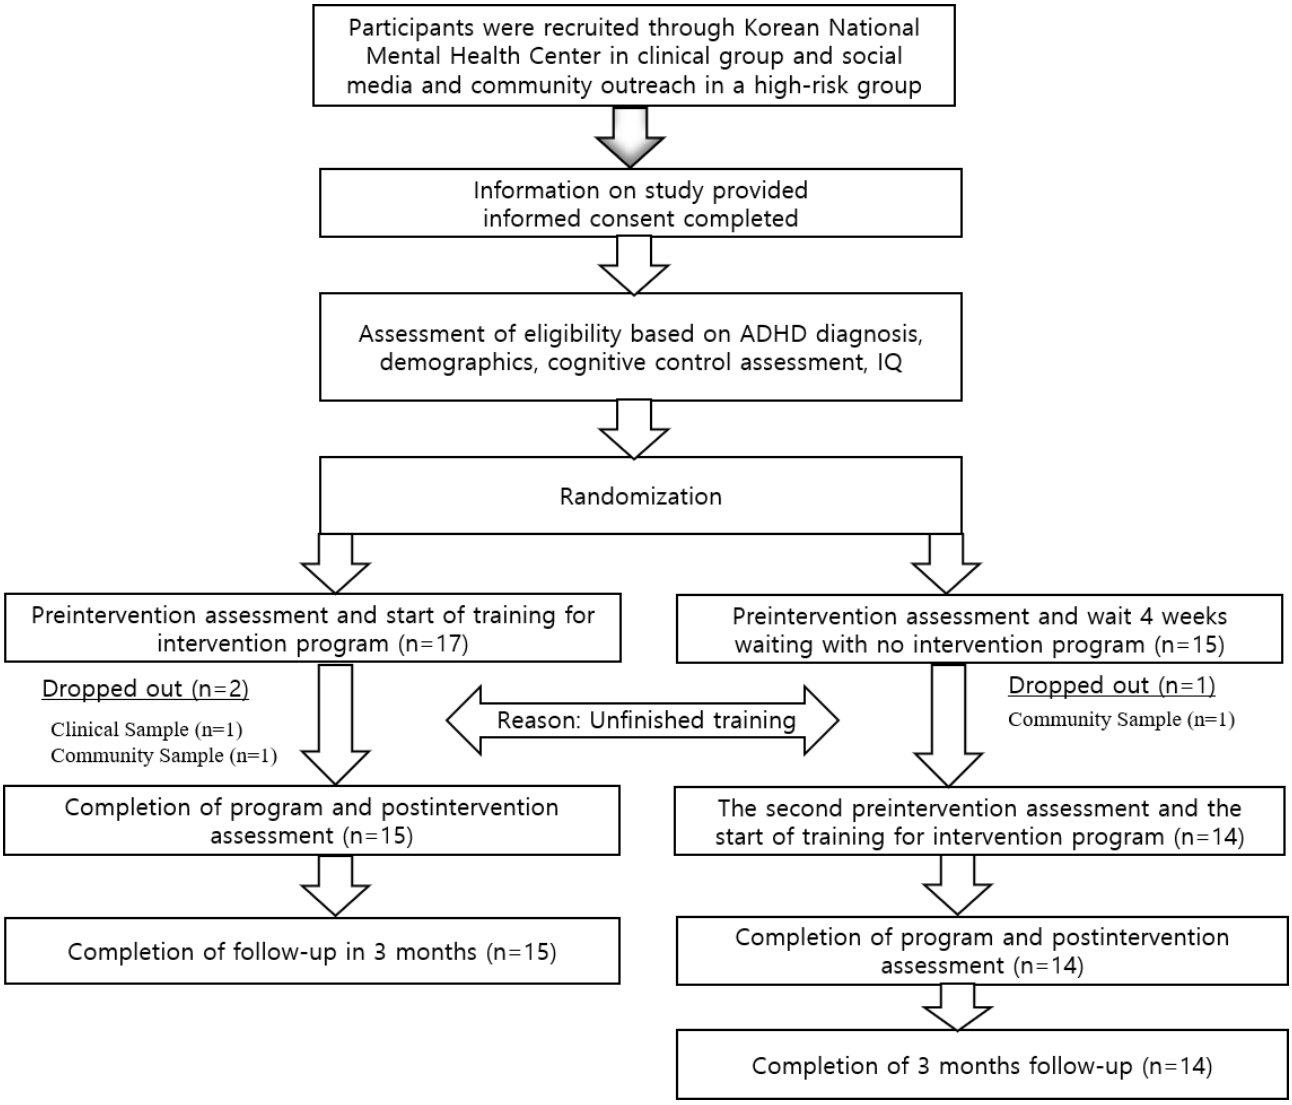
Data analysis was performed using Jamovi software [38]. Demographic data were summarized by calculating means, SDs, and frequencies. Game-related behaviors were analyzed, including login frequency, instances of exiting games midway, total game time, total trial numbers, correct-incorrect counts, and reaction times. Paired 2-tailed *t* tests evaluated retest effects. The main analysis used repeated-measures ANOVAs to assess training effects at 3 time points, such as pretraining, posttraining, and 3 months posttraining. Scatter plots depicting pretest, posttest, and follow-up test results were generated using the *ggplot* function [39,40] in Jamovi software [38]. In addition, the Pearson correlation analysis was conducted between game-related behaviors and difference scores between pretests and follow-up tests in the Stroop test and CBCL total score, attentional problem score, and ADHD score. Training response patterns were analyzed using the *k*-means clustering method, applying Lloyd algorithm to identify distinct clusters based on standardized *z* scores (mean 0, SD 1) from difference scores between pretests and follow-up tests in the Stroop test and CBCL total score, attentional problem score, and ADHD score. Group comparisons were conducted using independent 2-tailed *t* tests across various parameters, including IQ subscales (verbal comprehension, perceptual reasoning, working memory, and processing speed) and game behaviors (correct/incorrect ratios, total response times, total trial numbers, number of exits during games, and login frequencies).

Ethical Considerations

This study received approval from the institutional review board (SWU IRB-2020A-56; Multimedia Appendix 2). Written informed consent was obtained from participants and their parents, with each participant receiving 90,000 KRW (US $70) upon completing all evaluations. Data were anonymized.

Results

Participant Characteristics and Retest Effects



Basic data analysis indicated that the mean age of the participants was 11.3 (SD 1.13) years, with ages ranging from 10 to 14 years (no retest group: 11.1, SD 1.28 years; no training retest group: mean 11.5, SD 0.94 years). A visual representation of the entire process depicting subsequent posttests and follow-up assessments can be found in Figure 2. The mean total

XSL•FO
RenderX

IQ (K-WISC-IV) was 94.2 (SD 16.5; no retest group: mean 95.4, SD 15.97; no training retest group: 93, SD 17.62). The gender distribution among the 29 particpants comprised 21 (72%) boys and 8 (28%) girls. There was no significant group difference regarding gender ratio, with a chi-square (χ^2) test resulting in P=.07.

The retest effects, assessed using paired t tests, revealed no significant changes between initial assessments and reevaluations without intervention across various measures (t_{13}=−1.979, P=.07 for CTT 1; t_{13}=−0.711, P=.49 for CTT 2; t_{13}=−0.899, P=.39 for Flanker test from NIH toolbox; t_{13}=−1.773, P=.10 for Stroop test; t_{13}=1.224, P=.30 for CBCL Total score; t_{13}=1.694, P=.11 for CBCL Attention Problems score; and t_{13}=1.224, P=.24 for CBCL ADHD score).

Figure 2. Flow diagram of the study. ADHD: attention-deficit/hyperactivity disorder.

Effects of VR Training on Cognitive and Behavioral Measures

Table 1 details the observed training effects across pretest, posttest, and follow-up assessments. Repeated measures ANOVA revealed significant effects in the Stroop test ($F_{2,56}$=4.97; P=.01; ηp^2=0.151; pretest<posttest P=.006), CBCL Total Problems Score ($F_{2,56}$=21.0; P<.001; ηp^2=0.429; pretest<posttest P<.001; pretest<follow-up test P<.001), CBCL Attention Problems Score ($F_{2,56}$=11.7; P<.001; ηp^2=0.294; pretest<posttest P<.001; pretest<follow-up test P=.002), and CBCL ADHD score ($F_{2,56}$=3.46; P=.04; ηp^2=0.110; pretest<posttest P=.03). Figure 3 presents plots comparing the within-group results from the pretest, posttest, and follow-up tests, created using *ggplot2*. CTT1 and CTT2 and the Flanker test from the NIH toolbox did not demonstrate any significant effects among the pretest, posttest, and follow-up test.

Analysis of Training Response Patterns

A Pearson correlation analysis revealed significant positive correlations between the correct response ratio and the difference scores on the CBCL Total Problems, Attention Problems, and ADHD scales. Furthermore, significant correlations were found between the mean correct response time and the difference scores on the Stroop Color-Word test, as well as the CBCL Attention Problems and ADHD scales. The total login frequency was also significantly correlated with the difference scores on all 3 CBCL scales (see Table S1 in Multimedia Appendix 3 for details). The k-means cluster analysis, which used *z* scores of the difference between pretest and follow-up on the Stroop test and CBCL scales, produced 2 distinct clusters. Cluster 1 (n=10) did not show significant improvement, while cluster 2 (n=19) exhibited overall improvements from pretest to follow-up. A comparative analysis did not reveal any significant differences between the 2 clusters in age or on the IQ-related indices. However, there was a borderline significant difference in gender distribution between the clusters (χ^2_1=3.84; *P*=.05). Furthermore, a significant association was found between sample type (clinical vs community) and cluster membership (χ^2_1=8.03; *P*=.005) (see Tables S1 and S2 in Multimedia Appendix 4 for details). In addition, there were significant differences in game-related behavioral variables, including mean correct response time (t_{27}=−2.56; *P*=.02) and the correct response ratio (t_{27}=2.60; *P*=.02). These results suggest that a longer correct response time and a lower correct response ratio were associated with better training outcomes. The detailed results are presented in Table 2 and Figure 4.

Discussion

Principal Findings

This pilot study provides preliminary evidence that a novel, at-home VR cognitive training game can significantly improve cognitive control and parent-reported ADHD symptoms in children. Notably, these therapeutic gains were sustained at a 3-month follow-up, and an analysis of a nonintervention group confirmed that the improvements were not solely attributable to test-retest effects. The study also demonstrated high feasibility. The integration of a telemonitoring system was effective in maintaining excellent adherence to the 20-day protocol, overcoming common challenges associated with remote interventions.

However, the Flanker test from the NIH toolbox and the CTT did not show significant training effects. This lack of significant findings may stem from the nature of these tasks, which primarily assess more automatic attentional processes, in contrast to the Stroop test, which targets controlled attention. Prior research has suggested that basic attention networks can exhibit unstable changes with repeated testing, making such measures potentially less sensitive to short-term training improvements [41]. A k-means clustering analysis was conducted based on changes observed in the Stroop Color-Word test, CBCL total behavioral scores, attentional problems, and ADHD symptom scores. This analysis revealed distinct patterns of training response among the identified clusters. Overall, the 2 clusters displayed contrasting trends: one group demonstrated a positive training effect, while the other showed no clear improvement. Notably, there were no significant differences in age and IQ indices between the clusters, suggesting that age and general intelligence did not account for the observed variability in training outcomes. Interestingly, the positively responding cluster exhibited longer correct response times and lower correct response ratios compared to the nonresponsive group. Although these findings appear counterintuitive, they may reflect greater engagement or more sincere participation, indicated by a higher number of total trials and longer reaction times, which could underlie the observed improvements. Notably, a significant association was found between the participant source (clinical vs community) and training response, with the community sample being less responsive to the training than the clinical sample. While the baseline assessment showed no significant differences between the 2 groups in IQ, age, or attention-related problems, the difference in training outcomes may suggest lower motivation in the community sample. However, given the small size of the community group, this interpretation is speculative and requires further investigation.

XSL•FO
RenderX

Limitations

Despite these compelling findings, several critical limitations must be acknowledged. First, the study lacked a control group, which limits the ability to draw causal conclusions about the effects of the training. The within-subjects design, without a parallel control, restricts the interpretation of training efficacy in a more systematic and rigorous manner. Second, the relatively small sample size (N=29), along with imbalanced participant characteristics, particularly in terms of gender distribution and medication status, reduces the generalizability and statistical power of the findings. Third, the study did not assess higher-order cognitive functions, such as executive functioning. Incorporating such measures could have provided a more comprehensive understanding of the relationship between neuropsychological test performance and parent-reported behavioral outcomes.

Conclusion

In conclusion, the newly developed VR-based cognitive control game, enhanced with a modified adaptive staircase algorithm and supported by a telemonitoring system, demonstrated its potential as an accessible and effective at-home intervention for children with ADHD symptoms. Building on research showing that user characteristics influence engagement with tele-mental health services [42], an important next step is to explore which specific user profiles benefit most from this VR-based intervention.

Abstract

Background: Children and adolescents with attention-deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) often face structural and psychological barriers in accessing medical care, including economic costs, long wait times, and stress of attending new medical environments. The COVID-19 pandemic accelerated the adoption of telehealth services to overcome these challenges. However, few studies have assessed the satisfaction levels of children and adolescents diagnosed with neurodevelopmental disorders and their caregivers when they use telepsychiatry, particularly in Japan.

Objective: This study aimed to evaluate satisfaction by conducting telepsychiatric assessments in children and adolescents diagnosed with ADHD or ASD and their caregivers and to identify factors associated with higher satisfaction levels.

Methods: A total of 68 patients aged 6 - 17 years with a confirmed diagnosis of ADHD or ASD and their caregivers participated in this study. The participants were recruited from Keio University Hospital and four collaborating institutions in Japan. Each patient and their caregiver underwent two assessment sessions, one face-to-face and the other via telepsychiatric assessment (a remote video tool), in a randomized order. Upon completing both assessments, the participants completed a satisfaction questionnaire using a 5-point Likert scale that covered aspects such as audio and video quality, seamless communication, perceived warmth, reduced burden, and the ability to behave naturally. Spearman rank correlation coefficients and multiple regression analyses were performed to identify factors associated with overall satisfaction.

Results: Among the patients, 70% (47/67) reported being “satisfied” or “very satisfied” with the telepsychiatric assessment, and 88% (60/68) of caregivers reported similar satisfaction levels. Multiple regression analysis showed that in children, high satisfaction was associated with seamless viewing of the screen, reduced burden of hospital visits, and the ability to speak naturally during the assessment. For caregivers, visual clarity and the child’s natural behavior were crucial factors.

Conclusions: Telepsychiatric assessments are an effective and practical option to provide care for children and adolescents diagnosed with ADHD or ASD and their caregivers, offering high levels of satisfaction. Technical reliability and reduced travel burden significantly contributed to positive experiences. However, ensuring that children and adolescents behave naturally and feel a sense of warmth during remote assessment is crucial to maximizing their satisfaction. Telepsychiatric services can enhance the quality of health care, making them valuable supplementary tools for clinical practice.

KEYWORDS

attention-deficit/hyperactivity disorder; autism spectrum disorder; telepsychiatry; telehealth; caregivers; ADHD; ASD; mobile phone

Introduction

Neurodevelopmental disorders, including attention-deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD), are complex disorders caused by genetic and environmental factors. Early detection and intervention are crucial to prevent comorbidities, such as anxiety and depression [1,2]. Children and adolescents with neurodevelopmental conditions and their families frequently encounter structural and psychological barriers to obtaining medical treatment.

Structural barriers include economic costs [3,4], taking time off work [5], lack of treatment availability owing to a shortage of trained psychiatrists [6,7], and long-distance travel to specialized clinics [8]. Psychological barriers that impede engagement with neurodevelopmental disorder services include direct caregiver distress, the stigma associated with ASD and ADHD and their treatment [9,10], and low self-efficacy in accessing and implementing treatment [11]. For children and adolescents with neurodevelopmental disorders, traveling to medical appointments and being in unfamiliar medical settings can worsen behavioral problems and increase psychological stress [12].

In recent years, the development of information and communication technology has led to the widespread adoption of telehealth, in which individuals communicate via video calls over long distances. During the COVID-19 pandemic, in-person medical care was limited owing to the increased risk of infection from face-to-face contact. As an alternative, telepsychiatry proved to be an effective method in psychiatric care. This is attributable to most psychiatric assessments and treatments relying on medical interviews, behavioral observations, and patient conversations.

Numerous studies have reported high satisfaction with the use of telepsychiatry in the field of psychiatry [13,14]. However, few studies have focused on children with neurodevelopmental disorders. The treatment setting for children with ASD conditions and intellectual developmental disorders at a pediatric hospital in the United States during the COVID-19 pandemic received a 91% satisfaction rate for telepsychiatric health assessments [8]. Reisinger et al [15] investigated the satisfaction of telehealth assessments in children with ASD. They found that 88% of caregivers reported being satisfied with the assessments, with some implications for factors related to satisfaction. Galvin et al [16] surveyed caregivers of children with ADHD in Ireland regarding their satisfaction with the remote consultations they had received. Most participants (62.3%) reported being comfortable communicating with their health care professionals via telehealth consultations, and only 34.4% reported that their child was comfortable communicating through their telehealth experience. However, responses were not directly obtained from the children.

Despite the above reports, few studies have investigated satisfaction with telepsychiatry among children with ASD and ADHD and their caregivers, particularly in Japan. Studies on the advantages and disadvantages of using remote assessment for neurodevelopmental disorders in children remain limited, particularly regarding the satisfaction of children undergoing the assessment. Previously, we reported the reliability of remote ADHD assessment compared to face-to-face assessment in children with ASD or ADHD and their caregivers [17]. We used intraclass correlation coefficients to confirm that the assessments conducted remotely were comparable to those conducted face-to-face. This study aimed to examine the acceptance of remote evaluations by end users, particularly children with ASD or ADHD and their caregivers, and identify the factors associated with higher satisfaction.

Methods

Participants

Kurokawa et al [17] provide a detailed description of the related research methodologies. Patients were recruited at the Keio University Hospital and four collaborating institutions (Shimada Ryoiku Medical Center for Challenged Children, Aiiku Clinic, Tokyo Metropolitan Children's Medical Center, and Tsurugaoka Garden Hospital). The inclusion criteria were as follows: (1) confirmation of the Diagnostic and Statistical Manual of Mental Disorders diagnoses of ADHD and ASD, (2) age 6 - 17 years at the time of obtaining consent, and (3) stable treatment for 3 months before obtaining consent. The exclusion criteria were as follows: (1) either the child or caregiver had a hearing or visual impairment that made it challenging to use remote tools, even with corrective devices, such as glasses or hearing aids; (2) caregivers did not have the information related to the participants' early childhood; (3) comorbid symptoms, such as hallucinations and delusions, made it challenging to involve the participants in the study, as determined by the clinician; and (4) there were plans to initiate new treatments, such as pharmacotherapy or psychotherapy, during the observation period. This study was conducted in line with CONSORT (Consolidated Standards of Reporting Trials) guidelines (Checklist 1).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and the Ethical Guidelines for Medical and Health Research Involving Human Subjects (Japan). Informed consent was obtained from all the caregivers. For children, an informed consent form that was tailored to their age and understanding was used, and written confirmation of their consent was obtained after careful explanation. Regarding confidentiality, a designated data manager assigned each participant a unique study

XSL•FO
RenderX

identification number and managed all records exclusively under this number thereafter. The correspondence table linking personal identifiers to study IDs was stored either in a locked cabinet within the Department of Psychiatry and Neurobiology at Keio University School of Medicine or on a password-protected computer with restricted access. All subsequently collected data and background patient information (eg, diagnosis, sex, and age) were handled solely by study ID and were completely separated from personal identifiers, such as participants' names, dates of birth, patient numbers, or addresses. The study protocol was approved by the Ethics Committee of Keio University School of Medicine (20190301). This study is registered in the UMIN Clinical Trial Registry (UMIN000039860).

Study Procedure

For baseline evaluation, the Autism-Spectrum Quotient–Japanese version for children, Conners 3 Japanese version to evaluate ADHD symptoms by caregivers, Strengths and Difficulties Questionnaire to assess social adaptation, and Short Sensory Profile to assess sensory characteristics were administered. Background information and data such as age, sex, diagnosis, medication, duration of illness, and intelligence test results were collected from medical records.

Patients and caregivers underwent assessments twice on different days, either face-to-face or remotely, in randomized order. The remote smartphone assessment tool "Curon" (MICIN Co Ltd) was used for the telepsychiatric assessment. The participants were seated in front of a smartphone in their homes and introduced to a remote evaluator. Remote evaluators administered their evaluations from a room at the Keio University Hospital using a personal computer. Assessments began after confirming the absence of interruptions in the video or audio environment. None of the raters was involved in the participants' assessments or treatment during their usual visits.

Upon completing the face-to-face and remote assessments, the participants were provided with a questionnaire to report their satisfaction with the assessment.

Satisfaction Questionnaire

The survey assessed the levels of satisfaction and feasibility associated with the use of telehealth tools during assessment interviews. A 5-point Likert scale ranging from 1=strongly disagree to 5=strongly agree was used to collect responses. The questions covered include: (1) audibility during telehealth assessments, (2) clarity of video presentation, (3) communication issues compared to in-person assessments, (4) lack of warmth or personal touch that made the patient feel uneasy, (5) perceived benefits of less time and burden compared to in-person hospital visits, and (6) whether the child could behave naturally compared to a face-to-face assessment. The participants were allowed to provide free-text comments on each item to illustrate their experiences.

Statistics

Analyses were conducted to identify the crucial factors related to overall satisfaction with the telehealth tools used by patients and their caregivers. Spearman rank correlation coefficients were used to identify factors strongly associated with overall satisfaction with remote assessment among patients and caregivers. These factors included age, sex, diagnosis, severity of ASD and ADHD, other survey items, waiting time for the initial consultation, and travel time to clinic appointments. The Wilcoxon rank sum test was used for binary categorical data.

Subsequently, multiple regression analysis was conducted to examine the factors associated with overall satisfaction. Variables showing strong correlations in the preliminary exploratory data analyses and those based on theoretical grounds were selected using a forced-entry method to develop the models. Separate models were developed for the patients and caregivers. For patients, the analysis included age, sex, main diagnosis, clarity of auditory and visual reception, difficulty in expression, sense of warmth, perceived reduction in time and psychological burden compared with usual care, and seamless speaking naturally. The variance inflation factor was calculated to address multicollinearity, with variables exceeding a variance inflation factor of 10 being excluded from the model. Data analysis was performed using SPSS Statistics (version 28; IBM Corp). The significance level was set at .05. All statistical tests were 2-tailed.

Results

The study initially enrolled 75 participants but concluded with 74, as one participant dropped out owing to scheduling conflicts over the 3-month period. Upon excluding 16 individuals for whom comprehensive satisfaction survey data were not obtained, 68 children and their caregivers were included in the analysis (Figure 1).

[g]ADHD-RS-IV: attention-deficit/hyperactivity disorder rating scale-IV.

Figure 2 shows the responses of patients and their caregivers to each question. Additionally, 70% (47/67) of children reported being “satisfied” or “very satisfied.” Among caregivers, 88% (60/68) reported being “satisfied” or “very satisfied.” Regarding seamless hearing, 91% (61/67) of the children answered that they could “hear well,” “hear very well.” For caregivers, 96% (65/68) responded with “hear well” or “hear very well.” Regarding screen visibility, 75% (50/67) of children found it “easy to see” or “very easy to see.” Similarly, 94% (64/68) of caregivers found the screen “easy to see” or “very easy to see.” Regarding difficulties in communicating during the interviews, 58% (39/67) of children responded “not at all” or “no” regarding whether it was challenging to express themselves compared to face-to-face assessments. Among caregivers, 81% (55/68) responded “not at all” or “no.”

XSL•FO
RenderX

Figure 2. Responses of patients and their caregivers to each question. (A) Overall satisfaction, (B) seamless hearing (voice), (C) seamless seeing (video), (D) comparison of face-to-face consultation with seamless expression of message, (E) comparison of face-to-face consultation with warmth or physical touch, (F) comparison of face-to-face consultation with reduced time travel, and (G) comparison of face-to-face consultation with children's ability to walk and behave naturally.

When asked if they felt uneasy owing to a lack of warmth or connection compared to face-to-face assessments, 70% (47/67) of children answered "not at all" or "no." For caregivers, 91% (62/68) responded "not at all" or "no."

Regarding the reduced time and burden of traveling for appointments, 70% (47/67) of children felt it was "beneficial" or "very beneficial." Among caregivers, 81% (55/68) reported it was "beneficial" or "very beneficial." Regarding their feeling that they could act naturally, 66% (44/67) of children responded "agree" or "strongly agree." However, only 31% (21/68) of the caregivers responded "agree" or "strongly agree." Regarding security concerns, 76% (52/68) of the caregivers responded "not at all" or "no."

In the free text, responses highlighted that for some children and caregivers, being at home facilitated relaxation during the assessment interviews, indicating that the home environment positively affected the participants' experience.

Many responses from the free text indicated that the caregivers were relieved about saving time. They reported that they had to consider the time for the patient's appointment, as well as the travel time, while managing other children's schedules. Some caregivers expressed psychological stress as follows: "I have to take my child out of school for appointments, and I always struggle with whether I must prioritize their medical care or their education because the visits are often on weekdays."

The caregivers had different opinions, including how "the child's behavior was too relaxed during the remote assessment and differed from their in-person assessment," whereupon they questioned the validity of the assessment. The difficulty of securing a private space yielded dissatisfaction with remote assessments. Some caregivers expressed difficulty with regard to the child exhibiting abnormal behavior in the presence of other family members owing to the lack of privacy during remote assessment.

Subsequently, the factors correlated with overall satisfaction were examined using the Spearman rank sum test. In children, the results indicated that factors associated with satisfaction included "seamless hearing" (r=0.315; P=.09), "visual clarity" (r=0.501; P<.001), "seamless expression of oneself" (r=−0.357; P=.03), "feel warmth and human touch" (r=−0.254; P=.04), "reduced burden of hospital visits" (r=0.357; P=.03), "ability to act naturally" (r=0.514; P<.001), and "conners scores" (r=−0.292; P=.02) reflecting lower ADHD severity. The Mann-Whitney U test showed that girls had higher satisfaction levels than boys (P=.04), and children with a primary diagnosis of ADHD reported higher satisfaction (P=.005).

Factors correlating with overall satisfaction among caregivers were examined using the Spearman rank sum test. The results showed that the factors associated with caregivers' satisfaction included "seamless hearing" (r=0.308; P=.01), "visual clarity" (r=0.503; P<.001), "ability to express oneself" (r=−0.341; P=.004), and "the child's ability to act naturally and as usual"

XSL•FO
RenderX

(r=0.284; P=.02). No correlations were found between categorical factors.

Finally, a multiple regression analysis including these factors showed that, for children, "visual clarity" (β=.361; t_{53}=3.353; P=.001), "reduced burden of hospital visits" (β=.238; t_{53}=2.475; P=.02), and "ability to speak naturally and as usual" (β=.243; t_{53}=2.272; P=.03) were crucial factors that influenced their level of satisfaction (adjusted R^2=0.508). For caregivers, "visual clarity" (β=.352; t_{63}=2.954; P=.004) and "the child's ability to act naturally and as usual" (β=.223; t_{63}=2.086; P=.04) were found to be significant (adjusted R^2=0.265).

Discussion

Principal Findings

This study evaluated the satisfaction levels with telepsychiatry among children with ADHD and ASD and their caregivers and identified factors associated with satisfaction. Satisfaction with telepsychiatry was high, with 88% (60/68) of caregivers reporting being "satisfied" or "very satisfied." The acceptance of telehealth remained favorable despite the lower satisfaction rate (47/67, 70%) among children. For children, the factors most strongly associated with high satisfaction included "seamless visibility," "reduced burden of travel," and "ability to speak naturally and be themselves." For caregivers, the items most closely related to high satisfaction were "seamless visibility" and "the child being able to behave naturally and as they usually would."

The children and caregivers reported high satisfaction with the "seamless hearing" and "clarity of the video," confirming the technical reliability of telepsychiatry tools. These findings are consistent with those of previous studies [15], suggesting that the technical aspects of telepsychiatry significantly contribute to overall satisfaction.

In previous studies, symptom severity was associated with satisfaction. This study did not yield similar results. However, the study results showed that children with weaker ADHD traits reported higher levels of satisfaction. This result contradicts that of a previous study, suggesting that the children in this study were in stable condition during treatment. When ADHD symptoms were less severe, the children found it easier to concentrate, even in a web-based setting with various environmental distractions at home, which might otherwise hinder engagement.

The responses also indicated that the children experienced significant relief and satisfaction from the reduced time burden associated with travel. This is in agreement with that of a previous study [16]. Considering the long-term nature of treatment for children with neurodevelopmental disorders, reducing caregiver burden is crucial.

Responses from the free text indicated that caregivers had to consider the time for the patient's appointment and the travel time while managing other children's schedules, highlighting the difficulties they experienced. Some caregivers also expressed psychological stress from having to take their children out of school for appointments, reflecting the challenge they faced in balancing medical visits. This was often on weekdays with academic responsibilities. However, with telepsychiatry, appointments can be scheduled after school, eliminating the need to choose between education and medical care, thus reducing the burden on caregivers.

A critical factor that influenced the satisfaction of children and caregivers was their ability to "act naturally" during telepsychiatric assessments. Children who reported feeling less natural or perceived a lack of warmth during remote assessments had lower satisfaction levels. This highlights a potential limitation of telepsychiatry, where the absence of direct human interaction can negatively impact the patient experience. Previous studies highlighted similar concerns, underscoring the importance of addressing the psychological aspects of telehealth to improve patient engagement [5]. Additionally, it has been established that using telehealth as a supplementary tool after a relationship has been established with an assessor or physician is essential.

The assessment of this "natural behavior" was based on subjective self-report or caregiver report using a Likert scale, inherently limiting the objective understanding of specific behavioral manifestations in a remote setting. Therefore, incorporating objective behavioral observation (eg, clinician ratings or video analysis) in future research is important to better define this critical concept and inform the development of more effective remote assessment practices.

As represented in the free-text questionnaire, caregivers faced difficulty sustaining their psychological safety during the assessment interviews when discussing sensitive topics, owing to the fear of being overheard by children in the adjacent room. This is a crucial consideration in many Asian countries, particularly in small households and high household density. When securing a sufficiently soundproof private room at home is impossible, it is crucial to provide an external setting that allows the child and caregiver to be separated and conduct the assessment in a safe and secure environment.

Limitations

This study has several limitations. First, the sample size was insignificant, and the data were collected from specific hospitals in Japan, limiting the generalizability of the results. Second, the results were based on the extent to which telepsychiatric assessments were conducted only once. The satisfaction with using telepsychiatry over a longer period was unclear. Third, the participants in this study were children who had already been diagnosed, and as stated in the inclusion criteria, were relatively stable with no plans to start new medications or psychotherapy within the next 3 months. Therefore, these findings may not be applicable to cases in which the child is undiagnosed and attending consultation for the first time or to patients in the acute phase. Fourth, a selection bias existed because the participants in this study were individuals who were already interested in remote assessments or telepsychiatry. Fifth, while smartphone ownership rates are high in Japan, a significant portion of the population remains unfamiliar with digital devices, as noted by the concept of "digital divide." Therefore, caution must be exercised when generalizing these results.

XSL•FO
RenderX

Comparison With Prior Work

Compared with previous studies, Reisinger et al [15] reported that 88% of caregivers of children with ASD were satisfied with remote assessments. Similar to this study, high satisfaction was observable. However, the participants were limited to children with ASD and their caregivers. Galvin et al [16] reported that 62.3% of caregivers of children with ADHD felt comfortable with telemedicine, whereas the children's comfort level was significantly lower at 34.4%. This study offers novelty compared to previous studies by directly evaluating the satisfaction of children themselves.

In this study, factors associated with children's satisfaction included "seamless viewing of the screen," "reduction in the burden of clinic visits," and "the ability to speak naturally." For caregivers, "seamless viewing of the screen" and "the child's ability to behave naturally" influenced their satisfaction. This finding aligns with those of Reisinger et al [15], which also showed that satisfaction is affected by technical reliability and seamless use.

However, children with mild ADHD symptoms were reportedly more satisfied. This point was not indicated in previous studies, suggesting that telemedicine is challenging for children with difficulty concentrating.

This study focused on Japan and demonstrated the acceptability of telemedicine in contexts with different cultural and social backgrounds. Considering many previous studies focused on Western countries, data from Japan are valuable and may contribute to improving health care access and reducing the burden on caregivers. Moreover, this study demonstrated that children with mild ADHD symptoms were more satisfied with telemedicine, a finding that has not been reported in previous studies.

Conclusions

This study examined the acceptance of remote evaluations by end users, particularly children with ASD or ADHD and their caregivers, identifying the factors associated with higher satisfaction. Each child and their caregiver underwent two assessment sessions, one face-to-face and the other via telepsychiatry (a remote video tool), in a randomized order. The results revealed that telepsychiatry is an effective and practical option for children with ADHD and ASD and their caregivers. Technical reliability and reduced travel burden are the crucial factors that contribute to satisfaction. Applying the findings of this study to clinical practice requires strengthening the support system to help children feel at ease and experience warmth during remote assessments, which is essential for enhancing the quality of telepsychiatric services, particularly for children with pronounced ADHD symptoms. With suitable environmental adjustments, telepsychiatry can be a valuable supplementary option.

Abstract

Background: With the provision of home infusion therapy in children with acute or long-term illness on the rise, eHealth technologies have the potential to bridge the transition between hospital and home. However, eHealth interventions intended to support parents in managing home infusion therapy are sparse. Gaining insight into the needs and experiences of parents and health care professionals is crucial to developing feasible and sustainable eHealth interventions that target their needs. This study describes the first phase of a research study designed to develop and evaluate an eHealth intervention to support home infusion therapy.

Objective: This study aimed to identify the experiences and needs of parents and health care professionals during home infusion therapy and their preferences for digital features in a future eHealth intervention.

Methods: A qualitative study was conducted at 3 pediatric departments at a university hospital in Denmark. We individually interviewed 17 parents of 14 children who had received home infusion therapy with a portable pump. In addition, 5 focus groups were conducted with 15 health care professionals. We conducted a qualitative content analysis of the data, which we collected from February to July 2020.

Results: We identified 6 subthemes that we merged into 3 main themes: increasing safe self-management at home; adapting information and responsibility to individual changing needs; and requesting digital features to ensure skill level, safety, and quality of care. The analysis showed that parents and health care professionals had corresponding needs and preferences, for example, a need for a high sense of safety and easier ways to communicate during home infusion therapy. Both groups emphasized the need for digital features to improve problem-solving and communication as a supplement to existing care to promote a safe environment, self-management, and quality of care. A vital issue was that an eHealth intervention should be aligned with the workflow of health care professionals and comply with regulations regarding confidentiality in communication and data sharing.

Conclusions: Our study highlights the needs that parents and health care professionals have for increased safety and easier access to communication when receiving and providing home infusion therapy. The findings will be used to help develop an eHealth intervention supporting home infusion therapy tailored to individual needs.

Introduction

Home infusion therapy for children with acute or long-term illnesses is becoming increasingly common due to its benefits, such as supporting children and their families in maintaining their everyday lives and improving the child's health outcomes [1]. This therapy can be provided by nurses in hospitals or municipalities, home care agencies, or by nonprofessional

XSL•FO
RenderX

caregivers such as parents or guardians. Transitioning care tasks from a hospital to a home setting is complex and requires well-functioning, coordinated collaboration between health care professionals and parents [2]. Parents have reported feeling anxious and insecure if they lack support, experience with, or knowledge about care tasks such as administering medications and observing symptoms that they must manage at the hospital and at home [3]. Furthermore, studies show that parents' administration of oral medication at home is a high-risk area for medication errors [4-7]. Thus, it is vital to ensure that parents are comfortable and confident when managing care tasks at home.

eHealth interventions can be a means to support parents since they provide digital resources for managing home infusion therapy. According to the World Health Organization [8], eHealth can increase communication and data sharing between health care professionals and patients and improve accessibility and patient participation by electronic technologies. The use of eHealth expanded radically during the COVID-19 pandemic [9], but various barriers remain before integration into pediatric clinical practice is completely successful [10-13]. Studies have reported that the use of eHealth in pediatric clinical care can bridge the transition from hospital to home and increase interaction between the two by efficiently and conveniently providing information and communication [14-16]. This helps promote confident self-management among parents in treating and caring for children with various medical needs at home [2,15-17], improve symptom control in the child, and reduce parental worries and insecurity [2,18-22]. However, the availability of eHealth interventions for families of children with acute or long-term health conditions as well as the evidence supporting eHealth in pediatric clinical practice, remains still limited [23-25].

At the outset of this study, children and adolescents were given the opportunity to start antibiotic infusion therapy using a portable pump at a university hospital in Denmark and then continue treatment at home. Parents were trained by nurses and supported with printed materials and resources on the hospital's website. The provision of home infusion therapy began to expand to include other types of medications and delivery methods, thereby placing greater responsibility on the parents. No eHealth interventions were available to support home infusion therapy and there was uncertainty about the extent of parents' and health care professionals' needs and the specific content that they may need for eHealth support. Previous research have shown that extensive support is essential when parents perform caregiving tasks at home [3,26]. However, less is known about how parents and health care professionals employed at hospitals perceive their needs and preferences related to home infusion therapy and eHealth support. According to Medical Research Council's framework [27], exploring the needs of intervention users is a crucial first step in developing an intervention. Applying a participatory design [28], future users are involved to gain an understanding of their situation and respond to their experiences, needs, and preferences. This approach ensures that a future eHealth intervention would target their needs and be sustainably implemented [11,28-30]. Therefore, the aim of this study was to identify the experiences and needs of parents and health care professionals regarding home infusion therapy, in addition to their preferences for including digital features in the development of a future eHealth intervention.

Methods

Design

An exploratory qualitative design was applied to get relevant input from the users to the future development of a supportive eHealth intervention. This study is a part of the developmental phase of a larger research program with the overall goal of developing and testing an eHealth intervention to support parents and health care professionals during pediatric home infusion therapy. The Medical Research Council's framework for the development and evaluation of complex interventions [27] and a participatory design [28] framed the overall research project. The framework guides researchers through 4 interconnected phases, development, feasibility, evaluation, and implementation. Engaging the users of the eHealth intervention throughout the research study ensured the developmental relevance of our study and its feasibility in clinical practice, improving the probability of successful implementation [26].

Setting

The study was conducted in 3 pediatric departments at a university hospital in Copenhagen, Denmark, 1 specializing in oncology and hematology (20 in-patient beds), 1 in organ and infection diseases (12 in-patient beds), and 1 day hospital (7 beds), with around 2000 combined admissions annually.

Home Infusion Therapy

In 2018, the departments started offering home infusion therapy with portable pumps as an option to children with diagnoses such as cancer or with an acute infection with no underlying condition. The therapy was primarily used for intravenous antibiotic treatment and always initiated during hospitalization at an in-patient ward or in an out-patient setting. The children had a central venous catheter or midline catheter. A nurse informed and trained primarily one of the child's parents before home infusion therapy was initiated and administered the portable pump to the child at the hospital before discharge. The child returned the following day to the hospital to receive a new dose in the pump or to discontinue treatment. The parent's task was to clinically observe the child, the pump and infusion at home, and react if problems arose, such as reactions to the medicine or a pump alarm sounding. If the child had a serious reaction, the parent was instructed to immediately call an ambulance. Health care professionals also taught some parents how to change the pump medication or replace the elastomeric pump with a new one to allow the family to stay at home 1 or 2 additional days before returning to the hospital,

Participants

A purposeful sampling strategy of children, parents, and health care professionals was used to obtain rich and varied data on the home infusion therapy [31]. Inclusion criteria for children were 0 to 18 years of age, having received home infusion therapy with a portable pump with any type of medication,

XSL•FO
RenderX

having the parent living with the child part or full time, and the parent speaking Danish or English. Most children receiving the therapy had an underlying long-term illness, but children with an acute infection with no underlying condition were also approached. In total, 14 children and their parents were informed about the study, and all agreed to participate. The children were invited to participate in an interview together with their parent, which resulted in 13 children participating, 2 of whom actively joined in. In 3 families, both parents participated and were interviewed jointly or separately (Table 1). Inclusion criteria for health care professionals were: (1) nurse or a physician, (2) working at one of the 3 departments, and (3) had experience with providing home infusion therapy. A total of 15 health care professionals were approached, and all agreed to participate.

		Paid leave due to child's illness part time	1

Data Collection

Data were collected from February to July 2020. Parents were interviewed based on a 2-part exploratory semistructured interview guide. The first part covered experiences and needs regarding home infusion therapy in terms of provision of and responsibility for it, preparation and training, and sense of safety, worries, and challenges. The second part presented concrete

XSL•FO
RenderX

examples of digital features to generate ideas on how technology could address the needs and preferences of the child and parent, in addition to focusing on how an eHealth intervention could support home infusion therapy. We asked which digital features to include, such as possible advantages and disadvantages, experience with digital technologies, and what features are important to have in an eHealth intervention. The eHealth Literacy Framework provided the underlying inspiration for the questions in the second part to understand user needs and prerequisites when new digital health services are introduced [32]. The interviews were conducted by the first author (n=16), at one of the pediatric departments in a meeting room or an in-patient room lasting and lasted 30 to 120 minutes, though 1 was done by phone.

Health care professionals were interviewed in 5 separate focus groups with a semistructured interview guide corresponding to the guide for parents though tailored to their professional role. The focus group interviews, which lasted 60 to 90 minutes, were held in a meeting room at one of the pediatric departments. The interviews were recorded and transcribed verbatim.

Data Analysis

A qualitative content analysis of the transcribed interviews was used comprising a 5-step iterative and inductive approach based on Graneheim and Lundman [33] to identify any patterns and variations in participant experiences. First, 2 authors [HH and MLO] read the text independently to gain an overall understanding. Second, they identified meaning units in terms of words, sentences, and paragraphs that related to the study aim. Next, the meaning units were condensed, organized, and coded using NVivo software (Lumivero). Fourth, the codes were compared with identify similarities and differences, before being organized into subthemes. Finally, the subthemes were compared and analyzed, after which they were merged into main themes. The defined main themes had a consistent pattern of underlying meaning in terms of the condensed meaning units, codes, and subthemes. To strengthen the trustworthiness of the study, the same 2 authors discussed the meaning units, codes, subthemes, and themes throughout the analysis until reaching consensus. Initially, individual and focus group interviews were analyzed separately as 2 datasets. During the data analysis, it became apparent that the subthemes overlapped, and data were analyzed together. In the last phase of the analysis, all authors reflected on and discussed the main themes and subthemes.

Trustworthiness

The authors discussed the analysis, interpretations, and themes at seminars and presentations with key health care professionals involved in home infusion therapy and other researchers to enhance credibility. The authors also discussed their preunderstanding to consider how it may influence data collection and analysis, all of us are experienced in conducting qualitative studies. The first author [HH], who is a nurse, has experience with implementing home infusion therapy at the 3 departments but did not have any clinical contact with the families before the interviews. The health care professionals knew HH, which may have hampered them from freely expressing themselves, but her knowledge of home infusion therapy may also have made them feel confident enough to provide in-depth responses to the interviews.

Ethical Considerations

The Danish Protection Agency approved the study (P-2019 - 392), while approval from the Regional Research Ethics Committees for the Capitol Region of Denmark was not required since it only assesses studies that collect biological material. The study adhered to the Declaration of Helsinki, International Ethical Guidelines for Health-Related Research Involving Humans, and current Swedish and European law. All participants were assured that participation was voluntary and that they could withdraw from the study at any time without affecting their child's treatment or the health care professionals' work. All participants provided written informed consent and were assured confidentiality. When applicable, the children received age-appropriate information about the study based on their cognitive abilities, language skills, and legal guardian's preferences.

Results

Overview

The amount of experience parents and health care professionals had with home infusion therapy ranged from doing it a few to multiple times. The parents expressed that it enhanced their child's well-being and the whole family's due to having a greater opportunity to spend everyday life together more at home. They were willing to take on the additional caregiving tasks and responsibility due to the benefits associated with doing so. The health care professionals also described how the child and family benefited and how important the option of home infusion therapy was.

Three main themes were identified comprising six subthemes: (1) increasing safe self-management at home, (2) adapting information and responsibility to individual changing needs, and (3) requesting digital features to ensure skill level, safety, and quality of care (Textbox 1). The themes and subthemes were bound together in an overarching theme "managing the extended responsibility of home infusion therapy." This theme encompasses the core experience of the increased responsibility parents take on when managing the therapy and the health care professionals being responsible for therapy taking place outside the hospital. Digital features were described as means to support that responsibility.

The first and second themes describe the needs of parents and health care professionals based on current experiences with home infusion therapy, while the third main theme present the digital features proposed to meet the needs of both groups in a future eHealth intervention (Figure 1).

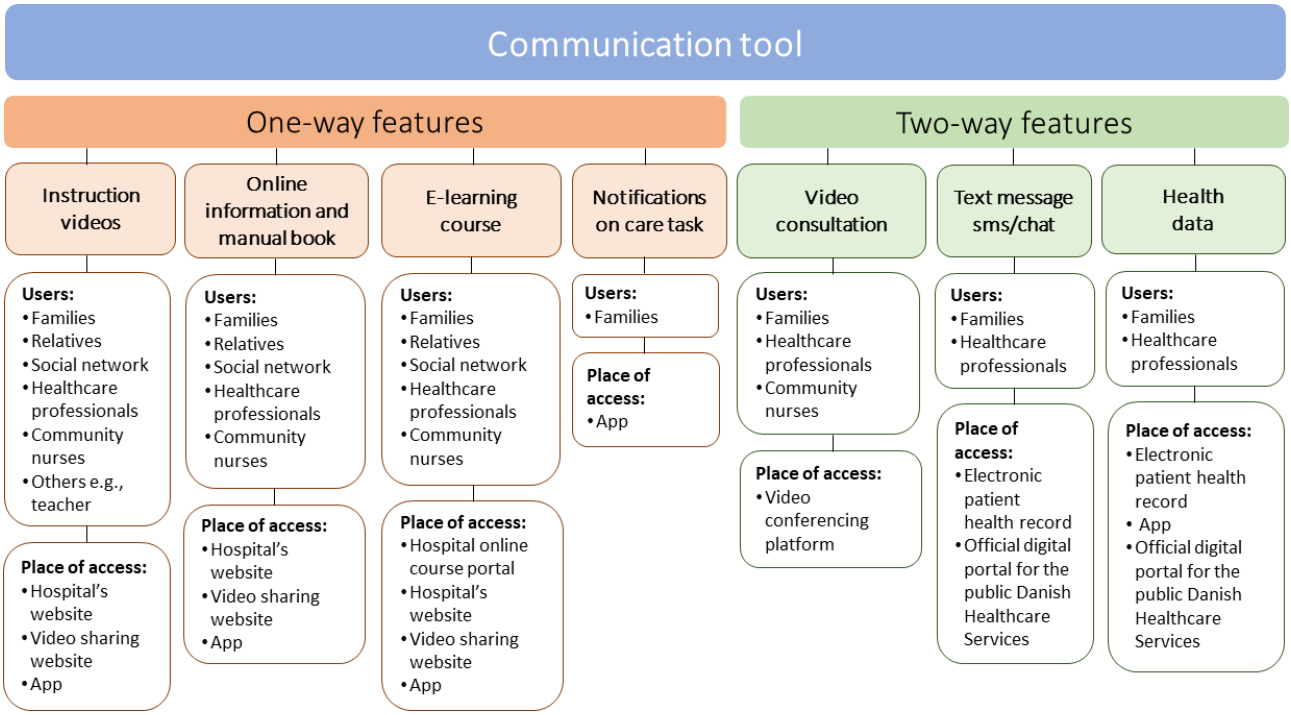
Textbox 1. Main themes and subthemes.



Overarching theme:

- Managing the extended responsibility of home infusion therapy

Main themes and their subthemes:

- Increasing safe self-management at home
  - Need for standardized information, training, and shared problem-solving
  - Being in control of home infusion therapy and feeling safe
- Adapting information and responsibility to suit individual needs
  - Repeating individualized information and training
  - Desire to share the responsibility
- Requesting digital features to ensure skill level, safety, and quality of care
  - Access to online one-way communication of knowledge and training
  - Access to interactive communication and support

Figure 1. Digital features proposed by parents and health care professionals for a future eHealth intervention.

Theme 1. Increasing Safe Self-Management at Home

Subtheme: Need for Standardized Information, Training, and Shared Problem-Solving

Overall, parents described that they were confident about the information and training they had received on how to manage home infusion therapy, and they had not experienced any problems with the pump or the child's health. But some felt that the information and training were too sparse. They appreciated the information booklet, even though they did not always have it with them when they needed it. The hospital website provided information and guidelines, but finding either one was sometimes difficult and time-consuming if immediate support was required.

Some parents thought that the information and training they received was inconsistent, making both them and their child feel insecure. They requested uniform guidelines and training regardless of which health care professionals or department taught them about managing the care tasks. They also felt unsure if they called for assistance and spoke with a health care professional who lacked the skills to provide support, sometimes forcing families to travel to the hospital.

> *I felt stressed when it [pump] sounded an alarm that showed 'low reservoir volume'. I think it was actually*

XSL•FO
RenderX

> *when the infusion bag was full. And then I called the ward after trying everything I could do at home. But when you call in the evening, there isn't necessarily anyone at work who knows much about the pump. So, they didn't know what I should do either.* [Mother 232]

Health care professionals who seldom had the task of giving parents information and training about managing the portable pump worried about how to maintain their professional skill level, making them feel insecure professionally and concerned about how that could affect the children and parents.

> *We don't provide home infusion that much at our ward and the more you physically deal with it [pump] in your hands, the better, safer, and more familiar you get with it when you teach the parents.* [Health care professional 113]

Subtheme: Being in Control of Home Infusion Therapy and Feeling Safe

The parents described that the pump was easy to manage and that they did not experience many problems related to the pump and infusion, or that their child experienced adverse effects. If a pump alarm went off, they were mostly able to manage the issue at home. They felt particularly worried if an alarm sounded due to air bubbles in the infusion set. In such situations they expressed a need for different interaction than a telephone call with the health care professionals because it had the potential to resolve problems and thereby avoiding a hospital visit.

> *I think, I think that there's a need for extra support in those kinds of situations when it [pump] acts up.* [Mother 73]

Parents described how they wanted to take on responsibility for their child's home infusion therapy as it was a way to have control over their situation. Even though they generally felt secure about the information, training, and support they received, some parents still worried about something unexpected happening, making them feel vulnerable about being home alone without a health care professional nearby. They stated that they would appreciate more support to improve their sense of safety and control of the situation.

The health care professionals also described the need to have more control when discharging a child to home infusion therapy, mentioning that they felt an extended sense of responsibility toward the child and home treatment that they sometimes found difficult to fulfill since they were unable to monitor the child's condition in the same way as at the hospital. The health care professionals lacked having a sense of the family's capacity at home; for example, they could not assess whether the procedures and observations the parents took on had been performed correctly. This lack of control preoccupied them as they worried about the risk of medication errors and adverse events. The health care professionals needed reassurance that the parents had conducted the necessary observations and procedures to help increase their feeling of control concerning the treatment they had initiated, especially because they felt responsible for the child's well-being, treatment, observations, and transferring such specialized care tasks to the parents without their presence to safeguard them at home.

> *And then there's the issue of whose responsibility it is when you hand it [therapy] over to the parents? Because I agree that they only want the best for their child. There's no doubt about that.* [Health care professional 117]

Theme 2. Adapting Information and Responsibility to Suit Individual Needs

Subtheme: Repeating Individualized Information and Training

Parents described feeling mentally burdened by their child's illness, especially those whose child had long-term illness. They had difficulty remembering and comprehending information and training, causing them to request the possibility to repeat information and training once they returned home.

> *You're bombarded with things that I, as a parent, must be able to gain an overview of, including how the pump works. Then, when you get home you think: "God, what was it that they said about that?" And in that situation, it would be really nice if you could seek help [digitally/online]: "Could you tell me again, what I should do, when I should do this and that?"* [Mother 173]

The health care professionals also worried that the parents did not always have the mental surplus to handle new or additional tasks in relation to home infusion therapy. They expressed a need for providing more individualized support to parents at home as they saw the parents' mental surplus as changing over time. It was important for them to ensure that the parents felt safe and were not additionally burdened by managing home infusion therapy.

> *Maybe we could come by to force them to accept it [home infusion], because we've been used to that. Then there's a psychological aspect to it, where you constantly have to determine where they are in the treatment trajectory: "Do you still feel secure about doing home care?" Because I think the families experience a tremendous number of mental ups and downs.* [Health care professional 262]

Subtheme: Desire to Share the Responsibility

The parents described that they would like to involve other caregivers and professionals in the home infusion therapy to share the responsibility, also their child if the child wanted to be involved. Often only one parent was trained to manage the pump and medicine, leaving them with the sole responsibility. One parent said that her partner did not want to help with it due to how unsure it made him feel.

> *He's perhaps afraid of ending up doing something wrong [with the pump] that may harm our son, which I think might paralyze him a little in terms of his ability to act.* [Mother 196]

Another parent described how the partner, who had not been trained at the hospital, panicked at home when an alarm on the

XSL•FO
RenderX

pump went off. Parents also emphasized the need for additional support to facilitate training and guidance at home to increase the sense of safety and control for the child and other caregivers with the therapy and to support shared responsibility. Like the parents, the health care professionals supported and emphasized the need for parents to share the responsibility for managing home infusion therapy, for example, with grandparents and daycare staff.

> *One of the disadvantages of home treatment is that all of the responsibility lies with one parent, or two, to manage it [the pump]. It's a great deal to have to take care of regularly.* [Health care professional 270]

However, the health care professionals found that letting the parents supervise others was challenging because they worried that training others might put an additional burden on the parent or potentially be problematic regarding quality of care and safety.

Theme 3. Requesting Digital Features to Ensure Skill Level, Safety, and Quality of Care

Subtheme: Access to Online One-Way Communication of Knowledge and Training

Parents suggested that online information, guidelines, and instruction videos would be helpful and should be easily accessible in one place, for example, the hospital's website or an app, making it more straightforward and quicker to find information and training, which would potentially allow parents to solve technical problems themselves.

> *I've actually thought of something that could be really nice, being able to watch a short video, if there's something that's tricky, instead of having to read about it. Because you can't be sure that you'll have the peace of mind to understand it [written information] when you're in the middle of a crisis.* [Mother 29]

> *Sometimes they call and say that they can't find it. They've lost their information material and manual, so they ask: "What should we do when she gets a fever or becomes flush or?"* [Health care professional F2]

If information on paper got misplaced or was forgotten, a digital version would always be available. Parents suggested that explanatory instruction videos could be developed to show how to solve the most common problems, for example, removing air bubbles in the infusion set or resolving other practical technical issues related to the pump. The health care professionals supported the idea of having information, guidelines, and instruction videos available online to provide professional reassurance that the parents could find information targeted their needs and skills. They explained that instruction videos could also meet their own needs for maintaining their skill level, along with e-learning. Furthermore, both parents and health care professionals expressed how online material would ensure that the information and skills the parents acquired were aligned with the health care professionals. However, the health care professionals had concerns about how to regularly keep online material and instruction videos updated based on the newest evidence-based practices.

Parents and health care professionals described how online guidelines and instruction videos could help bolster sharing responsibility for managing home infusion therapy for those who did not receive training at the hospital. Parents also expressed that this would be useful for children interested in self-managing their therapy, also because they were already familiar with using digital platforms with videos. Instruction videos also represent a useful tool for those who learn better visually, just as they can be subtitled or dubbed into different languages, improving access to allow more families to receive home infusion therapy.

Subtheme: Access to Interactive Communication and Support

Parents also mentioned the benefits of video consultations for receiving guidance in managing the pump and resolving any issues with the pump at home to avoid traveling to the hospital. Video consultations would also provide visual advantages that were absent in ordinary telephone conversations in terms of guidance and preventing misunderstandings.

> *A support feature would be very good to have. If you [nurses] had a smartphone available to make video calls to film what the pump says, because my wife panicked a little bit and the communication on the phone with the nurse [at the hospital] was not that great; the nurse and my wife misunderstood one another. So, I just drove him to the hospital.* [Father 112]

Health care professionals also requested the option of using video consultations to reassure parents that their observations were relevant and to guide them in shared problem-solving. Video consultations could potentially improve their sense of safety and professional control by allowing them to assess the child's condition and the parent's management of the therapy.

> *You're sure that the parents know how to change the infusion bag. And if you're in doubt at home, it's evening and you call and you can't be guided on the phone, then it would be nice be able to see it to avoid any misunderstandings.* [Health care professional 208]

However, the health care professionals had concerns. Even though the child was visible on video, they could not use their clinical judgment based on all their senses compared with face-to-face clinical observations at the hospital. They were uneasy about care becoming too digital.

> *I think it's a good idea [home care], but I also worry about not seeing the children: "How are you doing and how do you look?" Can the parents always assess that? The nursing loses something; it simply becomes too digital. That involves using your eyes, touch, and sense of smell and whatever else we run around doing.* [Health care professional 133]

Both parents and health care professionals stressed that the work procedures and settings for digital interactions would require

XSL•FO
RenderX

aligning expectations. For example, video consultations include specific requirements, such as the need for computers with the right equipment, setting up consultations in a confidential setting, and how to manage scheduling consultations, also in the evening and at night, not to mention having skilled health care professionals available to provide support 24/7.

Parents were also interested in being able to send data to the hospital, such as their child's blood pressure or pictures of skin changes to reassure the parents and health care professionals regarding the parents' observations. However, some parents had misgivings about perhaps feeling pressured to provide more data than they could manage. In addition, parents and health care professionals alike were uneasy about when and who was responsible for assessing and reacting to the data at the hospital, and the timespan in which parents could expect to receive an answer. Managing incoming measurements would be required for this to succeed and make all parties feel safer. Furthermore, parents and health care professionals suggested that the parents could also receive notifications to ensure that care tasks like taking their child's temperature and assessing intravenous access were performed at the right time.

Discussion

Principal Findings

We found that parents and health care professionals largely had corresponding needs for safety in home infusion therapy but that their preferences for digital features in a future eHealth intervention to meet those needs were based on different rationalities. It was vital that everyone felt safe about using home infusion therapy, and they suggested various digital features to meet their needs to have consistent knowledge, problem-solving skills, reassurance that the parents could manage the home infusion therapy and their child's well-being, maintain their skill level, and share responsibility with more than one parent. They emphasized the need for an eHealth intervention that provides additional communication support to existing care to enhance safety, self-management, and quality of care.

Comparison With Previous Work

A key finding was how home infusion therapy was linked to the extended responsibility of the parents and health care professionals, the former at home without the presence of a nurse, and that latter in terms of having the professional responsibility without being present in the child's home. We suggest that this extended responsibility generates specific needs and preferences for the digital features a future eHealth intervention should have.

Parents found their responsibilities manageable and felt greater sense of control when they had adequate information and training, along with access to skilled health care professionals when contacting the hospital without these resources, they felt unsure. Two other studies describing the parents' experiences of insecurity and fear of overlooking something important when their child received home intravenous therapy suggested improvements to decrease worries, such as enhanced preparation, alignment of expectations, and accessible visually based and text-based information [3,34]. Another study also found that parental management of care for their child after surgery at home felt insecure, for example, they were unable to identify postoperative complications [35]. The information they had received was partially incomplete, and there was a gap in support at home, such as some health care professionals lacking the right knowledge to provide support contacted by parents [35]. Even though the parents in our study had some similar experiences, they were generally satisfied overall but would like to see digital features bolster existing support.

Another aspect of the extended responsibility was the health care professionals' concerns about their ability to clinically assess the child's condition and to know how the parent was managing home infusion therapy. These concerns challenged their professionalism and ethics. For them, the setup comprised nursing at a distance, causing them to worry about how to ensure quality of care. They suggested that various digital features could bridge this distance and had to correspond to the parents' needs. Both parents and health care professionals suggested monitoring, such as sending temperature data to the hospital and notifications to parents to remember tasks. These features would help meet their need for reassurance and increase their sense of safety. One study showed that participants valued notifications as reminders for activities to be carried out at home [36], while another study on designing a home monitoring system for children with a medically complex condition showed how parents preferred to track symptoms to identify early changes in their child's health that could lead to an appropriate intervention [37]. However, parents in our study also worried that they would feel pressured to provide more monitoring and data than they could manage. As a result, adjusting the amount of monitoring and continuously assessing how parents manage at home is important to avoid increased caregiver stress.

The suggestions parents and HCPs provided in our study are comparable with the study by Nkoy et al [37] on the needs of caregivers for designing a home monitoring system for children with a medically complex condition. The parents wanted a mobile health tool that included features to track symptoms and report their child's symptoms that was user friendly, in addition to having the ability to report interventions provided at home, have direct access to hospital through text messaging, and real-time sharing of data, not to mention the capacity to upload a photo or video for the health care professionals [37]. Two studies in which parents managed nursing care for children after surgery or born prematurely developed a successful eHealth tablet for the aforementioned reasons [17,38]. The parents were given an eHealth tablet before their child was discharged from a highly specialized department and that allowed them chat, make video calls, send photos, write daily reports, and get feedback from health care professionals, which facilitated early detection of complications. These features provided support and easy access to communication with health care professionals, creating a sense of security that the parents highly appreciated [17,38]. Due to similarities with our study, this suggest that a corresponding eHealth intervention could support the families and health care professionals in our study.

However, the health care professionals were also concerned that digital features might exacerbate the distance between them

XSL•FO
RenderX

and the family, which is in line with a study on mobile health clinic appointments on parenteral nutrition at home done through a tablet [39]. Parents and health care professionals were very satisfied with how convenient and easy communication was, but the health care professionals reported that the inability to make accurate clinical assessments using the tablet was a significant challenge [39]. Research also shows that another concern is that telemedicine may depersonalize the patient and clinician relationship due to a lack of in-person interaction [11,40]. These key concerns must be taken into consideration when developing an eHealth intervention and will be explored further in the subsequent studies of the development and evaluation of the intervention in this research project.

Another concern was the reservations health care professionals had regarding workflow and setting, for example, how to organize and assess incoming data and chats at all times of day. Furthermore, organizational issues like maintaining confidentiality had to be considered when doing planned and unplanned video consultations. The study with the eHealth tablet showed that parents felt they had to wait too long to receive answers or feedback from health care professionals at the hospital [17]. Another study reported that clinicians emphasized the importance of having clear guidelines for scheduling and use of telemedicine in pediatric emergency settings [11]. Finally, a systematic review on factors concerning the success and failure of eHealth interventions also showed how workflow caused several barriers to success [41]. Accordingly, it is important to consider the needs of health care professionals, as motivating them to use telehealth can otherwise be challenging [42,43].

The extended responsibility that home infusion therapy entails emphasizes the importance of adjusting information and training, in addition to managing the capacity and needs of the individual child and parents. The parents' mental resources varied during their child's treatment, and research shows how parents obtain and act differently regarding health-related information concerning their child [35,44]. Both parents and health care professionals suggested that digital features could support the individualized aspects as the parents could, when necessary, repeat information and training, solve problems, and receive guidance. In addition, the parents and health care professionals in our study were preoccupied with sharing their responsibility with others to avoid distorting the amount of caregiving placed on one parent. Studies show that telemedicine can address these issues, by communication in greater alignment with the parents' own preferences and pace, not to mention that of families who live far from the hospital and wish to avoid the time and expense transportation and parking [17,38,45].

Strengths and Limitations

This study's strengths include its participatory design, which involved families and health care professionals at the beginning of the development process. The demographics and experiences of the sample of children with acute or long-term illness is also varied, just as both mothers and fathers were included, not to mention children to some extent. The child was invited to participate with their parent, and 13 children were present at the interview, 2 of whom participated actively. However, separate interviews would improve our understanding of the child's needs since the parent may withhold experiences and opinions due to the child's presence. Age-specific methods could have been used to involve and interview children, which would have provided additional insights into their unique needs and preferences. Children will be involved and interviewed in the evaluation study of this research project. The study is conducted in a specific geographic and health care setting, which may limit the generalizability of the findings to other countries and settings with different health care systems.

Data were collected during the early phase of the COVID-19 pandemic, and video consultations and other telehealth options were not used at the department on a regular basis at that time. This may have influenced participants' perceptions of eHealth and impacted the results in the sense that their technology readiness was limited. Since then, the use of telehealth has increased extensively in Denmark and abroad, perhaps causing our findings to appear obvious.

Conclusions

Our study highlights the need parents and health care professionals have for increased safety and easier access to communication when receiving and providing home infusion therapy. Their needs and preferences corresponded with each other, and they suggested key digital features for a pediatric eHealth intervention to provide consistent knowledge, skills, and problem-solving during home infusion therapy. The study emphasizes the need to increase access to home infusion therapy by using digital features, and our findings can provide clarity in terms of developing an eHealth intervention to support pediatric home infusion therapy tailored to individual needs.

Acknowledgments

The authors would like to express great gratitude to the participating families and health care professionals for sharing their experiences with us. This research is part of the research program eChildHealth supported by FORTE (R-257-A14720) and the research program iCOPE supported by European Regional Development Fund (2019-5934). The study was supported by grants from iCOPE and FORTE.

Abstract

Background: The COVID-19 pandemic was a paradigm shift in global health care. This situation highlighted the role of telemedicine in adapting to the care requirements of pediatric patients and their families by facilitating remote consultations and ensuring continuity of care.

Objective: We aimed to establish the usefulness of a telemedicine program for caregivers of children with complex chronic conditions.

Methods: We performed a quasi-experimental pre-post intervention study of a telemedicine program, regarding health care system use and caregiver quality of life while comparing two periods: before and during the COVID-19 pandemic. This study included caregivers of children with complex chronic conditions followed-up in a specialized unit.

Results: A total of 34 families were included. The mean number of visits per year was higher in the preintervention period for both primary care consultations (*P*=.03) and hospital-specialized medical consultations (*P*=.03). The number of emergency room visits per year was lower in the pandemic period compared to the prepandemic period (*P*=.01). In both groups, an improvement in caregiver quality of life was detected at 12 months (*P*=.03). However, the Rosenberg self-esteem scale score for the primary caregiver was significantly lower at 3 months compared to the baseline (*P*=.03).

Conclusions: Our study demonstrates that the use of a telemedicine program resulted in decreased scheduled face-to-face care visits and a reduction in the number of emergency department visits. Regarding the caregiver quality of life, outcomes were poorer among families whose children were affected by neurological conditions or were diagnosed at an older age.

Introduction

Technological advances and progress in medicine have reduced infant mortality [1,2]. These survival successes have contributed to an increase in the prevalence of incurable diseases and disability, which leads us to reassess the way we approach and organize health services to adapt them to these new care needs [3,4].

In high-income countries, children with a complex chronic condition (CCC) represent 0.67% - 5% of the pediatric population; however, they consume up to 40% of total health expenditure, involving a high level of care both in and out of hospital, primary care, and non-health services [5-9].

The prevalence of life-threatening or life-limiting illnesses has increased in recent decades, with an estimated 61.1 per 10,000 children aged 1 - 19 years in the United Kingdom. As reported,

XSL•FO
RenderX

approximately 30% of these children have cancer; the remaining 70% comprise a combination of conditions, mainly neurodegenerative, metabolic, and genetic. Of these, 50% children will require the specialized care of a pediatric palliative care unit [10,11].

Therefore, a new strategy is required to transform the current care model, which is focused on treatment—where the patient is a passive subject—into a proactive model more centered on the needs of patients and their caregivers. In this revised model, the patients have more information and autonomy to play an active role in managing the disease [12,13].

In this context, new information and communication technologies (ICTs) provide tools that enable access to a wide range of resources. Numerous studies have endorsed telehealth as a supplementary approach to in-person care for managing chronic diseases [14]. However, the effectiveness of telehealth as a replacement for face-to-face care in patients with chronic conditions remains unclear [15,16].

In 2020, the COVID-19 pandemic transformed medical care through telemedicine with a demand for remote health care and telehealth [17,18]. While the world faced an unprecedented pandemic, patients with chronic diseases required special attention on an ongoing basis and, if warranted, an adaptation of their usual care [19]. This need arose as health care systems were overwhelmed, with most resources diverted to manage COVID-19 patients and their associated complications. The resulting strain on primary and hospital care made in-person evaluations for patients with chronic conditions especially challenging [20].

In complex chronic patient and pediatric palliative care units, telemedicine provides an accessible and equitable tool. With these tools, families can remain in contact with professionals by establishing a schedule for specific services in a time-effective manner and adapted to the stage of the illness [21,22].

Due to the COVID-19 pandemic and considering the vulnerability and fragility of these patients, some of the tools offered by ICT for the continuity of care have become even more useful, as they allow nonface-to-face visits; but with a capacity comparable to face-to-face visits, minimizing the risk of infection, and reducing the need to travel to a medical center [23]. Moreover, these tools may enhance treatment adherence, prevent medication errors, and foster greater engagement in self-care practices [24].

This study aimed to develop and evaluate a telemedicine program for the care of children with CCCs or those receiving palliative care, both before and during the COVID-19 pandemic, within a specialized pediatric palliative care unit.

Methods

Study Design and Setting

We designed a quasi-experimental pre-post intervention study in the Complex Chronic Patient and Palliative Care Unit of a pediatric tertiary hospital.

The study population comprised children with CCCs or those needing palliative care and their families. Inclusion criteria required that children meet the definition of medical complexity algorithm defined by the Seattle Children's Hospital Group and score at least 6,5 points on the PedCom Scale [25,26]. Participants also had to be followed-up in the Complex Chronic Patient and Pediatric Palliative Care Unit of the hospital and had a high level of complexity, defined not only by the identification of the children as complex chronic patients but also by high consumption of resources: two or more hospital admissions, at least one admission to intensive care, or six or more visits to the emergency department in the last twelve months [27]. Patients older than 18 years or those whose families did not provide informed consent were excluded.

Ethical Considerations

The study protocol was in accordance with the Declaration of Helsinki. All caregivers were informed about the study and signed a consent form, with no financial compensation provided. All data were anonymized to ensure confidentiality. This study was approved by the Research Ethics Committee of Malaga in May 2017 (reference: PIN-0287 - 2016).

Telemedicine Program Description

The telemedicine program was remotely managed and controlled by the hospital and its technical support center. It comprised three main functionalities:

1. Communication: The technology used was an Android-based smart TV platform connected to a television, which allows access to advanced telecommunication and medical device management services. It allows videoconferencing between patient (through the TV) and hospital (via PC), or between the patient and the medical professional (via PC, tablet, or smartphone), based on session initiation protocol technology (ie, market standard).
2. Information and training: Through the platform, families accessed a menu of audiovisual contents. The contents were developed by the professionals of the unit. This includes: information including telephone numbers of interest for caregivers; individualized access to videos, according to specific CCCs, with recommendations, procedures, theoretical and practical workshops including specific training such as nutritional management for patients receiving enteral support, oxygen therapy, or cardiopulmonary resuscitation, and PowerPoint presentations on neonatal techniques and care, secretion aspiration, and monitoring and respiratory care; and information on the current vaccination schedule.
1. Health care: The platform allowed clinical assessment via video call, with the option of requesting tests (laboratory and radiological), modification of technological support parameters, and issuing electronic medical prescriptions.

During recruitment, to avoid selection bias caused by the digital divide for families who did not have internet access at home, it was provided through project funding.

XSL•FO
RenderX

Evaluation of the Program

The evaluation of the program was undertaken through the comparison of two one-year time periods; before the pandemic (March 2019 to February 2020) and during the pandemic (March 2020 to February 2021).

Sociodemographic variables described included age, gender, primary caregiver (parent or both parents), number of siblings, place of residence, and country of origin.

- Evaluation of face-to-face health care variables were categorized as follows: (1) scheduled: primary care consultations, hospital outpatient consultations per year, number of outpatient consultations in the Unit, number of home visits made by the Unit, number of scheduled hospital admissions; (2) urgent: number of emergency room visits, and number of urgent hospital admissions.
- Evaluation of telephone health care variables: (1) number of calls from the Unit to caregivers and (2) number of calls from caregivers to the Unit.
- Caregiver reported outcomes: (1) the Rosenberg Self-Esteem Scale [28,29], (2) the Positive and Negative Affect Schedule (PANAS) [30,31], (3) health-related quality of life of primary caregivers (EuroQol-5D-5L) [32], (4) short Zarit Caregiver Burden Interview (ZARIT) scale to assess primary caregiver burden [33,34].

The evaluation of the telemedicine program was carried out with periodic assessments (ie, baseline, 3, 6, and 12 months) of the health care variables and caregiver reported outcomes. The last assessment was carried out 12 months after the start of the intervention. The health care data was collected by telephone and the tests by mail and email.

Data Analysis

Data analysis was performed using free R software (version 4.0.2; R Foundation for Statistical Computing). The Shapiro-Wilk test analysis was performed to determine the normality of the study variables. Data were presented as mean (SD) values in normal distributions or as median (IQR) for non-normal distributions. For independent quantitative variables, Student one-tailed *t* test was used for normally distributed data, and the Mann-Whitney *U* test for not normal distributed data. The Wilcoxon signed-rank test was performed to analyze differences in the non-normal distributions, and the paired *t* test for normal distributed data. To compare qualitative variables, the χ^2 test was used for independent samples and McNemar test for related samples. A *P* value <.05 was considered statistically significant. *P* values were adjusted using the Benjamini-Hochberg correction to control for multiple comparisons.

Results

Study Population Characteristics

A total of 34 patients were included, ranging in age from 3 months to 14.2 years, with a median age of 4.9 years; 53% (18/34) were female participants. The most common CCC that affected our patients was neurological 73% (n=25), followed by gastrointestinal 71% (n=24), respiratory 50% (n=17), cardiovascular 41% (n=14), and oncological 21% (n=7). In addition, neurological CCCs were also the most frequent primary CCC in 47% (n=16), with cerebral palsy being the most prevalent neurological disease (11/16, 69%).

The primary caregiver was the mother in 82% (n=28) and 47% (n=16) of the families received social assistance; 91% of the families (n=31) received psychological care. A total of 29% (n=10) of the families were from a foreign country and 41% (n=14) had no other children; the number of children per family ranged from 0 to 5, with a median of 1.

Impact of the Telemedicine Program on Health Care Activity During the Pandemic

Regarding scheduled care, bivariate analysis showed that the mean number of visits to primary care consultations per year was higher in the pre-pandemic period (*P*=.03), as well as more hospital specialty consultations (*P*=.03) (Table 1).

In terms of emergency care, there were significant differences in the number of emergency department visits per year during the compared to the prepandemic period (*P*=.01), with fewer visits during the pandemic. No significant differences were found in emergency hospital admissions between the two periods (Table 1).

Regarding telephone care provided by the Unit, we noted a nonsignificant increase in the number of calls made by the Unit during the pandemic (*P*=.06). However, there was a significant increase in telephone calls made by caregivers to the Unit during the pandemic compared to the pre-pandemic period (*P*=.003) (Table 2).

There were no significant differences between the mean length of hospital stays (measured in days) before and during the pandemic.

Tables 1 and 2 display the variables related to the health care provided.

XSL•FO
RenderX

Table . Analysis of variables associated with face-to-face health care activity.

Type of care activity	Prepandemic period with telemedicine, mean (SD)	Pandemic period with telemedicine, mean (SD)	*P* value
Scheduled			
Primary care consultations	9.2 (9.9)	6.6 (5.9)	.03
Scheduled consultations hospital specialties	29.6 (19.2)	23.4 (19.2)	.03
Nurse consultations at CC[a] and PPC[b] Unit	8.3 (6.8)	10.1 (9.5)	.54
Pediatrician consultations at CC and PPC Unit	6.7 (5.6)	7.2 (5.6)	.77
Nursing home visits at CC and PPC Unit	3.1 (5.3)	2.4 (4.8)	.20
Pediatrician home visits CC and PPC Unit	2.8 (5.0)	2.1 (4.4)	.09
Scheduled admissions	0.6 (1.0)	0.6 (0.8)	.60
Urgent			
Emergency hospital visits	3.6 (4.0)	2.1 (2.1)	.01
Urgent hospital admissions	1.4 (1.5)	1.2 (1.5)	.19

[a]CC: complex chronic.

[b]PPC: pediatric palliative care

Table . Analysis of variables related to telephone health care activity.

Type of care activity	Pretelemedicine period, mean (SD)	Pandemic period with telemedicine, mean (SD)	*P* value
Unit calls to caregivers	36.4 (34)	48 (26)	.06
Caregivers calls to the Unit	6.2 (7.8)	10.5 (9.5)	.003

Impact of the Telemedicine Program on the Caregiver-Reported Outcomes

Significant differences were seen in the visual analogue scale (VAS) of the EuroQol five-dimension (EQ-5D) quality of life test of the primary caregivers at 12 months compared with baseline, with an increase in VAS scores at 12 months (*P*=.03).

The Rosenberg self-esteem scale scores of the primary caregivers were significantly lower at 3 months than at baseline (*P*=.03). There was a significant negative correlation between the short Zarit Caregiver Burden Interview (ZARIT) scale for primary caregiver burden at 6 months and the number of siblings (adjusted R^2=0.37; *P*=.009). The VAS score of the EQ-5D quality of life scale for primary caregivers at 12 months correlated negatively and significantly with age at diagnosis of the child's illness (adjusted R^2=0.24; *P*=.04).

The difference in the index value of the EQ-5D quality of life scale for primary caregivers from baseline to 3 months was negatively correlated with the age at patient admission (adjusted R^2=0.97; *P*=.007).

In the analysis of the relationship between caregiver quality of life and the different types of CCCs, the difference in index value of the EQ-5D quality of life scale for primary caregivers from baseline to 3 months was negatively correlated with neurological disease (adjusted R^2=0.89; *P*=.03).

Table 3 shows the results of the tests at baseline and at 3, 6, and 12 months.

Discussion

Principal Findings

The development of telemedicine programs has transformed care for patients with chronic illnesses or those in palliative situations. Several studies including the one by Prabhakaran et al [35], highlights the effectiveness of a mobile health intervention in primary care settings within rural Indian communities. This initiative focused on preventing and managing cardiometabolic conditions, depression, and related risk factors among adults. In pediatrics, evidence-based studies, including the consensus developed by the Italian Societies of Telemedicine, Preventive and Social Pediatrics, and Pediatric Primary Care, among others, have demonstrated the critical role of telemedicine in managing patients with chronic conditions (eg, cardiology, respiratory, or neurology) or those requiring palliative care. These findings underscore the potential of telemedicine to enhance healthcare delivery by facilitating improved collaboration among multidisciplinary professionals and patients, creating innovative opportunities to optimize clinical outcomes and service quality [36].

In our study, the most common condition was neurological, which is the most frequent condition as described in literature indicating that neurological patients are the most prevalent. Our findings are in accordance with prior research, with neurological CCCs being the most frequent, followed by gastrointestinal and respiratory CCCs. Also coinciding with published findings, the mother most often fulfilled the role of the primary caregiver [13,37-41].

During the COVID-19 pandemic, as seen in other studies, a decrease was observed in both scheduled and urgent care for children with CCCs, similar to trends in the general pediatric population and among children with special health care needs [42-49].

The increase in telephone consultations during the pandemic, both initiated by the Unit and caregivers, especially the increase in calls from caregivers, may be explained by the decrease in face-to-face care in primary care and in specialized hospital care during this period. This finding highlights the support provided by the Unit via telephone to minimize the impact of the pandemic on children with CCCs, as described in several studies focused on specific care strategies aimed at this particularly vulnerable population [50].

In our study, the absence of significant differences in scheduled or urgent hospital admissions, has been described in other studies on telemedicine in children with CCCs [22]. This may be due to the high complexity of the patients included in this study, where pandemic-related factors may not have influenced the number of hospital admissions or the length of hospital stays.

Several studies have described the importance of the psychosocial needs of children with CCCs and their families and how these needs, especially concerning mental health increased during the pandemic [51,52]. To date, few studies have demonstrated improvements in the quality of life of caregivers from telemedicine programs, often due to the cross-sectional design of studies without multiple cut-off points. Our study highlights the importance of conducting studies that monitor the impact and benefits of these programs throughout the intervention to verify their usefulness [53-55].

In our study, a greater burden on primary caregivers was detected in families with more children, a demographic factor not previously described and one that should be considered to reinforce support for these families.

The quality of life of the primary caregivers measured by the VAS value of the EQ-5D scale at 12 months was poorer in those with children with CCCs diagnosed at an older age. Similarly, we found a negative correlation between the difference in the EQ-5D quality of life scale of the primary caregivers at 3 months, compared to baseline in children with CCCs who were older at admission to the Unit. Our analysis revealed that both the child's age at diagnosis and age at Unit admission were inversely associated with parental quality of life, showing the

XSL•FO
RenderX

most pronounced negative impact at 3- and 12-month follow-up during the pandemic. The influence of the age of the child with a CCC on the quality of life of the primary caregivers during the pandemic has not been examined previously and merits further investigation as a potential modulator of the quality of life of the parents.

Published studies on the impact of neurological diseases have shown an increased family, work, and economic burden on primary caregivers, specifically on caregivers of children with cerebral palsy [56]. In our study, a negative correlation was found between the index value of the EQ-5D quality of life scale of the primary caregiver at 3 months, compared to baseline with neurological CCCs, which was also the most frequent CCC observed.

The observed lower self-esteem among the primary caregivers at 3 months of the telemedicine program during the pandemic setting may be explained by the effects of full confinement, including reduced psychosocial and family support, adaptation of home care with a change in care support, and the increased care burden. This reduction in the quality of life of the primary caregiver at 3 months has not been evaluated in other studies and may be useful for reinforcing psychosocial support to families, considering this period as a turning point in caregiving. Conversely, the observed improvement in VAS of the EQ-5D quality of life test may reflect an increased quality of life at 12 months, which could be attributed to adaptation to the situation as well as decreased isolation measures one year after the pandemic.

It is important to leverage the growth of the ICTs during the pandemic for the benefit of patients, especially those who are most vulnerable and with specific care needs such as children with CCCs. Telemedicine provides equity in care and efforts should be made to evaluate the impact of telemedicine programs in patients, primary caregivers, and health care teams, taking into account the clinical, economic, and quality of life variables in patients and their families monitored over time.

Limitations

The use of telemedicine prior to the pandemic was demonstrated to be effective in children with CCCs, both in reducing the number of emergency department visits and costs [55,57-61]. However, in our study, it was challenging to determine with certainty whether the decrease in urgent or unscheduled care could be attributed to the COVID-19 pandemic or the telemedicine program intervention. During the pandemic, there was a decrease in emergency department visits, as many caregivers were afraid to go to hospitals to avoid infections in their children [43,45]. In addition, we must take into account the decrease in respiratory symptoms due to the confinement and isolation measures described in several studies [45,47,49]. Studies with larger and more homogeneous samples should be carried out after the pandemic to assess whether its effectiveness in terms of care is maintained without the interference caused by the pandemic.

Conclusions

In our study, the use of a telemedicine program during the pandemic resulted in a decrease in scheduled face-to-face care and a reduction in the number of emergency department visits compared to the prepandemic period. Conversely, we observed an increase in telephone support without any impact on hospital admissions. We identified the most vulnerable families in this group of patients, including those with a child affected by a neurological condition, those who had an older child when the disease was diagnosed, and families with a greater number of children. These insights allowed could help guide the redirection of limited resources. Our findings indicated that the telemedicine program was effective in the supporting care of children with CCCs and their families.

Acknowledgments

SmartHealth TV Solutions developed and provided the technology for the project. The authors acknowledge SmartHealth TV Solutions for supporting the project technology and its COVID-19 adaptations. The authors also thank Maria Repice for assistance with the English version of the manuscript.

This project was supported by the Andalusian Public Foundation for Health and Biomedicine Research of Malaga (FIMABIS); project title: *Implementation of a Telemedicine Program in the Care of Complex-Pluripathological Chronic Patients and Patients Receiving Palliative Care in a Pediatric Home Hospitalization Unit* (PIN-0287-2016). This project received the II Unicaja Award for Innovation in Biomedicine and Health, which enabled the improvement and continuity of the project in 2019.

Abstract

Background: The early identification of developmental concerns requires understanding individual differences that may represent early signs of neurodevelopmental conditions. However, few studies have longitudinally examined how child and maternal factors interact to shape these early developmental characteristics.

Objective: We aim to identify factors from the perinatal to infant periods associated with early developmental characteristics that may precede formal diagnoses and propose a method for evaluating individual differences in neurodevelopmental trajectories.

Methods: A prospective longitudinal observational study of 147 mother-child pairs was conducted from gestation to 12 months post partum. Assessments included prenatal questionnaires and blood collection, cord blood at delivery, and postpartum questionnaires at 1, 6, and 12 months. The Modified Checklist for Autism in Toddlers (M-CHAT) was used to evaluate developmental characteristics that might indicate early signs of atypical neurodevelopment. Polychoric or polyserial correlation coefficients assessed relationships between M-CHAT scores and longitudinal variables. L2-regularized logistic regression and Shapley Additive Explanations predicted M-CHAT scores and determined feature contributions.

Results: Twenty-one factors (4 prenatal, 3 at birth, and 14 postnatal) showed significant associations with M-CHAT scores (adjusted *P* values<.05). The predictive accuracy for M-CHAT scores demonstrated reasonable predictive accuracy (area under the receiver operating characteristic curve=0.79). Key predictors included infant sleep status after 6 months (nighttime sleep duration, bedtime, and difficulties falling asleep), maternal Kessler Psychological Distress Scale scores, and Mother-to-Infant Bonding Scale scores after late gestation.

Conclusion: Maternal psychological distress, mother-infant bonding, and infant sleep patterns were identified as significant predictors of early developmental characteristics that may indicate emerging developmental concerns. This study advances our

understanding of early developmental assessment by providing a novel approach to identifying and evaluating early indicators of atypical neurodevelopment.

early developmental signs; neurodevelopmental screening; risk factors; prediction; early intervention; longitudinal study

Introduction

Early identification of neurodevelopmental disorders and timely intervention are crucial for optimizing developmental outcomes in children [1]. Children exhibit considerable individual differences in their developmental trajectories during the first year of life, particularly in preverbal social behavior skills [2]. These differences have emerged as crucial areas of study in neurodevelopmental research, as some behavioral characteristics observed during infancy may represent early indicators of developmental concerns [3-5]. Similar to how the concept of mild cognitive impairment has facilitated early intervention in preclinical stages of dementia [6], identifying early indicators of developmental concerns may enable more timely and effective support strategies. However, the complex nature of early development, with its inherent variability and multiple influencing factors, has made it challenging to identify and interpret these early indicators reliably.

Multiple factors influence early childhood neurodevelopment, including prenatal conditions such as maternal immune activation [7], stress [8], and nutritional status, as well as postnatal factors including parental depression [9,10] and early life experiences [11]. Recent research has also highlighted the importance of biological factors such as cytokine profiles [12-14] and sleep-wake rhythms [15-18] in early neurodevelopment. While these factors have been studied individually, their complex interactions across time and their cumulative impact on neurodevelopmental trajectories remain poorly understood.

This study is an exploratory longitudinal investigation conducted in Japan, following mothers and children from the perinatal period (20 weeks of gestation) to the end of infancy (12 months of age). Using an innovative explainable artificial intelligence methodology, we aimed to visualize and analyze how various longitudinal factors interact to influence individual neurodevelopmental trajectories during infancy. Specifically, we assessed preverbal social behavior skills at 12 months of age as potential early indicators of developmental concerns using the Modified Checklist for Autism in Toddlers (M-CHAT) [3,5], and systematically evaluated how multiple observed factors throughout the first year of life contributed to these developmental characteristics. This approach enables a comprehensive understanding of the temporal dynamics and relative importance of various factors in shaping early neurodevelopmental trajectories, potentially identifying key time points and factors for early intervention.

Methods

Recruitment

This study is part of an ongoing multicenter Japanese longitudinal research conducted by 6 collaborating institutions—namely, Kyushu University Graduate School of Medicine, Kagawa University School of Medicine, Tohoku University Graduate School of Medicine, Kyoto University School of Medicine, Fukuoka City Children's Hospital, and RIKEN. Pregnant women were recruited between October 2018 and June 2020 at 5 of the collaborating institutions (excluding RIKEN). Overall, 200 women who fulfilled the inclusion criteria (aged ≥20 years, pregnant with a gestational period of less than 26 completed weeks, and fetus in stable condition) agreed to participate. The exclusion criteria were the requirement for proxy consent or the inability to provide voluntary consent. These criteria were established by the Ethical Guidelines for Medical and Health Research Involving Human Subjects to ensure that severe comorbidities or extreme factors would not influence the results of this study. Participants were followed up by visiting the affiliated facilities at midgestation (24 - 26 weeks), late gestation (34 - 38 weeks), at birth, and 1 month post partum. Their children were enrolled at birth and followed up by mailing questionnaires at 1, 6, and 12 months of age. By November 2022, a total of 147 participants and their children had completed the 12-month follow-up. Two patients were excluded due to meeting the exclusion criteria for chromosomal abnormalities: 1 with trisomy 21 and another with an unspecified chromosomal abnormality. The third excluded patient was born at 25 weeks' gestation weighing 734 g, thus meeting both the criteria for very low birth weight (<1000 g) and extreme preterm birth (<30 weeks). These 3 cases were consequently removed from the study population. This study was prospectively registered in the UMIN Clinical Trials Registry (UMIN000034837) on November 9, 2018. While registered in a clinical trial registry, this research is an exploratory study, not a clinical trial. It uses nonpredefined analytical methods, which distinguishes it from traditional clinical trials with preset end points and analysis plans. The registration was carried out for transparency, despite the exploratory nature precluding a detailed prespecified analysis plan. This study was reported according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines.

Maternal Assessment

Peripheral blood collected at mid- and late gestation and cord blood at birth was used to measure levels of 1,25-dihydroxyvitamin D, 25-hydroxyvitamin D, melatonin, and cytokines (interleukin [IL]-17A, IL-10, IL-1β, IL-6, and tumor necrosis factor). The participating mothers completed a series of questionnaires at mid- and late gestation and at 1 month

XSL•FO
RenderX

post delivery (Multimedia Appendix 1). Maternal hematological biomarkers (vitamin D, melatonin, and cytokines) were measured from blood samples collected during prenatal check-ups and from umbilical cord blood at delivery. While prenatal check-ups typically occur during daytime hours, we did not standardize the exact timing of blood collection. Similarly, as birth times vary unpredictably, umbilical cord blood collection times were inconsistent across subjects. Maternal sleep status was evaluated using the Pittsburgh Sleep Quality Index [19] to assess the quality of sleep and the 3D Sleep Scale (3DSS) [20] to assess sleep regularity (the "sleep phase" item). The Edinburgh Postnatal Depression Scale (EPDS) [21] and Kessler Psychological Distress Scale (K6) [22] were used to assess depression and anxiety disorders, respectively, during pregnancy and post partum. The late gestation questionnaire also included the Autism-Spectrum Quotient Japanese short version (AQ-J-10) [23]. At 1 month post partum, the Japanese version of the Mother-to-Infant Bonding Scale (MIBS-J) [24] was used to assess the mothers' feelings toward their babies.

Infant Assessment and Outcomes

When the children were 1, 6, and 12 months of age, mothers completed questionnaires regarding the children's sleep status (Multimedia Appendix 2). To assess early developmental characteristics in infants, we focused on the acquisition of standard preverbal social behavioral skills and the presence of behaviors commonly associated with autism spectrum disorder (ASD). Specifically, we administered the Japanese version of the M-CHAT at 12 months of age to systematically evaluate these early developmental characteristics. The M-CHAT—a parent-completed dichotomous questionnaire designed for children aged 16 - 30 months—is an effective primary screening tool for ASD and other developmental concerns in the general population [3,5]. In our study, we aimed to identify children showing potential developmental concerns at an earlier stage, specifically at 12 months of age. To achieve this, we developed a unique 10-item version of the M-CHAT, informed by age-specific achievement rates observed in a separate observational study of the general Japanese population. Given that prelinguistic social behaviors vary significantly with age, we included in our analysis 4 age-independent ASD-specific behavioral abnormalities (Q11, Q18, Q20, and Q22) and 6 prelinguistic social behaviors (Q1, Q2, Q4, Q10, Q12, and Q14) that are reported to be consistently achieved by 12 months of age in the general population [4]. The items included were as follows: (Q1) "enjoying being swung," (Q2) "interest in other children," (Q4) "enjoying peek-a-boo," (Q10) "eye contact," (Q11) "oversensitive to noise," (Q12) "response to smile," (Q14) "response to name," (Q18) "unusual finger movement," (Q20) "wonder if deaf," and (Q22) "stares at nothing." Children who fulfilled any of the 10 total M-CHAT items (M-CHAT score ≥1 point) were defined as the M-CHAT positive group.

Statistical Analysis

Descriptive statistics were used to investigate the characteristics of the participating mothers and their infants. Continuous variables—listed as the median and IQR—included maternal age, 1,25-dihydroxyvitamin D, 25-hydroxyvitamin D, melatonin, IL-17A, IL-10, IL-1β, IL-6, tumor necrosis factor, 3DSS (phase), Pittsburgh Sleep Quality Index global score (PSQIG), EPDS, K6, AQ-J-10, MIBS-J, and umbilical artery blood pH. Categorical variables—listed as frequencies and percentages—included the child's sex, maternal smoking history, educational level of parents, annual household income, gestational age at birth, birth weight, Apgar score at 5 minutes, delivery type, answers to sleep-related questions at each period, and the M-CHAT score. Thereafter, the correlation coefficients between the variables were calculated considering the aforementioned categorical variables and 3DSS (phase), PSQIG, EPDS, K6, AQ-J-10, and MIBS-J as ordinal variables. Polyserial correlation coefficients were computed for the relationships between ordinal and continuous variables; further, polychoric correlation coefficients were computed for the relationships between ordinal variables. These polychoric and polyserial correlation coefficients, as well as Pearson correlation coefficients for continuous variable pairs, were calculated using the lavCor function from the *lavaan* package in R software (R Foundation). Wald tests were performed to assess the statistical significance of each correlation. To address the issue of multiple comparisons arising from these correlation tests, false discovery rate correction [25] was subsequently applied to the resulting *P* values. This was performed using the p.adjust() function in R software. Adjusted *P* values (p.adjust) of <.05 were considered statistically significant.

Correlation Analysis

In this study, the relationships between variables affecting the M-CHAT score were represented by network structure. The nodes were variables that showed significant polychoric or polyserial correlations with the M-CHAT score ($|r| \geq .2$, p.adjust <.05). The nodes were arranged according to the data collection period.

Classification Model for the M-CHAT Positive Group

We implemented a classification model using a logistic regression algorithm with potential regularization in the scikit-learn Python package (version 3.1.2) to predict the M-CHAT positive group in infants aged 12 months. We used features of maternal and child demographics, laboratory values, and questionnaire results from the midgestation to 12 months post partum that exhibited a significant correlation (p.adjust<.05) and $|r| \geq .2$ with the M-CHAT score. This model, overall, used 20 features. The data obtained at 12 months of age had missing values, which were completed with missForest—a modern method based on random forests that efficiently addresses missing data imputation among multivariate data without cross-validating with the test data [26]. This method involves inherent randomness, potentially leading to variability in imputed datasets. In our study, we did not set a fixed seed during the missForest imputation. The mother-child dataset was divided into a training set (N=100) for training the prediction model and a test set (N=44) for evaluating the model's performance by using the train_test_split function in scikit-learn. To address the imbalanced nature of our dataset, we used the "stratify" parameter in the train_test_split function, specifying the binary M-CHAT outcome (positive or negative) as the stratification variable. This approach ensured that the distribution of M-CHAT

XSL•FO
RenderX

outcomes was maintained across both the training and test sets. The models were optimized by adapting a grid search method for the hyperparameter "C (regularization strength; 10^{-5}, 10^{-4}, 10^{-3}, 10^{-2}, 10^{-1}, 1, 10, 10^{2}, 10^{3}, 10^{4}, or 10^{5})," "penalty (norm of regularization; L1, L2, elastic net, or none)," and "solver (algorithm in optimization; "newton-cg," "lbfgs," "liblinear," "sag," "saga")." When specifying elastic net as the penalty, we validated by varying the l1_ratio from 0 to 1 in steps of 0.1. The performance of the logistic regression model was evaluated on the test set after ensuring missing data imputation. The model outputs class probabilities to predict the M-CHAT positive (M-CHAT score≥1) group. The optimal threshold for the model was determined by the Youden index.

The model's performance was evaluated using the area under the receiver operating characteristic and precision-recall curves. The relative importance of each feature for predicting M-CHAT scores was examined and visualized using Shapley Additive Explanations (SHAP) [27]. SHAP is a model-agnostic, game-theoretic, unified method that computes a Shapley value to account for each feature's contribution to a particular forecast. SHAP values are computed using an additive feature attribution method to approximate the Shapley value of the model's conditional expectation function. LinearExplainer [28] was used to calculate SHAP values for the logistic regression model. For the decision plotting that simulates the M-CHAT prediction pathway of each sample using SHAP, we specifically used samples with higher M-CHAT scores (M-CHAT scores 2 - 4) within the M-CHAT positive group to focus on cases that might represent early developmental concerns.

Data analysis was performed using the open-source software R (version 4.1.2) and Python (version 3.8.5; Python Software Foundation). The correlation analysis results were visualized using Cytoscape (version 3.9.1; Cytoscape Consortium).

Ethical Considerations

This study was approved by the Ethics Review Committee on Research Involving Human Subjects at Doshisha University (No. 22063) and, subsequently, by the Ethics Review Committees at each affiliated institution (No. 22064). Written informed consent was provided by each pregnant woman at the time of the visit at the affiliated facility. Data was deidentified immediately upon collection. A secure, separate database is maintained to connect study IDs with participant details, accessible only to authorized personnel. The research description clearly states the following points: (1) women are free to participate in the research and withdraw their consent, (2) refusal of participation in the research has no implications per disadvantages in medical care, and (3) participation in the research entails no increased cost burden or rewards.

Results

Description of the Sample

The characteristics and results for the 144 mother-child pairs included in the final analysis are presented in Table 1 and Multimedia Appendix 2. These maternal background and perinatal data were obtained by combining information from medical records and parents' reports up to the first month postpartum check-up. The median maternal age was 36 (IQR 32-29) years, and 3 (N=144, 2%) mothers had a smoking history during their current pregnancy. The most prevalent educational level for both parents was a university degree (48/144, 33% mothers and 64/144, 44% fathers). Annual household incomes varied among the participants, with the most common bracket being 4 to 6 million yen (approximately US $36,000 to US $56,000, based on a currency exchange rate of US $1=JP ¥107-112 that was applicable during the study period) per year, reported by 46 (N=142, 32% of the population) families. Of the children, 86 (N=144, 60%) were female, 129 (N=144, 90%) were born at 37 weeks or later, and 3 (N=144, 2%) were born between 30 and 33 weeks. Birth weight ranged from 3000 g to 3999 g in 122 (N=144, 85%) children; all 5-minute Apgar scores were 7 (N=144) or higher. The median umbilical artery blood gas pH was 7.29 (IQR 7.26 - 7.33). The delivery type was vaginal in 87 (N=144, 60%) cases (Table 1). Throughout the pregnancy, the 3DSS (phase) median score was 10 (IQR 9-12). From midgestation to 1-month postpartum, PSQIG exhibited an increasing trend with median scores of 5 (IQR 3-7), 6 (IQR 4.5-9), and 8 (IQR 6-10), respectively. This indicates that mothers' sleep conditions tended to worsen during the period up to 1 month after childbirth. The median EPDS scores were relatively low across all 3 time points: 3 points in midpregnancy, 4 points in late pregnancy, and 2 points at 1 month post partum. Similarly, K6 scores remained low at 1, 2, and 1, respectively. The median AQ-J-10 score at late gestation was 2 (IQR 1-3), and the median MIBS-J score at 1 month post partum was 1 (IQR 0-3; Multimedia Appendix 2).

The Distribution of the M-CHAT Score Among Children Aged 12 Months

The distribution of the M-CHAT scores among the 144 children aged 12 months was as follows: 105 (73%) children scored 0, 30 (21%) scored 1, 5 (3.5%) scored 2, 3 (2.1%) scored 3, and 1 (1%) scored 4. All 6 preverbal social behavior items (Q1, Q2, Q4, Q10, Q12, and Q14) used to score the M-CHAT in this study exhibited achievement rates of 95% or higher. Specifically, for the question on smiling response (Q12), only 1 parent reported that their child did not smile back when smiled at. Similarly, regarding concerns of hearing impairment (Q20), only 1 parent expressed concern that their child might be enduring hearing difficulties. Of the 39 children who scored 1 or more, 29 (74%) received scores for age-independent and ASD-specific behaviors (particularly Q11, Q18, and Q22; Multimedia Appendix 3).

Interrelationships Between M-CHAT Score and Each Variable

To examine the relationship between the M-CHAT score and other variables during each period, polychoric or polyserial correlation coefficients were calculated and presented in a heatmap (Figure 1). Using the correlation heatmap, variables that significantly correlated with the M-CHAT score were identified. The M-CHAT score was positively correlated with maternal serum melatonin levels in midgestation and cord blood IL-1β; the M-CHAT score showed a weak positive correlation with cord blood IL-10 (r=.18). By contrast, the M-CHAT score exhibited a negative correlation with maternal serum IL-1β levels in midgestation and cord blood IL-6 levels. The M-CHAT score was positively correlated with EPDS and K6 scores in late gestation and with K6 and MIBS-J scores at 1 month post partum. For infant sleep questions, the M-CHAT score was significantly correlated with shorter sleep duration, bedtime, and difficulty in falling asleep (moodiness and required time). Detailed correlation coefficients are presented in Multimedia Appendix 4.

Correlation analysis was performed to determine the interrelationships among factors potentially influencing early developmental characteristics as assessed by M-CHAT scores (Multimedia Appendix 5). Strong positive correlations (r≈1.0) were found between cord blood IL-6 and IL-1β levels and between weekday and holiday bedtimes of children aged 6 months. Nodes at late gestation, cord blood, and 1 month post partum were strongly and positively correlated with each other within the same observation period. In children aged 6 months, a negative correlation was found between “nighttime sleeping hours” and “bedtime,” and a positive correlation was found between “staying awake for ≥1 hour at nocturnal awakening” and “takes long (≥1 hour) to fall asleep.” A negative correlation was found between IL-1β levels in the midgestation period and “short sleep duration” in children aged 1 month; a positive correlation was observed between melatonin levels in midgestation and “takes long (≥1 hour) to fall asleep” in children aged 6 months. K6 and EPDS scores in the late gestation were positively correlated with K6 scores in 1 month post partum and also positively correlated with “staying awake for ≥1 hour at nocturnal awakening” in children aged 6 months. “Wakes up several times at night, does not sleep and takes several hands” in children aged 1 month was positively correlated with “takes long (≥1 hour) to fall asleep” in children aged 6 months. “Bedtime” among children aged 6 months was positively correlated with “bedtime on holidays” among children aged 12 months (Multimedia Appendix 5).

Assessment and Visualization of Factors Contributing to Early Developmental Characteristics

To assess longitudinal influences associated with early developmental characteristics as measured by M-CHAT scores, we conducted feature importance analysis using SHAP on a logistic regression model with L2 regularization ("C"=0.1, "penalty"="L2," "solver" = "liblinear," area under the receiver operating characteristic and precision-recall curves and the confusion matrix shown in Multimedia Appendix 6). The optimal threshold was determined by the Youden index to be 0.32. The logistic regression model attained reasonable predictive performance (area under the receiver operating characteristic curve=0.79, 95% CI 0.62 - 0.95; Multimedia Appendix 6). While the point estimate falls within the acceptable range (0.7 - 0.8), the CI extends below 0.7, indicating some uncertainty in its discriminative ability. The model's utility should therefore be interpreted within the context of the dataset and application. The SHAP beeswarm plot (Figure 2A) assesses the contribution of each feature of the total sample to the model. The order of the feature values obtained by SHAP and the contribution of each feature is high, and this ranking is relative, for example, it does not indicate which rank is particularly important. When examining variables in order of their contribution strength, we found high contributions from bedtime at 12 months, nighttime sleep duration and irritability at bedtime at 6 months, and maternal K6 and MIBS-J scores during late pregnancy and 1 month post partum. Specifically, later bedtimes, shorter nighttime sleep duration, higher K6 and MIBS-J scores, and irritability at bedtime promoted classification into the M-CHAT positive group. The characteristics that moderately contributed to such a classification were variables related to the sleep status of children aged 1-6 months and maternal melatonin levels. The 6 characteristics with the lowest influence were predominantly cytokine levels, EPDS score, "wakes up several times at night, does not sleep, and takes several hands" in children aged 1 month, and bedtime for children aged 6 months. The SHAP decision plot (Figure 2B) simulates the decision pathway for predicting classification into the M-CHAT positive or negative (M-CHAT score=0) groups in the order of observation period. All 9 randomly sampled cases with M-CHAT scores of 0 were correctly predicted to be the M-CHAT negative group. In some M-CHAT positive cases, the predictive risk began to increase owing to the deterioration of the maternal K6 and MIBS-J scores and infant sleep status for children aged 6 months. Conversely, there were cases in which the predictive risk did not change for maternal factors but increased rapidly for factors related to the child's sleep after 6 months of age.

Discussion

Temporal Dynamics of Early Developmental Characteristics: Individual Patterns and Contributing Factors

In recent years, the number of cases of neurodevelopmental disorders has increased rapidly, becoming a significant social concern. While genetic factors have been extensively studied, identifying genes that correlate with symptoms alone is insufficient to understand developmental mechanisms. The clarification of how environmental factors interact with genetic predisposition in the developmental process remains an urgent research priority [29].

In this study, we assessed early developmental characteristics through social behavior patterns and analyzed how these patterns emerge during infancy. The SHAP analysis provided a novel approach to assess and visualize how multiple longitudinal factors contribute to individual neurodevelopmental trajectories. Specifically, our analysis focused on cases showing elevated M-CHAT scores (2 - 4 points), including those exceeding the conventional ASD screening cutoff value (M-CHAT score of 3+). This analysis revealed distinct temporal patterns in the emergence of early developmental characteristics. Some cases showed an increased risk of M-CHAT positive classification during late gestation, primarily associated with elevated maternal K6 scores. Other cases demonstrated increased risk due to disrupted infant sleep patterns after 6 months of age. Additionally, we observed cases where substantial increases in K6 and Mother-to-Infant Bonding Scale (MIBS) scores at 1-month postpartum markedly elevated the predicted probability of M-CHAT positive classification.

These results indicate that early developmental characteristics associated with elevated M-CHAT scores emerge through several distinct dynamic patterns, involving multiple interacting factors. The SHAP methodology enabled the quantification of each factor's relative contribution to these patterns. Based on our findings, we suggest that targeted follow-up assessments focusing on maternal anxiety disorders in late gestation and infant sleep characteristics at 6 months—particularly sleep duration, bedtime, irritability upon falling asleep, and extended periods of wakefulness—may be particularly valuable for the early identification of developmental concerns.

Temporal Relationships Between Early Developmental Characteristics and Longitudinal Factors

Correlation analysis revealed that relatively strong correlations between factors within the same period were observed between similar factors such as maternal physical and mental status, sleep difficulties in children, and inflammatory cytokines. However, correlations between factors with different observation periods were more limited than correlations within the same period. Our analytical method does not pursue a causal relationship.

Early Sleep Difficulties as Indicators of Emerging Developmental Characteristics

Recent research has established clear interactions between sleep patterns and neurodevelopment in young children. During early brain development, sleep patterns and neural maturation progress in parallel, significantly influencing cognitive performance [16,17]. Notably, studies have demonstrated associations between infant sleep patterns and brain structure, including hippocampal volume [18]. Children who later receive

XSL•FO
RenderX

neurodevelopmental disorder diagnoses often experience more persistent and complex sleep problems compared to their typically developing peers [30]. Several longitudinal studies have identified early sleep difficulties as potential risk indicators for diagnosis of later ASDs [18,30]. Specifically, shorter sleep duration, delayed sleep onset and wake times, and frequent midday awakenings have been associated with an increased likelihood of subsequent ASD diagnosis. The timing of sleep-related interventions appears crucial, with recommendations focusing on the period between 3 and 6 months of age, when circadian rhythms become established in the suprachiasmatic nucleus [15,31]. Our findings align with and extend this literature: M-CHAT scores at 12 months showed significant correlations with multiple sleep-related characteristics, including reduced sleep duration, later bedtime, and difficulties with sleep onset (including irritability and prolonged time to fall asleep). These results suggest that infants showing early signs of developmental concerns, as indicated by elevated M-CHAT scores, may already be experiencing sleep-related challenges. Early identification of these sleep patterns could provide opportunities for targeted interventions, potentially benefiting not only the infant's sleep and neurodevelopmental trajectory but also family functioning and overall cognitive outcomes.

Relationship Between Inflammatory Markers and Early Developmental Characteristics

Increasing evidence suggests that chronic inflammation plays a role in atypical neurodevelopment, although the underlying mechanisms remain unclear. For example, microglia, crucial for brain maturation and function, are increasingly recognized to play a decisive role in various developmental and cognitive conditions [32]. Microglia produce inflammatory mediators and reactive oxygen species, potentially leading to neuronal degeneration, white matter abnormalities, and decreased neurogenesis observed in conditions such as ASD or schizophrenia [32]. The secretion of signaling molecules and cytokines may promote crosstalk between microglia and astrocytes, leading to endothelial dysfunction and blood-brain barrier permeability impairment [33]. Multiple studies have reported increased concentrations of inflammatory cytokines such as IL-6 and IL-1β and a decrease in anti-inflammatory cytokines (IL-10 and transforming growth factor [TGF]-β) in the peripheral blood and cerebrospinal fluid of individuals with ASD [12,13,33]. The persistent elevation of these inflammatory cytokines may reflect ongoing inflammatory processes [14].

Maternal infections during pregnancy and early childhood are known to influence early development, and changes in cytokine profiles may be shaped by environmental exposures during prenatal and early childhood periods [32]. Typically, the maternal immune system shifts to a more tolerant state during pregnancy, characterized by a decrease in inflammatory cytokines and an increase in regulatory cytokines [12]. However, mothers whose children later receive neurodevelopmental diagnoses have been reported to have significantly higher levels of various inflammatory cytokines and chemokines, such as IL-1α, IL-4, IL-6, and interferon [IFN]-γ in serum during midpregnancy [34,35]. Studies have also reported alterations in melatonin secretion in individuals with ASD, particularly decreased secretion of melatonin and its metabolites at night and altered circadian rhythm [33]. Low maternal melatonin levels during pregnancy have been associated with an increased likelihood of subsequent ASD and intellectual disability diagnoses [36], although there is no consensus on this matter. Contrary to previous research, our study found associations between increased melatonin and decreased IL-1β and M-CHAT scores in midpregnancy. These associations were not observed in maternal blood in late pregnancy. Factors such as the intensity, timing, and duration of maternal inflammatory responses may be crucial for influencing the developing child's brain. Differences in sample processing and clinical sample variation may also contribute to these findings.

Higher levels of IL-1β in neonatal samples have been associated with an increased likelihood of ASD diagnosis [37]. Moreover, neonatal samples from infants later diagnosed with ASD showed decreased levels of many cytokines (IFN-γ, IL-2, IL-4, IL-6, and IL-10), suggesting reduced immune cell activity in the neonatal period [38]. Interestingly, consistent with previous studies, our analysis found significant correlations between increased IL-1β and decreased IL-6 in cord blood and M-CHAT scores. These results suggest 2 possibilities: first, the cytokine profile in umbilical cord blood samples may predict subsequent developmental characteristics similarly to neonatal samples; second, the M-CHAT assessment at 12 months may effectively identify early developmental concerns before formal diagnostic evaluations. However, these observed relationships between IL-1β and M-CHAT were derived using polychoric or polyserial correlation analysis, and statistical significance might be lost if other statistical methods accounting for outliers were applied. Given that these cytokine data showed very low predictive contribution to the model, and considering that IL-1β is a bioactive substance that can be unstable and challenging to measure in blood in clinical settings, the correlations found in this study should be interpreted with caution.

Maternal Psychological Well-Being as a Predictor of Early Developmental Characteristics

Focusing on maternal mental and physical status, it has been previously reported that persistent anxiety during pregnancy is significantly associated with ASD in children [8]; further, persistent depression is associated with developmental delay at 18 months [9]. Our study found correlations between K6, EPDS, and M-CHAT, consistent with previous reports. Notably, we identified a significant positive correlation between MIBS and M-CHAT scores at 1 month post partum. While previous studies have shown strong correlations between MIBS and EPDS from early postpartum through 12 months [10], our study is among the first to examine MIBS scores as an independent predictor of early developmental characteristics. Although enhanced parent-child bonding may not directly improve social functioning in children with ASD [39], our findings suggest that MIBS assessment may be valuable for the early identification of developmental concerns.

Our longitudinal analysis demonstrates that early postnatal maternal psychological measures—including emotional state (EPDS), psychological distress (K6), and MIBS—correlate with infant developmental characteristics as assessed by M-CHAT

XSL•FO
RenderX

scores. These findings emphasize the importance of comprehensive maternal psychological monitoring in the postpartum period. Even when EPDS scores do not indicate clinical depression, attention to other maternal psychological indicators, particularly MIBS and K6 scores, may provide valuable insights for early developmental screening.

Limitations

This study has several limitations. First, the pathogeneses of neurodevelopmental disorders are multifactorial; therefore, the presence of unobserved confounding factors cannot be excluded when interpreting the findings of this study. The interrelationship of various sleep and psychological measures (Pittsburgh Sleep Quality Index, K6, MIBS, EPDS, etc) assessed at different time points may introduce potential biases. Parental ratings of child sleep status are inherently subjective and could be influenced by parents' own psychological stress or sleep issues, potentially affecting the results. Additionally, the collection and measurement of maternal and cord blood biomarkers lack standardized timing protocols and do not account for diurnal variations, necessitating consideration of potential measurement errors in the analysis.

Second, the sample size is small, and the results are preliminary. Future studies should validate these findings using larger samples. Only Japanese participants were included in this study, and no analysis of cultural and social influences due to racial or ethnic differences was conducted. Furthermore, there was considerable variation in the number of mother-child pairs recruited across study sites. While recruitment was not intentionally biased, potential disparities in research resources and physician-patient relationships among facilities may have influenced informed consent rates. Of note is that our longitudinal study may not be fully representative of the Japanese population.

Third, the use of M-CHAT scores at 12 months as an indicator of early developmental characteristics has inherent limitations. While M-CHAT is a validated screening tool, our assessment was based on parent-reported scoring, and due to the short observation period, we were unable to confirm subsequent neurodevelopmental diagnoses. In an ongoing study, we plan to assess ASD using the Kinder Infant Development Scale and Social Responsiveness Scale 2nd edition at 36 months of age.

Conclusions

Understanding the characteristics of early development and their predictors is essential for improving strategies for early detection and support of neurodevelopmental problems.

Our study demonstrates that a systematic analysis of multiple longitudinal factors can reveal important patterns in early development, particularly in preverbal social behaviors as assessed by M-CHAT scores at 12 months. The results indicate that early developmental characteristics are influenced by several key factors, particularly maternal-infant bonding, maternal anxiety, and infant sleep patterns. The temporal dynamics of these relationships suggest that monitoring specific combinations of factors—including maternal psychological well-being and infant sleep patterns—may enhance our ability to identify early signs of developmental concerns. Future studies with larger and more diverse population samples are needed to validate these findings and establish their generalizability for clinical practice.

Acknowledgments

We would like to dedicate this paper to our wonderful colleagues, Y Konishi and Kiyomi Tsukimori, who died during the production of this paper. KS, Y Konishi, and EK designed this study. AO, SI, Y Kasahara, KK, Y Kitadai, Y Kimura, Y Konishi, KN, HM, and SM collected the data. DK wrote the first draft of this paper and made revisions. DK, AO, TI, SO, AH, and EK collated and analyzed the data. All the authors edited this paper. This work was supported by the Japan Society for the Promotion of Science (JSPS) KAKENHI (grant JP21K02356 to AO, TI, and SM). This work has been supported by RIKEN Healthcare and Medical Data Platform Project.

Data Availability

The data and code that support the findings of this study are available from the corresponding author, EK, upon reasonable request. The data are not publicly available as it contains information that could compromise the privacy of research participants.

Conflicts of Interest

Y Kimura received collaborative research funding and patent royalties from Atom Medical Inc. All other authors declare that they have no conflicts of interest.

Abstract

Background: Early childhood caries (ECC) remains a common childhood condition that affects 600 million children worldwide. Providing parents with support for oral health behavior change can address ECC risk factors and complement preventive clinical care. Mobile health (mHealth) text message programs that are co-designed and evaluated by parents and health professionals using behavior theory have been shown to be effective in improving oral health outcomes.

Objective: This study aimed to describe the co-design process, development, and content evaluation of a text message program designed to promote oral health behavior change among parents of children diagnosed with ECC using the Behavior Change Wheel (BCW) framework.

Methods: The *SmilesUp* mHealth program was co-designed with parents in 2 stages using the BCW, a widely used theoretical framework to underpin mHealth programs, recommended by the World Health Organization. Through focus groups with parents in phase 1, the BCW was used to understand parental perspectives by identifying barriers and enablers and selecting target behaviors that could be feasibly delivered within a mHealth intervention. Barriers and enablers were mapped to the relevant theoretical domains and behavior change technique (BCT) of the BCW. Phase 2 evaluated content acceptability, measured by understandability, usefulness, and appropriateness of the program through questionnaires with parents and health professionals. Highly rated messages were finalized into an algorithm for the SMS text message program.

Results: In phase 1, the overall target behavior was parental behavior change to support good oral health, including oral hygiene, reduced dietary sugar intake, and bedtime routines for their children. The 5 intervention functions focused on education, modeling, persuasion, environmental restructuring, and enablement, and 16 BCTs focused on addressing the motivational enablers and knowledge gap barriers identified by the parents. A total of 111 draft health messages were developed and mapped to the BCTs. In phase 2, a total of 2045 reviews of the 111 draft messages were completed by parents (14/31, 45.2%) and health professionals (17/31, 54.8%). Parents rated 77.4% (86/111) and health professionals rated 61.2% (68/111) of the messages as understandable, useful, and accepted. The messages that were considered understandable, useful, and appropriate by both groups were incorporated into the *SmilesUp* 12-week semipersonalized SMS message program.

Conclusions: The *SmilesUp* mHealth program uses behavioral theory to address knowledge gaps in tooth brushing, diet, and bedtime routines identified by parents. It provides parents with convenient, bite-sized nudges of information to support oral health–promoting behaviors in the home context. Robust content development and evaluation are crucial initial steps before further investments are made to conduct a clinical trial to assess the effectiveness of the program.

KEYWORDS

mobile health; mHealth; dental caries; prevention; co-design

Introduction

Early childhood caries (ECC) remains a complex childhood disease that affects 600 million children worldwide [1]. In Australia, children with the most severe cases of ECC may require hospital admission, impacting approximately one in every 250 children [2]. Parents play a key role in preventing ECC by changing known modifiable oral health lifestyle behaviors [3]. Providing mothers, fathers, carers, and parents (from here on referred to as "parents") with adequate and appropriate support for this behavior change remains key to sustainably improve oral health outcomes for their children across the life course [3]. ECC disease management approaches that focus on prevention and behavior change through motivational interviewing have been implemented over the past decade [4]. However, these strategies are time-intensive, costly, and have had limited population reach [5]. The widespread use of mobile phone technologies offers a valuable opportunity for modern health systems to increase the reach for prevention programs through prevention-focused digital health interventions [6]. These interventions can help drive sustainable oral health behavior change at scale [7,8]. While there are existing oral health mobile apps available, most focus only on tooth brushing and have been created for school-aged children or young adults [9,10]. These apps fail to comprehensively address the interrelated risk factors (oral hygiene, diet, and bedtime routines) specific to the prevention of ECC. Furthermore, many of these apps require the use of paid data, which can be prohibitive for some lower socioeconomic families, exacerbating potential disparities in digital health literacy [11,12]. Selecting an affordable medium to deliver digital health interventions can support equitable access to digital behavior change support among vulnerable populations [11]. Thoughtfully co-designed SMS interventions informed by behavioral theory have shown promise in improving general health behavioral outcomes, equitably and at scale [13-15]. To ensure practicability, mobile health (mHealth) programs should be compatible with any SMS text message systems used within existing digital health infrastructure. Making message delivery free or low cost will support equitable access to digital oral health interventions for diverse families at risk of ECC.

Involving and consulting consumers from the inception of the *SmilesUp* program development is crucial for developing effective content and features of the mHealth program [16]. Understanding the needs and preferences of parents enables health systems to develop mHealth interventions that genuinely support the health goals of the target population [17]. Furthermore, the latest World Health Organization (WHO) guidelines on mHealth emphasize the importance of a pragmatic approach, where developers of mHealth programs must balance consumer needs with the existing digital infrastructure and budget constraints within health systems [7]. Involving parents, health professionals, and policymakers early in the development process is crucial for creating feasible and scalable prevention-focused oral mHealth interventions [18].

Many co-designed mHealth programs supporting behavior change have used behavioral theory and content evaluation to ensure a robustly designed program [19-22]. The Behaviour Change Wheel (BCW) framework is a widely used theory for designing mHealth and digital health interventions [23-27]. It takes into account the broader social and legislative contexts, as well as societal limitations that may affect the desired outcomes of the target population [28]. Recently, the oral health academic community has recognized the importance of using the BCW to underpin the development and evaluation of behavior change interventions, including mHealth programs [29,30]. Similarly, the WHO guidelines emphasize the use of the BCW's Capability, Opportunity, Motivation-Behaviour (COM-B) model as the comprehensive behavior change theory of choice for intervention development [28]. By using behavioral theory and content evaluation, interventions can comprehensively address barriers and enablers related to oral health behaviors identified by both parents and health professionals within health systems to reduce the ECC burden[7]. This mixed methods study aimed to use BCW behavioral theory to co-design and evaluate the content acceptability of *SmilesUp*, an SMS-based mHealth intervention for parents of children with ECC.

Methods

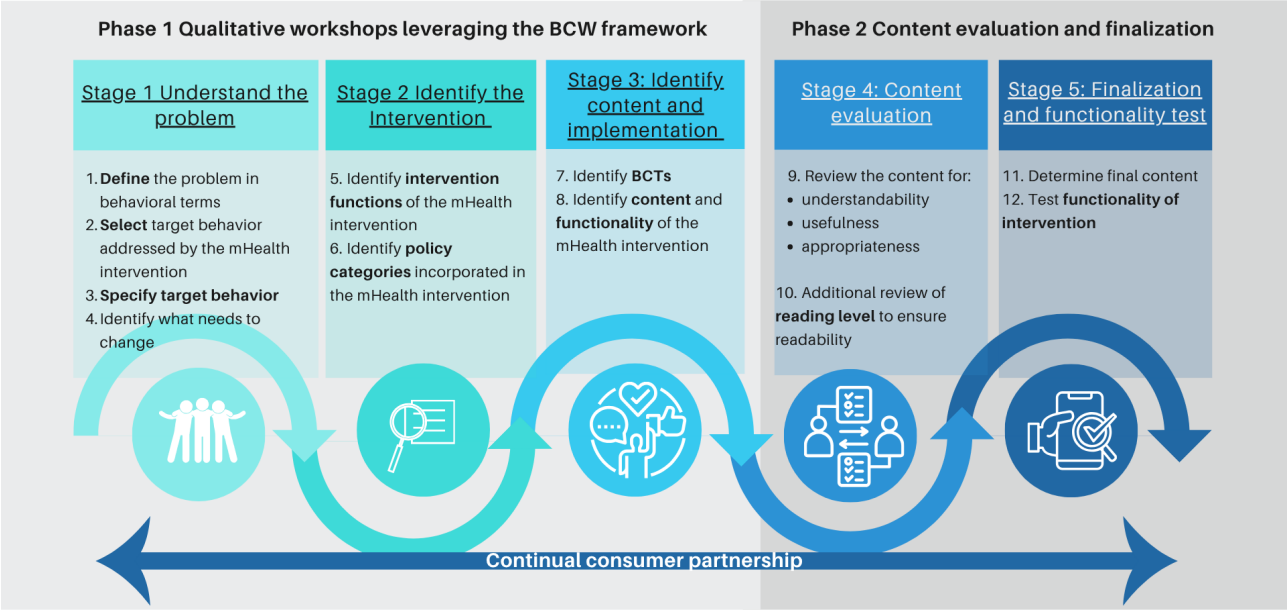
Participants and Recruitment Setting

The study was conducted in public dental services in New South Wales (NSW), targeting families receiving care and the oral health staff working with these families at 2 tertiary pediatric referral centers. NSW Health public dental services offer a range of safety-net dental services, including general anesthetic appointments for children who meet an eligibility criterion [31]. The service also prioritizes emergency situations and vulnerable populations at highest risk of dental disease [31,32].

Recruitment of parents for the co-designed workshops was conducted through recruitment flyers in the waiting rooms of the pediatric dentistry tertiary centers. Health professionals were also recruited via a flyer that was circulated via email from the heads of departments at the 2 tertiary centers and the state-based health promotion and policy team. Purposive sampling of parents with a child diagnosed with ECC accessing NSW public dental services ensured representation of the end-user perspectives of the final *SmilesUp* program. Similarly, only health professionals who were working within NSW public dental clinics or for the state-wide oral health promotion team were invited to participate.

Ethical Considerations

Ethics approval was obtained and approved by the Western Sydney Local Health District Research ethics department (2022/ETH01920). As part of the recruitment process, all participants for both phases were given a participant information sheet and provided e-consent through Research Electronic Data Capture (REDCap) or via a paper consent form before joining



XSL•FO
RenderX

workshops, semistructured interviews, or completing the questionnaire. For participants attending in person focus groups, recurtiment flyers outlined that they would be reimbursed for their travel and parking expenses; no other compensation was provided. All research data collected were deidentified and procedures were conducted in alignment with the National Statement on Ethical Conduct in Human Research from the Australian National Health and Medical Research and the Declaration of Helsinki.

Overview of the Co-Design Process

This study used a 2-phase co-design approach, incorporating BCW and a mixed methods evaluation similar to previously published methodologies [21,33]. Phase 1 involved qualitative methods [34] to understand the oral health barriers and enablers faced by parents, identify target behaviors, and draft intervention content. Phase 2 focused on evaluating content validity by measuring understandability, usefulness, and appropriateness with both parents and health professionals (Figure 1).

Figure 1. SmilesUp mobile health (mHealth) intervention co-design process, including the Behaviour Change Wheel (BCW) framework and content evaluation and finalization. BCT: behavior change technique.

Phase 1: Qualitative Workshops Leveraging BCW

Overview of Phase 1

Phase 1 used all 3 stages of BCW (Figure 1) to understand parents' barriers and enablers, mapping these to intervention functions, behavior change techniques (BCTs), and text message content. Co-design workshops and semistructured interviews were conducted between February 2, 2023, and July 15, 2023. Data were collected by a trained qualitative researcher who had experience working within NSW Health public dental services, and sessions were conducted in person or via video calls if requested by participants. All workshop participants' anonymity was maintained through pseudonyms, and transcription was managed with the NVivo (Lumivero) qualitative data analysis software [35]. Parent and health professional sessions were held separately to reduce power dynamics and encourage open discussions [36,37].

Stage 1: Understanding the Problem

In the first stage, qualitative workshops and interviews were conducted with parents and oral health professionals to explore barriers and enablers related to 3 key oral health behaviors: oral hygiene, dietary sugar intake, and bedtime routines. These were mapped to the COM-B model to define a target behavior that could be supported by mHealth messaging.

Stage 2: Identifying the Intervention Options and Policy Areas

Stage 2 used the BCW mapping process to select intervention functions and policy areas to address the barriers and enablers identified in stage 1. These identified intervention functions also had to have the capacity to be incorporated into the format of the mHealth program.

Stage 3: Identifying BCTs and Drafting Content

In stage 3, BCTs were chosen based on the Acceptability, Practicability, Effectiveness, Affordability, Safety, and Equity (APEASE) [38] criteria, and content for the intervention was drafted and mapped to the original barriers and enablers. Within the BCW, the APEASE criteria ensures that the content is pragmatic and relevant for both the parents and the health system's existing digital infrastructure [28]. This process informed the content of the initial draft text message bank.

Phase 2: Content Evaluation and Final Functionality

Overview of Phase 2

Phase 2 developed the information gathered from the phase 1 co-design workshops by conducting a broader consultation with parents and health professionals to further evaluate the content (stage 4) before finalising the content and functionality of the *SmilesUp* program (stage 5).

XSL•FO
RenderX

Stage 4: Content Evaluation by a Broader Range of Parents and Health Professionals

A questionnaire based on previously published methodologies [15] was developed to measure the understandability, usefulness, and appropriateness of the draft content. This questionnaire was given to a wider group of parents and health professionals to assess the acceptability of SMS text message content [15]. We recruited until all messages were reviewed by at least 2 parents and 2 health professionals. The SMS text message content reviews were collected through questionnaires on REDCap and through paper forms when requested by parents [39]. To prevent survey fatigue, each participant was only required to provide feedback on the understandability, usefulness, and appropriateness of approximately 20 messages [15]. Additionally, to ensure the readability of the messages, a grade 5 reading level or below was set to ensure the readability of the program for our target population. All final messages were assessed using the Sydney Health Literacy Lab (SHeLL) reader to verify this reading level was met before they were included in the final set [40].

Stage 5: Finalization and Functionality Determination

In the finalization phase, messages were mapped back to the originally identified barriers and enablers (phase 1) to ensure that all identified needs and BCTs were addressed. Qualitative data were also analyzed to inform decisions about the program's functionality, including the duration, frequency, timing, and sequencing of the SMS text message schedule.

Results

Participants

Members included in the co-designed workshops were parents 30% (6/20) currently using public dental services, as well as health professionals 70% (14/20), including dental practitioners, health promotion policy officers, dietitians, and IT managers providing clinical services or developing programs for oral health services within NSW Health. This diverse group provided a broad perspective, shared existing high-quality digital health promotion resources (interactive websites or online videos) that could be incorporated into the program, and guided the features of the program to address target behaviors. The inclusion of various dental practitioners and dietitians ensured a comprehensive approach to oral health promotion information that addressed the specific barriers and enablers identified by parents. Additional parents (14/31, 45.2%) and health professionals (17/31, 54.8 %) were recruited for phase 2 to ensure a broader perspective beyond that of the initial co-design groups.

Phase 1: Co-Design Outcomes Using BCW

The results from the mixed methods data collection and analysis were progressive, integrated, and structured according to our methods (Figure 1). Phase 1 results are presented within the 3 stages set by BCW [28].

Stage 1: Understanding the Behavior

Workshops with parents and health professionals identified 15 enablers and 10 barriers to address 3 key oral health risk behavioral categories: oral hygiene, diet, and healthy bedtime routines. These barriers and enablers were mapped to BCW's COM-B model of behavior categories: *physical capability*, *psychological capability*, *physical opportunity*, *social opportunity*, *reflective motivation*, and *automatic motivation*. We found that while parents had the *physical capability* to perform oral health–promoting behaviors, they lacked specific knowledge (*psychological capability*) about selecting the best toothpaste, brushing techniques, and choosing low sugar snacks for their children. Most of the enablers were linked to *motivation* (*automatic*) and *capability* (*knowledge*) where parents sought reminders and information to help them develop consistent oral health habits.

Therefore, the problem was defined as the need to increase parents' oral health literacy encompassing both knowledge (*psychological capability*) and motivation (*automatic and reflective*) for adopting healthy oral behaviors to prevent ECC. A comprehensive tabulated description of the target behavior for the *SmilesUp* SMS text message program using BCW framework is found in Table 1.

XSL•FO
RenderX

Table . Using the Behavior Change Wheel (BCW) framework to identify the specific target behavior for the *SmilesUp* SMS text message program.

Question (BCW step)	Response
What is the target behavior?	Participation in a structured SMS messaging intervention to perform oral health–promoting behaviors in the home context.
Who needs to perform the behavior?	Parents of children with ECC[a], undergoing dental treatment within select NSW[b] Health public dental clinics, including but not limited to children waiting for a general anesthetic appointment for dental treatment.
What does the person need to do differently to achieve the desired change?	Participate in a co-designed and semipersonalized structured SMS messaging program that supports a range of healthy oral health behaviors, including oral hygiene, diet, and bedtime routines.
When will they do it?	Parents will engage with the SmilesUp 12-week program after their initial clinical appointment, which provides additional support to the oral hygiene and dietary advice provided by their clinicians, with messages sent at times nominated by the parents at the start of the program.
Where will they do it?	In the home context.
How often will they do it?	The program will be sent 2 - 3 times per week. However, most key behaviors related to ECC (eg, tooth brushing) will need to be conducted daily.
With whom will they do it?	With their children and other relevant members of their family.

[a]ECC: early childhood caries.

[b]NSW: New South Wales.

Stage 2: Intervention Options and Policy Areas Identified

Intervention options and policy areas from the BCW were identified based on the initial data around barriers and enablers collected from parents and clinicians. These were then mapped to the previously identified barriers and enablers (Multimedia Appendices 1 and 2). Parents and clinicians recommended incorporating 5 intervention functions and 10 theoretical domains into the *SmilesUp* mHealth intervention. The 5 intervention functions were education, persuasion, modeling, enablement, and environmental restructuring [38]. The 10 theoretical domains framework included knowledge, skills, beliefs about capabilities, optimism, beliefs about consequences, reinforcement, intentions, goals, memory, and social influences [38].

The *SmilesUp* program aligns with two specific policy areas identified in the BCW: (1) communication and marketing and (2) service provision [38]. The program sits at the intersection of these policies because it is delivered as a communication tool to support and encourage behavior change as part of the comprehensive, value-based clinicalservice provided to families with the NSW public dental service.

Stage 3: BCTs and Drafting Content Identified

Specific BCTs were determined using a feasibility lens based on the APEASE criteria with perspectives from parents and high-level stakeholders [28]. A total of 16 BCTs were identified and mapped to the 15 enablers and 10 barriers previously determined by the consumer co-designers in stages 1 and 2 (Multimedia Appendices 1 and 2). These BCTs were chosen for their feasibility and relevance to an mHealth intervention with the goal of enhancing parents' capability and motivation of oral health–promoting behaviors in the home context (Multimedia Appendices 1 and 2). The specific BCTs included were as follows: "1.4 Action planning"; "2.4 Self-monitoring of behavior"; "4.1 Instructions on how to perform behavior"; "5.1 Information about health consequences"; "5.3 Information about social and environmental consequences"; "5.6 Information about emotional consequences"; "6.1 Demonstration of the behavior"; "7.3 Reducing the prompts/cues"; "7.6 Satiation"; "8.2 Behavioral substitution"; "8.3 Habit formation"; "9.1 Credible source"; "12.1 Restructuring the physical environment"; "12.4 Distraction"; "13.1 Identification of self as a role model"; "15.1 Verbal persuasion about capability." An example of how the BCTs were comprehensively mapped to the barriers or enablers, theoretical domains framework, and policy functions is provided in Multimedia Appendices 1 and 2. This information informed the program's functionality, including the need for semipersonalization of the messages to include the child's name, and for parents to select the timing of the messages to suit their lifestyles, thereby supporting ongoing engagement and sustained long-term behavior change.

The draft content, co-designed with 20 participants including 6 (30%) parents and 14 (70%) health professionals, addressed the barriers and enablers and corresponded to the intervention functions and BCTs identified earlier. The draft message bank included 111 messages, some of which were adapted from the bank of messages from the WHO's *BeHealthy BeMobile* program, with locally relevant web-based links specific to the target population [7]. These web-based resources were in alignment with Australia's National Consensus Statement on Oral Health Messages [41] and were developed by government agencies and professional associations including NSW Health and the Australian Dental Association [41]. New messages were created to address specific knowledge barriers identified by the parents, such as the consumption of dried fruit and vitamin gummies that had been noted in stage 1. Additionally, BCTs were incorporated into the content and features of the mHealth program to support parents using the final *SmilesUp* program.

XSL•FO
RenderX

Phase 2: Content Evaluation and Final Functionality Determination

Stage 4: Content Evaluation Findings by a Broader Range of Parents and Health Professionals

In phase 2, of the 31 participants, 14 (45.2%) parents and 17 (54.8%) health professionals reviewed the 111 draft SMS text messages, providing a total of 2045 ratings, which included 805 (39.4%) parent reviews and 1240 (60.6%) health professional reviews. The sample size was determined by data saturation, which was reached when all messages were reviewed twice—once by a health professional and once by a parent consumer accessing NSW public dental clinics. For a message to be considered acceptable, it needed to receive a "yes" favorably on all 3 categories of understandability, usefulness, and appropriateness. Of the 111 draft messages, 86 (77.5%) messages were rated favorably by parents, while 68 (61.3%) messages were rated favorably by health professionals. A total of 56 (50.5%) messages were considered acceptable and useful by both parents and health professionals.

These 56 messages were further tested for readability using the SHeLL reader [40]. Two (1.8%) messages that exceeded the grade 5 reading level were removed.

Stage 5: Program Finalization and Functionality Determination

The final set of messages was mapped to oral health behaviors, barriers, enablers, intervention functions, and BCTs. Based on the final functionality determination, only 36 messages were required. Therefore, 18/56 (32%) messages that addressed similar barriers and enablers were removed to avoid redundancy. The final set included 12/36 (33.3%) messages addressing oral hygiene, 16/36 (44.4%) addressing dietary sugar intake, and 6/36 (16.7%) on bedtime routines. An example of how a barrier is mapped to an intervention function, a BCT and the SMS text message content for the program, is found in Table 2.

Table . Example of a barrier and enablers mapped to the Behaviour Change Wheel (BCW) framework and SMS text message content.

Barrier or enabler identified	COM-B[a]	TDF[b] and intervention function	Policy function	BCT[c]	Text message examples
Forgetfulness (barrier)	Motivation (automatic)	Reinforcement and enablement	Communication or marketing service provision	2.3 Self-monitoring of behavior; 4.1 Instructions on how to perform behavior; 13.1 Identification of self as a role model; 15.1 Verbal persuasion about capability	"Have you watched your children brushing their teeth today, did they do a good job? Brushing your teeth together can help them learn great habits @SMILESup"
Receiving reminders and tips (enabler)	Motivation (automatic)	Reinforcement and enablement	Communication or marketing service provision	8.3 Habit formation	"A little reminder for you to help [child name] brush their teeth before they go to bed. If they have clean teeth before they sleep, it will prevent tooth decay. @SMILESup"

[a]COM-B: Capability, Opportunity, Motivation-Behaviour.

[b]TDF: Theoretical Domains Framework.

[c]BCT: behavior change technique.

Finalizing the program's functionality included decisions about the duration, frequency, timing, and sequencing of the SMS text message algorithm. After consulting parents and considering the behavior change literature [42], the program was set for 12 weeks with an average of 3 messages per week, totaling 36 messages. Parents could semipersonalize the program by including their child's name in the messages and choosing the time they received the messages to best fit their lifestyles. The sequencing initially focused on bridging knowledge gaps identified by parents during the first month, with more reminders and messages targeting motivation scheduled for later in the program.

The message schedule and practice sequence were delivered using the Westmead Applied Research Centre's TextCare platform, a cloud-based system designed to semipersonalize the content and frequency of SMS text messages. TextCare includes built-in safety, privacy, and security systems with in-built data analytics, including an automated opt-out feature to measure engagement from parents. The messages are primarily 1-way, providing practical tips and strategies to prompt behavior change. The TextCare platform was monitored by a clinician researcher. RC tested the program for 1 month before delivering the program to parents.

Discussion

Principal Findings

This study reports the outcomes of a co-design and content evaluation of the *SmilesUp* SMS text message intervention, aimed at supporting parents of children with ECC in promoting oral health behavior change. Guided by the BCW, the intervention incorporates 16 BCTs to address motivation and knowledge gaps identified by parents. Of the 111 drafted messages, 56 (50.5%) text messages that were evaluated to be

XSL•FO
RenderX

understandable, useful, and acceptable by both parents and health professionals were programmed into the 12-week semipersonalized SMS text message program. This paper highlights the importance of involving parent end users at the beginning of the design process to ensure that the intervention addresses their needs in developing oral health–promoting behaviors for their children. This co-design work lays the foundation for future studies to test the effectiveness of the mHealth intervention for changing oral health behaviors [43].

Strengths and Limitations

A major strength of our study is the robust co-design process, structured around the BCW behavioral theory using mixed methods to incorporate perspectives from both parents and health professionals. The BCW, including the COM-B model of behavior change, ensured that the target behaviors were matched with the 16 BCTs to address identified barriers and enablers. The study aligns with the WHO's goal of optimizing digital technologies for oral health within its Draft Global Oral Health Action Plan (2023‐2030) and serves as an example of how a mHealth program can address ECC localized to the Australian context [44].

Methodologically, our study builds on the existing methods from other lifestyle-related behavioral studies [15,21,25,45-47] and is one of the few studies in the field of dentistry using a theory-driven design for mHealth programs focused on behavior change [48-50]. Our process was pragmatic, systematic, and grounded in behavioral theory. Although the formal triangulation of data was not conducted, qualitative findings informed content development, which subsequently guided the quantitative data collection. The quantitative insights were subsequently synthesized with the initial qualitative findings to ensure alignment with the original aims of the program. This iterative process led to the development of a distinctive program that addressed multiple oral health risk factors. Previous mHealth programs in oral health tended to focus on single risk behaviors, for example, on bedtime routines [49] or on diet [51]. Although specific to the Australian context, the robustness and adaptability of this program enables other countries to also co-design, adapt, and localize an mHealth program. This is especially important in lower resourced areas, including low- and middle-income countries in the Asia-Pacific region [52] and more globally [7,53]. Where both oral health consumers and practitioners are increasingly using digital technologies to enhance the preventive potential of oral health[54]. Furthermore, by using the BCW, this study contributes to the dental scientific community's understanding of effective BCT approaches used to improve oral health–related behaviors in the long term [20,29,30].

Raising the standard of mHealth design and involving end users in the design process is essential to ensure confidence in the impact that mHealth interventions can have on improving health outcomes. Continual consultation with parents shaped the content and functionality of the *SmilesUp* program, ensuring it was patient centered and designed for vulnerable families using NSW Health public dental clinics [18]. This approach aligns with value-based health care systems that prioritize the consumer voice [55] and enhances confidence in mHealth interventions and their potential impact. By using co-design and content evaluation, the *SmilesUp* program completed content acceptability testing to inform policy and funding decisions before further investments are made for efficacy testing.

A limitation of the current *SmilesUp* program is the 1-way SMS text messaging format. Although newer mobile health tools like mobile apps and wearables seem more advanced [56], our use of the APEASE framework and consumer consultation shows that SMS text messaging still remains an effective, equitable, and widely accepted option for patients and practical for health systems [15,57-60]. Furthermore, compared with standalone mobile apps, the TextCare platform enables analytics on message delivery and replies to assess the reach and engagement of the program. These data are critical for a process and feasibility evaluation before health systems make larger investments into digital health infrastructure to further embed programs like *SmilesUp* into their existing digital health management systems [56,61].

Future Directions

This co-design work is the first step before we conduct future research to test the effectiveness of the program in improving oral health behavioral outcomes, especially among parents of children at a high risk of ECC [43,62,63]. The effectiveness trial will be conducted in public dental care settings using the COM-B model to inform analytical strategies and outcome measures [43,64,65]. Future studies will also examine opportunities to expand the program for broader reach by translating the content to other languages and scaling the program to reach more families.

Conclusions

SmilesUp is a robust, co-designed, and behavioral theory–driven mHealth intervention developed to support parents, especially those from vulnerable and low socioeconomic families, to adopt key oral health behaviors to prevent ECC. By involving end-user parents in the co-design process, applying behavioral theory, and evaluating the content, the program ensures that it addresses specific knowledge gaps related to brushing, diet, and bedtime routines. This is a crucial first step before conducting a planned future trial to test the effectiveness of the mHealth intervention for behavior change and the prevention of ECC.

Acknowledgments

The authors would like to thank the consumers and health professionals at the Paediatric Dental Departments of the Sydney Dental Hospital, Sydney Local Health District, and the Westmead Centre for Oral Health, Western Sydney Local Health District, for their involvement in the study. No specific project funding was received for this study.

Abstract

Background: Globally, 10% of pregnant women and 13% of postpartum women experience mental disorders. In Bangladesh, nearly 50% of mothers face common mental disorders, but mental health services and trained professionals to serve their needs are scarce. To address this, the government of Bangladesh's Non-Communicable Disease Control program initiated "Wellbeing Centers," telemental health services in selected public hospitals.

Objective: This study examines implementation outcomes, including adoption, accessibility, acceptability, feasibility, usefulness, need, experience, perception, and expectations of the Wellbeing Centers, with a focus on antepartum and postpartum women.

Methods: Between January 2023 and August 2024, we interviewed 911 antepartum and postpartum women receiving mental health services and 168 health care providers at 6 Wellbeing Centers in 4 districts in Bangladesh. Data collection involved both quantitative and qualitative methods. Implementation outcomes were measured following the World Health Organization's implementation research framework. Depression and anxiety symptoms were assessed using the Patient Health Questionnaire-9 and Generalized Anxiety Disorder-7 questionnaires. Descriptive statistics and adjusted odds ratios (aORs) with 95% CIs were used to evaluate the implementation outcomes. Qualitative information was obtained through in-depth interviews and key-informant interviews.

Results: Almost all health care providers (165/168, 98.2%) reported that the Wellbeing Centers were feasible to implement in their health facilities; however, about half (84/168, 50%) felt that trained staff to operate them were insufficient. Almost all women agreed that the Wellbeing Centers were acceptable (906/911, 99.8%), useful (909/911, 99.8%), and enhanced access to mental health care (906/911, 99.5%). Patients visiting district-level hospitals had higher odds of access (aOR 1.5, 95% CI 1.1-2.0) to Wellbeing Centers. Moreover, 77.4% (705/911) of women experienced depression symptoms, and 76.7% (699/911) experienced

XSL•FO
RenderX

anxiety symptoms. About 51.8% (472/911) experienced tiredness or lack of energy, 50.9% (464/911) felt nervous, anxious, or on edge, 57.2% (521/911) felt worried, and 3.8% (35/911) had suicidal ideation almost every day. Patients visiting district hospitals had higher odds (aOR 2.6, 95% CI 1.8-3.78) of depression and anxiety symptoms compared to the patients visiting subdistrict-level hospitals. Decreasing trends in Patient Health Questionnaire-9 scores (from mean 14.4, SD 0.47 to mean 12.9, SD 0.47) and Generalized Anxiety Disorder-7 scores (from mean 13.3, SD 0.49 to mean 12.5, SD 0.48) between 2 counseling sessions indicated improved mental health in the antepartum and postpartum women. The Wellbeing Centers' services were appreciated for their privacy and being free and accessible. However, stigma, postpartum illness, and long waiting times prevented some women from using these services.

Conclusions: To our knowledge, this is the first implementation research assessing telemental health in public health facilities involving trained psychologists and psychiatrists. Our study highlighted the increased accessibility, feasibility, acceptability, and utility of Wellbeing Centers for antepartum and postpartum women in Bangladesh, supporting their scale-up in similar settings.

Introduction

Background

Maternal mental health problems are common during pregnancy and after birth [1]. It is recognized as a global public health issue, as approximately 10% of antepartum and 13% of postpartum women experiencing some sort of mental health disorders [2]. The prevalence of maternal common mental disorders is high (49%) in Bangladesh, which underscores a need to screen for depression and anxiety symptoms during pregnancy and postpartum period [3,4]. Around 1 in 5 women experience depressive symptoms during pregnancy, and around 1 in 3 women experience anxiety in rural Bangladesh [4]. In a different study, postpartum women in rural Bangladesh reported that 11% had depressed symptoms, 35% had anxiety symptoms, and 3.4% had both depression and anxiety symptoms [5]. A recent study suggested that postpartum depression symptoms have been more common among impoverished rural mothers during the shutdown in Bangladesh [6-8].

Adverse Effects of Maternal Mental Disorders During the Antepartum and Postpartum Periods

Pregnant women with low education, history of economic difficulties, poor marital relationships, family history of any common mental disorder, poor social and partner support, bad obstetric history, current or previous exposure to violence, preference to have a male child, history of abortions, and disturbed family environment are more likely to report any kind of antepartum and postpartum mental disorders [4,9-13]. Maternal depression may cause negative health-related behaviors and adverse outcomes, including psychological and developmental disturbances in infants, children, and adolescents [14]. Women with severe mental disorders also have increased risks of pre-eclampsia, antepartum and postpartum hemorrhage, placental abruption, impaired intrauterine growth, abortion, and cesarean section, and stillbirths are associated with antepartum and postpartum depression and anxiety [14-19]. Severe mental disorders result in suicide, a leading cause of maternal death in pregnancy and the postpartum period, which contributes to maternal mortality and low quality of life [1,20,21].

Why Videoconference-Based Counseling Is Appropriate as an Intervention for Maternal Mental Disorders in the Context of Bangladesh

Early detection and treatments are necessary to address these maternal mental health issues. Maternal mental disorders are treatable using effective counseling and therapies [22]. However, the availability and access to mental health services are somewhat limited in rural Bangladesh. In addition, the number of available psychologists and psychiatrists is very low. Bangladesh has an estimated 260 psychiatrists, or approximately 0.16/100,000 population, as well as 700 nurses who provide mental health specialty care (0.4/100,000), and 565 psychologists (0.34/100,000) mostly concentrated in urban settings [23]. Providing in-person mental health care with limited capacities such as very low designated government facilities with few specialty service providers is difficult [23].

However, Bangladesh has very good network coverage, which can be used for telehealth counseling services. Telemental health services, which gained popularity during the COVID-19 pandemic, are also commonly used in Bangladesh [24]. Several studies have found that telephone-based treatment significantly improved short-term symptoms and considerably alleviated the advancement of postnatal depression [25,26]. Evidence suggests that digital psychological interventions for mental health problems in developing countries are effective when usual care for mental health problems is minimal [27]. Another study reported that mothers experienced less maternal depression after receiving videoconference-based counseling [28]. Videoconference-based counseling has emerged as a practical and efficient means of providing mental health treatment in resource-limited communities for reducing symptoms of psychiatric disorders and helping to improve quality of life [29-33].

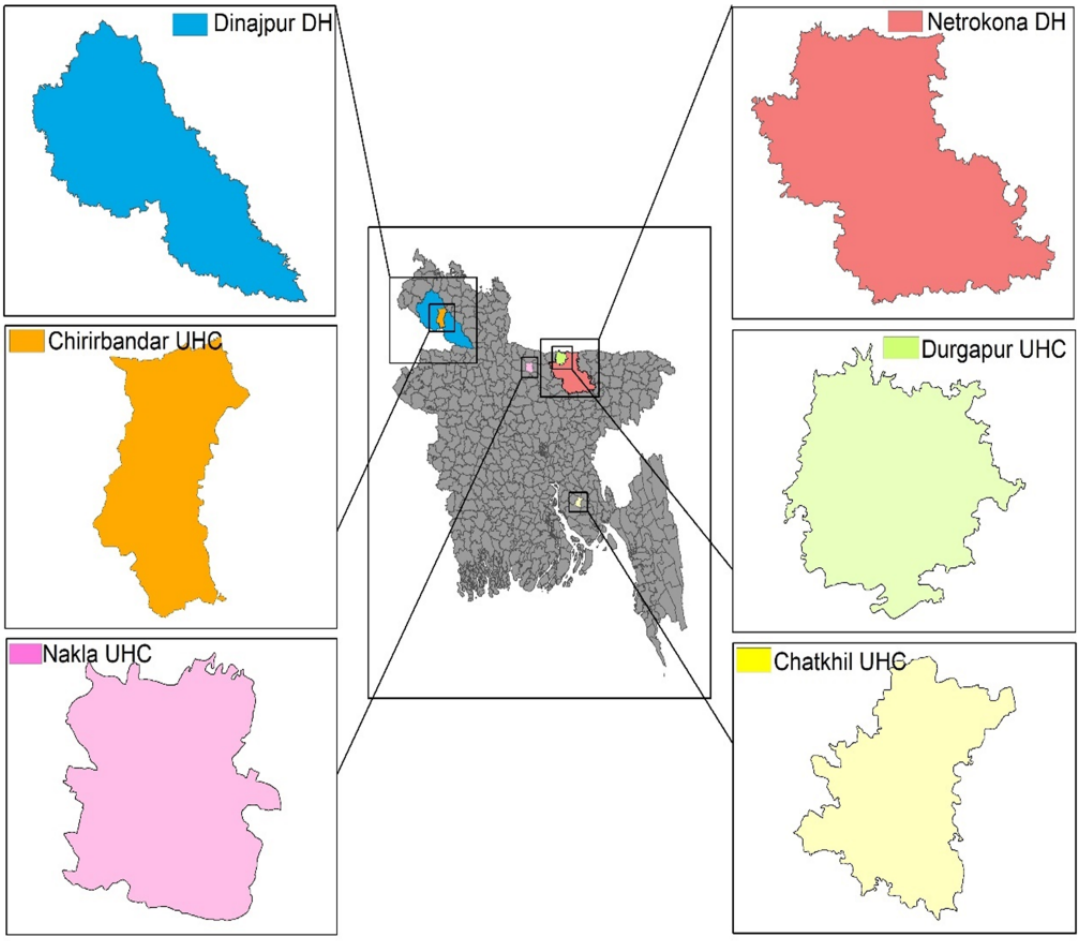
Implementation of Wellbeing Centers in Collaboration With the Non-Communicable Disease Control Program of the Government of Bangladesh

Cognizant of this reality, the Non-Communicable Disease Control (NCDC) program of the government of Bangladesh (GoB) initiated the telemental health service called "Wellbeing Centers" in 6 public hospitals of Bangladesh to provide

XSL•FO
RenderX

telemental health services with facilitation support from the International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b). General patients along with women with maternal mental health disorders can take personalized and specialized counseling support from a pool of psychologists and psychiatrists through videoconference counseling at the Wellbeing Centers [34,35]. It is important to know whether these services are adequately benefitting the targeted population in a larger number of facilities for scaling up these Wellbeing Centers in other districts in Bangladesh since no study ever explored it in Bangladesh.

Aims



The primary aim of this study is to assess the implementation outcomes (feasibility, accessibility, adoption, acceptability, usefulness, need, experience, perception, and expectation) of the Wellbeing Centers in selected district and subdistrict hospitals of Bangladesh. We will also explore the prevalence of depression and anxiety symptoms in the targeted population as a secondary outcome for demonstrating the need for such mental health care.

Methods

Study Setting

A total of 6 Wellbeing Centers were implemented in district hospitals (DHs) and 4 *upazila* (subdistrict) health complexes (UHCs) in Dinajpur district of Rangpur division and Netrokona district of Mymensingh division. Two other subdistrict-level health care facilities were from Nakla in the Sherpur district and from Chatkhil in the Noakhali district. Selected health care facilities were Dinajpur DH, Netrokona DH, Durgapur UHC, Chirirbandar UHC, Nakla UHC, and Chatkhil UHC (Figure 1). The NCDC program of the Directorate General of Health Services suggested carrying out the Wellbeing Center services in these enlisted 6 health care facilities.

Figure 1. Study sites. DH: district hospital; UHC: upazila health complex.

Study Design

An implementation research study was conducted, where the NCDC program designed, developed, and demonstrated an implementation model to introduce Wellbeing Centers for providing telemental health services. The study used both quantitative and qualitative data collection. Implementation facilitation support was provided, and assessments were conducted by icddr,b, an international health research organization based in Bangladesh.

Study Participants

Antenatal and postnatal women who visited to the outpatient settings (mainly antenatal care [ANC] and postnatal care [PNC] corner) and received counseling from Wellbeing Centers of the 6 selected health care facilities were enrolled in this study. A total of 911 women in antepartum and postpartum periods

XSL•FO
RenderX

received care from the Wellbeing Centers, and 168 health care facility managers and providers directly involved in the implementation were surveyed and reincluded in this analysis. The health care facility managers and providers included civil surgeons of the corresponding districts, hospital superintendents of the corresponding DHs, subdistrict health and family planning officers of the corresponding UHCs, resident medical officers (RMOs) of corresponding DHs and UHCs, physicians, and gynecological consultants from the outpatient departments.

Development of the Wellbeing Centers at the Health Care Facilities

Overview

The NCDC program of the Directorate General of Health Services, Ministry of Health and Family Welfare of Bangladesh received implementation support from the icddr,b along with other institutions, such as the National Institute of Mental Health (NIMH) and Department of Clinical Psychology, University of Dhaka, to establish the Wellbeing Centers.

Creating a Pool of Psychologists and Psychiatrists

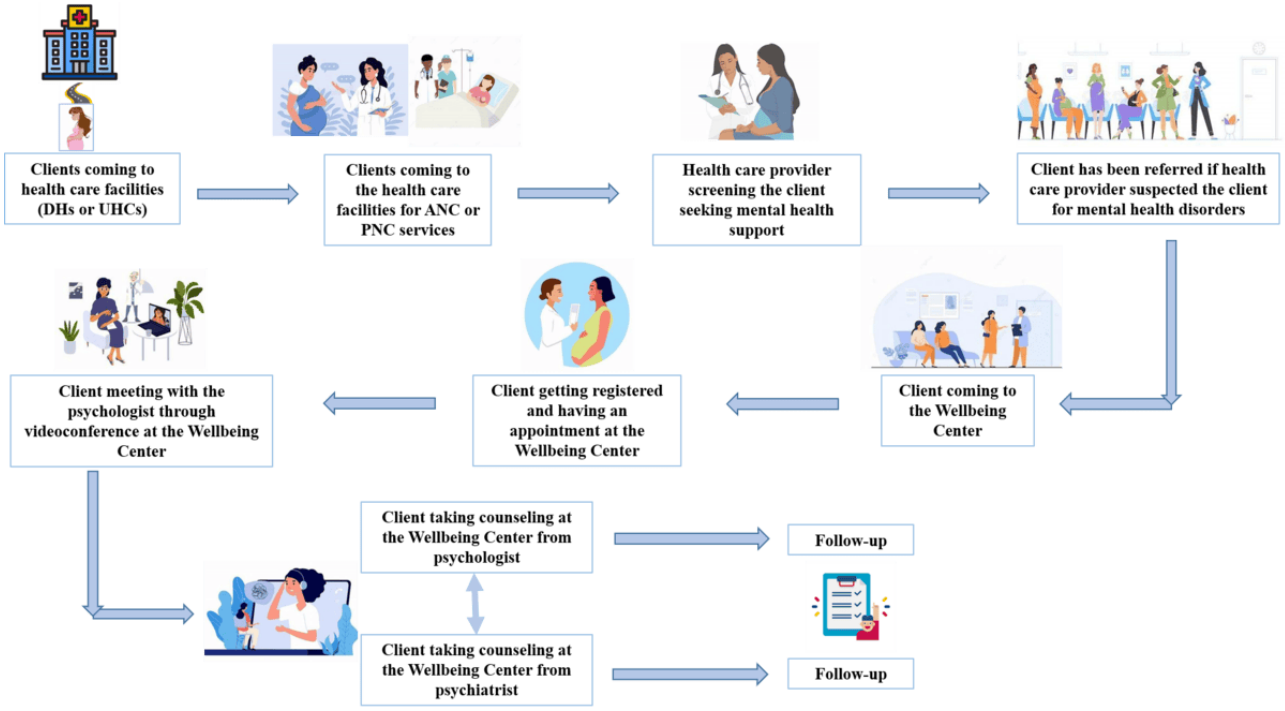
A pool of trained psychologists and psychiatrists has been formed to deliver mental health care services. This pool of psychologists and psychiatrists was guided and mentored by professional bodies from clinical and counseling psychology and psychiatry.

Establishment of the Wellbeing Centers

Equipment and technology recourses included a computer, an internet connection, and a webcam in each Wellbeing Center at the facility. To establish an internet connection, an internet router was provided. In cases of electrifying fall, an uninterrupted power supply was used. Psychologists and psychiatrists and patients were provided with headphones to cancel or isolate ambient noise. With the help of a digital platform, appointments were scheduled. Patients were connected with the psychologists through videoconferencing. In the hospital, a room was allocated for the Wellbeing Center. This room was dedicatedly used for telemental health, maintaining appropriate privacy and confidentiality. The webcam and video monitor were placed at the client's eye level to best approximate a face-to-face interaction.

Training

Health care administrators, expertise in mental health, along with facility managers partnered with icddr,b to facilitate training and workshops for district and subdistrict-level health care providers (such as RMOs, physicians, gynecological consultants, and health workers). Additionally, the implementation support team organized the orientation of both government and program-supported health workers to promote the Wellbeing Center activities. Training content covered the use of depression and anxiety screening tools, patient reception, appointment scheduling, communicable liaison, the integration of mental health services in outpatient settings, effective web-based patient engagement, the use of technology in delivering mental health services, patient referral processes, follow-ups, and crisis management.



Service Provision

At first, women who came to seek health care service at ANC or PNC corners of the health care facilities were referred by the physicians or gynecological consultants to the Wellbeing Centers. Afterward, a health worker screened and redirected women of antepartum and postpartum to a Wellbeing Center and registered the client's through the digital platform using their name and phone number. The health worker noted the availability of psychologists, and an appointment was then fixed. By creating a digital meeting link, the patient's information and schedule were shared with the psychologists. Patients were supported by the health worker to prepare and make necessary arrangements for connecting to the psychologists through videoconference ensuring adequate privacy.

Psychologists assessed clients' mental health disorders using psychometric tools and then provided tailored counseling. Psychologists designed additional management plans and follow-ups based on the clients' improvement dimensions. When counseling proved insufficient to address moderate to severe instances, clients were referred to the NIMH's psychiatrists. Then, the health worker made an appointment and used videoconference-based counseling to connect with the psychiatrist for further treatment. Each client had a second screening by a health worker using the Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-7 (GAD-7) during follow-up sessions in order to measure the degree of change in their mental condition (Figure 2).

XSL•FO
RenderX

Figure 2. Mental health service delivery mechanism of Wellbeing Centers. ANC: antenatal care; DH: district hospital; PNC: postnatal care; UHC: upazila health complex.

Data Collection

Both quantitative and qualitative methods were undertaken to collect data. Quantitative data were collected using tablets, and qualitative interviews were done using audio recorders. We developed a data entry interface for this implementation research to manage data. A quantitative survey was conducted among women by trained health workers. A structured quantitative questionnaire was used to collect data on demographics [36,37], validate depression and anxiety symptom screening in outpatient settings [38-41], and assess implementation outcomes including acceptability, usefulness, and adoptability [42]. Assessment of feasibility among health facility managers was determined using the World Health Organization's (WHO) improving health system and services for mental health guideline [42]. Qualitative information was received by trained researcher using in-depth interviews (IDIs) and key informant interviews (KIIs). All data collection tools are presented in detail in Multimedia Appendices 1-4. About 10 qualitative IDIs were conducted on experiences, perceptions, and expectations regarding the videoconference-based mental health counseling among women who received ANC and PNC in the health care facilities at the Wellbeing Centers. Moreover, 15 KIIs were conducted among the health care facility managers, RMOs, physicians, psychologists, psychiatrists, and health workers. The number of antepartum and postpartum women who took follow-up sessions was 51.

Study Measures

Basic demographic information included age (years), types of care (ANC and PNC), religion, profession, education (years completed), household income (taka per month), and catchment area (subdistrict and district) were determined. The WHO's implementation research in health care guideline was followed in terms of defining acceptability, usefulness, feasibility, and adoption [42]. Table 1 provides detailed indicator information for all the implementation outcomes assessed in this study.

The PHQ-9 [43] and the GAD-7 scales [44] were used to evaluate depression and anxiety in outpatient settings, respectively [39,41]. The PHQ-9 is a 9-item questionnaire that assesses depression symptoms in a range of 0=not at all to 3=nearly every day. The PHQ-9 score ranges from 0 to 27, with mild, moderate, moderately severe, and severe depression symptoms equating to cutoff values of 5, 10, 15, and 20, respectively. The GAD-7 is a 7-item questionnaire that measures anxiety symptoms on a range of 0=not at all to 3=nearly every day. The GAD-7 scale has a score range of 0 to 21, with mild, moderate, and severe anxiety symptoms equating to cutoff values of 5, 10, and 15, respectively. Figure 3 presents the logical framework of the telemental health intervention in reducing the common mental health disorders among pregnant and postpartum women.

Data Analysis

Quantitative Analysis

Stata (version 15.0; StataCorp) was used for this analysis. We have presented descriptive statistics (frequency and percentage) with 95% CIs. For measuring the effect of various factors (age, types of care, religion, profession, education, household income, and catchment area) on the accessibility of the Wellbeing Centers and need-related indicators (depression, anxiety, and both depression and anxiety), 4 separate fitted models were constructed. Multiple logistic regression models were applied to compute the adjusted odds ratios (aORs) with 95% CI. In the adjusted models, accessibility was considered if a woman "strongly agreed" that the Wellbeing Center increased the accessibility of mental health services. Severe depression symptoms were coded as "1," and others (mild, moderate, and moderately severe depression) were coded as "0." For anxiety, severe anxiety symptoms were coded as "1," and mild and moderate anxiety symptoms were coded as "0." When a participant was found to have both severe anxiety and depression, we documented this as the co-occurrence of the 2 conditions using a binary response format (1 and 0). Wald statistics were used to assess the model adequacy. We presented the differences in depressive and anxiety symptoms of antepartum and postpartum women occurring nearly every day using radar plots. At the 5% level of significance, the statistical significance of the estimates has been reported.

Qualitative Analysis

All audio-recorded interviews, supplemented with field notes, were transcribed verbatim. The transcriptions were then read through several times by all the researchers to get more familiar with the data. The transcriptions were manually thematically analyzed using an inductive approach [45,46]. The three stages of the analysis included (1) reading the interview transcripts; (2) highlighting the related words, coding them in relation to the text, and thereafter classifying them; and finally, (3) identifying the themes with reflective notes. The data were coded and categorized according to the emerging themes. Data were analyzed by NVivo (QSR International) qualitative data analysis software. To respect the anonymity of each participant, no personal identifying information was presented in the result.

Ethical Considerations

The icddr,b Institutional Review Board granted the study ethics approval (protocol PR-22103). All the eligible women have given written informed consent prior to the enrollment. All data were anonymized or deidentified. No monetary compensation was provided to participants for this research. Consent has been granted from identifiable individual features of research participants or users in any images of the manuscript or supplementary material.

Results

Quantitative Findings

The selection process of the patients from the facilities with Wellbeing Center for antepartum and postpartum women is shown in Multimedia Appendix 5. Between January 2023 and August 2024, 16,203 patients visited the outpatient department, from whom 5863 general patients received services from Wellbeing Centers. Among them, 4450 women visiting the ANC and PNC corners received services from 6 Wellbeing Centers. We have considered only the 911 antepartum and postpartum women who received mental health services at the Wellbeing Center.

Table 2 presents the background characteristics of the antepartum and postpartum women who received services from Wellbeing Centers. The majority of the women were young adults aged 20-24 years. Most of the women (n=817, 89.7%) who received mental health services at the Wellbeing Centers and NIMH were referred during ANC visits. Only 2.2% (n=20)

XSL•FO
RenderX

of the women were involved in any income-generating activities. In total, 54.6% (n=497) of the women completed secondary-level education, and 46.9% (n=427) were from the low-income group. A total of 70.6% (n=643) of the counseling receiving women visited the subdistrict-level facility.

Figure 4 presents the WHO-guided implementation outcomes, feasibility, accessibility, acceptability, usefulness, and need of the Wellbeing Center. Among 168 providers, almost everyone (165/168, 98.2%) reported that the Wellbeing Center is implementable at the facilities. Half of the providers (84/168, 50%) agreed that the facilities have trained staff to maintain the Wellbeing Center. Among the users, almost all antepartum and postpartum women agreed that the Wellbeing Center is increasing accessibility, and it is acceptable and useful for them, as antepartum and postpartum women experience depression and anxiety throughout the period. Around three-fourths of the users had moderate to severe anxiety or depressive symptoms, which demonstrated the need for mental health care.

Figure 5 presents the percentage of women who experienced depressive and anxiety symptoms nearly every day in the past 2 weeks, as indicated by the PHQ-9 and GAD-7 scales. Half of the women (472/911, 51.8%) experienced a lack of energy nearly every day, and 36.6% (333/911) experienced a lack of interest and pleasure. Around one-third of women faced issues with trouble falling asleep or sleeping too much and poor appetite or overeating almost every day. In total, 3.8% (35/911) had suicidal ideation almost every day. Among the anxiety symptoms, 57.2% (521/911) worried too much about different issues, and 50.9% (464/911) experienced nervousness almost every day in the past 2 weeks.

The health care providers reported the need for telemental health in their respective facility:

> *Due to the shortage of well-trained psychiatrists nearby, we have to take treatment from the divisional level health facilities, which is time-consuming and costly. Ensuring proper mental health service district and upazila-level hospital requires service like tele-mental.* [KII-15, health worker, Nokla UHC, age 42 years]

Table 3 summarizes the effect of various factors on accessibility and need-related indicators. The odds of increased perceived accessibility were lower among patients receiving PNC compared to ANC with aOR 0.45 (95% CI 0.27-0.74). Women with lower education and lower income had higher perceived accessibility. Patients visiting DHs had higher odds of perceived accessibility (aOR 1.48, 95% CI 1.1-2.0). Patients visiting DHs had 3 times higher odds (aOR 2.58, 95% CI 1.82-3.68) of experiencing both depression and anxiety symptoms, expressing the need for mental health services through the Wellbeing Center.

Figure 6 presents the change in average scores of PHQ-9 and GAD-7 between the first and second counseling sessions of the antepartum and postpartum women. The average PHQ-9 score decreased from 14.4 (SD 0.47) to 12.9 (SD 0.47), and the average GAD-7 score decreased from 13.3 (SD 0.49) to 12.5 (SD 0.48) between these 2 sessions, indicating the usefulness of Wellbeing Center. These changes were statistically significant with $P<.001$.

The proportion of people taking follow-up counseling is shown in Multimedia Appendix 6. Only 15.1% (51/338 suggestions of follow-up visits) took follow-up counseling among the patients who were suggested a follow-up session.

Qualitative Findings

Perception and Experience Regarding Wellbeing Center Services During the Antepartum and Postpartum Periods

Positive Attitude of the Service Providers

The positive attitude of psychologists and health workers of the Wellbeing Centers strengthened the telemental health services compared to other health services. The health workers of the center cordially received the antepartum and postpartum women who were referred by the physicians. During the counseling session, psychologists listened to their problems and issues attentively and provided video counseling, which gives them better feelings about the service at the Wellbeing Center. A pregnant mother mentioned the following:

> *I feel scared to share my all problems with a physician! I just responded to what the doctor wanted to know. But in the audio-visual call, a counsellor gives a welcoming tone which influenced me to share my mental health issues clearly.* [IDI, female, age 32 years]

Cost and Accessibility

Earlier, antepartum and postpartum women who experienced mental health disorders had to get treatment from the regional medical college hospitals or have to go to specialized hospitals. Because of the Wellbeing Center, people can get mental support on their doorstep. From the Wellbeing Center, anyone can get free-of-cost and hassle-free treatment. Those who seek mental health treatment from private hospitals have to spend considerably more money on paying psychiatrist fees, unethical financial gain of clerks, medication, transportation costs, etc. Nevertheless, patients found videoconference-based counseling at the Wellbeing Centers more convenient than the traditional treatment system, as they do not require any treatment costs, and it provides easy treatment access at their doorsteps. A service receiver mentioned the following:

> *If I come here [Wellbeing Center] it will save my money and I get treatment from a good specialist that won't cost me money.* [IDI, female, age 22 years]

Privacy and Confidentiality

While the antepartum and postpartum women received counseling, nobody was present in the room to ensure privacy and confidentiality. Service receivers' privacy is a prime concern at the Wellbeing Centers, as patients receive services in a separate room that ensures privacy during the counseling. A service receiver said the following:

> *During in-person consultations, I did not freely communicate to the doctor [psychiatrist-private chamber] because of the other patient's presence in the waiting area. But in the Wellbeing Center, I do not have worries about violation of [my] privacy while getting audio-visual counseling in a separate room.* [IDI, female, age 24 years]

Name

The name of the mental health service center is Wellbeing Center to overcome the stigma and social taboo associated with psychological support needs. Whenever antepartum and postpartum women and their caregivers come to the corner, they do not hesitate to seek care. This may be due to the perception of a safe and supportive space that encourages open discussion of mental health issues without fear of judgment. The term "well-being" did not demonstrate any stigma. A health worker mentioned the following:

XSL•FO
RenderX

We do not use the term mental health corner, instead we use "Mon-Shastho Kendro" [Wellbeing Center] to avoid the stigma. When doctors refer them to the Wellbeing Centerthey do not feel hesitation. [KII, health workers, age 33 years]

Barriers to Using the Wellbeing Center Services

Stigmas and Taboos

During the pregnancy period, mothers experience numerous negative emotions. Though they can understand that their mental condition is changing, they cannot share their problems due to stigmas and taboos. Even more, they do not disclose their mental health problems to their husbands and family members. Fear of family violence and potential disruption of marriage often prevent pregnant women from disclosing their mental health issues. A pregnant mother mentioned the following:

> *I do not share my problems with my family members, if I share my mental problems with them then they may make any comments on this that will be very frustrating to me.* [IDI, pregnant mother, age 29 years]

Postpartum Illness

During the postnatal period, mothers are unable to receive mental health treatment from the Wellbeing Center for their physical illness and lack of support from the family. Moreover, after childbirth, the physician referred the mothers to the Wellbeing Center based on the mental health examination. However, sudden release from the hospital is a reason for not receiving the services. A health worker mentioned the following:

> *Within the 42 days [postnatal period], mothers were physically sick to come. Those who are referred by the physician, sometimes get a sudden release from the hospital. Therefore, they do not come for mental health services.* [KII, health assistant, age 33 years]

Long Waiting Times

During the follow-up visit, antepartum and postpartum women have to wait in the ANC and PNC corner for taking services. Some patients were in a rush to receive the service, but it was not possible to give them an opportunity, as other patients were also on the waiting list. This may be due to the patient load and the ANC and PNC corners operating on a first-come, first-served basis. A pregnant mother mentioned the following:

> *I feel unsteady while waiting for [receiving] the mental health service. There are only three seats in the waiting room, and three mothers already waiting there to receive the service. Therefore, I and my husband have to stand up for around thirty to forty minutes which causes the irritation.* [IDI, pregnant mother, age 18 years]

Discussion

Principal Findings

Our research demonstrated that telemental health services through the Wellbeing Center are feasible, acceptable, useful, and highly needed among women. It has increased accessibility to mental health services to pregnant or postpartum women with a lower level of income and education. The health care providers felt a need for more staff with appropriate training to implement this intervention at the hospitals, who are lacking in Bangladesh. The women visiting the DHs have a higher level of depression and anxiety symptoms, demonstrating a critical need for mental health services. Our follow-up assessment scores on depression and anxiety symptoms after the first counseling sessions demonstrated a decrease in the average scores, which indicted the effectiveness of the Wellbeing Centers. The service beneficiaries recommended the intervention because of the positive attitude of the service providers; the services being free of cost, private, and confidential; and its sensitive naming. However, they also mentioned some barriers to receiving care from Wellbeing Centers, which included social stigma, postpartum illness, and long waiting times at the facility to use the service.

To the best of our knowledge, this is the first implementation research that assessed the WHO implementation outcome variables of a facility-based telemental health intervention, the Wellbeing Centers, for antepartum and postpartum women that is operated by the GoB. We have pioneered in proposing an implementation model for mental health care including a pool of trained psychologists and psychiatrists who provided counseling and medications for mental health issues through videoconferencing in the Wellbeing Centers at the public health facilities in Bangladesh.

Some public hospitals in Bangladesh had initiated telemedicine units as a part of their routine care system. However, telemental health services through Wellbeing Centers differ from general telemedicine in several ways. Telemental health often involves specialized platforms designed to provide psychological assessments, therapy, and psychiatric consultations. In contrast, telemedicine includes a broader range of remote clinical services, including primary care, specialist consultations, and follow-up visits. Telemental health is a specialized subset of telemedicine focusing on mental health. While both telemental health and telemedicine use videoconferencing, phone calls, and other digital communication tools, telemental health platforms are tailored to address the unique needs of mental health care, such as ensuring patient privacy and providing a comfortable environment for discussing sensitive issues. This specialization can lead to better patient engagement and satisfaction in mental health care compared to general telemedicine [47]. This type of service is expected to vary according to the differences in context and health systems. Our research focused on the implementation outcomes of telemental health care. This provides evidence to support the scale-up of telemental health care through Wellbeing Centers.

Adoption and Acceptability

A significant proportion of Bangladeshi mothers have common mental health issues during the antenatal and postnatal period [4,48]. Most mental health care facilities are clustered around urban areas, while rural women do not have access to mental health care in Bangladesh. Since maternal mental distress among these rural mothers may cause adverse maternal and child health outcomes, appropriate interventions can address maternal mental distress among the Bangladeshi maternal population. Evidence supports the effectiveness of digital psychological interventions,

XSL•FO
RenderX

especially in low- and middle-income countries where mental disorders contribute significantly to the global burden of disease [49,50]. Globally, these services offer private, personalized support, connecting disparities in mental health care for those facing challenges accessing traditional services or face-to-face services [49]. Global evidence emphasizes the role of telemental health service as an equivalent and effective method, particularly in delivering mental health services to remote areas with limited resources. A significant number of users in our study provided strong evidence on the adoptability and acceptability of the telemental health services through Wellbeing Centers in Bangladesh. Services through Wellbeing Centers minimized travel, offering cost-effective and accessible psychological and psychiatric services.

Feasibility

The health care providers perceived that the telemental support through the Wellbeing Center is highly feasible. However, they also felt that the facilities lacked appropriately trained staff to maintain these centers. Banbury et al [51] stated that staff require comprehensive training to sustain and expand telehealth use in the facilities. These trainings should focus on knowledge, skills, and competencies in using telehealth as well as the broad factors of policies and understanding technologies to support the service providers [51]. Studies have discussed concerns around a lack of appropriate training to be able to conduct remote mental health care effectively and safely [52]. The government should ensure adequate training and supportive supervision for health providers (such as RMOs, physicians, gynecological consultants, and health workers) on mental health disorder assessments of pregnant and postpartum mothers, psychosocial services, as well as information and communication technology to maintain Wellbeing Center activities.

Accessibility

In the context of Bangladesh, mental health services face challenges due to limited resources and a shortage of professionals, relying heavily on the NIMH in Dhaka [53,54]. The new mental health policy of Bangladesh prioritizes community-based services, with nongovernment organizations contributing scalable models, including telemental health initiatives [55,56]. Access challenges still persist despite some voluntary counseling platforms, due to their lack of visibility [57,58]. These programs are not also integrated into the government system. Despite progress and current provisions for service delivery, issues like low help-seeking, inadequate service delivery, and persistent stigma emphasize the need for telemental health services on a larger scale [59]. Integrating telemental health services with these services is essential for improved mental health care [58]. Wellbeing Centers increased perceived accessibility among antepartum and postpartum women. Perceived accessibility was significantly higher among lower socioeconomic groups and lower educated groups. One of the reasons for this could be the free-of-cost facilities at public hospitals that are near their location.

Need

We looked into the need for well-being by looking at the depressive and anxiety symptoms prevalent among our targeted patients. Two-thirds of the women who sought services from the Wellbeing Center had moderate to severe indications of depression and anxiety. In addition, we observed a high level of anhedonia or lack of interest and tiredness among the women in the last 2 weeks. These highly prevalent symptoms indicated the need for Wellbeing Centers for the targeted mothers. El Sayed et al [60] reported that fatigue and anhedonia were prevalent and commonly reported in the post–COVID-19 period. A study by Costa et al [61] also reported that the prevalence of perinatal depression increased during the COVID-19 pandemic, which may be due to changes in the profile of specific depressive symptoms. Pearson et al [62] conducted a study where they reported that women experiencing anhedonic depressive symptoms during pregnancy had significantly larger systolic blood pressure responses toward infant distress than nondepressed pregnant women. Special attention should be given to anhedonia and fatigue-related symptoms of perinatal depression to ensure that they are adequately managed.

Among the other depressive symptoms, our finding that 3.8% (n=35) of patients experienced suicidal ideation is a significant concern, reinforcing the need for enhanced mental health interventions in Bangladesh. Scientific studies discussed the complexity of suicidal ideation, noting that it often goes unreported due to stigma and fear of judgment [63]. Suicidal ideation is influenced by a complex interplay of biological, psychological, and social factors. While some biomarkers have been identified to predict the risk of suicide, the underlying causes of suicide remain largely unclear. More research is needed to understand the root causes of suicidal ideation. Digital tools, such as mobile apps and telehealth services, can effectively monitor and reduce suicidal thoughts by providing real-time support [64]. Additionally, telehealth-supported decision-making has been found to significantly reduce suicidal ideation [65].

Our study also found that the level of worry and nervousness in the past 2 weeks was significantly higher among pregnant and postpartum women. More than half of the women experienced these symptoms of anxiety in the past 2 weeks almost every day. Tarafa et al [66] conducted a study in Ethiopia and assessed the factors associated with pregnancy-related anxiety among pregnant women attending ANC follow-up. Unwanted pregnancy, high perceived stress, young age, depression, low income, and poor social support were significantly associated with pregnancy-related anxiety. The overall prevalence of pregnancy-related anxiety in this study was slightly lower 32.7% [66]. It is worth noting that this study assessed only pregnancy-related anxiety while we included both pregnant and postpartum mothers. Appropriate intervention and focus are needed to address these worries and anxieties of pregnant women and postpartum mothers in Bangladesh through Wellbeing Center activities.

We report higher depression and anxiety and perceived accessibility among the women who took Wellbeing Center services at the district-level facilities compared to the subdistrict-level facilities. The reason can be regarded as an indirect effect of urbanization. A recent meta-analysis conducted by Cadman et al [67] assessed the influence of the urban environment in pregnancy and postpartum depression. Exposure

XSL•FO
RenderX

to air pollution and road traffic congestion may increase maternal depression. The urban family structure, with a lack of family support, may also induce higher levels of depressive and anxiety symptoms in Bangladesh. A study conducted on adolescents researched screen-related sedentary behavior, finding that the use of social media caused 2 times higher depression among urban adolescents [68]. A large proportion of our users of Wellbeing Centers were adolescents. Therefore, urgent initiatives should be taken to control the spread of depression and anxiety among the urban population, especially for mothers. In summary, at the district-level facilities, the need for mental health services was higher among the antepartum and postpartum women, which necessitated a strengthened focus on providing equitable services through the Wellbeing Centers in Bangladesh.

Usefulness

While we found the Wellbeing Centers to be feasible and acceptable, our study also indicated small improvements during the follow-up counseling sessions for the targeted patients. A review by Hilty et al [34] reported that telemental health is effective for diagnosis and assessment across many populations, including adults, children, older people, and people of different ethnicities, and for disorders in home and facility settings. This review urged that more research should be conducted on service models, specific disorders, issues regarding culture and language, and cost. Ensuring follow-up visits after the first counseling session is important for the sustained impact of telemental health services. However, we have not observed many women taking follow-up services in our Wellbeing Centers. Special initiatives such as follow-up phone calls or reminders should be ensured to increase follow-up sessions when needed and recommended.

Experience, Perception, and Expectation

Our research explored the experiences and perceptions regarding the Wellbeing Center activities, which revealed several strengths of and barriers to using these services. The users acknowledged the positive attitude and patience of the counselors during the service sessions. In Bangladesh, in-person psychiatric services are expensive and may not be affordable for underprivileged women. The Wellbeing Center services were completely free of cost, which attracted the targeted patients. Furthermore, these Wellbeing Centers ensured the privacy and confidentiality of the patients while providing psychological or psychiatric support. Many women were comfortable while expressing their problems and mental health issues, as they were reassured by this confidentiality. Finally, the women praised the naming of the service, which also addressed the stigma around mental health. The women also mentioned that existing stigmas and taboos on seeking mental health services prevented them from seeking care. However, almost all users of the Wellbeing Centers agreed that these services were acceptable to them. Further research is necessary to understand the actual state of stigma in the community regarding mental health care seeking.

Our quantitative data suggested that more women during pregnancy used Wellbeing Center services compared to postpartum women. Our qualitative finding echoed this finding as women reported postpartum illnesses were a barrier for them to seeking mental health care. Finally, few women mentioned that the long waiting time repelled them to receive services from the Wellbeing Centers. With the high demand and popularity, the system experienced a high patient load and struggled to satisfy all patients with timely services.

Comparison With Prior Studies

Recent studies on telemental health interventions have shown promising results, particularly in the context of the COVID-19 pandemic, which accelerated the adoption of remote mental health care. Research indicates that telemental health, including videoconferencing and phone-based therapy, is generally as effective as in-person care for a variety of mental health conditions [47]. Our research found similar results in terms of feasibility, utility, and effectiveness. A recent systematic review on implementation strategies for telemental health published in 2023 by Appleton et al [52] highlighted that telemental health can improve access to care, especially for individuals in remote or resource-limited areas. Our study echoed them in terms of the role of telemental health support in increasing the accessibility of mental health care in Bangladesh. While most studies on telemental health mentioned positive outcomes, one of the meta-analyses on mobile phone–based telemental health interventions by Goldberg et al [69] suggested that the effectiveness of these interventions can vary based on the specific mental health condition and the technology used. Our study could not compare the efficacy of the Wellbeing Centers compared to other phone-based or community-based methods. We recommend further research and trials to understand the actual benefits of using Wellbeing Centers compared to other types of services.

Strengths

Our study has several strengths, based on which we have identified the major findings discussed earlier. This study was conducted in 6 facilities, which provided us a reasonably large sample of pregnant and postpartum women attending antenatal and postpartum care. It involved a rigorous analysis using WHO-guided implementation variable, which ensured standardization with other global implementation research on telemental health services. Our intervention was provided through the government system; therefore, these findings will be valuable for the GoB for scaling up the intervention to a higher number of facilities. This paper focused on the pregnant and postpartum women. However, the services are also provided to general patients. Therefore, findings might provide additional evidence while assessing the implementation outcomes for general patients.

Limitations

We also acknowledge some limitations of our study. First, this study was conceptualized based on the WHO framework and implementation outcome variables. The WHO's implementation outcome variables may have limited the opportunities of capturing other potential outcome variables that may be important for assessing implementation aspects of the Wellbeing Centers. Second, we acknowledge the fact that we did not randomly select our demonstration sites for Wellbeing Centers. Therefore, the result may not be generalizable to the whole

XSL•FO
RenderX

country. In Bangladesh, there are regional variations that have an impact on access to health care as well as service quality. Our selected sites reasonably capture the variations of the service provision and quality. Third, we also acknowledge that we have selected the DHs based on their functionality. The inclusion of low-performing districts could make our results more generalizable. However, this was not possible because of implementation cost challenges. Fourth, in this analysis, we could not assess the rate of adoption of the Wellbeing Center services, as we could not capture the true denominator of how many women needed mental health support among those seeking ANC or PNC from the facilities. Finally, this analysis only assessed symptoms of depression and anxiety as mental health issue. Other disorders could also have been included to strengthen this study.

Conclusions

This implementation research study demonstrated the feasibility, acceptability, and usefulness of introducing the telemental health service Wellbeing Centers for antepartum and postpartum women at Bangladeshi facilities. We are confident in our conclusions, as we saw the services increased the perceived accessibility of mental health services with minimal influence from other factors. Appropriate staff training is required to maintain these centers. We recommend that psychologists and psychiatrists have patience and a positive attitude while maintaining the privacy of patients during the scale-up of the model. We also recommend future studies on cost-effectiveness and postimplementation follow-up to evaluate the sustainability, effectiveness, and impact over a longer time period. The experiences and learnings from this implementation research can support generating evidence-based decisions related to the introduction and scaling-up of the Wellbeing Centers in Bangladesh and other low- and middle-income countries.

Acknowledgments

This research protocol or activity or study was funded by the Department of Foreign Affairs, Trade and Development through Advancing Sexual and Reproduction Health and Rights (grant SGDE-EDRMS-#9926532, purchase order 7428855, project P007358). The International Centre for Diarrhoeal Disease Research, Bangladesh is also grateful to the governments of Bangladesh and Canada for providing core or unrestricted support.

Authors' Contributions

ATH developed the manuscript as the first author with support from AER. AER and MSS guided ATH in designing the study and developing the manuscript as joint senior authors. SEA and MRA reviewed the results and guided the team in interpreting the results. MHR, RMM, and EA contributed to data management and statistical analyses. MAH conducted the qualitative interviews, and TA, NGU, and PC supported in qualitative data management. SMHI supervised the implementation and field activities. HUA, MKM, JMJ, FS, SAS, FA, and MJB provided guidance in validating the psychological and psychiatric information of the study. MAK and SMMR provided support in developing the intervention strategy. SA, SJ, and AA reviewed the first draft of the paper. All authors contributed to the interpretation of the results and read and approved the final version of the paper.

As a student advocate actively involved in heart health promotion among youth, I was interested in the study entitled "Exploring Health Educational Interventions for Children With Congenital Heart Disease: Scoping Review" [1]. The authors identified a gap in age-appropriate educational tools for younger children in the interventions, highlighting the importance of using playful, developmentally tailored strategies to engage them in learning about their cardiac condition.

This insight dovetails precisely with the broader realm of pediatric health literacy, wherein the convergence of cognitive development and medical comprehension calls to attention unique barriers. Children with congenital heart disease (CHD) face difficulties in understanding abstract medical concepts and their condition [2]. Considering this, narrative medicine holds great potential in increasing the relatability, digestibility, and applicability of knowledge by reframing biomedical concepts into metaphorical storytelling. Thus, children with CHD may be able to internalize their medical journey in ways that align with their developmental stage and personal experiences, gaining a sense of agency and coherence.

Similarly, the role of ludic and entertaining pedagogical tools emerges as a pivotal mediator of developmental trajectories across cognitive, social, and emotional domains. Health care providers, especially pediatricians and family physicians, must actively ensure that play is healthy and safe [3]. Whether it be a story-driven game or a cardiac-themed toy, interactive tools may significantly advance educational interventions through tangible learning modalities that convert abstract principles into concrete experiences. As such, the cardiac health journey becomes one of engagement, where the child becomes a conscious, active participant in their medical education rather than a mere recipient of information.

The teddy bear hospital concept in particular exemplifies this symbiotic relationship between play and education, demonstrating efficacy in reducing children's health care–related anxiety, improving their health care knowledge, and enhancing their well-being through playful role-playing in a health care setting [4]. By softening the edges of medical procedures, this model dismantles the intimidating walls of the clinical environment, transforming it into a less foreign and more approachable space for younger children who are not as impacted by traditional educational interventions.

Yet another crucial dimension of children's play surfaces through physical activity. Children with CHD and their parents recognize the importance of physical activity, but uncertainty in their health environment contributes to inactivity despite minimal professional restrictions [5]. An area ripe for intervention, physical activity guidelines could incorporate real-time feedback mechanisms that build confidence and ensure safety to promote physical exercise as an act of healing and empowerment, rather than a source of anxiety.

In tailoring educational messaging by age, we can raise the effectiveness of CHD interventions, recognizing and respecting that children are not simply "mini teenagers" and much less "mini adults." Such an approach must, therefore, incorporate elements of embodied cognition, experiential learning, and psychological support to create a comprehensive educational framework that addresses the specific cognitive and emotional needs of children with CHD. Only in this way can we create immersive and engaging learning environments that make complex cardiac concepts accessible to the young minds often underrepresented while fostering psychological resilience and physical confidence.

Abstract

The first 1000 days of a child's life, spanning from the time of conception until 2 years of age, are a key period of laying down the foundations of optimum health, growth, and development across the lifespan. Although the role of health prevention programs targeting families and children in the first 1000 days of life is well recognized, investments in this key period are scarce, and the provision of adequate health care services is insufficient. The aim of this viewpoint is to provide a holistic digital health framework cocreated with policy makers, health care professionals, and families to support more effective efforts and health care programs dedicated to the first 1000 days of life as the first line of prevention. The framework provides recommendations for leveraging on behavioral intervention technology and digital therapeutics solutions augmented by artificial intelligence to support the effective deployment of health prevention programs to families. The framework also encourages the adoption of a citizen science approach to co-design and evolve the digital health interventions with all relevant stakeholders in a real-world research perspective.

(JMIR Pediatr Parent 2025;8:e55235) doi:10.2196/55235

KEYWORDS

digital health; digital therapeutics; behavioral intervention technology; prevention; citizen science; first 1000 days

Introduction

The first 1000 days is a continuum that begins with pregnancy and ends at the child's second birthday. It is a unique period laying down the foundations of optimum health, growth, and development across the lifespan [1], but it can also represent a period of potential vulnerability where the way mothers and children are cared for has a profound influence on a child's ability to grow, learn, and thrive [2]. Although the role of the first 1000 days of life is well recognized [2,3], investments in this key period are scarce, and the provision of adequate health care services and interventions is insufficient [1].

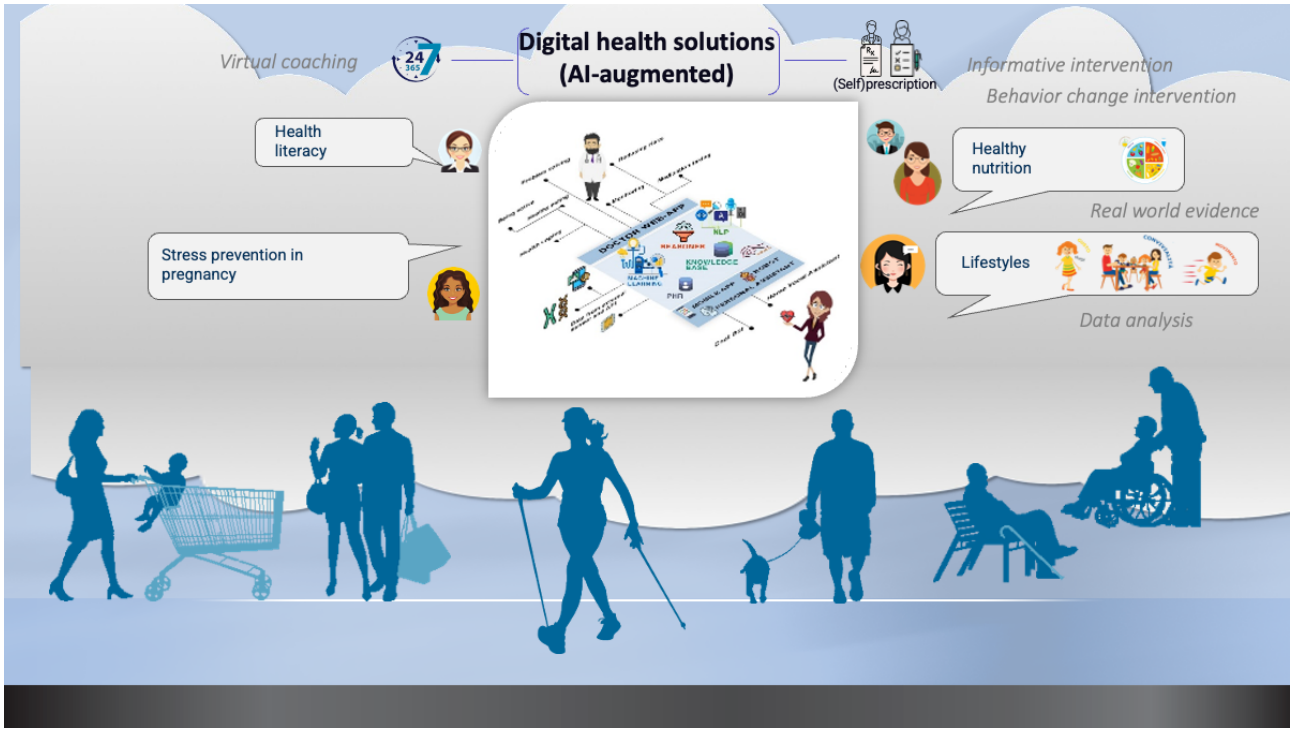
In this viewpoint, we address current challenges and opportunities in the development of effective health care interventions for the first 1000 days, by leveraging on a holistic digital health (DH) framework that can help to optimize efforts in the cocreation of these interventions with the support of policy makers, health care professionals, and families. The framework leverages on state-of-the-art approaches and opportunities in the design of behavioral intervention technology (BIT) and artificial intelligence (AI)–augmented digital therapeutics (DTx) for prevention and care, such as the Integrate, Design, Assess, and Share (IDEAS) framework [4] and the DTx Real-World Evidence (RWE) framework [5]. It complements these approaches by stressing the importance of facing the design and validation challenges within a longitudinal perspective based on citizen science and real-world evidence, to cocreate and evolve the DH interventions in a more pragmatic and sustainable way.

Health Prevention Strategies and Challenges in the First 1000 Days

The first 1000 days are characterized by 3 main periods of intervention, preconception, pregnancy, and infancy, which are key for ensuring children's healthy growth [1,3]. Health prevention programs and strategies during the preconception period address biomedical, behavioral, and social risks factors that may affect a pregnant woman's health, by providing nutritional and physiological support; identification and prevention of risks, such as toxic exposures [6,7]; and support in the adoption of changes in lifestyle [3]. Health prevention programs and strategies should also be maintained in the interconception period, going from childbirth until the birth of a subsequent child [8]. During pregnancy, the main areas of prevention typically regard nutrition, stress, and exposure to environmental contaminants [3,9]. The Italian Ministry of Health identifies 11 thematic areas that focus on prevention in the first 1000 days, including nutrition, lifestyle, parental literacy and skills, and mental health [10].

In different countries, public health care programs and interventions have been developed to support families in the

XSL•FO
RenderX



first 2 years after birth [11-14], promoting health literacy and behavioral change of parents in key areas such as nutrition, lifestyles, and mental health. Notwithstanding the large amount of data and guidelines supporting the importance of establishing efficient health care services in the first 1000 days, these health prevention strategies have not been efficiently converted into comprehensive and integrated programs enabling adequate support to parents and infants during this period [1,15,16].

In this viewpoint, we advocate that this gap is also due to a lack of deployment of DH solutions that support evidence-based educational and behavioral interventions for families and are designed for being acceptable, inclusive, engaging, equitable, scalable, and sustainable over the lifespan. Recent reviews of health professional-delivered interventions during the first 1000 days have shown that so far, most interventions were delivered in individual or group face-to-face sessions and that optimal intervention, in terms of timing, content, dose, mode of delivery, theory, and active ingredient, have yet to be established [15].

In our vision, DH technologies can play a key role in supporting the deployment of health prevention strategies and programs in the first 1000 days (as the first line of prevention) as well as over the individuals' lifespan. The kind of automation, engagement, and decisions supported by DH empowered by AI are commonly reviewed by domain experts before they can be implemented in a treatment plan, a process called augmented intelligence or intelligence amplification [17], wherein AI technology informs and augments, rather than replaces, health care professionals' experience and cognition [18].

As depicted in Figure 1, prevention programs addressing key areas of intervention, such as nutrition, lifestyle, mental health and well-being, health literacy, and education, may be more effectively translated into behavioral intervention solutions. These interventions should be informed by evidence-based theoretical approaches and a diversity of potential technologies to ensure a scalable, sustainable, accessible, and cost-effective delivery of prevention strategies. To address the challenges of effectively designing such solutions we call for a holistic DH framework helping to combine behavioral, technical, and methodological components in the intervention design process to ensure a translation of health strategies into better prevention and health outcomes for the target populations.

Figure 1. Digital health solutions delivering prevention programs in the first 1000 days and over the lifespan. AI: artificial intelligence.

A Holistic DH Framework for Cocreation With Stakeholders

Opportunities and Challenges of DH Deployment

Recent advances in the development of DH solutions provide unprecedented opportunities for deploying health prevention strategies and programs with the support of BITs or DTx. BITs typically include sensor-trackers (eg, heart rate and step count), AI-augmented chatbots (automated conversational agents), and momentary ecological assessments (which can repeatedly assess individual's behaviors and experience them in real time) [19-21].

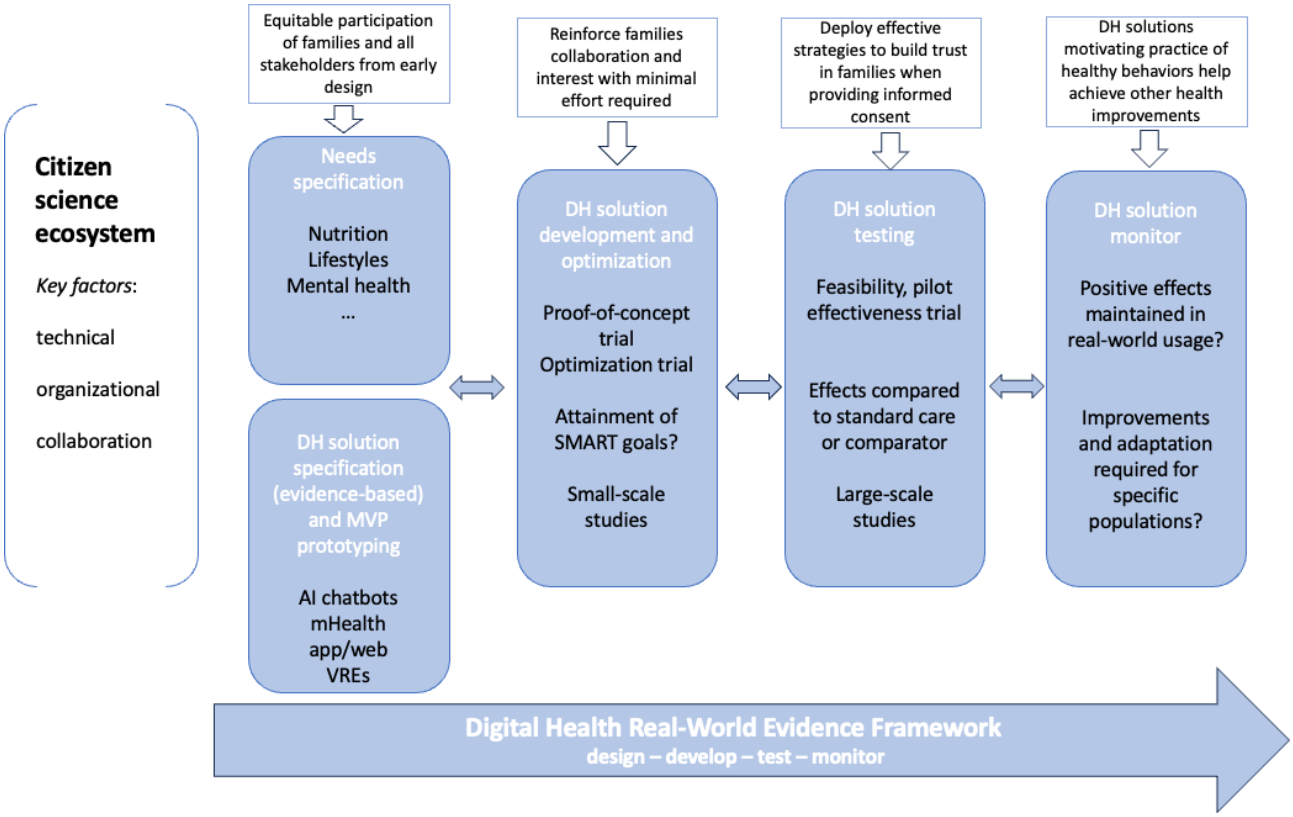
DTx are defined as tools to deliver evidence-based health interventions (using, for example, cognitive behavioral theory as an active ingredient for treatment) through different types of potential technological solutions as excipients (eg, mobile health apps, web apps, chatbots, or virtual reality [VR] environments) [22-24].

Both BITs and DTx are DH solutions that can improve health outcomes, reduce burdens on health care professionals, and increase access to and usability of interventions [25,26]. Common goals of DH include improving lifestyle, by facilitating behavior change in diet, physical activity, or sleep, or improving mental health, such as care for depression, anxiety, or symptoms

XSL•FO
RenderX

of stress. DH solutions are often complex interventions [27], as they can include multiple components, such as goal-setting or problem-solving elements and AI algorithms that adapt provision of support to each person's changing needs. The goal of including these components in DH solutions is that they can simultaneously provide safe, effective, accessible, sustainable, scalable, and equitable support for individual and population health [28]. However, accomplishing an effective integration of these components in DH solutions is very difficult, and recent efforts have been made to provide guidance in the design, development, and assessment of these solutions by leveraging on the evidence offered by real-world data produced over usage of these digital tools, to better understand the trajectories of intervention outcomes over time [5].

The Framework Development



The holistic DH framework (Figure 2) is aimed at supporting the future deployment of DH solutions for prevention in the first 1000 days.

The authors of this paper first conducted a review of state-of-the-art frameworks relevant to inform the design and validation of these solutions. The review identified strengths and limitations of 4 main frameworks commonly deployed in the design of digital interventions: (1) the IDEAS framework, aimed at supporting the development of digital interventions for health behavior change and based on the IDEAS phases [4]; (2) the ORBIT (Obesity-Related Behavioral Intervention Trials) model [29], aimed at guiding the design of evidence-based behavioral treatments to prevent and treat chronic diseases, based on the 4 phases of design, preliminary testing, efficacy, and effectiveness research; (3) the MOST (Multiphase Optimization Strategy) model [30,31], aimed at optimizing the development of behavioral, biobehavioral, and biomedical interventions; and (4) the DTx RWE framework [5], inspired by ORBIT and based on the 4 phases model of development (design, develop, test, and monitor). The review also included the citizen science approach [32] as a relevant method informing the cocreation of DH solutions with the participation of all stakeholders. Citizen science has been defined as the general public engagement in scientific research activities, when citizens actively contribute to science either with their intellectual effort or surrounding knowledge or their tools and resources [33].

The holistic DH framework was then developed in a 2-way process. First, 1 author (SG) selected the combination of components from the DTx RWE framework and citizen science approach most relevant to provide a comprehensive overview of the research steps to be taken to design and deploy digital interventions for health prevention programs. In a second step, a draft version of the framework was discussed at length in a meeting among the 3 authors (SG, OMI, and SF) and revised based on the feedback provided.

We present the key components of the holistic framework in a case study providing guidance and recommendations for ensuring a more effective deployment of health prevention programs in the first 1000 days by, at the same time, leveraging on the potential of DH solutions.

Figure 2. Holistic DH framework to cocreate with stakeholders. AI: artificial intelligence; DH: digital health; mHealth: mobile health; MVP: minimum viable product; SMART: Specific, Measurable, Actionable, Realistic, Timely; VRE: virtual reality environment.

Application of the Holistic DH Framework

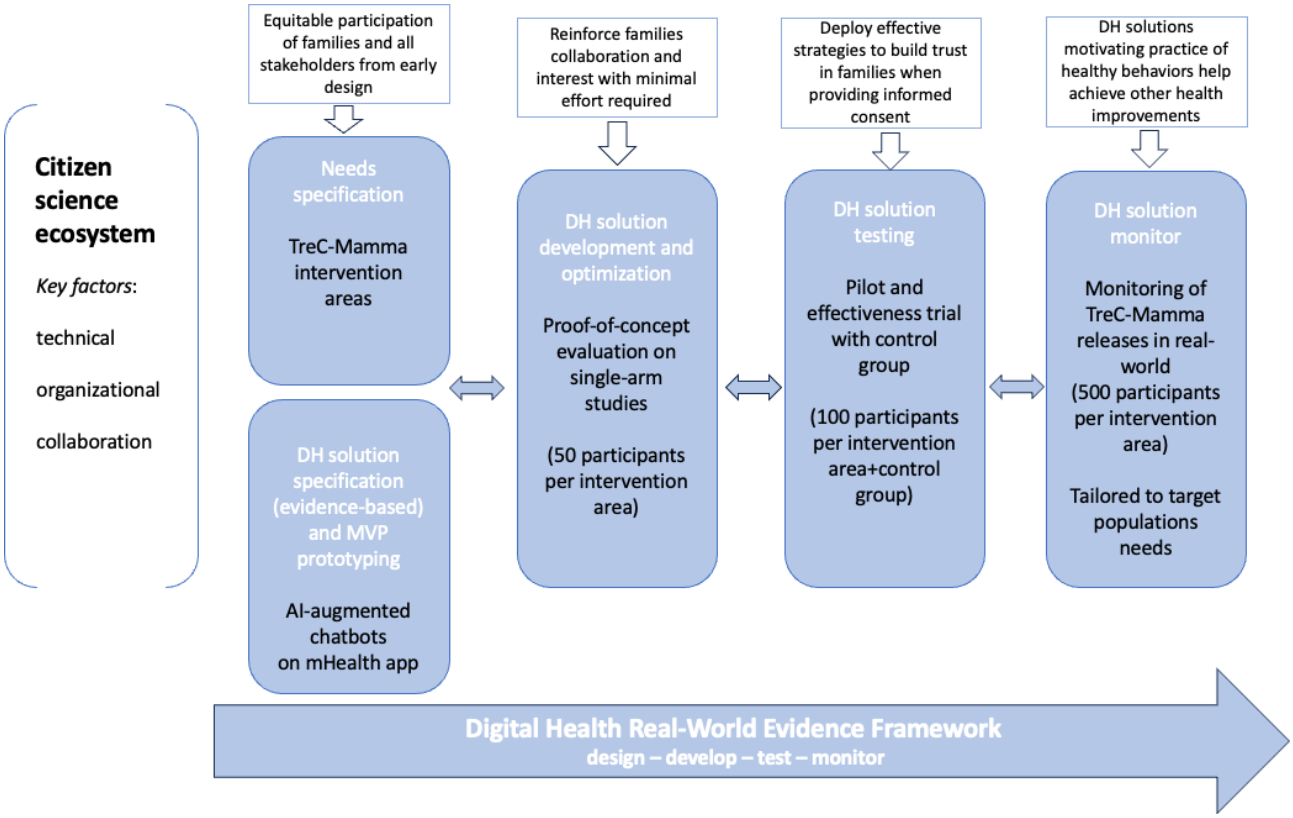
To illustrate the potential of the holistic DH framework in guiding the cocreation of effective prevention programs in the first 1000 days, we present examples of ongoing activities started by our research team in tackling the issues of digitizing prevention programs currently available to citizens in the Trentino region (Italy) for the pregnancy and infancy periods (birth path), working together with health professionals (gynecologists, obstetricians, and pediatricians) at the local health care system, with policy makers at the local Department of Health and Innovation, and with the target user populations (families). The main intervention areas addressed so far regard providing parental literacy to women and families during the first 1000 days (Figure 3), and providing pregnant women with healthy nutrition and psychoeducational DH programs for stress prevention from the 4th month of gestation [34-37]. The overall goal of introducing digital tools to support current prevention programs was to facilitate the adoption of a holistic strategy to target barriers in the delivery of these programs, such as reaching women living in rural areas having difficulties in accessing health care services or belonging to vulnerable populations, but also to improve ongoing prevention programs' development by incorporating holism, precision prevention, timeliness, and cost-effectiveness [19,38].

The design phase for these DH solutions started from a series of participatory sessions with all stakeholder groups (health professionals, policy makers, and families) to achieve an in-depth knowledge of the prevention needs in the target areas and to specify the requirements and prototyping of the DH tools by providing equitable consideration of the different stakeholders' perspectives, as well as building empathy and acknowledgment of any power differential [32].

From a technological point of view, it was decided to realize a secure and privacy-preserving DH platform providing virtual coaching functionalities by means of AI-augmented digital assistants available on mobile app (or coaching avatars in VR) each specialized for delivering DH intervention in a target prevention area.

Chatbot technology, using AI-augmented tools including machine learning and natural language processing, has been introduced into the health sector to address current health care challenges, such as shortage of health care providers and lack of health care access, showing several positive effects in supporting tailored intervention, which is better able to address users' needs over a digital treatment [39].

At the current stage of DH solutions development, a chatbot-based mobile app supporting women and families during the first 1000 days, named TreC-Mamma (Digital Health Research and Digital Health Innovation Lab, Fondazione Bruno Kessler), has already been released, and it is in use by more than 1000 users in the region. The aim of the TreC-Mamma solution is to provide an initial platform for collecting real-world evidence on the impact of DH solutions deployment during the first 1000 days, thus informing the development and refinement of more advanced AI-augmented digital assistants for the different intervention areas, by relying on a larger involvement and participation of families in the cocreation process. Parallel research activities are ongoing for assessing the developed proof-of-concept DH solution minimum viable products (MVPs) targeting healthy lifestyles and stress prevention during pregnancy. Specifically, virtual coaching on healthy nutrition and physical activity is provided to pregnant women by using microlearning and motivational modules validated by domain experts. For stress prevention, a chatbot-based solution deploying a digitally adapted version of the Self-Help+ protocol developed by WHO (World Health Organization) [40] has been implemented and preliminarily validated with mental health experts.



Small-scale studies are currently running to assess the MVPs' usability, acceptance, scalability, etc for further refinement and optimization based on the attainment of benchmark criteria such as the SMART (Specific, Measurable, Actionable, Realistic, Timely) goals [41]. These studies, typically involving small samples of pregnant women and their families, are also contributing to reinforce their collaboration and interest in the research project goals in the long-term, aiming to minimize the effort requested from citizens if they participate in the cocreation process.

Once the development and optimization phase of the digital assistants is completed, these DH solutions will be integrated into the TreC-Mamma platform and will be available for use by families to undergo more large-scale testing in the form of feasibility pilot trials or effectiveness trials. The ultimate goal of this testing phase is to compare the effects of the DH interventions with standard of care in the local health care system, with other relevant comparators, or by means of randomized controlled trials. In preparation of this testing phase, we are already devising an effective strategy to build trust in the project aim and solutions among families that are using the TreC-Mamma platform, facilitating the collection of their informed consent through the platform (asking them to sign a so-called "agreement with the citizen"), and clearly explaining the type of data and intended use of their data for a dynamic improvement of the platform in a citizen science perspective.

In a more long-term view, the TreC-Mamma platform will allow us to monitor the effects of our released DH interventions to assess whether their positive effects are maintained over real-world usage. In this monitoring phase, additional requirements and needs may arise from families and other stakeholders, leading to improvements and further adaptations of our solutions to fulfill evolving needs to address new areas of prevention or specific needs of target populations. As a positive side effect of deploying our DH solutions for motivating families to practice healthy behaviors in the first 1000 days, we foresee the potential achievement of health improvements in other prevention areas (eg, chronic disease prevention, such as gestational diabetes, type II diabetes, and depression) contributing to the realization of more comprehensive prevention goals and strategies.

Figure 3. Holistic DH framework applied to *first 1000 days* interventions. AI: artificial intelligence; DH: digital health; mHealth: mobile health; MVP: minimum viable product

Conclusions and Future Work

The holistic framework presented aims to provide guidance in the design and deployment of DH solutions supporting prevention strategies in the first 1000 days. It can be used to realize DH interventions in a more effective and participatory approach, leveraging on the contribution of the different stakeholders. It can help researchers in addressing the complex goal of realizing AI-augmented DH solutions by optimizing the resources available in the design process. This can be achieved by deploying a sociotechnical platform able to facilitate the engagement of citizens in the different stages of the intervention validation, as well as the effective use of real-world data for supporting the evolution and adaptation of the intervention to the target user populations.

Among the strengths of the framework presented is that it sheds light on unprecedented opportunities for deploying DH technologies in the attempt to realize more scalable, sustainable, and cost-effective solutions for prevention. It is also based on a concrete example of ongoing applied research for prevention in the first 1000 days that is supporting the feasibility of the approach proposed. We also believe that the framework illustrated can be of help in designing DH solutions for different application fields targeting health prevention and care with other target populations. By combining real-world evidence with citizen science research, it can help to overcome some limitations of previous DH frameworks like IDEAS by, for example, better supporting multidisciplinary teams' work beyond the initial intervention design and refinement, providing evidence for the adoption of the most effective behavioral strategies as derived from large-scale deployment of the digital solutions, and showcasing the sustainability of the digital solutions deployment, which may facilitate their more structural adoption and support by policy makers and users in the target communities.

However, there are also some limitations involved in the framework adoption and in its generalization to different contexts. Most of the real-world experience reported in the case study presented regards DH solutions design and development, while key outcomes derived from the test and monitor phases are still lacking. Therefore, more validation data on the framework application in real-world settings are needed, and this objective will be part of our future work. In addition, the AI-augmented features recommended to tailor the coaching of the digital assistants to the user needs require considerable design and development efforts, which may consume more tangible and intangible resources [42]. Key ethical considerations should also be considered when applying AI algorithms and techniques in DH solutions development, including bias minimization, transparency, and users' privacy and safety protection [43,44].

Notwithstanding these limitations, we think that grounding DH design efforts in a real-world evidence practice informed by a citizen science approach may contribute to establishing more productive dialogues among the stakeholders involved, as well as to facilitating faster innovation outcomes in the implementation of prevention programs.

Abstract

Urgent pediatric hospital readmissions are common, costly, and often preventable. Existing prediction models, based solely on discharge data, fail to accurately identify pediatric patients at-risk or urgent readmission. Remote patient monitoring (RPM) leverages wearable technology to provide real-time health data, enabling care teams to detect and respond to early signs of clinical deterioration. Emerging evidence suggests RPM may be a promising strategy to improve pediatric postdischarge outcomes and reduce urgent hospital readmissions.

(JMIR Pediatr Parent 2025;8:e60802) doi:10.2196/60802

KEYWORDS

medical information; remote patient monitoring; RPM; telehealth; pediatric readmissions; patient care management; chronic condition; readmission; disease management; intervention

Introduction

Untreated clinical deterioration in pediatric patients with chronic conditions can lead to urgent hospital readmissions, impacting the health of children, imposing a significant burden on health care systems, and delaying the care of others [1,2]. The rates of pediatric urgent readmissions, unplanned hospitalizations occurring within 30 days of discharge that require immediate medical intervention, vary from 3% to 19% across pediatric hospitals and up to 40% of them may be preventable [2]. The data available at discharge have not proved useful for predicting readmissions, especially for postdischarge causes such as medication-related failures [3]. Remote patient monitoring (RPM) may be a viable approach to detecting the early stages of clinical deterioration that ultimately lead to urgent readmission. A variety of wearable monitors enable the timely identification of deteriorating disease management and interventions to remediate it [4-6]. Used appropriately, wearable technology has the potential to help care teams reduce urgent readmissions. We argue that care models that leverage RPM have the most potential to allow care teams to reduce urgent hospital readmission for patient with chronic disease by identifying complications that may otherwise escalate into serious health concerns.

Challenges in Predicting Readmissions

Several studies have shown that predicting urgent pediatric hospital readmissions at the time of discharge is challenging, particularly for general- and for complex-subspecialty patient hospitalizations [2]. Initial efforts in this domain have concentrated on the identification of risk factors using odds ratios from data available at the time of discharge [3]. However, few of these studies have been externally validated or demonstrated to reduce readmissions in practice.

A systematic review of predictive models for 30-day unplanned pediatric readmissions found poor-to-moderate performance across most models [2]. Of the 37 models reviewed, all models except one had an area under the curve (AUC), a flawed but broadly recognized benchmark, below 0.8. The review assessed the quality of these studies to be moderate to low across all domains. Most studies lacked adequate representation of the broader pediatric population, often examining patients from only a single hospital. Many studies lacked sufficient consideration of potential confounders in their analyses.

XSL•FO
RenderX

Tools for predicting unplanned readmissions, such as the High Acuity Readmission Risk Pediatric Screen Tool, LACE (Length of stay, Acuity of admission, Comorbidity, Emergency department use), LACE-SDH (which adds Social Determinants of Health), LACE+, Epic's readmission risk model, and SQLAPE demonstrate only moderate performance, with AUCs ranging from 0.61 to 0.80 [7]. These modest performance metrics likely overstate the usefulness of such models for targeting limited resources to the relatively few patients with high risk of readmission [8]. Existing models likely fail to predict pediatric readmissions effectively because they rely on static data captured at the time of discharge, which does not reflect the evolving nature of recovery. Moreover, many are based on simple scoring systems or regression models that may inadequately account for the complexity of pediatric health trajectories.

It is not surprising that data available at the time of discharge are not sufficient to predict pediatric readmissions. Posthospitalization care is complex and lacks robust quality standards. Up to one-third of pediatric discharges may be associated with discharge-related care failures. Medication adherence serves as a prime example. A study of 157 caregivers revealed that 70% encountered medication-related failures [9]. These findings highlight the pressing need for improved postdischarge monitoring and/or interventions.

RPM

RPM offers promise for preventing readmissions. It is a technology-enabled approach to precision population health that facilitates the continuous capture and transmission of patient health metrics to medical practitioners when patients are not in the clinic. Portable devices have been validated for monitoring activity levels, sleep quality, heart rate, oxygen saturation, blood pressure, and glucose levels. Data from portable devices are often used to help manage chronic disease and detect deteriorating health in pediatric and adult populations [4-6,10,11]. Remote data acquisition and algorithm-supported analyses enable clinicians to detect health deterioration and adverse symptoms or health patterns when patients are not in the clinic. This enables timely investigation by the care team and, when appropriate, interventions to prevent the escalation of minor health concerns into serious complications.

Evidence for the effectiveness of RPM is already emerging in specific pediatric populations. An RPM intervention using continuous glucose monitors (CGMs) in pediatric patients with type 1 diabetes led to significant improvements in glucose control [6]. A small prospective study on pediatric patients receiving automated peritoneal dialysis resulted in a 45% reduction in hospitalization rates, significant increase in ultrafiltration, and significant reduction in systolic blood pressure [12]. RPM for children with single ventricle heart disease is now supported by the American Heart Association, after RPM contributed to mortality reductions of over 40% over an 8-year period [13]. RPM can also lead to more efficient workflows for health care providers, potentially reducing the time spent on routine checkups. For example, the conjunction of CGM with an automated tool was associated with improved outcomes and reduced provider screen time [6,14].

Health care systems adopting RPM will need to consider how to integrate workflows into existing clinical systems [15]. Effective implementation may include developing standardized protocols for alert management, integrating multiple monitoring devices into unified systems, and clearly defining care team responsibilities for responding to patient data. Implementing interoperability features that generate reports for inclusion into patients' medical records and import monitoring statistics into electronic medical record flowsheets can streamline clinical workflows [15]. A successful example comes from a CGM-based intervention that used a dashboard to prioritize patients for review, which was later adapted into a nationally available platform for broader adoption [15]. When an RPM system demonstrates efficacy within a single clinic, the standardized approach can facilitate expansion across multiple health care settings, creating opportunities for wider implementation and continuous improvement in patient care.

While RPM offers significant potential, barriers to access may affect its equitable implementation. Digital disparities, including limited internet access and device availability, could restrict RPM use [6,11]. Approximately 20% of US households lack access to a smartphone. In addition, variation in caregiver technological proficiency may affect adherence to monitoring protocols, and limited digital literacy can influence program engagement [11]. Addressing these challenges requires consideration of technology accessibility, device subsidization, user-friendly interfaces, and culturally appropriate education [6,11]. RPM programs "should be designed to accommodate populations with low health literacy and numeracy, with language preferences in mind" [11].

Proof-of-concept studies are necessary to determine how the implementation of RPM can reduce pediatric readmissions in the real clinical setting. Initial studies should focus on the assessment of technical feasibility within existing health care systems along with thoughtful mapping of how RPM would integrate into the clinical workflow of the care of the chronic pediatric patient. As these studies scale, outcome measures should capture not only clinical outcomes, but also include patient-reported outcomes and cost-effectiveness [16]. Pilot studies can then inform the design of larger randomized controlled trials comparing standard discharge protocols to those enhanced with RPM and allow scaling of its implementation [17].

Conclusions

Urgent pediatric hospital readmissions are common and preventable. Existing readmission prediction models are not sufficient to identify the patients at highest risk, especially those associated with care failures. RPM is a promising tool that offers real-time data transmission, streamlined operational procedures, and scalability. As RPM technology becomes more accessible, its potential to transform pediatric postdischarge care and reduce urgent readmissions warrants further investigation. Advancing this work may enable more proactive and effective strategies to improve health outcomes and reduce urgent readmissions.

Abstract

The trove of information contained in child maltreatment narratives represents an opportunity to strengthen the evidence base for policy reform in this area, yet it remains underutilized by researchers and policy makers. Current research into child maltreatment often involves the use of qualitative methodologies or structured survey data that are either too broad or not representative, thereby limiting the development of effective policy responses and intervention strategies. Artificial intelligence (AI) approaches such as large language models (AI models that understand and generate language) can analyze large volumes of child maltreatment narratives by extracting population-level insights on factors of interest such as mental health and treatment needs. However, when applying such methods, it is useful to have a framework on which to base approaches to the data. We propose a seven step framework: (1) data governance; (2) researcher vetting; (3) data deidentification; (4) data access; (5) feasibility testing of baseline methods; (6) large-scale implementation of black box algorithms; and (7) domain expert result validation for such exercises to ensure careful execution and limit the risk of privacy and security breaches, bias, and unreliable conclusions.

KEYWORDS

artificial intelligence; large language models; child maltreatment narratives; text mining; benefits and risks; research framework

Smarter Tech, Safer Kids

The World Health Organization estimates around 1 in 2 children worldwide experience physical, sexual, and emotional abuse and neglect [1]. In Australia, the monitoring of child maltreatment (ie, “all forms of physical and emotional ill-treatment, sexual abuse, neglect, and exploitation that results in actual or potential harm to the child’s health, development or dignity” [2,3]) relies on administrative data provided by child protection departments for local and national reporting purposes [4-6]. However, the structured nature of these data limits the reporting of more nuanced information such as maltreatment types, treatment needs, and mental health, preventing the ability to answer key questions. For example, the 2021 Australian Child Maltreatment Study [6] recorded the prevalence of physical abuse and sexual abuse at 32.0% and 28.5%, respectively, whereas the Australian Bureau of Statistics [5] in the same year reported that 1 in 7 (14%) children experienced physical and sexual abuse. Several factors contribute to such discrepancies, including the use of different methodologies (eg, self-report, cross-sectional surveys, and surveillance through administrative data), varying definitions of abuse and age ranges, and biases due to the small sample sizes and response rates [7-9]. While high-level reporting is important, both sources fail to provide a comprehensive picture of child maltreatment necessary for effective policy responses. Characteristics such as uncommon maltreatment subtypes and treatment needs are lacking. Indeed, the Australian Productivity Commission states that “with technological developments and advances in analytical techniques, not only is the volume of data being generated and collected growing, but so too is the scope to make use of data in innovative ways in every sphere of life” [10]. Child protection should be no exception to this.

Research in child maltreatment has predominantly utilized statistical and artificial intelligence (AI) approaches such as artificial neural networks and predictive risk modeling applied to structured child protection administrative data [11-15]. Studies on health administrative records focused on developing models to predict cases of sexual abuse [11], physical abuse [12], and overall maltreatment [13-15], with robust performance. Furthermore, information has been successfully extracted using text mining techniques such as word embeddings, bag-of-words, and feature selection from free-text health notes [16-19] to detect physical abuse.

XSL•FO
RenderX

Nevertheless, rarely tapped sources of unstructured information in this area are child maltreatment narratives containing detailed descriptive accounts of incidents or experiences of physical or emotional harm to a child. These document the initial reasons for coming to the attention of authorities (ie, intake report), descriptions of a child's experience of abuse or neglect, psychologists' assessments, police and medical records, and a detailed history of child protection involvement. They also describe abuse types, substance use and abuse, recorded injuries, mental and behavioral problems, physical health conditions, parental and family characteristics, and the types and conditions of the accommodation. Utilizing the information contained within the narratives could fill existing knowledge gaps by highlighting less common abusive behaviors (eg, social abuse, coercive control) and enriching definitions and measures of abuse types and mental illnesses [20-22]. A limited number of studies have used these narratives to automatically extract information. Victor et al [23] and Perron et al [24,25] applied machine learning algorithms such as random forest and k-nearest neighbors on caseworker summaries to identify domestic violence events and opioid-related maltreatment risks, respectively. In addition, Saxena et al [26] used topic modeling to explore the concept and definitions of "risk" on child maltreatment records with promising performance. Despite the advent of newer technologies to conduct text analysis such as large language models (LLMs; AI models that can understand and generate language), limited attempts have been made [27,28] to implement this approach. In particular, Perron et al [27] reported an F_1-score of 89% - 95% for their model to classify and extract substance-related problems, while more recently, Stoll et al [28] noted their approach to classify maltreatment subtype yielded a superior performance against human reviewers by 10%.

However, automatically mining information from child maltreatment records faces significant limitations [23-28]. Most importantly, the lack of sufficient training data restricts the AI model's capacity to learn complex patterns [29] such as nuanced indicators of abuse. In addition, the limited contextual understanding (even when using LLMs), along with the inconsistencies in narrative style and language, as caseworkers may document—or omit—events of child maltreatment through various terms, descriptions, and writing style, can lead to inaccurate outputs and falsehoods [26]. This is particularly critical when analyzing data related to Indigenous populations requiring a specific cultural lens through which to examine the data. Relying exclusively on one data type (eg, administrative data) can also skew the results and present an inaccurate picture [30].

Benefits Versus Risks

To manually process such voluminous and diverse information is extremely time consuming and not without significant challenges, including a lack of human resources to inspect large scale data and the associated high cost. AI pipelines, particularly applications of LLMs, offer a solution for efficiently processing vast amounts of child maltreatment narratives, comprehending the text for a broader range of tasks (ie, summarization, classification) [27,28,31], and offering potentially greater quality control due to its standardized approach compared to other (eg, qualitative) methods [32]. A primary concern of child protection services is to safeguard and monitor those in their care who may be at risk of maltreatment and neglect. Timely processing of many thousands of cases provides the possibility for professionals and policy makers to make faster decisions (eg, identifying clusters of abuse or mental illness using geographic areas) by predicting the severity of future abuse or allocating resources to high-prevalence communities and intervene earlier. Consequently, new evidence-based protocols for early intervention and prevention can be developed aimed at improving outcomes for children and families.

While appealing, AI applications come with security risks (eg, malware, data leakage), performance issues (eg, "AI hallucinations"), technical limitations (eg, black box bias), and ethical conundrums (eg, machine vs human decisions). Hidden malware or malicious code within unvetted AI algorithms with built-in third-party components could result in leaking sensitive information residing in child maltreatment narratives [33,34]. Child protection departments are extremely cautious about providing data access (making this data some of the most difficult to access) as children's data privacy risks could expose them to further harm. When the data involve Indigenous populations, additional cultural considerations for access, governance, and interpretation are required. Even with data access approval, challenges related to narrative data quality, such as data omission, will persist as researchers have limited control over these factors. Cultural and linguistic biases, as well as selection bias in the training data, also pose risks for misinterpretation of findings. In particular, LLM performance can be vulnerable due to "hallucinations" or misinformation with models generating inaccurate or false conclusions. This is further amplified by black box bias [35-37], since the decision-making process is not visible or understandable by humans and, therefore, it is hard to conduct any detailed error analysis.

For these reasons, AI-generated misinformation can have larger implications due to false positives and negatives, fabrication of summarization, and misclassifications. In child maltreatment cases, this could lead to the misidentification of mental health disorders, abuse and neglect misclassification, and unnecessary family separation [38-42]. Falsehoods could be interpreted as gold standards. Therefore, child maltreatment policies require a decision framework that draws conclusions from both machines and humans, with the final decision relying on human expertise. While some may propose automated approaches can reduce human errors, bias, and the time required to process reports, replacing human decision-making with AI-powered approaches requires ethical protocols to be in place. Relying exclusively on algorithms and their outputs should be discouraged as they lack the complexities and subtleties of human reasoning and decision making [43-47]. Human judgement needs to take priority over AI outputs [48] and adhere to research ethics and legal standards [49-51]. Machine-made choices bear potentially severe consequences when it comes to enhancing the evidence base and policy translation leading to social injustice and population oversurveillance [48]. Considering the inherent risk of biases [52,53] (ie,

XSL•FO
RenderX

underrepresented groups sampling bias) and the cost of hardware requirements, security protocols, and manual code inspection, it is difficult to apply such algorithms widely without the appropriate precautions.

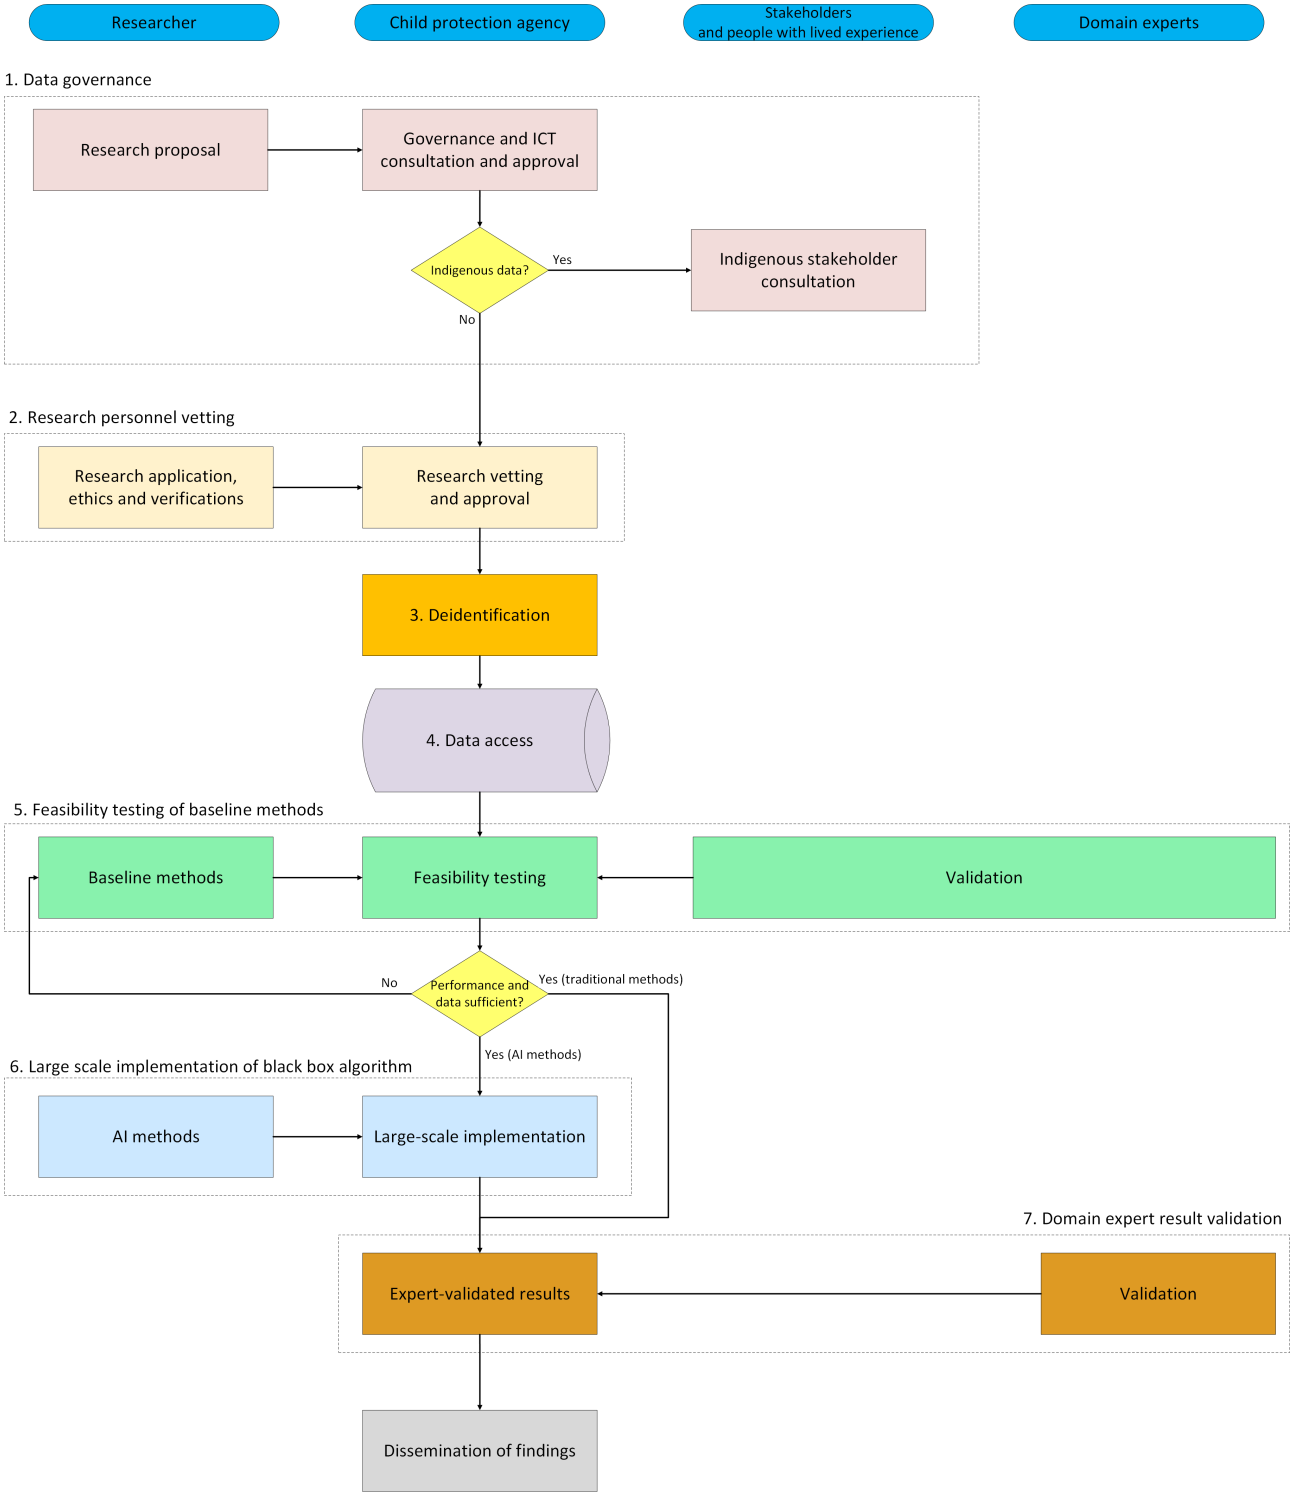
Risk mitigation strategies are essential to ensure the appropriate application of automated approaches in areas such as child protection. First, using deidentified data and downloadable models from verified sources minimizes the risk of leaking private information. The incorporation of local LLMs could be set up using a virtual machine and offline to prohibit data access and the possibility of reidentifying personal records if information were to be siphoned off through hidden malware. False outcomes could be mitigated through improved quality of input data, further training to improve the model's understanding and designing clear, precise instructions for the model (ie, design prompt) that steer its response towards accurate information [47,48]. Governance infrastructures are also necessary to ensure appropriate handling of such sensitive data and the generated findings, especially if these data involve Indigenous populations, which would require input from key stakeholder groups and people with lived experience to ensure culturally sensitive analysis and interpretation. Finally, pipelines need to have expert-in-the-loop architecture to improve the quality and reliability of results. Ensuring that pipelines powered up by LLMs operate transparently with domain experts' input not only protects against biased decision-making but also aligns with efforts to safeguard personal data, as some algorithms can obscure the processes that may compromise fairness and privacy.

Proposed Framework

Existing research using AI approaches on child maltreatment narratives follows the establishment of the technical pipeline to extract information and obtain data access. Additional steps (eg, governance, data deidentification, researcher vetting) are also required to not only enhance the performance of such approaches but to limit security risks, ensure translatable outputs, and boost public confidence in such approaches. For these reasons, we propose a seven-step framework for processing child maltreatment narratives with LLMs or any black box algorithm: (1) data governance (including cultural considerations where appropriate), (2) researcher vetting, (3) data deidentification, (4) data access, (5) feasibility testing of baseline methods, (6) large-scale implementation of black box algorithms, and (7) domain expert result validation. These steps align with Gillingham's [48] principles of algorithmic accountability in social work and existing policy guidelines on AI for children [54,55] that prioritize children's safety, well-being, data privacy, and AI transparency. Although Gillingham's principles are rooted in decision support tools, they are relevant due to the generated results potentially contributing to policy making and translation.

The seven steps include:

1. Data governance: this foundational step focuses on establishing appropriate data governance infrastructures on both the child maltreatment data and the generated outputs. Key stakeholder agencies such as departments of child protection and information and communication technology services along with ethics committees must be engaged before any data analysis takes place. If the data relate to Indigenous populations, it is necessary to include relevant community representatives to ensure the analysis interpretation and dissemination of findings are culturally appropriate and align with Indigenous data sovereignty.
2. Researcher vetting: researchers need to be vetted (eg, have no track record of criminal activity, have previous experience with handling and analyzing sensitive data, be domestically based) to ensure responsible research, including a working with children government check. Signing a nondisclosure agreement can further minimize potential risks such as data privacy breaches and identity theft.
3. Data deidentification: as child protection data contains extremely sensitive information (eg, name, addresses, date of birth), to minimize privacy breaches, deidentification of child maltreatment narratives is recommended. Thus, in the unlikely event of data leakage, deidentification ensures that no identifiable information is exposed in the dataset.
4. Data access: accessing child protection data should be done within the vicinity of child protection agencies who can assign researchers limited access and maintain history logs of accessed or modified documents. Such an approach will ensure transparency and provide the capacity for tracking errors and auditability.
5. Feasibility testing of baseline methods: conducting a feasibility test before any large-scale implementation is important. Implementing simpler approaches that rely on lexical pattern identification (eg, rule-based) or traditional machine learning algorithms offers a controlled, auditable environment with enhanced security reducing the risk of unintended data exposure, allowing for more interpretability on potential errors (ie, false positives, false negatives) without requiring an extraneous number of resources and costs [56].
6. Large scale implementation of black box algorithms: the implementation of black box approaches or algorithms ensures efficient and effective large-scale processing of voluminous datasets. Evaluation metrics such as precision and recall ensure robust performance and support scalable research to address knowledge gaps in child maltreatment. Models such as LLMs can assist in the contextual understanding and scalability of the research to ultimately narrow the information gap within specific research aims in child maltreatment. These applications can be applied offline through a secure virtual machine environment. Through this approach, child protection organizations can ensure that researchers have no means of extracting and downloading identifiable data without explicit approval from participating governmental departments.
7. Domain expert result validation: the returned results need to be validated by domain experts in child maltreatment to ensure that the extracted or generated information does not lead to inaccurate or misleading conclusions. This can be done by manually checking a random sample of narratives and conducting interannotator agreement (via metrics such as Cohen κ coefficient) between 2 to 3 experts. Disagreements between domain experts regarding claims



XSL•FO
RenderX

may require researchers to retrain and re-evaluate their method. This evaluation and validation process will ensure the findings' accuracy and relevancy are aligned with ethical standards such as the policy guidance for AI for children [54] or transnational frameworks for AI and children's rights and well-being [55], ensuring accuracy and fairness and limiting risks of potential harm before being used towards shaping existing or new policies and protocols.

Our proposed 7-step framework offers a novel research pipeline specific to ethical and secure use of AI in child maltreatment research. By introducing data governance, the inclusion of stakeholders with lived experience and structured deidentification processes and feasibility testing, the framework prioritizes both ethical and cultural safety while promoting analytical rigor. Incorporating domain expert validation further enhances the interpretability, contextual relevance, and ethical soundness of AI outputs—elements that are largely absent in the current literature. An illustrative example of a brief case scenario is presented in Figure 1. While it is understood that the framework may not apply to all contexts—given that protocols can vary across countries and may not have Indigenous cultures—the core principles are common. Adhering to these principles supports data privacy and cultural sensitivity and helps mitigate the uncaptured context problem and bias mitigation within the field through domain expert result validation [57].

Conclusions

As the complexity and scale of child maltreatment increases and the volume of information expands, an opportunity exists to apply new and sophisticated approaches that rely on AI to strengthen the evidence base by processing large volumes of narrative data. However, with this opportunity come risks that need to be minimized. The implementation of AI methods, particularly black box methods such as LLMs, should follow a framework of seven key steps—(1) data governance, (2) researcher vetting, (3) data deidentification, (4) data access, (5) feasibility testing of baseline methods, (6) large-scale implementation of black box algorithms, and (7) domain expert result validation—to ensure culturally sensitive governance, minimization of privacy risks, improvement data analysis, and optimization of AI usability in strengthening the evidence base for child maltreatment. Further research is needed to evaluate the framework's effectiveness and practice to improve policies and lead to better outcomes in child protection.

Abstract

Background: Standard urotherapy for childhood incontinence involves traditional tools like paper bladder diaries, timer watches, wetting alarms, and uroflowmeters. However, little is known about how these tools are experienced by today's digitally native children.

Objective: This study aimed to explore how children undergoing urotherapy perceive and experience these commonly used tools, with the goal of informing more engaging and child-centered design approaches.

Methods: A qualitative focus group design was used with purposive sampling of children undergoing in-clinic urotherapy group training. In total, 19 participants (13 boys and 6 girls) aged 9-13 years took part in focus groups of 3 to 4 children, held at the hospital. A child-friendly focus group toolkit was used to facilitate discussion through creative and playful exercises. A total of 7 focus groups were conducted, including 2 repeated sessions, until thematic saturation was reached. All sessions were held in Dutch, video- and audio-recorded, and transcribed verbatim. An inductive conventional content analysis was conducted using a dual-coder approach to identify and iteratively refine emerging themes.

Results: Four themes emerged: (1) attitudes and motivation: ranging from willingness to engage in urotherapy and use tools to reluctance or resistance; (2) social acceptance: highlighting the impact of peer perception, fear of being bullied, and opportunities to break the taboo and reframe tools as socially desirable; (3) contextual influences: including dissatisfaction with school toilets and limited child involvement at doctor visits, contrasted with the positive peer support experienced during group therapy; and (4) digital integration: children saw many traditional tools as outdated and suggested gamified, smart alternatives. The drawings created by children during the exercises served as a creative reflection of these thematic findings.

Conclusions: Involving children in research and design is essential for creating interventions that are truly child-centered. Through creative, qualitative methods, this study uncovered rich insights into children's experiences with urotherapy tools, pointing to 4 key design priorities: personalization, stigma-free design, adaptability, and digital innovation.

Introduction

Background

Daytime urinary incontinence affects many school-aged children (5 - 13 y) [1,2], often leading to low self-esteem, feelings of shame, and stress, thereby negatively impacting the child's quality of life [3,4]. Standard urotherapy is the recommended first-line treatment for daytime urinary incontinence [5]. During standard urotherapy, children receive age-appropriate information and instructions on drinking and toileting habits, which need to be repeatedly practiced in order to reach optimal results [6,7]. There are a variety of tools designed to support

XSL•FO
RenderX

urotherapy, such as bladder diaries [8], timer watches [9], wetting alarms [7], and uroflowmeters [10].

Traditional bladder diaries consist of paper-based schedules where patients are required to manually record their urinary output (using a measuring cup), fluid intake, and incidents of urine leakage over a span of several days [1]. Bladder diaries provide the child, parent, and clinician with insights on symptoms and therapy progress and help to create self-awareness of voiding and drinking habits [5,11,12].

Timer watches sound an alarm at fixed time intervals to remind the child to drink and void regularly [9]. This tool encourages children not to postpone going to the toilet until they experience an urgent need or have accidents, but rather to urinate at set intervals with a more relaxed pelvic floor (ie,timed voiding).

Although primarily used for nighttime urinary incontinence, wetting alarms may also be used for children dealing with persistent daytime urinary incontinence [7]. These alarms involve specialized underwear with conductive material that triggers an alarm when wet. The purpose of the alarm is to restore a child's bladder signal awareness and promote an appropriate response to it.

Finally, traditional uroflowmeters consist of a weight-based sensor with a urine receptacle on top, placed under a commode chair with funnel. They measure urine flow during urination and can be used for real-time biofeedback [13,14]. Through this feedback, children can better understand their voiding function and work toward normalizing their uroflow patterns.

Study Rationale and Objectives

Despite its clinical potential, standard urotherapy is often challenged by low motivation and poor compliance [15]. Traditional tools may no longer align with the expectations of today's digitally native children [16]. Yet, little is known about how these tools are perceived by children or how they influence their overall experience with urotherapy.

This study aims to gain a deeper understanding of the experiences, needs, and desires of pediatric patients regarding urotherapy and its tools. The ultimate goal is to inform the development of more engaging and child-centered interventions and tools that better align with their expectations.

Methods

Study Design

The study used a qualitative focus group research design, following the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines. The focus group collected data on the experiences of pediatric patients with urotherapy and its tools.

Participants and Recruitment

A purposive sampling strategy was used to recruit participants who were undergoing in-clinic urotherapy group training (voiding school) at the Wilhelmina Children's Hospital of the University Medical Center Utrecht [17,18]. In this 10-day program, children are admitted to the hospital, staying overnight on weekdays and returning home over the weekend. The program includes a timed voiding and drinking schedule monitored through a bladder diary, along with the use of wetting alarms, repeated uroflowmetry biofeedback, and daily therapeutic sessions, all under the guidance of urotherapists.

All children who were enrolled in the program during the study period from February 2023 to April 2023 were considered eligible for participation in the focus group study. The inclusion and exclusion criteria were determined by the urotherapy program itself and included children aged 8 to 13 years with functional urinary incontinence that was refractory to standard urotherapy and who were fluent in Dutch. Children were excluded from the program if they had an anatomical or neurological cause for urinary incontinence, recurrent urinary tract infections, or unmanaged constipation. In addition, children were excluded if their cognitive functioning was below the level of a 6-year-old or if their IQ was below 60. These assessments were carried out by the clinical team of the Wilhelmina Children's Hospital. During the first intake, an extensive psychosocial history was taken by the urotherapist, including school functioning. Children were expected to attend at least grade 3 of primary school in the Netherlands, be able to read, tell time, follow instructions, and attend either regular or special primary education. If there was any doubt about IQ or developmental delay, a psychological report was requested.

Information about the study was presented to both the child and a parent in written and verbal forms at the initiation of the urotherapy program, upon hospital admission. A total of 19 participants (13 boys and 6 girls), aged between 9 and 13 years (Table 1), participated in the study after parental informed consent was obtained. In addition, children aged 12 and older provided written consent, while younger participants gave assent. The children took part in focus groups of 3 to 4 participants, corresponding to the group they were assigned to within the urotherapy program. One child discontinued participation early due to difficulties with concentration and behavior that disrupted the group dynamics.

Table . Participant characteristics (N=19).

Characteristic	Participants, n (%)
Sex	
Male	13 (68)
Female	6 (32)
Age group (years)	
<10	5 (26)
10 - 11	9 (47)
≥12	5 (26)
Diagnosis	
Overactive bladder	8 (42)
Voiding postponement	3 (16)
Dysfunctional voiding	2 (11)
Other	6 (32)
Comorbidities	
Neurodevelopmental or behavioral[a]	6 (32)
Other medical[b]	3 (16)
None	10 (53)

[a]Reported comorbidities included attention deficit disorder, attention deficit hyperactivity disorder, autism spectrum disorder, and dyslexia.

[b]Reported other medical comorbidities included hemophilia, leukemia and history of preterm birth.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki. The Medical Ethics Review Committee NedMec reviewed the study protocol (22/955; decision date: November 15, 2022) and determined that it did not fall within the scope of the Dutch Medical Research Involving Human Subjects Act (WMO). This decision was based on the nonexperimental nature of the study, which involved no medical intervention and focused solely on exploring children's experiences with existing urotherapy tools through focus group discussions. To ensure institutional oversight, the study was additionally reviewed and approved by the division management of the University Medical Center Utrecht.

Written informed consent was obtained from parents and from participants aged 12 years or older; younger participants provided assent. All data were pseudonymized before analysis. No compensation was provided for participation.

Data Collection

All focus group sessions were conducted at the Wilhelmina Children's Hospital during the in-clinic urotherapy program. The sessions were moderated by the first and third authors, both female researchers with no previous relationship to the participants. At the time of the study, the first author was a PhD candidate and the third author a master's student at the University of Antwerp, Faculty of Design Sciences. The first author received formal training in qualitative research and was responsible for organizing and moderating the session. The third author supported the session through observation and note-taking.

At the start of each session, the researchers introduced themselves, explained their roles, and shared the purpose of the study. It was explained that the researchers were interested in designing better tools and services for children with urinary incontinence. The first author disclosed her background in pediatric health design research and her professional role in a urology-focused medical device company, acknowledging a personal and professional motivation to improve urotherapy experiences.

To support the children's comfort at the start of the session, a urotherapist involved in their treatment was present. Once a safe and relaxed atmosphere was established, the urotherapist left the room, allowing the children to engage freely in the discussion with the researchers. Data collection was facilitated using a child-friendly focus group discussion toolkit, informed by existing literature and specifically designed for this study [19]. The goal was to create a safe and inspiring context where participating children could comfortably share personal experiences in a creative and playful manner (Figure 1). It consisted of an icebreaker and warm-up, collaging exercise, pen, and paper feedback, and a superhero character drawing (Table 2).

XSL•FO
RenderX

Figure 1. Child-friendly focus group discussion toolkit used in this study. (**A**) Collaging exercise where children shared emotions and personal experiences in various contexts. (**B**) Pen and paper exercise with cardboard toilet prop to share feedback and ideas on different urotherapy tools.

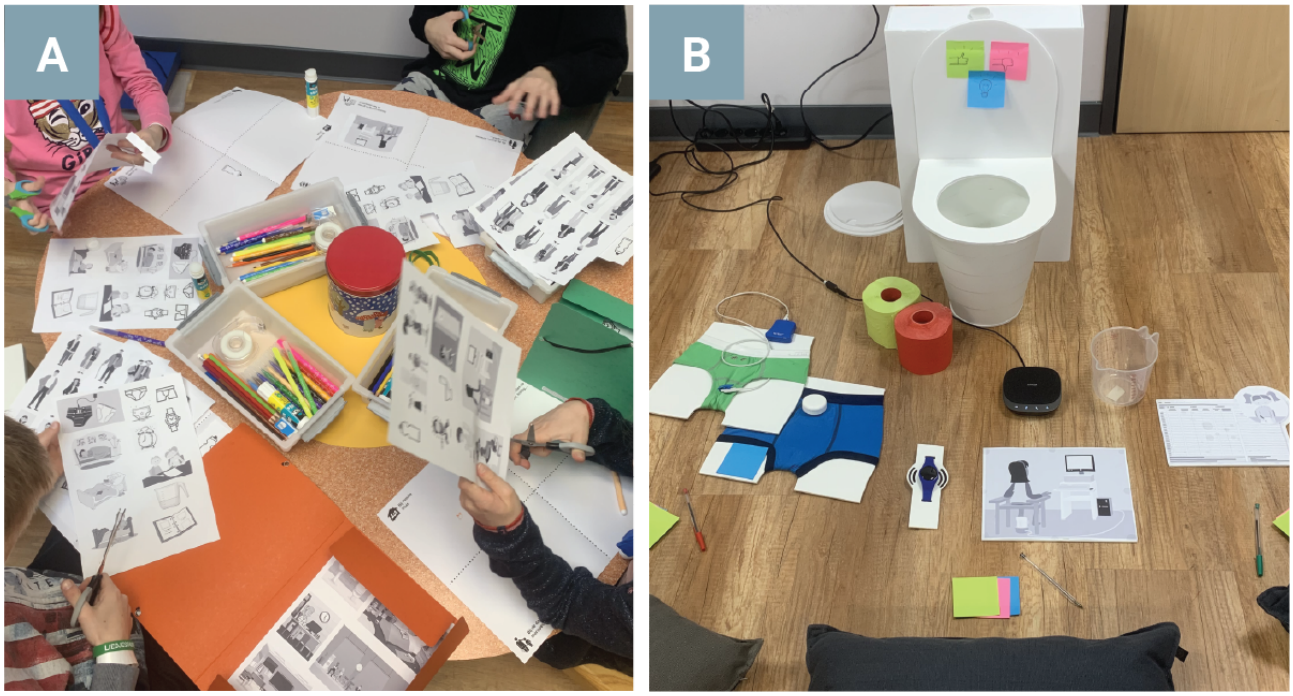

Table . Overview of focus group toolkit exercises.

Toolkit exercises	Description	Guiding questions
Icebreaker and warm-up	Children passed a toilet roll and shared personal facts. Followed by a group mind-mapping activity focused on drinking, going to the toilet, and bladder training.	"What is your name and age?," "What are your hobbies?," "When you hear the word ___, what comes to mind first?"
Collaging exercise	Children created collages about different settings (home, school, doctor visits, and group training) from the perspective of their bladder problems. They then presented their collages and discussed them in the group.	"What happens in those different contexts?," "How do you feel in those contexts?," "Who or what is there to support you?"
Pen and paper feedback	Children reflected on urotherapy tools (bladder diaries, timer watches, wetting alarms, and uroflowmeters) by drawing or writing their thoughts on paper. These were thrown into a cardboard toilet prop and then randomly drawn to prompt group discussion.	"What do you like and don't like about this tool?," "What ideas do you have to make it better?"
Superhero character drawing	Children drew a superhero who, like them, also happens to have a bladder problem. They then presented their superheroes and described their powers and coping strategies.	"What is your superhero's name?," "What superpowers do they have?," "How do they deal with their bladder problems?"

Each session lasted between 1.5 and 2 hours. Data collection concluded upon reaching "thematic saturation" (ie, when no new themes are uncovered by additional sessions) [20]. This saturation point was achieved after 7 focus groups, including 2 repeated sessions where 2 groups participated in an additional session on another day. These follow-up sessions were conducted to explore certain themes in more depth.

All focus group sessions were conducted in Dutch, video and audio recorded, and transcribed verbatim. The excerpts quoted in this paper were translated into English by the first author, with the aim of preserving the original meaning and tone. Due to the young age of participants, transcripts were not returned, and member checking was not conducted. However, to enhance the credibility and trustworthiness of the findings, they were cross-checked with health care professionals involved in the treatment of the participating children.

Data Analysis

A conventional content analysis [21] was used to inductively derive meaning from the focus group data, following three main phases: preparation, organization (including coding), and reporting.

In the preparation phase, the first author repeatedly watched the video recordings and read the transcripts to gain a comprehensive understanding. This phase allowed the researcher

XSL•FO
RenderX

to become familiar with the content and begin identifying meaningful units (segments of the text) of analysis.

In the organization phase, relevant segments of text were manually highlighted and open-coded using Microsoft Excel. Through several iterations of coding and code modification, a codebook was developed. The transcripts were then further coded by pairs of master's students, using a dual-coder approach to ensure consistency. As coding progressed, subcategories emerged and were iteratively grouped into broader themes, capturing patterns across the dataset. This hierarchical structure of codes, subcategories, and themes constituted the coding tree developed during analysis.

In the reporting phase, the first author prepared the preliminary structure of the emerging themes, which were then discussed and validated within the multidisciplinary research team, including a pediatric urologist, 2 urotherapists, and 2 medical product designers. This collaborative step ensured a diversity of viewpoints and enhanced the trustworthiness of the analysis. The final themes were defined based on consensus within the team and formed the basis for the study's results.

Results

Overview of Themes

Four main themes emerged from the analysis that provide insight into how children perceive and engage with urotherapy and its tools: (1) attitudes and motivation (2) social acceptance, (3) contextual influences, and (4) digital integration. The structure of the themes and subthemes is shown in Textbox 1.

Textbox 1. Theme structure.

Attitudes and motivation

- Willingness to engage in training and use tools
- Resistance or ignoring support
- Parental involvement and tension
- Fear of dependence and desire for autonomy

Social acceptance

- Need for discreet design
- Fear of being bullied
- Openness as a way to break taboo
- Reframing tools as socially desirable

Contextual influences

- Bladder behavior varies by setting
- Dissatisfaction with school toilets
- Disconnection at the doctor's office
- Peer support during group urotherapy

Digital integration

- Children are digital natives
- Traditional tools seen as outdated
- Ideas for gamified, smart solutions
- Awareness of digital pitfalls

Theme 1: Attitudes and Motivation

Children expressed diverse attitudes and varying levels of motivation toward engaging with urotherapy and its tools. For instance, a clear willingness to participate in training emerged, along with recognition of the value urotherapy tools could offer in managing their condition. Tools were described as useful for reminding them to go to the toilet, increasing awareness of bladder signals, and providing objective data to better understand their condition.

> *If your mom or dad don't remind you to go to the toilet, then you have to do it yourself. That's when the timer watch is really helpful.* [P3, male, 10 y]

> *When you wear the wetting alarm, you can actually feel what it's like when you leak. When it starts beeping, you know what that feeling means. Without it, you don't really know what to pay attention to.* [P11, male, 10 y]

> *A bladder diary helps you see how much you pee. If you just go to the toilet normally, you can guess, but you don't really know. But with a measuring cup, you know exactly. If it's very high or very low, the doctors*

XSL•FO
RenderX

> *can figure out if something's wrong or not, and then they can help you.* [P12, female, 9 y]

In contrast, expressions of reluctance or resistance were also observed. This included deliberately ignoring advice or recommendations like pretending to go to the toilet, disregarding alerts from reminder tools, or even ignoring their own bladder signals in favor of continuing preferred activities.

> *You can fake going to the toilet. Just go to the bathroom without actually peeing, and then come back.* [P3, male, 10 y]

> *I didn't always go to the toilet when the timer watch went off. Sometimes I just didn't feel like it and kept playing. I just turn off the alarm.* [P7, male, 8 y]

> *I'm pretty stubborn. I usually ignore my bladder signal. Even if an alarm goes off, I ignore it because I really want to finish my game. And then… well, I usually end up wet.* [P11, male, 10 y]

Children reported that in these situations parents became more involved in supporting their urotherapy routines. This involvement sometimes led to feelings of tension, frustration, or being controlled. The use of certain tools to enforce behavior was mentioned as a potential trigger for arguments between children and parents.

> *After I turned off the timer watch, my mom reprogrammed it to go off every thirty minutes and she turned up the volume so my teacher would hear it too and make sure I actually went to the bathroom.* [P1, male, 9 y]

> *Keeping a bladder diary at home is so annoying. Like, if you're mad at your mom and you need to go to the bathroom, you still have to fill it in, and then she'll yell, "Fill it in!"* [P13, female, 10 y]

> *My mom looks at my uroflow curves and then complains, like, "Such small voids!"* [P14, female, 13 y]

In addition, children expressed concerns about becoming dependent on certain urotherapy tools, emphasizing their desire for autonomy. They discussed how rigid, time-based routines set by tools like timer watches do not always align with real-life situations. They also described these tools as temporary aids to support their progress toward independent bladder control.

> *I don't like the timer watch because it makes you depend on it. When it beeps, you have to go, but what if you're busy and can actually hold it? Or what if you just don't need to go?* [P16, male, 12 y]

> *You don't have a uroflow toilet at home, so you can't really see how you pee. But in the end, you should be able to do it without one.* [P11, male, 10 y]

Theme 2: Social Acceptance

Social acceptance emerged as a significant theme, reflected in the importance participants placed on how they are perceived by peers. A recurring concern was that urotherapy tools were not discreet and could attract unwanted attention in social settings, leaving children feeling singled out.

> *If you're outside and the timer watch starts beeping every hour, your friends are like, "Why does he keep beeping?"* [P2, male, 11 y]

> *I had to keep a bladder diary at school once, but it was so annoying. Everyone in the class would look at me when I had to do it.* [P14, female, 13 y]

> *If you wear the alarm around your neck, everyone knows you're doing bladder training.* [P11, male, 10 y]

In addition, children reported being bullied for their bladder problems. To cope with this, they described efforts to hide symptoms and to be very selective about who they trusted with information about their condition.

> *I had an argument with my little brother and then I wet my pants, which happens more easily when I'm stressed. And then he yelled "Ew, gross! Run away! Run away!"* [P8, male, 11 y]

> *Only my teachers know. I don't tell anyone else, because I know I'll get bullied again. Like once during gym class, someone saw I had a wet spot. But I grabbed a glass of water and pretended to spill it on myself so they'd think it was just water.* [P2, male, 11 y]

In contrast, children expressed that openness about their bladder problems could serve as a way to break the taboo. For those who chose to do so, this openness was met with peer support and contributed to greater self-acceptance.

> *I did my school presentation about my bladder problem. That really helped me, because now my classmates support me. I also have a really good best friend who visits me a lot, and we often talk about it.* [P4, male, 9 y]

> *I think it's important that you can still fit in at school, even with this problem. Almost my whole class knows about it.* [P3, male, 10 y]

Timer watches were not always associated with stigma. Children described that, when designed in a playful, everyday style, the watches could attract desired attention. In these cases, the timer watch was seen as a stigma-free and unique accessory that could be proudly shown to peers.

> *I had one of those timer watches once in rainbow colors, and some kids said, "Wow you have a really cool watch!"* [P3, male, 10 y]

> *When the other kids in the class don't have a watch, they get really jealous.* [P4, male, 9 y]

Theme 3: Contextual Influences

The collaging exercise in particular revealed how various contexts influence children's bladder behavior (Figure 2). Different contexts, such as home, school, or sports, led to varying patterns of hydration, awareness of bladder signals, and incontinence frequency. Gaming and sports were identified as contexts where urine leaks occurred more frequently due to distraction, while school environments were associated with greater attentiveness and fewer incidents.

XSL•FO
RenderX

Figure 2. Example of a collage created by a participant (gray text represents the English translation).

At home I game a lot, and then it sometimes goes wrong. I get wet. Because while gaming, I don't really feel my signals. At school it goes better, because I pay attention to my bladder. I also drink less at home. [P11, male, 10 y]

I swear, when I get wet, it's usually during sports. It just leaks without me noticing. [P2, male, 11 y]

At school or with my friends, I drink a lot and then I go to the bathroom quickly. At home, I barely drink anything. I have to manage everything myself there, and then I forget. [P5, female, 9 y]

At school, I don't really drink anything, so I don't have to pee. [P15, female, 12 y]

Furthermore, specific contexts such as school toilets present their own unique challenges. Dissatisfaction with school toilets was a recurring theme, with children highlighting issues related to poor hygiene and restrictive policies.

At our school, the toilets smell really bad. [P15, female, 12 y]

The toilets at school are really, extremely gross. [P11, male, 10 y]

I got punished at school because I had to go to the toilet. [P8, male, 11 y]

I can go to the toilet at school whenever. Only sometimes they lock the entrance door. [P11, male, 10 y]

Similarly, the doctor's office presented its own challenges as a context. Children reported feeling disconnected during consultations, as interactions were often directed more toward their parents. In these situations, they described becoming disinterested, confused, or disengaged.

The doctor mostly talks to my mom. I just start playing with something, because I don't understand everything they're saying. Then my mom gets mad and says, "Hey, you have to pay attention!" [P11, male, 10 y]

We sometimes go to a doctor, but I don't really know what he does. [P6, female, 9 y]

When I'm at the doctor's office, I go to the toilet just because I don't like being there. [P13, female, 10 y]

In contrast, children described their experiences with in-clinic group therapy very positively. A key factor mentioned by children was the peer support they received from others going through similar challenges. Being part of a group was described as giving them a sense of belonging, trust, and shared understanding, which contrasted with the feelings of isolation often experienced at home or in other settings.

XSL•FO
RenderX

> *I really looked forward to it. It's actually like a sleepover. You can talk to each other 24/7. And it's just nice to be in a room together, play a game, or go gaming together. You sit next to each other, so you can see what's happening. At home, you're really just doing everything on your own.* [P11, male, 10 y]
>
> *It's just nice when someone you really trust and like has the same problem as you.* [P3, male, 10 y]

Theme 4: Digital Integration

As digital natives, the children are highly familiar with digital technologies. This was reflected in the focus groups through references to the regular use of smartphones, games, and other digital technologies.

> *Well, that's literally who I am: phone, selfies, calling.* [P15, female, 12 y]
>
> *At first, I only had two and a half hours of screen time on my phone, but now I'm just allowed to use it as much as I want.* [P17, male, 12 y]
>
> *At home I game a lot. Gaming is my hobby.* [P11, male, 10 y]
>
> *Everything is digital these days.* [P4, male, 9 y]
>
> *I'm not much of a writer.* [P14, female, 13 y]

In discussing urotherapy tools, children referred to their familiarity with digital platforms and contrasted this with traditional tools, such as paper-based bladder diaries or longstanding tools like wetting alarms and timer watches. They reported that these traditional tools were outdated, inconvenient, and misaligned with their digital preferences.

> *The wetting alarm and timer watch are old-fashioned!* [P9, male, 9 y]
>
> *It's annoying that you have to write everything down in your bladder diary. You just want to get on with what you're doing.* [P11, male, 10 y]
>
> *I'm okay with using the measuring cup, but not the paper chart. It's just inconvenient.* [P12, female, 9 y]
>
> *When the wetting alarm goes off, it just vibrates or beeps, but that's kind of basic and just makes you nervous. It should go off in some other, more fun way.* [P3, male, 10 y]

Children also came up with creative suggestions for smart, gamified solutions to enhance the appeal, engagement, and usability of urotherapy tools. These ideas included digitizing traditional tools such as bladder diaries.

> *The bladder diary should be digital so it's quicker to use.* [P3, male, 10 y]
>
> *There should be something that fills in the bladder diary automatically.* [P13, female, 10 y]
>
> *The timer watch should also let you record when you've been wet, like a bladder diary.* [P3, male, 10 y]

Among the ideas expressed were advanced features, such as smart algorithms capable of predicting when the bladder is full or when it is time to drink. It was also suggested that these systems could include self-learning capabilities, adapting over time based on user behavior and feedback.

> *Something that beeps when your bladder is full, instead of when you're already wet.* [P8, male, 11 y]
>
> *Something that predicts when you need to drink and pee using sensors that track how much you've drunk over time, and then tells you when you'll need to pee. You can see it in an app, and maybe even give feedback on whether the prediction was right or not.* [P16, male, 12 y]

Gamification also emerged as a strategy to increase engagement, with ideas such as turning uroflowmetry into a game through scoring systems that reward performance and progress.

> *There should be a mini game on the uroflow toilet. One time I set the record. I think it was 330 ml.* [P10, male, 10 y]
>
> *You could get a score for your uroflow graph, for example, 25 points for "Nice," 50 for "Good," 75 for "Perfect," and 100 for "Excellent." But it's important that the points always stay positive.* [P19, male, 13 y]

Finally, an interactive training buddy, such as a virtual animal or bottle avatar (Figure 3), was proposed as a way to provide age-appropriate encouragement and a sense of companionship.

XSL•FO
RenderX

Figure 3. Children's drawings illustrating concepts for a digital training buddy. (**A**) Little animal that walks across your uroflow curve; (**B**) little bear that reminds you to go to the toilet; (**C**) bottle that gets happier the fuller it gets to remind you to drink.

There could be a little animal, one you get to choose, that walks across your uroflow curve. [P6, female, 9 y]

If you haven't peed in a while, a little bear shows up in the game you're playing on your phone, taps the screen, and says, "You have to go to the toilet!" [P13, female, 10 y]

To help you drink more, there's a bottle on your phone that fills up and gets happier the fuller it gets. When it's completely full, it looks really happy. [P6, female, 9 y]

Despite enthusiasm for digital solutions, children also raised concerns. These included excessive phone use, technical malfunctions, or limitations, and the risk of fostering an overly competitive mindset through gamified features, which could result in disappointment.

If I start doing the bladder diary on my phone, I'll end up looking at other stuff and three hours later, I'm still on my phone. [P14, female, 13 y]

If there's a technical error, your data might not get saved. [P19, male, 13 y]

If you're out and forget your phone, and that's where the bladder diary app is, then you'd have to go back and get your phone. [P18, male, 11 y]

If you make it into a game, then you really want to win, but if you don't succeed, you might feel embarrassed or disappointed, and that's not really nice. [P11, male, 10 y]

Thematic Reflections in Children's Superhero Drawings

The superhero drawing exercise served as a creative and expressive validation of the findings from the focus groups, visually reflecting the core themes that emerged throughout the study. The characters children designed included elements that represented their attitudes, experiences, and desires.

The theme of attitudes and motivation included representations of superheroes who showed a willingness to participate in training and make use of urotherapy tools. For example, child 3 (male, 10 y) created "Captain Underpants," a popular Dutch children's book character, with a wetting alarm attached to his underpants (Figure 4A). Similarly, child 14 (female, 13 y) illustrated the "Time Controller," using tools like the timer watch to master toilet timing (Figure 4B). Child 2 (male, 11 y) envisioned a well-trained superhero with a powerful metal sphincter to prevent urine leakage.

In contrast, child 10 (male, 10 y) created "Diaperman," a robot with an infinite diaper supply (Figure 4C), and child 4 (male, 9 y) a superhero with laser eyes to remove the bladder. These superheroes may reflect a desire for convenience or unrealistic quick fixes rather than commitment to training, aligning with the subtheme of resistance toward training under the same theme of attitudes and motivation.

The theme of social acceptance also emerged through characters such as "Mister Pee" (child 8, male, 11 y), whose superpower is making bullies wet their pants so they can understand what it feels like (Figure 4D), an embodiment of the fear of being bullied. In contrast, characters like Spiderman with a wet spot (Figure 4E) or Superman with a diaper (child 11, male, 10 y) reinforced the idea that bladder problems can affect anyone,

XSL•FO
RenderX

even strong and popular superheroes, supporting the subtheme of openness as a way to break the taboo.

Child 12 (female, 9 y) designed different superhero accessories that grant the power to completely stop urination, but only when worn (Figure 4F). This drawing was categorized within the theme of contextual influences, as it illustrated how bladder control was imagined as dependent on specific situations or conditions.

Finally, many superheroes across drawings were equipped with tools and gadgets, hinting at the theme of digital integration, particularly the subtheme of gamified and smart solutions. These imaginative tools and gadgets often combined functionality with fantasy.

Figure 4. Children's superhero drawings. (**A**) "Captain Underpants" with wetting alarm; (**B**) "Time Controller" with timer watch to master toilet timing; (**C**) "Diaperman" with an infinite diaper supply; (**D**) "Mister Pee" with the power to make bullies wet their pants; (**E**) Spiderman with a wet spot; (**F**) Different superhero accessories to prevent urination while wearing them.

Discussion

Principal Findings

This qualitative focus group study revealed that children's experiences with urotherapy and its tools are shaped by a combination of (1) attitudes and motivations, (2) the need for social acceptance, (3) contextual influences, and (4) a strong desire for digital integration. As digital natives, children perceived many traditional urotherapy tools as outdated and misaligned with their expectations. They expressed a need for tools that support autonomy, discretion, and adaptability. Tools designed in a playful, everyday style were considered less stigmatizing and more socially acceptable. Their own innovative suggestions, ranging from smart predictive algorithms to gamified platforms and interactive training buddies, reflect a desire for more advanced, technology-driven solutions. At the same time, they acknowledged potential pitfalls, such as overuse or dependence on technology.

Strengths and Limitations

We conducted a qualitative study using a novel focus group discussion toolkit comprised of creative and playful exercises tailored to our objectives. While qualitative research in pediatric urology is an emerging field, its potential to capture the lived experiences of young patients is increasingly recognized [22]. The creative exercises used in this study enabled children to share personal and sensitive experiences in a child-friendly and expressive manner, demonstrating the potential of creative methodologies to enrich data quality and participant engagement. To our knowledge, no previous study has adopted such an approach in this field.

This study also has limitations. First, the focus group sessions were relatively long (1.5 to 2 h), which posed challenges in maintaining participants' attention and cooperation.

XSL•FO
RenderX

Nevertheless, the variety of creative and engaging exercises helped sustain children's attention. Second, the generalizability of findings is limited due to the purposive sampling of children undergoing the most intensive form of urotherapy, in-clinic group training in a tertiary care center. Despite this, we believe some transferability exists. These participants can be considered experts by experience, having undergone a broad spectrum of care ranging from outpatient to inpatient urotherapy. Moreover, their strong interest in advanced digital solutions likely reflects a broader trend among children growing up in a digitally native generation. Therefore, while findings should be interpreted within context, they provide valuable insights for improving urotherapy practices and inspiring the design of future urotherapy tools, particularly those involving smart, digital innovations.

Comparison With Prior Work

Our findings align with previous research demonstrating the social impact of peer dynamics, including a desire to conceal bladder problems and fear of bullying [23,24]. Similarly, our results are consistent with earlier studies highlighting contextual challenges, such as dissatisfaction with school toilets [25,26] and limited involvement during doctor consultations, in contrast to the positive influence of peer support experienced during group therapy [27]. Finally, children's interest in gamified, smart solutions aligns with the findings of our concurrent scoping review on innovative, technology-driven, digital tools for managing pediatric urinary incontinence [28]. Many of the tools identified in this review were described as engaging for children, improving patient compliance and leading to high levels of patient satisfaction and preference. Their gamification ideas aligned with the serious games described in the review, further validating the appeal of playful, story-driven engagement strategies. Similarly, the concept of prevoid alarms, which featured prominently in the review, was also proposed by children.

Both the scoping review and the focus group point to critical design features for future product development, including adaptability, personalization, and smart connected systems. What the focus group adds, however, is an important user-centered depth. To truly personalize treatment or tools, one must understand the child's individual context: attitudes, motivation, social context, and emotional needs. Yet, as the focus group revealed, children are not always actively involved during medical consultations, raising the question of how personalization can occur without their active participation. Importantly, the focus group study demonstrated that children can articulate their needs and preferences, especially when supported by creative, child-friendly methods. Their creative input provided a valuable entry point into co-design and communication strategies, as explored further in the Implications and Future Directions section.

Implications and Future Directions

Building on the children's creative ideas shared during the focus groups, we designed a conceptual smart urotherapy solution [29]. This concept incorporates smart algorithms capable of predicting bladder fullness and optimal drinking times by connecting a smart drinking bottle with a home-based uroflowmeter (Figure 5). These devices are linked through a reminder watch, which offers personalized voiding prompts based on the child's fluid intake and estimated bladder capacity. To reduce stigma and enhance social appeal, the design shifts the focus from urination to drinking and features playful, child-friendly esthetics. A digital training buddy, displaying various hydration and urgency states, provides companionship, support, and motivation throughout the therapy process.

Figure 5. Smart urotherapy concept: a smart drinking bottle, reminder watch, and home-based uroflowmeter are interconnected to deliver personalized voiding and drinking prompts via a digital companion on the watch.

Findings also highlight the need for improved child involvement during doctor visits. Children often lacked awareness of their care pathway, suggesting a need for more child-centered communication. The creative methods used, particularly the superhero drawing activity, proved effective in facilitating meaningful dialog and capturing children's emotions, motivations, and experiences. These insights have informed follow-up research focused on further analyzing the drawings to develop a "urotherapy superhero family," intended as a conversation tool during consultations (Figure 6). By inviting children to select a hero companion that represents them during treatment, the tool aims to enhance child engagement, support

XSL•FO
RenderX

emotional expression, and promote a more active role in their care trajectory.

Figure 6. A first design of a urotherapy superhero family, intended as a conversation tool between children and health care providers to promote engagement and a greater sense of child involvement.

Conclusions

This study's use of qualitative and creative methods enabled a rich understanding of how children engage with urotherapy and the tools that support it. It revealed that their experiences are shaped by a complex interplay of personal attitudes and motivations, social dynamics, contextual factors, and a strong desire for digital integration. These insights offer direction for developing future tools that prioritize personalization, stigma-free design, adaptability, and digital innovation. Including children's voices in research and design is essential to ensure that interventions are not only clinically effective but also meaningful and engaging, ultimately contributing to more child-centered care.

Acknowledgments

The generative artificial intelligence tool ChatGPT by OpenAI was used to improve language and readability. The tool provided inspiration on how to rephrase parts of the manuscript, but final edits and decisions were made by the authors. This research is part of a PhD project partially funded by the Flanders Innovation and Entrepreneurship Baekeland grant (project ID HBC.2021.0836) and the company Minze Health.

We also thank the urotherapists at the Wilhelmina Children's Hospital of the University Medical Center Utrecht for their collaboration, support, and for providing time for the sessions within their training program. A special thank you goes to the participants, with the support of their parents, for dedicating their valuable time and contributing to this work.

Data Availability

Full transcripts and recordings from the focus groups cannot be shared due to privacy and ethical reasons; however, anonymized excerpts or thematic summaries are available from the corresponding author on reasonable request.

Authors' Contributions

Conceptualization of the study was carried out by LB, JV, GDW, AV, and LVC. The investigation was conducted by LB and RFB. LB was responsible for the formal analysis, data curation, and original draft preparation. Review and editing of the manuscript were undertaken by LB, GDW, AV, LVC, and ANL. Supervision was provided by GDW, AV, and LVC. Project administration was handled by ANL. The final manuscript was critically reviewed and approved by all authors.

Abstract

Introduction: Adolescent girls and young women in sub-Saharan Africa (SSA) represent 4 out of every 5 newly diagnosed HIV cases among adolescent girls and young women globally. Leveraging augmented reality (AR) technology for HIV prevention and treatment holds significant potential among young people. However, there is a knowledge gap regarding the acceptance of AR by adolescent girls and young women in SSA.

Objective: This study aimed to assess the likelihood of adolescent girls and young women in Cameroon using AR for HIV testing, prevention, and treatment. The study findings will lay the groundwork for developing AR-based interventions to prevent and treat HIV in Cameroon and beyond.

Methods: This was a cross-sectional survey conducted in Yaounde, Cameroon, in which 637 adolescent girls and young women were recruited using a combination of multistage cluster and snowball sampling techniques. We used an electronic survey to collect data on participants' knowledge, prior use of AR technology, and likelihood of using AR technology for HIV prevention and treatment, and associated factors. Multivariate ordinal regressions were used to analyze the factors associated with the likelihood of adolescent girls and young women using AR to prevent HIV.

Results: The study showed that 84% (536/637) of adolescent girls and young women had never heard of AR before this study, and only 8% (49/637) had prior experience using AR. Participants' median age was 22 (IQR 21 - 24) years, with the majority (362/637, 56.8%) aged between 21 and 25 years. Despite the low usage rate of AR among participants, there was a high likelihood of using AR to promote HIV prevention and treatment. Specifically, 72% (459/637) of participants reported that they were likely to use AR to visualize the HIV transmission process, while 73% (465/637) and 74% (471/637) reported the likelihood of using AR to learn about pre-exposure prophylaxis (PrEP) and how HIV medication lowers HIV viral load, respectively. More importantly, 54% (342/637) and 50% (319/637) of participants reported that they were extremely likely to use AR to learn the correct way of using condom and self-testing for HIV, respectively. The high likelihood of using AR to prevent and treat HIV was associated with a higher education level (P=.01), having ever tested for HIV (P=.03), and a history of previously using health apps or searching for health information on their phones (P<.001).

Conclusions: The likelihood of using AR technology to promote HIV prevention and treatment is high among adolescent girls and young women in Cameroon. Future research should focus on exploring the preferred features of AR-based digital health interventions and consider methods of implementing them in the context of Cameroon or SSA.

Introduction

In sub-Saharan Africa (SSA), the most vulnerable population for HIV is adolescent girls and young women [1]. Among adolescent girls and young women globally, 4 out of every 5 newly diagnosed HIV cases occur in SSA [2,3]. Cameroon, a lower-middle-income country with a population of 29 million, has the highest HIV prevalence rate in West Central Africa. Women, particularly those aged 15‐49 years, are disproportionately affected by the virus [4-7]. This health disparity among women is related to various factors, including limited access to health care resources, unbalanced power dynamics in sexual communication, reduced awareness of risk behaviors associated with HIV, and the absence of an enabling environment for women [8]. Consequently, the number of new infections among adolescent girls and young women in Cameroon is more than twice that of their male counterparts [9]. To eliminate the burden of HIV, the government of Cameroon has initiated national strategic plans aimed at reducing the HIV incidence by 65% by 2023 [7]. Although Cameroon is making progress in the fight against HIV, with a 50% decrease in HIV prevalence among people aged 15 to 64 years in the past 14 years, the 65% goal has not yet achieved [10]. This shortfall is associated with factors at individual, health system, and structural levels, including delays in diagnosis and linkage to HIV care, as well as insufficient engagement among persons who initiate care [11]. To end HIV in Cameroon, the national strategic plans of Cameroon emphasize the importance of providing adolescents and young people the right skills to protect themselves from HIV [7]. Under this backdrop, it is necessary to develop and test innovative, effective, and culturally appropriate approaches to enhance efforts in fighting against HIV in Cameroon, reduce health disparities, and promote HIV testing and pre-exposure prophylaxis (PrEP) use among adolescent girls and young women [12].

Innovative technologies, such as augmented reality (AR), have been integrated into mobile health (mHealth) interventions to promote user engagement, enhance interactive learning, and provide tailored health information [13]. AR is broadly defined as a technology, usable on devices such as smartphones, tablets, glasses, headsets, and so on, that overlays computer-generated information, such as avatars, images, and sounds, onto the users' real environment in real time to enhance users' interactive experience [13,14]. Additionally, a major technical limitation of conventional HIV prevention strategies is their lack of offering an interactive and immersive environment to enhance users' experience [15-17]. To young people who are more open to technology, AR-based mHealth interventions could offer innovative solutions, through its immersive and interactive qualities, to enhance HIV health education, communication for behavioral change, and reduce stigma. For example, studies have found that AR applications have the potential to significantly increase user engagement, promote information retention, and enhance users' satisfaction [18]. Furthermore, AR-based interventions have the capability to influence people's perceptions of HIV prevention, potentially revolutionizing health education and behavior change initiatives, with youth as the primary target audience [19].

Despite their potential, most AR-based mHealth interventions have been conducted in high-income countries, leaving insufficient evidence of their applicability in low-income settings [20]. Some AR-based interventions, including "Floating heart" 3D imaging [21], mLearning [22], BodyExplorer [23], and FlexAR [24,25], have demonstrated preliminary but significant outcomes in medical education. However, their application to improve HIV prevention (including condom use and HIV PrEP uptake) is very sparse. Also, implementing AR interventions in resource-limited settings often faces technical challenges, including the need for smartphones with AR capabilities and reliable internet connections. A previous analysis has highlighted a high ownership of smartphones and access to the internet among adolescent girls and young women in Yaounde, Cameroon [17], indicating a favorable environment for implementing digital health interventions like AR-based mHealth programs. Understanding how adolescent girls and young women in Cameroon perceive and engage with AR technology is crucial for designing effective, culturally tailored health interventions. To date, the usability and effectiveness of AR technology in HIV prevention among adolescent girls and young women in Cameroon and the SSA region is unknown. Therefore, this study aimed to assess the likelihood of adolescent girls and young women using AR for the promotion of HIV testing, prevention, and treatment. This study also sought to identify factors associated with the likelihood of adolescent girls and young women adopting AR-based health interventions, informing the design of future AR-based mHealth interventions in Cameroon and the SSA region.

Methods

Study Sample and Data Collection

This was a cross-sectional study conducted from February to June 2023, in which 637 participants were recruited from Yaounde, Cameroon, where a variety of adolescent girls and young women were residing. To be eligible to participate in this study, individuals must be cisgender women aged 18 to 30 years, able to understand the study questions, and mentally healthy enough to voluntarily give informed consent.

The study procedures have been published elsewhere [17]. In brief, participants were recruited using a multistage cluster sampling technique based on Cameroonian health districts and health areas, combined with a snowball sampling technique wherein a consenting participant referred other potential participants. This recruitment method was chosen to ensure the inclusion of participants with diverse demographic backgrounds within Cameroon. Data were collected as pseudonymized data using a survey questionnaire implemented on Yale Qualtrics, a secure electronic survey platform. The Qualtrics questionnaire was administered with the assistance of 2 well-trained enumerators, who could hand their phones to participants to select their own responses, especially for sensitive questions. For reasons of data protection and confidentiality, participants' identifier codes were only known to the 2 enumerators involved in fieldwork and JJNN, who possesses the signed inform consent forms.

Ethical Considerations

This study received ethical approvals from the Yale University Institutional Review Board (ID: 2000033713) and the Cameroonian Centre Regional Ethics Committee for Human Health Research (initial ID: CE number 02058/CRERSHC/2022, and extension ID: CE number 02058/CRERSHC/2023). Additionally, this study has received administrative authorization from the Cameroonian Centre Regional Delegation for Public Health. Data were pseudonymized and all participants provided informed consent.

Measures

Sociodemographic and Baseline Characteristics

Sociodemographic variables included age, monthly income, educational level, and geographical zone of origin. Other characteristics included sexual orientation, phone ownership and use, awareness of AR, and previous experience with AR. Specifically, phone ownership was measured by the question "Do you own or have access to the following devices on a daily basis (check all that apply: landline telephone, mobile phone without internet access, smartphone, tablet, laptop, and personal computer)?" Participants' awareness of AR was measured by the question "Have you ever heard about Augmented Reality (Yes or No)?" For those who were aware of AR, their previous experience with AR was measured by the question "Have you ever used Augmented Reality (Yes or No)?" For participants who had used AR, a follow-up question was asked to study the features of AR that they used: "Why do you use Augmented Reality in your daily life? Select all that apply (Immersive, interactive, virtual world, embodiment, sensory feedback, other, please specify)."

Likelihood of Using AR

The primary outcome variable was the likelihood of using AR for health purposes, measured as a composite score of 7 subscales. The seven subscales measured the likelihood of leveraging AR to (1) visualize the HIV transmission process, (2) demonstrate the correct way of using a condom, (3) introduce daily PrEP, (4) depict the HIV testing process in a clinical or NGO setting, (5) show the HIV self-testing process, (6) explain the process of receiving HIV treatment, and (7) illustrate how HIV medication lowers the HIV viral load. Participants' responses to each subscale were measured using a 5point Likert scale, ranging from 1 (extremely unlikely) to 5 (extremely likely). For example, the likelihood of leveraging AR to visualize the HIV transmission process was measured by the question: "If we build an Augmented Reality (AR) app for you to visualize the HIV transmission process, how likely would you be to use the AR?" and the likelihood of leveraging AR to demonstrate the correct way of using a condom was assessed by the question: "If we build an Augmented Reality (AR) app demonstrating the correct way of using condom, how likely would you be to use the AR?" A composite score was calculated for each participant as the mean score of the seven 5-point Likert subscales, rounded to the nearest whole number. Specifically, for each of the above subscales, we quantified their responses using a scale ranging from 1 to 5, followed by calculating the mean of these responses and rounded the results to the nearest whole number within the same Likert scale.

Statistical Analyses

Statistical analyses were conducted using R software version 4.3.1 (R Core Team). Categorical variables were presented as absolute and relative frequencies, as well as cross tabulations of the likelihood categories to use AR. Proportions of the likelihood to use AR for HIV prevention were calculated, where the numerators were the number of participants who selected any of the ordinal response categories (ie, extremely unlikely, somewhat unlikely, neither likely nor unlikely, somewhat likely, and extremely likely), and the denominator was the total number of study participants. To determine factors associated with the likelihood of using AR for health purposes, ordinal logistic regression was applied using the "*polr*" function. Univariate analyses were initially conducted to identify covariates of interest (with $P<.10$), which were then put together in a model to adjust for each other's effect in a multivariate analysis. The level of significance for the multivariate analysis was set at 5%. The exhaustive list of independent variables of the univariate analyses include: age group, region of origin, sexual orientation, education level, employment status, monthly revenue, marital status, housing condition, ownership of (or access to) smartphone or tablet with internet, history of health app use or phone for health information search, HIV testing situation, sexually transmitted infection diagnosis within past 6 months, vulnerable sexual behavior and PrEP awareness.

Results

Participant Characteristics

Participants' median age was 22 (IQR 21 - 24) years, with the majority (362/637, 56.8%) aged between 21 and 25 years. Most participants were heterosexual (599/637, 94%), unmarried (485/637, 76.1%), and were unaware of PrEP (519/637). We also found that 93.9% (598/637) of participants had access to a smartphone, 42.4% (270/637) had access to a laptop or personal computer, and 9.9% (63/637) owned a tablet or iPad [17]. Among the 637 participants, 84.1% (n=536) had never heard of AR, and only 7.7% (n=49) had used AR. Among those who had ever used AR, 51% (25/49) used virtual world, 20% (10/49) used embodiment features, 10% (5/49) used interactive elements, 10% (5/49) used sensory feedback, and 8% (4/49) used immersive features.

Likelihood to use AR for Health Purposes and Associated Factors

Overall, the likelihood of using AR for health purposes was high, with 72.8% (464/637) of participants somewhat or extremely likely to use AR, compared to 10.5% (67/637) of participants somewhat or extremely unlikely to use AR. It should be noted that for each of the health purposes, at least 45% (287/637) of participants were extremely likely to use AR, with 53.7% (342/637) preferring to use AR for learning condom use and 50.1% (319/637) preferring to use AR for learning the process of HIV self-testing (Table 1).

[a]OR: odds ratio

[b]Only variables with *P*<0.1 in univariate analaysis are shown in this table.

[c]aOR: adjusted odds ratio.

[d]STI: sexually transmitted infection.

Upon adjusting for all key covariates in a multivariate model, an increasing likelihood to use AR for health purposes was independently associated with a higher level of education (*P*=.01), having used a health-related app before or using a phone to search for health-related information (aOR 2.2, 95% CI 1.41 - 3.42; *P*<.001), and having tested for HIV, notably less than 12 months ago (aOR 1.7, 95% CI 1.41 - 2.62; *P*=.03), compared to those who have never undertaken an HIV test. Additionally, a decreasing likelihood to use AR for health purposes was independently associated with participants who identified as sexual minorities (aOR 0.5, 95% CI 0.28 - 1.01; *P*=.04), compared to heterosexual participants.

Discussion

Principal Findings

The integration of AR into HIV prevention strategies holds promise for enhancing education, improving accessibility, and ultimately reducing the spread of HIV. However, there is a knowledge gap regarding how AR technology, which garners increasing interest worldwide, can be best used for HIV prevention in resource-limited settings. This study seeks to address the literature gap on the feasibility of using AR technology for HIV prevention among adolescent girls and young women in the Cameroonian context. The findings of this study have provided valuable information on the likelihood of Cameroonian adolescent girls and young women to use AR to

XSL•FO
RenderX

learn about HIV testing, prevention, and treatment. Overall, there was a low prior knowledge of AR among adolescent girls and young women, accompanied by an even lower prior use of AR technology. Despite this, the likelihood of adolescent girls and young women using AR was high, with at least 45% indicating they were extremely likely to use AR interventions for HIV testing, prevention, and treatment, such as acquiring knowledge about HIV transmission, HIV testing, self-testing processes, correct condom use, HIV treatment, daily PrEP, and information on how HIV medication reduces viral load. This finding is particularly significant given that a study conducted in the Northwest region of Cameroon showed a high prevalence of inconsistent condom use among young women with HIV [26]. To end HIV in Cameroon and SSA, more comprehensive educational programs on sexual and reproductive health for adolescent girls and young women, including distribution and empowerment of female condom use, are necessary.

This study also indicated that leveraging AR is worth exploring in Cameroon. Globally, the awareness and use of AR for adolescent girls and young women in resource-limited settings is low compared to their counterparts in high-income settings [27]. This is mainly due to differences in access to AR technology, internet connectivity, and the integration of AR in education and entertainment [27]. Despite this, there have been a few commendable initiatives on the use of AR in SSA, notably in medical training, where it has shown to enhance the learning process and performance through more interactive and engaging experiences [28,29]. These initiatives, along with our study finding on the high likelihood of using AR among adolescent girls and young women, indicate that leveraging AR for HIV prevention in SSA is possible and should be given serious consideration.

This consideration is further justified by the interactive nature of AR technology. Compared with many early mHealth interventions, mobile apps embedded with AR technology can provide an immersive, interactive learning environment for people to receive real-time information, motivation, and behavioral skills. Considering the widespread adoption of smartphones among young people in resource-limited settings and the permeation of digital technologies in developing countries, AR-based mobile apps have significant potential for facilitating behavior change communication in HIV prevention efforts. For example, in a context where the ability of adolescent girls and young women to negotiate condom use during sexual acts is greatly influenced by a lack of comprehensive knowledge on HIV and cultural and social norms [30-32], AR technology, through interactive and educative role-play scenarios, may enhance their ability to effectively negotiate and correctly use condoms. Despite the lack of previous research on AR for HIV prevention among adolescent girls and young women, we believe that the expanded use and integration of technology-delivered interventions, such as mobile apps, websites, live chats, chatbots, vending machines, virtual reality and AR, when guided by theoretical frameworks, can assist adolescent girls and young women in engaging in self-care for HIV testing and prevention [33,34]. For instance, in 2018, the Joint United Nations Programme on HIV/AIDS (UNAIDS) teamed up with Google and Makhulu Media to release a series of virtual reality educational films on HIV testing. These films were distributed in clinics, schools, and communities across South Africa to encourage people to test for HIV, potentially reshaping attitudes and reducing HIV-related stigma [35].

Our study has identified several factors associated with the likelihood of adolescent girls and young women to use AR technology for health purposes. We observed that adolescent girls and young women with at least secondary education level were more likely to use AR for HIV prevention than those with less education. This might be because individuals with higher levels of education tend to have better digital literacy skills as education provides opportunities for engagement with digital technologies and developing necessary digital competencies [36,37]. We also observed that those who had previous exposure to mHealth apps and/or sought health-related information on mobile devices were more likely to accept AR use compared to those who did not use health apps or use their phones for health information inquiries. Given that mobile devices are integrated into everyday life, offering numerous opportunities to enrich the learning experience, prior exposure to smartphones in learning activities might have made them familiar and comfortable with technology-based health interventions [38].

In this study, we also found that adolescent girls and young women who had undergone HIV testing within the past 12 months had a higher likelihood of using AR for HIV prevention compared to those who had never been tested. This increased likelihood might be attributed to the counseling and education services related to HIV testing, which have raised awareness of HIV vulnerability and the preventive behavioral changes that should be adopted, thus increasing their openness to the potential role of AR technology in HIV prevention. Additionally, adolescent girls and young women who identified as sexual minorities (bisexual, lesbian, or other), compared to heterosexual, exhibited lower likelihoods to use AR for HIV-related services. This may be due to a lack of tailored HIV prevention that specifically address the needs and concerns of sexual minorities given the legal and social environment around same-sex relationships in Cameroon. It could also be due to stigma and discrimination based on sexual orientation, which may create barriers to accessing health care services, thus influencing the health care utilization and behavior of young female sexual minorities [39]. Furthermore, cultural and societal norms within certain communities in Cameroon may marginalize such populations [40].

Limitations

Although our study has contributed valuable knowledge to the field of leveraging AR in Cameroon to prevent HIV among adolescent girls and young women, its findings should be applied with consideration of the following limitations. First, although we used multistage cluster sampling that randomly selected 4 health districts followed by the selection of at least 2 health areas from each health district, which increased the representation of adolescent girls and young women from the various regions of Cameroon based in Yaounde, our study sample was ultimately recruited using the snowball technique, relying on referrals from participants' personal networks. This limits the generalizability of our study findings to all regions

XSL•FO
RenderX

of Cameroon notably semiurban and rural areas which potentially lack the infrastructure to effectively run digital interventions. Second, while investigating their likelihood of using AR technology, we provided participants with an AR definition but did not provide an actual AR device or intervention; therefore, participants' understanding of AR technology might be limited to only a conceptional level rather than with deeper user experience. This might have brought some biases within participant feedback and responses. Nonetheless, building on the findings of this study, our team aims to develop an AR-based mHealth intervention in the future to promote HIV prevention among adolescent girls and young women within the metropolitan cities of Cameroon.

Conclusions

Our study reveals that the likelihood of leveraging AR for HIV prevention among adolescent girls and young women in Cameroon is high, particularly among those with higher educational levels and those who have previously used mobile apps for health purposes. The findings lay the foundation for the necessity of developing and testing AR-based interventions to prevent HIV in Cameroon. These interventions should be based on behavioral theories, Cameroonian culture, and the preferences of adolescent girls and young women in Cameroon.

Acknowledgments

We thank the two enumerators, Apeh Alfred and Pepah Grace, for their time and efforts in helping collect data and in answering questions in our weekly Yale-Cameroon research project meetings. This study received funding from Yale University School of Nursing through the PRIME (Pilot Research, Innovation, and Maximum Health Equity / Excellence) Research Grant and the Faculty Research Support Fund for Zhao Ni.

Abstract

Background: Pediatric to adult health service (AHS) transition is a challenging time for many adolescents and young adults with chronic illness. As the responsibility of illness management shifts from parents to the young person themselves, many young people fail to transition in a timely manner, which has important health consequences. Mobile apps show potential in assisting young people to self-manage their condition during this vulnerable time, but empirical data on app uptake as well as efficacy with respect to transition outcomes and illness control are lacking.

Objective: This study aimed to evaluate the usage of a mobile app called "TransitionMate" (TMApp) by adolescents and young adults, which was purpose-built to support chronic illness self-management for youth undergoing transition. Secondary aims were to assess AHS attendance and changes in illness control over the first 12 months post transition. Upon demonstration of TMApp feasibility (49/70, ≥70% of participants using TMApp at least once a month), a randomized controlled trial was planned to test app efficacy in relation to transition and illness control outcomes.

Methods: Young people aged 16 - 19 years who were transitioning out of 2 major pediatric hospitals in Sydney, New South Wales, Australia, were recruited. Just before transition, participants' demographic and clinical details were collected, and TMApp was installed on their mobile devices. Participants were contacted by telephone at 6 and 12 months for information on self-reported usage, app usefulness, and other feedback. Quantitative cohort-level usage data, including the number of times specific app features were accessed, were tracked via mobile analytics. At 12 months, electronic medical records from participants' designated AHS were accessed for data on AHS attendances, measures of illness control, and unplanned hospitalizations.

Results: In total, 73 adolescents and young adults (30 male; median age 18, IQR 17-18 y) were recruited, with 1 withdrawing participation in the first month. Participants were primarily from 3 chronic illness subgroups—diabetes mellitus (n=23), inflammatory bowel disease (n=19), and cystic fibrosis (n=9). Of the total, 50% (36/72) of participants reported using TMApp at 1 month post transition. Self-reported usage rates fell to 25% and 11% at 6 and 12 months, respectively. Mobile analytics data broadly corroborated self-reported usage. Furthermore, 8 participants who continued to use TMApp for 12 months gave a median usefulness rating of 8/10. Over two-thirds (48/72, 68%) of participants successfully transitioned to their designated AHS by 12 months. Among the successful transitioners who had illness control data available on electronic medical records, over 80% (24/30) maintained a stable or improved illness status at 12 months.

Conclusions: TMApp was not used regularly enough by our young people to demonstrate feasibility and justify progression to a randomized controlled trial. Despite low app uptake, most participants successfully transitioned, suggesting that TMApp had minimal influence on transition outcomes.

Introduction

Mobile phone technology is a significant part of everyday life and is seen as an attractive tool for both health care and health research. The management of chronic illness, where patients must maintain day-to-day routines to have good control of their condition, is a potential clinical situation where mobile apps might be useful.

One particular age group that may benefit from using mobile apps to manage their chronic condition is adolescents and young adults. First, young people, as digital natives, are confident users of mobile technology [1]. Second, adolescents undergo a challenging period of transition from pediatric to adult health services (AHS), whereby the responsibility of managing their chronic condition shifts substantially from the parent to the young person themselves [2]. Consequently, many young people neglect to monitor their health, adhere poorly to existing therapy, lose contact with any health care, and fail to transition in a timely manner [3,4]. Factors further contributing to suboptimal transition include inadequate communication between pediatric and adult services [5], decreased condition-specific illness knowledge in the AHS [6], and the lack of equivalent AHS [7]. Many of these issues are common among this age group, irrespective of chronic condition. Enhancing young people's capacity to competently and autonomously self-manage their condition is thus a key strategy to retaining them in the AHS and improving their transition experience [8,9]. Importantly, self-management skills are imperative for preventing loss of illness control and unplanned hospitalizations arising from acute morbidity [10,11].

While it is often assumed that adolescents and young adults will embrace mobile apps for managing their health, evidence to support this assumption is modest. In total, 2 systematic reviews to date have assessed the use of apps for youth self-management of chronic illness [12,13]. One of these reviews focused on transition and found some improvement in patient satisfaction related to self-management following the use of apps [13]. However, neither study was able to draw conclusions about app efficacy pertaining to transition outcomes, owing to insufficient and heterogeneous data. Other studies, such as those evaluating the "iManage" app (Cincinnati Children's Hospital Medical Center) for youth self-management of sickle cell disease [14-16], have generated useful information on app design, functionality, and acceptability with respect to consumer involvement, although efficacy data are yet to be available. Thus, knowledge gaps exist around understanding what role mobile apps play in the self-management of chronic illness for adolescents and young adults. Specifically, there is a need for more quantitative data on app usage and comparison of app uptake across different chronic conditions [17,18]. Empirical evidence on app efficacy with respect to transition outcomes and illness control is also lacking.

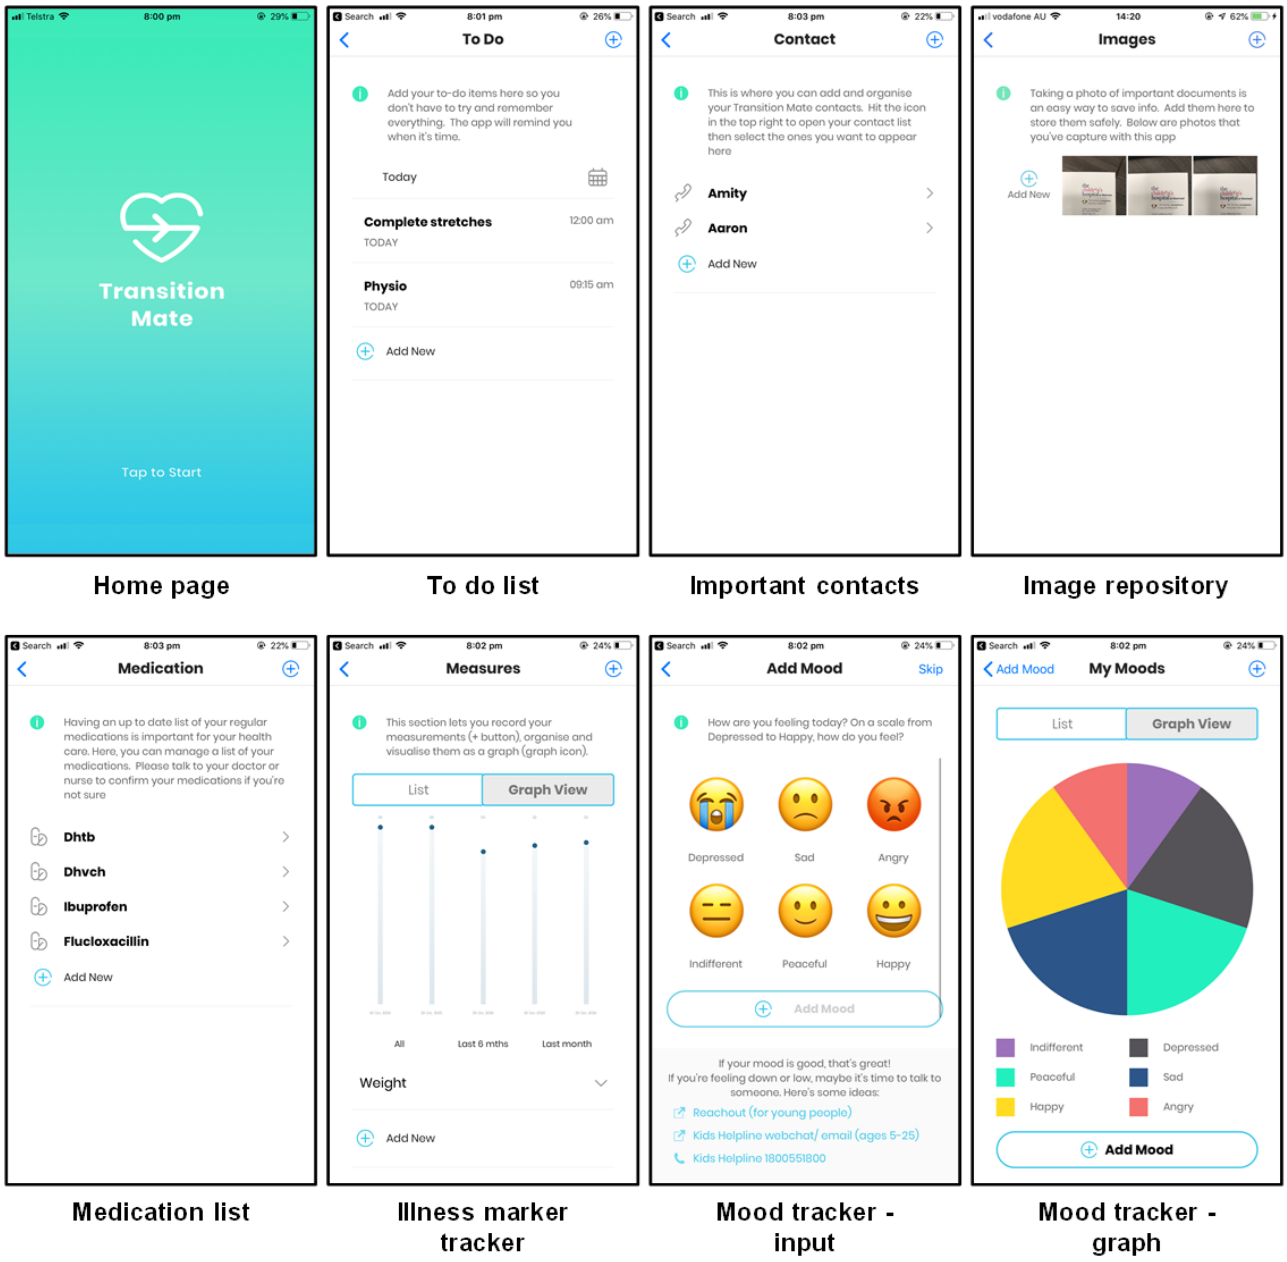
This study describes pilot testing of a mobile app called "TransitionMate" (TMApp), which was purpose-built to support adolescents and young adults in self-management during the vulnerable period of transition from pediatric to AHS. The app was designed as a generic (non–illness-specific) tool to address common issues around transition that could be used broadly across different health care settings and by patients with different conditions. The primary aim of this study was to evaluate young people's usage of TMApp. Secondary objectives were to assess AHS attendance and changes in illness control over the first 12 months post transition. The working hypothesis was that regular and long-term usage of TMApp would predict successful transition. Upon demonstration of app feasibility (defined as a minimum usage frequency of once a month by ≥70% [49/70] of participants based on power calculations), a randomized controlled trial was planned to test efficacy of TMApp in relation to transition and illness control outcomes [19]. Both the primary and secondary objectives were necessary before embarking on the randomized controlled trial.

Methods

TMApp

TMApp was developed from a prototype that was designed in collaboration with the University of Sydney School of Electrical Engineering, involving a team of medical professionals and software engineers [20].

A brief iterative participatory design process was used for developing the prototype. Initial ideas around what functionalities to include were informed by patient needs identified in the transition literature [21-23], through clinician experience, as well as experience from the software engineers who had previously built mobile apps for adult chronic illness. Furthermore, a focus group involving 10 adolescents and young adults with chronic illness was conducted to gain further insights into what young people wanted from a self-management app. Five required features were identified in this process, including automated reminders, the ability to log and view trends for illness data, a medication list, a mood tracking function, and a centralized repository for storing important contacts, referral letters, and medical histories as young people often struggled to recall this information when speaking to a new health care provider [24].



A prototype was subsequently built using the above information. Screenshots of each feature were presented to several clinicians and researchers with expertise in adolescent health, and further refinements were made accordingly. This review-and-refine process was repeated several times. Following this, the prototype was tested in a group of young adults with chronic illness who had recently undergone transition [25]. Feedback received from this user group was the need for a to-do list as well as customizable content and displays to suit individual illness management needs, among other improvements (eg, graphics and bug fixes). This feedback, along with the prototype, provided the framework for a commercial developer to build TMApp in its final form. Overall, the commercial app development process was lengthy, interrupted by insufficient funds, and resulted in the relatively simple TMApp, that again had user testing with further refinements.

The final version of TMApp had the following features: (1) to-do list; (2) reminders for health appointments and other health-related activities; (3) contact information for health care

XSL•FO
RenderX

and emergency professionals; (4) image repository for prescriptions, reports, results, and clinic letters; (5) medication list; (6) tracking of illness control markers; and (7) an emoji-based mood tracker (Figure 1). Participants received monthly automated notifications via the app to encourage use. These notifications included prompts for setting goals, checking medications, and obtaining new prescriptions, with no reply option available.

Figure 1. Screenshots of the main features on the TransitionMate mobile app.

TMApp was deployed on 2 major mobile operating systems—Apple iOS and Android (Google). For Apple iOS, TMApp was deployed through the App Store, whereby participants were given a promo code for free download onto their mobile device. To limit unintended downloads, it was made clear in the App Store that TMApp was intended for research participants only. For Android, deployment was through an Android Package Kit (.apk) file that was downloadable via a weblink emailed directly to participants. Technical support for TMApp was provided remotely by the commercial developer.

Study Design and Setting

This pragmatic, single-arm, pilot trial was conducted at 2 tertiary pediatric hospitals in Sydney, New South Wales, Australia—The Children's Hospital at Westmead and Sydney Children's Hospital, Randwick.

The main study time points were baseline, 6 months, and 12 months. The baseline visit occurred during the final routine clinic appointment at the pediatric hospital and involved the collection of patient demographic, clinical, and contact details, including an assessment of psychological distress and transition readiness. Installation and setup of TMApp also occurred during this visit. Follow-ups at 6 and 12 months involved a

XSL•FO
RenderX

telephone-administered semistructured questionnaire on (1) TMApp usage in the past month (daily, weekly, monthly, or never), (2) app features used most frequently and why, (3) AHS attendance (if they have attended or booked an appointment), and (4) illness control knowledge (if they could recall their markers of illness control and if any tests were done post transition). One additional question was included at 6 months, which asked participants to recall their TMApp usage during the first month of the trial. The 12-month questionnaire sought additional feedback, including a usefulness rating, whether TMApp was easy to use, whether they would recommend TMApp to others, and suggested improvements. Electronic medical record (eMR) data were sought from participants' designated AHS at 12 months, including (1) the number of AHS attendances in the past year; (2) primary, and if available, secondary measures of illness control; and (3) unplanned hospitalizations in the previous 12 months. Further details on the methodology are provided in the full trial protocol [19]. Reporting of this research study is in accordance with the CONSORT (Consolidated Standards of Reporting Trials) Pilot Trials checklist (Checklist 1).

Recruitment and Eligibility

Participants were recruited from May 2019 to May 2020 (between COVID-19 pandemic lockdowns). Adolescents with a chronic illness were approached with a study information pack by their treating teams during their penultimate routine clinic appointment. Patients were eligible if they were aged 16 - 19 years, undergoing transition to an AHS within the next 12 months, and consented to using TMApp and being contacted for study follow-up. Patients were excluded if they were non–English speaking, had no access to a personal smartphone, had an intellectual disability affecting questionnaire completion, had a primary diagnosis of mental health, active cancer, or were in a terminal state, or were using another transition-focused mobile app.

Transition Outcomes and Illness Control: Measurement and Definitions

Transition Outcomes

Using the eMR data obtained from AHS, we defined engagement as ≥1 recorded attendance at the participant's designated AHS within the first 6 months post transition. Retention was defined as ≥1 further attendance between 6 and 12 months post transition. If AHS appointments were expected to be annual, 1 attendance within the 12-month study period was defined as engagement. A participant was deemed to have transitioned successfully if they had ≥1 AHS attendance by 12 months. Unsuccessful transitioners were defined as those who did not engage with the AHS they were referred to or could not be contacted to ascertain if they had transitioned elsewhere.

Illness Control

Quantitative measures of illness control (primary and, if available, secondary) were obtained at baseline by accessing eMR data from the pediatric health service. At the end of the study, participants' designated AHS were contacted to obtain eMR data on subsequent measures of illness control and the number of unplanned hospitalizations.

Markers of illness control were specific to each chronic condition and were provided by clinicians from each pediatric specialty service, generally based on empirical evidence. Examples of common and clinically accepted markers of illness control are illustrated in Table 1. Participants were deemed to have experienced a deterioration in illness control if their primary or secondary markers showed a value that reflected a worse clinical state for their condition. Conversely, no change or a positive change in markers over time was indicative of stable or improved illness control.

XSL•FO
RenderX

Table . Clinically accepted markers of illness control and definitions for deterioration in illness control over 12 months.

Chronic illness and markers of illness control	Definitions for deterioration
Diabetes mellitus (type 1 and 2)	
HbA_{1c}[a]	≥1% increase
Cystic fibrosis	
FEV1[b]	≥10% decrease
Weight[c]	≥5% decrease
Inflammatory bowel disease	
CRP[d]	≥75% increase from ULN[e]
Weight[c]	≥5% decrease
Other chronic illnesses	
Hospitalization	≥1 unplanned hospitalization related to chronic illness

[a]HbA_{1c}: glycosylated hemoglobin.

[b]FEV1: forced expiratory volume (liters per second).

[c]Weight was considered a secondary illness marker for cystic fibrosis and inflammatory bowel disease.

[d]CRP: C-reactive protein.

[e]ULN: upper limit of normal (based on normative range defined by the laboratory providing the measure.

Psychological Distress and Transition Readiness

Participants completed the Kessler Psychological Distress scale (K10) and the Transition Readiness Checklist (TRC) at baseline. The K10 is a validated, 10-item scale that assesses an individual's mental distress related to depression and anxiety symptomatology [26]. The TRC is a 27-item tool developed by the Royal Children's Hospital (Melbourne, Australia) that assesses self-management skills covering the areas of illness knowledge, administrative and organizational capabilities, and self-advocacy [27].

Mobile Phone Analytics Data

Quantitative, cohort-level data on TMApp usage were obtained from Flurry Analytics (Flurry Inc). Variables of interest were the number of TMApp-active devices for each month of the study and the number of times each app feature was accessed. Due to privacy reasons, it was not possible to link mobile analytics data to individual user activity.

Statistics

Power Calculation

An estimated 70 participants were needed to achieve a minimum sample size of 49, with attrition predicted at 30%. A sample of 49 participants would have ≥80% power, based on a 1-sided significance level of 0.05, to detect an increase in the rate of successful transition from pediatric to adult care by 15% (eg, from 70% - 85%). This sample size was considered feasible given the number of adolescents with chronic illness who transition out of the 2 study hospitals annually.

Data Analyses

Results are presented as data aggregated for the entire cohort, except where sex differences were considered and when condition numbers were large enough for subgroup analyses. Normality was assessed via the Kolmogorov-Smirnov test. Associations between categorical variables were analyzed using chi-square tests. Mann-Whitney *U* tests were used to compare transition outcomes between subgroups. Significance was set at $P<.05$. Summary statistics are presented as means (SD) or median (IQR) for continuous variables, and frequency or percentage for categorical variables. Statistical analyses were performed using IBM SPSS Statistics version 24 (IBM Corp).

Ethical Considerations

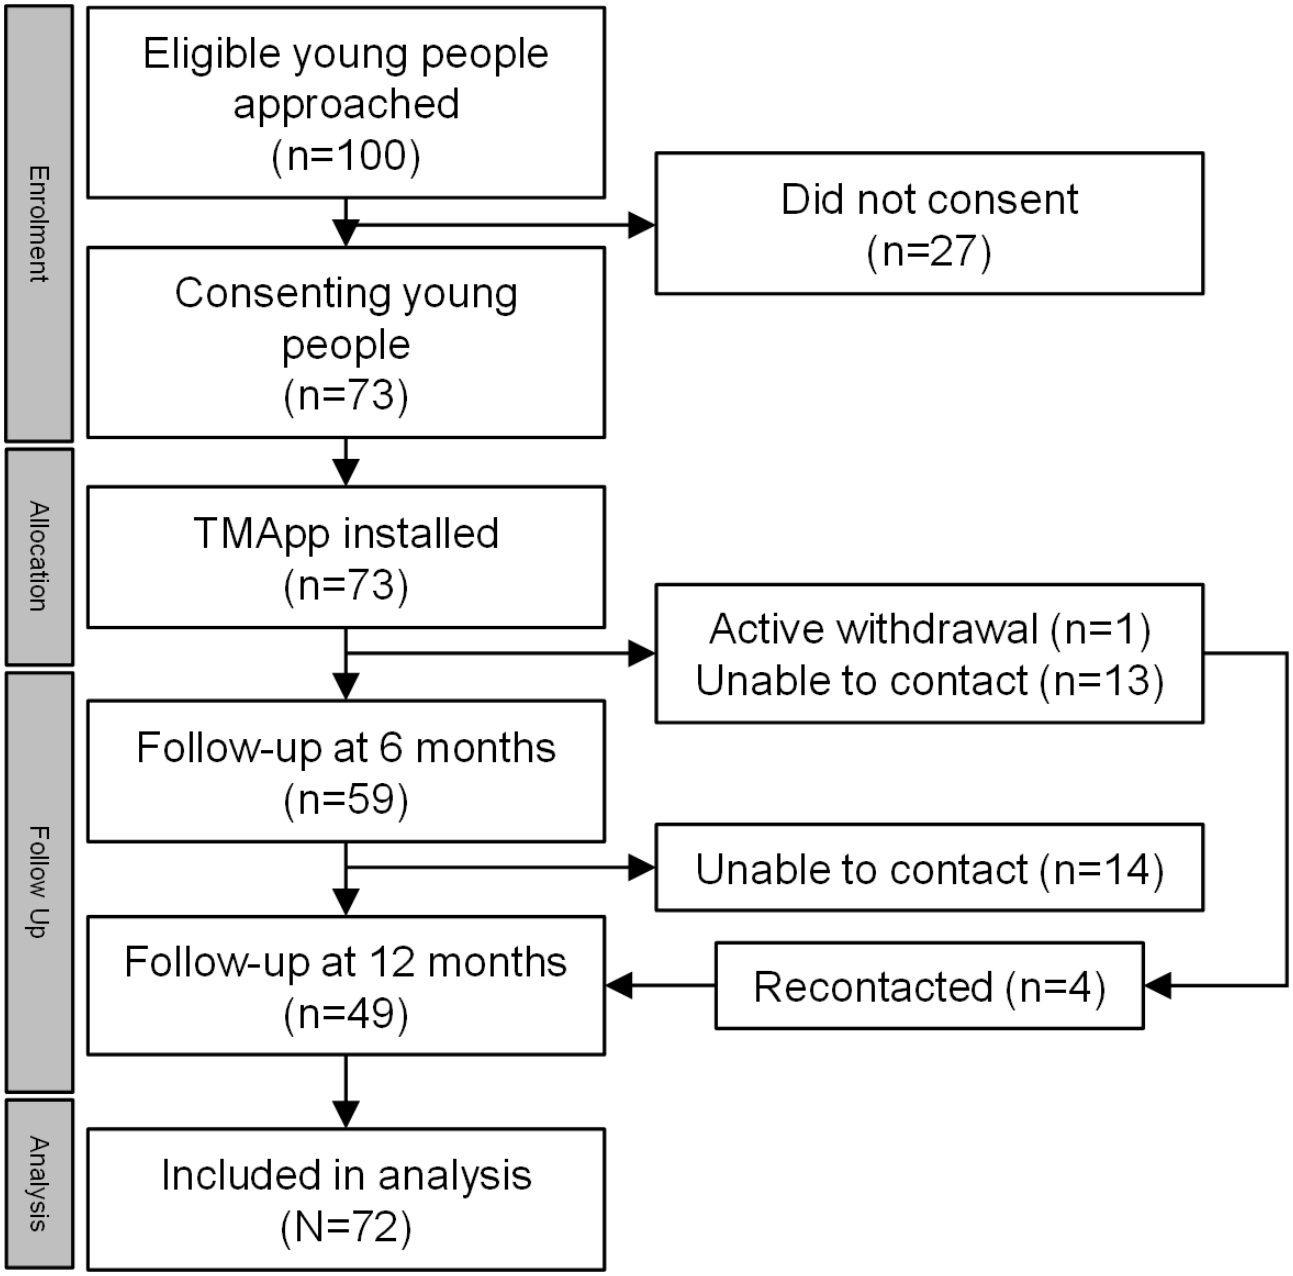
The study was approved in 2017 by the Sydney Children's Hospital Network Human Research Ethics Committee (HREC/17/SCHN/385). Due to lack of human resources and a prolonged app development process, the study did not commence recruitment until 2019. Signed informed consent was sought from parents and carers or from adolescents and young adults if they had reached 18 years.

Participants did not receive compensation for their involvement in the research.

All hard copy data (including questionnaire, phone call, and interview data) are stored in a locked filing cabinet in The Children's Hospital at Westmead, Academic Department of Adolescent Medicine. Access to these data is restricted to staff involved in the research. Research data are deidentified upon receipt by the investigators using participant code numbers to preserve anonymity. Deidentified digital data are stored under password protection on a restricted-access network drive within the Sydney Children's Hospital Network. Only the principal investigators have access to the participant reidentification list, and this list is stored separately as hard copy data. All data collected for the study will be preserved for 7 years from the date of obtaining maturity for young people who are older than 18 years, or for 7 years after the completion of the study for those aged more than 18 years. The hard and soft copies will

XSL•FO
RenderX

be destroyed at this time under specific Human Research Ethics Committees protocols for destruction of paper and digital data.



Results

Participant Characteristics

A total of 100 adolescent patients were approached, with 73 (30 male; median age 18, IQR 17-18 y) consenting to take part in this study. One participant withdrew within the first month of the study, citing lack of interest and was excluded from analyses. At 6 and 12 months, 83% (60/72) and 68% (49/72) of participants could be contacted for follow-up, respectively (Figure 2).

The majority (51/72, 70%) of participants were from 3 chronic illness subgroups: diabetes mellitus (type 1 and 2; n=23), inflammatory bowel disease (n=19), and cystic fibrosis (n=9). Other chronic conditions in the remaining participants are outlined in Table 2. Median scores for the K10 (17 out of 50) and TRC (70 out of 81) were, respectively, in the lowest category for mental distress and the highest category for transition readiness (Table 2).

Figure 2. Study flowchart. Of the 73 participants who consented to this research, only 1 was excluded from analysis due to withdrawal of consent. TMApp: TransitionMate app.

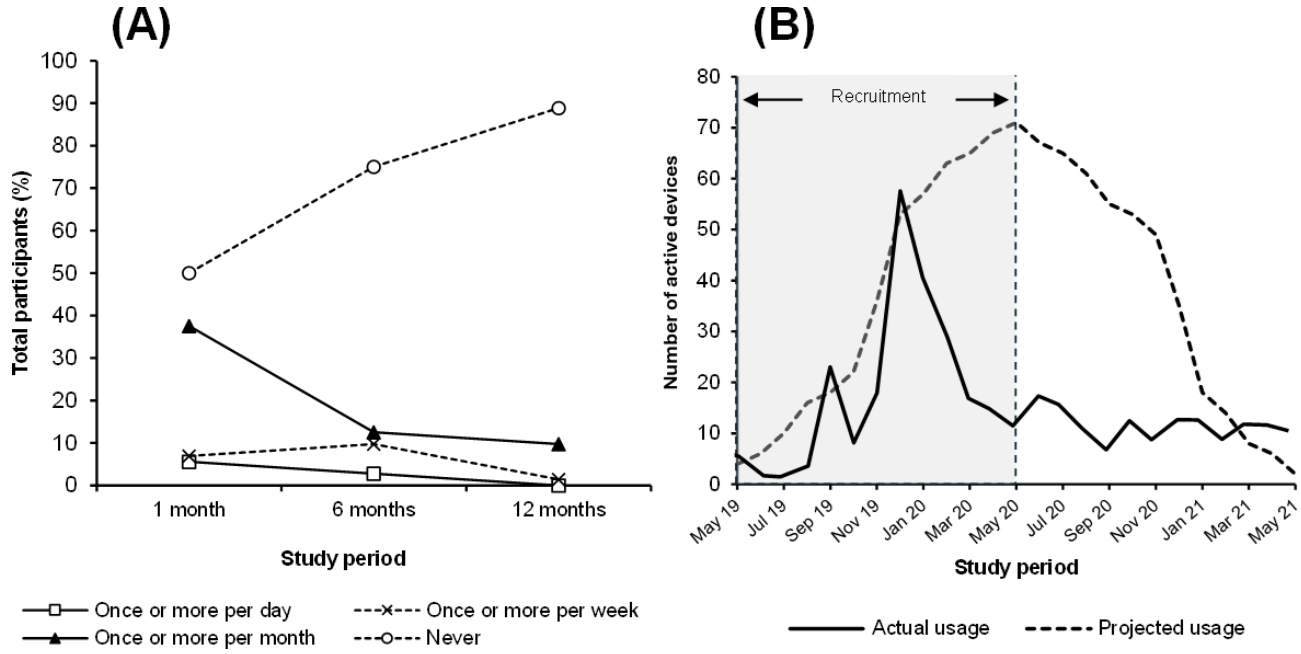
[c]One participant had missing data for the K10 and TRC.

[d]Categories for TRC scores: Unlikely transition ready (27-54); Transition ready (55-81).

TMApp Usage

At 6 months, 36 of the 72 (50%) participants reported having used TMApp at least once in the first month post transition, with 4 daily and 5 weekly users (Figure 3). By 6 months, past-month TMApp usage decreased to 18 (25%) participants, with 2 daily and 7 weekly users. At 12 months, 8 (11%) participants reported past-month TMApp usage, with no daily and 1 weekly user.



Aggregated usage data from mobile analytics showed peak usage at mid-recruitment, after which TMApp usage rates fell well below projected rates calculated based on monthly use by all participants (Figure 3). At study completion, TMApp was removed from the iOS App Store to limit unintended downloads and contamination of app usage statistics.

Across the chronic illness subgroups, self-reported TMApp usage was highest among participants in the "other" group (Figure 4). Diabetes, being the largest chronic illness subgroup, had the second lowest self-reported TMApp usage at 1 month (10/23, 43% reported use) and the lowest TMApp usage at 6 months (2/23, 9%). No participants with diabetes reported using the TMApp at 12 months.

The top 3 most used features reported by participants were the to-do list (n=14), medication (n=14), and mood tracker (n=11) functions. Mobile analytics data broadly corroborated participant self-reports, with the mood tracker recorded as the most accessed feature over 12 months, followed by the to-do list and medication functions (Figure 5).

TMApp Usefulness and Other Feedback

The primary reason participants gave for not using TMApp was that they felt no need to use it (n=24). Other reasons were forgetting to use the app (n=5), changing phones (n=4), low app usefulness (n=3), lack of time (n=1), and preferring paper to apps (n=1). In terms of potential improvements, participants suggested the incorporation of health records, nutritional information, additional visual components, and a medication reminder alarm feature. Furthermore, 7 participants stated that the existing features were adequate. Among the 8 participants who continued to use TMApp at 12 months, a median usefulness rating of 8 out of 10 was given. In addition, 16 participants found TMApp easy to use and would recommend it to other young people with a chronic illness as they transition into adulthood.

6- and 12-Month Outcomes

The eMR data obtained from AHS showed that 49 out of the 72 participants successfully engaged with their designated AHS by 6 months. By 12 months, 48 of these participants were retained in the same AHS. Males exhibited a nonsignificant tendency for higher AHS engagement (23/29, 79% vs 26/43, 60%; P=.09) and retention (23/29, 79% vs 25/43, 58%; P=.06) compared with females. The proportion of successful (n=49) versus unsuccessful (n=23) transitioners did not differ between chronic illness subgroups (diabetes: 17/23, 74%; inflammatory bowel disease: 13/19, 68%; cystic fibrosis: 8/9, 89%; other: 11/21, 52%; P=.21). Similarly, K10 and TRC scores as well as primary markers of illness control at baseline did not differ between the successful and unsuccessful transitioners (Table 3).

Markers of illness control (obtained from AHS eMR) for the 3 major illness subgroups remained stable over the course of the study (Tables 4-6). Around 80% of participants (for whom follow-up eMRs were available) showed stable or improved illness status at 6 months (17/21) and 12 months (24/30). In total, 8 participants had unplanned hospitalizations recorded on eMR, including 5 with cystic fibrosis, 2 with diabetes, and 1 with inflammatory bowel disease. Furthermore, 1 participant with cystic fibrosis had 3 hospitalizations over the study period.

Of the 23 participants who had not engaged with their designated AHS by 12 months, 17 were contactable at follow-up. Reasons given for nonattendance were: (1) participant had not yet chosen an AHS to visit (n=3), (2) parents were arranging appointments

XSL•FO
RenderX

for a later date (n=2), (3) delaying transition until after their final school year examinations (n=2), (4) planning later transition (n=2), and (5) hesitancy over visiting a health service during the COVID-19 pandemic (n=2). Furthermore, 1 participant was uncertain how to schedule an appointment, and 5 did not offer an explanation.

Table . Comparison of baseline psychological distress and transition readiness scores and baseline markers of illness control between successful and unsuccessful transitioners. Data are presented as median (IQR). Statistical comparisons were performed using the Mann-Whitney *U* test.

Baseline measure	Successful transitioners[a] (n=49)		Unsuccessful transitioners[a] (n=23)		*P* value
	n	Median (IQR)	n	Median (IQR)	
Kessler Psychological Distress Scale (K10)[b]	48	16 (12 - 21)	23	21 (13 - 28)	.10
Transition Readiness Checklist (TRC)[c]	48	69 (66 - 76)	23	71 (64 - 76)	.60
Primary marker for illness group					
Diabetes mellitus (HbA_{1c}[d]; %)	17	7.2 (6.9 - 8.6)	6	7.7 (6.7 - 9.3)	.92

Deteriorated (n)	1		1	

[a]eMR: electronic medical record.

[b]CRP: C-reactive protein (the most widely used serum indicator of inflammation).

[c]eMR records were only available for 37 participants due to limited data availability. A shift toward telehealth consultation in response to COVID-19 social distancing regulations was major contributor to missing data as many illness control assessments were not conducted.

Discussion

Principal Findings

To our knowledge, this is the first clinical trial to evaluate the uptake of a generic app to enhance pediatric to AHS transition in young people living with a chronic illness. This was designed as a feasibility study to determine usage over the vulnerable 12 months after young people leave wrap-around pediatric care and have more autonomy. Results from both the self-reported and quantitative usage data showed that TMApp was not used frequently enough to justify feasibility and efficacy testing in a randomized controlled trial. Not needing to use the app and forgetting to use the app were the top reasons given for nonuse. Other contributors to low usage may include the generic (ie, non–illness specific) design of the app, transition perceived as being of low priority, and TMApp's simple design compared with other commercial apps for managing chronic illness. The high usefulness ratings obtained from this study were likely to be biased, as feedback was only given by a small subset of highly engaged study completers. The nonanonymized nature of the follow-up interviews may have also yielded more positive but less truthful feedback. Given that we were unable to link the mobile analytics data to individual user activity, this study serves more as an observational study of the transition from pediatric to AHS.

TMApp was developed with input from adolescents and young adults to support transition in young patients with chronic illness. While the overall frequency of app usage was low with declining rates over time, TMApp was rated as useful and easy to use among those who did regularly access it to support their health service transition. This result is comparable with a pilot study of the "iManage" app for youth self-management of sickle cell disease. The iManage studies described challenges in maintaining user engagement despite observing improvements in self-efficacy and management of pain and mood [15]. Our attrition rates are also comparable with other studies of mobile health app use among adolescents and young adults [28,29]. Research suggests that enhancing brightness, color schemes, and gamification functions could boost health app usage among youth [30-32]. Other modifications, such as conversational style

XSL•FO
RenderX

interactions, speech bubbles, avatars, and illness-specific customizations (eg, importing of glucose monitor data), that were suggested by young adults during prototype testing could have also boosted usage rates in this study, although budgetary constraints precluded their inclusion in the final version of TMApp. Adding social interaction elements (either with the health care team or peers with similar conditions) was also suggested by young people who used the app. Such features may improve engagement and help strengthen social support systems for young patients [33,34], although these would introduce safeguarding and privacy issues. A full-time app moderator would have been required to manage the online interactions and respond promptly to any health emergencies that could have been communicated through the app. Our research team had neither the human nor the financial resources to support this. Finally, while our app development process incorporated some aspects of participatory design, a greater level of youth collaboration using youth-led and co-design principles would have allowed us to better understand their self-management needs, motivations for health technology use, and could have resulted in better usage rates.

Over two-thirds of the cohort (49/72, 68%) successfully transitioned to their designated AHS by 12 months. By comparison, varying rates of successful transition have been described in other studies, which range from approximately 20% to 90% [35-38]. Neither sex, chronic illness subgroup, nor baseline levels of distress and transition readiness were significantly predictive of successful transition in our small cohort, despite some research suggesting that AHS engagement is higher among young females [39-41]. Our relatively high rate of successful transition is likely attributed to the efficient local clinical protocols governing patient transition to adult care [42,43], especially for the main illness subgroups. Ongoing parental assistance in scheduling AHS appointments, as alluded to by some participants, also likely facilitated successful transition. Our current data suggest that implementation of the TMApp in conjunction with existing clinical procedures would have made minimal contributions to improving the transition process. For the 6 participants who did not engage with their designated AHS and were uncontactable at follow-up, it was not possible to ascertain whether they failed to transition or sought care from a different AHS, and this population requires further study. A unique barrier to transition experienced in this study was anxiety around attending medical appointments during the COVID-19 pandemic. The shift toward telehealth during pandemic lockdowns may have also delayed transition plans for some participants, given that many young people express a preference toward face-to-face over telehealth consultations [44,45].

The majority of participants who engaged with an AHS showed stable or improved illness markers and had low hospitalizations (except for one participant with cystic fibrosis). While we were unable to track illness control and hospitalizations in those who did not attend their designated AHS, our data support proactive follow-up for no-shows at AHS.

The key strengths of the study are, first, the follow-up methodology that involved obtaining posttransition eMR data on health service engagement and illness control, thus reducing reporter burden and error. Second, the mobile analytics data served as a valuable tool to quantify true app usage, despite only aggregate data being available due to user privacy restrictions. Third, TMApp was a generic mobile app designed to cover a wide range of chronic illnesses. This improves equity of access for individuals with rarer conditions where illness-specific self-management apps may not be available, but also limits the extent to which the app could be personalized. The major limitation was undoubtedly the low rates of usage, and the reasons for this have been discussed. Outsourcing app development to a commercial entity also introduced financial and logistical constraints that resulted in a relatively rudimentary TMApp design. Based on our current experiences, in-house development and maintenance are the only viable options for mobile health apps that have a small user base.

Conclusions

This pilot study did not demonstrate the feasibility of TMApp as it was not used regularly enough by adolescents and young adults with chronic illness in the first 12 months of transition. Over two-thirds of participants successfully transitioned despite low app usage, which is likely attributed to effective transition care protocols already in place, among other facilitators. Enhancing features, such as gamification and social networking capabilities, could help increase young people's app uptake and need to be tested. Importantly, future studies of mobile health apps for adolescents and young adults should include objective usage metrics like mobile analytics, as standard user feedback can be subject to considerable bias.

Acknowledgments

Initial funding for the development of the TMApp was provided by the New South Wales Health Agency of Clinical Innovation (ACI). ACI had no role in the design of the study, the collection, analyses and interpretation of data, and the preparation of this manuscript for publication. The research team would like to acknowledge the young people who took part in this study and provided valuable insights into the transition process. Further acknowledgments to Ms Tina Cunningham, Drs Sharon Medlow, Jane Ho, Vathsala Agarwalla, and Vhari Forsyth for their contributions at various stages of this study, all the medical specialty departments and staff who assisted with participant recruitment, as well as medical records staff at the adult hospitals for their assistance in adult health service data collection.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Asthma is one of the most common pediatric conditions affecting millions of US children. Digital health apps may provide children and their caregivers (parents or legal guardians) with ways to manage asthma and improve health and educational outcomes.

Objective: As digital health technology becomes more prevalent to help manage chronic conditions, like asthma, this study examined the reported benefits and barriers of caregiver interactions with an asthma-specific app. The app, created by physicians and digital health development professionals, was designed to educate, inform, and help caregivers manage the health of their child. We evaluated app logins and feature use (collectively defined as "app engagement") for caregivers of children with asthma aged 5 - 11 years. We examined whether (1) app engagement differed due to children's demographic and asthma health characteristics, (2) themes about app engagement emerged from caregiver-reported app experiences, (3) these themes correlated with demographic and asthma health characteristics, and (4) engagement with the app was associated with reduced school absences.

Methods: Eighty caregivers and their children with asthma participated between September 2019 and November 2020. Pretest (Time 1) and posttest (Time 2) data were collected over 6 months on caregiver and child demographic and health characteristics, health care usage, app engagement, and app experiences. Additionally, caregiver app engagement data and child health care data were collected retrospectively, 2 years prior to the start of the study. We used a mixed methods design, which included correlation, regression, chi-square, and content analysis to examine caregiver app engagement.

Results: Most caregivers were mothers (76/80, 95%) and had a college degree (45/80, 56%). Children's mean age was 8.76 (SD 1.79), and all were English speakers (80/80, 100%). About half of the participants were White children (43/80, 54%), and 26% (21/80) of them had uncontrolled asthma. Logistic regression revealed that caregivers of White children (OR [odds ratio] 8.57, 95% CI 1.68-43.65) with uncontrolled asthma (OR 17.81, 95% CI 2.36-134.24) who earned a college degree (OR 6.94, 95% CI 1.38-34.87) were statistically significantly more likely to use the app than caregivers of children of other races with controlled asthma without a college degree (P<.001). Qualitative findings support and expand on the logistic regression results. Five themes regarding app engagement emerged, including relevancy, acceptability and understandability, technology limitations, educational barriers, and information and communication benefits. Caregivers also identified specific app features that may promote child health and education.

Conclusions: Understanding caregiver and child experiences in using digital health technologies for managing asthma may inform ways to support app engagement among caregivers and their children in the effort to improve patient health outcomes.

Introduction

Current Knowledge of Asthma and Digital Health

Childhood asthma is a chronic lung disease that affects 4.7 million children in the United States [1]. Uncontrolled asthma can be disruptive and costly to families and payors. Approximately 60% of children with asthma between 5 and 11 years of age have an asthma exacerbation each year, resulting in school absences (52%), emergency department visits (19%), and hospitalizations (5%) [2]. Uncontrolled asthma also contributes to an annual economic burden on families and health care systems. In 2013, the estimated total direct costs of pediatric asthma in the United States approached 6 billion dollars, averaging between US $3076 and US $13,612 per child [3]. These health and economic burdens disproportionately affect children who are Black, Latinx, and from lower-income families, due in part to systemic racism and unequal access to quality health care, housing, and education [4,5].

Compounding the health and economic issues, children with asthma are at higher risk for educational difficulties stemming from chronic absenteeism [6]; asthma exacerbations contribute to about 10.5 million school absences each year [7]. As chronic absenteeism contributes to lower math and reading abilities compared to children who are not repeatedly absent [8], there is a need to develop tools to improve children's asthma to keep them healthy and in the classroom. One worthwhile approach to support improved asthma management may be to use digital health apps [9]. However, because a digital divide in usage exists based on race, ethnicity, income, and geographic location [10-14], the question remains as to whether digital health tools are appropriate for use across a diverse population of caregivers (parents or legal guardians) and their children.

Digital Health Apps: How to Support Asthma Management?

Leveraging digital health apps to improve pediatric asthma management may contribute to improved asthma health for children from underserved populations and those with uncontrolled asthma. Recent indications show digital health technologies may aid in addressing health equity concerns among marginalized patient populations as they frequently engage with specific app features [14]. Moreover, digital health tools are more likely to be used when children have uncontrolled asthma [9,10], as they often require frequent health care usage and engage with several digital health tools [14]. These tools may help improve children's health outcomes [15], as studies reveal these devices support medication adherence [16] and caregiver asthma knowledge [17], contributing to improved pediatric asthma health within 6 months [15,18]. As these patient populations have recently increased usage of mobile devices [19], including engagement with digital health apps [20], there is an opportunity to increase their access to health care and improve their health outcomes. Moreover, improved asthma health may reduce school absenteeism, thereby improving educational outcomes [21].

However, the reasons for app engagement are unclear, with studies highlighting potential barriers to app engagement; thus, further study is warranted. Access issues may include a lack of broadband internet or smartphone devices [22]. However, many individuals who have access to these technologies have suboptimal engagement due to a lack of knowledge, understanding, or guidance on how or why to use them for managing health needs [12]. Further, specific features may be more relevant for certain populations. For example, one study found that families receiving Medicaid—US government-funded health care services for low-income patients—accessed digital health educational resources more often than non-Medicaid recipients [14]. The authors posited that the frequent use of educational features among Medicaid recipients was due to a lack of access to health care information elsewhere. Further research is needed to understand these apparent contradictions in app use across patient populations.

Benefits and barriers of app engagement include whether patients consider the app relevant, understandable, and acceptable to use [23-25]. Moreover, as certain features may be considered more beneficial for certain populations [14], benefits and barriers may differ across diverse patient populations. As digital health tools become more widely implemented in pediatric health care institutions, it is vital to examine whether these technologies may yield equitable benefits for children. Consequently, it would be valuable to learn whether and why caregivers choose to use health apps for managing their child's health care. In addition to supporting health outcomes, this information could assist app developers in targeting users' needs, interests, and preferences, potentially motivating increased app engagement.

Purpose

The purpose of this study was to examine the benefits and barriers of digital health app engagement among caregivers of school-aged children with asthma. As such, we focused on children aged 5 - 11 years because after the age of 11 years, many children take responsibility for most of their asthma care [26]. Understanding factors that contribute to caregiver app engagement may help to uncover whether app engagement correlates with improved child health and education, including for those at risk for these poor outcomes. We explored four research questions:

1. Does app engagement differ based on demographic and asthma health characteristics? We hypothesized that (1) caregivers of White children and caregivers with higher socioeconomic status would be more likely to engage with the app than caregivers of children of other races and lower socioeconomic status [11,14], and (2) caregivers of children with uncontrolled asthma would be more likely to engage with the app than caregivers of children with controlled asthma [9,10,14,15].
2. Do app engagement themes emerge from caregiver-reported experiences about the app? We hypothesized that caregiver-reported experiences about app engagement would yield themes around relevancy, acceptability, and understandability [23-25].
3. Do app engagement themes correlate with demographic and asthma health characteristics? We wanted to understand whether identified themes related to benefits and barriers

XSL•FO
RenderX

of app engagement vary across diverse children with asthma. We hypothesized that (1) families with higher educational attainment would endorse more benefits of app engagement than less educated families [11,12] and (2) those of children with uncontrolled asthma would endorse more benefits of app engagement than families of children with controlled asthma [9,10,14,15].

4. Is app engagement related to reduced school absences? We hypothesized app engagement would help improve asthma management [15,18], thereby reducing chronic absenteeism.

Methods

Study Design and Procedure

This mixed methods, multisite, observational retrospective and prospective study included 6 months of active data collection and 2 years of retrospective data collection. Retrospective asthma health data were collected to avoid potential underreporting, as seasonality contributes to asthma management [27]. Moreover, obtaining 2 years of retrospective asthma control scores increased the likelihood of their collection, which are provided by caregivers and entered into the electronic health record (EHR) at scheduled patient care visits. Retrospective app engagement data, commensurate with asthma health data, and prospective data were recorded in the app. Prospective data were collected at study start (Time 1) and 6 months later (Time 2), consistent with previous digital health and asthma research [15,18].

Participants

Caregivers of children who were patients of Nemours Children's Health (NCH) and who had an asthma diagnosis were emailed recruitment notifications with access to a secure REDCap (Research Electronic Data Capture; Vanderbilt University) link to learn more about the study. Of the 154 caregivers who accessed the link, 148 (96%) were interested, and 126 (85%) of those interested were eligible for enrollment. Children were eligible if they were aged 5 - 11 years, had a diagnosis of asthma, and had a visit with a provider in the Nemours allergy or pulmonology departments within a year prior to consent. Caregivers were required to be a parent or legal guardian fluent in conversational English to match the language of the app. Families across Nemours US locations (Northeast and Southeast) were eligible whether they had the app or not. Per consent, we limited enrollment to 1 child per family. Almost two-thirds of eligible participants (64%, 80/126) consented to participate, 100% (80/80) completed all pretest study activities, and 80% (64/80) completed both pretest and posttest study activities.

Measures and Data Collection

Demographic Questionnaire

The Parent Research Questionnaire was a 28-item researcher-developed questionnaire about demographic characteristics (eg, income, race, ethnicity, and education level) and health characteristics (eg, family history of asthma). The questionnaire took about 10 minutes to complete. It has been used in previously published work [9], and it has asthma-specific items that were developed for study purposes, such as age of asthma diagnosis, family history of asthma, and asthma triggers. Data were collected at Time 1.

App Experience Survey

The App Experience survey was a 36-item researcher-developed questionnaire about caregiver app engagement (Section A in Multimedia Appendix 1) to understand caregiver engagement of a novel digital health app, which has been used in previously published work [9]. The survey took about 15 minutes to complete and included multiple-choice and open-ended items about feature engagement and app experiences (eg, reasons for using or not using the app, frequency of features used, and benefits and barriers of app use) and school absences due to asthma. Data were collected at Time 1 and Time 2.

Nemours App

Physicians and digital health development professionals at NCH developed a caregiver-facing digital health app, the "Nemours app," with features designed to support patients at NCH with asthma and their caregivers. Caregivers log in to the app via mobile devices or desktops and are logged out after 30 minutes of inactivity. The app has been in use since February 2018 and includes traditional portal mainstays, such as telehealth and messages, which can be used as frequently as desired, as well as asthma-specific features (Table 1). As this was an observational study, only resources provided by NCH were available, including contact information for technical support, an app demonstration video, and medication reminders (if selected by caregivers). Participants reported hearing about the app via emails, providers, family, friends, searches for digital health apps, and this study.

We defined "app engagement" as logging into the app at least once and using at least 1 identified app feature (Table 1). We defined a caregiver who did not log in or use any features during the study as a "nonapp engager" [28].

XSL•FO
RenderX

Table . App features.

Feature	Type	Description
Reminders	Asthma-specific	Set medication reminder notifications to support asthma medication adherence.
Medication images	Asthma-specific	View images to identify controller versus quick relief medications.
Medication videos	Asthma-specific	Watch videos demonstrating proper asthma medication usage.
Asthma educational resource	Asthma-specific	Read articles and terminology word banks to learn about asthma.
Asthma symptom tracker	Asthma-specific	Track asthma control levels, symptoms, limitations, and the air quality index. The data are linked to the electronic health care record so that providers may access patients' tracker entries between office visits.
Asthma action plan	Asthma-specific	Access individualized, provider-created, asthma action plans. Download and share it as a PDF or use it interactively to receive real-time feedback on actions that may help to resolve an exacerbation.
Air quality alerts	Asthma-specific	Receive alerts for dangerous levels of air quality to remind children to carry quick relief medication.
Telehealth	General	Participate in video visits with health care providers.
Messages	General	Communicate with health care providers.

Health Care Records

Data were obtained for asthma diagnosis and severity (as specified by the child's provider), asthma control, and health care usage (eg, asthma-related emergency department visits, urgent care visits, and hospitalizations) from the EHR. Asthma control was obtained from childhood asthma control test (C-ACT) scores in the EHR. Available C-ACT scores ranged from 0 to 9. Mean scores provided an average asthma control level per child. Scores above 19 were defined as "controlled," and scores of 19 or below were defined as "uncontrolled" [29].

Power Analysis

This study was part of a larger project for which we conducted an a priori power analysis to determine the sample size [9]. Sufficient power was estimated with n=40. To account for the 50% attrition typical in digital health research [30], we enrolled 80 caregivers and their children.

Data Analysis

We used a mixed methods approach to examine caregiver app engagement. We first conducted a preliminary correlation analysis to identify statistically significant (P<.05) demographic (eg, child age, government public assistance, parent learning problems, and transportation difficulties) and health characteristics (eg, family asthma history, asthma triggers, and health care usage) to include as predictors in the analysis for research question 1.

To address the first research question, we conducted logistic regression to evaluate the relation between the identified demographic and health characteristics and caregiver app engagement. Child race, maternal education level, and asthma control level were statistically significantly related to app engagement and were used as predictors in the regression model. The variables were dummy coded for the analysis: maternal education level (0=high school degree or less, 1=associate's, bachelor's degree or higher), child race (0=Other races, 1=White child), and asthma control level (0=controlled, 1=uncontrolled). Logistic regression was used because the outcome variable, app engagement, was dichotomous (0=nonapp engagement, 1=app engagement) [31]. Listwise deletion was used to address missing values for asthma control level in the analysis. As a result, 14 nonapp engagers and 13 app engagers were removed from the final regression analysis (n=53). For research question 1, missing data ranged between 0% and 34% (asthma control level missing at 27/80, 34%) and were missing completely at random per Little Missing Completely at Random test (χ^2_3=3.5; P=.33). Multiple imputation analyses were similar to the nonmultiply imputed analyses; thus, nonmultiply imputed findings are presented. For transparency, we included the multiply imputed findings (Section B in Multimedia Appendix 1).

We also conducted post hoc analyses because although all participants completed the Time 1 app experiences survey, 19% (15/80) of the data were missing for the Time 2 survey. Thus, we examined whether there was a difference between app engagers and nonapp engagers who completed the Time 2 survey. We also examined the relation between key demographic and health characteristics and completion of the Time 2 survey. Further, we examined whether frequency of app use was correlated with caregiver-child demographic and health characteristics.

XSL•FO
RenderX

For the second research question, content analysis was conducted to identify app engagement themes about caregiver app experiences. Caregiver responses were organized and coded in Excel (Microsoft) by the first author. Analysis of codes and themes was conducted in SPSS (IBM Corp). We used a combined approach. First, we used a deductive approach to examine a priori codes that were created to uncover themes regarding app benefits and barriers, including relevancy, understandability, and acceptability [23-25]. After that, we used an emergent approach because of the novelty of the Nemours app by using open coding in which additional codes could be added after initially reviewing the data [32]. We also used axial coding to combine related codes [33]. Coding was considered complete when only a few uncoded data remained [34,35]. Finally, the first and third authors double-coded 31% (5/16) of randomly selected caregiver open-ended response sections, which demonstrated strong percent agreement (0.92) and high interrater reliability (κ=0.87). For the third research question, we used nonparametric correlation analyses (Spearman) due to nonnormality to examine the extent to which themes about app relevancy, understandability, acceptability, benefits, and barriers were related to demographic and asthma health characteristics.

To address the fourth research question, we used chi-square analysis because both variables, app engagement (0=nonapp engagement, 1=app engagement), and school absences (0=none, 1=1 - 5, 2=6 - 10, 3=more than 10), were categorical. We examined whether app engagement was related to decreased school absences between Time 1 and Time 2. We calculated the difference score between school absences at Time 1 and Time 2. Initially, listwise deletion was used, resulting in 13 nonapp engagers and 3 app engagers being removed from the analysis (n=64). Overall, missing data ranged between 0% and 20% (school absences missing at 16/80, 20%). Data were missing not completely at random per Little Missing Completely at Random test (χ^2_1=15.0; P<.001), as nonapp engagers had more missing school absence data (13/31, 42%) than app engagers (3/49, 6%). As multiple imputation typically leads to less biased results than listwise deletion [36,37], we conducted these analyses and included predictor and covariate variables to help account for missingness [36]. The multiply imputed analyses yielded significant results, whereas the nonmultiply imputed analyses did not. As such, we present the nonmultiply imputed findings because it is likely a more conservative estimate. For transparency, we also included the multiply imputed findings (Section C in Multimedia Appendix 1). Additionally, we conducted post hoc analyses because, given that maternal education, race, and asthma control are associated with school absences [38], we examined whether these characteristics, plus app engagement, were related to a decline in school absences.

Ethical Considerations

The study was conducted between September 2019 and November 2020 and was approved by the Nemours Institutional Review Board (approval number 1422315). REDCap, a web-based app for secure data capture and storage [39,40], was used for study recruitment (via a rolling admission process), parental or legal guardian consent, data collection, and participant communication. Survey data were collected securely online via REDCap and items appeared in a consistent order. Page numbers varied from 4 to 7 because an adaptive format was used, and items ranged between 8 and 14 per page because of the variation in item format. Participants were informed of the study investigators, purpose, approximate time to complete surveys, security of data storage on password-protected files or servers, and the voluntary nature of participation. Quantitative data were obtained from multiple-choice survey items and qualitative data were obtained from open-ended survey items. A US $50 gift card was provided to incentivize participation. For additional information, see Lewis et al [9].

Results

Participant Characteristics

Participating children's race and ethnicity largely reflected that of pediatric patients with asthma in the US population, including a slight overrepresentation of White children and a slight underrepresentation of Latinx children [1]. The child sample, as identified by caregivers, and the US population, respectively, was 54% (43/80) and 44% (2,074,381/4,675,475) White, 24% (19/80) and 23% (1,058,310/4,675,475) Black, 12% (10/80) and 5% (221,110/4,675,475) multiracial, 1% (1/80) and 2% (108,819/4,675,475) Asian, and 9% (7/80) unreported; 12% of the child sample (10/80) and 24% (1,102,471/4,675,475) of the US population were Latinx. The 49 caregivers who engaged with the app logged in at least 3 times, exceeding our engagement criteria (at least one log in), and engaged with at least one of these features, including reminder notification (n=1, 2%), medication images (n=17, 35%), asthma symptom tracker (n=32, 65%), asthma action plan (n=11, 22%), air quality index (n=9, 18%), telehealth video visits (n=9, 18%), and messages (n=28, 57%). Child and caregiver demographic statistics are presented in Table 2. For additional information about participants, see Lewis et al [9].

Predicting App Engagement From Demographic Survey and Health Care Records

The full logistic regression model was statistically significant, (χ^2_3=24.5; *P*<.001), and well specified, as the Hosmer-Lemeshow Test was not statistically significant (*P*=.84). The model explained approximately 52% of the variance for app engagement (Nagelkerke R^2=0.52) and correctly classified 83% of the cases. Caregivers of White children were about 8.5 times more likely to engage with the app than caregivers of children of other races when controlling for maternal education and child asthma control level (OR [odds ratio] 8.57, 95% CI 1.68-43.65; *P*=.01). Caregivers with a college degree were nearly 7 times more likely to engage with the app than caregivers with a high school diploma when controlling for child race and asthma control level (OR 6.94, 95% CI 1.38-34.87; *P*=.02). Caregivers of children with uncontrolled asthma were almost 18 times more likely to engage with the app than caregivers of children with controlled asthma when controlling for maternal education and child race (OR 17.81, 95% CI 2.36-134.24; *P*=.01).

Post Hoc Analyses to Examine Survey Completion and Frequency of App Use

Responses about app engagement were skewed to those who engaged with the app, as they were statistically significantly more likely to complete the Time 2 survey than those who did not engage with the app (χ^2_1=17.9; *P*<.001). However, logistic regression and crosstabulations revealed no statistically significant relation between key participant characteristics and Time 2 app experience survey completion. Moreover, frequent app engagement (logged in ≥24 times) was not significantly correlated with (1) child and caregiver demographic characteristics including age, race, ethnicity, education, receiving public assistance, and transportation issues and (2) child health, including age diagnosed with asthma, family asthma history, asthma triggers, health care usage, and asthma control.

Themes That Emerged via the App Experience Survey

Nearly all caregivers (75/80, 94%) responded to at least one of the 16 open-ended response sections in the survey with an average of 28.31 (SD 17.58) responses per section. Five themes (2 a priori—relevancy and acceptability or understandability—and 3 emergent—technology limitations, educational barriers, and information and communication benefits—themes) from 408 coded comments resulted from the content analysis about caregiver app experiences (Table 3). One theme was whether the app was relevant for family use to manage asthma, with more caregivers stating the app was not relevant (eg, child's asthma was controlled; 12/80, 15%) than relevant (1/80, 1%). Another theme identified the "acceptability" and "understandability" of the app. More caregivers noted the app was easy to use and understand (56/80, 70%) relative to those who noted it was difficult to use and understand (23/80, 29%). Two themes were specifically related to barriers. First, caregivers noted technology limitations (17/80, 21%), such as difficulties with internet connection and technical issues (eg, during telehealth). Educational barriers (29/80, 36%) included being (1) unaware of the app or its features, (2) unclear about the app's potential benefits or purpose, and (3) unsure of how to use the app. The final theme pertained to the app's information and communication benefits (51/80, 64%), such as gaining information about child health and being able to communicate with a child's care team.

Benefits	• App Engager: “Love the ability to message providers directly.” • App Engager: “A good way to get data and communicate with your provider.” • App Engager: “Easily shows doctor current health.”	51	163

Content analysis also revealed specific app features caregivers identified as a benefit to app engagement based on their experience with the app or based on app feature information shared via the study survey (Table 4). The most frequently reported beneficial app features were messages (25/80, 31%), access to health care records (24/80, 30%), and the asthma symptom tracker (19/80, 24%). These app features were often noted as beneficial for communication purposes and for gathering and sharing information about children’s asthma health.

Table . Caregiver-reported beneficial app features.

Features (n=80)	Examples	Caregivers, n	Total comments, n
Air quality index	• App Engager: “To check air Quality”	5	5
Asthma action plan	• Nonapp Engager: “To print action plan for schools and camp”	6	6
Telehealth video visits	• App Engager: “Having the option to stay home and still have a follow up visit with the doctor”	8	10
Medication reminders, refills, and education	• App Engager: “I use it for action plans and prescription renewals.”	9	11
Asthma symptom tracker	• App Engager: “I like the asthma tracker so that I can see if there is a pattern to when his asthma flares up.”	19	25
Health care records	• App Engager: “I can see details from all past appointments. I find it easier to use than [our] pediatricians so I use it if I have a question about her growth, asthma and medication history” • App Engager: “I like that I can refer back to this app after an appointment in case I forgot something the doctor said.”	24	32
Messages	• App Engager: “Love the ability to message providers directly.”	25	39

Correlation Between App Engagement Themes and Demographic and Health Characteristics

Statistically significant correlations were found between demographic and health characteristics and app engagement themes, specifically themes around relevancy, acceptability or understandability, educational barriers, and information and communication benefits (Table 5). Regarding relevancy, caregivers of children with dust allergies reported more benefits to understanding how the app could be helpful (ρ=0.23; *P*=.04), whereas caregivers with learning problems noted more barriers (ρ=0.27; *P*=.02). Regarding acceptability or understandability, caregivers of Asian children noted more benefits regarding the ease of use and clarity of the app (ρ=0.23; *P*=.04), whereas caregivers of children with pollen allergies (ρ=0.30; *P*=.01) and controlled asthma (ρ=−0.30; *P*=.03) shared more barriers. Caregivers of Asian children (ρ=0.28; *P*=.01) and of children with pollen allergies (ρ=0.24; *P*=.03) reported more app

XSL•FO
RenderX

educational barriers. Finally, caregivers of White children (ρ=0.30; *P*=.01) and caregivers who did not receive public assistance (ρ=–0.37; P<.001) reported more access to asthma-related health information and provider communication benefits because of their app engagement.

[a]Indicates statistically significant correlations.

Relation Between App Engagement and Caregiver-Reported School Absences

Chi-square analysis revealed that app engagement was not statistically significantly related to the school absence difference score (0=no change in absences, 1=absences reduced by 1 category, 2=absences reduced by 2 categories, 3=absences reduced by 3 categories) between Time 1 and Time 2 (χ^2_3=2.6; *P*=.46). As we did not find a statistically significant relation with this analysis, we also conducted a chi-square test to evaluate the difference in school absences for all children, regardless of app engagement. When examining this difference, we found a statistically significant decline in absences for all children between Time 1 and Time 2 (χ^2_9=99.9; *P*<.001). Further, we found that more caregivers reported “no absences” at Time 2 (33/80, 41%) than at Time 1 (28/80, 35%). We would expect fewer caregivers reporting “no absences” later in the year at Time 2, as we asked about cumulative school absences over the past year. These discrepancies suggest the results may be uninterpretable, warranting further research. We present this data, despite the limitations, because this was a planned study analysis. Additionally, as findings differed between nonmultiply imputed and multiply imputed data (Section C in Multimedia Appendix 1), the results must be interpreted with caution. Despite the discrepancies with the absentee data, for transparency, we included post hoc findings indicating child race and asthma control are statistically significantly related to school absences (Section D in Multimedia Appendix 1).

Discussion

Principal Findings

Understanding facilitators and challenges from caregivers and children who use digital health technology is key to uncovering ways to improve app engagement to potentially improve child health and educational outcomes. Using a mixed methods approach, this study demonstrated key demographic and health characteristics related to app engagement and revealed themes that further supported these findings. These themes may uncover factors that improve engagement among caregivers and children with diverse demographic and health characteristics. Three important findings were gleaned from this work, contributing to the nascent field of digital health research. First, quantitative and qualitative findings revealed racial, educational, and health-related differences in app engagement. Second, the app may have the potential to help improve communication between caregivers, children, and health care providers. Finally, caregivers identified app features that may help support child health and education.

Gaps in App Engagement

Caregivers of White children with uncontrolled asthma who earned a college degree were more likely to engage with the app than caregivers of children of other races with controlled asthma without a college degree. This suggests there may be an educational and racial gap in app engagement, consistent with previous research [12-14]. As a digital divide persists [9-14], care must be taken to understand potential reasons for this gap in app engagement. In this study, caregiver-reported app experiences supported the quantitative results and provided potential reasons for a divide between families of different racial and educational backgrounds.

Regarding educational and racial gaps, caregivers with a history of learning problems in school and caregivers of Asian children reported more educational barriers to app engagement. These caregivers reported receiving limited information about how to use the app to help manage their child's asthma or about the potential benefits of app engagement. This lack of education about the purpose and potential benefits of the app was well captured by this app engager's response: "I have no idea what I am supposed to use the app for in regards to my child's asthma." Video tutorials may be useful in addressing this educational barrier by facilitating app engagement among caregivers and children [23], whereby potential benefits of app engagement are highlighted, and app feature use is demonstrated. Video tutorials could also identify available features, such as access to health care educational resources, which may enhance interest among families who may perceive or experience a lack of access to these resources [14]. Additionally, creating digital health video tutorials may be particularly beneficial for families from low educational backgrounds because video tutorials are supportive of families with low literacy skills, thus reducing educational and literacy-related barriers to understanding how and why to use digital health apps [17,41]. Thus, integration of more educational supports, such as video tutorials, may improve engagement by making app engagement easier, potentially narrowing health disparities among racially, ethnically, and educationally diverse populations [12].

Findings from this study, consistent with our previous study [9], revealed that caregivers of children with uncontrolled asthma were more likely to use the app than caregivers of children whose asthma was controlled. Caregivers of children with controlled asthma shared more barriers, with understanding and using the app with comments such as, "Not sure how [the app] will help us. My daughter seems to be doing well," noting that the app is "Difficult to understand and use…" and "Difficult to find things quickly." These caregivers may be unsure why they should use it ("Not sure how [the app] will help us..."). Perhaps video tutorials could also be used to inform families of the potential benefits of continued monitoring of asthma symptoms, even when asthma appears under control, given that asthma can be unpredictable and seasonal [27]. Additionally, caregivers of children whose asthma is controlled may be less familiar with navigating the app because they do not engage with the app, or they engage with it less frequently than caregivers of children whose asthma is uncontrolled. This suggests a barrier to app use may be due to a lack of instruction, further suggesting an app video tutorial may be beneficial. Others have found that asthma interventions appear to be more effective for children with uncontrolled asthma, as these children are most at risk for poor health outcomes [15]. As such, a 2-pronged approach may be a worthwhile solution, in which informational video tutorials provide potential benefits of app engagement for all children with asthma and also highlight features that may best serve children with uncontrolled asthma, including enhanced communication opportunities with their child's asthma health care team.

App-Facilitated Communication

Pediatric asthma management may be facilitated by improved communication between health care providers and families. When providers and families engage in effective communication strategies, clinical decisions can be made jointly, thereby assisting treatment plan adherence [42]. Notably, using digital health technology is associated with improved communication between families and providers [9,43]. A randomized controlled trial found that children who received remote patient monitoring and health care provider feedback demonstrated statistically significantly higher asthma treatment adherence than children who only received remote patient monitoring [44]. Consequently, communication with the health care team in conjunction with digital health technology may be key for effectively improving treatment plan adherence. Similarly, results from our previous study indicated that 67% (33/49) of caregivers who used a digital health app reported that using the app led to improved communication with their child's health care team [9]. The qualitative results from this study further support this previous finding, as the most frequently reported app theme that emerged was about communication benefits. Specifically, 40% (163/408) of the comments referred to communication and information sharing as a benefit of app engagement. One app engager captured their experience with app-related communication by reporting it is, "A good way to get data and communicate with your provider." As such, this study highlights that app-facilitated communication may serve

XSL•FO
RenderX

to strengthen provider-family communication, which could help improve children's asthma health.

Two app features frequently reported as helpful and that could promote communication were the message system and the asthma symptom tracker. When reporting about messages, an app engager shared they "Love the ability to message providers directly." Another app engager noted the tracker is beneficial because they "…can see if there is a pattern to when [their child's] asthma flares up." These reports about app-facilitated communication features highlight tools that may support treatment adherence and improve asthma outcomes.

Potential Benefits of the App for Health Care and Education

In addition to app-facilitated communication features, messages, and asthma symptom tracker, caregivers identified several other app features as potentially beneficial. Unsurprisingly, the 3 most frequently reported beneficial app features, messages, health care records, and the asthma symptom tracker, aligned with the most prominent theme about app information and communication benefits. As noted, caregivers shared that engaging with messages and the asthma symptom tracker supported communication between themselves and their child's health care team. Caregivers also reported that having access to their child's health care records was informative. For instance, one app engager noted, "I like that I can refer back to this app after an appointment in case I forgot something the doctor said." Other features were also identified as informative, as caregivers reported that the air quality index helped them check the air quality, and app medication features could help with medication adherence. These features may help support asthma management and lead to improved health outcomes.

Despite the ambiguous school absence findings, many caregivers identified potential benefits of app features for school purposes, namely asthma-specific app features. For example, one non-app engager shared that they would "print action plan for schools and camp." Sharing asthma treatment plans, particularly asthma action plans, with schools is recommended by the National Heart, Lung, and Blood Institute to inform school personnel of child-related asthma needs and keep children safe in schools and may help reduce school absences or time away from the classroom [6]. We also found an overall reduction in school absences from Time 1 to Time 2. However, future research is necessary to explain the overall reduction in school absences. This study took place during the early period of the COVID-19 pandemic, during which childhood asthma morbidity was significantly reduced [45], as children were inside more frequently and perhaps exposed to fewer triggers. This explanation was supported by findings from this study, as one caregiver shared that the reason they were not engaging with the app was because "She is inside more due to [COVID-19]." Despite the historical and school absentee data limitations, most caregivers reported the benefits of app engagement and highlighted asthma-specific features that may be beneficial for their child's asthma-related health and education. As such, it is worthwhile for health care systems to consider that app engagement, particularly engagement with disease-specific app features, may be beneficial for the children and caregivers they serve.

Limitations and Future Research

As many people were using virtual technologies for health care and for schooling during the study time frame (from September 2019 to November 2020) due to the COVID-19 pandemic, this may have influenced caregivers' perspectives about engaging with digital health technology. Missing data were another limitation, as 20% (16/80) of school absentee data were missing at Time 2 and these data were not missing at random, likely because statistically significantly fewer nonapp engagers than app engagers completed the Time 2 survey. Post hoc analyses are consistent with previous research indicating that other characteristics, such as race and asthma control, are related to school absences [38]. However, we caution that the main and post hoc findings about school absences may be uninterpretable due to the history-related artifacts in the absentee data. Despite this limitation, we presented the data because assessing school absences was an important hypothesis to examine and part of the planned study analysis. Future digital health research is needed to examine the relationship among app engagement, absenteeism, and family characteristics to identify approaches that may help improve school attendance. A future study should also collect absentee data from school systems instead of relying on caregiver-reported data, which may help to limit any misreporting of the number of school days missed. For this observational study, we relied on existing data, using C-ACT data available in the EHR. Consequently, only a subsample of C-ACT scores was included in the analyses (53/80, 66%). Future research should collect these data directly for study purposes to limit the amount of missing data. Several biases must also be considered, as our findings may not generalize to a broader population. Although this study took place across the northeastern and southeastern United States, we examined a digital health app designed to support pediatric patients at a specific health care institution and developed a specific survey to obtain data about caregivers' app experience. As such, institutional biases may be present, and future research is warranted. However, many of the features examined, including the messages, tracker, and air quality index, are used in other pediatric digital health apps [18]. Thus, we expect findings from this study may be informative and relevant to other institutions, caregivers, and children. Despite a diverse racial, ethnic, and socioeconomic sample, most app engagers were White families and well-educated; thus, selection bias may be present. Sampling bias also may exist, even though most eligible participants consented.

Overall, findings from this study show initial relations between family characteristics and app engagement; however, a larger, more diverse study sample is needed to better understand the reasons underlying app engagement. Although we did not find significant correlations between frequent app engagement and participant characteristics, correlational results between app themes and these characteristics suggest they should be considered in future research. Future research should also consider using partial correlations to further examine the relation between app engagement themes and participant characteristics. Other caregiver characteristics, such as being a health care

XSL•FO
RenderX

professional and having previously engaged with digital health tools, should be considered, as this may indicate that these caregivers have greater knowledge of asthma and experience with digital health apps and may be more likely to engage with the app. Finally, post hoc analysis revealed responses about app engagement were skewed toward app engagers, as they were more likely to complete the Time 2 survey than nonapp engagers. Despite this skew, most participants completed the Time 2 survey (n=65). Furthermore, post hoc analysis revealed that race and maternal education were not statistically significantly related to completion of the Time 2 survey. Importantly, future digital health studies must work to engage a large, diverse patient population to ensure collecting a representative view of app engagement.

Conclusions

App engagement continues to demonstrate a digital divide in which children and their caregivers from lower educational and marginalized racial and ethnic backgrounds appear less likely to engage with these tools. Caregiver-reported reasons for not engaging with the app revealed gaps that health care systems need to address to improve the experience and potentially increase engagement of more diverse patient populations. A key finding from this study revealed technological and educational barriers to app engagement. These barriers may be reduced by use of video informational technologies to help better inform caregivers and their children about potential benefits of app engagement and to explain how to use the app. As apps become more ubiquitous in pediatric health care systems, these institutions must strive to ensure that the digital divide does not further exacerbate long-standing equity concerns. This study uncovers some barriers to app engagement and provides some recommendations to assist with reducing gaps in access to and use of digital health technology, which may potentially help improve health and educational outcomes for children.

Acknowledgments

The authors acknowledge the support of the Nemours Foundation, Nemours Virtual Health and Informatics, the research study team, and the caregivers and children who participated, without whom this research would not be possible.

Funding

The work was supported by the Nemours Foundation. Publication made possible in part by support from the Nemours Children's Health Grants for Open Access from Library Services (GOALS).

Data Availability

Datasets generated during this study may be available from the corresponding author on reasonable request.

Authors' Contributions

KL contributed to conceptualization, methodology, investigation, formal analysis, writing–original draft. CMZ-G and KVB handled conceptualization, methodology, writing–review, and editing. AM was involved in validation, investigation, writing–review, and editing.

Conflicts of Interest

The authors are employees of the health care institution that created and markets the freely available app described in this manuscript. Despite this, there is no competing financial interest.

Abstract

Background: The electronic version of the Control of Allergic Rhinitis and Asthma Test for Children (CARATKids) has the potential to enhance pediatric telemonitoring but has not yet been validated.

Objective: This study aimed to validate the electronic version of CARATKids against the paper-based version.

Methods: A cross-sectional study was conducted between April and December 2024 in a tertiary hospital in northern Portugal. Children with asthma or allergic rhinitis and their caregivers were recruited during pulmonology outpatient appointments. CARATKids comprises 13 yes or no questions, 8 addressed to the child and 5 to the caregiver, and the total score ranges from 0 to 13. The electronic CARATKids was made available through a mobile app. Both paper and electronic versions were administered in a randomized order before and after the appointment. In addition, participants' preferences between the two administration versions were assessed. Internal consistency (Cronbach α), reliability (intraclass correlation coefficient [ICC], Bland-Altman analysis), and convergent validity (Spearman coefficient) were analyzed following COnsensus-based Standards for the selection of health Measurement INstruments (COSMIN) guidelines.

Results: A total of 51 children (median 9, IQR 8-11 years; n=29, 57% male) and respective caregivers (median 41, IQR 7-45) years were included. The CARATKids total score was similar across the paper (median 5, IQR 3-8) and electronic (median 5, IQR 3-7) versions. The internal consistency was 0.79 for the paper version and 0.83 for the electronic version. The reliability between the two versions was excellent (ICC 0.95, 95% CI 0.91 - 0.97). The Bland-Altman analysis showed strong agreement between the two versions, with a mean difference of 0.04 (95% CI −1.99 to 2.07). The Spearman correlation between the two versions was 0.95 (P<.001). In total, 63% (n=32) of children and 61% (n=31) of caregivers were indifferent to the version used, while 33% (n=17) and 35% (n=18), respectively, preferred the electronic version.

Conclusions: The electronic version of CARATKids appears to be equivalent to the paper-based version of the questionnaire, with good acceptance by children and caregivers. CARATKids implementation in mobile health technologies has the potential to enhance remote child monitoring and optimize the management of asthma and allergic rhinitis.

Introduction

Asthma affects 5% - 6% of children worldwide and is a leading cause of disability among those aged 5 - 14 years old [1,2]. The condition significantly impacts the quality of life and productivity of both children and their caregivers, leading to substantial costs, with a disproportionate burden on ethnic minority groups and economically disadvantaged populations [3-5]. Allergic rhinitis, another common condition, often develops early in life, with a prevalence of 8.5% at ages 6 - 7, rising to 14.6% in those aged 13 - 14 years old [6]. The symptoms of allergic rhinitis have a profound negative impact on children's physical and emotional health, sleep quality, and daily activities [7]. Epidemiological and clinical studies have highlighted the strong link between asthma and allergic rhinitis, leading to the widely recognized concept of United Airways Disease, particularly evident in children [8]. Implementing effective monitoring strategies tailored to individual needs can optimize health outcomes for children with these conditions and their caregivers.

Patient-reported outcome measures (PROM) for asthma and allergic rhinitis assess key aspects of care and provide insights into patients' perceptions of treatment response over time [9,10]. The Control of Allergic Rhinitis and Asthma Test for Children (CARATKids) is the first questionnaire to simultaneously assess allergic rhinitis and asthma control in children aged 6 - 12 years old [11]. It is validated in 7 languages and is a recognized PROM used in clinical practice [11-16]. While the CARATKids paper version remains a valuable tool during scheduled in-person appointments, it often provides limited insight into the child's health trajectory in the period in-between appointments, as it relies on a recall period of 2 weeks. In this context, electronic patient-reported outcome measures (ePROMs) offer a complementary solution by enabling continuous long-term tracking and monitoring of symptoms, allowing health professionals to make more informed decisions based on real-life patient data [17-19]. This approach facilitates a more proactive and personalized approach to child care, allowing health professionals to identify trends and changes in a patient's condition over time [17,18,20]. In addition, ePROMs can offer numerous advantages, including greater patient acceptability, enhanced data quality, and higher response rates, while providing additional benefits for health systems and research [17,18,20,21].

The Allergic Rhinitis and its Impact on Asthma guidelines, implemented in over 70 countries, have evolved to include integrated care pathways with mobile technology for individualized and predictive medicine [22]. There is now an opportunity to increase access to asthma and allergic rhinitis care, ensure better disease control, bridge equity gaps, and control costs. A mobile app version of CARATKids could play a key role in integrating telemonitoring technologies to support remote management of pediatric asthma and allergic rhinitis.

The adult and adolescent version of the Control of Allergic Rhinitis and Asthma Test (CARAT) questionnaire has already been validated for mobile app use, demonstrating psychometric properties comparable to those of the paper version [23]. To date, CARATKids has only been validated in its paper version [11]. An electronic version of CARATKids should be validated comparing with the traditional paper-based questionnaire before being implemented in a clinical setting [24,25].

The primary objective of this study was to validate the electronic version of CARATKids for children with asthma or allergic rhinitis using a mobile app compared to the paper version. A secondary objective was to investigate the CARATKids preferred version, paper or electronic, by children and their caregivers.

Methods

Study Design

This cross-sectional study was conducted at the Pediatrics Department of Hospital de S. João, a public tertiary care hospital in northern Portugal, from April to December 2024. Children and their caregivers were invited to participate during scheduled pediatric pulmonology appointments. This study followed the guidelines on measurement properties for patient-reported outcomes of the COSMIN (COnsensus-based Standards for the selection of health Measurement INstruments) initiative. This study was reported in compliance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guidelines [26].

Ethical Considerations

Ethical approval for this study was obtained from the Ethics Committee of São João Local Health Unit (approval 316/20; addendum dated April 19, 2024). Caregivers provided written informed consent, and informed assent was obtained from the children before data collection. Participants had the right to refuse to participate or to withdraw from the study at any time, without penalty or prejudice, and without needing to provide a reason. No financial compensation was provided to participants for their involvement in this study.

Participants

The sample size was set at a minimum of 50 children and their respective caregivers, following COSMIN guidelines [27]. Participants were selected by physicians based on convenience, specifically on days with a lighter appointment workload and when a researcher was available to assist with data collection. Children aged 6 to 12 years with a scheduled pediatric pulmonology appointment were included if they had a confirmed or suspected diagnosis of asthma or allergic rhinitis. Children were excluded if they had a major respiratory disease other than asthma or allergic rhinitis, or any other medical condition potentially contributing to respiratory symptoms. Caregivers were excluded if they were minors. Both children and caregivers with insufficient knowledge of the Portuguese language or unable to understand or answer self-reported questionnaires were excluded.

Data Collection

Demographic data from children (sex, age, height, weight, and school year) and their caregivers (sex, age, and level of education) were first collected in a paper case report form. In addition, to estimate the level of digital literacy, both children

XSL•FO
RenderX

and caregivers were asked about smart device ownership and whether they had ever downloaded and used a health or fitness app. The CARATKids questionnaire was administered in a randomized order, either as a paper version (pCARATKids) or an electronic version (eCARATKids), with one format completed before and the other after the pediatric pulmonology appointment. Time in-between the two assessments, pCARATKids and eCARATKids, was recorded. Following the administration of both versions, children and caregivers answered about their preference for the paper version, the electronic version, or their indifference between the two.

CARATKids

The Portuguese original version of CARATKids was used in this study [28]. The questionnaire comprises 13 yes or no questions, with 8 items directed to the child and 5 to the caregiver, referencing a recall period of the previous 2 weeks. Each positive response is assigned a score of 1 point, while a negative response is scored as 0. The total score, which ranges from 0 to 13, is calculated by summing the positive responses. Higher scores indicate poorer control of asthma and allergic rhinitis. Child, caregiver, and total scores were calculated. The CARATKids total score was categorized into 3 levels of disease control: controlled (<4), insufficiently controlled (4 or 5), or uncontrolled (>5) [11]. Throughout the study, participants were not informed of their scores or the corresponding disease control classification to prevent any potential influence on their responses. Participants completed both the pCARATKids (see Multimedia Appendix 1) and eCARATKids with support available from a researcher upon request. The eCARATKids was accessible through the InspirersKids mobile app (MEDIDA), which is available for both iOS- and Android-based devices, and was installed on the researchers' smartphones. With this mobile app, questions are presented one at a time rather than displaying the entire questionnaire at once (see Multimedia Appendix 2). A pop-up notification alerts users when the child's section is completed, and the caregiver's section begins. The app could be used offline (to facilitate its use in the clinical context) and, whenever an internet connection was available, the app automatically transferred the eCARATKids answer files to a secure server at Faculdade de Medicina da Universidade do Porto, from which the files could be accessed only by authorized researchers [29].

Data Analysis

Descriptive analyses, including the median (IQR) and the absolute and relative frequencies, were performed to characterize the children and their caregivers, as well as to describe CARATKids scores and version preferences.

Given the sample size, the Kolmogorov-Smirnov Test was conducted to assess the normality of the data. If the data followed a normal distribution, parametric methods were applied; otherwise, nonparametric methods were used.

The internal consistency of both pCARATKids and eCARATKids was assessed using Cronbach α. The relative reliability between the two versions was determined using the intraclass correlation coefficient (ICC), using both two-way mixed single measures, while the absolute reliability was evaluated through Bland-Altman plots. Convergent validity between the traditional paper-based version and the mobile app version of CARATKids was assessed through Spearman rank correlation coefficient. According to COSMIN methodology, Cronbach α, ICC, and Spearman correlation coefficients equal to or greater than 0.70 indicate good measurement properties [27].

All statistical analyses were performed using IBM SPSS Statistics (version 29.0.1.0), with the level of significance set at $P<.05$.

Results

Participants Characteristics

A total of 62 children and their respective caregivers were recruited; however, 2 dyads did not answer one of the CARATKids format due to lack of time, and 9 dyad answers to eCARATKids were lost due to failure in the transfer to the secure server and were excluded. Therefore, only 51 dyads were included in the final analysis. Table 1 presents the demographic and clinical characteristics of the participants. Children's median age was 9 years (IQR 8 - 11), and 57% (29/51) were boys. Caregivers' median age was 41 years (IQR 37-45), and 82% (42/51) were female. Children's median school year was 4th grade (IQR 2nd–6th), and 73% (37/51) of caregivers had at least secondary education.

Table . Demographic and clinical characteristics of the participants.

Characteristics	Children (n=51)	Caregivers (n=51)
Male, n (%)	29 (57)	9 (18)
Age (years), median (IQR)	9 (8-11)	41 (37 - 45)
Years of education, median (IQR)	4 (2-6)[a]	—[b]
Secondary education or higher, n (%)	—	37 (73)[a]
Smart device ownership, n (%)	45 (88)	50 (98)
Health or fitness mobile apps use, n (%)	12 (24)[a]	33 (65)

CARATKids Scores

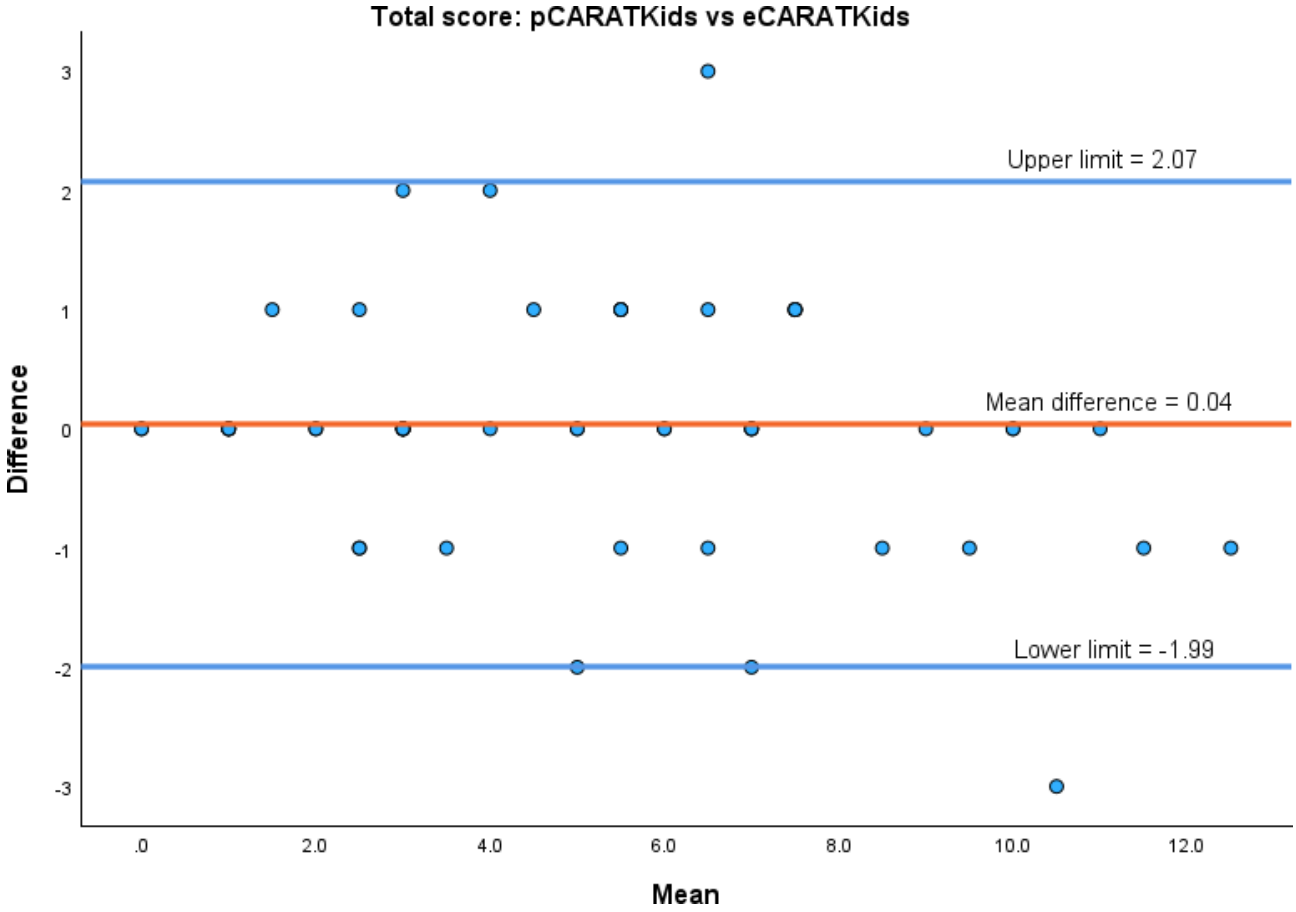
The median total score was 5 (IQR 3-8) points for pCARATKids and 5 (IQR 3-7) points for eCARATKids. Disease was not controlled in 49% (25/51) of patients based on pCARATKids and in 45% (23/51) based on eCARATKids (see Table 2). A total of 24 (47%) children answered the eCARATKids first, and 4 children (8%) required assistance in reading the test in both paper and electronic versions. pCARATKids and eCARATKids were assessed with a median time interval of 41 (IQR 22-65) minutes. The time in-between assessments did not significantly influence the difference in total scores between the paper and app versions (see Multimedia Appendix 3).

Table . Control of Allergic Rhinitis and Asthma Test for children (CARATKids) scores and classification assessed on paper (pCARATKids)[a] and on the app (eCARATKids)[b].

Scores	pCARATKids (n=51)	eCARATKids (n=51)
Children's subscore, median (IQR)	4 (2-5)	4 (2-5)
Caregivers' subscore, median (IQR)	1 (0 - 2)	1 (0 - 2)
Total score, median (IQR)	5 (3-8)	5 (3-7)
Total score classification, n (%)		
Controlled	18 (35)	19 (37)
Insufficiently controlled	8 (16)	9 (18)
Uncontrolled	25 (49)	23 (45)

[a]pCARATKids: paper version of Control of Allergic Rhinitis and Asthma Test for Children.

[b]eCARATKids: electronic version of Control of Allergic Rhinitis and Asthma Test for Children.



CARATKids Measurement Properties

The internal consistency of the CARATKids total score was above 0.7 in both versions (pCARATKids Cronbach α=0.79, 95% CI 0.56 - 1.00 and eCARATKids Cronbach α=0.83, 95% CI 0.62 - 1.00). The children's subscore had a Cronbach α of 0.65 (95% CI 0.30 - 1.00) for the paper version and 0.71 (95% CI 0.38 - 1.00) for the electronic version, while the caregivers' subscore had a Cronbach α of 0.75 (95% CI 0.32 - 1.00) for the paper version and 0.78 (95% CI 0.38 - 1.00) for the electronic version.

The CARATKids demonstrated an excellent relative test-retest reliability (ICC 0.95, 95% CI 0.91 - 0.97). This high reliability was maintained when CARATKids subscores were considered: children's subscore (ICC 0.90, 95% CI 0.83 - 0.94) or caregivers' subscore (ICC 0.94, 95% CI 0.90 - 0.97). The absolute reliability between the paper-based (pCARATKids) and electronic (eCARATKids) versions was good, with a mean difference between the two versions of 0.04 points and with 95% CI ranging from −1.99 to 2.07 (see Figure 1). The data points are evenly distributed around the mean difference line, with no significant proportional bias observed (see Figure 1 and Multimedia Appendix 4).

RenderX

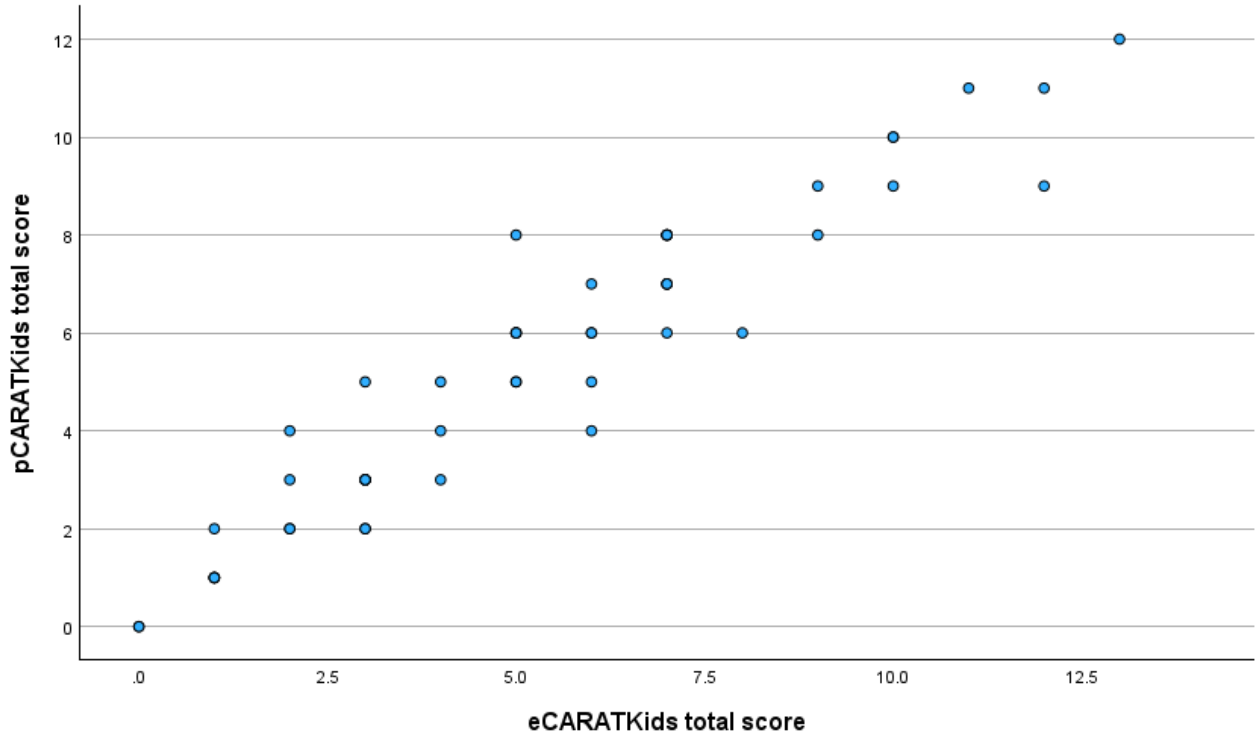

Figure 1. Bland-Altman plot of the total scores of Control of Allergic Rhinitis and Asthma Test for children (CARATKids), assessed on paper (pCARATKids) and on the app (eCARATKids). The blue lines represent the 95% CI.

Regarding convergent validity, the overall correlation between paper and mobile app scores was strong (ρ=0.95; *P*<.001; see Figure 2). When analyzed separately, both the children's (ρ=0.89; *P*<.001) and caregivers' (ρ=0.93; *P*<.001) subscores demonstrated strong positive correlations (see Multimedia Appendix 5).

RenderX

Figure 2. Scatter plot showing the relationship between Control of Allergic Rhinitis and Asthma Test for children (CARATKids) total score on paper (pCARATKids) and on the mobile app (eCARATKids).

CARATKids Preferred Versions

Most of the children (63%, 32/51) and caregivers (61%, 31/51) reported being indifferent to the used versions, while 33% (17/51) of children and 35% (18/51) of caregivers preferred the electronic version (see Multimedia Appendix 6).

Discussion

Principal Findings

This study demonstrated that the electronic version of CARATKids, administered via a mobile app, is a valid and reliable alternative to the paper-based format for assessing asthma and allergic rhinitis control in children. The electronic version exhibited psychometric properties comparable to those of the traditional paper-based version, confirming its equivalence. Furthermore, the mobile app version was highly accepted by both children and caregivers, emphasizing its feasibility and user-friendliness.

Comparison With Previous Work

The internal consistency of CARATKids was evaluated using Cronbach α, which exceeded 0.7 for the total score in both the paper and electronic versions, meeting established psychometric standards [27]. The eCARATKids version demonstrated a Cronbach α of 0.83, comparable to that of the pCARATKids version in our study (Cronbach α=0.79). These findings are consistent with results from other studies using paper versions, including the multicenter Portuguese version of CARATKids (Cronbach α=0.80), as well as the Brazilian (Cronbach α=0.81), Turkish (Cronbach α=0.84), and Dutch (Cronbach α=0.81 - Cronbach α=0.85) validations [11,12,14,15]. Furthermore, the internal consistencies of the electronic versions of CARATKids and CARAT (Cronbach α=0.72 - Cronbach α=0.81) were found to be similar [23].

The intraclass correlation coefficient (ICC 0.95, 95% CI 0.91 - 0.97) further confirmed the strong test-retest reliability of the electronic version. In the validation of the mobile app's adult version, CARAT, the ICC between the paper and electronic versions ranged from 0.65 to 0.85 [23]. The reliability of the CARATKids results was further supported by Bland-Altman, which revealed a high level of agreement between the two versions. These apparently superior results may be attributed to the shorter time interval between administrations in this study (median 41 min, IQR 22-65 min) compared to the adult app validation study, in which 85% of participants completed both the paper and electronic versions on the same day, but still with a longer interval between administrations (median 0 d, IQR 0 - 2 d). Our study also revealed good convergent validity between pCARATKids and eCARATKids (ρ=0.95), indicating that both versions yield highly comparable results. In the validation of the adult mobile app version, the correlation was lower, ranging from 0.64 to 0.82 [23]. This difference may once again be explained by the shorter time interval between administrations in our study, which likely minimized variability due to changes in symptoms and increased recall bias. Furthermore, the response format may have contributed to this difference, as the children's version is based on a yes or no format, whereas the adult version is answered on a 4-point Likert scale [11,23].

Beyond psychometric validation, the study assessed patient and caregiver acceptability. Most children (63%, 32/51) and caregivers (61%, 31/51) were indifferent to the used version, and approximately one-third preferred the electronic version, while only 4% (2/51) favored the paper version. This distribution

XSL•FO
RenderX

suggests that eCARATKids does not introduce additional burden or complexity for users, as the relatively low preference for the paper version (4%) and the significant proportion favoring the electronic version (approximately one-third) indicate a notable openness to digital tools among this population. These findings align with trends observed in other pediatric studies evaluating preferences for ePROMs. For example, in orthopedic studies, 70% of participants preferred the electronic version, while in rheumatology, 83% were either indifferent or preferred the electronic version [30,31]. Furthermore, this high level of acceptability may further increase even more, considering that patients value features such as real-time progress tracking, motivational reminders, and personalized feedback [32].

Strengths and Limitations of the Study

The evaluation of the CARATKids questionnaire's reliability adhered to the COSMIN Risk of Bias guidelines, ensuring a methodologically robust approach [33]. Standardized measurement conditions were maintained throughout the study: both the paper-based and electronic versions were completed in the same controlled environment. Participants exclusively used the researcher's smartphone to complete the eCARATKids, with no use of personal devices, thereby minimizing variability in response conditions. To further reduce potential bias, the researchers responsible for administering and scoring the questionnaires were blinded to previous results. In addition, participants were not informed of their total scores after completing each questionnaire, preventing any potential influence on subsequent responses. The randomized administration of pCARATKids and eCARATKids—alternating before and after appointments—was designed to mitigate order bias and any potential influence of the clinical consultation on questionnaire responses.

Despite the promising findings, this study has several limitations that warrant consideration. First, the research was conducted at a single tertiary care hospital with the minimum recommended number of participants by COSMIN, which may restrict the generalizability of the results to other health care settings, such as primary care or community-based clinics. Although the order of questionnaire administration was randomized, we did not assess if answering the electronic version first had a role on the psychometric properties obtained. The short time interval between administrations also leaves open the possibility of learning effects, which could influence responses. In addition, eCARATKids was completed on the researchers' smartphones rather than on the participants' personal devices. While this approach streamlined the process by avoiding installation delays and bypassing internet restrictions in the clinical environment, the use of an unfamiliar device may have introduced unintended biases or usability challenges compared to responses provided on the child's or caregiver's own device.

To overcome these limitations, future studies should adopt a multicenter approach aiming to include at least 100 participants, ensuring a more diverse population and broader applicability using the patient's own device. In addition, a larger interval should separate pCARATKids and eCARATKids applications. According to COSMIN, the time interval in-between administrations should be long enough to prevent recall bias yet short enough to ensure that patients have not undergone changes in the construct being measured [27]. A time interval of about 48 hours or 1 week is often considered suitable for the evaluation of patient-reported outcomes instruments [23,34]. Future studies could benefit from the inclusion of additional reliability statistics recommended by COSMIN, such as the McDonald ω, and evaluate the responsiveness of eCARATKids over time, detecting changes in symptoms longitudinally. Future research could additionally explore the acceptability of eCARATKids among health care professionals, as this study focused primarily on children and caregivers.

Future Directions

Given these promising findings, eCARATKids emerges as a feasible alternative to paper-based assessments, reinforcing the growing adoption of ePROMs in pediatric asthma and allergic rhinitis care. Ongoing studies are assessing ePROMs' impact on chronic diseases, including in pediatric populations [35,36]. However, a systematic review on telemonitoring of pediatric asthma in outpatient settings identified a significant gap in the literature regarding technologies specifically designed for preschool children [37]. Further research and collaboration among healthcare providers, researchers, and technology developers are essential to advancing telemonitoring for pediatric asthma [37]. With this study, we contribute to bridging this gap.

To further improve eCARATKids, future versions of the app could include features such as biweekly reminders to encourage regular symptom tracking and improve adherence. Users could also receive immediate feedback after completing the questionnaire, including their total score and the corresponding classification of symptom control. Visual tools, such as an integrated dashboard with graphs or charts, could help caregivers track symptom changes over time, promoting better self-management. In addition, enabling users to easily share their results and symptom trends with their pediatrician would support remote consultations and personalized care. These updates could enhance patient engagement, streamline clinical decision-making, and ultimately improve asthma and allergic rhinitis management in children. Future studies could assess the impact of these features on adherence, symptom monitoring, and clinical outcomes.

Conclusions

This study demonstrated that eCARATKids is a valid and reliable alternative to the paper-based format for assessing asthma and allergic rhinitis control in children. With strong psychometric properties and high acceptability among children and caregivers, eCARATKids has the potential to enhance telemedicine strategies and facilitate remote pediatric monitoring. Its integration into mHealth platforms could further optimize disease management and contribute to improving health outcomes in pediatric asthma and allergic rhinitis care.

Abstract

Background: Parents of preterm infants often face challenges in transitioning from hospital to home, requiring reliable and accessible information to support their caregiving. Mobile health interventions have the potential to supplement postdischarge education and empower parents by providing tailored, evidence-based information.

Objective: The primary objectives of this study were to develop an information app (e-TOP) using a participatory design approach, incorporating input from parents and health care professionals, and evaluate its usability.

Methods: A 2-phase, mixed methods design was used for this study. In Phase 1, the app was developed through iterative focus group discussions with parents of preterm infants, parents with limited health literacy, and TOP interventionists. In Phase 2, a usability study was conducted over 6 months with parents of preterm infants. Usability was assessed with a broad range of measurements: thinking aloud sessions, user engagement analytics, 2 questionnaires, the system usability scale (SUS), a customized satisfaction survey, open question sections, and semistructured interviews.

Results: The collaborative approach with end users and experts for the development led to a fully functional e-TOP app. Expert review and content validation ensured that information was clinically accurate, accessible, and relevant to parental needs. For the usability testing, a total of 58 families (116 participants) were recruited and 69 participants actively used the app. The median cumulative e-TOP usage per participant in 6 months (26 weeks) was 39 minutes (IQR 8.8 - 53.0). The median number of actions was 64.0 (IQR 33.5 - 88.0). The e-TOP app received a median SUS score of 75 (IQR 67.5 - 80.0), indicating good usability. Participants rated their overall median satisfaction at 7.0 (IQR 7.0 - 8.0) out of 10. While the app was perceived as useful for finding information on prematurity-specific topics, engagement declined over time. Qualitative feedback highlighted a need for improved navigation (eg, a search function), expanded content (eg, motor development and sensory processing), and more interactive features (eg, chat support and parental community forums).

Conclusions: The e-TOP app is a valuable digital resource that can supplement postdischarge care by providing tailored, evidence-based, and accessible information for parents of preterm infants. While usability scores were high, engagement trends and retrieved feedback suggest the need for enhanced retention strategies, such as push notifications, timeline-based navigation structure, interactive tools, and adding (practical) content. Future iterations to improve the inclusivity of the e-TOP app require strategies to engage fathers and parents with limited health literacy skills.

Introduction

Background

In the Netherlands, 6.9 % of the children are born prematurely (before 37 weeks of gestational age) [1]. Although advances in perinatal and neonatal care have significantly improved survival rates for preterm infants [2], preterm birth still accounts for 66% of all deaths occurring before or during the first month after birth [3]. Prematurity also has large adverse effects on children's motor, cognitive, and socioemotional development [4]. Giving birth to a premature infant is also a disruptive start for parents [5]. Parents of preterm infants often experience a range of mental health problems, such as anxiety and depression [6]. The dependency on medical and health professionals can challenge the formation of a secure infant-parent relationship and parents' self-efficacy in their ability to independently care for their infant [7]. The transition to home following discharge is known as challenging. Without the 24/7 access to health care professionals, parents of preterm infants feel unprepared for this new situation and lack confidence in their capacity to care for their infant [8]. Despite efforts to improve parents' readiness for discharge and the availability of follow-up services, many parents of preterm infants continue to experience unmet needs for support and practical information after leaving the hospital [9,10]. As the infant's care needs and developmental milestones evolve during the first year, the informational needs of parents of preterm infants also shift accordingly. Providing tailored information about the consequences of prematurity and the specific health, behavioral, and developmental needs of premature infants can strengthen parental self-efficacy, enhance their sense of security in caring for their infant, and potentially reduce health care use [11,12].

Search for Information

After returning home, parents of preterm infants search the internet for information on topics, such as infant crying, choice of formula, common illnesses, and developmental stages. While they use search engines, social media, or mobile health (mHealth) apps, finding appropriate and reliable information on the unique challenges of caring for a preterm infant at home remains difficult [8,9]. The use of mHealth could support a shift from time- and professional-dependent access to information toward a more autonomous approach, empowering parents to obtain information whenever and wherever they need it. However, for mHealth apps to be useful and effective, they must address the specific information needs of parents of preterm infants [13,14]. In addition, the app must be user-friendly [15] and the information accessible and easy to understand for parents across varying levels of education and health literacy [16].

mHealth Apps

mHealth education interventions for parents of premature infants were developed over the last decades. However, Richardson's evaluation of mobile apps targeting parents of infants in the neonatal intensive care unit (NICU) revealed that many apps are lacking quality and credibility or do not contain content identified by parents as important [17]. In contrast, the study on the NICU2HOME app provides high-quality information on infant and self-care during and after the NICU stay and showed promising results in enhancing parental self-efficacy and discharge preparedness [18]. Despite the rich body of literature regarding parental needs for information after discharge, available apps targeting the postdischarge period are limited. A systematic app review of mobile information apps for parents of preterm infants after hospital discharge found that, while the overall quality of the identified apps was acceptable, they insufficiently addressed key postdischarge concerns, such as information on transitions in nutrition, sleep patterns, or developmental stages [19]. This lack of targeted content may contribute to the limited usage and adoption of these apps, a common pitfall when end users and stakeholders are not adequately involved in the design process [20]. Participatory design approaches, such as the design thinking method, ensure that user requirements are accurately captured from the perspective of the end users, thereby enhancing usability and facilitating effective implementation [21-24].

The Dutch Context: TOP Program

In the Netherlands, a 1-year home-based responsive parenting intervention (TOP program) is standard care for very preterm infants and their parents and is currently expanded for moderate to late preterm infants. Pediatric physical therapists with an additional 1-year TOP training and affiliated with the Dutch Expertise Center for Premature Infants (EOP) carry out the TOP program. The strength-based and process-oriented intervention consists of 7 key strategies to enhance parental understanding of the infants' behavioral and developmental needs [25]. An important key strategy is to provide parents with information about their infant's behavioral and developmental needs. To enhance parents' knowledge and understanding of their infants' needs, TOP interventionists provide verbal information transfer and an individualized written parental report with strength-based recommendations accompanied by photos taken during the home visit. Despite the benefits of face-to-face care, there is a need for a complementary mHealth intervention that enhances information retention, supports parental confidence in managing their infant's care, and potentially reduces their reliance on health care professionals [9,14]. Therefore, we aim to complement and enhance the existing Dutch TOP program by addressing gaps in information retention and supporting professionals in delivering reliable information to parents. Before conducting more extensive research to measure its effectiveness, developing an information app that ensures that user requirements are effectively incorporated and is tailored to the specific needs of parents of preterm infants is crucial.

The aim of this study was two-fold: (1) to develop a postdischarge information app (e-TOP) for parents of premature infants and (2) to evaluate its usability.

XSL•FO
RenderX

Phase 1: Development of the e-TOP App

Phase 1 Methods

Setting

The study was performed between October 2021 and November 2023 by the EOP, affiliated with the Amsterdam University Medical Center, in collaboration with the Amsterdam University of Applied Sciences.

Ethical Considerations

The study was approved by the Medical Ethical Committee of the Stichting Amsterdam UMC (NL78996.018.21). All participants received an information letter detailing the study's objectives, timeline, content, target group, data management practices, and privacy considerations. Subsequently, informed consent forms were obtained. Participants were officially enrolled in the study upon providing written consent. Data were pseudonymized. Participants did not receive any compensation.

Participants

The user-centered design approach for the development of the prototype started with 3 focus groups, 1 with TOP interventionists and 2 with parents of preterm infants. A pragmatic sampling approach was used, drawing on available data from the EOP center to identify and invite participants (TOP interventionists) with relevant experience across different contexts [26]. For focus group 1, TOP interventionists with more than 5 years of experience, representing different geographic and socioeconomic regions, were approached. For the parent focus groups, participating TOP interventionists approached potential eligible and interested families within their caseload. Parents were included if they (1) participated in the TOP program for at least 3 months and (2) were able to understand and speak the Dutch language. Focus group 3 specifically involved parents of preterm infants with limited health literacy (LHL). These parents were identified and recruited by the TOP interventionist by using the following 2 additional criteria: (1) parents struggle with understanding and applying the information provided during the intervention or in the parent report and (2) fulfill the criteria for LHL according to the Dutch checklist to recognize LHL [27].

Focus Group Meetings

The script for the focus group meetings was developed collaboratively with the research team, guided by the 2 main objectives of the sessions (Multimedia Appendix 1). First, to verify the identified need for information on the 10 topics previously found in our qualitative research [13] and to enrich these with participants' personal experiences. Second, to elicit preferences regarding content, topics, design, and navigation of the app.

To address the first objective, the research team formulated open-ended questions and prompts for each of the 10 topics. These were designed to stimulate reflection, encourage sharing of personal experiences, and allow for the addition of new themes. Examples and short scenarios were incorporated to help participants relate the topics to their own context.

For the second objective, the script included guided activities involving visual and textual materials, such as screenshots of existing parenting apps, information cards, mock-ups, and text samples. These were selected and designed by the research team to support discussion on specific design features (eg, tone of voice, level of detail, and visual presentation) and to facilitate comparison between different styles. See Figure 1; information cards and Figure 2; mock-ups.

Figure 1. Information cards.

XSL•FO
RenderX

Figure 2. Mock-up.

The draft script was reviewed in 2 rounds by the research team to ensure alignment with the study objectives, clarity of language, and feasibility within the planned 2-hour sessions. Minor adjustments were made following pilot testing with a small group of colleagues to refine the sequence of questions and ensure smooth transitions between topics.

We conducted 3 focus group sessions. In the first meeting, 8 female TOP interventionists participated. Five interventionists worked in an urban setting with a diverse population in a challenging socioeconomic environment.

In the second focus group, 9 parents (5 mothers and 4 fathers) participated. Their mean age was 35.6 years (SD 5.8). For 5 parents, it was their firstborn, and for the other 4 parents, it was their second child. Their infants' mean gestational age was 30 weeks and 2 days (SD 19.0). In the third focus group meeting, 6 mothers with LHL participated with a mean age of 31.6 years (SD 2.2). For 5 mothers, it was their firstborn infant, and for 1 mother, her third child. Their infants' mean gestational age was 29 weeks and 1 day (SD 21.8).

The three 2-hour online focus group meetings were organized in the evenings, which was indicated by participants as the most convenient time. The focus groups were facilitated by an independent female researcher, MM. She was not involved in the study design or analysis. The first author (MF) attended the focus groups to take field notes but did not lead the discussions. The 3 focus group meetings were audio-recorded, relistened to, and summarized. Findings were discussed within the research team.

Phase 1 Results

Overview

The results of the focus group discussions with TOP interventionists and parents provided valuable insights that shaped the development of the e-TOP app, directly influencing its content and design refinements. TOP interventionists recommended not to use the age-based developmental norms strictly**,** as individual variation among preterm infants is substantial. Instead of providing medical guidance, the app should direct parents to contact their general practitioner or pediatrician when necessary. Additional topics identified by participants were the digestive system, reflux, constipation, medication management, sensory overload and stimulation, parent-infant attachment, and bonding. Parents expressed a preference for clear, supportive, and actionable information. Information should have a layered content structure, allowing simplified messages and scientifically substantiated information. A summary of these findings is provided in Table 1. We used them as a guideline for the further development of the e-TOP app.

XSL•FO
RenderX

Table . Results of focus group meetings.

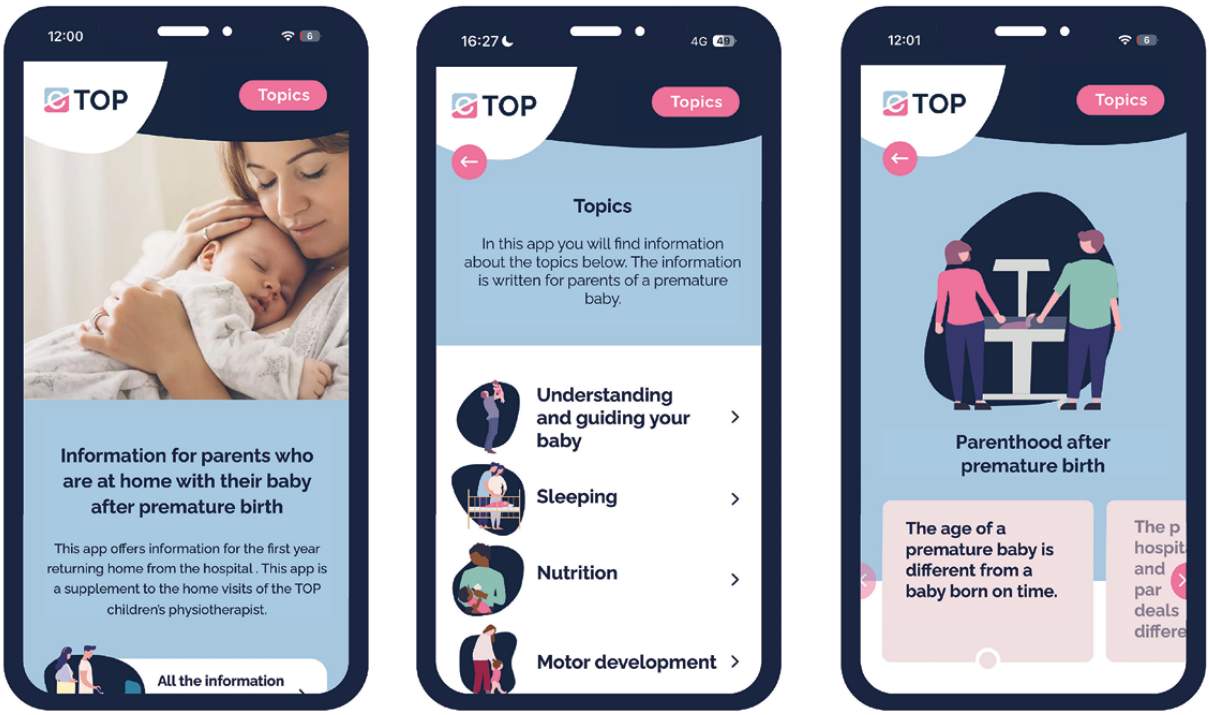
Topics	Focus group 1[a]	Focus group 2[b]	Focus group 3[c]
Participants' associations with a digital information source.	• Reliable and user-friendly digital source aligns well with the needs of young parents.	• An app can offer practical guidance to support everyday care. • Given the limited experience of general practitioners and Dutch health services with prematurity, the app could also be a valuable source.	• Participants expressed curiosity and recognized the usefulness of an app in addressing their concerns.
What questions do parents have?	• Ten topics most frequently searched align with participants' concerns, validating the app's content. In addition, practical information on adequate sensory input and the use of slings is needed.	• Different experiences with gavage feeding at home, a need for more tailored information. • What can I do with my premature infant?	• Participants sought information on baby positioning, especially with the preferred head position. • In addition to the shown topics: reflux and gavage feeding tips. Information about constipation.
About which topics do parents seek additional information?	• Information about constipation, intestinal cramps, reflux, or medication.	• Feeding, sleep patterns, sensory overexcitability	• Inconsolable crying. • Psychological support for anxiety. • Premature clothes. • Information about long-term effects of oxygen.
What support do parents need?	• Finding psychological support for themselves.	• Need for a readily accessible professional after discharge.	• Information on available services, particularly for single moms.
Where do they look for information?	• Communities including Facebook groups and consumer association websites.	• Parents shared their favorite websites, but they are often not specific to premature infants.	• Forums such as 24baby are used. • Other parents with experiences serve as key sources of information.
Presentation of information	• Adaptability to literacy levels. Videos and animations in multiple languages for less literate parents.	• Varied content preferences. Different preferences: some participants liked text-based information, others favored videos.	• Preference for animation (visually oriented). • Practical demonstrations with videos for making the crib. • Interactive features such as a chat box for quick response. • Peer experiences. Some valued real-life success stories; others were not interested in fellow sufferers.
Navigation	• A structured topic design, with an FAQ chapter.	• Search button to improve content discoverability.	• Clicking through for more detailed information.
Information cards	• Reassuring and supportive tone is essential. • Normalizing and comforting tone of voice is important.	• Concise messages can raise questions. The messages should not oversimplify.	• Informative, necessity to be able to search further for more extensive information.
Text validation	• Be aware of the tone of voice, clarity of the information.	• Comforting information is important. An informal tone of voice is nice, it relates to parents and feels personal.	• Easy-to-read text, supplemented by practical examples on what to do. • Information can be more casually read, like you talk to a trusted friend or relative. • It needs to be valid information.

XSL•FO
RenderX

Topics	Focus group 1[a]	Focus group 2[b]	Focus group 3[c]
Depth of information	• Layered information structure. Parents need to be able to explore in-depth details or stay at a simpler level.	• Different headings can help to make content more accessible.	• Information should clearly explain the differences in care for premature infants.
Scope of information	• Coverage for the first year, aligning with the TOP program.	• Guidance on more complex cases should refer parents to the health care professionals. Potential integration with a hospital app could enhance usability.	• Developmental milestones per week. Receiving updates about what your baby is doing in relation to other infants (corrected for prematurity)

[a]TOP interventionist.

[b]Parents of preterm infants.



[c]Parents of preterm infants with limited health literacy.

From Prototype to a Functional e-TOP App

To create content for the app, experts were recruited through the researchers' network. Health care experts were selected based on their expertise regarding prematurity or related topics, such as feeding, sleep, or motor development. To address user needs, the following 4 steps were taken. First, the topics parents indicated in our prior research [13] were complemented with the findings of the focus group meetings. Experts drafted comprehensive information on these topics. Two members of the research team (MF and EM) finalized the content in 3 rounds of review and refinement. Second, the Dutch Expertise Center for reducing health inequities provided support to improve the readability, whereafter the text was simplified by the first 2 authors (MF and EM) to that of the reading ability to understand everyday health information (B1/B2). Key messages for each topic were formulated at level A2 for parents who prefer to read short sentences with familiar words[28]. In addition to text, a read-out-loud function was added. Third, the first 2 authors (MF and EM) included images and picture stories. Fourth, video content, either developed by health care experts from different fields or retrieved from the EOP library, was added. Videos consisted of interviews, demonstrations of parent-infant interaction, and explanations of infant behavioral signs. To clarify the content, videos had voice-overs and subtitles.

Simultaneously with creating content, we collaborated with a design company (ZIGT) to build a functional prototype of a web app accessible on smartphones, tablets, and desktop devices. The research team organized and posted all content leading to the final functional e-TOP app (see Figure 3).

Figure 3. e-TOP app.

XSL•FO
RenderX

Phase 2: Evaluation

Phase 2 Methods

Participants

For the evaluation of the e-TOP app, the sample was composed of parents with a very preterm born infant (below $32^{0/7}$ gestation) and moderate preterm born infants ($32^{0/7}$-$34^{6/7}$ weeks of gestation). Parents of very preterm infants received the TOP program (routine care, reimbursed by the basic package of insurers), and parents of moderate preterm infants received a shortened TOP program in a study context [29]. In addition to the home visits by the TOP interventionists, all participants received access to the e-TOP app.

Procedures

TOP interventionists were recruited using an invitation email distributed by the EOP center. Fifteen TOP interventionists responded to be available for participation in the study. They received a 1-day training in the intervention and research protocol including the informed consent procedure. The enrollment took place between November 2022 and March 2023. TOP interventionists introduced the study to eligible parents within their caseload. The requirement for parents to take part in the study was to be able to read and speak Dutch. When interested, parents received an information letter from the study center. If they agreed to participate, an informed consent visit was scheduled. Upon signing the informed consent, both parents received a unique access code and an animation video explaining how to install the e-TOP app. In addition, at the start (T0), parents were invited via email to complete a questionnaire on sociodemographic information including age, educational level, employment status, and family structure. Parents had continuous access to the app for the duration of 6 months. During this period, Matomo analytics was used to collect user data and thinking aloud tests were performed. At the end of this period (T1), parents received a follow-up invitation to complete questionnaires assessing their experiences, and 10 participants were invited for an interview.

Usability

For a comprehensive evaluation of the usability of the app, we used qualitative and quantitative measurements. User data provided insights into objective usage engagement, while qualitative data highlighted usability needs and identified issues for further improvement [30].

Usability Testing: Thinking Aloud

Thinking aloud tests were used to gain insights into the ease of use and navigation experiences with the app [31,32]. While navigating the app, parents were encouraged to express their thoughts, frustrations, questions, and feedback in real time. The tests were conducted by 2 students from the faculty of health of the University of Applied Sciences Amsterdam, supervised by author VV.

For the sample technique, a stepwise approach was used to ensure that the final participant list for the thinking aloud session included a varied sample across different levels of app engagement. The selection process involved the following steps: (1) all families were initially screened for e-TOP app installation. (2) For each participant, the total app usage time (in seconds) was calculated. (3) Quartiles of app usage time were determined, and participants were divided into 4 usage groups. (4) Each group was randomly ordered using a randomization tool. (5) Three participants per group (n=12) were approached by email for participation.

Participants were asked to complete 3 tasks: (1) determine when your infant can pick up a small object, (2) identify what actions you can take as a parent when your child is anxious about touch, and (3) calculate your infant's corrected age. After completing each task, participants rated the difficulty using the Single Ease Question [33], which scores task performance on a scale from 1 (very difficult) to 7 (very easy). Afterward, parents were asked questions regarding the content (eg, "Are there any topics you would like to add?"), usability (eg, "How was your experience with the e-TOP app?"), and comprehension (eg, "Did you understand the answers you found when searching for information?"). These sessions were screen-recorded, and audio transcripts were generated.

User Data

User data were monitored and analyzed with the web analytics tool Matomo [34]. Users were defined as those who accessed the e-TOP app more than once. The main metrics of interest were installs, visits, visit duration and change of usage over time, and visited topics.

To allow participants to provide immediate feedback on the app, the e-TOP app included a prompt at the end of each page asking, "Was this information helpful?" with 2 response options: yes or no. After selecting an option, a comment box appeared, allowing users to provide additional feedback.

Usability Questionnaires

The Dutch version of the system usability scale (SUS) was used [35]. The SUS is an easy-to-use, valid, and reliable questionnaire for usability assessment of mHealth apps. The scale consists of 10 statements, which can be completed within 10 minutes. All items are scored on a 5-point Likert scale from "strongly disagree" to "strongly agree." Scores per item are converted to an overall SUS score, which ranges from 0 to 100, with higher scores indicating better usability. Overall scores from 0 to 50 indicate "not acceptable," scores from 51 to 67 indicate a marginal level of usability, and scores from 68 to 100 indicate "acceptable to excellent" levels of usability [36].

To measure user experience and appropriateness of the content, a customized 10-item questionnaire was used. Seven statements were scored on a 5-point Likert scale from "strongly disagree" to "strongly agree." Two statement examples are: "The e-TOP app helps me to find information about premature birth" and "The pictures and videos help me to understand the information." Overall satisfaction with the app was scored on a numeric scale from 1 to 10 with 1 indicating very dissatisfied to 10 indicating extremely satisfied. Two open-response questions allowed participants to provide unrestricted and more subjective answers: "What information did you miss when using

XSL•FO
RenderX

the e-TOP app?" and "Do you have suggestions to improve the e-TOP app?"

Interviews

The interview guide was developed in collaboration with the research team. Questions were formulated to address predefined aspects considered critical for evaluating the app's usability. These aspects were derived from the study objectives and focused on identifying strengths, limitations, and opportunities for improvement.

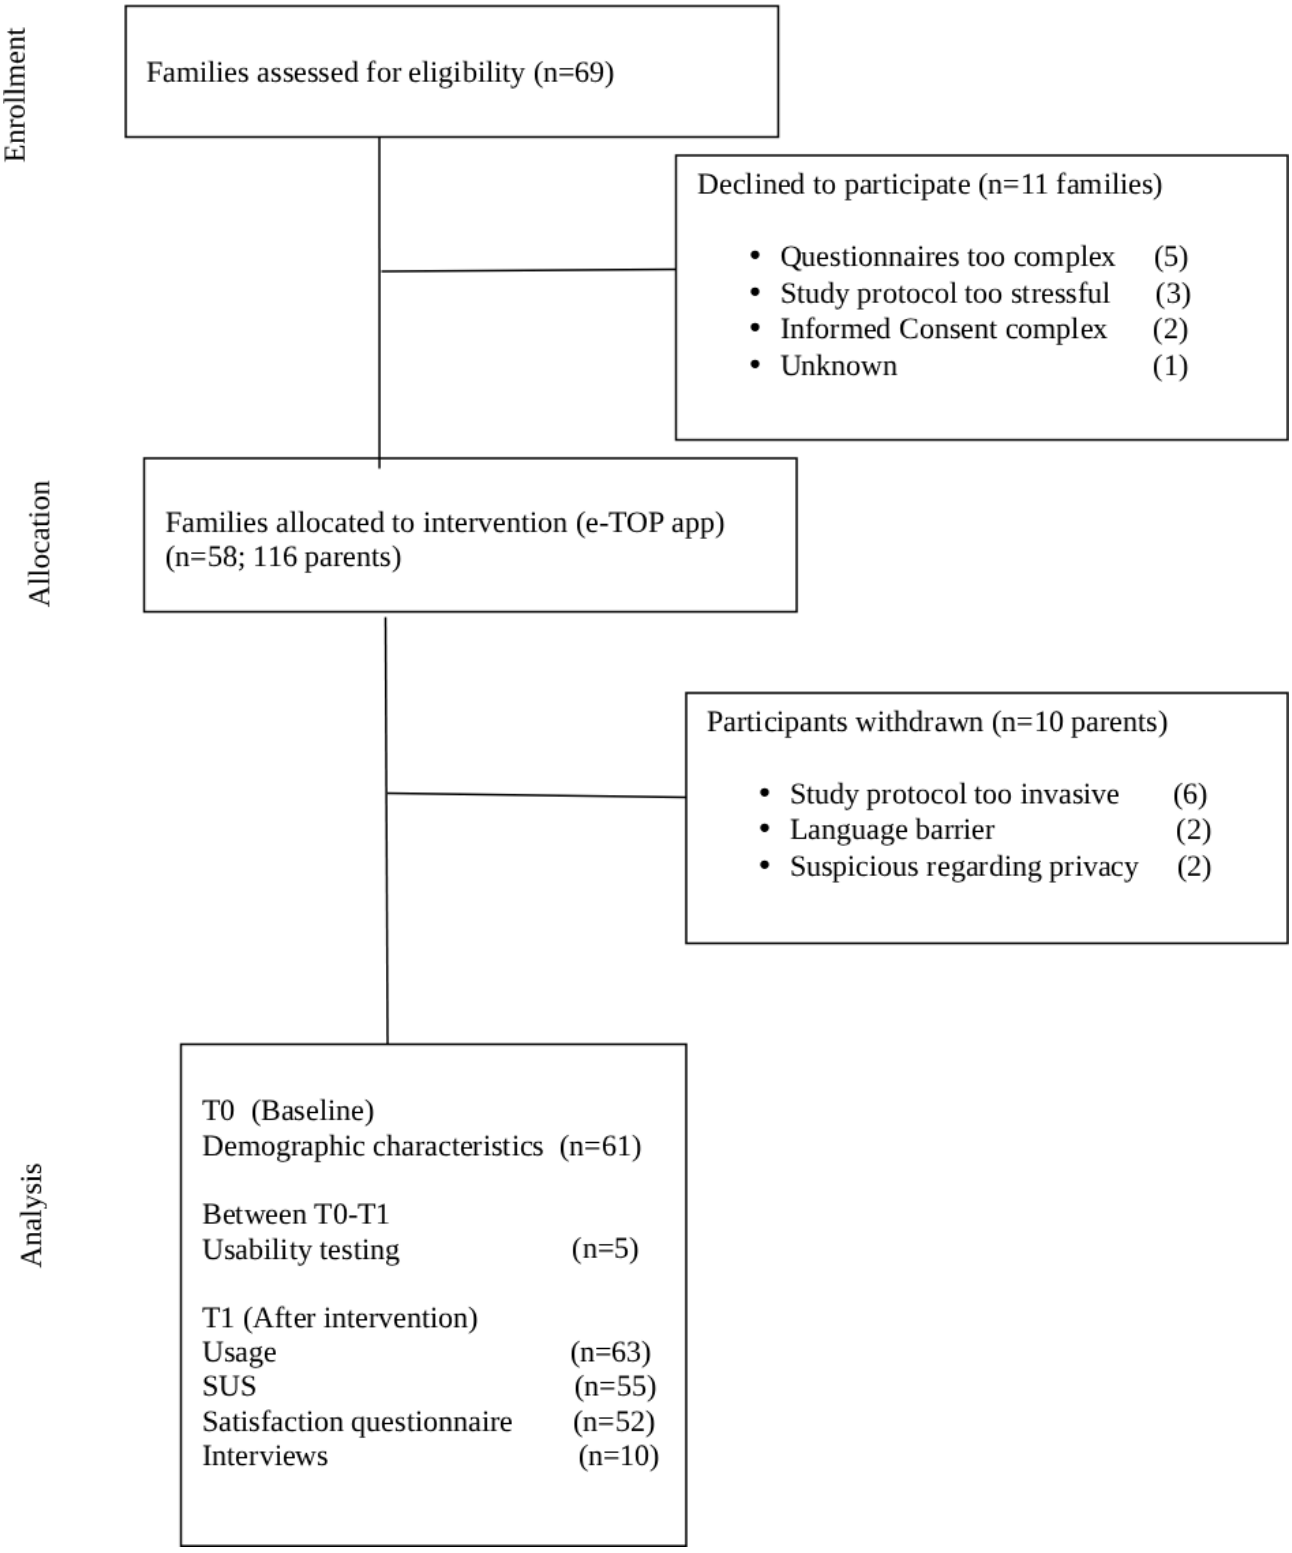
To gain a more in-depth understanding of the experiences with the e-TOP app, a subgroup of participants (n=10) was invited for a semistructured interview with the first author (MF) to discuss their experiences with the e-TOP app in more detail. Purposeful sampling, including educational level, gender, and e-TOP app usage, was used to obtain a heterogeneous sample.

Interviews were scheduled at a time convenient for the parents (by phone or video call). The interview guide was set up to elicit direct, actionable feedback on app usage (Multimedia Appendix 2).

Data Analysis

Questionnaire data were collected using the Castor database (Electronic Data Capture, Ciwit BV, 2021). Descriptive statistics were used to describe the participants and the user data (installs, visits, visit duration and change of usage over time, and visited topics). Questionnaire data were checked for normal distributions using a graphical summary of data and descriptive statistics. The median score with IQR was used in case of skewed distributions.

For the qualitative data collected through thinking aloud sessions and interviews, a pragmatic thematic analysis approach was used [37]. For the thinking aloud analysis, initial open coding was analyzed and discussed within the project group and subsequently categorized into themes. Subthemes were then developed under each main theme to capture more specific insights. In addition, user comments and open questions from the questionnaires were evaluated and categorized by the first author (MF). Ultimately, the qualitative analysis resulted in 4 overarching themes: user experience, content, navigation, and functionality.



Phase 2 Results

Participants

A total of 69 families with a preterm infant were assessed for eligibility by 15 TOP interventionists. Of these, 58 eligible families, consisting of 58 fathers and 58 mothers, agreed to participate, signed informed consent, and received the access code for the e-TOP app. Five families (10 participants) withdrew from the study after signing informed consent and receiving the first questionnaires. At T0, 61 participants completed the demographic questionnaire (see Figure 4 for flow diagram). For participant characteristics, see Table 2.

Usability Results

Thinking Aloud

Ultimately 5 participants (3 fathers and 2 mothers) were willing to schedule an appointment to perform the Thinking aloud tasks. The ease of use was rated as follows: Task 1 had a mean score of 6.4 (SD 0.55), Task 2 a mean of 6.0 (SD 0.89), and Task 3 a mean of 6.0 (SD 1.22) on a scale from 1 to 7, indicating that all 3 tasks were easy to perform. Participants appreciated the app, the tone of voice, and the understandability of the information. Participants provided explicit and actionable recommendations regarding content and functionality. For example, regarding content, participants expressed a desire for more information on health issues and medication. They also expressed interest in instructional videos on techniques, such as holding and carrying their baby. Regarding functionality, a home button, a scroll arrow, and a search function were missed.

User Data

In total, 69 participants (47 mothers and 22 fathers) used the personal access code to log in. Due to ad blockers, tracking data were available for 63 participants. The median cumulative e-TOP usage per participant during 6 months (26 weeks) was 39 minutes (IQR 8.8 - 53.0). The median number of actions was 64.0 (IQR 33.5 - 88.0). Most actions and the largest time spent on the app were registered during the 2 weeks after receiving the access code. See Figures 5 and 6 for further details. Multiple participants visited all 10 topics during the first 2 weeks. The total amount of visits per topic declined after this period with another peak in visits between weeks 11 and 17. The most visited topics in the app were nutrition, sleep, and correcting age for prematurity (Table 3).

Figure 5. Time spent per week.

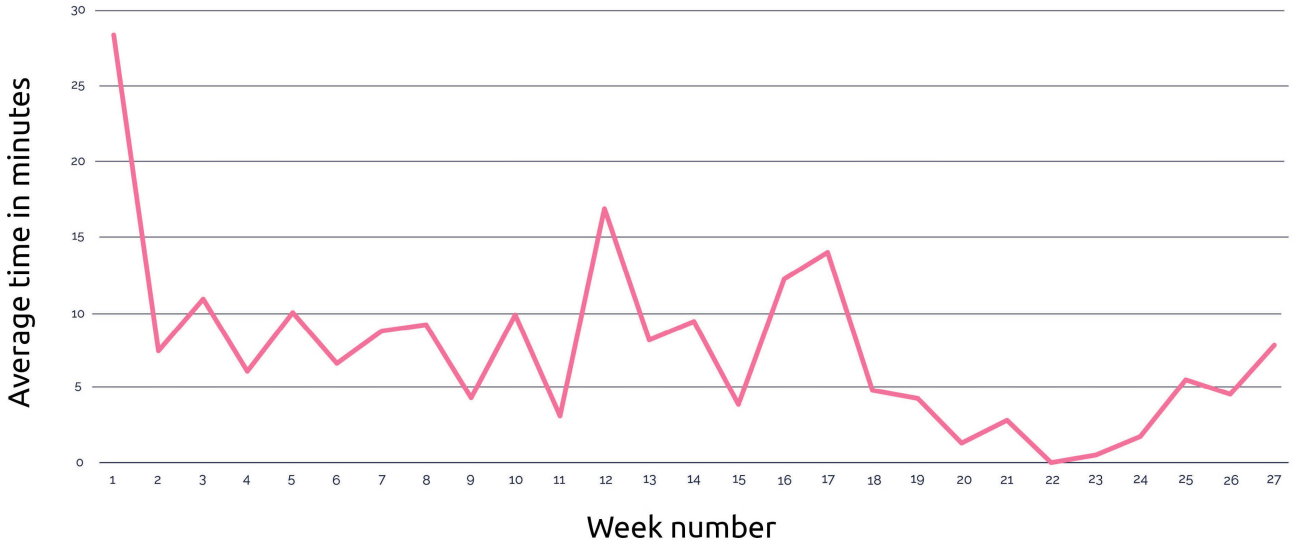

Figure 6. Actions per week.

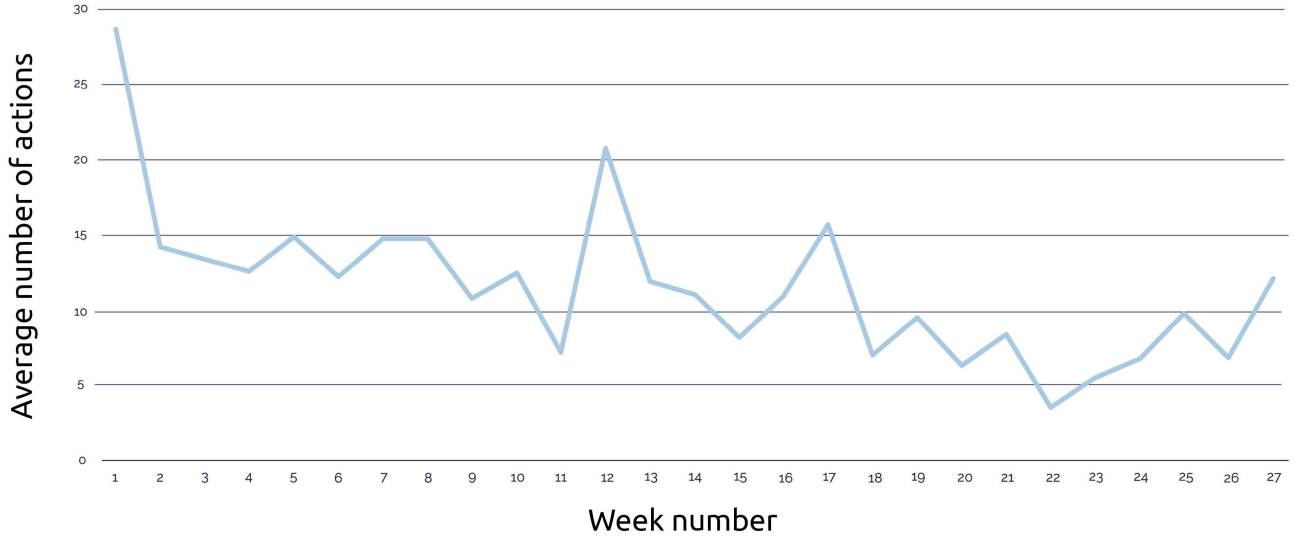

Table . Visited topics on the e-TOP app.

Topic	Total number of visits	Peak visits (week)
Nutrition	81	17
Sleep	79	6
Correcting age	54	3
Understanding your baby	49	4
Long-term consequences	44	14
Motor development	42	11
Returning to work	33	4
Parenting	25	4
Infant health	23	4
Follow-up	21	9

Usability Questionnaires

A total of 55 participants completed the SUS, yielding a median total SUS score of 75.0 (IQR 67.5 - 80.0), indicating generally good usability. The app was rated positively for its ease of use, functional integration, and user confidence.

Participants gave the app an overall satisfaction of 7.0 (IQR 7.0 - 8.0), on a scale of 1 - 10. Content satisfaction was rated

XSL•FO
RenderX

with a mean score of 3.7 (SD 0.89) and the app's appearance was considered attractive, with a mean score of 3.6 (SD 0.83) on a scale from 1 to 5. Participants found the pictures and videos particularly helpful (mean 4.0, SD 0.56) and expressed that the app was helpful in addition to face-to-face care from the TOP interventionist (mean 3.5, SD 0.99).

Qualitative Data

Data collected through thinking aloud sessions, interviews, and written comments from the app's comment box were categorized in 4 themes: user experience, content, navigation, and functionality (see Table 4).

Table . Integrated results matrix for quantitative and qualitative data.

Themes	Quantitative findings (questionnaires and thinking aloud)	Qualitative findings (interviews and comment box)	Meta-inference
User experience	• Overall satisfaction: median 7.0/10 (IQR 7-8) • Visual attractiveness: mean 3.6/5	Users appreciated the depth and specificity of information and the app's tone. However, they missed tailored responses and desired more interactive features.	Parents appreciate the user experience, yet desire more individualized and interactive features.
Content	• Content rating: mean 3.7/5 (SD 0.89) • Visual helpfulness: mean 4.0/10 (SD 0.56)	Content was viewed as highly relevant and unique to prematurity. Suggestions included more on motor development, practical care, and instructional videos.	Content meets core needs, but parents want more concrete, in-depth, and visually supported information tailored to daily care.
Navigation	• Median total SUS[a] score of 75.0 (IQR 67.5 - 80.0)	Parents found the app easy to use and appreciated its tone; they missed a search button and clearer navigation	Usability is high, but navigation challenges (especially in locating specific info) call for interface redesign and better structure.
Functionality	• Task ease thinking aloud: mean 6.1/7 (SD 0.89) • Usage: median 39 minutes (IQR 8.8-53) over 6 months	Parents appreciated the functions in the app, but had some suggestions for improvements.	Functionality is strong but could be elevated by improved orientation, content sharing, and age-specific organization (eg, timeline).

[a]SUS: system usability scale.

User Experience

Participants appreciated the specificity and depth of information provided yet expressed concerns about retrieving tailored answers to specific situations. As a participant in the interview stated, "The only thing I couldn't find was whether it's possible to swim with a premature baby and at what age that is safe". The app facilitated users' understanding of infant behavioral cues and sleep patterns. However, parents also preferred direct interaction with a TOP interventionist, indicating a desire for more personalized and human support. For example, a mother stated in the interview that "The TOP interventionist explained it to me personally, so I found that easier and more comfortable." Suggestions were given to incorporate interactive features, such as chat support or a parent community, indicating a preference for increased interactivity and social connection within the app.

Content

The content was generally deemed useful and relevant to the specific needs of parents with premature infants. As 1 participant noted in the comment box, "It gives information you cannot find on the internet, all content is related to premature birth." Suggestions for improvement emerged from both the interviews and the comment box. Requests for additional practical tips, along with more in-depth information on motor development and health-related concerns, highlighted opportunities to expand the scope of information. As a participant stated during the interview: "More information about motor development, like crawling, creeping, and sitting, would be helpful." Another parent expressed during the interview, "I would like there to be more concrete information, such as a chart with a baby weighing this much should drink this much." Videos were highlighted as particularly effective for conveying complex concepts, such as sleep patterns and infant signals.

Navigation

While users found the landing pages clear and well-organized, they reported difficulties with lengthy chapters and locating specific information. As a participant during the interview reported: "Searching for specific information is more difficult if you don't know under which chapter to search." Another participant reported in the comment box: "The sub-chapters contain too much information and not so easy to find answers to your questions." The need for enhanced navigation design, such as the inclusion of a search function, a home button, and scroll arrows, was suggested and could enhance information retrieval. A participant explained during the thinking aloud session: "If there was an arrow next to the app indicating that there's more room to scroll down, you might have looked further."

Functionality

A timeline-based structure reflecting the developmental stages of premature infants was suggested as a potential solution to improve content organization. One participant stated in the comment box: "It would also be helpful if there was a timeline showing what a child should do at each (corrected) age." The ability to share information easily with family members,

XSL•FO
RenderX

particularly regarding hygiene practices for visits, emerged as a key functional improvement.

Discussion

Overview

This study aimed to develop and evaluate a digital information source (e-TOP) to address the specific information needs of parents caring for preterm infants during the first year postdischarge.

Development of the App

To develop the e-TOP app, a user-centered design approach was used. The feedback from the 3 focus groups with TOP interventionists and parents of premature infants, including parents with LHL, directly influenced the app's content and design. The cocreation and iterative process between experts, the design company, and the research team was highly successful in shaping the app's functionality and refining its design and content. This collaborative approach ensured that the final prototype of the e-TOP app was both user-friendly and rich in relevant, evidence-based information, tailored to meet the diverse needs of its users. This methodology aligns with established practices in mHealth app development, emphasizing the importance of participatory design including health professionals to meet user needs [21-24].

Parents with LHL were actively engaged during the focus group meetings in the developmental phase of the e-TOP app. They expressed a need for clear, actionable information, preferably content in multiple formats, with an accessible tone and simplified messages. The app therefore incorporated features, such as simplified language (Level 1), multimedia content, and "read-out-loud" functionality to accommodate parents with LHL, with videos and text at different reading levels. This preference is supported by research indicating that visual-based interventions, particularly videos, are effective in improving health literacy and comprehension of health-related information [38].

Usage and Usability

Participants engaged with the app for a median total of 39 minutes (IQR 8.8-53.0) during the 6-month study period. The number of recorded actions per participant had a median of 64.0 (IQR 33.5-88.0), but usage varied significantly between participants. Differences in purpose, target groups, and the lack of user engagement metrics make comparison to other parenting apps challenging, as also described in Li's systematic review of commercial mHealth parenting apps [39]. The e-TOP app is designed as an additional information source; if we compare the results to educational health apps, longer but less frequent sessions are found [40]. This found gap calls for established standardized benchmarks for digital engagement in neonatal mHealth interventions.

While the app was perceived as useful for finding information on prematurity-specific topics, user data revealed a decline in engagement after the initial 2 weeks. These differences in intent to use versus lower nonusage attrition are found in other web-based parenting interventions [15]. The e-TOP engagement peaked at week 11 and week 16. Parents revisited the app at key developmental milestones, such as rolling over, reaching for toys, and the transition to solid foods. Integrating features such as search functionality, interactive (push notifications and chat function), and timeline-based navigation could enhance the e-TOP app's long-term utility [41,42].

SUS distribution with a mean SUS score of 68 is considered a suitable usability for Digital Health apps [43]. The e-TOP app demonstrated acceptable-to-good usability with a SUS score of 75.0 (IQR 67.5-80.0). By complementing the SUS with a customized satisfaction survey and data collected through thinking-aloud sessions, interviews, and written comments from the app's comment box, this study followed best practices of combining quantitative ratings with rich qualitative findings for the usability testing [30]. Participants provided actionable feedback across key areas. By integrating these improvements, the e-TOP app can enhance usability, ensuring it remains a valuable long-term resource for parents of preterm infants.

Limitations and Opportunities for Future Research

The total study period of 2 years and restricted finances necessitated pragmatic approaches to the evaluation of the usability. We used several qualitative and quantitative methods, but we had to make compromises impacting the study methodology, such as the reliance on a single author for qualitative data analysis which may introduce bias. Integrating multiple researchers into the thematic analysis process not only enriches the analysis through diverse perspectives but also enhances the credibility and trustworthiness of the research findings [44].

Although parents with LHL contributed to the development of the app, the study faced challenges in recruiting parents with LHL for the evaluation phase. Their limited representation in the evaluation phase underscores a broader challenge in engaging these parents in research [45]. Barriers such as complex consent processes and digital questionnaires have hindered participation in our study. Allowing parents to first establish a connection with the researchers or interventionists and using postponed consent is expected to promote inclusivity. Also, verbal consent or simplified forms could foster inclusivity. Although improved comprehension and trust may have positive effects on study enrollment, we emphasize the active involvement of the target group in the early stages of research projects when developing the study design, procedures, and the selection of measurements [46].

This study had a high attrition of the fathers; only 32% of the fathers used the app and 25% completed the usability questionnaires. In general, retaining participants in studies using mHealth apps has been described as challenging [47]. The finding of higher attrition among fathers aligns with the results of the study on the NICU2HOME app (Garfield [18]), in which high usability scores were similarly observed among mothers, but lower engagement among fathers was noted [10]. Xie [48] also found in her systematic review of digital interventions for fathers of infants from conception to 12 months postpartum that fathers have expressed the need and desire for access to relevant, accurate, and up-to-date information on infant care and challenges associated with new parenthood and called for

XSL•FO
RenderX

interventions that target father-identified priorities [49]. These studies and our findings highlight the importance of gaining a deeper understanding of perceived barriers to engaging fathers.

The usability evaluation confirms that the app was responsive to the needs of parents with a premature infant. Given the evidence supporting user-centered iterative development, we strongly advocate for proceeding with the implementation of the e-TOP app, ensuring it remains a valuable and available resource while integrating continuous user feedback by using real-time analytics, for example, engagement metrics [50,51]. Future research should focus on assessing the effectiveness by evaluating how app usage translates into improved parental confidence and decision-making in caregiving with the goal of reducing dependency on health care professionals and fostering parental autonomy.

Conclusion

The e-TOP app has demonstrated strong potential to complement information transfer to the face-to-face care after discharge and to bridge the information gap for parents when they leave the hospital. While usability findings are promising, continued development, customization, and integration of the app with health care systems are necessary to maximize its long-term impact. By addressing user engagement, content expansion, accessibility, and health care integration, future versions of e-TOP can become an essential tool for empowering parents of preterm infants and improving neonatal postdischarge care.

Acknowledgments

We would like to thank all involved parents and TOP interventionists for providing us with valuable feedback and photo and video material. We thank the experts for their uncompensated commitment to provide the e-TOP app content. We especially would like to thank our facilitator for the focus group meetings, Marion Matthijssen (MM), and the Dutch parent association Care4neo. This research was co-financed by Regieorgaan SIA, part of the Netherlands Organization for Scientific Research (NWO).

Abstract

Background: Sudden unexpected infant death (SUID) is a leading cause of death for US infants, and nonrecommended sleep practices are reported in most of these deaths. SUID rates have not declined over the past 20 years despite significant educational efforts. Integration of prenatal safe sleep and breastfeeding education into a pregnancy app may be one approach to engaging pregnant individuals in education about infant care practices prior to childbirth.

Objective: This study aims to assess whether pregnant individuals would engage with prenatal safe sleep and breastfeeding education provided within a pre-existing pregnancy app. Secondary objectives were to compare engagement among those at high and low risk of losing an infant to SUID and to assess the importance of end user push notifications for engagement.

Methods: This prospective observational study was conducted from September 23, 2019 to March, 22 2022; push notifications were removed on October 26, 2021. TodaysBaby (University of Virginia, Boston University, and Washington University), a mobile health program in which safe sleep and breastfeeding video education was originally provided via texts, was embedded into the MyHealthyPregnancy app (Naima Health LLC). Pregnant mothers who received prenatal care within the University of Pittsburgh Medical Center hospital system were randomized to receive either safe sleep or breastfeeding education beginning at the start of the third trimester of pregnancy and ending 6 weeks post partum. Pregnant persons were designated as high risk if they lived in the 5% of zip codes in Allegheny County, Pennsylvania with the highest rates of SUID in the county. The primary outcome was engagement, defined as watching at least 1 video either in response to a push notification or directly from the app's learning center.

Results: A total of 7572 pregnant persons were enrolled in the TodaysBaby Program—3308 with push notifications and 4264 without. The TodaysBaby engagement rate was 18.8% with push notifications and 3.0% without. Engagement was highest in the initial weeks after enrollment, with a steady decline through pregnancy and very little postpartum engagement. There was no difference in engagement between pregnant persons who were low and high risk. The most viewed videos were ones addressing the use of pacifiers, concerns about infant choking, and the response of the body to the start of breastfeeding.

Conclusions: Integrating safe sleep and breastfeeding education within a pregnancy app may allow for rapid dissemination of infant care information to pregnant individuals. Birthing parents at high risk of losing an infant to SUID—a leading cause of infant death after 1 month of age—appear to engage with the app at the same rates as birth parents who are at low risk. Our data demonstrate that push notifications increase engagement, overall and for those in high-risk zip codes where the SUID education is likely to have the most impact.

Introduction

Sudden unexpected infant death (SUID) is a leading cause of death among US infants, with nonrecommended sleep practices reported in most of these deaths [1]. After a major decrease in the SUID rate immediately after the American Academy of Pediatrics released its 1992 recommendation that infants be placed on their backs to sleep, the rate has plateaued despite extensive educational efforts [2,3]. There continue to be racial and socioeconomic disparities in SUID, with rates higher among Black infants and infants who live in poverty [4-6]. The disparity can be marked, for instance, in Allegheny County, Pennsylvania in 2017 - 2022; 35% of all SUID occurred in 5.6% (7/124) of zip codes (Berger R, MPH, MD, unpublished data, personal communication, May 2024).

Parental education in the newborn nursery has been an important approach to reducing the risk of SUID [7-9]. Information about modifiable risk factors for SUID, including prone or side sleep position, not breastfeeding, sharing a sleep surface, use of soft bedding, and exposure to nicotine/smoking, alcohol, drugs, and illicit substances, when routinely incorporated into newborn education, can change parental practice [4,10]. In one 4-armed randomized controlled trial of hospital quality improvement (QI) and mobile health (mHealth) in 16 US hospitals, new parents were enrolled in an mHealth program (TodaysBaby; University of Virginia, Boston University, and Washington University). The videos in TodaysBaby were designed with parental input from mothers of young infants (our target population); mothers were involved design of the videos and provided suggestions before and during video production and provided feedback after video production [9]. Participants in the randomized controlled trial were randomized to receive emails or texts with links to short (<2 min) videos about either breastfeeding or safe sleep for 60 days. The videos were aimed at changing attitudes and dispelling misconceptions about safe sleep and breastfeeding. In this study, parents who received only safe sleep messaging were 10 percentage points more likely to use safe sleep practices than parents who received no safe sleep messaging. Additionally, racial and ethnic differences in reported safe sleep practices were eliminated in those who received safe sleep messaging. To our knowledge, this is the only randomized controlled trial evaluating video education as an approach to improving safe sleep practices.

The MyHealthyPregnancy (MHP; Naima Health LLC) app is a commercially available evidence-based patient-facing smartphone app and provider-facing portal developed to monitor and model individual risk during pregnancy and provide easy, actionable feedback to patients. The app also offers connection to relevant resources both within and outside the health care system and notifies the individual's care team if a critical risk (eg, preterm labor and suicidal ideation) is reported through the app. The primary goal of the app is to reduce unwanted outcomes both during pregnancy and in the early period after delivery through more timely risk detection and intervention [11-14]. End users were involved in the design, development, and deployment of the technology and the design approach was grounded in person-centered frameworks to advance reproductive health equity [11,15].

The primary objectives of this study were to assess whether the TodaysBaby educational program could be integrated into the MHP app, whether users of the app would engage with the TodaysBaby content, and whether there were differences in knowledge and attitudes related to safe sleep among pregnant persons who were assigned to the safe sleep versus breastfeeding education. A secondary objective was to assess whether parents of infants at the highest risk of SUID—as defined by zip code—were similar in their rates of engagement, knowledge, and attitude compared with those living in low-risk zip codes. TodaysBaby was the first infant-specific education to be integrated into the MHP app, which is otherwise entirely focused on pregnant persons' health and pregnancy.

Methods

Overview

Providers at prenatal clinics in the University of Pittsburgh Medical Center (UPMC) health system could prescribe the MHP app (iOS version 1.4.7, Android version 1.8) to pregnant patients at their first prenatal appointment as part of a prenatal care QI initiative sponsored by UPMC and at no cost to the patient. The internal protocol for prescribing MHP was to send a text-based invitation with a unique web link to the patient's phone, which allowed app users to download the app from the Android or Apple app store. App users electronically consented to share identifiable data with their health care provider and anonymized aggregate data for research. An additional specific consent was provided for enrolling in TodaysBaby. Participants did not receive financial compensation for app use or TodaysBaby participation. At the time of consent, patients were randomly assigned to the safe sleep or breastfeeding group in a 2:1 ratio. High-risk patients—defined by zip code as described below—were enrolled in a 3:1 ratio to the safe sleep group.

All participants were recruited during pregnancy at prenatal clinics. While we recognize that pregnant individuals and parents may be of any gender and that transgender men and gender-nonbinary people may also give birth, we did not collect additional information about biological sex or gender identity from participants. We refer to participants as pregnant persons throughout the manuscript.

MHP users completed an initial onboarding process in which they completed questions about demographics, medical history, and baseline risk factors. Throughout the course of their pregnancy, app users were offered the opportunity to answer questions about their experiences and symptoms through app-embedded screeners, questionnaires, and open-ended text entries. Starting at 32 weeks of pregnancy (based on the due date entered by the user), participants started receiving texts with links to videos ("push notifications" or "pushes") at predefined intervals. The decision to start TodaysBaby at 32 weeks was a change from the original TodaysBaby study, in which the education started at the birth of the infant [9]. We chose not to start earlier than 32 weeks to minimize the likelihood of pregnancy loss among study participants.

There were 21 pushes with 18 videos for each group (safe sleep and breastfeeding): 14 pushes in the prenatal period and 7 in

XSL•FO
RenderX

the postnatal period. A total of 12 short quizzes about intentions related to sleep and breastfeeding were pushed at similar intervals. All videos were also available to all users in both groups at any time in the app's learning center (LC), which was a section of the app providing educational articles and video links on a variety of pregnancy-related topics.

The video topics for both the safe sleep and breastfeeding groups are summarized in Textbox 1.

Textbox 1. Video topics for the safe sleep and breastfeeding groups.

Safe sleep

- Importance of sleep position
- Choking and sleep position
- Importance of sleep space
- Bed-sharing
- Handling advice from others
- Mattress safety
- Soft bedding
- Feeding baby in bed
- Pacifiers
- Dangers of smoking
- Infant sleep patterns

Breastfeeding

- Importance of breastfeeding
- How to start breastfeeding
- How often to breastfeed
- Hunger cues
- What to do if baby is always hungry
- Benefits of breast milk
- How long it takes for milk to come in
- Latching on
- Avoiding breast discomfort/pain
- Dealing with fussy baby
- Getting support from others
- Economics of breastfeeding
- Breastfeeding when returning to work

On October 26, 2021, the push notifications and videos were removed; the videos remained in the LC for pregnant persons who downloaded the MHP app.

Ethical Considerations

The project was approved by the UPMC QI Committee (reference number 1613). App users consented the publication of anonymized aggregate data during app onboarding. An additional consent was provided during app onboarding to a subset of MHP users to opt in to participation in the TodaysBaby program.

Statistical Analysis

The number of videos watched via push notification or from the LC was aggregated. Data from the push notifications indicated that some videos were possibly clicked, so the aggregation was done once for definitely clicked videos and separately to include both and possibly clicked videos. Partial viewings of a video were counted as a viewing of that video. Engagement was defined as watching at least 1 video either in the LC or in response to a push notification. A binary indicator of high- versus low-risk zip codes was created.

Descriptive statistics such as frequency and percentages were used to examine demographic factors for the entire sample as well as the high- and low-risk groups. Individual chi-square tests were used to examine 2 × 2 combinations by group (safe sleep vs breastfeeding), engagement, high-risk zip codes, and frequency of video viewership. A standard of 5% probability of type 1 error was used.

Results

Overview

Between September 23, 2019, and October 26, 2021, 43% (3635/8453) of pregnant persons who were prescribed the MHP app enrolled. Of these, 91% (n=3308) consented to receive TodaysBaby content—2407 in the sleep group and 901 in the breastfeeding group. There were no demographic differences between those who did or did not enroll in the MHP app [13]. The demographics of participants who enrolled in TodaysBaby are summarized in Table 1.

Table . Demographics of MyHealthyPregnancy app users who consented to TodaysBaby.

		Overall users (n=3308)	Pregnant person living in a higher SUID[a] rate area in Allegheny County (n=297)	Pregnant person living in a lower SUID rate area in Allegheny County (n=1562)
Maternal age (years), mean (SD)		29.8 (5.4)	30.3 (5.8)	30.7 (5.1)

[a]SUID: sudden unexpected infant death.

[b]GED: General Educational Development.

Engagement

Video Watching in Response to a Push Notification

Overall, 11% (368/3308) of all participants clicked on at least one of the push notifications they received. Of those who clicked, 53% (194/368) clicked only 1, 26% (94/368) clicked on 2 unique notifications, and the remaining 21% (80/368) clicked on 3 or more unique push notifications (maximum 20 push notifications). An additional 36 participants clicked on at least 1 push notification but because they closed the app immediately after clicking on the notification, it is not possible to be sure whether they read the information provided. If the possible clicks are included, then 12.2% (404/3308) of all participants clicked on a push notification. By comparison, 9.0% (300/3308) of users clicked on at least 1 monthly mental health

XSL•FO
RenderX

push notification which was part of the MHP app but not part of TodaysBaby.

Video Watching From the LC

Overall, 10.4% (347/3308) watched at least 1 video directly from the LC and not in response to a push notification; 6.2% (206/3308) watched at least 1 breastfeeding video from the LC, and 7.4% (345/3308) watched at least 1 safe sleep video from the LC.

Overall Engagement Rate

Overall engagement, defined as watching at least 1 video either in response to a push notification or from the LC, was 18.8% (623/3308).

Video Watching

The frequency with which videos were watched ranged from 1% (35/3308) ("why you should not smoke around your baby") to 4.7% (154/3308) ("a reminder about pacifiers"). Over 9% (300/3308) watched at least 1 of 3 pacifier-related videos. Over 98% (613/623) of the watched videos were watched only once (Table 2).

Table . Frequency with which the 10 most popular safe sleep and breastfeeding videos were watched.

Video name	Number of views
A reminder about pacifiers	154
Should I give my baby a pacifier?	106
Will my baby choke on the stomach?	105
Will my body know what to do when I start breastfeeding?	98
Why sleep position matters	97
How often should I feed my baby?	90
What is the safest mattress?	89
How do I know when my baby is hungry	86
What about bedding and bumpers?	84
What makes a baby a good sleeper	70

Timing of Video Watching

Timing of video watching during pregnancy could only be assessed for app users for whom the TodaysBaby integration took place during their first pregnancy with the app. The "weeks gestation" field was not consistently accurate for users who had used the app with previous pregnancies because some had not logged the date when the first pregnancy ended.

Of the 3308, 43% (n=1431) users were using the app for the first time. The mean time during gestation, when videos were watched, ranged from 19 weeks of gestation ("How long should I breastfeed?" and "More about pacifiers") to 32 - 33 weeks ("What can I do when my baby is fussy" and "Breastfeeding can save you time and money"). Many of these videos were watched through the LC before the TodaysBaby curriculum was available (at 32 wk of gestation) on the MHP app.

Engagement Rate After Removal of Push Notifications

From October 27, 2021 to March 22, 2022, after the push notifications were stopped, of the 4264 participants who downloaded the MHP app, 3.0% (n=127) watched any TodaysBaby videos. Overall, 2.0% (n=85) watched at least 1 breastfeeding video, and 2.0% (n=85) watched at least 1 safe sleep video. The use of the LC was also significantly lower among pregnant persons who did not receive pushes versus those who did (127/4264, 3% vs 347/3308, 10.4%; $P<.001$).

Engagement of Participants in High-Risk Zip Codes in Allegheny County

Of the 3308 users, 58% (n=1859) were from Allegheny County; of these, 16% (297/1859) lived in a high-risk zip code and 84% (1562/1859) lived in a low-risk zip code. Demographic characteristics of the TodaysBaby participants from high-risk and low-risk zip codes are found in Textbox 1.

Among those with high-risk zip codes, 219 were randomized to safe sleep and 78 to the breastfeeding group. Overall engagement in this group was 21.5% (62/297), 10.8% (32/297) clicked on at least 1 TodaysBaby push notification, and 12.5% (37/297) watched at least 1 video from the LC. View rates of safe sleep and breastfeeding videos were similar for both high-risk and low-risk groups.

There was no difference in the engagement of users from high-risk and low-risk zip codes, with the push notifications (32/297, 10.8% vs 185/1562, 11.8%; $P=.60$) or the LC videos (182/1562, 11.6% vs 37/297, 12.5%; $P=.70$).

Quizzes

Overall, 12.0% (409/3308) of all users took at least 1 of the 12 quizzes. Of those who took at least 1 quiz, 54% (222/409) took only a single quiz. Except for quizzes 1 and 6, the completion rate was very low (Table 3). Quizzes 1 and 6 coincided with the user getting a push notification on the same day related to a change in the stage of fetal development. The push notification on the day of quiz 1 (32 weeks gestation) was "Pregnancy is full of many joys and challenges! Reflect on yours now with

XSL•FO
RenderX

your mental health check-in" and the one on the day of quiz 6 (35 weeks gestation) was "Welcome to week 35! Time to put that hospital bag next to your door! Visit MHP for a list of recommended items to pack." There was no difference in response rate between the safe sleep and breastfeeding groups or between high- and low-risk users.

Table . Number of responses to each of the 12 quizzes.

Quiz number	Number of responses
1	279
2	32
3	32
4	44
5	48
6	211
7	62
8	34
9	32
10	25
11	1
12	2

The responses to questions in quizzes 1 and 6 demonstrate that app users plan to breastfeed (83.2%), plan for their baby to sleep in a safe location (97.9%), and plan for their baby to sleep on his or her back (94.6%) (Table 4). There was no difference in the quiz responses between groups (safe sleep versus breastfeeding or high versus low risk).

Table . Responses to quizzes 1 and 6.

Quiz number and quiz question	Response
Q[a]1Ques[b]1: When I first bring my baby home, I plan to breastfeed	83.2% agree or strongly agree
Q1Ques2: When I first bring my baby home, I plan to have him/her sleep in an adult bed	2.1% agree or strongly agree
Q1Ques3: When I first bring my baby home, I plan to place him/her on the side to sleep	5.7% agree or strongly agree
Q1Ques4: When I first bring my baby home, I plan to place him/her on the stomach to sleep	3.9% agree or strongly agree
Q1Ques5: When I first bring my baby home, I plan to place him/her on the back to sleep	94.6% agree or strongly agree
Q1Ques6: When I first bring my baby home, I plan to give him/her a pacifier	34% agree or strongly agree
Q6Ques1: I will be taking a medication or substance that may make me sleep more deeply	10.9% yes or unsure
Q6Ques2: I am currently on prescribed opioids/pain medication/methadone or Subutex/suboxone	1.9% yes
Q6Ques3: I currently use tobacco products	7.6% yes

[a]Q: quiz.

[b]Ques: question.

Discussion

Principal Findings

This is the first study, to our knowledge, to evaluate the use of a mobile app as a means of delivering safe sleep education to pregnant persons with the goal of addressing the risk of SUID. While mHealth tools have been used to explicitly encourage breastfeeding and other care behaviors, the use of an mHealth tool to address safe sleep is novel [16,17]. Over the past 20 years, the way in which young adults receive information has shifted. Smartphone ownership is ubiquitous among reproductive-aged individuals in the United States, with similar distribution by race and ethnicity [18]. A vast majority of smartphone owners use their phones to access health

XSL•FO
RenderX

information, with pregnancy being one of the most popular health app domains [19-21].

In addition to their popularity as an information source, there are several clear advantages to the dissemination of information through a mobile app. An app allows for the dissemination of information much more broadly and quickly than face-to-face education or information via educational pamphlets. It also provides the opportunity for users to obtain the information at a time and place which is convenient for them and it allows for the education to be provided as many times as desired and for it to be provided in the same way each time. Receiving inconsistent information even within a single setting such as a primary care physician's office or newborn nursery can contribute to misinformation.

Timing of education is also critical. While previous safe sleep and breastfeeding education programs have focused on parents after childbirth, parents make many decisions about sleep and feeding practices during pregnancy. In a study by our group, we found that pregnant mothers often purchased cribs and made decisions about sleep practices in their third trimester (Berger R, MPH, MD, unpublished data, 2021). Much of the safe sleep and breastfeeding education in the health care system takes place in a physician's office or newborn nursery after birth, which may not coincide with when parents or other caretakers want or need to hear this information. For this reason, we included TodaysBaby within the MHP app starting at 32 weeks, which was a change from the original TodaysBaby study, in which the education started at the birth of the infant [9]. Our data demonstrated that many of the videos in the LC center were watched before any of the app users began receiving the TodaysBaby curriculum. The LC provides the opportunity for pregnant persons to find the information they are most eager and willing to learn and may be most amenable to incorporating new information. As a result of this finding, integration of the TodaysBaby curriculum earlier in the pregnancy is a possible future change.

One of the challenges of safe sleep education provided in a physician's office or birthing hospital is that there is a set curriculum; it would be very difficult to tailor education to each parent. In a recent study by our group, parents described interactions with their pediatricians related to safe sleep. Most parents reported that their pediatricians asked if they were practicing safe sleep and if they responded they were, there was no further conversation (Sahud H, unpublished data, personal communication, 2024). Here, an additional advantage of app-based content delivery is that the education can be tailored. Our study showed distinct differences in popularity (as determined by number of views) depending on the topic of the videos. This suggests that parents know the specific topics they are interested in or need additional information about (eg, pacifier use) and may not want to spend time learning about other (potentially already-familiar) infant-related topics even though each of the videos was <2 minutes in length.

This study also allowed us to see the natural engagement rate with the TodaysBaby content when deployed outside the context of a controlled study environment in a nonincentivized manner. Our approach allowed for dissemination to a large number of users which would not be possible with an in-person dissemination strategy. Since the field of digital health does not yet have a consensus definition of how to measure and report engagement [22], and very few published studies share engagement rates for specific embedded features and content within a larger intervention (eg, embedding TodaysBaby within the MHP app), it is difficult to interpret our engagement rate of 18.8%. Two studies evaluating specific intervention-embedded content in nonincentivized tool use demonstrated much lower engagement rates (eg, <1% of users completed all modules in 1 mHealth tool; approximately 3.5% completed a single assessment in another) than ours [23,24]. There may be an opportunity to increase engagement by focusing on high-interest video topics and beginning the TodaysBaby curriculum earlier in pregnancy when the overall engagement with the app is higher. Although fewer than half of the videos were watched in response to pushes, when the pushes were removed, the overall engagement dropped from 18% to 3%. Moreover, engagement with quizzes was highest when those quizzes coincided with push notifications containing fetal development information. This suggests that push notifications are critically important to engagement, and push notifications with time-sensitive or high-interest content may be leveraged to engage individuals with aspects of the tool that they would otherwise not seek out. The similar engagement rates between users living in communities with high and low rates of SUID are consistent with other data from the MHP app which has demonstrated that pregnant persons at the highest risk for pregnancy-related complications had similar or higher levels of engagement (Naima Health, unpublished data). This finding has important implications for SUID prevention and potentially for the identification of populations most likely to benefit from access to the MHP app. It is also encouraging that the engagement with videos about maternal health within the MHP app was watched as frequently as videos within the TodaysBaby curriculum since it suggests that mothers are equally willing to watch videos about their baby's health and their own health.

Limitations

There are limitations to this study. Those individuals who downloaded the app may not be representative of the larger pregnant population. For example, these individuals may be more comfortable with seeking out information through technology and may not reflect the population in greatest need of the TodaysBaby information. Because of the low response rate for the quizzes, it was not possible to assess whether engagement with the app correlated with changes in safe sleep or breastfeeding intentions. All participants were English-speaking; there is current work on an app that will be in both Spanish and English (Krishnamurti T, unpublished data, personal communication, June 2024).

Conclusions

Our data demonstrate that it is possible to embed safe sleep and breastfeeding education into an app designed to improve outcomes during pregnancy; that the engagement level is encouraging, especially when compared with other published studies of intervention-embedded education within a health-related app; and that this engagement was equally as

XSL•FO
RenderX

high among pregnant persons at the highest risk of an SUID. Using an app to disseminate information allows for widespread and rapid dissemination and provides users with the opportunity to choose which education they are interested in and when they are interested in receiving it. Simply having access to this education—as was available in the app LC—is not sufficient for engagement, and push notifications are critical for engagement. Future research should focus on assessing whether engagement with the app and TodaysBaby curriculum correlates with changes in safe sleep practices.

Abstract

Background: Acute pharmaceutical exposure in children can lead to severe health outcomes and contribute to the inefficient use of medical resources.

Objective: This study aimed to investigate the clinical characteristics and outcomes of children with acute pharmaceutical exposure to guide the development of preventive strategies and educational initiatives.

Methods: We analyzed real-world data from electronic medical records of children admitted to the emergency department of a pediatric hospital for acute pharmaceutical exposure between January 2019 and December 2023. Clinical data, including laboratory test results, interventions, and outcomes, were collected. We compared different exposure events and conducted logistic regression analysis to identify risk factors for hospitalization.

Results: A total of 653 children were included in the study. The most common drugs involved in exposure were vitamins (149/653, 22.8%), nonsteroidal anti-inflammatory drugs (92/653, 14.1%), and psychiatric drugs (74/653, 11.3%). In total, 74.3% (469/631) of patients with complete clinical manifestation data showed no symptoms after exposure, and 68.1% (445/653) of patients did not require specific therapy. Toxicology screening was performed for 11% (72/653) of the children, and 69.4% (50/72) of these tests were positive. Independent risk factors for hospitalization included multisystem involvement (odds ratio [OR] 4.575, 95% CI 1.709-12.251, *P*=.002), psychiatric drugs (OR 6.280, 95% CI 2.189-18.020, *P*=.001), and intentional poisoning (OR 12.892, 95% CI 2.222-74.796, *P*=.004).

Conclusions: Children with acute pharmaceutical exposure exhibit diverse clinical characteristics and outcomes, with most requiring no specific treatment. However, immediate toxicology screening and clinical intervention are essential for those exhibiting rapidly developing or multisystem symptoms, as well as those with intentional exposure or exposure to known highly toxic substances. Future pediatric health care policies should emphasize safe storage practices and public education on the prevention of pharmaceutical exposure.

KEYWORDS

acute pharmaceutical exposure; children; poisoning; characteristics; outcomes

Introduction

Acute poisoning is one of the major public health issues affecting children around the world [1,2]. It can cause severe harm to children and bring immense economic and emotional burdens to their families. As children always lack the ability to metabolize harmful substances, serious physiological and psychological impacts were often observed, even resulting in disability or death [3]. According to the World Health Organization (WHO) report, accidental poisoning is a major contributor to accidental injury-related deaths in children, particularly in limited-income countries, where the mortality from poisoning is more pronounced [4]. Recent studies reported a significant decline in overall childhood poison exposures, but a decrease in poisoning-related fatalities was not observed [5]. Surveys in China also indicate that poisoning events still

XSL•FO
RenderX

frequently occurred [5-8]. Meanwhile, acute poisoning has become a common reason for pediatric emergency visits in some regions, accounting for 0.1% - 0.5% of such visits [9,10]. Thus, acute poisoning remains a serious public health concern for pediatrics.

Children, particularly infants and preschoolers, spend the majority of their time at home. Children's strong curiosity, poor discernment ability, and weak protective awareness make them a high-risk group for pharmaceutical poisoning, often leading to acute poisoning incidents. In addition, unsafe storage of pharmaceuticals or chemicals, inadequate child supervision, nonauthoritative parenting, maternal employment, and lack of family support can also lead to pharmaceutical exposure and poisoning in children [11,12]. For example, Song et al [13] analyzed 586 cases of hospitalized children with acute poisoning and found that the main causes of poisoning included medications (37.7%), pesticides (28.5%), and rodenticides (29.9%). Li et al [14] showed that most poisoning incidents among children are accidental, with 70.4% occurring at home. Accidental poisonings are more common in young children, particularly in those aged 1 - 3 years, whereas intentional poisonings are more common among adolescents [15,16]. Furthermore, the clinical manifestations of acute poisoning in children are diverse, and some severe cases presenting consciousness disturbances and circulatory failure can be life-threatening.

Notably, a large proportion of studies focused on pediatric pharmaceutical exposures and related poisoning events have been carried out; however, the epidemiological characteristics and clinical manifestations or outcomes of exposed populations, as well as the toxic substance types and prevention efforts, are often limited to specific research geographical areas, cultural backgrounds, and time periods. Furthermore, with the continuous discovery and development of new drugs, the characteristics of exposed populations are constantly changing, necessitating continuous updates and expansions of the relevant knowledge to meet new challenges for preventing acute poisoning in pediatrics. Additionally, in cases of children with acute pharmaceutical exposure, most parents or caregivers are often unsure whether the drugs are truly dangerous to their children, leading them to immediately take the children to the emergency room. The excessive anxiety and lack of professional knowledge in this population may result in the unnecessary use of pediatric emergency resources. While some exposure incidents indeed require urgent medical intervention, in many cases, the exposure events do not immediately endanger life [17,18].

In light of the aforementioned information, in this study, we retrospectively analyzed the acute pharmaceutical exposure cases from the emergency department of a pediatric hospital located in northern China. By summarizing the epidemiological characteristics and clinical manifestations and outcomes of the patients, this study aims to explore the recent common drugs involved in acute pharmaceutical exposure and the related outcomes, and to propose recommendations for preventing and managing acute pharmaceutical exposure in children.

Methods

Sample Collection

This retrospective study included children with acute pharmaceutical exposure who were admitted to the emergency department of the Capital Center for Children's Health, Capital Medical University between January 1, 2019, and December 31, 2023. All participants were aged 18 years or younger. The inclusion criteria for the patient group were age at assessment between 0 and 18 years, and admission due to pharmaceutical exposure. The exclusion criteria were incomplete records (patients lacking key clinical information such as basic demographic data, type of pharmaceutical substance exposed to, or clinical outcomes), admission due to chronic pharmaceutical exposure, and repeat visits (repeated visit records refer to the follow-up visit records of children with acute pharmaceutical exposure who come to the hospital for further check-ups). Totally, 653 eligible patients were included.

Data Preprocessing and Variables Extraction

For the patients who met the inclusion criteria, more detailed clinical information was extracted from their anonymized electronic medical records. Specifically, the variables directly extracted from the structured fields of the electronic records included age, gender, residence, admission time, types of pharmaceutical substances (eg, vitamins, psychotropic drugs, and nonsteroidal anti-inflammatory drugs [NSAIDs]), reasons for acute pharmaceutical exposure (intentional, suicidal, or accidental ingestion), exposure location, exposure season, methods of arrival, caregiver's education level, and clinical outcomes (discharge without treatment, emergency observation, and hospitalization).

The following variables were manually extracted from the unstructured text in the electronic medical records: clinical manifestations (eg, no symptoms, gastrointestinal symptoms, and neurological symptoms), clinical interventions (eg, no specific therapy, gastric lavage, and specific antidotes), and laboratory test results (routine blood test, biochemical test, coagulation function test, and toxicology screening).

The extraction of unstructured data was performed by 4 pediatric emergency physicians with extensive experience. All physicians underwent training on the data extraction content and methods before the process to ensure the accuracy and consistency of the data collection.

All eligible patients were grouped into the following age categories: infancy (<1 year), toddler (≥1 to <3 years), preschool (≥3 to <6 years), school age (≥6 to <12 years), and adolescence (≥12 to <18 years). The pharmaceutical exposure reasons were categorized as intentional and unintentional. The types of drugs involved in acute pharmaceutical exposure were categorized into 13 groups, namely vitamins, NSAIDs (such as ibuprofen and acetaminophen), psychotropic drugs (eg, antidepressant, antiepileptic, and sedative), cardiovascular drugs (eg, antihypertensive and diuretics), antihistamines, respiratory drugs, topical skin drugs, antimicrobial drugs (eg, antibiotic, antiviral, and antifungal drug), endocrine drugs (eg, antidiabetic

XSL•FO
RenderX

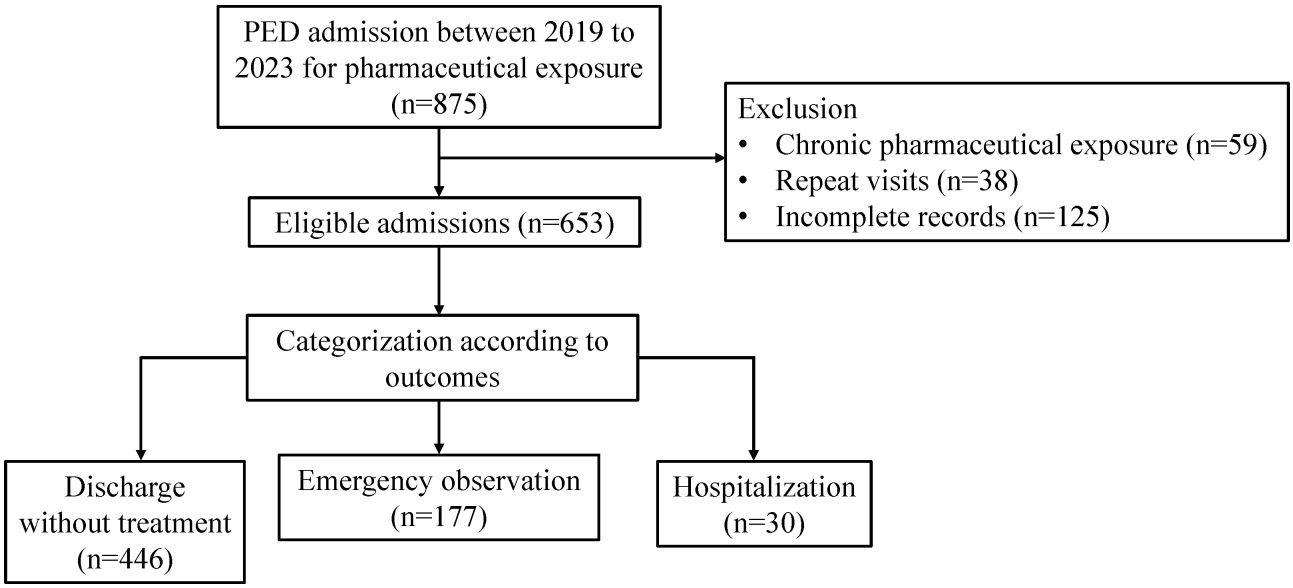
and hormone), herbal medicine, digestive drugs, immunosuppressants, and others.

After completing the above variable extraction and transformation, 22 patients lacked clinical manifestation data. For laboratory tests, 435 children underwent routine blood tests (C-reactive protein, white blood cells, and platelets), 437 children underwent biochemical tests (liver enzymes, myocardial enzymes, and renal function), 418 children underwent coagulation function tests, and 72 patients underwent toxicology screening. Except for these, all other variables had no missing values. In this study, we did not perform imputation for the variables with missing values, and we only used the actual valid data for each variable for the following data comparison and statistical analysis.

Statistical Analysis

All analyses were conducted using SPSS (version 26.0; IBM Corp) and Python (version 3.11; Python Software Foundation). The mean level of numerical variables was measured as mean (SD), and differences between different groups were analyzed using 2-tailed *t* tests. Besides, categorical data were measured with frequencies or percentages, and differences between groups were analyzed using the chi-square test, and Fisher exact tests were used when more than 20% of theoretical frequency was less than 5. In addition, univariate and multivariate logistic regression were used and odds ratios (OR) with 95% CIs were calculated to define the risk factors associated with hospitalization for acute pharmaceutical exposure. A *P* value of <.01 was considered statistically significant.

Ethical Considerations



All methods were performed in accordance with the relevant guidelines and regulations. Since we used anonymized data, and this study did not constitute human subject research, the need for written informed consent was waived by the ethics committee of Children's Hospital Affiliated to Capital Institute of Pediatrics, due to the retrospective nature of the study (SHERLLM2024029).

Results

Characteristics of Children With Acute Pharmaceutical Exposure

From January 1, 2019, to December 31, 2023, 653 adequate pediatric patients with acute pharmaceutical exposure were admitted to our pediatric emergency department (PED; Figure 1). The male-to-female ratio among patients was 1.04:1, with a slightly higher proportion of males. The average age of the patients was 4.7 (SD 4.1) years, with toddlers aged 1 - 3 years old accounting for the highest proportion (253/653, 38.7%; Table 1). Analyzing the age distribution by gender, 56.9% (325/571) of the children under 12 years were male and 43.1% (246/571) were female. Among children aged 12 years and older, 11% (9/82) were male and 89% (73/82) were female, which indicated the gender ratio of patients varies across the 2 age groups.

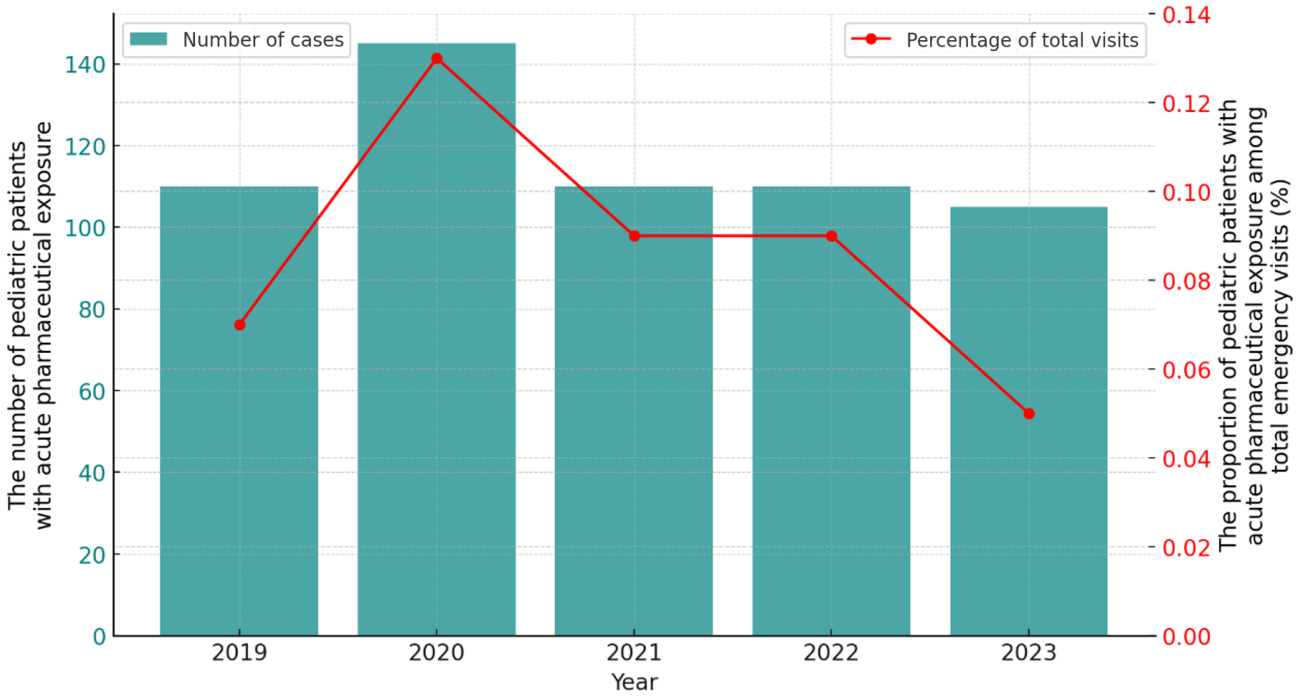
Table . Characteristics of children with acute pharmaceutical exposure admitted to the pediatric emergency department from 2019 to 2023 (N=653).

Demographic characteristics	Participants, n (%)
Sex	
Male	334 (51.1)
Female	319 (48.9)
Age group	
Infant	47 (7.2)
Toddler	253 (38.7)
Preschool	209 (32)
School age	62 (9.5)
Adolescence	82 (12.6)
Residence	
Urban	574 (87.9)
Rural	79 (12.1)
Exposure place	
Home	608 (93.1)
Others	45 (6.9)
Exposure time	
8 AM to 4 PM	231 (35.4)
4 PM to midnight	356 (54.5)
Midnight to 8 AM	66 (10.1)
Exposure season	
Spring	136 (20.8)
Summer	148 (22.7)
Autumn	175 (26.8)
Winter	194 (29.7)
Exposure reason	
Accidental	575 (88.1)
Intentional	78 (11.9)
Caregiver	
Parents	457 (70)
Grandparents	76 (11.6)
None	102 (15.6)
Others	18 (2.8)
Education level of caregiver	
High school or less	112 (17.1)
Undergraduate or vocational college degree	355 (54.4)
Master’s degree or above	132 (20.2)
Unclear	54 (8.3)



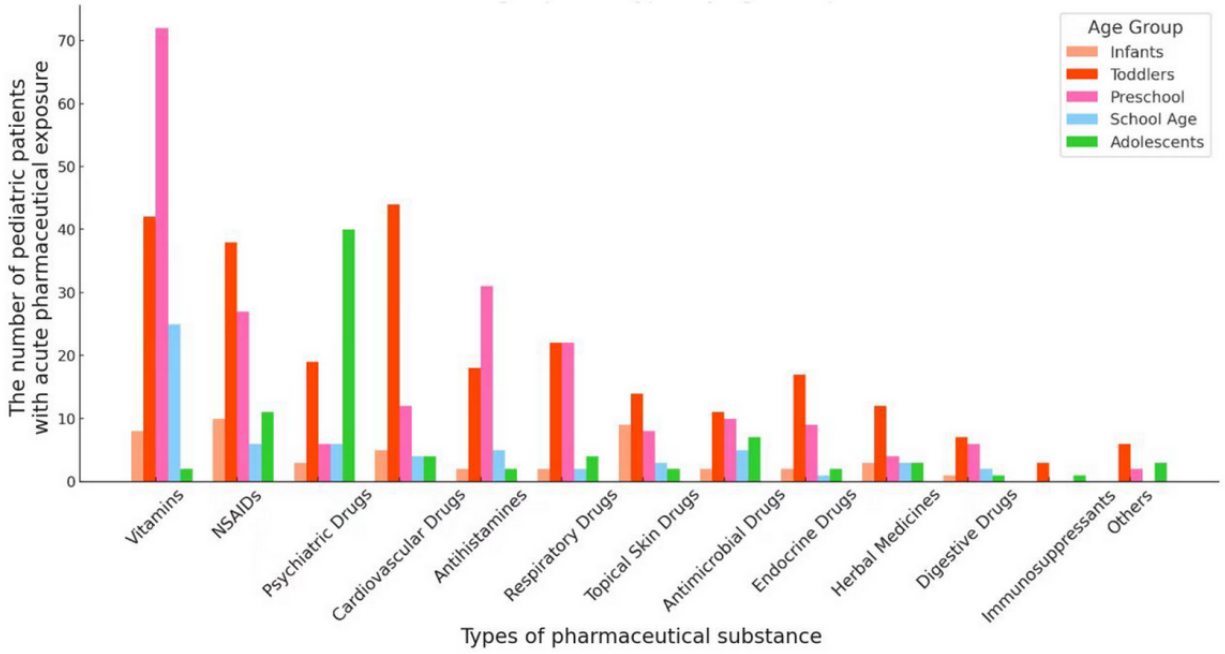
Most pharmaceutical exposure incidents primarily occurred at home, with the peak period mainly occurring between 4 PM and midnight (356/653, 54.5%). Regarding seasonal variations, the number of children visiting the PED for acute pharmaceutical exposure was highest in winter. The primary caregivers at the time of exposure events were parents, and 54.4% (355/653) of the caregivers were college or undergraduates. In addition, analysis of the exposure reasons showed that 11.9% (78/653) were intentional, while the remaining 88.1% (575/653) were accidental. There were 208 poisoning cases (31.9%) resulting from acute pharmaceutical exposure, with 31.3% (65/208) being intentional and the remaining 68.7% (143/208) accidental. In

XSL•FO
RenderX

our study, the diagnostic criteria for drug poisoning include the presence of corresponding clinical manifestations, abnormal laboratory results indicating organ damage, or toxicology tests showing drug concentrations reaching toxic levels.

In terms of changes over time, the annual number of emergency visits due to acute pharmaceutical exposure fluctuated between 107 and 149 over the past 5 years, with a significant increase in admissions in 2020 (Figure 2). The number of patients in other years did not show significant differences. This increase in the year 2020 may be attributed to prolonged home stays and heightened parental vigilance during the early stages of the pandemic, which led to more admissions related to acute pharmaceutical exposure. The annual proportion of admissions due to acute pharmaceutical exposure ranged from 0.05% to 0.13% of the total number of PED visits.

Figure 2. The annual number of pediatric patients with acute pharmaceutical exposure and its proportion in the total annual number of emergency department visits.



Types of Pharmaceutical Substances

In this study, the drugs involved in acute pharmaceutical exposure were categorized into 13 groups (Figure 3). Totally, vitamins emerged to be the most common in all patients (149/653, 22.8%), followed by NSAIDs (92/653, 14.1%; Table S1 in Multimedia Appendix 1). Notably, the proportion of psychotropic drugs is also high (74/653, 11.3%), of which antidepressants accounted for 64.8% (48/74). Besides, cardiovascular drugs (mainly antihypertensive; 56/69, 81.2%) and endocrine drugs (mainly hypoglycemic agents; 11/31, 35.5%) are also common exposure substances (Table S1 in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 3. The distribution of pharmaceutical substances across different age groups.

Furthermore, the types of pharmaceutical substances varied across different age groups. NSAIDs (10/47, 21.3%) and topical skin drugs (9/47, 19.1%) were the most common substance in infants. While in toddlers, cardiovascular drugs (44/253, 17.4%), vitamins (42/253, 16.6%), and NSAIDs (38/253, 15%) were more prevalent. Preschool and school-age children were most frequently exposed to vitamins, accounting for 34.4% (72/209) and 40.3% (25/62), respectively. In adolescents, psychiatric medications were the most common type (40/82, 48.8%), followed by NSAIDs (11/82, 13.4%; Table S1 in Multimedia Appendix 1). It is worth noting that there were 29 patients (29/653, 4.4%) involved in multiple drug exposures, and 46.4% (12/29) of them were adolescents.

While the pandemic may have slightly influenced the absolute number of admissions (Figure 2), it did not substantially alter the underlying epidemiological trends of pediatric pharmaceutical exposures (Table S2 in Multimedia Appendix 1). Analysis of the types of pharmaceutical substances across different year groups showed temporal fluctuations. For example, between 2020 and 2022, the proportion of neuropsychiatric drug exposure was higher compared with both 2019 and 2023. Conversely, during the pandemic, the proportion of respiratory system drug exposure was lower than before and after the pandemic (5.7% vs 12.1% and 12.1%, respectively). However, the types of pharmaceutical substances involved remained largely consistent across these periods (chi-square test, P=.03; Table S2 in Multimedia Appendix 1).

Clinical Manifestations of Acute Pharmaceutical Exposure

In general, for the 631 patients with complete clinical manifestation data, 74.3% (469/631) did not exhibit obvious symptoms after acute pharmaceutical exposure, while the remaining patients showed one or more system involvements. For instance, 13% (82/631) of the patients showed the involvement of the gastrointestinal system, such as nausea, vomiting, abdominal pain, and diarrhea (Table 2). In total, 6.5% (41/631) of patients exhibited neurological symptoms like dizziness, drowsiness, and even coma in some severe cases; these children are mainly associated with excessive use of antidepressants and sedative overdoses. Cardiovascular symptoms were observed in 4.1% (26/631) of the children and manifested as pallor, sweating, and, in some severe cases, hypotension. In addition, multisystem involvement was noted in 9.5% (60/631) of the cases, and dermatological symptoms were observed in 1.4% (9/631) of the cases.

XSL•FO

[g]CKMB: creatine kinase (CK)-MB.
[h]ALT: alanine transaminase.
[i]CREA: creatinine.

In our study, the majority of patients underwent basic laboratory tests, including routine blood tests, biochemistry tests, and coagulation profiles tests. Among these tested populations, as shown in Table 2, the most frequent abnormalities were white blood cell count elevation (58/435, 13.3%) and myocardial enzyme elevation (55/437, 12.6%). Relatively, creatine kinase-MB was frequent in patients exposed to psychiatric drugs (14/49, 28.6%), cardiovascular drugs (10/38, 26.3%), and antimicrobial drugs (6/27, 22.2%; Table S3 in Multimedia Appendix 1). In the antimicrobial drugs exposure group, the proportion of elevated white blood cells and CRP is high (both are 7/26, 26.9%). In addition, in our study, 72 patients underwent toxicology screening, and the total positive rate was 69.4% (50/72); the positive results indicate drug concentrations exceeding therapeutic levels (Table S4 in Multimedia Appendix 1).

Clinical Interventions and Outcomes of Acute Pharmaceutical Exposure

Before admission, 3.5% (23/653) of the children received emetic treatment, and 1.2% (8/653) of them received drainage from their parents or other caregivers. However, most children with acute pharmaceutical exposure were asymptomatic or showed mild symptoms; 68.3% (446/653) of them did not need specific treatment (discharge after a short observation or without treatment), while the remaining patients received one or more clinical interventions. Gastric lavage was the main treatment strategy for drug removal (145/653, 22.2%), followed by specific antidotes (39/653, 6%) and activated charcoal (38/653, 5.8%). In this study, respiratory support was provided in 1.1% (7/653) of the admitted children when airway protection was necessary due to respiratory or circulatory failure. Extracorporeal techniques like continuous renal replacement therapy,

XSL•FO
RenderX

hemoperfusion, or plasma exchange were used in 0.8% (5/653) of the patients (Table 3).

Table . Clinical interventions and outcomes of patients with acute pharmaceutical exposure (n=653).

Clinical interventions	Participants, n (%)
No specific therapy	445 (68.1)
Gastric lavage	145 (22.2)
Specific antidotes	39 (6.0)
Activated charcoal	38 (5.8)

Comparison Between Intentional and Unintentional Acute Pharmaceutical Exposures

In this study, 11.9% (78/653) of the children experienced intentional acute drug exposure, with an average age of 13.6 years (Table 4). Of these, 88.5% (69/78) were female and 94.9% (74/78) had a history of depression. Psychotropic drugs were the most common pharmaceutical substances involved in exposure (42/78, 53.2%). In contrast, the average age for unintentional exposures was 3.3 years, with a relatively balanced gender ratio. For unintentional exposures, vitamins were the most common pharmaceutical substances involved in exposure (125/575, 21.7%). In addition, among patients with intentional exposure, 26 underwent toxicology screening, with a positive rate of 92.3% (24/26), which is significantly higher than the unintentional exposure groups (26/46, 56.5%; P=.004). Intentional exposures resulted in more severe clinical outcomes, with a significantly higher hospitalization rate compared with unintentional exposures (20.5% vs 2.4%, $P=1.486\times10^{-8}$). Detailed information is provided in Table 4.

No	62 (79.5)	561 (97.6)	

[a]*P* value was calculated with chi-square test, except for comparisons between different hospitalization outcomes, which were calculated with Fisher exact test.

[b]Not applicable.

[c]The total number of patients with toxicology screening results was 72.

Factors Influencing Hospitalization for Acute Pharmaceutical Exposure

Univariate analysis indicated that gender, ages 12 - 18 years, multisystem involvement, psychiatric drugs, multiple drug exposures, and intentional exposure were significant risk factors for hospitalization (*P*<.01; Table 5). The hospitalization rate was significantly higher for females (25/319, 7.8%) compared with males (5/334, 1.5%), patients over 12 years (20/82, 24.4%) compared with those under 12 years (10/571, 1.8%), patients with multisystem symptoms (19/60, 31.7%) compared with those without (11/593, 1.9%), psychiatric drug exposures (21/74, 28.4%) compared with other drugs (9/579, 1.6%), multiple drug exposures (7/29, 24.1%) compared with single drug exposures (23/624, 3.7%), and intentional poisoning (16/78, 20.5%) compared with accidental ingestion (14/575, 2.4%). For the variables that were significant in univariate analysis, further multivariate analysis was conducted. Further multivariate analysis showed that multisystem symptoms, psychiatric drug, and intentional exposure were independent risk factors for hospitalization (*P*<.01; Table 5).

XSL•FO

No	561	14				

[a]For univariate analysis, only variables with *P* value <.05 were shown in the table.

Discussion

Principal Findings

This study provides a retrospective analysis of 653 cases with acute pharmaceutical exposure from 2019 to 2023. Our results suggest that toddler and preschool-age groups are more likely to be exposed to drugs. This finding also aligns with Soave et al's [19] study, which reported an average age of 30 months for poisoned children, highlighting the vulnerability of this age group to drug exposure. Following exposure, most children exhibited no symptoms and did not require specific therapy. The most common manifestations were gastrointestinal symptoms, along with elevated white blood cell counts, which were the most frequent abnormal laboratory test results. We also found that multisystem symptoms, psychiatric drugs, and intentional poisoning were associated with hospitalization after acute pediatric pharmaceutical exposure. Notably, female adolescents with mental health issues were more likely to experience intentional exposure, and positive toxicology screening rate, multisystem involvement, and hospitalization incidence were higher in intentional poisoning group [20].

Regarding regional distribution, this study reveals that 87.9% of the acute pharmaceutical exposure events occurred in urban areas, which could be attributed to the hospital's location. Research from different regions could show significant differences in the incidence and main types of poisoning in children. For example, studies in Zhejiang [7] and southwestern China [14] found poisoning was more common among rural children, with pesticides and insecticides being as the primary toxic substances. This difference may be due to the higher prevalence of agricultural activities and more frequent chemical use in these areas. In addition, 93.1% of pharmaceutical exposure in our study occurred at home, consistent with previous studies [21,22]. Urban families, especially those with young children, often stockpile medications for common illnesses, inadvertently increasing the likelihood of children accessing these drugs. This highlights the importance of safe storage practices at home. In addition, the peak times for exposure incidents were between 4 PM and midnight, likely due to lapses in parental supervision during this period, as children are more likely to access medications after school. Parents, who were the primary caregivers in 57.2% of cases, generally had a college or university degree, reflecting the central role of parents in our

XSL•FO
RenderX

studied area. Despite this, the frequency of pediatric drug exposure suggests a need for greater efforts in educating families about medication safety and preventive measures.

Various studies have indicated that psychiatric medications are commonly associated with acute poisoning in children. For instance, Vilaça et al [23] in Brazil found that anxiolytics (mainly benzodiazepines) were the primary drugs involved in poisoning, followed by analgesics. Anderson et al [24] in the United Kingdom reported that benzodiazepines accounted for 19% of poisoning cases, while Santiago et al [25] in Spain also found that benzodiazepines and detergents were the most commonly involved toxicants. These findings contrast with our results, where vitamins were the most common type of drug exposure, particularly among toddler, preschool and school-aged children. This discrepancy may be due to the fact that caregivers in our study population often keep vitamin supplements at home. However, these vitamins, often presented in candy or liquid form, can attract children and increase the risk of accidental ingestion. Caregivers tend to underestimate the risks associated with vitamins, considering them "harmless," even though high doses of certain vitamins (eg, vitamins A and D) can cause severe toxic reactions. Therefore, it is crucial to educate caregivers on the safe storage and proper use of vitamins. In the infant group, NSAID exposure was relatively high, aligns with other studies [23]. NSAIDs (eg, ibuprofen and acetaminophen) are commonly used to relieve fever and mild to moderate pain, and fever is prevalent among infants, leading to NSAIDs being a staple in homes. This increases the risk of accidental ingestion, with a significant proportion of infant exposure resulting from caregivers misusing doses, leading to overdose and poisoning incidents. In addition, our study also found that exposure events involving psychiatric medications, primarily antidepressants, were most common among adolescents.

It is also worth noting that 11.9% of the children were intentionally exposed to drugs, primarily among adolescents, with females accounting for 89% of this group. Intentional exposure typically involves larger doses or multiple drugs, resulting in more severe symptoms. Similar to previous studies [26,27], the rate of multiple drug ingestion was higher in adolescents, often linked to suicidal or self-harm intentions, reflecting the vulnerability of this age group to mental health issues. Studies from the United States, Singapore, Taiwan, Sri Lanka, and other regions [28-31] also indicate that adolescent girls face greater psychological and social pressures, making them more prone to emotional fluctuations and self-harm behaviors. Addressing intentional drug exposure requires strengthened psychological interventions and social support, especially mental health screening and intervention, to prevent poisoning incidents. Collaboration among schools, families, and society is crucial to help adolescents establish a healthy mental state. Furthermore, multivariate regression analysis identified psychiatric drug exposure, multisystem involvement, and intentional poisoning as key factors influencing hospitalization in children with acute drug exposure. Werner and Platt's study [32] in Brazil also showed that intentionality was associated with hospitalization. For these high-risk children, early identification, close monitoring, and proactive intervention are essential to optimize treatment and reduce the severity and mortality of poisoning. More research is needed to refine and validate these factors to guide clinical practice and improve early management of acute drug poisoning.

In our study, most children exposed to drugs showed no clinical symptoms, indicating that many ingested drugs were in small doses or of lower toxicity. Symptoms, when present, primarily affected the digestive and nervous systems, followed by the circulatory system, with multisystem involvement in 9.5% of cases. This is consistent with a study in Chongqing, China [13]. Clinical manifestations in children are closely related to the type and dose of ingested drugs. Higher rates of involvement in the digestive, nervous, and circulatory systems are mainly due to the accidental ingestion of NSAIDs, psychiatric medications, and antihypertensive drugs, which are more likely to cause significant clinical symptoms. Laboratory tests are crucial for diagnosing and guiding treatment in children with acute pharmaceutical exposure. In this study, the majority of the children underwent laboratory tests, with common abnormal results including elevated white blood cell counts and myocardial enzymes. The former likely reflects an inflammatory response rather than an adverse drug reaction. Elevated myocardial enzymes suggest potential myocardial damage from acute drug poisoning, particularly with nervous system drugs, antihypertensive drugs, and NSAIDs [33,34], indicating these drugs have a higher likelihood of causing myocardial damage. In addition, some children exhibited coagulation abnormalities, while liver enzyme and kidney function abnormalities were relatively low, suggesting a lower risk of liver and kidney damage in this study. The study also found that almost all asymptomatic children had normal laboratory results, consistent with Wang et al's [35] study in the United States, which found no positive results in extensive screening and electrocardiography tests for asymptomatic children aged 12 years or younger. Therefore, the necessity of these tests in asymptomatic children with accidental drug overdoses remains debatable.

Clinical interventions for suspected drug poisoning include detoxification; specific antidotes; and, in severe cases, extracorporeal techniques such as continuous renal replacement therapy, hemoperfusion, and plasma exchange. However, only 0.8% of patients required these advanced treatments. Managing acute drug exposure in children necessitates a comprehensive approach, considering factors such as toxin type, ingestion time, dosage, clinical symptoms, and laboratory results. Toxicology screening, performed in 11% of cases with a 69.4% positive rate, is essential for identifying toxins and assessing the severity of exposure. Studies have shown that toxicology results can optimize treatment plans, preventing both overtreatment and undertreatment [36]. Despite this, 68.1% of children did not require specific treatment, suggesting a potential overuse of emergency services. Improving parental education and raising public awareness of the risks associated with drug exposure could help reduce unnecessary visits to the emergency department and optimize resource allocation. Most children with mild or no symptoms can be safely managed at home with proper guidance, while moderate to severe cases require medical observation or hospitalization. The average cost of a pediatric

XSL•FO
RenderX

emergency department visit, including laboratory tests, ranges from ¥1000 to ¥3000 (approximately US $140-US $420), placing a financial burden on families and straining hospital resources. This inefficiency may also contribute to delays in care for critically ill patients.

Generally, preventing accidental drug exposure in children is crucial for reducing poisoning incidents, easing emergency department pressure, and optimizing pediatric medical resource use. Families should store medications out of children's reach, preferably in locked cabinets, and avoid placing them in common areas like kitchens and bedrooms. Parents should also refrain from taking or handling medications in front of children to prevent curiosity and mimicry [37]. In addition, caregivers should be educated on recognizing early symptoms of poisoning and proper emergency response methods. Child-resistant packaging should be used to minimize the risk of accidental openings [38]. Public health departments should promote medication safety through community activities, brochures, and media campaigns. Schools should incorporate medication safety into health education curricula to teach children about proper medication use and potential dangers from an early age [39]. A comprehensive, multifaceted approach is essential to reducing unnecessary pediatric poisonings from pharmaceutical exposure.

Limitations

This study has several limitations. First, its single-center design limits the generalizability of the results, and multicenter studies are needed to validate these findings. Second, additional follow-up data are required to explore the long-term effects of pharmaceutical toxic exposures in children. Third, factors such as family health issues, dietary habits, and the pandemic-related lockdown measures were not considered in detail. The increased exposure to neuropsychiatric drugs may be linked to the significant rise in psychological stress faced by children and adolescents during the COVID-19 pandemic. Factors such as prolonged isolation, internet-based learning, and reduced social interactions likely contributed to a surge in anxiety, depression, and other mental health issues, which, in turn, increased the use and exposure to neuropsychiatric drugs. The preventive measures implemented during the pandemic, such as mask-wearing, social distancing, and limited outdoor activities, may have effectively reduced the transmission of respiratory infections, resulting in a decreased incidence of pediatric respiratory diseases and a significant reduction in respiratory drug exposure. Despite these limitations, our study provides valuable insights into the occurrence and outcomes of acute pharmaceutical exposures in children in recent years. Future research with larger sample sizes, longer time spans, and more follow-up data will allow for more comprehensive comparative analysis.

Conclusions

In conclusion, our study offers valuable insights into the epidemiological characteristics and clinical presentations of children with acute drug exposure. It also emphasizes the importance of ongoing education and preventive measures to reduce the risk of drug poisoning in children and optimize the use of emergency medical resources.

Acknowledgments

The study was supported by Capital Institute of Pediatrics Foundation for Youths (grant number: QN-2024-15) and Chinese Academy of Medical Sciences (CAMS) Innovation Fund for Medical Sciences (grant number: 2021-I2M-1-056).

Abstract

Background: While digital innovation, including chatbots, offers a potentially cost-effective means to scale public health programs in low-income settings, user engagement rates remain low. Barriers to participant engagement (eg, perceived difficulty of use, busyness, low levels of digital literacy) may exacerbate inequality when adopting digital-only interventions as alternatives to in-person programs.

Objective: This cross-sectional study nested within a 2×2 clustered factorial trial that followed the Multiphase Optimization Strategy principles investigated the relationship between behavioral determinants (ie, human and socioeconomic characteristics that facilitate the use of digital health interventions [DHIs]) and caregiver intention to use a digital public health intervention, ParentText, an open-source, rule-based parenting chatbot designed to promote positive parenting, improve adolescent health, and reduce risky behaviors.

Methods: Caregivers of adolescent girls (10 - 17 years; N=1034 caregivers) were recruited by implementation partners from a community-wide project aimed at HIV prevention in two districts of Mpumalanga, South Africa. A Digital Health Engagement Model was adapted from the technology acceptance model, the PEN-3 model theoretical frameworks, and the Theory of Planned Behavior to investigate the relationship between behavioral determinants and the intentions of caregivers to engage in ParentText. Community facilitators administered baseline surveys to caregivers during intervention onboarding. Regression models tested associations between behavioral determinants (ie, perceived ease of use, perceived usefulness, attitude, hedonic motivation, habit, price value, and social influence) and intentions of caregivers to use the parenting chatbot. Interaction effects were explored to examine whether individual-level sociodemographic and psychosocial characteristics moderate associations between overall behavioral determinants and intentions to use the chatbot.

Results: Caregivers reported a mean of 2.85 (SD 0.79) and 2.90 (SD 0.72) out of a maximum score of 4 regarding their intention to use their mobile data and to continue using ParentText in the future, respectively. Overall behavioral determinants predicted by 76% (odds ratio 1.76, 95% CI 1.72 - 1.81) the intentions of caregivers to spend mobile data and by 85% (odds ratio 1.85, 95% CI 1.81 - 1.90) their intentions to use ParentText in the future. Moderator analysis suggested the interaction effects of age, paternal absence, financial efficacy, and stress on the relationship between overall behavioral determinants and intention outcomes.

Conclusions: This is the first known study to investigate the associations between overall behavioral determinants and participant intentions to use a parenting chatbot in a low-income setting. This study identifies behavioral determinants of engagement for improved delivery of DHIs, considering the need to provide low-cost, scalable parenting support through digital platforms that

XSL•FO
RenderX

engage parents, especially those in low-income contexts. Future research should explore methods to investigate mechanisms that regulate behavior to enhance the development of DHIs.

digital health; engagement; adolescent health; behavioral determinants; chatbot-led parenting intervention.

Introduction

Background

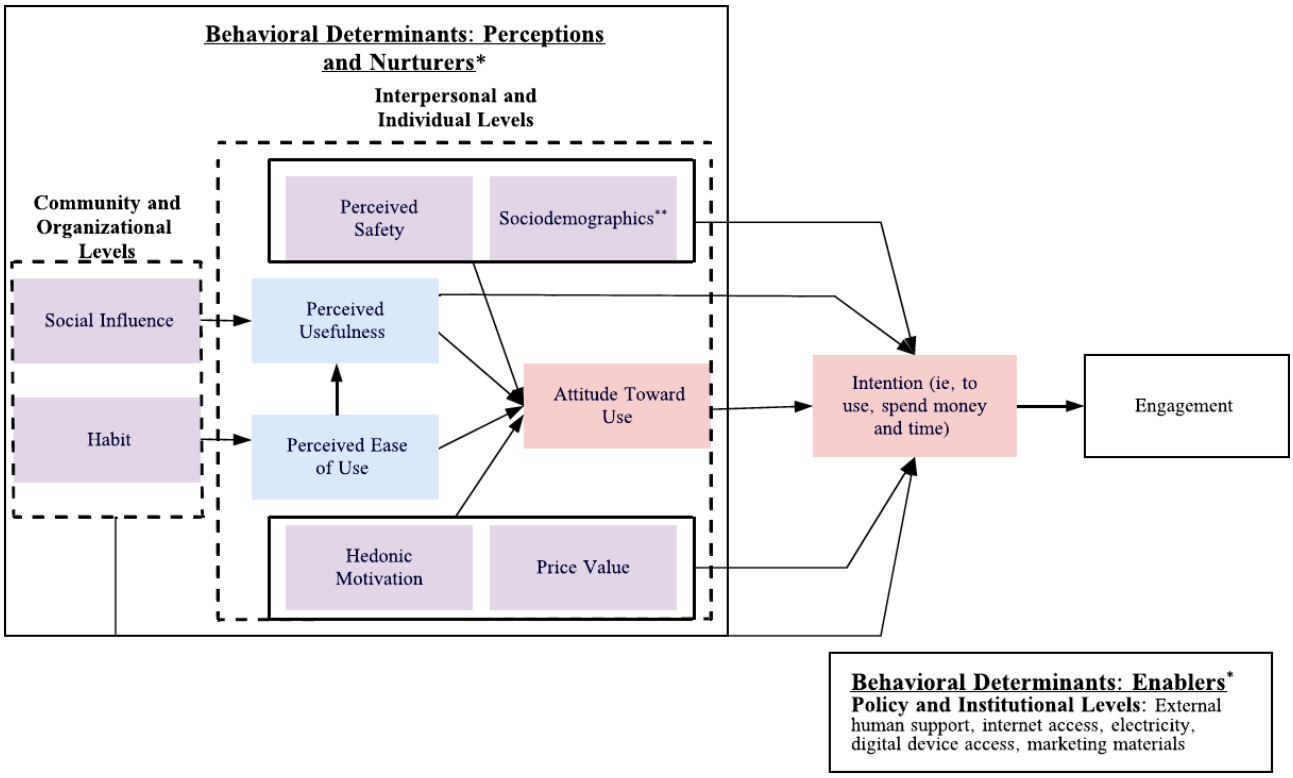
Research demonstrates the benefits of delivering public health interventions through digital platforms. In recent years, chatbots have been used to address structural barriers to accessing evidence-based interventions delivered through in-person programs [1,2], with increasing evidence suggesting their effectiveness in improving a range of health and behavioral outcomes, including mental well-being [3], supporting weight loss [4,5], and positive parenting practices [6]. While digital innovation offers a potentially cost-effective means to deliver public health programs at scale within low-income settings, user engagement rates are typically low [7]. Some of the identified critical barriers to participant engagement in digital interventions include the difficulty of use, lack of culturally adapted content (including human-like illustrations), low levels of digital literacy, and socioeconomic disadvantage—all of which can potentially exacerbate inequality when adapting digital alternatives from in-person programs [6,8,9].

Engagement in digital health interventions (DHIs) is theorized to be influenced by various factors or behavioral determinants. These include enjoyment, motivation, aesthetics and design, personal relevance, and ease of use [10,11]. We define "Behavioral Determinants of Engagement" as any factor characterized by attitudes, ideologies, and belief systems of the individual and the socioeconomic environment that influences the use of digital applications for behavior change. Even though behavioral determinants of health have been broadly studied and have been shown to influence behavior change [12,13], there is a gap in understanding the role of behavioral determinants on engagement in DHIs implemented in low- and middle-income country settings. The study of behavioral determinants in DHIs provides a broader approach to investigating the pathways leading to engagement by helping to identify individual and societal characteristics, such as socioeconomic status, sex, age, and geographic location, that may facilitate users' uptake. Previous studies have evaluated user acceptance of DHIs by investigating participants' (1) intention to use [14] and (2) engagement (ie, actual use) of the health technology [15]. Although actual engagement may suggest user acceptance of DHIs, understanding predictors of intention to use is an important predecessor of engagement in many behavior change theoretical models.

Measuring the Behavioral Determinants of Engagement

We combined the following models to develop a Digital Health Engagement Model (DHEM) that uses a multilevel approach to study how behavioral determinants predict intention as well as moderate the relationship between intention to use and engagement with DHIs: the Theory of Planned Behavior, the Technology Acceptance Model, and the PEN-3 Model. Ajzen's Theory of Planned Behavior [16] explains how personal beliefs, namely attitude (ie, positive or negative beliefs about potential outcomes of the desired behavior), subjective norms (ie, normative expectations of others related to enrolling in the desired behavior), and perceived control (ie, individual's perceptions of the ease of difficulty in performing the desired behavior), predict and explain behavior of individuals. Davis's Technology Acceptance Model [17] suggests that intention is determined by an individual attitude toward using a technology, which is mediated by perceived usefulness (ie, the achievement of job-related or personal goals due to the usage of the technology) and perceived ease of use (ie, how flexible, simple, and compatible the technology is) [18,19].

We drew from the relationships and expectations domain of the PEN-3 model to conceptually map predictors of intention retrieved from the Theory of Planned Behavior, the Technology Acceptance Model, and previous literature on digital health studies. We labeled those factors as behavioral determinants of engagement. Airhihenbuwa's PEN-3 Model foregrounds the role of cultural factors in developing public health interventions and incorporates three domains: cultural empowerment, cultural identity, and relationships and expectations [20]. The domain of relationships and expectations includes the constructs of perceptions, nurturers, and enablers. In the context of DHIs, perceptions can be positive if they contribute to an individual's active engagement with it (eg, users may perceive the DHI as a reliable source for finding health information) and negative if they negatively affect their active engagement with the DHI (eg, users may perceive that it is hard to manipulate the DHI) [18,19]. Similarly, positive enablers are the institutional resources encouraging the use of DHIs, such as clearly engaged marketing materials, broad network coverage, and external human support (eg, in-person or remote staff coaching for health technology use and troubleshooting support) [21-23]. On the other hand, negative enablers may include unsupportive structures for an individual's access and use of DHI, such as poor network coverage and low access to cell phones and electricity. Nurturers are positive when an individual has family or peer support in the use of DHI or negative when unsupportive



XSL•FO
RenderX

(eg, a user may be discouraged from using a parenting chatbot due to the negative opinions of their family members) [24].

The DHEM

The DHEM combines these theoretical frameworks by mapping behavioral determinants at three levels: (1) individual and interpersonal (eg, knowledge, attitudes, and beliefs affecting individual motivation toward the use of a DHI), (2) community and organizational (eg, beliefs and attitudes of close persons or groups toward the use of a DHI), and (3) policy and institutional levels (eg, resources within society and government promoting the use of DHI). In the DHEM, predictors of intention at the individual and interpersonal levels are perceived safety (ie, users' belief that their personal information is safe when accessing health technology), perceived usefulness, perceived ease of use, hedonic motivation (ie, enjoyment of the health technology), price value (eg, cost of health technology or network connection), attitude, and sociodemographics (eg, age, gender, income, education level, digital literacy). Predictors at the community and organizational levels are social influence (ie, user-perceived support from peers and family to use a DHI) and habit (eg, frequency of using digital technologies for communication and access to public services). In contrast, predictors at the policy and institutional levels are external human support, internet access, electricity, and digital device access (Figure 1).

Figure 1. The Digital Health Engagement Model. The blue boxes indicate variables that belong solely to the Technology Acceptance Model, the pink boxes indicate variables that belong to the Technology Acceptance Model and Theory of Planned Behavior, and the purple boxes indicate the external variables. The "*" indicates variables mapped under the Perceptions, Nurturers, and Enablers constructs of the PEN-3 model, while "**" indicates sociodemographics such as age, gender, income, education level, and digital literacy.

To guide the understanding of how the multidimensional aspects of intention may yield certain behavior outputs, the DHEM also incorporates a three-dimensional investigation of intention: (1) intention to use in the future, (2) intention to spend money (ie, pay to have access to DHI or network to use DHI), and (3) time to use in the future. The literature demonstrates that the intention–behavior relationship is dependent on time and contextual factors [25-27]. Therefore, in a low- and middle-income context where time and money constraints are often a reality, the three-dimensional study provides essential implications for advancing strategies for behavior change interventions, including those delivered digitally.

South African Context

South Africa makes for an interesting case study for exploring user engagement, given the growing presence of DHIs across its evolving digital landscape. There is promising evidence on the feasibility of implementing chatbot-led DHIs in the country [28,29]. In 2022, an estimated 70% of South Africa's population had internet access, and there were 162 mobile phone subscriptions per 100 people [30]. While chatbot-led public health interventions focused on health promotion and intimate partner violence prevention have been implemented in South Africa [28,29], evaluations of these interventions have documented no engagement rates. For instance, a South African chatbot-led study on intimate partner violence prevention reported no measure of user engagement [29].

Chatbot-led interventions, including those designed to promote positive parenting practices, have the potential to accelerate South Africa's progress toward achieving the United Nations Sustainable Development Goals 4 and 16 for children (such as increasing access to education, safety, responsive caring, and violence against children prevention strategies) [31]. Even though in-person parenting programs previously implemented

XSL•FO
RenderX

in South Africa have been shown to effectively target family factors (such as family relationship quality, abuse, and neglect) that influence adolescents' health and well-being and reduce the risk for early pregnancy and HIV infection [32,33], they remain difficult to scale at a national level. While low-cost, chatbot-led interventions offer a promising way to scale parenting programs, challenges related to user engagement and the limited research explicitly focused on this issue make it difficult to provide parenting support among those who may not be able to enroll in person due to access barriers such as employment, transportation, and childcare costs.

Study Objectives

The objectives of this study are as follows: first, to explore the factor structure for a locally adapted measurement of behavioral determinants; second, to examine how behavioral determinants of engagement are associated with the intention to use a chatbot delivered to parents and caregivers of adolescent girls as part of a hybrid-digital parenting intervention in South African low-income communities; and third, to investigate the moderating effect of individual-level sociodemographic and psychosocial characteristics on associations between determinants and intentions.

Methods

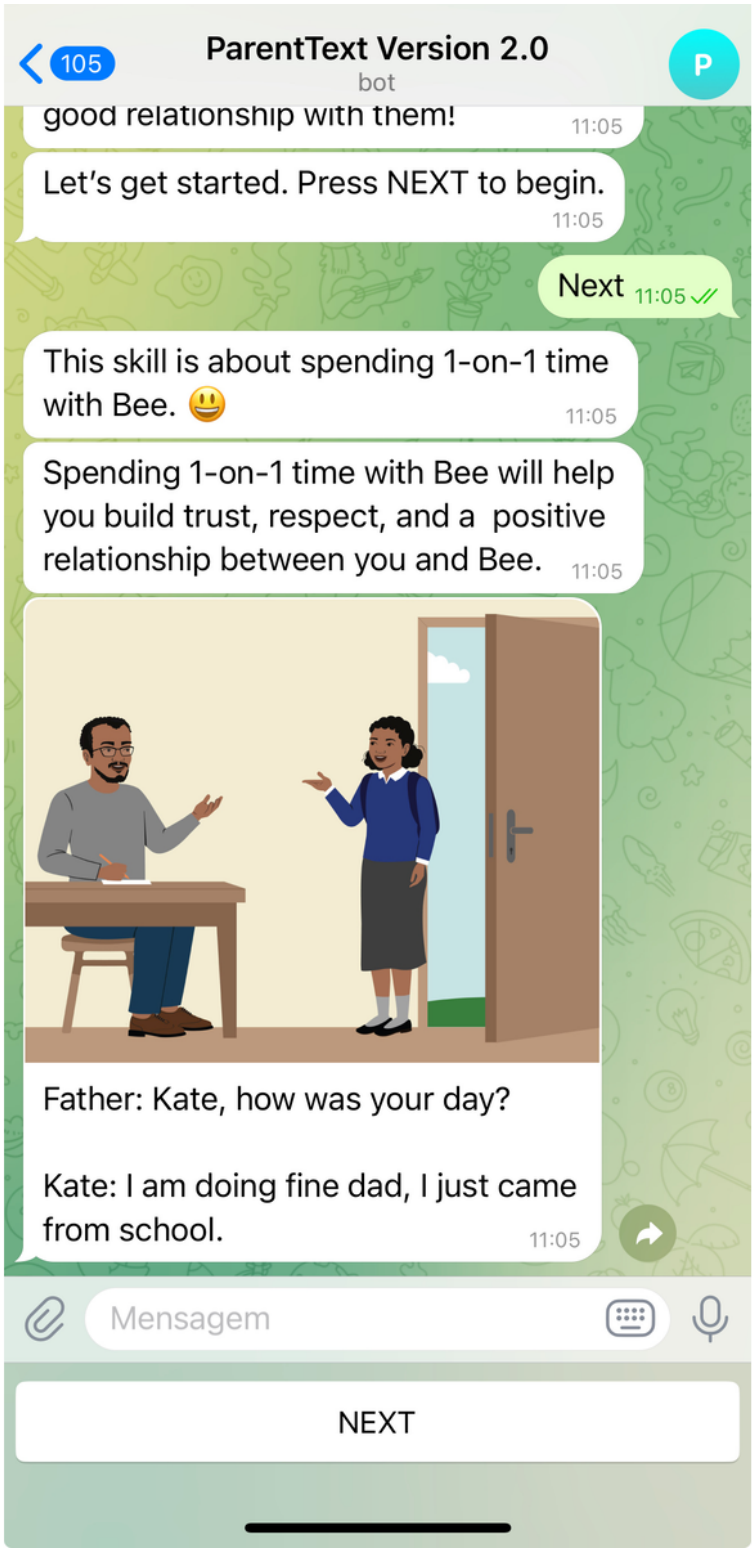
Study Design and Setting

This cross-sectional study was nested within a 2×2 clustered factorial trial (clusters were assigned to receive ParentText alone or combined with in-person sessions and a facilitated WhatsApp support group) that followed the Multiphase Optimization Strategy principles [34]. The trial aimed to optimize user engagement in the chatbot component of a hybrid digital parenting program developed by Parenting for Lifelong Health [34]. The program was implemented by mothers2mothers (m2m), a South African non-profit organization, as part of a large-scale HIV-prevention project "Children and Adolescents Are My Priority" (CHAMP) [34]. The CHAMP project was funded by the USAID (United States Agency for International Development) PEPFAR (US President's Emergency Plan for AIDS Relief) DREAMS (Determined, Resilient, Empowered, AIDS-free, Mentored, and Safe) Initiative, which focuses on strengthening family relationships and communications and providing biomedical prevention resources and HIV treatment to 28,500 adolescent girls, aged 10 and 19 years, and young women [35]. This study was delivered from August to December 2023 across municipalities in the Ehlanzeni and Nkangala Districts of Mpumalanga Province, South Africa. Mpumalanga is characterized by high literacy and high unemployment [36], and the areas in which the trial was implemented were mostly rural and peri-urban zones, with agriculture, fishing, and mining as the primary economic sectors [37].

Eligibility Criteria

Caregivers recruited from the CHAMP community project were eligible if they (1) were aged 18 years or older and spoke English, isiZulu, or siSwati, (2) were caring for an adolescent girl aged between 10 and 17 years, (3) were already enrolled in CHAMP, (4) were living in the same household with the adolescent girl for a minimum of four nights over the previous 3 months, (5) had access to a mobile phone compatible with WhatsApp, (6) were willing to provide written informed consent to participate in the full study, and (7) were willing to enroll in the parenting chatbot and receive messages via WhatsApp. Caregivers with severe learning disabilities or mental health disorders were ineligible.

Data Collection Procedures



Data collection was conducted by trained m2m facilitators who were also responsible for recruiting participants into the trial and delivering the intervention. Baseline data were collected from caregivers and adolescent girls at community settings. Facilitators led participants through the chatbot registration and first parenting module (ie, approximately 10 min of user interaction). After completion of onboarding activities, caregivers completed the behavioral determinants and intention to use the chatbot survey. Data from paper-based questionnaires were abstracted by trained data capturers using Open Data Kit for analysis.

Digital Health Intervention

ParentText is a mobile rule-based chatbot adapted from the Parenting for Lifelong Health suite of programs to address barriers to access and scale of in-person programs [34]. It delivers personalized and gamified scheduled and on-demand messages through text, audio, and visual messages using UNICEF RapidPro, an open-source platform for building interactive messaging systems and delivered through social messaging apps such as WhatsApp (see Figure 2). While the overall content package includes messages based on development stages for caregivers of children aged 0 - 23 months, 2 - 9 years, and 10 - 17 years, this study only used the content targeting caregivers of children aged 10-17 years. ParentText delivers content over nine positive parenting goals composed of 37 learning modules aiming to improve parent–adolescent communication (Figure 2), improve engagement in learning, improve adolescent mental health, and reduce risky behaviors by establishing a healthy routine with clear instructions and rules [34]. Modules are described in Table S1 in Multimedia Appendix 1.

XSL•FO
RenderX

Figure 2. A display of a vignette in ParentText on a smartphone screen.

Initial piloting of ParentText in South Africa found low participant engagement, with the reported proportion of participants accessing the content delivered across four topics ranging from 20% (20/96) to 28% (27/96) of the sample [38]. Based on results from the pilot evaluation, the chatbot was subsequently revised to enhance the user experience by incorporating personalization features and adding tools to improve usability and support ongoing engagement [39]. ParentText is also being tested in the preschool system in Malaysia and the social welfare system in Mexico [40]. Delivery in South Africa was intended to support positive parent–adolescent relationships and prevent HIV risk behaviors as a key component of the CHAMP project.

Measures of Behavioral Determinants

Existing literature and the DHEM guided the instrument development used to measure behavioral determinants and intention to use. While previous studies have identified

XSL•FO
RenderX

associations between behavioral determinants (ie, perceived usefulness, perceived ease of use, attitude, hedonic motivation, habit, price value, and social influence) with intention to use [7,41-43], we found no existing questionnaires that specifically assess the behavioral determinants of potential users in the context of a chatbot-led parenting intervention. For this reason, we developed a questionnaire to measure caregivers' perceptions specific to the chatbot and their general usage frequency of WhatsApp, the platform on which ParentText was hosted. Given WhatsApp's role as a communication tool, caregivers' frequency of use can offer insights into its usability within their social networks (eg, family, neighbors, and friends).

The behavioral determinants and intention to use questionnaires consisted of 16 questions that were tested with the local research team for improved contextualization and translation. The outcome intention to use was assessed using two separate items that asked caregivers about their intention to use ParentText in the future and their intention to spend their mobile data to use ParentText. Both items were rated on a Likert scale ranging from 0 (strongly disagree) to 4 (strongly agree). Behavioral determinants were assessed using 14 items across seven domains derived from the Technology Acceptance Model and its extensions [17,19]. Perceived ease of use was measured using two items assessing caregivers' perceived understanding and capacity to interact with the chatbot. Perceived usefulness was measured using seven items (eg, "I think that ParentText would help me learn how to manage my child's behavior"). The remaining five domains, attitude toward use, hedonic motivation, price value, habit, and social influence, were each measured using a single item. All 16 items were rated on a Likert scale ranging from 0 (strongly disagree) to 4 (strongly agree). The items are described in Table S2 in Multimedia Appendix 2.

Covariates such as age, gender, and financial efficacy (ie, how confident caregivers are in their ability to manage their finances) were also assessed prior to administering the determinants and intention questionnaire. The choice of covariates was based on previous research reporting that age, gender, and financial status are associated with users' intentions to use DHIs [44-46]. In all questions, participants were given the option to select the response, "I do not want to answer." All measures (Table S2 in Multimedia Appendix 2) and ParentText content were translated from English into isiZulu and siSwati, the local home languages spoken by participants adopting back-translation procedures.

Moderators

Moderators included age, absence of the father in the house, financial efficacy, anxiety, depression, and stress. Age was measured in years, and the absence of the father in the house was a binary variable (yes and no). Financial efficacy was measured on a scale ranging from "not at all true" (0) to "exactly true" (3). Stress was measured using the parental stressors subscale (6 items) of the Parental Stress Scale on a scale of 0 to 20 and anxiety and depression using the 4-item Patient Health Questionnaire on a scale ranging from 0 to 12 [47,48].

Statistical Analyses

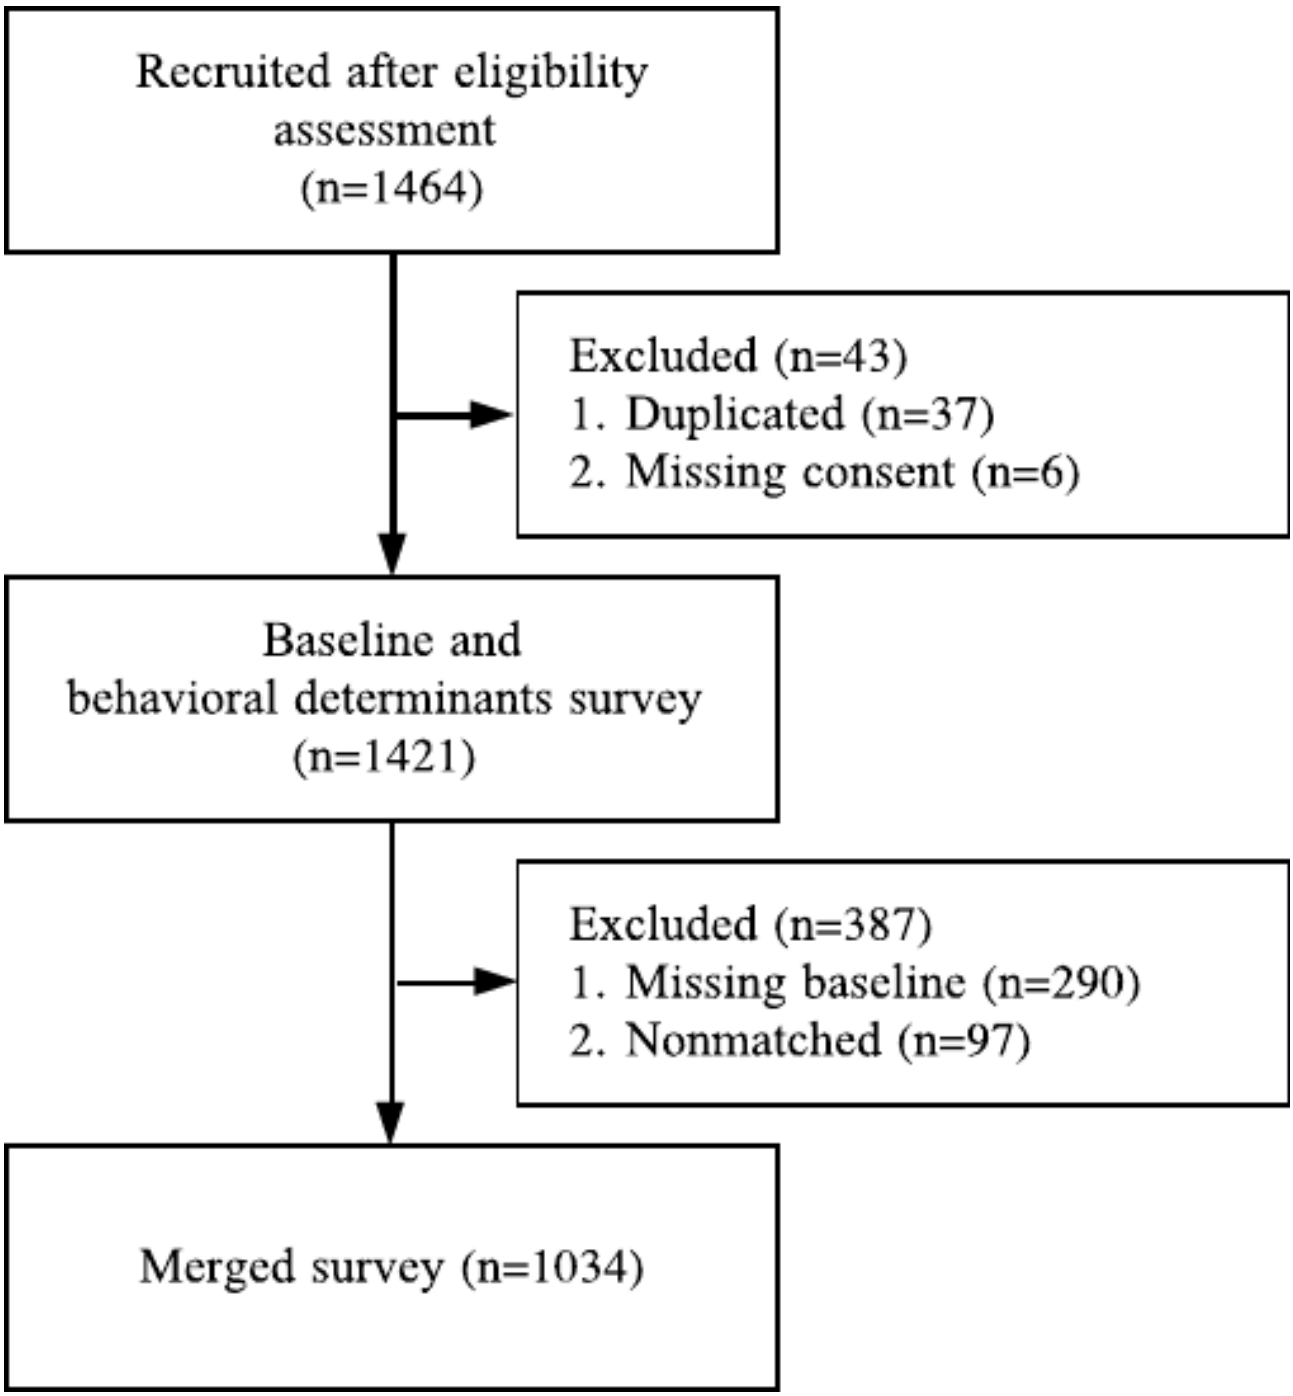
Data analysis was conducted using RStudio (R version 4.2.2) and Visual Studio Code (Python version 3.10.6) software. Missing data accounted for a maximum of 10% for predictor (n=91) and outcome (n=108) variables and was replaced using multiple imputation-chained equations following Graham and colleagues' recommendations [49]. Imputation was conducted using fully conditional specifications, predictive mean matching for numeric data, and polytomous regression for multicategory data. Twenty interactions were used to refine imputations, with five imputations created accounting for clustered standard errors. Beesley's stacked approach was conducted on the imputed datasets for weighing models and clustered standard errors to account for the between-cluster variance across the 32 clusters in the study [50]. Descriptive data was presented using frequencies and percentages for categorical variables and means and standard deviations for numeric variables.

To explore the factor structure of the behavior determinants measure, reliability analysis was performed on the extracted factors using Cronbach α and omega coefficients to assess the overall consistency, with $\alpha>.70$ representing high reliability, $.35>\alpha<.70$ representing medium reliability, and $\alpha<.35$ representing low reliability [51]. A collinearity test was conducted using Pearson's correlations and variance inflation factor (VIF), with VIF <1 representing no multicollinearity, 1>VIF <5 representing moderate collinearity, and VIF >5 representing high multicollinearity [52]. We also conducted principal component (PC) analysis to ensure that factors in the overall behavioral determinants composite construct contributed equally to it. PC analysis used individual scores of five factors (ie, attitude, hedonic motivation, habit, price value, and social influence) and the perceived usefulness (from 0 to 28) and the perceived ease of use (goes from 0 to 8) aggregate scores.

Next, to investigate how behavioral determinants and intentions to use are associated, ordered logistic regression models were applied to test for the predictive significance of behavioral determinants on both outcomes assessing caregiver intention to use ParentText. All four models (multivariable models with individual behavioral determinants and univariate models with the composite construct) included covariate adjustments for age, gender, and financial efficacy to account for confounding effects. Finally, to test the moderating effect of individual-level sociodemographic and psychosocial characteristics (ie, caregiver age, presence of the father in the house, financial efficacy, caregiver anxiety and depression, and caregiver stress), models with interactions between moderator and overall behavioral determinants construct were conducted. Results reports followed the Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (CONSORT-EHEALTH) checklist [53].

Ethical Considerations

Ethics approval for the study was granted by the University of Cape Town Center for Social Science Research Ethics Committee (reference: CSSR 2023/05), the University of Oxford Social Sciences and Humanities Interdivisional Research Ethics Committee (reference: R88177/RE001), and the Mpumalanga Department of Health and Department of Social Development (reference: R69569/RE003) [34]. Participants provided written informed consent prior to completing paper-based baseline surveys and were offered 50 ZAR internet bundles



XSL•FO
RenderX

(approximately US $2.60) as an incentive to participate in the study [34]. Deidentified data sets were stored securely in a password-protected server at the University of Oxford and paper-based surveys stored by the m2m South Africa office in compliance with the South African Protection of Personal Information Act [34].

Results

Out of the 1464 caregivers recruited for eligibility, 1034 were included in this study with matched baseline demographic and behavioral determinant surveys (Figure 3).

Figure 3. Study recruitment.

Caregiver Baseline Characteristics

Participating caregivers were predominantly female (94%, 974/1034), and the average age was 38 years (SD 9). Almost two-thirds reported that they were in a relationship (64%, 665/1034). Reported paternal absence rates were 51% (537/1034), which were slightly below the national South African average (58%) [47]. Most caregivers were the biological parent (81%, 847/1034), and 10% (125/1034) reported that the adolescent girl in their care was a paternal orphan (Table 1).

Female	1,034 (100.0)
Adolescent school enrollment (ie, school year), n (%)	
Grade 4 - 9	867 (83)
Grade 10 - 12	167 (16)
Caregiver anxiety and depression, mean (SD)	3.39/12 (3.21)
Caregiver stress, mean (SD)	8.60/20 (4.21)

[a]Partnered refers to married, civil, or noncivil partnership status.

[b]Higher values imply greater capacity to manage finances.

[c]Families where the father passed away or lives elsewhere.

[d]Includes caregiver-reported cognitive, learning, auditory, visual, physical (any motor limitations and difficulties in performing self-care activities such as getting dressed), and functional disabilities (any pre-existing non-communicable health conditions such as diabetes, cardiovascular disease, and cancer).

Descriptives of Behavioral Determinants and Intention

Caregivers reported a mean score of 2.99 (SD 0.55) out of 4 on their perceived usefulness of ParentText, a mean of 3.02 (SD 0.67) on their enjoyment, and a mean of 2.86 (SD 0.77) on perceived ease to interact with the chatbot. They also reported a mean of 2.91 (SD 0.70) on their perceptions that their peers and family would support them using ParentText and a mean of 2.81 (SD 0.78) on how worthwhile they believed it was to spend mobile data on the chatbot. The mean attitude of caregivers toward DHIs such as ParentText was 3.05 (SD 0.68) and WhatsApp usage habits was 2.76 (SD 0.85). Respondents also reported a mean of 2.85 (SD 0.79) and 2.90 (SD 0.72) regarding their intention to use their mobile data and to continue using ParentText in the future, respectively.

Psychometric Properties of Behavioral Determinants Measure

Principal Component Analysis

Results indicate that all seven items loaded relatively equally on the first PC, which accounted for 52% of the total variance of the overall behavioral determinant construct (52% PC1, 13% PC2, 9% PC3, 7% PC4, 6% PC5, 5% PC6, and 4% PC7). Using the scores from PC1, a summary composite score across all four subscales ranging from 0.67 to 18.64 was generated and used in the regression models (Table S3 in Multimedia Appendix 3).

Reliability Tests

The overall reliability of the instrument exceeded the acceptable threshold (α=.90; 95% CI 0.89 - 0.90; Ω=0.91). Reliability results for perceived usefulness, as measured by the α and omega coefficients, were also above 0.70 and thus considered high (Table S4 in Multimedia Appendix 3).

XSL•FO
RenderX

Association Between Behavioral Determinants and Intention to Use

Higher levels of overall behavioral determinants were positively associated with higher caregiver intention to use ParentText (intention to use in the future: odds ratio [OR] 1.85, 95% CI 1.81 - 1.90 and intention to use mobile data: OR 1.76, 95% CI 1.72 - 1.81; Tables 2 and 3). Individual behavioral determinant measures (ie, perceived usefulness and ease of use, attitude, hedonic motivation, habit) also emerged as positive predictors of both intention outcomes (Tables 2 and 3). Price value and perceived ease of use were not significantly associated with intention to use, while social influence was not significantly associated with intention to spend mobile data. The results of goodness-of-fit (Table S6 in Multimedia Appendix 3) indicate pseudo-R^2 values ranging from 17% to 37% in the overall behavioral determinants model and from 16% to 33% in the models with individual behavioral determinants, suggesting that the respective changes in the caregiver's intentions to use ParentText are well explained by all predictors. VIF indicated collinearity ranging from 1.02 to 2.95 (Table S5 in Multimedia Appendix 3). Tables S7 and S8 in Multimedia Appendix 3 report the results of multivariable logistic models conducted on unimputed data for sensitivity analysis.

Table . Multivariable logistic regression results testing associations between behavioral determinants and intention to use ParentText in the future[a].

Independent variable	OR[b]	95% CI	*P* value
Overall behavioral determinants	1.85 (0.01)	1.81 - 1.90	<.001
Perceived usefulness	1.10 (0.00)	1.08 - 1.12	<.001
Perceived ease of use	1.00 (0.02)	0.96 - 1.04	.99
Attitude	1.67 (0.03)	1.60 - 1.75	<.001

[a]Note: All models included covariate adjustments for age, gender, and financial efficacy. Clustered standard errors in parentheses.
[b]Odds ratio.

Moderator Analyses

Moderator analysis suggested more relevance of behavioral determinants in predicting caregivers' intention to use in families where fathers were absent (OR 2.03, 95% CI 1.79 - 2.41) than those where fathers were present. A greater relevance of behavioral determinants in predicting caregivers' intention to use was observed among caregivers experiencing higher levels of stress compared to those with lower stress levels (OR 1.09, 95% CI 1.05 - 1.14). Behavioral determinants were also more relevant in predicting intentions to spend mobile data among older caregivers in comparison to younger caregivers (OR 1.04, 95% CI 1.03 - 1.05), financially stressed families in comparison to those more financially stable (OR 0.38, 95% CI 0.30 - 0.48), and in families where fathers were absent in comparison to those where fathers were present (OR 2.34, 95% CI 2.01 - 2.72). No moderating effects were observed on baseline levels of caregiver anxiety and depression (Table 4).

Discussion

Evidence From the Theoretical Framework

Our findings highlight the positive associations between overall behavioral determinants and caregivers' intention to use the parenting chatbot, underscoring the strength of the composite construct in effectively capturing the seven underlying domains. For each one-unit increase in the overall behavioral determinants score, the odds of caregivers intending to spend mobile data on ParentText were 76% higher and the odds of intending to use ParentText in the future were 85% higher, compared to caregivers with lower scores. Similarly, individual behavioral determinant domains were also associated with intention, offering more nuanced insights into the context in which the chatbot was implemented.

Results demonstrated that perceived usefulness, attitude, and hedonic motivation were positively associated with intention to use, aligning with theory and with findings from previous research that reported such factors as positive predictors of intention to use [54,55]. Findings indicating positive associations between price value (ie, the perception that the chatbot was worth spending mobile data on) and intention to spend mobile data (Figure 4) warrant further discussion. Participants' prior knowledge that they would receive internet bundles to use ParentText may have influenced these observed positive associations. In low-income contexts such as rural and peri-urban South Africa, perceiving the value of ParentText and having a positive attitude toward DHIs may have influenced the intention of caregivers to use their data to interact with the chatbot instead of spending it on something else. There is ambiguity on the associations of financial cost to accessing a DHI with participants' intention to use, as some studies report negative [44,56], while others report no associations [57]. Our findings suggest that access to the internet, which, in the context of our study, has financial implications, may increase the acceptance of DHIs within low-income households.

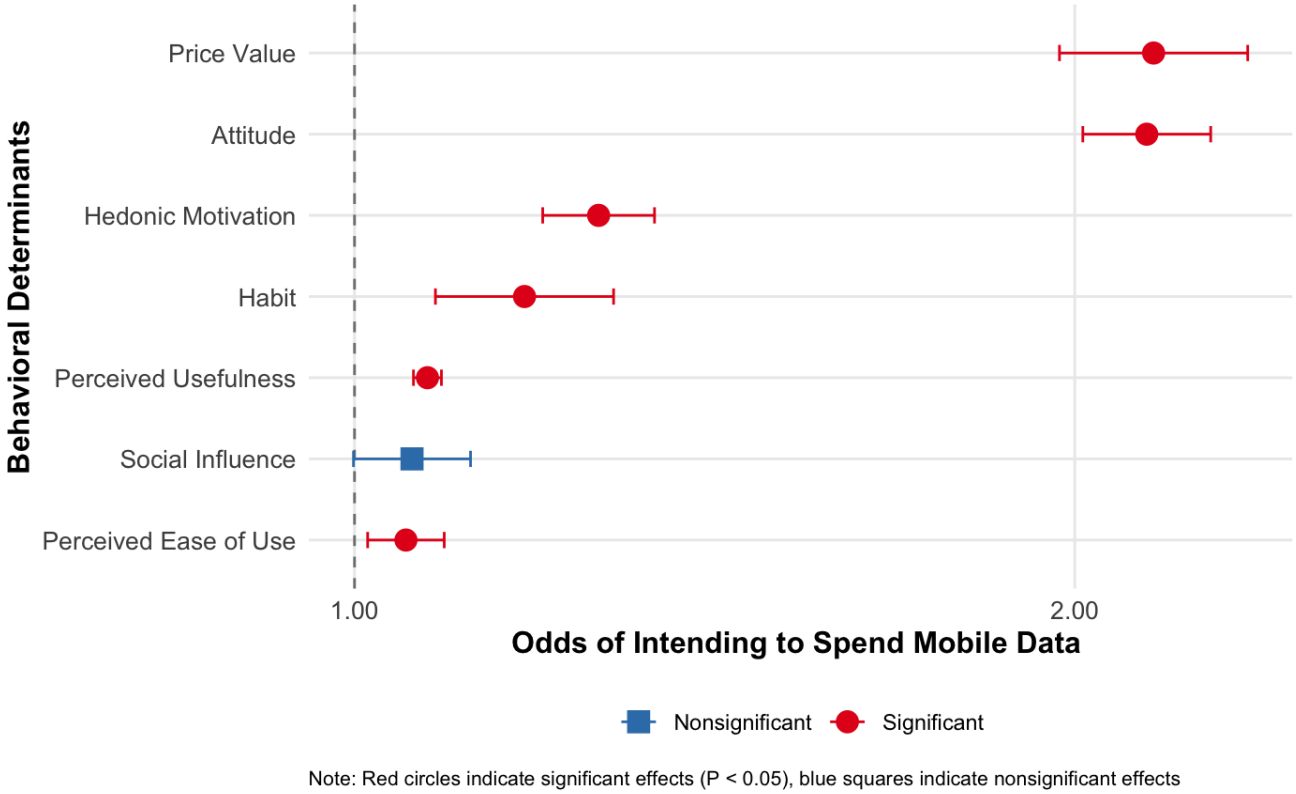
RenderX

Figure 4. Forest plot of logistic regression coefficients testing associations between behavioral determinants and intention to spend mobile data to use ParentText in the future.



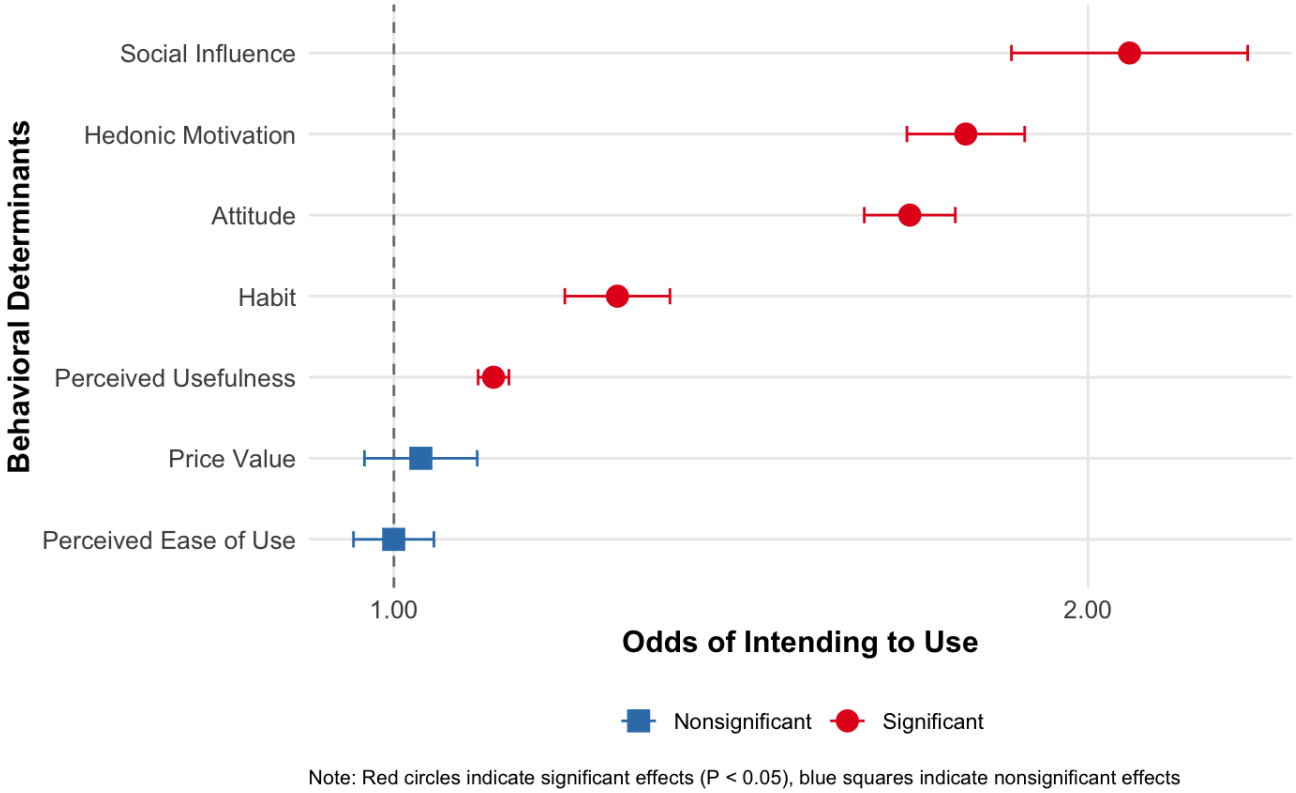


Figure 5. Forest plot of logistic regression coefficients testing associations between behavioral determinants and intention to use ParentText in the future.

Social influence, found in previous research to be associated with intention to use a DHI [57,58], was also positively associated with caregivers' intention to use ParentText (Figure 5,5), as measured by agreement with the statement, "People who are important to me think that digital tools such as ParentText could support me as a parent." In this study, participants responded to the questionnaire while in a group setting during onboarding, during which they may have been

XSL•FO
RenderX

aware of other caregivers' intentions toward using ParentText. Those factors may have positively influenced caregivers' impressions that their family and peers would support their usage of ParentText. In addition, results indicating positive associations between WhatsApp usage habits and intentions to use ParentText suggest the potential efficacy of adopting the most used and familiar communication platforms among potential DHI users to increase user acceptance.

Implication of Results in the South African Context

Our findings suggest that caregivers in South Africa who were introduced to the ParentText chatbot had positive intentions to continue to use it. Overall behavioral determinants became more relevant in predicting caregivers' intention to spend mobile data among families with older caregivers, families where the father was absent, and families that were less financially stable. These findings suggest that families with older caregivers, without fathers, or with greater levels of financial stress may require more structural support to engage in DHIs than those with younger caregivers, where fathers are present, and that are more financially stable. Therefore, there is great value in engaging fathers when delivering parenting chatbots, as previous research has reported their important role in families' health and well-being [59].

Study Strengths and Limitations

This study contributes to advancing the cycle of better development and implementation of DHIs by introducing a framework and a composite construct that explains the holistic role of behavioral determinants of engagement. In contexts where collecting data on all individual behavioral determinants is not feasible, the composite construct provides a practical alternative, allowing for the use of fewer items while still effectively capturing the multidimensional factors that influence users' intentions to engage with DHIs. Even though we could only investigate individual- and interpersonal-level factors and caregivers' personal impressions of community-level factors, their integration in the development and implementation stages can support good practices and help maximize DHI uptake.

Several limitations should be considered when interpreting our findings. First, selection bias may have influenced the results, as participants were caregivers already enrolled in the CHAMP program and owned WhatsApp-enabled phones, potentially representing a tech-savvy and intervention-positive subset of the population. Second, intention scores might have been skewed, as participants may have reported more positive intentions due to the provision of internet bundles, thereby confounding our results. Third, the cross-sectional design limited our ability to examine causal relationships between behavioral determinants and intention to use. Fourth, the behavioral determinants measurement did not capture policy-level enablers (eg, internet access, electricity), nor did we measure the participant's intention to spend time on the chatbot. Lastly, while we conducted face validity and tested the reliability of the behavioral determinant measures, we were unable to assess other types of validity due to the limited capacity of our research team.

Future Directions

Future research could employ a longitudinal or experimental design to investigate the relationships between behavioral determinants and intentions. It should also investigate how behavioral determinants and intentions are associated with engagement because a broader understanding of this pathway greatly supports efforts to improve the deployment of DHIs. Studies should also assess the construct, criterion, and content validity of the behavioral determinants and intention measurements and investigate the factors at the policy and institutional levels. Lastly, it is also essential to further investigate factors that are associated with positive intentions toward DHIs among those facing stress.

Conclusions

To the best of our knowledge, this is the first study to investigate how behavioral determinants of engagement are associated with the intention to use a parenting chatbot delivered in a low- and middle-income context. In conclusion, we recommend that developers and implementation scientists emphasize the value and quality of the DHIs while targeting aspects that enhance receptivity to social influence. Efforts to minimize network connection costs could also be provided through internet hotspots. The perception of affordability can trigger the sense that an individual is getting a good deal, which consequently leads to positive intentions. Similarly, implementation strategies that incorporate collaboration with community partners can foster positive normative influences toward DHIs, potentially leading to more favorable intentions toward use. The adoption of the most used communication platforms can also be prioritized to support positive intentions among potential users of chatbot-led interventions. While these early-stage findings suggest that chatbots may be effective platforms for overcoming barriers to accessing in-person programs in real-world settings, the generalizability of these results to other contexts remains uncertain.

Acknowledgments

The authors are grateful for the support received from mothers2mothers South Africa, Clowns Without Borders South Africa, Zoë-Life South Africa, the University of Cape Town, the Global Parenting Initiative, and all funders and partners who contributed to the implementation of this study. Similarly, the authors extend appreciation to the families and the community of Mpumalanga for participating in the study. This study is part of the Global Parenting Initiative, which is funded by The LEGO Foundation and Oak Foundation. This study also benefited from funding from the United States Agency for International Development (72067418CA00026) as part of the mothers2mothers South African Children and Adolescents Are My Priority project.

Data Availability

The datasets in this study are not currently publicly available due to ongoing analyzes. They will be made available via the Open Science Framework registration of the ParentText Optimization Study [60] upon study completion. In the interim, datasets are available from the principal investigators upon reasonable request.

Authors' Contributions

Conceptualization, development of the behavioral determinants of engagement survey, and creation of the behavioral determinants construct and digital health engagement model: MDGA; data curation: MDGA, JS, and SL; formal statistical analysis: MDGA; project implementation: AS, KB, SL, PZ, JS, ZM, HG, LM, DS, MDGA and CF; methodology: MDGA, GJMT, SV, FG, and JML; writing–original draft: MDGA; writing–review and editing: MDGA, SV, JML, and FG.

Conflicts of Interest

JML is the CEO and LM is the Chief of Solutions for Parenting for Lifelong Health (PLH), a charitable organization based in the United Kingdom that developed the ParentText, which is open access, licensed under a Creative Commons 4.0 Attribution Share-Alike license. JML has (and is participating) participated in several research studies involving the program, as an investigator, and the University of Oxford and University of Cape Town receive research funding for these. MDGA, JS, SL, ZM, FG, SV, HS, PZ, LM, and GJMT worked on other studies by PLH. The investigators will not benefit from any financial gains from implementing and disseminating this intervention. KB worked for Clowns Without Borders South Africa, a South African–based nonprofit organization responsible for providing capacity training and technical support on the delivery of PLH programs in Africa. The sponsor and funders did not influence any stage of the study design and were not involved in any stage of execution, data analysis, and dissemination of the study.

Abstract

Background: Children with developmental language disorder (DLD) often experience language difficulties that hinder their ability to acquire emotional competence. Poor emotional competence is associated with emotional and behavioral problems in young children.

Objective: This research involved two studies focusing on (1) the emotional competence of Mandarin-speaking children aged 5 to 7 years with DLD and (2) the efficacy, feasibility, and acceptability of a tele-intervention designed to enhance their emotional competence in Taiwan.

Methods: Five children with DLD from study 1 declined to participate in study 2, the emotional competence tele-intervention, and were excluded from the analysis. We compared the emotional competence of 20 Mandarin-speaking children with DLD to that of 24 children with typical language development (TLD). The children with DLD were, on average, aged 5.79 (SD 0.47) years, whereas the children with TLD were, on average, aged 5.93 (SD 0.31) years. We assessed the children's emotional competence, nonverbal ability, verbal comprehension, vocabulary acquisition, and expressive language skills. In study 2, all children with DLD included in study 1 engaged in an emotional competence tele-intervention. An interrupted time-series design was used to examine their emotional competence. In total, 20 children with DLD provided data on emotional competence evaluated using the Emotional Lexicon Test. These data were individually collected at 3 time points after study 1 (time 1). These phases included baseline (time 1 to time 2), during the tele-intervention (time 2 to time 3), and follow-up (time 3 to time 4), spanning approximately 18 to 20 weeks from time 1 to time 4. Recruitment, retention, and attendance rates were calculated to evaluate the intervention's feasibility, and participant mood was evaluated after each session to calculate the intervention's acceptability.

Results: No significant changes in the children's ability to understand basic or complex emotional terms were observed during the baseline period. However, changes were observed during the tele-intervention period, and these changes remained throughout the follow-up period. With a recruitment rate of 80% (20/25), all participants completed 4 intervention sessions, with retention and attendance rates exceeding 95% (19/20). A total of 90% (18/20) of the participants deemed each session to be acceptable.

Conclusions: Mandarin-speaking children aged 5 to 7 years with DLD exhibited lower emotional competence compared with their counterparts with TLD. Tele-interventions are effective in enhancing the emotional competence of children with DLD, demonstrating feasibility and acceptability for these children and their parents in Taiwan.

Introduction

Background

According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) [1], language disorder (ie, developmental language disorder [DLD]) is a communication disorder that broadly refers to childhood language difficulties and is not associated with any known biomedical condition [2,3]. These language difficulties can hinder children's acquisition of emotional competence, including their understanding of the nature and causes of emotions, their own feelings, their physiological reactions to these feelings, and their cognition surrounding an emotion or emotive event [4-7]. Language is strongly associated with emotional competence, as evidenced in our use of prosody to interpret emotional cues, recognize emotions, and understand what others may feel in various situations [8]. When children experience communication difficulties, their opportunities for social learning diminish, making conversations harder to process, misunderstandings more likely, and participation in discussions or play activities more challenging, which can, in turn, hinder their emotional competence [9]. Language also provides access to mental terms such as *think* and *happy*, which help children mentalize and help them identify, understand, express, and regulate their emotions [10]. These capabilities facilitate social interactions and indirectly aid in understanding the mental states of others [11]. Therefore, children with language acquisition difficulties tend to struggle with using these mental terms to learn the emotional or cognitive aspects of theory of mind. Notably, verbal interactions with caregivers play a key role in the development of emotion regulation skills, primarily because discussing emotions helps children connect their emotions to events and learn how to manage these emotions [12]. As children with DLD grow, they struggle to develop the capacity to internally regulate their emotions, with language playing a crucial role in self-reflection, response inhibition, and guiding behavior [13]. Furthermore, in young children with typical language development (TLD), poor emotional competence has been shown to be associated with emotional and behavioral problems [14].

Previous research examining the emotional competence of children with DLD and children with TLD has rarely focused on children who speak Mandarin as their native language [4,11,15]. If studies indicate that the emotional competence of Mandarin-speaking children with DLD lags behind that of their peers with TLD, as is the case for non–Mandarin-speaking children with DLD, this finding will support the presence of cross-linguistic and cross-cultural consistency in the emotional challenges faced by children with DLD. In children with developmental delays, speech and language delays are the most common disabilities [16]. DLD is a highly prevalent neurodevelopmental disability in Mandarin-speaking children [17,18], highlighting the importance of focusing on the emotional competence of this population. Therefore, further research is needed to evaluate the emotional competence of Mandarin-speaking children with DLD and determine whether early intervention is necessary.

Tele-interventions constitute a promising tool that offers a timely, accessible, and cost-effective solution for overcoming barriers to medical service delivery, such as transportation issues, shortage of skilled therapists, and insufficient facilities in rural areas [19]. This approach is particularly significant given that the special needs of children with DLD living in rural areas are often less adequately addressed than those of children living in urban areas [20]. Adopting tele-practice for early interventions holds great potential to address these disparities and support the development of emotional competence in children with DLD in underserved rural areas [19]. In Taiwan, the procedures, advantages, and challenges associated with implementing such interventions remain unclear. Therefore, in this study, we examined the efficacy, feasibility, and acceptability of emotional competence tele-interventions designed for Mandarin-speaking children with DLD in Taiwan.

Multiple studies have indicated that social stories are an effective means to help children acquire emotional knowledge [21-23]. Social stories have been widely used in clinical practice for children with autism spectrum disorder (ASD) [24]; however, the application of these stories for children with DLD remain understudied. To the best of our knowledge, few studies have focused on children with pragmatic language impairments [25], language impairments [26], and pragmatic disorders with behavioral difficulties [24]. Among the key factors that contribute to the efficacy of a social story is the display of the protagonist's emotional state and social interactions [27], along with labeling affective, physical, and perceptual changes with words describing the protagonist's mental state. These labels help children understand that different experiences can fulfill the same function as long as these experiences are perceived as having the same meaning [28]. The use of visual aids such as pictures or videos can enhance the emotional representation of potential causes, subjective feelings, physiological responses, and cognition during social interactions [29]. Thought bubbles can also be used to clarify the protagonist's emotional state and thoughts within the social context [30,31]. Hence, emotional competence interventions conducted using social stories through remote interfaces, also referred to as social story tele-interventions (SSTIs), are expected to enhance the emotional competence of children with DLD.

Objectives

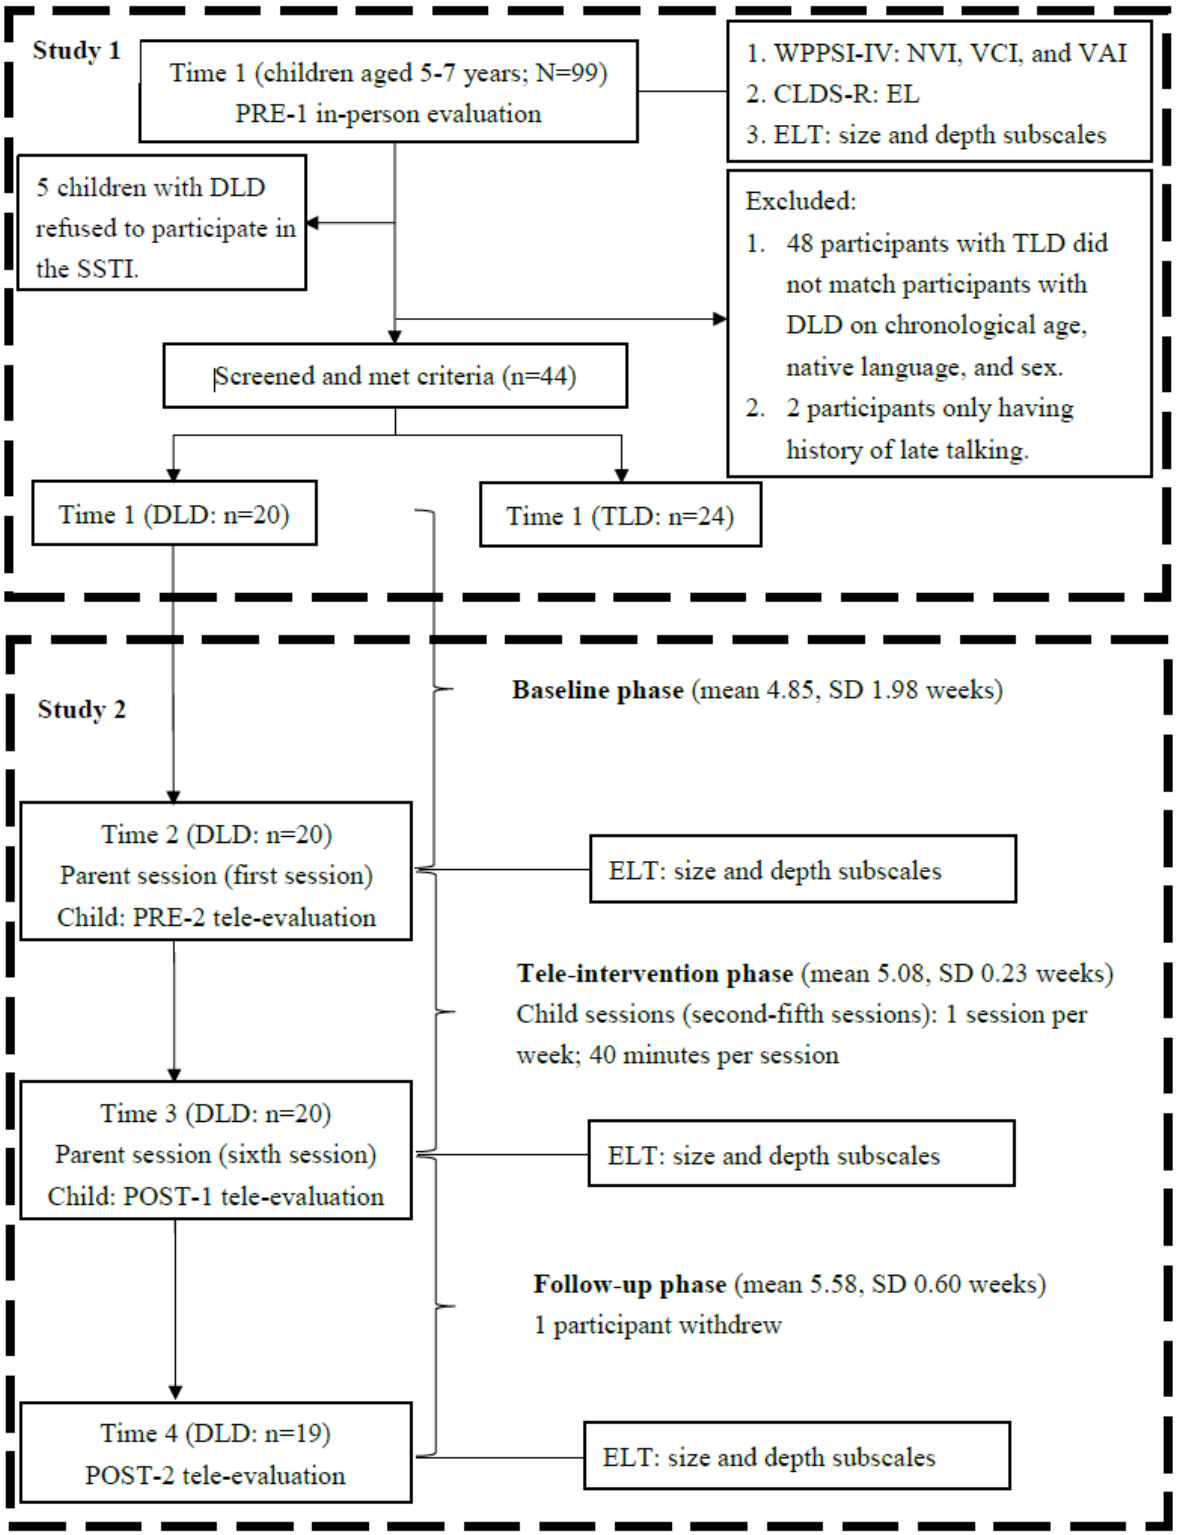
Preschool and early elementary school are critical periods in the development of a child's emotional competence; the child learns about self-regulation, and their level of emotional competence determines the severity and likelihood of behavioral problems [32,33]. In this research, we examined children in kindergarten and early elementary school. A total of 2 studies were conducted to explore 3 research questions. In study 1, our goal was to determine whether Mandarin-speaking children with DLD in Taiwan differ from those with TLD in emotional competence. We compared Mandarin-speaking children with

XSL•FO
RenderX

DLD to those with TLD in terms of the size and depth of their understanding of emotional terms at the ages of 5 to 7 years. We hypothesized that Mandarin-speaking children aged 5 to 7 years with DLD would exhibit lower performance in the size and depth of their understanding of emotional terms compared with their counterparts with TLD even with family language characteristics such as maternal educational level accounted for. In study 2, we used an interrupted time-series design to explore two questions: (1) Do SSTIs enhance the understanding of emotional language by Mandarin-speaking children aged 5 to 7 years with DLD relative to their baseline performance (ie, before the intervention)? (2) Are SSTIs a feasible and acceptable intervention for these children in Taiwan? We hypothesized that SSTIs would enhance the emotional competence of Mandarin-speaking children aged 5 to 7 years with DLD and that this tele-intervention would be both feasible and acceptable for them and their parents in Taiwan.

Study 1

Methods



This case-control study was conducted to compare the emotional competence of children with DLD to that of children with TLD.

Participants

A total of 99 children aged 5 to 7 years were recruited from parenting websites and local pediatric clinics in northern and central Taiwan. Figure 1 shows the process of recruitment in study 1. Children with DLD meeting the following matching criteria were included in the study: being within 3 months of the specified age range, having Mandarin Chinese as their native language, and being of the same sex as their matched counterparts. If >1 participant with TLD met these criteria and could be matched with a participant with DLD, they were all included in the analysis. A total of 48 participants with TLD who did not meet the aforementioned criteria and who completed only the in-person evaluation at the preintervention 1 time point (time 1) were excluded from the final analysis. In addition, 2 participants with only a history of late talking who also completed only the in-person evaluation at the preintervention 1 time point (time 1) were excluded from the final analysis. A total of 5 parents refused to participate in the subsequent tele-intervention program. Therefore, of a total of 25 parents of children with DLD, only 20 (80%) participated. Furthermore, ultimately, 44 children were included in the final analysis in study 1: 20 (45%) in the DLD group (mean age 5.79, SD 0.47 years) and 24 (55%) in the TLD group (mean age 5.93, SD 0.31 years).

Figure 1. Flowchart of study 1 and study 2. CLDS-R: Child Language Disorder Scale–Revised; DLD: developmental language disorder; EL: expressive language; ELT: Emotional Lexicon Test; NVI: Nonverbal Index; POST-1: postintervention time point 1; POST-2: postintervention time point 2; PRE-1: preintervention time point 1; PRE-2: preintervention time point 2; SSTI: social story tele-intervention; TLD: typical language development; VAI: Vocabulary Acquisition Index; VCI: Verbal Comprehension Index; WPPSI-IV: Wechsler Preschool and Primary Scale of Intelligence, Fourth Edition.

All participants with DLD had received a diagnosis based on the *DSM-5* criteria at the Early Developmental Evaluation Center, the official institution designated by the Ministry of Health and Welfare of Taiwan for identifying and evaluating children with developmental disorders before the age of 7 years. In Taiwan, the gold standard for diagnosing DLD requires confirmation through a converging evidence approach [34], which includes the assessment of delays in receptive and expressive language by board-certified speech and language pathologists using parental reports, standardized tests, and clinical observations. Clinical psychologists are required to confirm the absence of cognitive delays, and child psychiatrists and pediatric neurologists are required to determine whether any observed language delays are due to other

XSL•FO
RenderX

neurodevelopmental (eg, ASD) or neurological (eg, epilepsy) disorders. Establishing a DLD diagnosis through a converging evidence approach in clinical assessments and decision-making scenarios by medical professionals should be considered the gold standard. Participants with TLD had no known developmental or cognitive impairments.

Measurement

Family Characteristics

Data on family characteristics, including paternal and maternal mean age, paternal educational level and marital status, monthly family income, and number of siblings of the child participant, were collected from parent reports.

Child Characteristics

Data on child characteristics, including age, sex, developmental risk factors, and medical diagnoses, were also collected from parent reports. To confirm that the children met the inclusion criteria, their parents provided an early intervention assessment report issued by the Ministry of Health and Welfare. Among the developmental risk factors considered in this study were biological factors (eg, premature birth, low birth weight, genetic disorders, perinatal complications, and neurological conditions) and medical factors (eg, chronic diseases, infectious diseases, and hearing or vision impairments).

Evaluation of Nonverbal Ability

Nonverbal ability was measured using the Mandarin Chinese version of the Nonverbal Index (NVI) of the Wechsler Preschool and Primary Scale of Intelligence, Fourth Edition [35]. The NVI has an internal consistency reliability of 0.94 to 0.96 across various age groups and a test-retest reliability of 0.85 [35].

Evaluation of Language Abilities

A total of 3 dimensions of language abilities were evaluated: verbal comprehension, vocabulary acquisition, and linguistic expressivity. Verbal comprehension and vocabulary acquisition were evaluated using the Mandarin Chinese versions of the Verbal Comprehension Index (VCI) and Vocabulary Acquisition Index (VAI), respectively, of the Wechsler Preschool and Primary Scale of Intelligence, Fourth Edition [35]. The VCI and VAI have internal consistency reliability levels of 0.92 to 0.94 and 0.84 to 0.92, respectively, and both have a test-retest reliability of 0.86 [35]. Expressive language ability was evaluated using the Mandarin Chinese version of the Child Language Disorder Scale–Revised (CLDS-R) [36]. This subscale evaluates expressive language skills across multiple domains. These domains include (1) the ability to retrieve vocabulary or construct short phrases or sentences in response to questions that evaluate knowledge (eg, functions, general information, and analogies) acquired in the classroom and from one's lived environment; (2) phonological working memory, measured through sentence repetition tasks in which children verbally recall sentences of increasing length and grammatical complexity; and (3) narrative skills, evaluated through spontaneous image description and story retelling tasks with or without the aid of sequenced images. The internal consistency reliability of each CLDS-R subscale across different age groups ranges from 0.80 to 0.96, with a test-retest reliability ranging from 0.92 to 0.98 [36].

Evaluation of Emotional Competence

Emotional competence was evaluated using 2 subscales from the Emotional Lexicon Test (ELT) [37]: a depth subscale and a size subscale. Illustrations were drawn without displaying the facial expression of the protagonist to avoid influencing the children's responses. The depth subscale was used to evaluate the depth of understanding of basic emotional terms (BETs) and complex emotional terms (CETs). After the examiner read a story, they asked each child to label the emotional state of the protagonist and state the reasons underlying their responses (ie, explain the reasons underlying the protagonist's feelings in this context). This subscale evaluates the ability of children to retrieve emotional terms through a recall mechanism. Responses are rated depending on their quality on a scale with end points from 0 to 2, reflecting the varying degrees of children's understanding of emotional terms. In terms of interrater reliability, this subscale was evaluated by 2 raters, who reported a 95% agreement. Discrepancies in scores were discussed by the 2 raters to reach a consensus. The size subscale was used to evaluate the size of BETs and CETs. After the examiner read a story, they asked each child to determine which of 2 emotional state terms (eg, joyful vs fearful, scared vs ashamed, and delighted vs sad) better described the protagonist's emotional state. This subscale evaluates the ability of children to recognize emotional terms through a recognition mechanism. Each correct recognition response is assigned a score of 1 point, indicating the size of the child's emotional lexicon. These 2 subscales have been adopted in other emotional lexicon tests [38]. Each subscale consists of 14 cards with short illustrated stories, of which 6 feature basic emotions (joy, sadness, happiness, anger, fear, and disgust) and 8 feature complex emotions (shame, contempt, guilt, hate, envy, jealousy, pride, and loneliness). Hence, the scores on the depth subscale range from 0 to 28 points, and the scores on the size subscale range from 0 to 14 points. Each item in the ELT includes images to convey the story content, which in turn reduces the semantic comprehension load of the participating child. In this study, before the formal items were used, 2 questions and 1 example item were presented to determine whether the children could match the images with the oral content, indicating their understanding of the story. ELT has an adequate to high internal consistency (0.70-0.71) for CETs [39]. Its criterion-related validity scores with the Metacognitive Vocabulary Test and Peabody Picture Vocabulary Test–Revised are 0.80 and 0.74, respectively [40]. In addition, both hard- and soft-copy versions of the ELT were used. The hard-copy version was used for in-person evaluations, whereas the soft-copy version was used for tele-evaluations.

Procedure

After the children arrived at the laboratory with their parents, all parents were informed of the research procedures. All children successfully completed the 2 questions and 1 example item before the administration of the ELT proper, indicating their understanding of the story. All tests were conducted by licensed clinical psychologists and graduate students trained in child psychological assessment.

XSL•FO
RenderX

Ethical Considerations

The study design was approved by the institutional review board of Chung Shan Medical University Hospital in Taiwan (CS2-19046). During the in-person evaluation phase at the preintervention 1 time point (time 1), the researchers outlined the following: (1) study purpose, (2) data handling procedures, (3) privacy measures, and (4) participant rights, including the voluntary nature of participation and withdrawal options. All parents understood and provided their informed consent. This study was conducted in accordance with relevant guidelines and regulations for human participants. Privacy measures included secure data storage with access restricted to research team members only.

Data Analysis

Separate analyses of covariance (ANCOVAs) were conducted to determine the differences in the NVI, VCI, VAI, and linguistic expressivity scores between the 2 groups, with family characteristics used as a covariate. Chi-square and Fisher exact tests were used to compare group proportions with qualitative data for family characteristics (ie, parental educational level and marital status, monthly family income, and whether the child participant had siblings) and child characteristics (ie, sex and presence of developmental risk factors). In addition, a 3-way mixed-model multivariate ANCOVA was conducted, with group (TLD vs DLD) used as the between-group independent variable and emotion (basic vs complex) and understanding (size vs depth) used as the within-group independent variables, with maternal educational level used as a covariate. In case a statistically significant 3-way interaction was observed among group, emotion, and understanding, the simple main effects between TLD and DLD were examined. Effect sizes from ANCOVAs were calculated using the partial η_p^2, which could be directly translated into a percentage of explained variance. Using the basic framework by Cohen [41], we interpreted these effect sizes as small (η_p^2=0.01), moderate (η_p^2=0.06), or large (η_p^2=0.15). We also conducted a post hoc power analysis for ANCOVAs using G*Power (version 3.1.5) for a sample size of 44 participants, with α=.05 [42]. Post hoc power values of >0.8, between 0.6 and 0.8, and <0.6 were considered high, moderate, and low, respectively. All statistical analyses were conducted using SPSS Statistics (version 25.0; IBM Corp).

Results

Participant Characteristics

Table 1 presents the characteristics of the children and their parents in the TLD and DLD groups. Compared with the TLD group, the DLD group had a lower maternal educational level (N=44, χ^2_1=5.4, *P*=.04). Previous studies have found that mothers' educational level is related to children's social, emotional, and academic development [43]. Therefore, we controlled for this variable when conducting the ANCOVAs. However, no differences were observed between the 2 groups (*P*>.05) in terms of child characteristics (ie, mean age, sex, and risk factors) and family characteristics (ie, paternal and maternal mean age, paternal educational level and marital status, monthly family income, and whether the child participant had siblings).

Table 2 presents the NVI, VCI, VAI, and oral expression scores of the TLD and DLD groups during the evaluation at the preintervention 1 time point. No significant difference was observed in the NVI between the 2 groups (*P*>.05), as indicated by the ANCOVA results. However, compared with the TLD group, the DLD group exhibited significantly lower levels of verbal comprehension, vocabulary acquisition, and linguistic expressivity ($F_{1,\ 41}$=17.20, 11.89, and 10.91, respectively; *P*<.001, *P*=.001, and *P*=.002, respectively; η_p^2=0.30, 0.23, and 0.21, respectively; power=0.99, 0.94, and 0.92, respectively).

Emotional Competence Among Children With TLD and DLD

Figure 2 illustrates the size and depth of understanding of BETs and CETs for the TLD and DLD groups during the evaluation at the preintervention 1 time point. It also shows the main effects of emotion (Wilks $\lambda_{1, 41}$=34.17; *P*<.001; η_p^2=0.45; power=0.99) and understanding (Wilks $\lambda_{1, 41}$=72.97; *P*<.001; η_p^2=0.64; power=0.99). A post hoc analysis revealed that BETs outperformed CETs (*P*<.001), with the number of recognized emotional terms being greater than that of recalled emotional terms (*P*<.001). A statistically significant 3-way interaction was observed among group, emotion, and understanding (Wilks $\lambda_{1, 41}$=12.39; *P*=.001; η_p^2=0.23; power=0.66). Simple-simple main effect analysis revealed that the DLD group scored lower than the TLD group in terms of the depth of understanding of BETs and the size and depth of understanding of CETs ($F_{1, 164}$=37.20, 11.48, and 6.54, respectively; *P*<.001, *P*<.001, and *P*=.01, respectively; η_p^2=0.18, 0.07, and 0.04, respectively; power=0.86, 0.43, and 0.26, respectively).

Figure 2. Mean rate of correct answers for basic emotional terms (BETs) and complex emotional terms (CETs) for the typical language development (TLD) and developmental language disorder (DLD) groups during the evaluation at preintervention time point 1 (time 1). The vertical lines represent error bars with 1 SD. The asterisks indicate the significant simple main effects of group, revealing a higher mean rate of correct answers for the TLD group than for the DLD group. **P<.01; ***P<.001.

Discussion

Principal Findings

Few studies have compared the emotional competence of Mandarin-speaking children with DLD to that of children with TLD. In this study, we controlled for child and family characteristics in our research design and statistical analysis while comparing children with DLD and TLD. This approach increased the validity of our findings, indicating a lag between children with DLD and those with TLD in terms of emotional competence. It also enhanced the validity of study 2, which

XSL•FO
RenderX

examined the improvement observed in emotional competence among children with DLD after undergoing a tele-intervention.

The size of understanding of BETs among children aged 5 to 7 years with DLD was similar to that among their counterparts with TLD, indicating that children with DLD can understand basic emotional states in typical social scenarios. However, the depth of understanding of BETs among children aged 5 to 7 years with DLD was considerably lower than that among their counterparts with TLD, indicating that the ability of children with DLD to express their emotions through BETs may be limited. In addition, children with DLD were slower in understanding CETs compared with children with TLD in kindergarten and early elementary school years, indicating the delayed development and mastery of such concepts. Overall, our findings are consistent with those of previous studies [5-7,14,44] indicating that Mandarin-speaking children with DLD also exhibit impaired emotional competence. These findings suggest that the lag observed in emotional competence in children with DLD is a universal characteristic across countries and ethnic groups [45]. These findings underscore the importance of early interventions in improving their conceptual knowledge of emotional states.

In this study, children with DLD exhibited language functioning within the low but normal range, although their scores were lower than those of their peers with TLD. The study explored whether these children experienced delays in their lexical, grammatical, or articulatory development. In study 1, all children had been diagnosed with DLD in accordance with *DSM-5* criteria at the Early Developmental Evaluation Center, an institution designated by the Ministry of Health and Welfare of Taiwan to evaluate developmental disorders in children aged <7 years. Diagnosing DLD through clinical assessments with a converging evidence approach for clinical decision-making is regarded as the gold standard in Taiwan. In this approach, no single method serves as the deciding factor in making diagnostic decisions regarding the receptive and expressive language skills of individuals with DLD. Converging evidence refers to the concept that multiple pieces of assessment data must align and point in the same direction to support a diagnostic decision [34]. In specific test areas, the cutoff score may vary to maximize sensitivity and specificity in identifying those who are at a high risk of developmental problems. Nevertheless, no consensus has been reached regarding the cutoff values for the VCI, the VAI, and the CLDS-R expressive language subscale required for determining whether a child has DLD. In this study, the VCI, the VAI, and the CLDS-R expressive language subscale were used only to evaluate the language capabilities of children with DLD and compare them to those of children with TLD. Our goal was to determine whether the language capabilities of children with DLD lagged behind those of children with TLD, unlike nonverbal capabilities, for which no differences were observed between the 2 groups. Notably, we did not use the VCI, the VAI, or the CLDS-R expressive language subscale for diagnostic purposes in this study.

According to Bishop [46], DLD involves heterogeneous language features. In this study, we examined only the verbal comprehension, vocabulary acquisition, and expressive language capabilities of children with DLD and did not evaluate their speech perception, phonological awareness, or understanding and use of grammar. Therefore, we could not confirm whether children with DLD lag in these language dimensions. In addition, no consensus has yet been reached regarding the definition of DLD in terms of whether receptive or expressive language should be scored at a threshold of <1 or 1.5 SDs in standardized language tests [47]. Of a total of 20 children with DLD, 6 (30%) had received physical therapy, 19 (95%) had received occupational therapy, 18 (90%) had received speech therapy, and 6 (30%) had received psychological therapy, indicating that these children continually underwent systematic and structured interventions implemented by medical professionals to optimize their development during sensitive periods [48-50]. Therefore, although DLD can be qualitatively defined in accordance with the *DSM-5* [1] in medical and research contexts, no consensus has yet been established regarding its quantitative definition, including which tests to conduct and which cutoff criteria to apply. Furthermore, each quantitative definition may have unique implications for specific contexts in different countries or cultures, presumably reflecting the use of different measurement tools and cultural perspectives on children's development and delays [51]. Bishop [46] emphasized the importance of establishing a consensus regarding the quantitative definition of DLD to facilitate cross-linguistic and cross-cultural comparisons of the characteristics, developmental changes, and emotional competence of children with DLD over time.

Conclusions

In this study, low power values were observed for the simple-simple main effects of the size and depth of understanding of CETs. According to Ryou et al [52], a lower power value indicates a higher risk of a type II error, also referred to as a false negative, in which a statistical test does not call for the rejection of the null hypothesis when the alternative hypothesis is true. However, our group comparisons for the size and depth of understanding of CETs were significant, with moderate effect sizes. These comparisons mitigated the risk of type II errors in comparison to scenarios in which group differences were not significant. Therefore, increasing the sample size in future studies may aid in achieving more robust results.

Study 2

Methods

In this study, we used a prospective 1-group interrupted time-series research design situated within the context of a response-to-intervention instructional framework [53]. This study comprised a baseline phase, a tele-intervention phase, and a follow-up phase.

Participants

The same 20 children with DLD who participated in study 1 were included in study 2.

SSTI Characteristics

Intervention Sessions

This 6-week emotional competence tele-intervention comprised 2 sessions for parents (first and sixth sessions) and 4 sessions

XSL•FO
RenderX

for children (second to fifth sessions). In the first parent session, the mechanism of SSTIs designed for children to acquire emotional competence skills was introduced, whereas in the last parent session, the SSTIs and children's emotional competence skills acquired during the sessions and on a daily basis were reviewed. No home practice was offered after the 2 parent sessions, and no children were involved in these sessions. Each child's session included the presence of their parents and comprised the following elements: (1) a parent-child interactive game, that is, the finger trap game; (2) a 4-panel physical story comic; (3) a social story video (Multimedia Appendix 1) played for the participating child 3 times; and (4) a talk practice (retelling, prompting, self-narration, and imitation).

In the finger trap game, each parent places their palm facing down, and each child places their index finger underneath their parent's palm. Once a specific word (eg, *three*) is presented in a series of words (eg, *three*, *four*, *six*, *two*, *three*...), the parent attempts to rapidly close their open palm to catch the child's finger. Two 4-panel physical story comics are presented. The first comic, used in the first and second child sessions, depicts a balloon being blown away by the wind, floating up into a tree, getting caught on a branch, and popping. The second comic, used in the third and fourth child sessions, depicts a clear, sunny day that later turns cloudy and then rains heavily.

The themes and language content of these intervention sessions corresponded to the titles of 4 researcher-edited social story videos, namely, "Great with others," "Play game," "Grab a toy," and "Give a gift." In these social story videos, external causes lead the protagonist to have an emotional experience. The social stories developed in this study included 4 types of mental state terms: cognitive state terms such as *know*; desire state terms such as *want*; perceptual state terms such as *feel*; and basic emotional state terms such as *happy*, *sad*, *angry*, and *fear* [54]. Table 3 presents the mental state terms and their frequencies in each social story. Thought bubbles are used to display the beliefs, desires, intentions, knowledge, and moods of the story's protagonist as they arise from the interpretation of environmental cues (Multimedia Appendix 1). As shown in Multimedia Appendix 1, panel 2 displays the mental state for desire, panels 4 and 5 display the mental state for belief, panel 7 displays the mental state for intention, and panels 3 and 6 display the mental states for moods associated with desire and belief.

Table 3. Mental state terms and frequency, words, and length in each social story.

Social story	Mental state terms (frequency)	Words, N[a]	Length (seconds)
Great with others	• Know (n=6) • Want (n=6) • Feel (n=6) • Happy (n=6) • Sad (n=6)	115	95
Play game	• Know (n=6) • Want (n=6) • Feel (n=6) • Happy (n=6) • Angry (n=6)	118	104
Grab a toy	• Know (n=6) • Want (n=6) • Feel (n=6) • Happy (n=6) • Fear (n=6)	112	93
Give a gift	• Know (n=3) • Want (n=3) • Feel (n=3) • Happy (n=3) • Sad (n=3) • Angry (n=3) • Fear (n=3)	101	91

[a]Chinese character count.

The following instructions were given to the children for the talking practice. For retelling, the instruction was as follows: "Tell me about the story you just heard." For prompting, the instruction was as follows: "I have a few questions to ask you about this story." For self-narration, the instruction was as follows: "After listening to this story, it's your turn to share a story about how you grabbed a toy with someone." For imitation, the instruction was as follows: "Tell me the story one more time—I'll say a sentence, and then you repeat it."

Each session lasted approximately 40 minutes. A total of 4 sessions were delivered over 4 weeks, with 1 session per week. The quantitative and qualitative aspects of this intervention program are consistent with those outlined by Frizelle et al [55], who emphasized that, in an intervention program, the concept of efficiency is central to "dosage," which includes both quantitative (number of sessions, frequency, and duration) and qualitative (form) constructs.

XSL•FO
RenderX

Tele-Intervention Information and Communications Technology

The technical setup used by the 3 interventionists in their workrooms included a laptop equipped with Google Meet, a broadband internet connection, a web camera, a flexible lighting device to achieve optimal lighting, and a backdrop of an image showing the name of the interventionist to ensure optimal visibility during the tele-intervention sessions. The technical setup used by the participants included their own personal desktop computer or laptop (9/20, 45%), tablet (3/20, 15%), or smartphone (8/20, 40%), all equipped with Google Meet; an internet connection; and a web camera. All parents reported having internet access at their homes (fixed line or 4G or 5G cellular internet). They also reported a sound level of 55 to 65 dB, measured using a sound meter app. Throughout the tele-intervention sessions, the participants were asked to keep the video call in full-screen mode. All interventionists used the screen-sharing tool to present visual stimuli for the social story video and prompt pictures during the talk practice stage.

Measurement

Assessment of Emotional Competence

In this study, the ELT was used to evaluate the emotional competence of children with DLD. The study 1 section provides more details regarding this test.

Assessment of the Feasibility and Acceptability of SSTIs

Feasibility was evaluated based on recruitment, retention, and attendance rates to each session, and acceptability was evaluated based on the outcomes of each session. The participants were asked to either select 1 of 4 affect categories (happiness, anger, fear, and sadness) or remain neutral. Reports of happiness and neutrality were considered acceptable.

Procedure

As shown in Figure 1, the DLD group completed the in-person evaluation at the preintervention 1 time point (time 1). After 5 to 6 weeks, the SSTIs were administered. The parents attended the first parent session, and the ELT was administered during the tele-evaluation at the preintervention 2 time point (time 2). After 1 week, the DLD group received the SSTIs, which lasted 4 weeks (second to fifth session). In the sixth session, the parents were evaluated, and the DLD group was administered the ELT again during the tele-evaluation at the postintervention 1 time point (time 3). Finally, 5 to 6 weeks after time 3, the DLD group was administered the ELT once again during the tele-evaluation at the postintervention 2 time point (time 4). Only 1 participant withdrew from the study during the tele-evaluation at the postintervention 2 time point. The mean number of weeks between time 1 and time 2 and between time 3 and time 4 was similar (P>.05). Figure 1 shows the participant recruitment process. The period from time 1 to time 4 spanned approximately 18 to 20 weeks for each participant with DLD.

Ethical Considerations

This study was conducted in accordance with relevant guidelines and regulations for human participants. Privacy measures included secure data storage with access restricted to research team members only. The study design was approved by the institutional review board of Chung Shan Medical University Hospital in Taiwan (CS2-19046).

Data Analysis

When the data suggest a nonlinear relationship, piecewise linear growth models can be used to divide growth trajectories into >2 linear components, such as in interrupted time-series data [56,57]. In this study, we used a piecewise linear growth model with 3 slopes for each outcome: slope 1 to evaluate changes from the preintervention 1 to preintervention 2 time points (baseline), slope 2 to evaluate changes from the preintervention 2 to postintervention 1 time points (tele-intervention), and slope 3 to evaluate changes from the postintervention 1 to postintervention 2 time points (follow-up). We also hypothesized that the tele-interventions would have an effect. Generally, the absence of an intervention effect for baseline and follow-up indicates that emotional competence did not increase during the baseline phase and did not decrease during the follow-up phase. The HLM software (version 7.03; Scientific Software International) [58] was used to fit the piecewise linear growth model. All other analyses were conducted using SPSS Statistics (version 25.0). Estimates of intraclass correlation coefficients (ICCs) are often used to analyze the power of piecewise linear growth models [59]. These coefficients measure the similarity between data points within the same cluster and those in different clusters. They typically range from 0 (no similarity between clusters) to 1 (complete similarity between clusters). ICCs of >0.20 indicate that the model can detect actual differences in growth rates across different time segments [60]. Sufficient power is essential for study accuracy, making piecewise linear growth models suitable for analysis. Effect sizes are typically calculated for each period using the Cohen *d* for repeated measures [61]. Values of 0.2, 0.5, and 0.8 indicate small, moderate, and large effects, respectively [62]. The Cohen *d* was calculated using G*Power (version 3.1.5) [63].

Results

Changes in Emotional Competence Among Participants With DLD

In this study, the ICCs for BET size, BET depth, CET size, and CET depth were <0.001, 0.34, 0.30, and 0.46, respectively. The ICCs for BET depth, CET size, and CET depth were >0.20, indicating that the piecewise linear growth model was suitable for analysis. Figure 3 shows the mean change trajectories for the size and depth of BETs and CETs. Table 4 presents the results of multilevel piecewise growth models for estimating mean changes in 4 emotion outcomes in the tele-intervention during the baseline (preintervention 1 to preintervention 2 time points), tele-intervention (preintervention 2 to postintervention 1 time points), and follow-up (postintervention 1 to postintervention 2 time points) phases. Regarding BET size, no statistically significant change was observed during the baseline, tele-intervention, or follow-up phase (P>.05). Regarding BET depth, the rate of correct answers significantly increased during the tele-intervention phase (P<.001), but no significant change was observed during the baseline or follow-up stage (P>.05). Regarding CET size, no statistically significant change was observed during any phase (P>.05). Regarding CET depth, the rate of correct answers significantly increased during the

XSL•FO
RenderX

tele-intervention phase (*P*<.001), but no significant change was observed during the baseline or follow-up phase (*P*>.05).

Figure 3. Mean change trajectories for the size and depth of basic emotional terms (BETs) and complex emotional terms (CETs) during the baseline, tele-intervention, and follow-up phases. D-BET: BET depth; D-CET: CET depth; POST-1: postintervention time point 1; POST-2: postintervention time point 2; PRE-1: preintervention time point 1; PRE-2: preintervention time point 2; S-BET: BET size; S-CET: CET size.

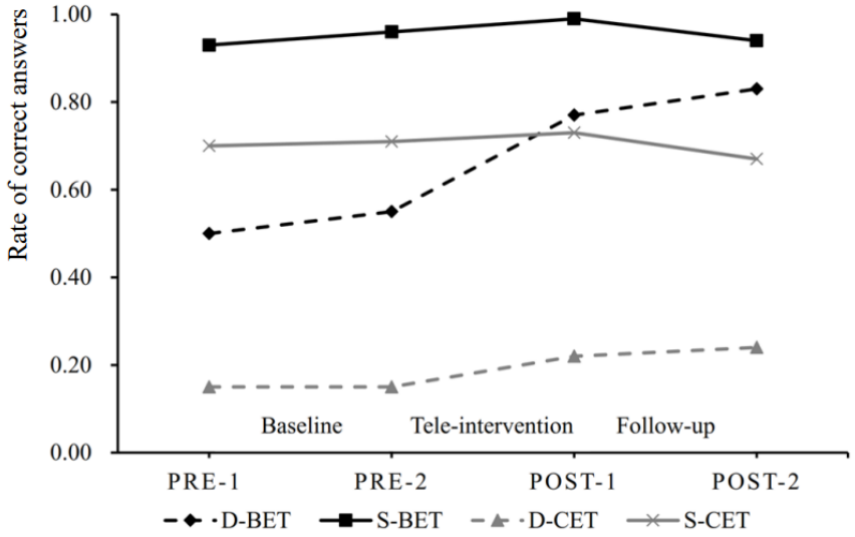

Table 4. Baseline, tele-intervention, and follow-up changes in multilevel piecewise models for emotional terms.

Variable	Size of BET[a], B (95% CI)[b]	Depth of BET, B (95% CI)[c]	Size of CET[d], B (95% CI)[e]	Depth of CET, B (95% CI)[f]
Fixed effect				
Intercept	0.93[g] (0.89 to 0.98)	0.50[g] (0.40 to 0.61)	0.69[g] (0.63 to 0.76)	0.15[g] (0.10 to 0.19)
Baseline	0.03 (–0.04 to 0.09)	0.05 (–0.03 to 0.13)	0.01 (–0.05 to 0.07)	0.00 (–0.05 to 0.05)
Tele-intervention	0.03 (–0.01 to 0.08)	0.21[g] (0.11 to 0.32)	0.03 (–0.05 to 0.10)	0.07[g] (0.04 to 0.10)

[a]BET: basic emotional term.

[b]Random effect—intercept (U_0): χ^2_{19}=15.4; *P*>.50.

[c]Random effect—intercept (U_0): χ^2_{19}=116.3; *P*<.001.

[d]CET: complex emotional term.

[e]Random effect—intercept (U_0): χ^2_{19}=54.2; *P*<.001.

[f]Random effect—intercept (U_0): χ^2_{19}=98.6; *P*<.001.

[g]*P*<.001.

Table 5 presents the means and SDs of various emotional term measures at 4 measurement time points. The effect sizes for changes during the baseline period (from the preintervention 1 to preintervention 2 time points) were small (Cohen *d*=0.00-0.26), indicating that the depth and size of BETs and CETs slightly changed during this period. During the tele-intervention period (from the preintervention 2 to postintervention 1 time points), large effect sizes (Cohen *d*=0.88-0.94) were observed for the changes in depth of BETs and CETs, whereas small effect sizes (Cohen *d*=0.12-0.27) were observed for the changes in size of BETs and CETs. During the follow-up period (from the postintervention 1 to postintervention 2 time points), small effect sizes (Cohen *d*=0.01-0.39) were observed for the changes in depth and size of BETs and CETs.

Feasibility and Acceptability of SSTIs

Of the 25 parents of participants with DLD, 5 (20%) did not take part in this study. Therefore, the recruitment rate for the program was 80% (20/25). At the preintervention 2, postintervention 1, and postintervention 2 time points, the retention rates were 100% (20/20), 100% (20/20), and 95% (19/20), respectively. During the 4 sessions, the attendance rates were 100% (20/20), 100% (20/20), 95% (19/20), and 100% (20/20). All participants (20/20, 100%) completed the 4 tele-intervention sessions, with only 5% of missing data at the postintervention 2 time point.

During the 4 sessions, the percentages of participants who reported being happy were 90% (18/20), 79% (15/19), 85% (17/20), and 90% (18/20), and the percentages of participants who reported being neutral were 10% (2/20), 11% (2/19), 15% (3/20), and 5% (1/20). Overall, the acceptability rates were 100% (20/20), 89% (17/19), 100% (20/20), and 95% (19/20) during the 4 sessions.

Discussion

Principal Findings

Tele-interventions are not a novel concept in medicine. However, to the best of our knowledge, this is the first study to integrate a social story intervention with a remote format to improve the emotional competence of children with DLD. In this study, a 3-stage process was used to observe changes in emotional terms among children with DLD. We discovered that changes in emotional competence occurred only during the tele-intervention phase, with no changes observed during the baseline phase before the intervention. These effects remained during the follow-up period after the intervention. Overall, this research design enhanced the validity of the results.

Our results indicated that SSTIs helped children with DLD deepen their understanding of BETs. In these SSTIs, 4 BETs were repeatedly used in various social contexts to reflect different individuals' mental states. This approach enabled the participants to understand that a single emotion word may be applicable to a range of scenarios (ie, unspecific use). The earlier these terms are integrated into the active vocabulary of children, the more their use aligns with that of adults. These findings are consistent with those of Grosse et al [64] indicating that children who learn words about emotions through cross-context scenarios can understand and use such vocabulary as adults. In this study, thought bubbles were used to enhance the children's understanding of representational mental states associated with emotional terms.

Although our intervention was not designed to introduce new CETs, we hypothesized that children with DLD would not seek to increase the size of their CETs and would rather seek to improve their understanding of the CETs that they had already learned. Overall, our findings indicate that SSTIs, which are based on a thorough understanding of BETs, can help children with DLD gain a deeper understanding of the CETs that they have already learned. Further systematic studies of domain-specific vocabulary are required to determine the effectiveness of SSTIs, including the size of emotion vocabulary and the depth of understanding.

Although social stories are often applicable to patients with ASD, similar to the application of such stories to children with ASD, the social stories designed in this study included visualizations of the story context, which can influence social storytelling by reducing extraneous cognitive demands [65]. When social stories are used as an intervention for children with DLD, adjustments may be required depending on the children's language levels. In this study, we used the thought bubbles corresponding to mental state words, which can also be used to clarify the protagonist's emotional state and mental thoughts within a social context. In other words, by making hidden thoughts and feelings explicit, children with DLD can gain a deeper understanding of their own and others' emotions and acquire the emotional language necessary to reflect upon and

XSL•FO
RenderX

discuss these emotions [66]. Given that children with DLD represent a highly heterogeneous group, when social story interventions are implemented for these children, their language levels must be considered. In other words, the vocabulary, syntactic structures, and story elements included must be carefully planned to ensure that they are within the instructional level and not the frustration level [67]. These strategies have the potential to enhance the expressive language output of children for discussing emotional topics, processing targeted emotional components, and engaging in tele-interventions.

Among the indicators of feasibility for evaluating a pilot program are recruitment, retention, fidelity, acceptability, adherence, and engagement [68,69]. In this study, we evaluated the indicators of recruitment (proportion of parents who were willing to participate), retention (proportion of parents who did not withdraw), and attendance (proportion of parents who attended all 4 sessions). Retention rates are often used as evidence of feasibility in early intervention studies [70,71], particularly for pilot programs [69]. A high retention rate indicates that the program has promise for further development. Future research is required to evaluate the indicators of fidelity, adherence, and engagement to strengthen feasibility assessments.

According to Gartlehner et al [72], clinicians and policy makers tend to differentiate between efficacy and effectiveness. These 2 constructs exist on a continuum where efficacy and efficiency are about whether an intervention functions well under ideal and real-world conditions, respectively. This study was conducted under ideal conditions, supervised by a clinical researcher with expertise in children with DLD. The sample size was small, and the participants were carefully selected—only children with a confirmed diagnosis of DLD were included. The outcomes focused on specific aspects of emotional competence, such as the acquisition of emotional terms, rather than on broader health measures. A short-term intervention was implemented to provide initial evidence of efficacy, with strict protocols for both care providers and families. Future studies should explore the effectiveness of this program for Mandarin-speaking children with DLD, but first, it is necessary to establish the importance of continually evaluating its intermediate- and long-term efficacy. Chorpita et al [73] have argued that, even if >10 successful replications support a particular treatment, this information would not be sufficient to determine whether this treatment is more suitable for a particular child than a treatment supported by only 2 instances of replication assuming the absence of predictors of differences in outcomes. This assumption underscores the importance of conducting effectiveness studies to determine whether intervention programs can be widely implemented in clinical settings. Therefore, future studies should examine our program's real-world effects in hospital settings, including its acceptability, feasibility, and cost versus benefit. They should also explore broader mental health outcomes, such as increased self-regulation or decreased behavioral problems, of tele-interventions designed for Mandarin-speaking children with DLD.

Some parents raised concerns regarding their children facing difficulties focusing on their lessons and interacting with their instructors on-screen. Generally, in-person interventions involve physical contact and social interactions, such as high fives, contingency, eye contact, and joint attention, which can help children focus. In contrast, web-based interactions involve only visual support and behavioral management strategies to keep children engaged [74-76]. Despite these limitations, we discovered that the parents and children who participated in the intervention had high attendance rates and reported positive emotions after the intervention, indicating the feasibility and acceptability of SSTIs among them.

In the past few years, many hospitals were closed to the public because of the COVID-19 pandemic, thus preventing the implementation of in-person interventions. Early interventions for children with developmental delays were also suspended. These measures resulted in an increase in tele-evaluations and tele-interventions in medical scenarios. Although specialized hospitals are currently available for children, tele-practice interventions are particularly valuable for families living in rural areas, who tend to face challenges such as time constraints and lack of transportation. In these areas, enhancing the adoption of tele-practice requires software and hardware support because of these areas' limited internet access and lack of hardware [77]. Currently, Taiwan is striving to expand its 5G infrastructure (through platforms such as OpenGov Asia, the Ministry of Digital Affairs, and ComSoc Technology), particularly in remote areas such as Penghu, to improve digital accessibility and support tele-practice. Enhancing the degree of acceptance among health care professionals and parents is essential for promoting child language development and raising awareness of the benefits of tele-practice [78,79]. Finally, tele-interventions can also be used as a hybrid model in conjunction with in-person services to enhance learning experiences and make efficient use of resources.

This study has some limitations. First, emotional competence was exclusively measured by determining the number of emotional terms that children with DLD were aware of and examining the depth of their understanding of these terms. These measures did not reflect whether the children's emotional regulation strategies or behavioral problems improved as a result of our intervention. Therefore, further studies are required to explore these aspects of emotional competence. Second, the period during which we evaluated the effects of the intervention was short. Therefore, further long-term follow-up studies are required to determine the long-term and cumulative effects of our tele-intervention. Third, although the Italian version of the ELT has demonstrated strong psychometric characteristics [40] and assesses both basic and complex emotional competence in children, the Chinese version of this test lacks support from psychometric data. As in previous studies [38], we evaluated children's understanding of emotion-related words by making them listen to stories and choose the correct terms to determine the quantity of emotion words. We subsequently asked them to explain their choices to gauge their depth of understanding. This approach, which relies on a single test, limits the concept of emotional competence in children. Therefore, future studies should involve various additional measures such as the Emotional Competencies Scale for Young Children [80] or collect data through parent questionnaires or transcript analyses

XSL•FO
RenderX

to determine whether children use emotion words in different contexts [81,82].

Conclusions

Mandarin-speaking children aged 5 to 7 years with DLD exhibit lower emotional competence than those with TLD even after adjusting for child and family language characteristics. Although DLD can be qualitatively defined in accordance with the *DSM-5* [1] in medical and research contexts, no consensus has yet been established regarding its quantitative definition, including which tests to conduct and which cutoff criteria to apply. Therefore, further research is required to establish a quantitative definition for children with DLD across languages and cultures and enable comparisons of emotional competence in children with DLD from different linguistic and cultural backgrounds. In addition, emotional competence tele-interventions effectively improve the emotional competence of children with DLD. They are also feasible and acceptable for both children and their parents. These findings indicate that tele-interventions can be a viable option for individuals who lack access to in-person services due to hospital shutdowns or barriers related to transportation, location, or time. Visual materials such as images and videos of children's interactions, implicit thoughts, and emotions should be used to understand and discuss emotional situations, with a preference toward realistic content. In addition, the language used in SSTIs should match the language capabilities of children. Although the results of our tele-intervention approach are satisfactory, future studies should explore its effectiveness in hospital settings to determine its real-world impact and examine broader mental health outcomes of tele-interventions for children with DLD. Further research is also required to address unresolved concerns regarding assessment, diagnosis, telephone consultation, internet support systems, and inconsistent intervention outcomes. Addressing these concerns can facilitate the expansion of tele-interventions to enhance other competencies in children with DLD and include a broader population with different medical conditions. Overall, this emotional competence tele-intervention, which can be used on pediatric populations, should be conducted as a participatory process involving children and their parents, with technology used to increase the convenience of the intervention, provided that efficacy is achieved. The findings show that using remote technology in home-based tele-interventions is effective, feasible, and well accepted. These interventions improve emotional skills in children with DLD and help support their parents.

Acknowledgments

The authors would like to thank the research team members and Chung Shan Medical University for their assistance, as well as the children and parents who participated in this study. This study was financially supported by the National Science and Technology Council of Taiwan (grants NSTC 108-2410-H-040-010-MY3 and NSTC 111-2410-H-182-036-MY4 to H-HL).

Abstract

Background: Alone time with health care providers is critical for adolescents, and several professional organizations recommend it. Alone time with providers promotes better utilization of health services, empowers adolescents to manage their health, and facilitates discussions on sensitive issues. However, only 40% of adolescents have private conversations with clinicians during visits. The advancement of mobile health technology provides an excellent opportunity to deliver effective interventions to promote adolescent-provider alone time with adolescents, parents, and providers.

Objective: This pilot study aims to explore the preliminary efficacy of a technology-based intervention designed to increase alone time with providers during well-adolescent visits and its impact on trustworthiness, parent-adolescent communication, sexual risk communication, parental monitoring, and parental support before and after the intervention.

Methods: A pre- and postintervention design was used. Participants were recruited through local clinics. After obtaining consent, participants accessed a study website to complete a baseline survey, independently interact with 4 educational modules on a website or cellphone, and complete a post-test survey 1 month after their well-adolescent visits. The surveys assessed alone time with providers, trustworthiness, parent-adolescent communication, sexual risk communication, parental monitoring, and parental support. Mixed model analysis and effect sizes were used to evaluate changes in these outcomes from pre- to postintervention.

Results: Thirty-two dyads (38 adolescents and 32 mothers) participated in this pilot study. About 86% (n=33) of adolescents and 87% (n=28) of mothers completed the pre- and post-test assessments and the intervention. This study found a trend toward an increase in alone time from 81.6% to 84.4%, albeit not statistically significant. Adolescents initiating alone time with providers rose from 6.45% (n=2) to 18.5% (n=5). Over 90% (n=26) of adolescents reported feeling comfortable in one-on-one interactions with providers postintervention. Mixed model analysis revealed significant improvements among adolescents in parental monitoring (z=2.93, P<.001), sexual risk communication (z=3.11, P<.001), parent-adolescent communication (z=3.11, P<.001), open family communication (z=2.00, P=.04), and parental support (z=2.87, P<.001). For mothers, significant improvements were found in parental monitoring (z=2.45, P<.001) and problem family communication (z=2.24, P=.03).

XSL•FO
RenderX

Conclusions: This pilot study demonstrates promising results regarding the preliminary efficacy of a technology-based intervention to increase alone time with providers during well-adolescent visits and to enhance communication and parenting practices. Improving access to alone time and strengthening communication between parents and adolescents facilitates discussions about sensitive topics, including parental monitoring, sexual and reproductive health, and may strengthen overall satisfaction with health care.

Introduction

Background

Despite notable improvements in several critical sexual and reproductive health (SRH) protective behaviors in recent years, young people remain considerably vulnerable to sexually transmitted infections (STIs), such as HIV, and unintended pregnancies [1,2]. Individuals aged 15-24 years account for 50% of all newly diagnosed STIs in the United States each year [3]. Adolescents face an elevated risk for STIs due to various factors, such as underutilization of SRH services, inadequate access to sexual health information, medical mistrust, privacy and confidentiality concerns, lack of awareness about their rights to confidential SRH services, and insufficient alone time with health care providers [3-6].

Alone time with health care providers promotes better utilization of health services and empowers adolescents to manage their health, express their emerging autonomy, and discuss sensitive health issues. The American Academy of Pediatrics and the Society for Adolescent Health and Medicine emphasize the importance of providing confidential health services and adolescent-provider alone time during well-adolescent visits [7,8]. Adolescents are more likely to seek health care and discuss sensitive topics when privacy is assured [9,10]. However, a recent medical expenditure panel survey analysis revealed that only 40% of adolescents had alone time with their clinicians during their last visit, and this rate was even lower among adolescents from low-income families, those without insurance, and those of Latinx ethnicity [11]. Another study published in 2022 reported that alone time increases adolescents' comfort discussing sensitive topics, yet only 31% of adolescents reported experiencing alone time with a provider [12]. A separate study, also published in 2022, showed that some clinics reported rates of adolescent-provider alone as low as 43% [13]. Despite this being a critical mechanism for improving confidential care, few intervention studies have explicitly focused on increasing alone time during well-adolescent visits [14].

Parents play a critical role in adolescents' health, including promoting alone time with health care providers. Understanding parents' perspectives on confidential adolescent health care is essential, and it can inform interventions to enhance the uptake of these services. A study found that 58% of parents believe adolescents should have alone time with their clinician [15]. Another study showed that while 89% of parents agreed that adolescents should be able to speak privately with their providers, 61% still preferred to be present in the examination room for the entire visit [6], When parents understand the role of alone time in adolescent health care they may advocate for their adolescent to have access to it, in the same way they might request vaccines or any other evidence-based preventative health service [9,10].

Research suggests that adolescents are accompanied to medical visits by their mothers in the majority of cases; therefore, it is essential to engage them in the intervention. Medical care for adolescents involves a triad of stakeholders, including adolescent health care providers, adolescent patients, and their parents [16]. It is essential to engage parents, especially mothers, in supporting their children's access to evidence-based health care and encourage alone time. Despite strong recommendations from professional organizations, few interventions focus on increasing alone time to adolescents. Research is needed to examine strategies to effectively increase alone time with health care providers during well-adolescent visits to improve health outcomes generally, as well as SRH outcomes, specifically.

Many parent-adolescent communication interventions focusing on sexual and reproductive health have shown improvements in parent-child communication and parent comfort with communication [17-20], with some resulting in reduced sexual risk behaviors among adolescents [18]. However, most interventions are resource-intensive and lack the feasibility to scale up in the real world. Research indicates that tailored, collaboratively developed communication messages delivered by optimal messengers (eg, peers and trusted adults) through youth-friendly communication channels can significantly encourage protective behaviors (eg, abstinence, consistent and correct condom use, and seeking confidential SRH services) among youth [21,22]. Technology-based interventions provide a promising model for delivering SRH messages and resources that can be scaled and accessed easily and have been proven to promote healthy behavior and can typically be easily accessed [23-25]. A recent web-based program for parents revealed that this type of intervention improved parent-adolescent communication quality and promoted a more positive attitude toward sexual health communication [26]. Another technology-based intervention study for adolescents also found that adolescents reported improvements in intentions for sexual communication, condom use, and self-efficacy to practice safer sex [27]. However, SRH technology-based interventions delivered to adolescents and their parents within the context of

XSL•FO
RenderX

primary care visits are limited, and none have focused on increasing alone time with providers.

Parents, especially mothers, can play a crucial role in guiding adolescents toward confidential SRH services and supporting effective communication with health care professionals. Developmentally and culturally tailored interventions that build parent and adolescent self-efficacy related to communicating about SRH, alone time, and parental monitoring are needed. In this study, we developed a technology-based intervention to increase alone time during well-adolescent visits and to promote alone time, communication, and parental monitoring among adolescents and their mothers to address this gap in the literature.

Theoretical Framework

The social-ecological model (SEM) was used to guide our study. The SEM emphasizes multiple levels of influence on the determinants of health. The levels include individuals (adolescents), interpersonal (mothers), organization (primary care clinics), community (cultural, values, and norms), and organizational (national guidelines) [28,29]. Given that health behaviors both shape and are shaped by the social environment, including interpersonal and organizational levels, the proposed intervention, technology-based resources to increase uptake of sexual health services for teens (TRUST), addressed adolescent's knowledge, attitude, and skill in navigating sexual health and SRH services, specifically accounting for interpersonal and social influences. The intervention also provided skill-building strategies for adolescents to advocate for alone time with their providers. Similarly, mothers received interactive advice about how to improve communication with adolescents related to SRH and parental monitoring. In addition to the SEM, this study considered the developmental stage of adolescents. Adolescence is a period of rapid physical, social, and cognitive development [30,31]. This dynamic period requires evolving approaches to sexual and reproductive health counseling. Because cognitive and physical development are different based on age, the TRUST intervention was tailored to the development stage of the adolescents enrolled.

Research Objective

The aim of this pilot study was to evaluate the preliminary efficacy of a technology-based intervention designed to increase adolescents' alone time with a health care provider during well-adolescent visits. The study also assessed secondary outcomes, including adolescent-mother trust, parent-adolescent communication, sexual risk communication, parental monitoring, and mother support before and after the intervention.

Methods

Ethical Considerations

The study was approved by the Institutional Review Board or Ethics Committee of the University of California, San Francisco (20-32013) on November 3, 2021. The clinical trial is registered on ClinicalTrials.gov (NCT07064070).

Study Design and Setting

The TRUST study used a pre-and post-test design to evaluate the preliminary efficacy of the TRUST intervention in increasing provider and adolescent alone time and improving parent-adolescent communication. All study procedures were carried out in the San Francisco Bay Area and included adolescent and pediatric clinical partners serving low-income and many non-English speaking patient populations, including families of Latinx and Chinese descent.

Inclusion Criteria

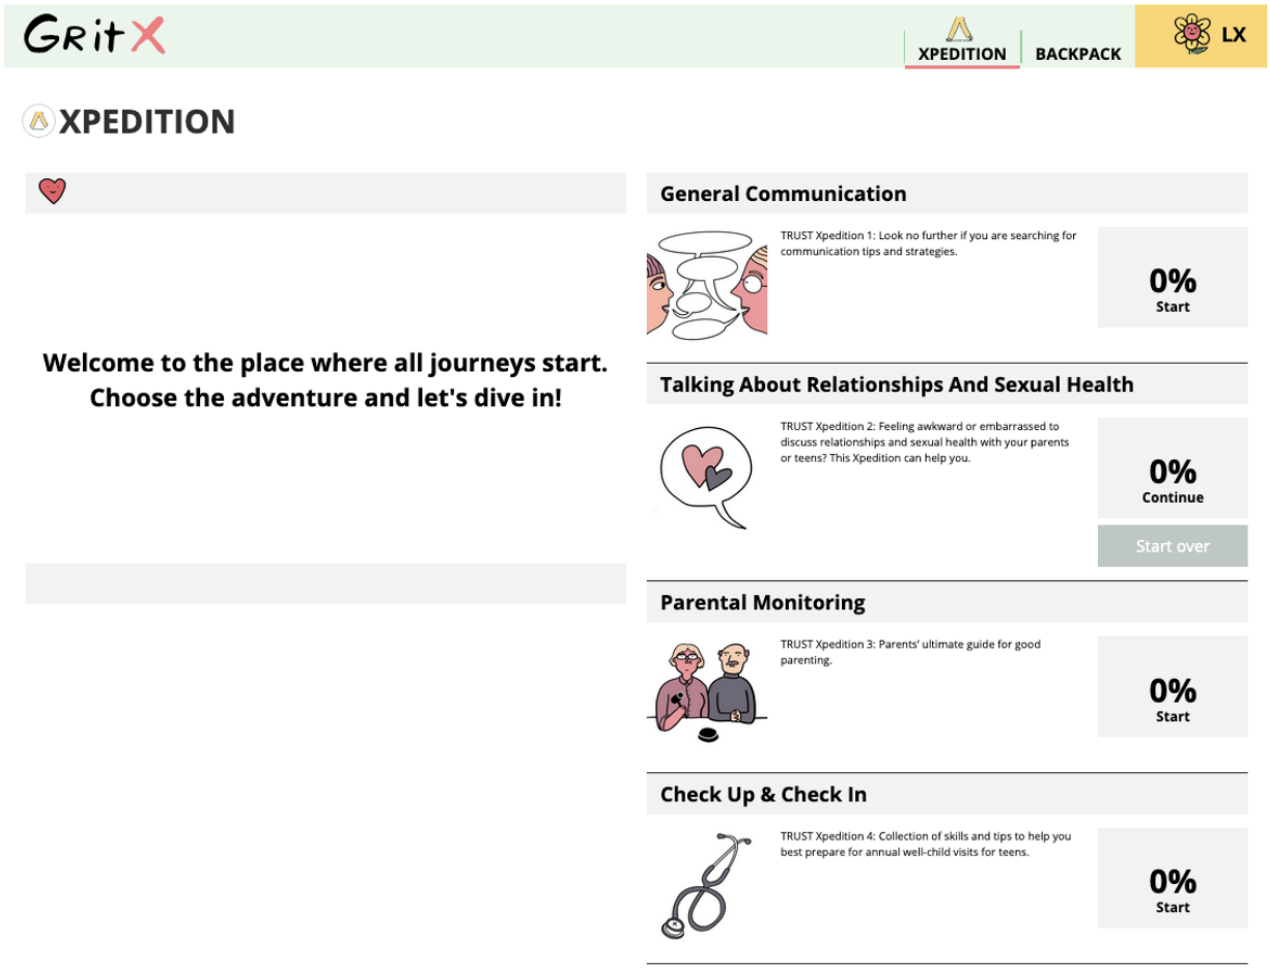
Adolescents could be included in the study if they were aged between 11 and 17 years, able to read and speak English, had access to the Internet (via phone or computer), and had a well-adolescent visit scheduled in the next 6 months. Mothers could be included if they had an adolescent enrolled in this study; spoke and read English, Cantonese, Mandarin, or Spanish; and had access to the Internet.

Recruitment

Recruitment was conducted at 3 primary care sites in the San Francisco Bay Area. A research champion at each study clinic assisted with recruitment, including by posting flyers in the common areas and exam rooms. Champions identified eligible adolescents with an upcoming well-adolescent visit. The study team sent a formal letter via email inviting the eligible family to enroll in the study. The invitation included (1) a description of the TRUST study objectives (ie, to promote adolescent health outcomes by increasing adolescent use of alone time), (2) a description of the intervention, and (3) details about the duration of the study and data collection, risk and benefits of participation, and safeguards for confidentiality. Interested adolescents and their mothers responded to the study invitation by email, phone, or text, or by accessing a screening form on the TRUST study website. All information was offered in English, Spanish, and Mandarin Chinese. A follow-up phone call or text message was made to interested participants to explain the study in greater detail, answer any questions, and assess eligibility.

Study Procedures

After obtaining assent from adolescents and consent from mothers, they were directed to the study website, where they could log in to complete the baseline survey assessment. Adolescents and their mothers completed the pretest assessment via a Qualtrics survey between 1 and 3 months before the scheduled well-adolescent visit. After completing the pretest assessment, participants had access to 4 interactive TRUST modules. Adolescents and their mothers were asked to complete these modules before the well-adolescent visit. About 1 month after completing their well-adolescent visit, another Qualtrics survey link was sent to the study participants for post-test assessment.



Intervention Description

The TRUST intervention includes interactive, evidence-based, culturally and developmentally appropriate modules to encourage adolescent alone time with a provider and improve parent-adolescent communication. It was hosted on the GritX website at the University of California, San Francisco [32]. Our modules were developed based on our work with the key stakeholders, including the youth advisory board, parent advisory board, and clinical partner advisory board (including

XSL•FO
RenderX

clinicians), and a review of the updated evidence [28]. The modules included: general communication, talking about relationships and sexual health, parental monitoring, and check-up and check-in (content focused on the importance of alone time). Modules were in English, Chinese, or Spanish (Figure 1).

Figure 1. Intervention modules.

Each interactive module consists of several key features and a roadmap: setting learning goals, assessment of knowledge and confidence, identifying learning topics, review of evidence-based guidelines and tips for the subject, opportunities for practicing skills, and a chance to save favorite information. Each module begins with learning goals and a simple assessment of knowledge on and confidence in the topic. For instance, participants were asked how much they knew about "why alone time between adolescents and health care providers is so important" and how confident they were to engage in "clear and respectful parent-adolescent communication." There is also a journal section where participants can write notes during their learning, and a virtual "backpack" where participants can store their favorite information. Virtual role-playing was used to engage participants in practicing different communication strategies. In addition, participants earned a badge after completing a module to encourage and motivate continued engagement. Each module took approximately 30-45 minutes to complete. Adolescents and their mothers could review and learn at their own pace and in the language of their choice (English, Chinese, or Spanish) using a smartphone or computer, and they could access resources via a password-protected website. If participants did not access a module within 2 weeks of enrolling in the study, a reminder text was sent to them. A detailed description of the intervention development has been published elsewhere [14].

Each participant received $20 after completing the baseline assessment, $20 after completing the well-adolescent visit, and $30 after completing the post-test assessment.

Measures

Adolescent Self-Reported Alone Time With Providers

To assess adolescents' alone time with their health care providers during well-adolescent visits, the research team used a specific item from the Young Adult Health Care Survey. The item asked, "Did you get a chance to speak with a doctor or other health provider privately during the last well-adolescent visit?" This question was clarified to mean one-on-one communication without parents or other individuals present in the room. The Young Adult Health Care Survey is a well-established survey that has demonstrated reliability and validity [33]. Participants also responded to who initiated the alone time with the primary care provider.

XSL•FO
RenderX

Measures of Trustworthiness

The construct of perceived trustworthiness was assessed using 3 items for adolescents and their mothers. The three items were as follows: (1) I can trust my mother/adolescent when we talk, (2) my mother/adolescent keeps her promises to me, and (3) my mother/adolescent is honest with me. Each item was rated on a 5-point Likert scale ranging from 1 (strongly agree) to 5 (strongly disagree). This scale allowed participants to express varying degrees of agreement or disagreement with each statement. The reliability and validity of these items are supported by previous research [34].

Parent-Adolescent Communication Scale

The parent-adolescent communication scale, developed by Olson (1985) [35], consists of 20 items that measure the quality of communication between adolescents and their parents. It is designed for both parents and adolescents to complete. Each item was rated on a 5-point Likert scale ranging from "strongly disagree" to "strongly agree," generating a total score and 2 subscale scores. The open family communication subscale reflects feelings of free expression and understanding in parent-adolescent interactions (eg, "When I ask questions, I get honest answers from my mother/father"). The problems in family communication subscale measures negative interaction patterns and hesitancy to disclose concerns (eg, "My mother/father tends to say things to me that would be better left unsaid"). Higher scores indicate better parent-adolescent communication. The parent-adolescent communication scale demonstrates good internal consistency [36,37].

Parent-Adolescent Sexual Risk Communication Scale III

The parent-adolescent sexual risk communication scale III, developed by Hutchinson [38], is an 8-item scale used to assess the extent of sexual risk communication between adolescents and their parents. The scale includes separate scales for adolescents to report communication with their mothers and fathers. In this study, we asked for communication with the mother only. Adolescents were asked to report how much information their mother communicated with them on a 5-point scale (1=none; 2=a little; 3=some; 4=a lot; and 5=extensive) and on the following topics between the ages of 10-18 years: birth control, sexually transmitted diseases (STDs), HIV/AIDS, condoms, how to protect yourself from HIV/AIDS, postponing or not having sex, peer pressure to have sex, and how to handle sexual pressure. The total scores range from 8 to 40, with higher scores indicating more extensive communication. Appropriate reliability and validity have been reported [38].

Parental Monitoring

This validated scale assesses the degree to which parents are informed about various aspects of their child's life [39]. This construct was measured using 9 questions that parents and adolescents answered on a 5-point Likert scale, ranging from 1 (no, never) to 5 (yes, almost always). Sample questions include, "Do your parents: know what you do during your free time? Know who you have as friends during your free time? Usually, know what type of homework you have? Know what you spend your money on?"

Parental Support (Mothers Only)

Mothers reported how often they support their child using a 3-item 4-point Likert scale (never to always). Sample items include, "How often do you let your child know you care about them?" and "How often do you listen to your child carefully?" Higher values indicate more supportive parenting. Adequate reliability has been reported [26].

Statistical Analysis

This pilot study aimed to explore the preliminary efficacy of the intervention. Descriptive statistics include the mean and proportion of participant demographic data and outcome variables. A mixed model analysis with intention to treat estimated the intervention's preliminary efficacy, controlling for age. This method allows us to use all available data, regardless of missing data. Six families with 2 adolescents were included in this study; family unit identification and individual unit identification were included as random effect parameters in the mixed model analyses. Effect sizes for pre- and postintervention outcome variables were assessed using the Cohen *d* index. Effect sizes were categorized as small (<0.20), medium (0.50), and large (>0.80). Statistical significance was determined with a *P* value set at <.05. All analyses were performed using Stata version 18.0.

Results

Sample Characteristics

Thirty-two dyads (38 adolescents and 32 mothers) participated in this study. The average age was 14.5 (SD 1.81) years and 49.06 (SD 7.9) years for adolescents and their mothers, respectively. Among the mothers, 10 out of 32 (31%) reported having a master's degree or higher, and 13 out of 32 (41%) had an annual household income greater than $120,001 (Table 1). Approximately 12 families identified themselves as European White (40%), 7 as Latinx (21.8%), and 13 as Asian (40.5%). Additionally, about 86% (n=33) of adolescents and 87% (n=28) of mothers completed the pre- and post-test assessments and the intervention (Table 2).

Very uncomfortable	N/A	1 (4)		

[a]Not applicable.

Adolescent-Reported Alone Time and Comfort Level

In terms of alone time with providers, 27 out of 32 adolescents (84%) reported having alone time with the provider at their well-adolescent visit after the intervention, compared to 31 out of 38 (82%) at baseline (χ^2_3=.01, *P*=.76). The number of adolescents who initiated alone time with a provider increased from 2 out of 31 (6%) at baseline to 5 out of 27 (19%) at follow-up. The number of mothers who initiated alone time remained nearly the same: 1 out of 31 (3%) at baseline and 1 out of 27 (4%) at follow-up. Regarding adolescents' comfort levels in one-on-one interaction with the provider at follow-up, 16 out of 28 (57%) felt somewhat comfortable, and 10 out of 28 adolescents (36%) reported feeling very comfortable (Table 2).

Communication Outcome, Parental Monitoring, and Parental Support

Mixed model analysis controlling for age revealed significant improvements among adolescents in sexual risk communication (*z*=3.11, *P*<.001), parent-adolescent communication (*z*=3.11, *P*<.001), open family communication (*z*=2.00; *P*=.04), parental monitoring (*z*= 2.93, *P*<.001), and parental support (*z*=2.87, *P*<.001; Table 3). For mothers, significant improvements were found in parent-adolescent communication: problem family communication (*z*=2.24, *P*=.03) and parental monitoring (*z*=2.45, *P*<.001; Table 4).

Effect Size Analysis

A small effect was found for the alone time variable (Cramér V=0.05). The results indicated varying effect sizes on secondary outcomes based on the Cohen *d* index for pre- and post-tests. For adolescents, small effect sizes were found in trustworthiness, sexual risk communication, problem in the family communication subscale, parent-adolescent communication, and parental support total score. A medium effect size was observed in parental monitoring. For mothers, small effect sizes were found in several domains, including problem-free family communication, parent-adolescent communication total score, and parental support total score. A large effect size (Cohen *d*=1.05) was observed in parental monitoring (Table 5).

[b]Significant at mixed model analysis.

Discussion

Principal Findings

This pilot study examined the preliminary efficacy of a technology-based intervention on alone time with a provider during well-adolescent visits by assessing trustworthiness, parent-adolescent communication, sexual risk communication, parental monitoring, and parental support before and after the intervention. We found an increase in reports of alone time with the provider at the last well-adolescent visit, increasing from 81.6% to 84.4%, although there was no statistical significance. We also found an improvement in the percentage of adolescents initiating alone time with a provider, which increased from 6.45% to 18.5%. Importantly, over 90% of adolescents reported feeling comfortable or very comfortable in one-on-one interactions with the provider after the intervention. In addition, this study revealed significant improvements in communication outcomes, parental monitoring, and parental support among adolescents. Small effect sizes were also noted in trustworthiness among adolescents. Significant improvements were also observed in parental monitoring and problem family communication among mothers. These findings suggest there is promise in using the technology-based TRUST intervention to improve adolescents' alone time at well-adolescent visits and improve parent-adolescent communication and parenting practices.

Empowering adolescents to have private conversations with health care providers is important because alone time during well-adolescent visits has been shown to facilitate discussions on sensitive health topics, including SRH, and ensure confidentiality in these matters [9,10,40]. Additionally, alone time with providers can enhance adolescents' satisfaction with their health care, which is crucial for ensuring continuity of care and better access to necessary health services [41]. Our pilot showed a particularly high level of reported alone time with primary care providers during well-adolescent visits at baseline, significantly surpassing the figures reported by Grilo et al [42], which ranged from 44% to 55% among nearly 2000 US youths. This suggests that our collaborating clinical sites adhere to professional recommendations to offer alone time. Despite this high baseline, we observed a 3% increase in alone time and a remarkable 12% increase in adolescents initiating alone time with their provider, suggesting the positive impact of the intervention. Although our intervention targeted adolescents and mothers, it may have indirectly influenced provider behavior by encouraging adolescent self-advocacy or maternal prompting.

XSL•FO
RenderX

In addition, while clinicians were not directly involved in accessing the intervention, we engaged them as an advisory group during its design phase to strengthen its impact. However, the factors driving provider-initiated alone time are complex and likely rooted in structural factors, clinic norms, and providers' own perspectives. Future studies should consider multilevel interventions that directly engage providers to enhance adolescent alone time during visits.

Our results reveal a low frequency of mother-initiated alone time, suggesting potential attitudinal or cultural influences. This underscores the importance of promoting the advocacy role of adolescents in requesting alone time. Future research should incorporate stronger parental components to better educate parents about the importance of encouraging adolescent-private time with health care providers.

In addition to the increase in alone time and the initiation of alone time by the adolescent, we also found improvements in various communication domains (parent and adolescent communication and SRH communication) and parenting areas (monitoring and support) reported by the adolescent after the intervention. Mothers reported an increase in parental monitoring and an increase in communicating about family problems. However, most observed effect sizes were small to medium. One possible explanation is the short interval between the intervention and follow-up, which may not allow sufficient time for meaningful changes to emerge in trust-building or established family communication patterns. Another possibility is that the brief, nonreinforced nature of the intervention may have limited its impact.

Strengthening communication skills between mothers and adolescents is particularly important. Improved parent-adolescent communication may enhance adolescents' ability to engage in appropriate SRH behaviors, use confidential health services when needed, and communicate more effectively with health care providers [15,19]. These findings are consistent with prior studies, suggesting that web-based programs for parents can improve the quality of parent-adolescent communication and foster a more positive attitude toward sexual health communication [26,27]. These results are consistent with 3 studies reporting an improvement in SRH communication after receiving the technology-based intervention [26,43,44], yet 2 studies found no significant difference [26,45].

Limitations

This pilot study reports the preliminary efficacy of a technology-based intervention, yet these results must be interpreted cautiously, as several limitations should be noted. First, the pilot study included a small sample size, comprising 32 dyads (38 adolescents and 32 mothers). This limited sample size may restrict the generalizability of the results to broader populations. Our study participants comprised mothers with high educational attainment, and a large portion reported high annual household income (41% earning over $120,001, the median household income in the San Francisco Area). This study sample may only reflect the San Francisco Bay Area population.

Second, our study used a quasi-experimental design without a control group; therefore, the results may be partially attributed to the intervention. The use of self-reported data may also increase potential bias. It is recommended that future studies include larger, more diverse samples and control groups, direct observation of alone time, and an extended follow-up period so that a comprehensive understanding of the intervention's efficacy can be established.

Third, while the TRUST intervention aimed to promote adolescent-provider alone time, it did not explicitly address psychological drivers of mistrust. The adolescent-mother trust, our secondary outcome, also did not show statistically significant improvement. Future studies should incorporate trust-building components to align more closely with the TRUST acronym.

Moreover, our baseline assessment of adolescent-provider interactions relied on retrospective self-reporting about participants' last health care encounter. This approach introduces methodological limitations such as potential recall bias due to varying time lapses between the actual encounter and survey completion. Future studies should implement real-time data collection after the actual encounter.

Finally, our study's high baseline alone time rate may reflect strong pre-existing clinic practices, as we mentioned earlier, which could have limited our ability to detect statistically significant changes, indicating a potential ceiling effect. Future studies should adopt a more diverse recruitment strategy to capture a wider range of baseline adolescents' behaviors.

Based on the literature and our clinical and research experiences, mothers are usually the primary caregivers of their adolescents. Therefore, this study included both adolescents and their mothers, forming a mother-adolescent dyad. A preliminary analysis indicated strong parental involvement from the mothers. However, due to the small sample size, it will be challenging to assess the impact of parental involvement on the outcomes. Future studies with larger sample sizes should include mediation analysis to evaluate the effect of parental involvement on outcomes. Despite these limitations, our technology-based, interactive intervention with tailored content actively equipped adolescents to advocate for alone time and improved adolescent-mother communication.

Conclusions

Our culturally grounded and technology-based intervention is one of the first aimed at improving rates of and comfort with provider-adolescent patient alone time. This pilot study demonstrates promising results regarding increased alone time with providers during well-adolescent visits and enhanced communication and parenting practices. These findings align with existing research on technology-based interventions and suggest that such approaches can effectively promote alone time with providers, strengthen communication, and support adolescents in engaging in private consultations, a foundational step toward promoting lifelong engagement in preventative health care.

Abstract

Background: Obesity rates among Saudi adolescents are increasing, with regional variations highlighting the need for tailored interventions. School-based health programs in Saudi Arabia are limited and often emphasize weight and body size, potentially exacerbating body image dissatisfaction. There is limited knowledge on the feasibility of non–weight-centric educational programs in Saudi Arabia and their effects on health behaviors and body image.

Objectives: This study aimed to (1) assess the prevalence of obesity using BMI-for-age *z* score (BAZ) and fat percentage among Saudi adolescents; (2) evaluate key health behaviors, cardiovascular fitness, and health literacy; and (3) assess the feasibility and impact of a low-intensity, non–weight-centric educational intervention designed to improve knowledge of macronutrients and metabolic diseases, while examining its safety on body image discrepancies.

Methods: A quasi-experimental, pre-post trial with a parallel, nonequivalent control group design was conducted among 95 adolescents (58 boys and 37 girls; mean age 16.18, SD 0.53 years) from 2 public high schools in Medina City, Saudi Arabia. Participants were randomly assigned to either the weight-neutral Macronutrient + Non-Communicable Diseases Health Education group or the weight-neutral Macronutrient Health Education group. Anthropometry (BAZ and fat percentage), cardiovascular fitness, physical activity, and eating behaviors were measured at baseline. Independent *t* tests and χ^2 tests were conducted to compare group differences, and a 2-way mixed ANOVA was used to evaluate the effect of the intervention on macronutrient knowledge and body image discrepancies. A total of 69 participants completed the postintervention assessments.

Results: The prevalence of overweight and obesity based on BAZ was 37.9% (36/95), while 50.5% (48/95) of participants were classified as overfat or obese based on fat percentage. Students with normal weight status were significantly more likely to have had prior exposure to health education related to metabolic diseases than students with higher weight status (P=.02). The intervention significantly improved macronutrient-metabolic knowledge ($F_{1,64}$=23.452; P<.001), with a large effect size (partial η^2=0.268). There was no significant change in students' body image from pre- to postintervention (P=.70), supporting the safety of these weight-neutral programs. The intervention demonstrated strong feasibility, with a recruitment rate of 82.6% and a retention rate of 72.6%.

Conclusions: This study reveals a high prevalence of obesity among Saudi adolescents, particularly when measured using fat percentage. The significant improvement in knowledge and the nonimpact on body image suggest that a non–weight-centric intervention can foster better health outcomes without exacerbating body image dissatisfaction. Region-specific strategies that prioritize metabolic health and macronutrient education over weight-centric messaging should be considered to address both obesity and body image concerns in adolescents.

Introduction

Childhood obesity has become a significant public health concern globally, with projections indicating a continued upward trend in the coming decades. Obesity is expected to rise dramatically among children aged 5 - 19 years, from an estimated 158 million in 2020 to 254 million by 2030 [1], representing a 60% increase over just a decade. Global estimates suggest that the overall prevalence of childhood overweight and obesity could reach 30% by 2030, with boys (34.2%) surpassing girls (27.4%) [2]. This trend is particularly alarming in middle- and high-income countries, where childhood overweight and obesity rates are projected to reach 58.3% by 2030 [2].

In Saudi Arabia, the obesity epidemic has mirrored global trends, with a marked increase in prevalence among both adults and adolescents. National estimates indicate that obesity prevalence among Saudi adolescents ranges from 22.3% to 23.5%, with some studies suggesting that nearly 35% of adolescents are overweight and 20% are obese [3-5]. Although BMI is a common tool for assessing obesity, it has limitations in distinguishing between fat and muscle mass. Notably, recent findings in Saudi Arabia highlight that BMI can underestimate obesity prevalence compared with body fat percentage [6]. For instance, while BMI data indicated an obesity prevalence of 29% (102/348) in men and 53% (314/593) in women, body fat percentage assessments revealed significantly higher rates of 83.9% (292/348) in men and 97.3% (557/593) in women [6]. This underscores the importance of using body fat percentage to provide a more accurate representation of obesity, particularly when evaluating related health risks.

Regional disparities in obesity prevalence further complicate the issue. Urbanized areas in Saudi Arabia report higher rates of obesity, influenced by factors such as physical inactivity, Westernized diets, and socioeconomic conditions [7]. Conversely, rural regions often exhibit lower obesity rates due to more traditional lifestyles that incorporate higher physical activity and different dietary patterns [7]. These regional differences emphasize the need to address physical activity behaviors and dietary habits in specific contexts. While all forms of physical activity are beneficial, current evidence indicates that vigorous-intensity exercise may be particularly effective in improving body composition, cardiorespiratory fitness, and cardiometabolic health markers in adolescents [8,9]. Despite this, there remains a gap in studies exploring the relationship between physical activity behaviors and cardiovascular fitness among adolescents in Saudi Arabia.

Adding to the complexity, decreased health literacy and higher-income levels have been linked to increased obesity rates in Saudi Arabia. This contrasts with trends observed in the United States, where lower-income levels are more commonly associated with higher obesity rates [10,11]. This highlights the crucial role of health literacy as a determinant of obesity prevalence and the importance of tailored educational interventions.

Despite the alarming trends, evidence-based interventions targeting adolescents in Saudi Arabia, particularly late adolescents in school settings, remain limited [12,13]. Schools provide an ideal environment for implementing cost-effective and sustainable obesity interventions, especially when these programs are theory-driven and tailored to meet the specific needs of the target population [14]. A review of the literature shows that only 7 school-based obesity intervention studies have targeted adolescents in Saudi Arabia, with an average age range of 12 - 14 years, and none focusing on high school students [12,13,15]. Furthermore, only 3 of these studies used theory-based approaches [12], and all used weight-centric messaging.

Since 2020, more than 100 organizations worldwide, including scientific societies and academic institutions, have endorsed joint international statements to eliminate weight stigma [16]. Non–weight-centric approaches, which emphasize overall health and well-being rather than solely focusing on weight loss, have gained traction in school-based obesity interventions [17]. These programs encourage healthy behaviors and promote a positive body image without stigmatizing students, addressing the negative outcomes associated with weight stigma such as anxiety, disordered eating, and even weight gain [18,19]. However, designing obesity prevention programs that avoid weight-based stigma remains challenging, prompting calls for expanded research in non-Western cultural settings [16,20].

No study in Saudi Arabia has yet documented the development or efficacy of non–weight-centric interventions. This study focused on Medina City to examine the impact of healthy lifestyle factors on obesity rates among late adolescents and to assess the effectiveness and safety of a low-intensity, non–weight-centric, noncommunicable diseases (NCDs) educational intervention. This regional focus aims to provide insights that can inform targeted, culturally sensitive obesity prevention strategies.

In summary, this study sought to (1) identify the prevalence of obesity using both BMI-for-age *z* score (BAZ) and body fat percentage among Saudi late adolescents in Medina City; (2) characterize health-related behaviors, cardiovascular fitness, handgrip strength, and health literacy levels; and (3) evaluate the feasibility and safety of a low-intensity health educational intervention aimed at empowering adolescents with improved NCD knowledge while monitoring its effects on body image discrepancy. This research aims to contribute to the development of effective, culturally appropriate interventions that promote adolescent health without reinforcing weight stigma.

Methods

Design

This study used a quasi-experimental, pre-post trial with a parallel, nonequivalent control group design to assess baseline anthropometry, health-related cardiovascular fitness components, handgrip strength, physical activity, and eating behaviors, as well as the feasibility of a low-intensity, school-based educational intervention aimed at improving critical thinking about the relationship between macronutrients and NCDs among high school students, while tracking safety measures such as body image discrepancy.

Participants

A total of 115 high school students from 2 public schools (1 for males and 1 for females) in Medina City, Saudi Arabia, were invited to participate. These schools were selected by the ministry of education's school health department. Of the invited students, 95 (58 males and 37 females) completed anthropometry and body composition measurements. Baseline surveys were completed by 85 students (53 males and 32 females). Four classes (2 females and 2 males) were randomly assigned to 1 of 2 intervention groups: the Macronutrient+ NCDs Health Education group (n=31) or the Macronutrient Health Education group (n=38).

Intervention: Green Apple

Overview

The LEAF program, an 8-session structured intervention, was developed to enhance critical thinking regarding macronutrients and their relationship to body energy and the prevention of cardiometabolic diseases. For this study, a pilot version, titled Green Apple, was conducted over two 45-minute sessions for female students and one 60-minute session for male students due to scheduling constraints. The intervention was based on best practices derived from evidence-based research into health literacy and behavior change [21]. The program was grounded in the Health Belief Model [22] and Social Cognitive Theory [23], incorporating the Transtheoretical Model for behavior change [24].

These theories provided the framework for understanding how adolescents perceive their risk of NCDs (eg, diabetes, hyperlipidemia, liver disease, stroke, and hypertension) and motivated them to adopt healthier behaviors through education, muscle building, and dietary modifications. The Green Apple program aimed to reduce chronic metabolic NCD risk by promoting visceral fat reduction and muscle building without focusing on weight loss or obesity. Participants were encouraged to follow the MyPlate dietary guidelines [25], emphasizing fiber and whole food consumption and engaging in muscle-building exercises. The program avoided topics related to obesity and sedentary behavior, instead focusing on metabolic health improvements.

Intervention Groups

The Macronutrient+ NCDs Health Education group included 3 educational topics covering nutrition and metabolic diseases (eg, diabetes and cardiovascular disease), highlighting the impact of macronutrition on metabolic health.

The Macronutrient Health Education group included 2 educational topics focused solely on healthy nutrition principles, dietary guidelines, food groups, and balanced eating.

Both groups received identical macronutrient content.

Measurements

Demographics

Baseline demographic data included age, self-reported weight and height, parental education levels, and monthly family income. Parental education was categorized as high (college degree or above) or low (high school degree or below).

Anthropometry

Body weight and height was measured using a portable digital scale (Omron BF511) to the nearest 100 g and a stadiometer to the nearest 0.1 cm. BMI was calculated as weight (kg) divided by height squared (m^2), and BAZs were classified using the World Health Organization 2007 Growth Reference for children and adolescents aged 5 - 19 years [26]. The BAZ categories were thinness ($-3 \leq BAZ < -2$), normal weight ($-2 \leq BAZ \leq +1$), overweight ($+1 < BAZ \leq +2$), and obesity ($BAZ > +2$).

Fat percentage was assessed using a bioimpedance analyzer (Omron BF511). Classification was based on McCarthy's age- and sex-specific fat percentile references, with the 2nd, 85th, and 95th percentiles defining underfat, overfat, and obese, respectively [27].

Cardiovascular Fitness

The Queen's College Step Test, a submaximal exercise test, was used to estimate the maximal oxygen consumption (VO_2max). Participants stepped on a 30.5- cm box at a set rate for 3 minutes [28]. The 30.5-cm step height was chosen for its suitability for adolescents [28]. VO_2max estimation: The pulse rate was measured postexercise using a pulse oximeter, following McArdle's protocol [29]. The equations for estimating VO_2max were as follows: girls: $65.81 - (0.1847 \times \text{pulse rate})$ and boys: $111.33 - (0.42 \times \text{pulse rate})$ [28].

Handgrip Strength

Handgrip strength was measured using a Takei Kiki Kogyo dynamometer, and the highest value from 2 trials for the dominant hand was recorded. Classifications followed age- and gender-specific percentiles [30].

Physical Activity

Physical activity was assessed using the Arab Teen Lifestyle Study physical activity questionnaire subscale [31], calculating total weekly energy expenditure in metabolic equivalent tasks (METs), with vigorous activities (6 METs) and moderate activities (4 METs) expressed in minutes per week.

Eating Habits

Eating habits were evaluated using the Arab Teen Lifestyle Study eating habits subscale, which measured positive eating habits (eg, fruit or vegetable intake) and negative eating habits

XSL•FO
RenderX

(eg, sugary drinks or fast food) based on weekly frequency [31], with a total scores ranging from 0 to 28 for positive habits and 0 to 35 for negative habits.

Sedentary Behavior

Sedentary behavior was measured using the Arabic Sedentary Behavior Questionnaire (SBQ) for weekdays [32]. The questionnaire included 9 items, and a total sitting time was averaged over 5 weekdays. Sitting ≥7 hours per day was considered highly sedentary [33].

Exposure to NCDs Health Education

Exposure to health education on NCDs was assessed using 4 yes or no questions regarding prior education on chronic diseases. A total score (0 - 4) was calculated.

Macronutrient-NCDs Knowledge

Macronutrient and NCDs knowledge was measured using an 18-item true-or-false quiz developed based on the Green Apple content. A total score (0 - 18) was analyzed, with an urgent need for intervention indicated if 70% or fewer answered correctly, a considered need at 71% - 89%, and no need at 90% or more [34].

Body Image Discrepancy

Body image discrepancy was assessed using 4 body size silhouettes [35]. Participants selected their ideal and perceived current body images, with discrepancies indicating body image concerns. A negative score represented a drive for thinness, while a positive score reflected a drive for increased body weight [36].

Ethical Considerations

The study protocol was approved by the Shaqra University ethics committee (ERC_SU_20230005). Written informed consent was obtained from parents, and student participation was voluntary. To ensure privacy and confidentiality, participant data were anonymized using unique identifiers, and data access was limited to authorized personnel. Baseline assessments were conducted prior to the intervention. The intervention was delivered on different days for males and females due to scheduling constraints. Postintervention assessments for macronutrient-NCDs knowledge and body image discrepancy were conducted, and participants received a key chain medley as a token of appreciation for their involvement.

Statistical Analysis

Overview

Descriptive statistics (means, SDs, and frequencies) were calculated for all variables. Independent *t* tests were conducted to compare males and females and students with and with no overweight or obesity on continuous variables, while χ^2 tests were used for categorical variables. A 2-way mixed ANOVA design was used, with 1 between-subjects factor (intervention type: macronutrient-NCDs vs macronutrient) and 2 within-subjects factors (time: pre-test and post-test) for 2 dependent variables: macronutrient-NCDs knowledge and body image discrepancy. Gender was included as an additional between-subjects variable to assess potential interactions with time and intervention type.

Statistical significance was set at $P<.05$. Sample size calculations using G*Power 3.1 indicated a required sample size of 34 participants to detect medium effects ($f=0.25$) with 80% power. Although an initial plan accounted for a 30% attrition rate, the final sample size exceeded the minimum requirement for detecting a medium effect size with 80% power, ensuring sufficient study power.

A 2-way mixed ANOVA was conducted to evaluate the effect of the Green Apple intervention on students' macronutrient-NCDs knowledge scores before and after the intervention and to determine potential gender interaction effects, given the significant difference in mean scores between males and females at preassessment.

Two borderline outliers with studentized residuals of −3.02 and −3.03 were identified but retained in the analysis. The data were normally distributed, as assessed by the Shapiro–Wilk test ($P>.05$). Homogeneity of variances ($P>.05$) and covariances ($P>.001$) were confirmed by Levene test and Box M test, respectively, except for postintervention body image discrepancy, which required Welch ANOVA.

Missing Data

A missing data analysis was conducted, revealing that 4% of data were missing across all items, with a maximum of 7% missing for certain variables (eg, "minutes' walk per day," "number of stairs per day," and "SBQ-listening to music, using computer, crafting"). Little MCAR test was applied to assess the randomness of the missing data, yielding a nonsignificant result ($P>.05$), indicating that the data were missing completely at random [37]. Expectation-Maximization was used to impute missing data for variables with 5% - 7% missing values. For variables with <5% missing data, series mean and series median imputation methods were used.

Two items from the physical activity scale ("regular dancing" and "house cleaning") were excluded due to cultural factors that led to inconsistent responses between male and female participants. This decision was informed by a review of similar studies conducted in the region [38,39]. Furthermore, family income was excluded from analysis because female students were often unaware of this information, which is considered sensitive, and younger students may not accurately understand their family's financial status [40]. The high absenteeism rate among female students during the intervention (approximately 28%) also contributed to some missing data, consistent with previously reported absenteeism rates in Saudi schools [41].

Results

Baseline Characteristics and Prevalence of Overweight and Obesity

Table 1 shows the baseline characteristics of the 95 participants (37 girls and 58 boys). The mean age of the total sample was 16.18 (SD 0.53) years, with girls having a significantly higher mean age than boys ($P<.001$). The mean BAZ score for the total sample was 0.44 (SD 1.42), with a significant sex difference

XSL•FO
RenderX

(*P*=.03). Furthermore, girls had a higher mean fat percentage than boys (28.58% vs 22.65%), but this difference was not statistically significant (*P*=.37). The combined prevalence of overweight and obesity based on the BAZ classification was 37.9% (36/95), with 16.8% (16/95) of participants classified as overweight and 21.1% (20/95) of participants classified as obese. When considering fat percentage, the combined prevalence of overfat and obesity was 50.5% (48/95), with 11.6% (11/95) of participants classified as overfat and 38.9% (37/95) of participants classified as obese. For the BAZ and fat percentage percentile categories, no significant sex differences were observed. Table 2 shows descriptive statistics for the distribution of the participants' weight status (normal BAZ and high BAZ) across different levels. These results suggest that there was no statistically significant relationship between parental education level (both mother and father) and the participants' weight category.

Table . Descriptive statistics based on sex (mean [SD] or fat percentage).

Variables	All (N=95)	Girls (n=37)	Boys (n=58)	Sex (significance) difference[a]
Age (years), mean (SD)	16.18 (0.53)	16.38 (0.64)	16.05 (0.39)	<.001

Cardiovascular Fitness and Handgrip Strength

Overall cardiovascular fitness levels, as measured using VO_2max, did not significantly differ between individuals in the normal and high body weight categories. The boys in the normal BAZ group had a slightly higher VO_2max (63.43 mL/kg/min, SD 10.69) than the boys in the high BAZ group (61.46 mL/kg/min, SD 9.77). However, this difference was not statistically significant (*P*=.81). There was a notable and statistically significant difference between the girls in the normal BAZ group (38.84 mL/kg/min, SD 1.83) and those in the high BAZ group (36.10 mL/kg/min, SD 3.65), with a *P* value of .014. This indicates that girls with overweight or obesity had significantly lower cardiovascular fitness levels than their peers in the normal group, suggesting a potential negative impact of higher body weight on cardiovascular fitness among girls. However, the distribution of handgrip strength categories did not show a statistically significant association with the BAZ classification (*P*=.67) (Table 2).

Health-Related Behaviors Based on Weight Status

Activity Behavior

Participants with a high BAZ had lower levels of METs minutes per week from vigorous-intensity activity (1505.56, SD 1743.45) than those with a normal BAZ (2360.92, SD 2914.76), with a significant difference (*P*=.047). No significant differences were observed in METs from moderate-intensity activity (*P*=.39).

Sedentary Behavior

The difference in sedentary behavior between the 2 groups was not statistically significant (*P*=.68), indicating similar levels of sedentary time regardless of weight status.

Eating Behavior

Positive eating behaviors were marginally lower in the high BAZ group (15.72, SD 6.84) than in the normal BAZ group (16.84, SD 5.98), but the difference was not statistically significant (*P*=.23). Furthermore, negative eating behaviors showed no significant differences between the groups (*P*=.93).

Macronutrient-Metabolic NCDs Knowledge and Need for Intervention

The participants with a normal BAZ reported higher exposure to metabolic NCDs education (3.36, SD 0.76) than those with a high BAZ (2.91, SD 1.28), with a significant difference (*P*=.02). However, no significant differences were observed in the macronutrient-metabolic NCDs knowledge scores between the 2 groups (*P*=.16). The majority of the participants were classified as having an urgent need for an educational intervention (59/85, 69.4%), and 30.3% (26/85) were classified as having a need for an intervention, with no statistically significant distribution between the 2 groups (*P*=.92).

The Green Apple Intervention Effectiveness

The final sample consisted of 69 participants, with 23 females (intervention=13, control=10) and 46 males (intervention=18, control=28).

Effect on Macronutrient-Metabolic NCDs Knowledge

There was a significant main effect of time on students' macronutrient-metabolic NCDs knowledge ($F_{1,58}$=23.263; *P*<.001), with a large effect size (partial η^2=0.286). This indicates that knowledge significantly improved from pre- to postintervention, and the magnitude of the change was substantial. Also, a significant main effect was found for intervention type ($F_{1,58}$=19.756; *P*<.001), with a large effect size (partial η^2=0.254). The Macronutrient + NCDs intervention had a greater effect on improving knowledge (Table 3). The interaction between gender and intervention type was nonsignificant ($F_{1,58}$=0.002; *P*=.99), with a very small effect size (partial η^2=0.00), indicating that the effect of the interventions on knowledge was consistent across genders.

Table . Changes in macronutrient-noncommunicable disease (NCD) knowledge and body image discrepancy across intervention periods.

	Baseline, mean (SE)	95% CI	Follow-up, mean (SE)	95% CI
Effect on macronutrient-metabolic NCDs knowledge				
Nutrition+ NCD	11.16 (0.56)	10.03 to 12.29	13.39 (0.42)	12.55 to 14.24
Nutrition	11.53 (0.55)	10.45 to 12.63	13.04 (0.41)	12.22 to 13.86
Effect on body image discrepancy				
Nutrition + NCD	−0.38 (0.17)	−0.72 to −0.03	−0.53 (0.19)	−0.90 to −0.16
Nutrition	−0.50 (0.167)	−0.84 to −0.17	−0.41 (0.18)	−0.77 to −0.05

Body Image Discrepancy

The effect of time on body image was nonsignificant ($F_{1,58}$=0.150; *P*=.70), with a small effect size (partial η^2=0.003), suggesting no significant change in students' body image from pre- to postintervention. Similarly, the interaction between gender and intervention type was nonsignificant for body image ($F_{1,58}$=0.182; *P*=.73), with a very small effect size (partial η^2=0.002), meaning that the interventions had similar effects on body image for both males and females. The effect of gender on body image was marginally significant ($F_{1,58}$=6.157; *P*=.052), with a medium effect size (partial η^2=0.064), suggesting a slight difference in body image perception between males and females. However, Welch ANOVA was used due to unequal variances between males and females on postintervention body image discrepancy, and the findings suggest that gender does play a

XSL•FO
RenderX

role in postintervention body image, with a statistically significant difference detected between males and females (Welch $F_{1,66.977}$=5.385; P=.02). This suggests that after accounting for unequal variances (based on Levene test), gender does have a significant effect on postintervention body image.

The Green Apple Intervention Feasibility

The high recruitment rate indicates strong initial interest and willingness to participate in the intervention, with 82.6% (95/115) of invited students enrolling in the study. Nearly 90% (85/95) of the recruited participants were engaged enough to provide comprehensive baseline data. The overall retention rate, based on completion of the pre- and postintervention questionnaires, was 72.6% (69/95). This indicates that a significant majority of the participants remained engaged with the study through to its conclusion, although there was a drop-off of 27.4% (26/95) from baseline to the postintervention phase. This dropout rate highlights some challenges in maintaining participant engagement over the study period. The retention rate was notably higher among male participants (46/58, 79.3%) than among female participants (23/37, 62.2%). This disparity was related to high absenteeism in the female school. Furthermore, one of the key challenges encountered was scheduling conflicts, particularly in the male school. These constraints impacted the intervention delivery, reducing the planned 2 sessions over 2 weeks to a single session on 1 day.

Discussion

Principal Findings

This study aimed to assess the prevalence of obesity among late adolescents in Medina City, Saudi Arabia, using both BAZ and fat percentage, and to evaluate the feasibility and effectiveness of a low-intensity, non–weight-centric educational intervention focused on macronutrient-metabolic disease knowledge. The findings indicate a high prevalence of obesity in this population, surpassing national averages. The Green Apple intervention effectively improved students' macronutrient knowledge without negatively affecting body image discrepancy, demonstrating its potential as a health education tool.

The prevalence of overweight and obesity based on the BAZ classification was 37.9% (36/95), with 21.1% (20/95) classified as obese. When using fat percentage, the prevalence was even higher at 50.5% (48/95), highlighting that BMI alone may underestimate obesity rates. This aligns with regional data, indicating that adolescent obesity trends in Medina reflect broader patterns observed in the western region of Saudi Arabia [7]. The effectiveness of the Green Apple intervention in significantly improving macronutrient-metabolic NCDs knowledge without impacting body image discrepancy underscores the potential for brief educational programs to enhance adolescents' understanding of nutrition and health.

Our study's obesity prevalence rates are consistent with findings from prior research in the western region of Saudi Arabia. For instance, a 2019 study reported a 35.3% (121/342) obesity prevalence among university students in Medina [42], indicating a persistent trend across educational levels. A 2021 study also found a similar overweight and obesity prevalence of 38.5% (44,826/116,656) among participants aged 17 - 25 years across different Saudi regions [43]. The higher prevalence of obesity in males (15/58, 25.9%) than in females (5/37, 13.5%) aligns with national data showing higher obesity rates in male adolescents [10].

The use of fat percentage as an additional measure provided a more nuanced understanding, revealing an obesity rate nearly double that of the BAZ classification. This supports prior research suggesting that fat percentage often results in a higher reported prevalence of obesity compared with BMI, sometimes by 1.5-3 times [44-46]. BMI fails to distinguish between muscle and fat mass, making fat percentage a more accurate indicator of obesity [45,46].

The study also identified a significant difference in VO_2max scores between the normal and high BAZ groups among females, with the normal group demonstrating better cardiovascular fitness. This finding suggests an inverse relationship between BAZ and cardiovascular health, emphasizing the importance of maintaining a normal BAZ for better fitness. Similar studies have shown a negative relationship between BMI and cardiorespiratory fitness in Saudi youth aged 8 - 15 years [47]. Furthermore, while the normal BAZ group had higher handgrip strength, there was no significant difference in percentiles between groups, indicating that low muscle strength is common among adolescents regardless of BMI. Previous studies have also reported low muscle strength among Saudi male adolescents aged 17 years [48] and no significant association between BMI and strength in college-aged females [49]. This study is the first to report age- and sex-specific handgrip strength percentiles for this population, an essential aspect for future research [30].

Also, the lack of significant differences in dietary behaviors between weight groups suggests that suboptimal eating habits are widespread. Both groups showed low fruit and vegetable intake and high consumption of sugary drinks, aligning with global patterns [50]. Sedentary behavior was similar between groups, reinforcing the need for targeted physical activity interventions. Our finding that vigorous physical activity correlates with lower obesity rates aligns with the Green Apple program's emphasis on high-intensity activity for metabolic health [51]. Current evidence suggests that vigorous intensity exercise may be particularly effective for improving body composition and health outcomes in adolescents [8,9]. These modalities also show promise for improving adherence. However, proper supervision and safety considerations are important, especially for higher-intensity activities and more research is needed to determine optimal exercise prescriptions and implementation strategies for this age group [8,9].

Our findings further revealed significantly lower exposure to NCD education among students with overweight or obese status compared with those with normal weight, and male students reported lower exposure than females. This could be linked to lower NCD knowledge among male teachers, as suggested by a recent study in Saudi Arabia [52]. The lower awareness about NCDs among young adults highlights the need for targeted interventions to increase education and awareness [53,54]. Early

XSL•FO
RenderX

education can lead to better outcomes by promoting preventive measures [54,55].

The efficacy of low-intensity, non–weight-centric educational interventions in improving knowledge is crucial for preventing metabolic NCDs. By focusing on macronutrient education without emphasizing weight loss, the Green Apple program demonstrates a promising approach to improving metabolic health in adolescents without affecting body image. Research on educational interventions in Saudi Arabia and Gulf Cooperation Councilcountries is limited, with existing studies primarily focusing on obesity awareness and metabolic NCDs such as diabetes [12,56]. Our study contributes to this field by showing that even low-intensity interventions targeting macronutrient and NCD knowledge can enhance health literacy. Importantly, this study targeted late adolescents, addressing a significant gap as previous research has mainly focused on younger adolescents (aged 12 - 14 years) [12,56]. The Green Apple program, as a pilot derived from the larger LEAF program, suggests a scalable model that integrates educational and behavioral strategies to promote sustainable health improvements by focusing on visceral fat reduction and muscle mass development.

The significant improvement in students' knowledge aligns with recent literature highlighting the importance of early NCD education [57,58]. The observed large effect size (partial η^2=0.286) further supports the intervention's effectiveness. Contextualizing nutritional information to metabolic health may enhance learning by linking knowledge to practical outcomes. Also, the nonsignificant interaction between gender and intervention type indicates that the content was equally effective for both male and female students, which is significant in a cultural context where gender-specific education is common [59]. This suggests that balanced content can be effective across genders. Finally, the nonsignificant effect on body image supports literature advocating for weight-neutral interventions to avoid adverse body image outcomes [60]. However, the significant postintervention body image difference between genders highlights the need for considering gender-specific perceptions in future program designs [61].

Limitations and Recommendations

Despite the positive outcomes, challenges such as scheduling and gender-specific retention highlight the need for flexible strategies. Limitations include the relatively small, single-region sample size, which may limit generalizability, and the short intervention period, which may not capture long-term effects. Self-reported data could introduce bias. Future research should involve larger, more diverse samples and longer interventions and consider digital family-based education methods, such as webinars and web-based workshops, to enhance parental involvement [62-64]. Engaging parents in school health education could yield better adolescent health outcomes [63,64].

Conclusions

This study underscores the high prevalence of obesity among Saudi adolescents and highlights the potential of low-intensity educational interventions to improve macronutrient knowledge. By emphasizing metabolic health and muscle building, the Green Apple program offers a promising non–weight-centric strategy for preventing chronic metabolic diseases. Future programs should focus on high-intensity physical activity and neutral weight messaging to address obesity and mental health comprehensively.

Acknowledgments

The authors would like to express sincere gratitude to the Ministry of Education School Health Department in Medina and all the participating schools for their invaluable support. All authors have read and agreed to the published version of the manuscript.

Abstract

This study examines the trends, patterns, and potential health disparities in health care utilization among children with medical complexity, before and during COVID pandemic through a retrospective chart review. Our findings show significant differences in the average number of visits per patient over the years and support the adoption of telehealth consultations, while highlighting concerns about demographic disparities.

(JMIR Pediatr Parent 2025;8:e65751) doi:10.2196/65751

KEYWORDS

children with medical complexity; pediatric; children; health care utilization; telemedicine; telehealth; virtual care; virtual health; COVID-19; SARS-COV-2; coronavirus; respiratory; infectious; pulmonary; pandemic; chart review; chart review study; retrospective chart review; retrospective chart review study

Introduction

Children with medical complexity are defined as children and youth with chronic and severe health conditions and substantial functional limitations that require specialized medical services, frequent hospitalizations, and coordinated care from various health care providers [1,2].

Telehealth was one of the efficient and creative solutions for care for children with medical complexity during the pandemic [3]. These children face numerous barriers to health care (eg, multiple visits per day, limited access and availability of clinicians, high cost of transportation, day-to-day life disruptions) [4]. Telehealth visits or remote virtual consultations offered numerous benefits at the onset of the COVID-19 pandemic, such as limited exposure, fewer transfers, and minimum travel for several types of patients and specialists, while also increasing the availability of consultations [5]. This alternative to in-person visits has proven to be effective in resource-limited countries with geographical barriers and has reduced the burden of negative consequences for chronically ill children [6]. After its rapid implementation during the pandemic, the attention has shifted towards equity and safety for children with medical complexity postpandemic, while focusing on clinical model refinement and addressing potential health disparities [7,8]. We explored health care utilization patterns among children with medical complexity over 3 years, before and after the pandemic.

Methods

Study Design and Participants

We performed a retrospective chart review study using data from a large health care setting on the East Coast between January 1, 2019, and December 31, 2021. Patients that were included in the study (N=435) were children with medical complexity (<22 years of age), diagnosed with ≥3 chronic conditions [9]. All patient mortality cases (n=5) during the selected period were excluded due to incomplete data for comparison.

Ethical Considerations

This study used deidentified chart data retrieved from electronic health records using *ICD-10* codes to identify the population. The data were fully anonymized before analysis, and no personal or identifiable information was accessed. The study was conducted in compliance with all relevant data protection regulations, including the HIPPA (Health Insurance Portability and Accountability Act). Institutional Review Board approval was obtained (IRB ID: Pro2023-0385) from Hackensack Meridian Health.

Data Processing and Analysis

A demographic summary and descriptive statistics were computed to analyze the distribution of demographic variables, years, and health care visit types, including counts, means, and standard deviations. To evaluate associations between these variables, the Pearson χ^2 tests of independence were conducted.

XSL•FO
RenderX

For variables showing significant associations (P<.05), we reported the effect size using Cramer's V [5] to determine the strength of the relationship. Additionally, posthoc pairwise comparisons were performed using χ^2 tests with adjusted significance levels to identify specific category pairs contributing to the observed differences. All analyses were performed using Microsoft Excel and SPSS software (version 29; IBM Corp) to ensure accuracy and consistency.

Results

Demographic Summary

Table 1 presents the demographic summary of the patients included in the study.

Table . Demographic summary of patients.

Variables	Patients, n (%) (N=435)
Age	
Infants (1-2)	55 (12.6)
Children (3-11)	231 (53.1)
Adolescents (12-18)	104 (23.9)
Young Adults (18-21)	45 (10.3)
Race/ethnicity	
Asian	65 (14.9)
Black	65 (14.9)
Hispanic	82 (18.9)
NonHispanic White	85 (29.5)
Other	67 (15.4)
Unknown	71 (16.3)
Insurance method	
Managed Care	302 (69.4)
Private	99 (22.8)
Other	34 (7.8)

Statistical Analysis

Table 2 provides descriptive statistics for the entire dataset. The data reveal that the highest total average was 16.74 appointments per patient before the pandemic in 2019. In 2020, with the onset of COVID-19, telehealth became a viable means of communicating with patients, while other types of visits and inpatient admissions decreased, resulting in a total average of 10.34 appointments per patient. Although mean of all visit types, including inpatient admissions increased in 2021, they did not return to the 2019 levels, leading to an overall average of 13.22 appointments per patient.

XSL•FO
RenderX

Table . Data description and findings. This table describes the mean and standard deviations of the number of visits for each visit type (telehealth, outpatient, emergency department) and admissions per patient.

Demographic variables	Visit types															
	Telehealth visits, mean (SD)				Outpatient visits, mean (SD)				Emergency department visits, mean (SD)				Inpatient admissions, mean (SD)			
	2019	2020	2021	*P* value	2019	2020	2021	*P* value	2019	2020	2021	*P* value	2019	2020	2021	*P* value

[a]Overall averages for each year with a *P* value for difference between the years

[b]Averages per year for each demographic group with a *P* value for the difference between demographic categories.

XSL•FO
RenderX

A χ^2 test of independence revealed significant differences between the years for telehealth visits (P<.001, Cramer's V=0.612), outpatient visits (P<.001, Cramer's V=0.396), emergency department visits (P<.001, Cramer's V=0.557), and inpatient admissions (P<.001, Cramer's V=0.405).

Among the demographic variables, a significant association was found between race or ethnicity and the number of outpatient visits for three years (P=.04, Cramer's V=0.008). Pairwise comparison for outpatient visits revealed three significant relationships between Asian (P=.02), Hispanic (P=.004), and other patients (P=.02) compared to nonHispanic White patients.

Discussion

Telehealth visits were introduced in 2020, and resulted in a notable decrease in other visit types and inpatient admissions, as reported in other studies [4]. Although 2021 saw an increase in these visit types compared to 2020, they did not return to prepandemic levels observed in 2019. This could be attributed to catch-up visits and admissions that were postponed due to safety reasons during the pandemic [10]. In addition, while many visits can be conducted via telehealth systems, some health care procedures require in-person visits; the safety of these in-person visits improved in 2021.

The reduction in in-person visits after introducing telehealth implementation aligns with another study showing lower hospitalization rates 3 months post discharge when telehealth was used for follow up [11]. Our study also found a reduction in emergency department visits after telehealth introduction, as shown in the literature [8]. Increasing the ease at which a family can access health care via telehealth can avoid some of the in-person struggles faced by families and improve satisfaction with health care interactions.

Our findings show that Asian, Hispanic, and other racial and ethnic groups, have significantly fewer outpatient visits, on average, than nonHispanic White patients. These findings partially align with recent research among Medicaid-insured children with medical complexity, which found that Black nonHispanic and Hispanic children had lower outpatient visit rates than nonHispanic White children [12]. Several reasons may contribute to lower out-patient visits among racial and ethnic minorities, including differential access to care [12], geographical dispersion, a reduced likelihood of receiving specialty referrals from primary care providers, and distrust in the health care system [13]. Significant differences in the number of visits could lead to health disparities, potentially disadvantaging minority groups, and should, therefore, be monitored and addressed.

The COVID-19 pandemic has shown the feasibility of telehealth visits. Although we found disparities based on race and ethnicity in outpatient visits, our findings support equity through telehealth visits for patients and reduced health care utilization. There was no increase in the need for inpatient services when using telehealth visits, which supports the idea that telehealth can be an effective solution for patients. Families can avoid transportation challenges and coordination issues when using telehealth visits.

Our study focuses on changes in health care utilization among children with medical complexity with 3 or more chronic conditions, providing valuable insights into trends within this population. However, we did not account for specific illnesses, clinical outcomes, or the quality of telehealth visits. Additionally, we did not consider environmental factors such as air pollution or pollen exposure, which could significantly influence utilization patterns among children with respiratory or allergic conditions [14]. To deepen our understanding, future research should include control groups or broader pediatric populations to contextualize these observed trends and address potential confounding factors. Additionally, qualitative analyses are needed to explore the reasons behind differences in utilization and disparities, offering a more comprehensive perspective on the challenges faced by this population.

In conclusion, our findings emphasize the need for continued adaptation and support for telehealth services among children, while monitoring demographic disparities in health care access. The introduction of telehealth at the onset of the pandemic coincided with significant decreases in in-person visits and inpatient admissions. Although health care utilization rebound in 2021, it remained below prepandemic levels, suggesting an ongoing adjustment in health care practices. Further, our findings indicate that racial and ethnic disparities persist in outpatient visit patterns. Continued support for telehealth implementation, coupled with targeted efforts to address disparities, are crucial for equitable health care access for all children with medical complexity.

Abstract

This pilot study of the redesigned Resilience Clinic, a group-based psychoeducational intervention designed to promote relational health and child and family resilience provides preliminary evidence that participation in this intervention is associated with decreased caregiver stress, anxiety, and child behavioral concerns.

(JMIR Pediatr Parent 2025;8:e67638) doi:10.2196/67638

Introduction

Since adverse childhood experiences (ACEs) including child maltreatment, family violence, parental substance abuse, and parental mental illness may increase health and behavioral risks [1,2], further research into preventive early childhood interventions, before the onset of ACE-associated sequelae is required [3]. The Resilience Clinic (RC) [4] is a primary care-based group psychoeducational intervention promoting resilience among children exposed to significant adversity. Initially serving children of all ages, this program was redesigned based on significant parent feedback to focus on early childhood (ages 0 - 5); the curriculum incorporates Circle of Security-Parenting (building secure attachment) [5] and Dovetail Learning (mindful stress management) [6] in 6 weekly, hour-long group sessions. This study explored whether participation in RC decreased measures of (1) caregiver stress, anxiety, and depression, and (2) child behavioral challenges.

Methods

This pilot study analyzed pre-post differences in caregiver-reported measures of behavioral health after RC participation. Eligibility criteria included children aged 0 - 5, referred by primary care providers following positive ACE screening; siblings were excluded. Eligible participants were allowed to join the intervention without joining the study.

Study measures included the Child Behavior Checklist (CBCL) for ages 1.5 to 5 years [7] to assess child behavioral challenges, Generalized Anxiety Disorder (GAD-7) [8] for caregiver anxiety, Patient Health Questionnaire (PHQ-8) [9] for caregiver depression, and Perceived Stress Scale (PSS-4) [10] for caregiver stress. Caregivers completed measurements at baseline and 3 months after intervention completion.

To estimate intervention effect sizes, we used Cohen *d* or (standardized mean difference), for paired samples. Cohen *d* value cutoffs of 0.2, 0.5, and 0.8 are considered as small, medium, and large effect sizes, respectively. *P* values were constructed from the Wilcoxon signed-rank test since the variables were not normally distributed, with significance set at $P<.05$.

This study was approved by the host institution's Institutional Review Board (22 - 37781) as minimal risk research. Signed informed consent was obtained from all participating caregivers. Data was stored on secure institutional servers and deidentified prior to analysis. Participants could receive up to $190 for completing all study activities.

Results

A total of 28 caregiver/child dyads were recruited; of these, 79% (n=22) preferred Spanish and 14% (n=4) preferred English. Median child age was 4.5 years (IQR 1.66) and 50% (n=14)

XSL•FO
RenderX

were male. Participants who completed both pre and post data collection were included in this analysis.

Three months post-intervention, caregivers reported large reductions in anxiety and perceived stress compared to baseline (Table 1).

Table . Pre-post changes in caregiver behavioral health measures.

Construct	Measures	Participants, n[a] (N=28)	Baseline scores median, (IQR)	Post intervention scores, median (IQR)	Cohen *d* (SMD)[b]	*P* value
Caregiver anxiety	GAD-7[c]	16	5.5 (1.75-9.25)	1.0 (0-4.25)	0.86	.01
Caregiver depression	PHQ-8[d]	4	8.0 (6.5-9.25)	5.5 (3.75-7.25)	0.63	.42
Caregiver-perceived stress	PSS)- 4[e]	18	7.0 (6-8)	4.0 (3-6)	0.92	.02

[a]Number of participants who completed both pre and postdata collection for that measure.

[b]SMD: Standardized mean difference.

[c]GAD-7: Generalized Anxiety Disorder-7-item.

[d]PHQ-8: Patient Health Questionnaire-8-item.

[e]PSS-4: Perceived Stress Scale-4-item.

Notably, the decrease in caregiver anxiety (GAD-7: d=0.86, P=.01) and caregiver-perceived stress (PSS-4: d=0.92, P=.02) suggested large and statistically significant intervention effect sizes for parental anxiety and perceived stress among RC participants. The PHQ-8 responses were limited as the full instrument was administered only if the PHQ-2 score exceeded 4, making it difficult to draw conclusions.

Similarly, moderate reductions were seen in postintervention measures of multiple child behavior challenges, including attention problems, aggression, externalizing problems, stress, and overall problems. The decrease in attention problems (d=0.72, P=.05) approached significance. Selected child behavior domains showing moderate postintervention score reduction are listed in Table 2.

All other CBCL domains showed small effect sizes (d<0.5), including emotionally reactive (0.27), anxious depressed (0.12), somatic complaints (0.46), withdrawn (0.36), sleep problems (0.16), internalizing problems (0.32), anxiety problems (0.02), autism spectrum problems (0.48), and oppositional defiant problems (0.40).

Table . Pre-post changes in the Child Behavior Checklist (CBCL).

Child behavior domain	Number of participants, n[a] (N=28)	Baseline scores, median (IQR)	Post-intervention scores, median (IQR)	Cohen *d* (SMD)[b]	*P* value
Attention problems	11	62 (57.5-67)	53 (51.5-62)	0.72	.05
Aggressive behaviors	11	64 (51.5-70)	56 (51-61)	0.53	.20
Externalizing problems	11	64 (53-70)	56 (48.5-60)	0.70	.11
Overall problems	11	68 (53.5-72)	58 (49.5-66.5)	0.50	.07
Stress	11	70 (53-72)	53 (52-62.5)	0.74	.09
Depression	11	63 (53-69.5)	56 (50-61.5)	0.52	.09
ADHD[c]	11	64 (59-71)	57 (52-65.5)	0.72	.08

[a]Number of participants who completed both pre and postdata collection for that measure.

[b]SMD: Standardized mean difference.

[c]ADHD: Attention deficit hyperactivity disorder

Discussion

Three months post-intervention, caregivers reported significant reductions in anxiety and perceived stress and moderate reductions in their children's attention problems, aggressive behaviors, externalizing problems, total problems, and stress and depressive problems. The decrease in caregivers' anxiety and perceived stress was significant (P<.05), and the reduction in child attention problems approached significance (P=.05). These findings suggest that participation in this group resilience intervention may help improve caregiver stress and anxiety and child behavior.

Study limitations include the small sample size and lack of a control group, which make the findings preliminary. Given these promising results, a randomized controlled trial is needed to confirm these intervention effects.

XSL•FO
RenderX

Given the age of these children, when mental health diagnoses are rare, most children would not otherwise be receiving mental health services. This pilot study indicates that similar primary care-based, preventative group interventions may offer meaningful improvements in caregiver and child behavioral health in the context of childhood adversity.

Acknowledgments

This intervention pilot study and evaluation were funded by a University of California ACES Aware Network (UCAAN) PRACTICE grant sponsored by the State of California-Department of Health Care Services (CA-DHCS) and the California Office of the Surgeon General (CA-OSG). The Stupski Foundation also funded program re-designing and implementation at the study's host institution, which preceded the community pilot reported in this manuscript. This publication was supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through UCSF-CTSI Grant Number UL1 TR001872. The study authors would also like to thank the following colleagues from the University of California San Francisco (UCSF) School of Medicine, whose work on a companion study informed the design of this one: Neeta Thakur, MD, Associate Professor, Medicine; Dayna Long, MD, Professor, Pediatrics; Nicki Bush, PhD, Professor, Psychiatry; and Danielle Hessler Jones, PhD, Professor, Family and Community Medicine.

Abstract

Participants in qualitative interviews designed to optimize the adaptation of a maternal postpartum depression intervention into a novel smartphone app noted that the app could be more useful if were delivered simultaneously to both parents; this calls for additional research on the feasibility and effectiveness of digital dyadic or stand-alone partner interventions to prevent postpartum depression.

(JMIR Pediatr Parent 2025;8:e71764) doi:10.2196/71764

KEYWORDS

digital perinatal mental health; postpartum depression prevention; nonbirthing partner; qualitative research

Introduction

Approximately 15% of women in the United States develop postpartum depression (PPD) [1]. The United States Preventive Services Task Force (USPSTF) recommends that women at risk for PPD participate in a program such as Mothers and Babies (MB), an in-person cognitive behavioral therapy (CBT)–based curriculum that prevents PPD [2]. Because smartphone app–provided CBT can reduce PPD symptoms and expand the reach of CBT programs [3], we used individual in-depth interviews with perinatal women to develop a novel app, MBapp, that adapts MB to a digital format [4].

During the interviews that guided app development, study participants noted that MBapp would be useful for their partner or would benefit their relationship with their partner. To explore MBapp's potential utility as a dyadic intervention, we conducted a qualitative analysis of emergent data obtained during thematic analysis from interviews that guided MB's adaptation into MBapp.

Methods

Overview

English- or Spanish-speaking women who were between 32 weeks' gestation and 6 months postpartum were eligible.

XSL•FO
RenderX

Consenting participants completed a virtual, individual, semistructured interview exploring their perspectives on perinatal mental health and pregnancy- or childbirth-related education and support [5]. They were also asked to provide feedback on draft versions of MBapp [4]. The interview agenda was not designed to elicit discussion on partners; therefore, partner data were emergent. As has been described previously [4,5], each interview was recorded, transcribed, and, after interrater reliability was confirmed, coded by 2 authors for consensus. Coded data were inputted into NVivo and interpreted using a thematic analytic approach. This paper includes only the emergent themes pertaining to participant-initiated perspectives of MBapp's utility for their partner or relationship with their partner.

Ethical Considerations

The study was approved by Women & Infant's Hospital of Rhode Island's institutional review board (1737296). Participants signed informed consent forms prior to participation and could opt out at any time. All data collected were deidentified, and participants received a US $50 gift card for completing the qualitative interview.

Results

As previously reported [4,5], the 25 interviewees were racially and ethnically diverse, with half primiparous, (n=13, 52%), half Spanish-speaking, (n=12, 48%), and half pregnant (n=13, 52%) (Table 1). Of the 25 women, 5 independently expressed, without any explicit prompting, that they saw value in providing MBapp to their partner. In this subgroup, 3 of 5 were Spanish-speaking, 2 of 5 were primiparous, and 3 of 5 were post partum.

Each of these 5 participants mentioned their interest in sharing MBapp with their partner when prompted to suggest ways to enhance the app's usefulness for perinatal women. The 5 women stated that providing MBapp to a partner would make it more effective as both a perinatal psychoeducational tool and a CBT-based program (Table 2). Some endorsed that MBapp could teach their partners how to improve communication and provide infant care, helping them be a more supportive partner. Others noted that MBapp could help their partners recognize the interplay between relationship dynamics, maternal isolation, and PPD symptoms. Each of these 5 participants was surprised that MBapp was planned to be delivered exclusively to the pregnant person.

Table 1. Sociodemographic and obstetric characteristics of study participants (N=25).

Characteristics	Values
Age (years)	
Median (IQR)	29 (24-35)
Range	20-43
Advanced maternal age (35 years or older at time of delivery), n (%)	6 (24)
Race, n (%)	
Black	5 (20)
American Indian or Alaska Native	3 (12)
Asian	2 (8)
White	6 (24)
Other[a]	9 (36)
Ethnicity, n (%)	
Hispanic	13 (52)
Language of interview[b], n (%)	
English	13 (52)
Spanish	12 (48)
Primiparous (pregnant with first child or recently delivered first child)	13 (52)
Pregnancy status, n (%)	
Pregnant	13 (52)
Postpartum	12 (48)

[a]Other: multiracial (White and Black): n=4; multiracial (White and American Indian or Alaska Native): n=3; multiracial (Black and American Indian or Alaska Native): n=2.

[b]Four participants spoke a combination of English and Spanish. Their interview language was categorized as the language that most of the interview was conducted in.

Table 2. Participant-elicited reasons that MBapp would be useful for their partner.

Themes	Quotes
Improve dyadic communication	"Maybe they're not knowing [how to] explain to the other partner how they're acting, like they're not being assertive enough, or they're being too aggressive. They can open [the app] up and show them, 'This is what is going on with us. This is how I feel like you're treating me,' so they can get more of a better understanding of how you feel." (English-speaking postpartum person with multiple children)
Increase partner's knowledge on infant care	"There is nothing like this for men. How is it possible that we are in the 21st century, and men don't know how to do things for their baby? My brother is like that. He will say, 'No, a woman does that.' And I say, 'No it's for men and women.'... There are a lot of men like him, who can't change a stupid diaper and don't fulfill their role fifty/fifty. The world could change when things like this [program] are mixed, for men and women." (Spanish-speaking pregnant person who is a first-time parent)
Effect of perceived partner support and maternal stress and isolation	"The emotional state you're in after giving birth, well. If you don't get support from your partner, you get stressed out.... Sometimes the baby starts crying and...many partners don't support you with that. That's when you get stressed. There comes a time when the woman starts crying because so many things build up that she explodes, and she feels alone." (Spanish-speaking pregnant person with a prior child)
Interplay between partner stress and maternal mental health symptoms	"People that are dealing with their spouses, like if they're stressed with each other, it's taking a toll on both of the parents, like on their mental health. Like, the mom will be dealing with postpartum [depression].... Fathers [must] understand how you have to do well with them to be doing well with yourself and with your baby" (English-speaking postpartum person with multiple children)

Discussion

This study presents emergent qualitative data from diverse perinatal women whose feedback was used to optimize MBapp, a novel app-based CBT program. Without prompting, 5 of 25 participants noted that MBapp would be more useful for them if it were also provided to their partners. Had the interview specifically queried about perceptions of partner use and involvement, the proportion of participants who reported MBapp would be more useful as a dyadic than a stand-alone intervention may have been higher. These emergent data align with the well-known bidirectional association between maternal and paternal perinatal mental health symptoms [6,7]. Though a small study has proven the feasibility of delivering in-person MB to both parents simultaneously [8], the feasibility and effectiveness of delivering MBapp—or other USPSTF-recommended psychotherapy [2]—as a digital dyadic intervention to prevent PPD has yet to be explored. Study strengths include a diverse study population and interviews conducted in English or Spanish. Furthermore, the study population can be considered sufficiently sampled per qualitative methodology principles [9]. Study limitations include exclusive recruitment at one obstetric clinic. Expanding data collection can assess whether these findings resonate in other populations. In addition, because the interviews were not intended to discuss partner status—much less partner support—the proportion of participants with partners (and supportive or unsupportive partners) is unknown. Lastly, emergent themes on partners were not identified until the data were analyzed; thus, thematic saturation was not achieved. In summary, this qualitative analysis demonstrates that an evidence-based maternal PPD-prevention intervention may be more useful if delivered simultaneously to both parents, potentially by being an upstream mediator of maternal PPD, as per dyadic coping theory [10]. Our results call for additional research examining not just the feasibility and effectiveness but the mechanisms of effectiveness of digital dyadic or stand-alone partner PPD prevention interventions.

Abstract

Background: In a world where children are increasingly sedentary, the need for innovative solutions to promote physical activity is felt more than ever. Exergames—interactive video games combining physical activity with gaming—are an attractive way to engage children in exercise while having fun. Although exergames have demonstrated several benefits for the health and physical activity of children and young people, the impact of these devices is poorly explored, especially in the school context.

Objective: This scoping review was aimed at analyzing the effects of exergames on motor skills, psychological well-being, and cognitive abilities in children and adolescents during physical education hours and play-based activities. Our specific goal was to explore and describe the effects of exergames in school programs and their potential to improve physical and mental health in educational settings.

Methods: We carried out our review in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. We searched 3 bibliographic databases from 2019 to June 2024 and included all scientific studies involving children and adolescents interacting with exergames during physical education lessons at school.

Results: Our database search produced 1694 articles. After performing 3 levels of screening (title, abstract, and full text), 25 articles were left. The majority of the studies confirmed that the use of exergames during physical education and playful sport activities is associated with a number of improvements. More specifically, these devices can provide motor benefits as well as psychological or cognitive benefits, such as cognitive flexibility and attentional functions, overall well-being, and a greater sense of self-efficacy, self-confidence, and mood.

Conclusions: These results may have significant implications for public health or education: exergames may become accessible and useful devices for promoting physical activity in young people, potentially benefiting motor skills but also psychological and cognitive functions, increasing children's participation in physical activities, and leading to a general improvement in their sense of self-efficacy and well-being. Exergames can improve children's physical and cognitive skills, thus becoming a complementary and additional device to traditional physical education exercises and helpful tools to increase physical movement in extracurricular activities.

exergames; active video games; physical education; physical activity; school; children; adolescents

Introduction

The World Health Organization (WHO) has underlined the importance of physical activity, which is beneficial to health and mental and physical well-being, for the prevention of noncommunicable diseases [1]. Insufficient levels of physical exercise or physical inactivity may contribute to the development of diseases, such as obesity and overweight, cardiovascular disease, and motor development–related disorders [2,3]. Especially in children and adolescents, sedentary behavior increased adiposity and led to poorer cardiometabolic health, fitness, and behavioral conduct or prosocial behavior, as well as reduced sleep duration [1]. According to data from the Italian Institute of Statistics for the 2017 - 2018 period, Italian children and adolescents did not engage in sufficient levels of physical activity [4] as recommended by the WHO, whereby they should practice at least 60 minutes of moderate to vigorous physical activity for 3 days in a week [5,6]. In addition, Italian Institute of Statistics data (2021) highlighted that continuous sporting activity in children and young people aged 3 - 17 years has

XSL•FO
RenderX

decreased significantly, from 51.3% to 36.2%, while sedentariness has increased (from 22.3% to 27.2%) [7]. This trend is in line with other countries [8-10].

In accordance with the above-mentioned data, schools are considered the main educational context for the promotion of physical activity. There are multiple opportunities for exercise in the context of school, such as during recess, sports, physical education (PE) lessons, and active movement to and from school [11]. Several studies have shown that school-based focused interventions have been effective in increasing children's physical activity levels, achieving up to 50% of the weekly requirement identified by the WHO [1,12].

PE lessons aim to promote motivation and physical exercise in students [12]. However, the role of PE in the school system has led to some criticism concerning the methods and tools that are currently being used during classes, which generate very low interest among pupils and students [13]. With specific reference to educational processes connected to physical and sporting activity, the scientific community is now investigating the effects of incorporating devices into traditional teaching in order to increase student motivation and participation [14].

Among the technological tools available today, there are exergames. Their introduction in everyday life contexts not only helps children and young people to achieve the recommended levels of physical activity but also has a positive effect on their lives, as exergames foster the acquisition and development of motor skills and abilities, increasing participation in sporting activity [15].

Exergames—also known as active video games—are an activity combining video games and motor exercise and requiring physical effort on the part of the child [16]. They are characterized by the use of audio or visual feedback on performance compared to traditional physical activity, thus making it more enjoyable [16]. These digital motor activities aim to stimulate motor and motivational skills [12].

Exergames are based on the conversion of real movements within a virtual environment, allowing players to be more active by practicing virtual sports, fitness exercises, and other playful physical activities [15].

In addition to making health-promoting behavior more attractive and desirable, exergames also offer numerous advantages, such as increased motivation and engagement and a greater possibility for fun and challenge [17]. Their pros are also evident when they are compared with traditional exercises [18]. Exergames are more engaging, increasing motivation to train and consequently improving both motor skills, such as balance and mobility [17], and cognitive skills [18,19]. Moreover, they allow players to focus more on the impact of their own movements during the game and less on movements for their own sake [20]. Finally, they are easily adaptable to various contexts—they require a console and screen or projector—and can be carried out either alone or in small groups, encouraging collaboration and cooperation [18].

As claimed by previous reviews, exergames are able to promote a physically active lifestyle in children and young people [21,22]. However, most of the previous reviews have focused on exergame use in specific contexts and situations, such as nutrition and obesity [23-25], chronic diseases [26,27], and physical activity in general [15,28-30]. Specifically, Lamas and colleagues [21] have evaluated the effectiveness of using exergames to promote nutrition education and physical activity in children and adolescents. Their review points out the effectiveness of using exergames to promote health and prevent obesity by interventions aimed at increasing children's and adolescents' nutritional knowledge and introducing healthier and more balanced diets [21]. Other meta-analyses have focused on the benefits of exergames in school settings, specifically regarding PE learning. In particular, they have shown that exergames can improve performance in PE education and suggest using exergames in small classes, limiting the implementation cycle to 1 - 2 months, and selecting games according to different age groups [31].

Although exergames have demonstrated various benefits concerning the health and physical activity of children and young people, no review has been carried out so far on their potential use and benefits in the school setting, exploring not only motor or physical effects but also psychological and cognitive effects.

Therefore, the aim of this study was to expand and update knowledge on the potential effects of exergames within the school context, considering the past 5 years. A scoping review was conducted to illustrate and analyze the effectiveness of the use of exergames in schools (children aged 6 - 18 years) during PE lessons and play or sports activities, to understand their benefits and advantages, and their future application as inclusive tools.

Methods

This review was conducted according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [32]. Four authors (IB, RN, ER, and SV) searched 3 bibliographic databases from 2019 to June 30, 2024: PubMed, Web of Science, and Scopus. The definitive search strategy is the following string: ("physical exercise" OR "physical education") AND ("exergaming" OR "active video games" OR "exergames" OR "interactive videogame" OR "technology") AND ("children" OR "adolescent") AND ("school" OR "school education" OR "education") NOT (meta-analysis OR review). For complete details of the search strings, refer to Multimedia Appendix 1. The search was manually completed, following the PCC (population, concept, and context) format (Table 1). We included all scientific studies involving children and adolescents, aged between 6 and 18 years, interacting with exergames during PE hours. We excluded papers not written in English, reviews and meta-analyses, and articles on adult participants or animals. We also excluded studies that used other types of technologies during PE hours or technologies with an evaluative purpose of sports performance and studies not related to the school setting.

XSL•FO
RenderX

Table . PCC (population, concept, and context) format.

Components	Description
Population (P)	• Children and adolescents aged 6-18 years
Concept (C)	• Experimental study with random or nonrandomized assignment, quasi-experimental study, cross-sectional study, natural experiment, and uncontrolled trial within exergames to assess motor, psychological, and cognitive skills • Exergames—devices using a digital game-based exercise system (eg, consoles such as Xbox 360 Kinect, HOPSports Brain Breaks, and Nintendo Wii Fit)
Context (C)	• Exergames during physical education lessons and other physical activity hours at school

All record titles and abstracts retrieved from the database search were screened by 4 blinded reviewers (IB, RN, ER, and SV), who excluded studies that did not meet the eligibility criteria. The same authors proceeded with the full-text screening of retained papers according to the inclusion criteria. In case of discordant opinions, the 4 authors voted to reach a decision. Interrater agreement was evaluated with the Fleiss kappa statistic (κ) [33,34]. Data from the articles were extracted into an extraction table, which includes columns for authors and year of publication; sample size, age, experimental groups, and country; methodology and duration of the sessions; outcome measures; and results.

Results

Our search from 3 databases produced 1694 articles. After screening titles and abstracts and removing duplicates, there were 57 articles. A total of 25 articles were included in this review. The PRISMA-ScR flowchart is shown in Figure 1. The interrater reliability for full-text screening was substantial across authors, with κ=0.65, κ=0.72, κ=0.68, and κ=0.71 [33,34].

All studies involve children and adolescents: 23 studies include elementary or middle school children, 1 study includes high school students [39], and another one includes the 8‐ to 18-year-old age group [47]. Most of the articles are fairly balanced between males and females, but sex difference is often not measured in statistical analyses. For 3 studies [40,56,57], the male-female distribution is not known. Most studies include the general population, while 2 studies include children with overweight or obesity [43,57]; 1 study includes children with attention deficit/hyperactivity disorder [44] and another study includes both children with attention deficit/hyperactivity disorder and fetal alcohol spectrum disorder; lastly, 2 studies include children diagnosed with intellectual disability [47,54]. Studies differ in research methodology: there were 6 randomized controlled trials [43-45,50,51,57], 8 nonrandomized controlled studies [12,35,36,38,39,47,53,58], 7 quasi-experimental studies [37,40,41,46,48,52,54], 2 cross-sectional studies [49,55], 1 case study [59], and 1 pilot interventional study [42].

The studies come from different countries, in particular, 2 from North America [49,58], 2 from South Africa [38,57], 4 from South America [35,36,40,51], 6 from Asia [37,39,43,44,47,48], 10 from Europe [12,41,42,45,46,50,53-56], and only one study includes different populations [52].

Thus, their length varied, too, from a minimum of a single session to a maximum of 3 months. In 2 studies, the trial or training duration is not given [40,49]. Regarding the type of exergame used, 7 studies used dance-based exergames, such as Just Dance 2015 on Microsoft Xbox consoles [35,36,40,43,46,49] or Just Dance Now [12,53]. Three studies used videos from the HOPSports Brain Breaks package, which includes different sports such as baseball, basketball, soccer, volleyball, swimming, golf, football, and rowing [37,38,52]. Five studies used exergames based on specific sports such as Nintendo Wii Sports (bowling, boxing, tennis, cycling, table tennis, and basketball) or Wii Fit (yoga, muscle exercises, aerobic exercises, and balance games) or Xbox Sports Season 1 and 2 (including soccer, beach volleyball, bowling, table tennis, track and field, boxing, American football, baseball, darts, golf, skiing, and tennis) [39,43,47,51] or boxing and hula hooping on the Wii Nintendo console [57]. Eight studies used various games involving movement using the Wii balance board (eg, Feline Runner, Hungry Monster, and Whack-a-Slime) [41,54] or Xbox (eg, Kinect Adventures) [48,51] or still other platforms, such as D&J Humancare's Alchemist's Treasure [44], Obie [58], or Exercube's Sphery Racer [45,55]. Three studies developed specific exergames, building on existing ones [42,50,56].

All exergames could be played in a multiplayer mode, for example, by the whole class in some instances or small groups of 3‐4 in others.

The 25 studies were divided into three broad categories according to research objective and outcome measurement:

1. Research studying the effects on psychological or cognitive dimensions. There are 9 papers. The variables under investigation are psychological states or psychosomatic states [35,36]; self-esteem [36]; beliefs and attitudes and self-efficacy with respect to physical activity [37]; attention, concentration and response control, or executive function [44,46]; interest, enjoyment, commitment, flow state, and motivation [46,53,55]. All studies, except for two, found significant effects of exergames on the psychological variables under study. The two studies without significant effects or differences versus the control group specifically addressed intrinsic motivation, external regulation, decreasing amotivation, and perceived enjoyment [53,55].
2. Research studying direct effects on motor and anthropometric aspects or motor skills. There are 12 papers in total. The variables under investigation are physical fitness [38,43,45,57], anthropometric measures

XSL•FO
RenderX

[38-40,43,45,47,57,58], physiological factors [39], daily steps [39], and various motor skills [40,41,47,50,51,54,58]. Significant effects of the application of exergames on anthropometric variables were found in 11 papers [38], including papers on children with obesity [43,57], on various motor or locomotor components [40,41,50,51,54,58], on various physiological components [39], and on physical fitness variables [38,45]. In some of these cases [43,51,54], the significant increase in some or all motor skills or anthropometric variables pretest versus posttest did not differ from that of the control group. Only one study on children with intellectual disabilities did not find any effects [47], so exergames were rated as ineffective.

3. Research on the simultaneous effects on motor or physical aspects and psychological variables. There are 4 articles. The variables under investigation include both anthropometric variables [48,49,52], motor skills [48], physical literacy [42], or psychosocial factors such as enjoyment, self-efficacy, and social support [48,49], as well as beliefs and attitudes toward physical activity [52], and improvements in performance and concentration in other school subjects [42]. Significant effects of exergames were found on some anthropometric or motor variables [42,48,49,52], as well as on psychological variables such as attitude toward physical activity, self-efficacy, and learning [52], or motivation, engagement, and concentration in other school subjects [42]. In two studies [48,49], no effects were found on self-efficacy and psychosocial factors.

Discussion

Discussion of Included Studies

This scoping review focused on the effect of the use of exergames at school in different countries, during PE lessons and play or sports activities, in order to understand their benefits and advantages and their future applications. For these purposes, 25 articles were included.

Considering the majority of the studies, use of exergames during PE hours and playful sports activities is associated with a number of improvements; more specifically, these devices can provide psychological or cognitive as well as motor benefits for children and adolescents with a median age of 10 years. The studies presented use different types of games and vary in frequency, with an overall average duration of 7 weeks, in line with findings from a recent meta-analysis [31]. Below, the specific effects observed are discussed.

Discussion on Psychological or Cognitive Effects

We found 4 studies investigating the psychological effects of exergames. Based on them, we reached the conclusion that exergames played during PE hours or during didactic hours can help increase the students' sense of self-efficacy, vigor, learning, fun, and decrease tension, mental confusion, and perceived anxiety. In addition, they can improve the beliefs and attitudes that children and adolescents have toward sports and physical activities, leading to a general increase in exercise and physical activity [35-37,52]. Also, a review by Joronen and colleagues [59] aimed to observe nonphysical effects of exergames and found that exergames can increase situational interest and enjoyment during physical activity because they are perceived as being more enjoyable. For this reason, children are more likely to carry on playing exergames instead of traditional games. Despite some conflicting results, these researchers reported that successful experiences with exergames could increase perceived self-confidence and consequently the probability of future participation in motor activities [59]. An improvement in self-efficacy and self-confidence was also observed in a previous review and meta-analysis by Andrade and colleagues [60] investigating the effects of exergames in obese children. This could be related to the fact that exergames provide immediate feedback on the student's actions. The ability to see the outcome of their actions in real time may engage and motivate students to continue the activity.

As far as cognitive abilities are concerned, based on two studies taken into account, it can be concluded that an exergame-based intervention can improve executive-attentive functions, specifically selective attention, self-control, sustained attention, cognitive flexibility, and also the students' situational interest for the activity [44,46]. Additionally, some exercises with exergames can have positive effects on motivation and concentration in other school subjects, such as mathematics [42].

These improvements can also be observed at a physiological level, with alterations in event-related potential component N2 waves and cortical cingulate area activity, which are visible just after a single intervention [44]. Exergames would appear to better stimulate visual perception thanks to a virtual environment, which may be experienced by students as more dynamic and engaging. This thus suggests that exergames have attractive and interesting features for children, such as the nature of the game played, interactivity, and involvement through sounds and images. These features may increase participation in physical activity.

Although backed by only a few studies, these results were also confirmed in a previous review by Ramírez-Granizo and colleagues [61]: independently of the exergame used, cognitive performance significantly benefited from the sports or physical activity carried out using them. In particular, the use of electronic devices associated with motor activity seems to bring a general improvement in concentration, attention, and reaction speed.

Discussion on Effects of Motor Abilities

Most of the reviewed studies investigated the influence of exergames on various anthropometric parameters and physical performance. When compared to traditional physical activity interventions, exergames can demonstrably improve motor performance (such as jumping, running, shooting, football, and object control), flexibility and postural stability, and the students' physical fitness at a general level [40,41,45,51,54]. In addition, exergames can improve muscle mass, decreasing waist circumference and body fat [38,43,47], but they can also lead to a significant reduction in sitting time at weekends [39].

Exergames are effective tools for assisting in the acquisition of motor skills, thanks to the immediate feedback that children receive on their performance. In line with our findings, recent

XSL•FO
RenderX

reviews or meta-analyses found that interventions using exergames are effective in developing and improving several components of PE learning or physical fitness, such as agility, balance, and postural stability, while also benefiting the ability to control objects and locomotor skills [31,62]. It must be noted, however, that the authors concluded that their findings were not definitive due to the conflicting outcomes of the studies included in their review.

Despite this variability, most studies support the idea of integrating exergames into traditional PE lessons or using them during teaching hours. This approach can make physical activity more engaging for students while providing variety within the curriculum.

In summary, while current evidence points toward numerous benefits of exergames for improving motor skills and physical fitness among children and adolescents, ongoing research is essential to optimize their application and maximize their potential within educational settings. Further investigations can focus on which games are most effective and establish guidelines for their use to maximize the effectiveness and inclusivity of these tools (such as duration of use, single-player, or group gameplay).

Strengths and Limitations

As far as we are aware, this is the first scoping review aimed at investigating the motor, psychological, and cognitive benefits of exergame-based interventions in school settings and specifically during PE lessons and play activities.

While the primary strength of our study is its attempt to provide an up-to-date review—considering the last 5 years as a timeframe—of the effects of exergames on motor, psychological, and cognitive abilities, this study is not free of limitations, and, consequently, caution is required when interpreting its results.

First, we only included publications in English, which may have led to the exclusion of further available studies that explored this topic in other languages. Although the studies come from different continents, there is no complete heterogeneity. Second, no systematic review and meta-analysis were conducted to assess the effectiveness of exergames and the generalizability of the results.

Third, the studies considered in the review were highly heterogeneous and had several methodological biases. They used different types of exergames; the length was different as were outcomes and variables. For example, some studies used a single exergaming session [46,49], while other studies included several exergaming sessions, up to 3 months. Also, video games and devices were different across studies, and not all studies had a sufficient sample size or used sample randomization. All this could complicate the interpretation of findings and limit their generalizability.

Thus, more studies, such as systematic reviews and meta-analyses, are encouraged to reinforce the validity of the present findings.

Conclusions

In our scoping review of the effects of exergames on motor, psychological, and cognitive abilities during PE lessons and playful sports activities, we focused on the school context, given the central and important role that schools currently have in promoting physical activity in children and adolescents [11].

Our findings show that exergames can have a beneficial effect on children's motor skills, cognitive flexibility and attentional functions, and overall well-being, improving the sense of self-efficacy, self-confidence, and mood during PE lessons.

This may have significant implications for public health or education: exergames may become accessible and useful devices for promoting physical activity in young people, potentially bringing benefits not only on a motor skill level but also on a psychological and cognitive level, increasing children's participation in physical activities and leading to a general improvement in their sense of self-efficacy and well-being.

However, lack of knowledge of their potentials and benefits hinders their wider application. Furthermore, despite their effectiveness, their use is not yet common in the educational and school context.

For this reason, a more systematic application of digital technology in the school setting would contribute to improving and designing new immersive, effective, and inclusive interventions aimed at increasing the physical activity and well-being of children and adolescents. Exergames can improve children's physical and cognitive skills, enjoyment, and involvement in exercise and general well-being, thus becoming a complementary and additional device to traditional PE exercises and helpful tools to increase motor activity during extracurricular activities.

Abstract

Background: Evidence identifies that excessive screen time consumption during the crucial stage of life (0 - 3 years) significantly affects children's holistic development over time. In today's intricate socioeconomic setting, parents, especially working parents, face challenges in constantly supervising their children's activities, often turning to digital devices as a suitable substitute to keep them occupied. To address these issues, a mobile health (mHealth) app can emerge as a feasible solution to help parents manage digital habits for their infants while minimizing the harmful effects.

Objective: The aim of this scoping review from an mHealth viewpoint is to raise awareness among parents about the detrimental effects of unwarranted screen exposure in children younger than 3 years and recommend effective strategies for redirecting them to alternative developmental activities, promoting balanced digital engagement for their infants and toddlers within their domestic landscape.

Methods: A systematic search of academic databases, including Google Scholar, PubMed, IEEE Xplore, and Elsevier, was conducted. To discover existing child screen monitoring apps, searches were conducted in the Google Play Store and Apple App Store through specific keywords across regional marketplaces. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines were followed to organize the literature search process. Data collected from the studies were organized into a predeveloped Excel spreadsheet to facilitate analysis. Synthesized data were scrutinized to detect patterns, variances, and reasonable recommendations.

Results: While parents acknowledge the negative impacts of young children's excessive screen time, their dependence on digital devices survives due to today's modern lifestyle commands. In total, parents' insights were clustered into 9 separate categories, highlighting that parents often believe smart devices are beneficial for their children. A total of 6 intervention approaches for parents and 3 for pediatricians were summarized. A significant finding was parents' unawareness of the association between their own screen time and their toddlers' interactions with screen media. Additionally, parents also perceived existing intervention strategies positively and acknowledged them as helpful solutions. However, they also recognized that inadequate tools and insufficient time for execution caused the gap in these approaches.

Conclusions: The findings of this study underline the need for an empathetic tool to help parents manage their children's screen time efficiently. The development of a holistic mHealth app is presented that considers awareness, practical guidance, and personalized interventions to balance children's digital device use. The proposed solution could incorporate four essential features: (1) screen time tracking and monitoring, (2) a reservoir for parental training and guidelines, (3) an alternative activity advocator, and finally (4) an interactive artificial intelligence assistant. This study provides valuable insights into improving obedience to healthy screen use and fostering a digital ecosystem where technology itself functions as an advocate of child progress, instead of an obligation.

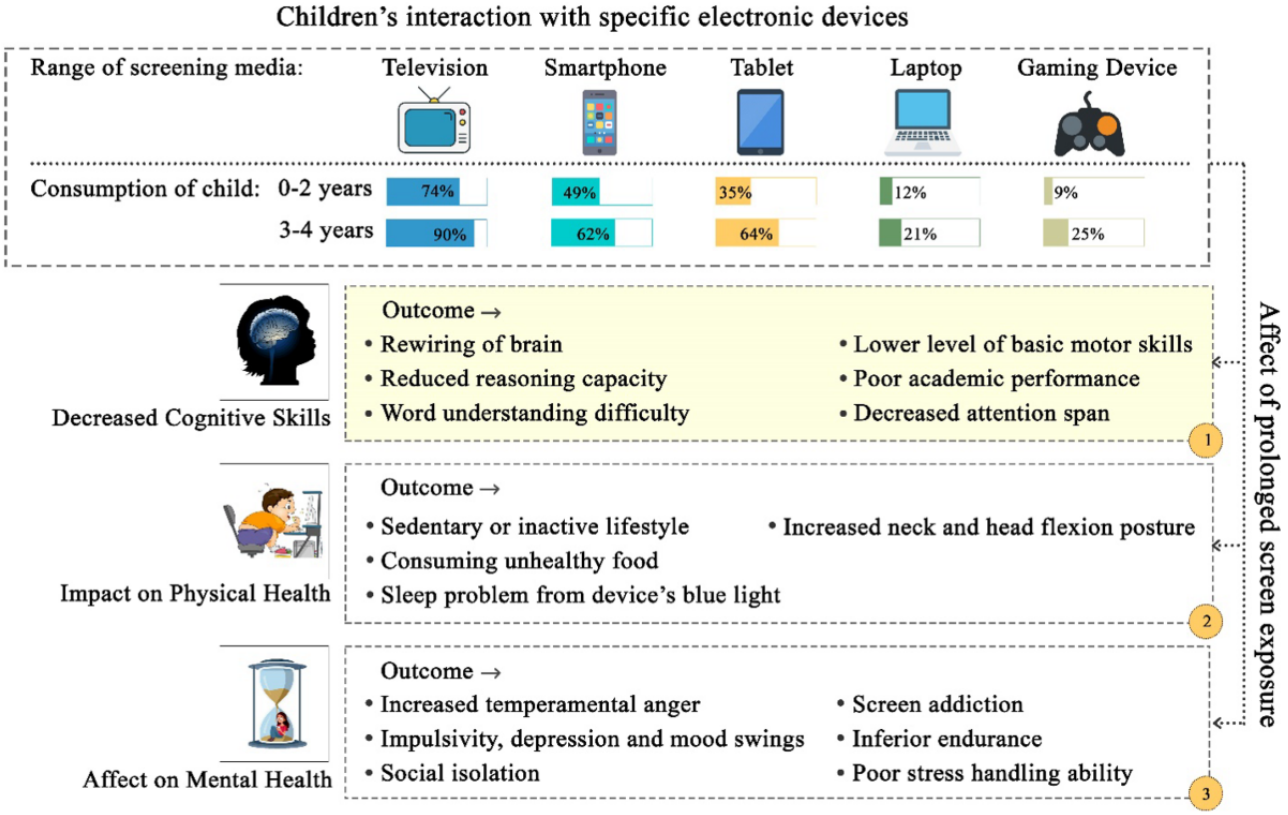
Introduction



The escalating inclination towards extreme screen time use among children has become a universal problem recently, with evidence pointing to imposing severe impacts on children's early childhood development, for instance, lower academic achievements, increased anxiety, difficulties in language acquisition, and other developmental setbacks [1-4]. The American Academy of Pediatrics (AAP), a leading authority dedicated to safeguarding children's welfare, restricts any form of screen media exposure for children younger than 2 years [5]. Nevertheless, studies have uncovered that almost 68% of children younger than this age bracket often surpass this threshold, spending around 2.05 hours of screen time each day, which is overwhelming [6,7]. In addition, watching television, one of the most conventional modes of screen media, for more than 2 hours per day was observed to be 83% in the United States, 78% in Australia, and 82% in Canada among toddlers aged 2 to 5 years, contributing to a sedentary lifestyle within approximately 34% to 94% of children, which are equally alarming [7,8].

The complex socioeconomic landscape further intensifies this issue, as modern parents face an array of obstructions in constantly monitoring their children's activities. Parents play a central role in influencing their young children's screen time habits, as their screen observation levels and behavior are greatly related to those of their children. Their positive attitudes toward screen time can unconsciously increase screen exposure to their young children, leading to behavioral imitation and delays in developmental outcomes [9]. Contrariwise, research indicates that reduced parental screen time is associated with reduced screen exposure in children younger than 3 years, increasing parent-child interactions that are crucial for early cognitive and emotional development [10]. With the limited scope of supervision, screen devices have emerged as a convenient child supervision tool, performing as a companion for struggling parents, leading to approximately 70% of parents ignoring the AAP recommendations, unintentionally contributing to the challenge of screen time management [11,12]. These observations highlight a disconnect between existing guidelines for limiting screen time in infants and the practical challenges parents encounter in limiting digital device use, which implies the need for a detailed reassessment of prevailing strategies to promote a balanced lifestyle that is practical for parents and protective of children's optimal growth and developmental needs.

The foundations for effective intellectual and analytical skill advancement are embedded in early childhood, which offspring usually adopt and develop within the initial 3 years of life [13]. However, throughout this critical stage, infants and younger toddlers are also enormously vulnerable to the harmful consequences triggered by long-lasting screen exposure [14]. Evidence implies that consuming a higher rate of screen time negatively impacts children's cognitive growth with a downstream influence on their physical, academic, and psychological outcomes, as illustrated in Figure 1 [15-17]. A psychological study from Korea involving kids between 24 and 30 months of age displayed a proportionate relationship between prolonged screen time and delays in language development and challenge-solving skills [6]. Similarly, higher television exposure at only 29 months of age was correlated with minimum vocabulary acquisition levels at a later age [18]. On the contrary, research has exhibited that watching high-quality programs under parental supervision has advantages, including attention span and vocabulary improvements, compared with children who do not watch such content at all. Such quality content often uses tactics including findable object labeling, proper formatting, the interaction between the child and characters, and a structured program outline, which can help in their developmental benefits [19]. Nonetheless, many of these affirmative statements targeting children younger than 2 years remain unproven, as stated in the 1999 AAP policy announcements [2,20,21]. These opposing outcomes infer a huge gap in our understanding and the need for an adapted rather than a one-size-fits-all answer.

XSL•FO
RenderX

Figure 1. Influence of excessive screen time on early childhood developmental spheres.

Previous studies regarding the potential consequences of screen time have largely targeted the age range of children between 5 and 7 years; nonetheless, limited attention has been given to children between 0 and 36 months. This study argues that instead of completely discarding the abundant presence of screen devices, it is crucial to adopt a parent-centric, rational strategy that aligns with today's contemporary lifestyles. This paper proposes that the development of a mobile health (mHealth) app can enable parents to manage their children's screen time and maintain a balance between technology consumption and mindful parenting. This study aims to acknowledge the research gaps, emphasize the existing blind spots, and offer appropriate solutions. To accomplish this, the paper addresses the following fundamental research questions:

RQ1: How does the absence of knowledge regarding the prospective threats of excessive screen use influence parental decision-making procedures?

RQ2: What alternative approaches have been identified that parents can successfully use to divert their children from unnecessary screen time while reinforcing their intellectual, physical, and emotional expertise in a home-based surrounding?

RQ3: How can these alternate strategies be seamlessly integrated into a holistic approach that mitigates the adverse effects of excessive screen exposure on young children's overall development?

We start by representing a systematic approach to reviewing existing and appropriate literature in the designated field, analyzing their insights, and revealing critical knowledge gaps in parental understanding regarding screen time management. Building on these insights, we present some actionable suggestions and explore the capability of developing a mHealth app as a rational tool for parents to help them create a better and healthier digital balance for their children younger than 3 years.

Methods

Overview

Through a structured methodology, broad topics can be investigated and blind spots in the existing literature can be identified [22]. We conducted this research using the methodological framework for scoping reviews proposed by Arksey and O'Malley [23], ensuring a meticulous and transparent approach. The methodological framework of this research is designed to provide a comprehensive understanding of the central research questions by identifying primary studies through different sources. Our framework is divided into 3 distinct phases, covering a thorough scoping criteria, a systematic literature search, and a data synthesis process, which are rigorously carried out to ensure alignment with our research objectives.

Scoping Criteria

In phase 1, we identified studies inspecting the reasoning behind parents' dependence on smart devices, their impact on children's early development, and the viability of alternative intervention activities. The study, furthermore, accounts for parents' misunderstandings regarding the positive effects of screen media consumption on their children's health development, alongside how their own digital habits influence their children's media use patterns. In this research, all contributory studies related to the critical research questions offering insights into the

XSL•FO
RenderX

behavioral and developmental implications of excessive screen use received preliminary approval. This phase was performed to encourage parents' early involvement in using effective solutions, preceding a more thorough investigation of the problem.

Systematic Literature Search

In phase 2, we used a systematic literature search to identify studies that complemented the work done in phase 1 and focused on suggesting, describing, evaluating, and implementing novel insights into mitigating screen dependency on children younger than 3 years. The literature review contained journal papers, peer-reviewed articles, and official reports obtained from academic databases such as JMIR, Google Scholar, IEEE Xplore, Elsevier, and PubMed. Advanced search features, such as MeSH terms in PubMed, along with targeted searches including Pediatrics and Parenting, mHealth and uHealth within JMIR were used to recognize the role of child- and parent-centered approaches using mobile apps, information technologies, engineering solutions, and expand the scope of infants and toddlers' health outcomes. We then formulated a series of specified keywords stemming from the research questions to group papers across the abovementioned databases, as detailed in Table 1. Additionally, to gather information on publicly available parental child monitoring mobile apps for smartphones, we conducted searches of the Google Play Store and Apple App Store using keywords like "Family," "Child," and "Safety" across regional marketplaces.

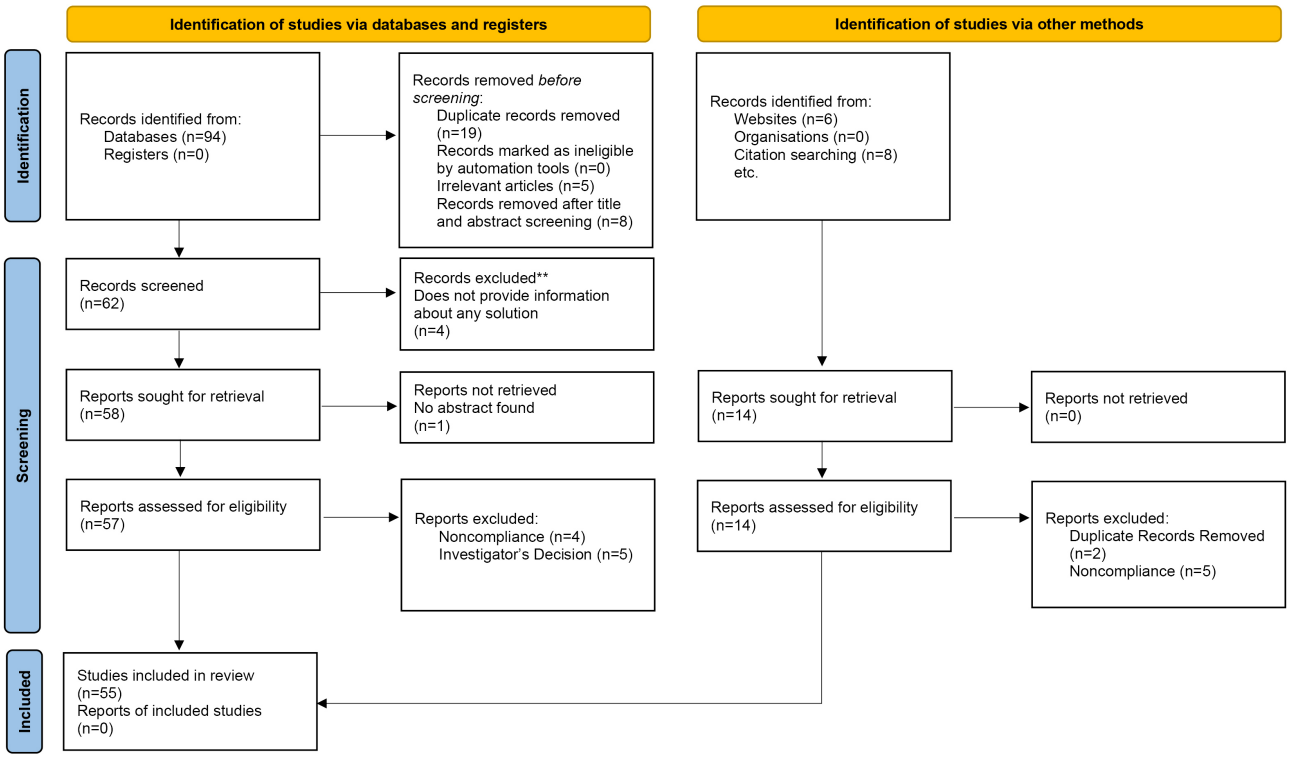
Table . Search strategy.

Search approach	Field	Context	Motivation
Primary search term	Screen use and child development	Early childhood screen use	Parental monitoring solutions
Synonyms	"infants," "young toddlers," and "early childhood"	"cognitive growth," "psychological development," "sedentary lifestyle," "screen time," "factors and dominance of screen viewing," "risks of extreme screen media," and "alternate solutions"	"mHealth," "software system," "software application," and "safety"

Publications were eligible for inclusion if they were written in English, issued in interdisciplinary conference proceedings, satisfactory journals, or as official reports formed by a government constitution. Broad eligibility criteria were used to maximize the possibility of finding appropriate information, such as the studies that demonstrated expertise in child health science and child psychology, explored alternative strategies to reduce screen dependency such as outdoor activity or mHealth apps, and involved in a discussion related to the detection of effects, connections, and solutions for children younger than 36 months. Researchers applied exclusion criteria to ensure consistency in screening and to maximize the possibility of excluding unsatisfactory literature. The exclusion process involved 2 stages of screening, an initial removal of duplicate and irrelevant articles based on titles and abstracts followed by an exclusion of studies that were not peer-reviewed, published in gray literature, and unrelated especially to child cognitive or behavioral growth, resulting in the elimination of approximately 48% publications of the primary pool.

Data Synthesis Procedure

The data synthesis was performed to categorize the selected papers for evidence synthesis and address the research questions briefly. Data collected from the studies included were organized into a predeveloped Excel spreadsheet to facilitate analysis. The extracted data encompassed bibliographical data (eg, author, title, year of publication, DOI), study characteristics (eg, type of study and sample demographics), contextual information (eg, screen media type, parental decision-making factors, perceived developmental impacts), and evaluation criteria (eg, parental behaviors, child performance, intervention strategies, and outcomes such as cognitive, behavioral, physical, and social development). Classification formats were developed to organize the efficacy of interventions (eg, screen time reduction, improved parental engagement, and coviewing) and their relevance to developmental outcomes. Data charting involved systematically populating the metadata from each study into predefined categories. Key findings were reviewed to ensure accuracy. The synthesized data underlined crucial insights: parental fallacies regarding screen time, gaps in existing policies, and the necessity for accessible, technology-motivated solutions. This phase highlighted the similarities and discrepancies across selected literature, offering recommendations that address the research questions and confirming that this study's conclusions achieve optimal reliability and scalability in diverse childcare settings.



Results

Overview

This scoping review tries to answer research questions presenting the significance of parental attitudes, perspectives, and practices related to screen use that influence the screen time pattern of their infants and toddlers. This study reveals that parents' lack of awareness regarding their own habits of screen use directly affects their toddlers' relationship with smart devices, impeding their healthy development. Hence, these outcomes highlight the necessity to educate parents on the implications of screen use to promote well-informed decision-making that can draw the odds out of screen device use. The results also highlight the importance of balanced use of screen time by children due to the modern parenting environment. The study selection process is illustrated in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart, as shown in Figure 2, which outlines the records identified, screened, and included in the final analysis.

XSL•FO
RenderX

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart displaying systematic literature search.

Significance of Consciousness in Parental Decision-Making (RQ1)

The findings from reviewed studies reveal the outcomes related to early childhood screen exposure, highlighting that the majority of parents remain unaware of how their own screen use directly influences the screen time behavior adopted by their infants and young toddlers [11,24]. As the principal guardians and decision makers, parents uphold a momentous role in shaping their children's early interaction with smart devices, who are tremendously susceptible to the potential consequences of excessive screen exposure during this critical development stage [13]. Thus, to construct more rational and informed guidelines regarding screen time limitations, it is essential to further investigate parental decision-making procedures, incorporating their values and theories in today's modern settings. In Table 2, we categorized parents' perceptions towards their positive beliefs in smart devices for their children. The results of children's screen viewing depend heavily on wrong impressions of their parents' decisions regarding the age inappropriateness of content, exposure to background media, allowing screens during mealtimes, and so forth. For example, studies have identified that regularly exposing a toddler to noise made from television or other digital content playing in the background while a child is engaged in another activity can disrupt their focus, reduce verbal interactions, and delay vocabulary growth [15,20,25,26]. Similarly, dependence on any mode of screen device during sleep time often results in reduced parent-child bonds and a disrupted sleep pattern.

XSL•FO
RenderX

Table . Observations of parents as opposed to their actual impact.

Parents observations	Decision-making factors	Effects on cognitive development	Additional impacts	Reference
Protected from external world	Parents from unsafe neighborhoods prefer providing screen time to keep their toddlers indoors.	• Higher screen dependence at school age • Less attention span	• Higher risk of obesity • Aggressive behavior	[2,27]
Screen media as an educational tool	Confidence that programs that target younger toddlers are educational and enhance child development.	• Decreased child vocalizations. • No considerable linguistic abilities • Reduced school-connectedness	• Inverse impact on self-esteem.	[2,6,15,28]
Background media use	Children exposed to adult contents (termed as background noise) while being engaged in other activities.	• Delayed vocabulary development because of less “talk time”. • Reduced focus on intellectual tasks.	• Distraction of children from current activities. • Reduced exposure to meaningful family interaction.	[15,20,25,26]
Media as a peacekeeper	Parents use screen devices to escape tension and concentrate on tasks such as food preparation, doing office work, or household duties.	• Decreased focus and attention span. • Both short and long-term speech delay	• Decreased parent-child interaction. • Less time for creative activities. • Weakened psychological outcome.	[11,24,26]
Bedtime media use	Parents comprehending that screen time helps in calming children to sleep.	• Adverse outcome on speech delivery.	• Resistance to sleep • Condensed sleep length	[20]
Touchscreen benefits for motor development in infants	Belief that early touch screen interaction boosts fine motor skill advancement.	• Experiencing “video deficit”— difficulties while transitioning from 2D to 3D objects • Troubled motor skills.	• Disrupted mental flexibility. • Higher Body Mass Index (BMI)	[11,14,26]
Use of smart devices as an indication of status	Societal pressure to endlessly purchase latest screen gadgets to children for status.	• Delayed cognitive, and verbal advancement.	• Limited outdoor play opportunities. • Tendency towards a sedentary lifestyle	[2]
Underestimation of media consumption	Parents underestimating their own children’s screen viewing length.	• Physical changes to brain structure • Challenges in information processing.	• Agitated behavioral change. • Higher obesity risk • Reduced sleep duration	[24]
Lack of consciousness of existing recommendations	Confusion or ignorance of existing standards, with a focus only on benefits of physical activity.	• Disproportionate attainment of cognitive indicators. • Possibilities of hyperactivity and inattention	• Health hazards later in life • Disrupted sleep and eating routine	[5]

Table 2 demonstrates that a significant number of parents allow screen time for their children due to an array of familial and societal reasons. Many parents who have newborns and younger toddlers use screen devices as a mode of distraction or a means to prevent conflict, manage household chores, or even put children to sleep. Some of them give their child the latest smart gadgets as a means of maintaining social status because of the perception of these devices as standing symbols. Some parents just view these devices as a convenient educational tool, believing screen media literacy will prevent their offspring from falling behind other children in an academic setting, while others are protective against the outside world and would choose for their children to stay indoors and be secure. Moreover, some parents underestimate their children’s screen time entirely, and others are merely oblivious to the recommendations. Such dependence on screen devices has normalized their presence in regular life, advocating to parents that screen use is an innocent and required aspect of advanced upbringing, often obscuring the potential harms associated with screen use which can be serious such as mood fluctuations, sleep difficulties, psychological and physical changes, reduced attention spans, and other health problems. Studies also highlight the influence

XSL•FO
RenderX

of convincing marketing campaigns that portray screen time as absolutely imperative for educational and entertainment purposes, further concealing the challenges associated with them [28]. These findings highlight the need to promote parental awareness and mindful digital engagement during early childhood. It is therefore crucial to present parents with evidence-based tools that can balance their child's screen use with developmental requirements.

Strategies for Moderating Screen Time in Younger Children (RQ2)

The studies indicate that the continuous presence of smartphones and other smart gadgets within households has become an inherent component in the lives of infants and toddlers [29]. Among this significant population, roughly 72% of children aged 0 - 8 years and 38% of children younger than 2 years have access to some mode of smart devices such as smartphones, iPads, or tablet devices [30,31]. Despite a plethora of studies emphasizing the short-term difficulties during infancy and continuing long-term complications in the subsequent growing phases, such smart devices remain an inevitable part of current parenting due to their ability to attract the minds of children successfully [13]. After acknowledging the consequences, authorities such as the AAP, the US Department of Health and Human Services, the Australian Department of Health and Ageing, and the Canadian Pediatric Society strongly instruct plummeting screen time as one of the significant urgent issues by entirely restraining media use on children younger than 2 years, and instigating rigorous boundaries for those between 2 and 18 years [20]. Figure 3 demonstrates the recommended duration of screen time and other developmentally supportive activities for children stated by AAP to enable healthy behaviors, such as including enough sleep, outdoor activities, and constant physical play that can successfully counterbalance screen exposure.

Figure 3. The advised total amount of screen time, physical/outside activity, and sleep for discrete age groups of children [13,17-20]. AAP: American Academy of Pediatrics.

AAP'S COMPREHENSIVE GUIDELINES FOR SCREEN USE, SLEEP, AND PHYSICAL ACTIVITY ACROSS ALL AGE GROUPS

- Address what type of media and how much screen time is appropriate for each child.
- Promote a child's cognitive, physical and mental health
- Cultivate healthy lifestyle

AGE GROUP	RECOMMENDED SCREEN TIME	DURATION FOR OUTDOOR ACTIVITY	TOTAL AMOUNT OF SLEEP
0-12 Months	No Screen Media	Not Satisfactory	12-16 h/day
12-24 Months	Minimum screen participation in the presence of a parent	Not Satisfactory	11-15 h/day
2-5 years	At most 1h/day, consumption of high-quality content only	0.5-1 h/day	10-14 h/day
6-12 years	No more than 1h/day and always closely supervise	1h/day	9-12 h/day
13-18 years	Maximum 2h/day with limitations on content	1h/day	8-10 h/day

The results depicted that extreme screen use in a family is strongly associated with a toddler's own screen viewing practices. Given that children younger than 2 years have very limited power over their adjacent surroundings and their actions are merely a replication of what their parents do around them, their screen habits are formed by what they perceive. For instance, studies highlight that if parents engage in more than 4 hours a day watching TV, their toddlers will be 3 times more likely to exceed the same duration [32]. Thus, parents need to regulate their own screen use and model positive examples as they are the chief contributors to their infants' long-term well-being. Childcare providers, more specifically pediatricians, play a fundamental role in supporting well-adjusted screen habits by educating parents and continually supervising parental adherence to the guidelines during scheduled appointments, assuring their proper implementation within households [20,33]. Therefore, intervention strategies should largely entail actions taken by parents as well as childcare providers, as each of them has a unique role in the infant's long-term betterment [33]. Given the increasing impact of modernization within home environments, the following intervention strategies demonstrated in Table 3 provide ideal directions for distinct family perspectives, and it is imperative to implement such principles as references for forthcoming actions. Considering the outcomes of various studies, 6 types of intervention approaches for parents and 3 for pediatricians have been distinguished, along with their expected outcomes as summarized in Table 3.

XSL•FO
RenderX

Table . Intervention strategies and their anticipated outcome.

Target contributor and recommended intervention strategies	Description	Expected outcome	Reference
Parents			
Restriction on child's screen time	Consistently control screen time throughout the day, avert using any screen device during meals or sleep, and turn off devices while not in use.	• Promote healthy eating behaviors. • Enhance language acquisition • Better quality of life	[13,15]
Limit parental screen time	Formulate home-based regulations on screen media specifically for parents.	• Reduces screen time of children through modeling. • Increased parent-child connectivity	[17,34]
Coviewing contents	Parents encourage co-watching high quality content, supervising what their children see and hear.	• Enhances cognitive development. • Encourages parent-child interaction • Significantly expands vocabulary during infancy	[6,13,24]
Focus on quality over quantity	Promote educational content which uses schemes to assist language training, contains naive story structures and allows child interaction scopes.	• Higher communication skills • Increases prosocial behavior. • Expands concentration. • Encourages positive racial outlook	[6,13,15,26]
Promote child-directed and age-appropriate media content	Recommend contents for younger children that contains longer displays, provides narration hints, labeling, and structured storytelling.	• Facilitates cognitive understanding. • Overcomes "video deficit". • Higher school readiness	[11,17]
Promote a healthy lifestyle.	Include outdoor activity, imaginative play, a regular sleep cycle, and a nutritious diet.	• Promotes locomotive skills, reduces childhood obesity, and improves metabolic health. • Influence adaptive health.	[35]
Pediatricians			
Set age-appropriate "media limits"	Discuss and enforce screen media restrictions for children younger than 2 years during scheduled visits.	• Fosters balanced screen behaviors at an initial stage	[20]
Encourage supervised independent play	Inform parents about independent play when they are unavailable but able to supervise their child.	• Builds perseverance and problem-solving expertise while remaining under surveillance	[20,33]
Explain the value of "unplugged play"	Encourage parents to engage children in hands-on, imaginative, and performing activities that interest them.	• Encourages creative thinking • Expands problem solving skills.	[3]

XSL•FO
RenderX

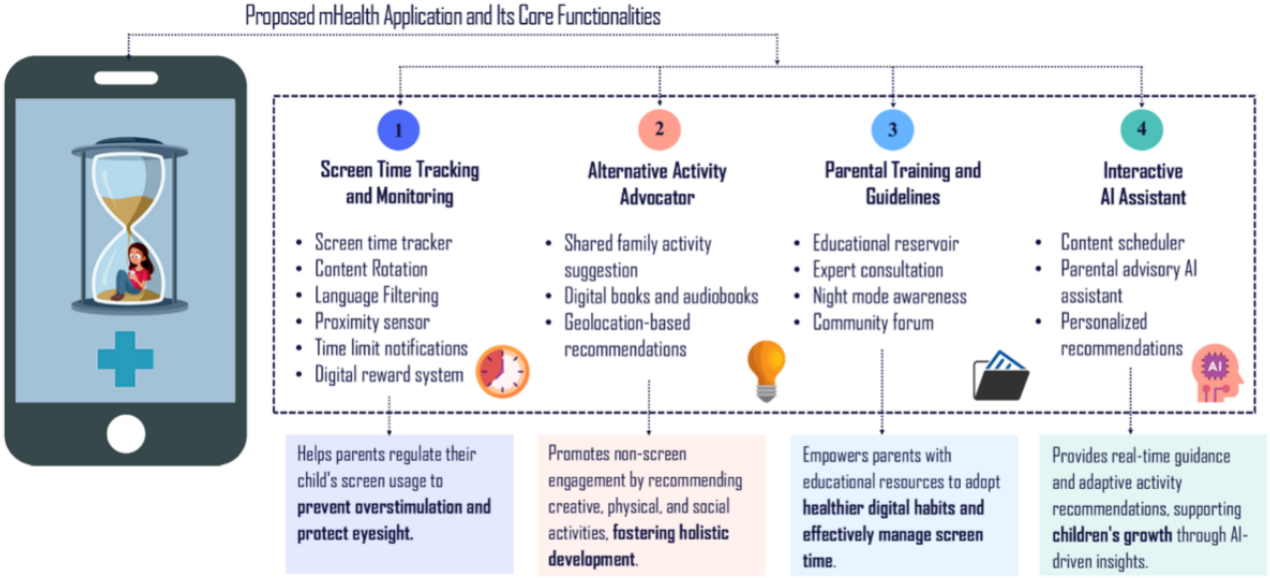
Developing a Holistic Strategy: A Pathway to Expand Children's Cognitive Advancement

Studies indicate that engaged, collaborative, and informed parenting can successfully reverse the detrimental impacts of excessive screen use while fostering complete development [36]. For instance, research has confirmed that the presence of a parent who actively gives statements or explanations on the content their child watches, starting from as early as 6 months, can have a positive impact on the infant's intellectual engagement and attention span [26]. However, modern life often restricts the scope and time for quality parent-child communications, as time-restrained parents face tight spots to implement these policies. Therefore, a balanced solution is needed that moderates the negative impacts of screen time while leveraging the advantages of using several digital tools [37]. As the research team reviewed some existing strategies to help parents balance screen time for their infants and toddlers, studies revealed some parental control mobile apps, such as Google Family Link, Apple Family Sharing, and Microsoft Family Safety, which primarily focus on screen time management for older children. However, these apps provide inadequate guidance for children younger than 3 years, which needs to be addressed through age-appropriate solutions to guarantee healthy early development.

Discussion

Principal Results

This study underlines that excessive screen exposure has extensive consequences on the overall well-being of infants and younger toddlers, putting this phenomenon into a different perspective. The consequences are far more serious, and they are not simply a result of screen exposure but are greatly interconnected with parental personal screen media use, attitudes, behaviors towards technology, and ignorance of the risks posed by digital devices. Parents' reliance on screens—whether as an opportunity of defense against the outside world, a means of distraction, a perceived educational tool, or even a status symbol—plays a critical role in offering their children a smart device. It is undeniable that the presence of smart devices will further reinforce with time, augmenting the urgent necessity for appropriate and practical interventions that encourage mindful digital engagement, particularly in the case of infants and toddlers.



Major intervention strategies identified in this paper include restricting screen time for both parents and their offspring, coviewing age-appropriate programs, and prioritizing nonscreen activities as they promote healthier behavior and increase parent-child connection [13,15,17,34]. More hands-on strategies, such as quality regulation of content, are also essential as younger children often lack the decision-making capabilities of which programs to watch. Therefore, the prevailing guidelines are necessary for a constructive learning experience for the younger generation [14,26]. Pediatricians also play an essential role as part of their responsibility is to advise parents on the best actions required for their children, for instance, inspire parents to establish age-appropriate time limits and suggest both supervised and independent play according to the child's interest. Such pursuits can cultivate a recognition of persistence and broaden their thoughts of the outside world beyond just screens [20,33].

Given the presence of technology in this modern world, it is evident that addressing the challenges related to screen time consumption requires leveraging technology itself. Studies suggest an urgent need for solutions that balance regulatory guidance with sustainable and parent-centric approaches tailored to today's sociocultural and socioeconomic realities [38,39]. Therefore, building on the understanding of the research assembled from an examination of RQ1 and RQ2, we recommend that a mHealth app can be an empathetic, practical, and scalable tool that will make supervising children's screen time easier for today's busy parents. The justification for this app is plain and simple; since digital devices have become an inseparable part of our daily lives and high-tech devices are already accessible to every parent, it would be a logical and feasible decision to leverage them to tackle this issue. Additionally, it would enable parents to oversee the digital ecosystem precisely and cautiously within a household.

The app could be built using the Scrum Agile software development methodology to ensure the progress of the app development process in an incremental and iterative way. Each sprint could drive the systematic execution of planning, design, coding, testing, and review, facilitating efficiency and high-quality outcomes. Backend development could be implemented using the Swift programming language within the Xcode IDE (Apple Inc) to facilitate development, organize events, and enhance data flow. User interface (UI) could be designed by leveraging UIKit and SwiftUI frameworks. Additionally, Swift Package Manager could be leveraged to ensure efficient dependency management, Git for version controlling of the codebase, and Firebase Software Development Kits for documentation and cross-platform app development of the scalable prototype. In delineating the direction for the development of this app, we believe four core components with their prominent features as absolutely principal for creating a holistic framework: (1) screen time tracking and monitoring (could allow parents to monitor screen use across multiple devices and set goals), (2) provision of parental training and guidelines (could provide resources to educate parents, boosting parental self-confidence in their capability for successful screen management), (3) alternative activity advocator (could propose nonscreen pursuits tailored to each child's preferences), and finally (4) interactive artificial intelligence (AI) (could present personalized suggestions to parents, assisting them to address the challenges proactively and reducing screen dependency) (Figure 4).

XSL•FO
RenderX

Figure 4. Prototype of a mHealth app along with the supervising features. AI: artificial intelligence.

Outline of the Key Features

Screen Time Tracking and Monitoring

While it is not realistic for parents to completely eliminate providing their children with screen devices, they can guarantee controlled use [40]. A screen time tracking and monitoring feature can allow parents to track their toddlers' daily screen use by showing detailed data insights across multiple devices [41]. This functionality can be accomplished by applying parental control application programming interfaces (APIs) that supervise and log screen time, along with frameworks like Xamarin or React Native, which can be used for combined codebases. To prevent cognitive fatigue and avoid overstimulation in children from repeated use of the same content, the app can periodically suggest changes in media content after a predefined duration. Younger children can struggle with multilingual content, often overwhelming their learning abilities [42-44]. Recognizing the challenges, the app could offer a language-filtering option that enables parents to streamline content into a single language, supporting early language development, supporting early language development—particularly for children with special requirements. To help parents manage screen exposure effectively, the screen time goals and alerts feature can inform parents with alerts when time limits come closer or are exceeded. Furthermore, a digital reward system can be incorporated to persuade adherence to screen time limits, applied through a gamification reward framework linked to databases to track the improvement. It is well known that prolonged screen exposure at close distances could be extremely detrimental to children's eyesight [45]. A proximity sensor feature could use smartphone infrared sensors to alert parents if devices are held too close to infants' and toddlers' eyes, reducing the risk of eye strain. Both Screen Time API and the UsageStatsManager API can be operated for iOS and Android, respectively, and all the segments can be seamlessly synchronized across various devices using cloud-based services such as Firebase or AWS, confirming convenience and ease of use for parents.

Parental Training and Guidelines

The parental training and guideline feature could perform as an all-inclusive educational resource for parents, so that parents do not feel ignorant. The function can offer reasonable resources such as videos, articles, or infographics to delineate the outcomes of excessive screen time and suggest effective strategies for regulating it, attained using a content management system that handles the content dynamically. To make the app more reachable and user-friendly for parents with varying levels of digital literacy and access to technology, the app could incorporate a LangChain model to provide concise summaries of critical research findings as Daily Educational Push notifications, guiding them to take their next actions. This approach would guarantee that parents have easy access to an ample number of resources, removing the need for independent research and allowing them to make informed decisions regarding their child's screen time. After clicking on the popper notification, parents could be seamlessly redirected to the detailed materials. Real-time updates can be acquired using services, for example, Contentful or Strapi. The platform can connect parents with certified child psychologists or pediatricians through audio or video calls for adapted guidance and strategies on screen time administration, using a booking system and secure calling features such as Twilio API. The blue lights emitted during screen time can significantly disrupt sleep time and sleep quality of infants and toddlers [46]. It is feasible to create collaborative tutorials using libraries such as Intro.js and connect them to the device API to design a scheduled Night mode module that offers step-by-step directions on lowering blue light emission during nighttime gadget use. Finally, a community forum module can facilitate parents in sharing tips, their experiences, hardships, and success stories on monitoring their child's screen time so that they always feel supported in their journey. Both the front and back end of this segment can be developed by using React.js and Node.js, ensuring appropriate authentication, fundamental for this facility to operate.

XSL•FO
RenderX

Alternative Activity Advocator

Nonscreen activities play a vital role in the holistic development of children aged 0 - 3 years, as this period determines future behavioral and health outcomes [47]. While outdoor play promotes physical health and improves motor skills, shared family activities and social interactions improve communication skills [48]. It can be challenging for parents to come up with ideas to lure their kids away from screens. The alternative activity advocator feature can be instrumental in promoting nonscreen engagement for children. Subsections falling within this section can incorporate (1) Shared Family Activities, which could offer constructive, age-appropriate family activities. Existing parental control techniques, such as Google Family Link, Apple Family Sharing, and Microsoft Family Safety, emphasize screen time tracking but do not offer any guidance for alternative activities. The proposed feature could include diverse activity categories based on a child's creative, active, social, and educational interests and recommend tasks accordingly. For instance, interactive activities like listening to nursery rhymes to nurture creativity, baby yoga to encourage physical activity, or a scavenger hunt to build an adventurous mindset [49,50]. Such activities can significantly help children meet milestones, establish a foundation for parent-child bonding, and build their motor, sensory, and communication skills. (2) The next subfeature could suggest the Provision of Digital and Audiobooks, delivering an assorted library of books suitable for a child's age and intensity of reading. The level of engagement will be higher if the picture books include colorful visuals, simple language, and interactive storytelling options to capture the attention of children, particularly infants or younger toddlers [51]. (3) Finally, the app could further incorporate Geolocation-Based Recommendations to identify nearby parks, playgrounds, or family activity centers where parents can arrange playdates with other families [52]. This way, parents can discover safe and engaging environments for their children to socialize with same-age children and develop their social interaction skills at an early age. A decision tree algorithm could be used, driven by data collected through in-app surveys and stored in a NoSQL database like MongoDB for flexibility to attain such distinctive offerings. Activity recommendation algorithms can be used using Python's scikit-learn or comparable libraries. These features would reduce reliance on screens while fostering creativity, physical activity, and real-world interaction in an organized manner.

Interactive AI

The mHealth app can incorporate another innovative attribute by channeling the power of AI to present parents with adapted guidance. An AI-based Content Scheduler can be developed to offer busy parents flexible options for planning their child's activities during mealtimes, play hours, and bedtime, offering real-time support. Automatic AI scheduling could leverage collaborative filtering, content-based recommendations, and context awareness to generate developmentally appropriate schedules. A Parental Advisory AI assistant can be established, using natural language processing libraries such as NLTK or spaCy in Python, incorporated with an AI chatbot framework, for instance, Rasa or Microsoft Bot Framework. Additionally, an AI-assisted Personalized Activity Advocator, leveraging the LangChain framework and advanced large language model capabilities, could deliver tailored recommendations for nonscreen activities and developmentally appropriate digital educational content [53-55]. Drawing from user survey data, collaboration history, and professional input, this feature could support the fundamental cognitive development goals for infants and toddlers. Additionally, A/B testing could be used to continuously improve the algorithms based on user feedback, ensuring relevance and accuracy.

To ensure strategic scalability, the app could primarily launch a freemium model, proposing a basic version tailored for home-based ecosystem to allow widespread adoption. Simultaneously, a premium model, available through subscription or payment, could be introduced for daycare or childcare environments, generating sustainable revenue. The basic version can be upgraded to a premium version with a subscription at any time, ensuring accessibility and long-term market success. We believe that by integrating this innovative solution along with all the recommended features, the app will promote healthy cognitive and emotional development, establish positive media habits, and adapt seamlessly to busy family dynamics.

All in all, by leveraging the revolutionary principles of information technology, machine learning, and AI, the proposed mHealth app could become a one-stop solution for confronting the challenges modern parents face in managing screen time for their children younger than 3 years. This novel app can act as an exclusive knowledge hub for screen time management, parenting guidelines, tips, and expert advice. A comprehensive framework, easy-to-understand UI, and integration of advanced functionalities are future ways to maintain the digital lifestyles of toddlers and infants.

Limitations

The outcomes of this research contribute to a deeper understanding of the significant correlation between screen time consumption, parental behaviors, and early childhood development. However, it is compulsory to address specific limitations. Existing studies often fail to consider individual variability among children and different family dynamics, such as socioeconomic factors, parenting styles, and cultural influences. Consequently, this oversight restricts the relevance or applicability of findings across discrete socioeconomic populations. Our research concentrated on general patterns about the effects of screen time without considering different family structures, but recognizes the necessity for future research to further examine these nuances.

The complex and continuously evolving character of the digital landscape presents difficulties in effectively managing screen time. Therefore, the proposed mHealth app, including the existing guidelines, must be pliable and capable of addressing emerging challenges presented to it. Leveraging AI and machine learning to offer continuous updates would provide parents with more control over the watched contents, guaranteeing continual efficacy.

Ensuring user engagement is another challenging procedure. Integrating AI with diverse user input data may demand model

XSL•FO
RenderX

training data adjustments. Future studies could use iterative refinement cycles and investigate additional algorithms to ensure optimal performance. Furthermore, the usability evaluation may reveal unexpected UI challenges. Executing iterative usability testing cycles with small groups could enable mitigating this challenge, allowing for design refinement.

Conclusions

A significant proportion of children begin engaging with smartphones and other screen devices at an earlier stage and for a longer period than childcare authorities advocate. The clear effects of the digital landscape and smart device availability highlighted in this study uncover critical research questions about program content, parental behavior, and the possible direct effects on infants and toddlers; highlighting that there is a pressing need for holistic, evidence-based approaches to address the developmental challenges associated with excessive screen time consumption among children aged 0 - 3 years. In response to this issue, the paper proposes integrating technology into the solution through a mHealth app constructed to balance the developing requirements of children with the pressures of modern parenting. The novel solution, along with its innovative features, could become a valuable partner in helping parents face repercussions, offering massive support from early childhood. The beneficiaries of this solution are the children themselves, who would obtain immense enrichment in their overall cognitive and emotional advancement through reasonable and practical screen use. The findings should also inspire parents and pediatricians to discuss children's screen habits, warn researchers to unpack the contradictions in the existing literature, and discover potential prospects for defensive interventions. Finally, the paper underlines the importance of further research so that the solutions can appear to be readily applicable and adaptable across all naturalistic home-based settings. With strong potential for commercialization and industry impact, the proposed mHealth app is poised to transform child well-being and promote lasting benefits for families and communities.

Abstract

Background: Early childhood is a critical period for shaping lifelong health behaviors, making early childhood education and care (ECEC) environments ideal for implementing nutrition and physical activity interventions. eHealth tools are increasingly utilized in ECEC settings due to their accessibility, scalability, and cost-effectiveness, demonstrating promise in enhancing educators' practices. Despite the potential effectiveness of these eHealth approaches, a comprehensive collection of available evidence on eHealth tools designed to assess or support best practices for nutrition or physical activity in ECECs is currently lacking.

Objective: The primary objective of this scoping review is to map the range of available eHealth tools designed to assess or deliver interventions aimed at improving nutrition or physical activity in ECEC settings, while evaluating their components, theoretical foundations, and effectiveness.

Methods: This scoping review adhered to the Joanna Briggs Institute methodology, in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. The objectives, inclusion criteria, and methods for this review were predefined and specified. Eligibility criteria were (1) early childhood educators (population); (2) eHealth (digital) technologies, such as websites, smartphone apps, emails, and social media; and (3) tools designed to assess or deliver interventions aimed at improving best practices for nutrition, physical activity, or both within ECEC settings (context). A search was conducted across 5 electronic databases (PubMed, Scopus, CINAHL Plus, ERIC, and Embase) to identify white literature, and 3 electronic databases (ProQuest, Google Scholar, and targeted Google search), along with hand-searching of reference lists, were used to identify gray literature. All literature was reported in English or French, with the search extending until May 2024. Separate data charting tools were used for white and gray literature.

Results: The search strategy identified 3064 results for white literature, yielding 2653 unique citations after duplicates were removed. Full texts for 65 citations were retrieved and screened for inclusion, resulting in 30 studies eligible for data extraction and analysis. The most common study design was a randomized controlled trial, comprising 16 studies (53%). The largest proportion of studies were conducted in the United States (11 studies, 37%). In total, 19 eHealth tools were identified, targeting nutrition (8 tools, 42%), physical activity (5 tools, 26%), or both nutrition and physical activity (6 tools, 32%). All tools were web based (19 tools, 100%). The gray literature search yielded 1054 results, of which 17 were moved to full-text screening, and 7 met the eligibility criteria for data extraction and analysis. The tools identified in the gray literature originated in Canada (4 tools, 57%) and the United States (3 tools, 43%). The majority targeted nutrition (4 tools, 57%) and were primarily web based (6 tools, 86%), with 1 mobile app (1 tool, 14%).

Conclusions: This scoping review mapped the available eHealth tools designed to improve nutrition or physical activity environments in ECEC settings, highlighting the growing emphasis on web-based tools and the need for psychometric testing.

XSL•FO
RenderX

Future research should systematically evaluate the effectiveness of these tools, particularly those addressing both nutrition and physical activity, to identify the key factors that contribute to long-term behavior change.

Introduction

Background

Unhealthy lifestyle factors, such as physical inactivity and unhealthy diets, are primary contributors to the rising incidence of chronic diseases [1-5]. These conditions are recognized as growing global public health problems, leading to significant treatment costs and imposing an economic burden on health systems, individuals, and society as a whole [6,7]. Health behaviors often originate in early childhood and can persist into young adulthood [8]. Research indicates that health behaviors, such as eating habits and physical activity levels, are modifiable risk factors for obesity and chronic diseases [9]. These behaviors often co-occur or cluster together [10,11]. An integrated approach to health promotion, addressing both dietary intake and physical activity simultaneously [10], is therefore essential during early childhood to improve population health across the lifespan.

The early years are a critical period for shaping health behaviors and outcomes [12], with early interventions regarded as an essential component of preventive health [13]. Early childhood education and care (ECEC) settings provide a unique opportunity to reach a large number of children during this pivotal developmental period, making them an ideal setting for behavioral interventions [12,14]. Moreover, early childhood educators, as part of the ECEC environment, are well-positioned to successfully implement nutrition and physical activity behavior interventions [15,16]. Evidence from prior research shows that professional training of early childhood educators in best practices for nutrition and physical activity is associated with improved dietary intake and increased physical activity levels in young children [17-20].

With the widespread use of the internet, online or eHealth interventions have experienced significant growth. eHealth refers to the use of digital technologies, such as the internet, digital gaming, virtual reality, and robotics, for promoting, preventing, treating, and maintaining health [21]. Examples of eHealth technologies include smartphone apps, websites, computer programs, SMS text messaging, and social media platforms [22]. Digital technologies offer several advantages, including lower costs, reduced participant burden, enhanced accessibility, and increased scalability, thereby extending the reach of behavioral interventions [23,24]. Prior research indicates that eHealth interventions within ECEC settings are highly acceptable and effective in improving early childhood educators' knowledge and practices related to nutrition and physical activity [25-27].

Behavior change theories can guide the selection of intrapersonal constructs to target in intervention development, as well as the choice of behavior change techniques to achieve desired behavioral outcomes [28]. Evidence suggests that behavior change interventions, whether internet-based or not, are more effective when guided by a theoretical framework [29]. A meta-analysis [29] found that interventions extensively informed by theory demonstrated larger effects compared with those lacking theoretical underpinnings. The use of theory not only enhances the efficacy of interventions but also facilitates their replication and future development [30]. Consequently, it is crucial to determine whether theory has been applied in the development of eHealth tools.

Recognizing the importance of early learning settings and educators in fostering healthy behavior development in children, researchers have developed, implemented, and evaluated health promotion interventions within childcare settings [31-33]. A preliminary search of PROSPERO, PubMed, the Cochrane Database of Systematic Reviews, and JBI Evidence Synthesis identified several relevant reviews. However, these reviews primarily focused on evaluating the effectiveness of in-person nutrition and physical activity interventions [34,35], interventions conducted in family-based centers [36,37], or those targeting older children and adolescents [33]. No current or in-progress systematic or scoping reviews address eHealth tools for promoting the best nutrition and physical activity practices in ECEC settings.

Objectives

To address this gap in the literature, we conducted a scoping review. This method is used to identify the types of available evidence in a field, explore key characteristics related to a concept, and analyze knowledge gaps [38]. This review aimed to achieve the following objectives: (1) identify existing eHealth tools used to assess or deliver interventions that improve nutrition or physical activity environments in ECEC centers; (2) describe the components of the eHealth tools, including technology type (eg, websites, smartphone apps, social media) and health purposes (eg, nutrition evaluation, physical activity promotion); (3) outline the psychometric properties of the eHealth tools, when applicable; (4) report the theoretical foundations used in developing the eHealth tools; and (5) identify any evidence gaps. The purpose of this study was to map the available evidence on eHealth tools currently used to

XSL•FO
RenderX

assess and support best practices for nutrition or physical activity in ECEC centers.

Methods

Overview

This scoping review followed established methods for such studies [39] and adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [40]. Methodological quality or risk of bias was not assessed, as the goal of this review was to provide a broad overview of existing evidence, regardless of methodological approach, to map the available evidence. This is consistent with guidance on scoping review methods [39]. Full details of the methods can be found in our published protocol [41]. The PRISMA-ScR checklist is included in Multimedia Appendix 1 [40].

Selection Criteria

Participants

This review considered studies involving early childhood educators within licensed ECEC programs, whether public or privately operated, providing full-day care for children aged 0-5 years. Studies focusing on educators in family-based settings, preschool programs where children attend for less than 4 hours per day, or before- and after-school care were excluded.

Concept

This review considered studies that explored eHealth tools designed to support nutrition or physical activity environments in the ECEC setting. eHealth tools were defined as digital technologies that (1) assessed or (2) delivered interventions to improve nutrition or physical activity environments and practices. eHealth tools that assessed the ECEC environment were included only if they provided feedback to the ECECs. Additionally, we included only studies where the eHealth tool was the primary component for assessment or intervention.

Context

This review focused on nutrition and physical activity environments in the ECEC setting, considering both the physical and social environments.

Types of Sources

For this scoping review, we considered all study designs, including quantitative, qualitative, mixed methods, protocols, experimental, quasi-experimental, and cross-sectional studies. Systematic reviews and meta-analyses were also included if relevant to the topic, with a primary focus on ECEC settings. Unpublished studies and gray literature were also considered as sources of information.

Search Strategy

Overview

The search strategy was developed in collaboration with 2 research librarians and aimed to capture both white and gray literature to encompass the full range of available eHealth tools.

White Literature

A preliminary limited search of PubMed and Scopus was conducted to identify articles on the topic. The text words in the title and abstract, along with the index terms used to describe the articles, were analyzed to develop a full search strategy for PubMed. This search strategy, incorporating all identified keywords and index terms, was then adapted for each included information source (see Multimedia Appendix 2). The databases searched included PubMed, Scopus, CINAHL Plus (EBSCOhost), ERIC (EBSCOhost), and Embase (OVID). The reference lists of all included sources of evidence were screened for additional white literature. The final search was conducted on October 4, 2023. For each database, a search alert was set up using its alert functions to track any new relevant publications for potential inclusion in the review. The final search alert was reviewed on May 5, 2024, and only 1 additional study was identified. All retrieved white literature was exported into Covidence software (Veritas Health Innovation) for screening and data extraction.

Gray Literature

Following the guidelines outlined by Godin et al [100], we conducted a thorough search of the gray literature to identify nonindexed sources such as dissertation abstracts, government documents, conference proceedings, educational materials, and reports. This was done through searches in (1) the ProQuest Database, (2) Google Scholar, (3) targeted web-based Google searches, and (4) hand searches of the reference lists of all included gray literature to identify additional relevant sources. The final gray literature search was conducted on April 30, 2024. All retrieved documents were exported into Microsoft Excel and assigned a unique identifier for screening and data extraction. Because of the potential volume of gray literature, we limited our review to the first 10 pages from Google Scholar and targeted web-based Google searches, based on title. Additionally, eHealth tools that required payment for access were excluded.

This review included studies and records published in English or French, with no date limitations.

Study Selection

Following the search, all identified records were uploaded into Covidence (for white literature) or Microsoft Excel (for gray literature). Title and abstract screening, full-text screening, and data extraction were performed by 2 independent reviewers (JH and LMZL) according to the inclusion criteria. Reasons for excluding full texts that did not meet the inclusion criteria were recorded and reported in the scoping review. Any disagreements between the 2 reviewers were resolved through discussion, and if consensus could not be reached, a third reviewer (KD) was consulted. The results of the search are reported and presented in a PRISMA-ScR flow diagram (Figure 1 in Results section).

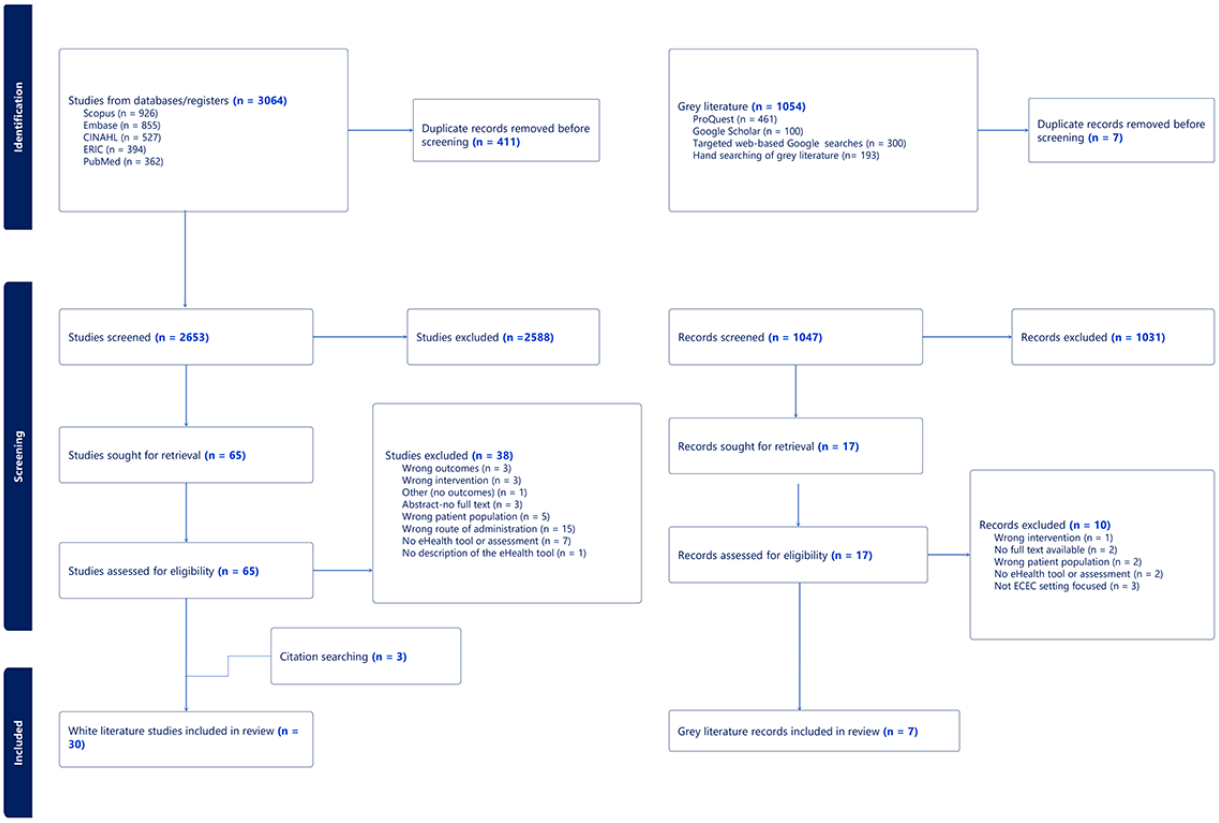
Data Extraction

Separate data extraction charting tools for white and gray literature were developed by the reviewers (Multimedia Appendix 3), as outlined in our published protocol [41]. The extraction tools, used to capture relevant study and eHealth tool characteristics, were piloted before the review to ensure

XSL•FO
RenderX

consistency in information collection. Any disagreements between reviewers were resolved through discussion.

Data Analysis and Presentation



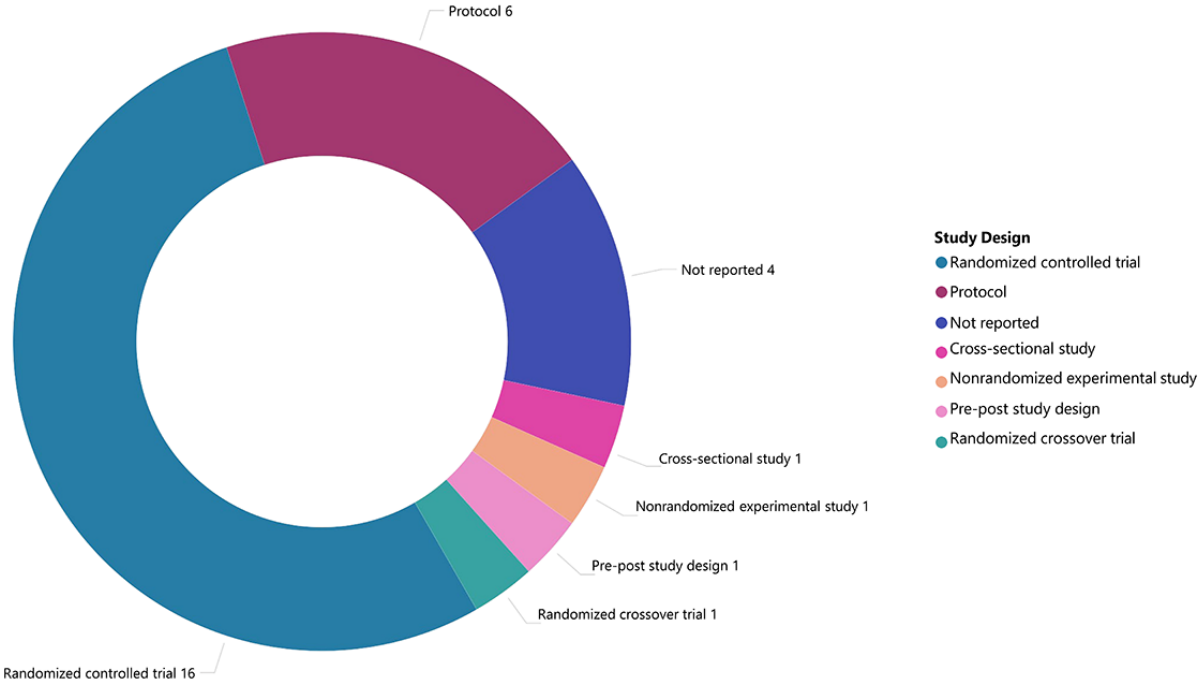
The extracted data were summarized using descriptive statistics (ie, frequency counts). The results were organized by each review question, highlighting study characteristics, eHealth tool characteristics, and the use of a theoretical framework. The findings are presented in a narrative summary, complemented by tables, charts, and illustrations.

Results

Literature Search and Selection Process

The white literature search yielded 3064 results, of which 411 were removed as duplicates. Titles and abstracts for 2653 records were screened for eligibility, and 2588 were excluded. Of the remaining records, 65 full-text articles were reviewed against the eligibility criteria. A total of 30 articles were included for data extraction (Figure 1). The gray literature search yielded 1054 results, of which 7 were removed as duplicates. Titles and abstracts of 1047 records were assessed against the eligibility criteria, and 17 were moved to full-text screening. Of these, 7 met the inclusion criteria and were included in the analysis. The PRISMA flowchart shows the selection process.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.



Included Records

A total of 30 research studies identified in the white literature were included in this review (Figure 1). Of these, 16 were randomized controlled trials, 6 were protocol studies, 1 was a cross-sectional study, 1 was a nonrandomized experimental study, and 1 was a randomized crossover control trial (Figure 2). Specific characteristics of the included studies are presented in Table 1, which reflects the study design, setting, and outcome measures. The study aims along with additional study details are provided in Multimedia Appendix 4. The largest proportion of studies were conducted in the United States (n=11, 37%) and Australia (n=11, 37%), followed by Canada (n=6, 20%) and Norway (n=2, 7%; Figure 3). The studies were conducted between 2016 and 2022. The baseline sample size ranged from n=13 to 2932. Of the 10 studies reporting participant sex, females comprised the largest proportion of participants ranging from 85% to 100%, with an average of 96% (Table 1). The mean age of participants ranged from 37.1 to 49.6 years.

A total of 7 records were identified in the gray literature and included in this review (Figure 1). These records represented community-based eHealth outreach initiatives related to nutrition or physical activity support for the ECEC community. Four of these initiatives originated from Canada and 3 from the United States.

[a]PA: physical activity.

[b]RCT: randomized control trial.

[c]NR: not reported.

[d]In Bruijns et al [45], participants included both preservice and in-service ECEs. Only data from in-service ECEs were reported, which aligns with our target population of educators in childcare centers.

[e]In Bruijns et al [45], Hazard et al [54], and Lee et al [60], participants included both center- and family-based childcare. For our purposes, we only included data from center-based childcare (eg, sample size). Gender and age are reported for all participants, as specific breakdowns were not provided.

[f]ELCC: early learning childcare center.

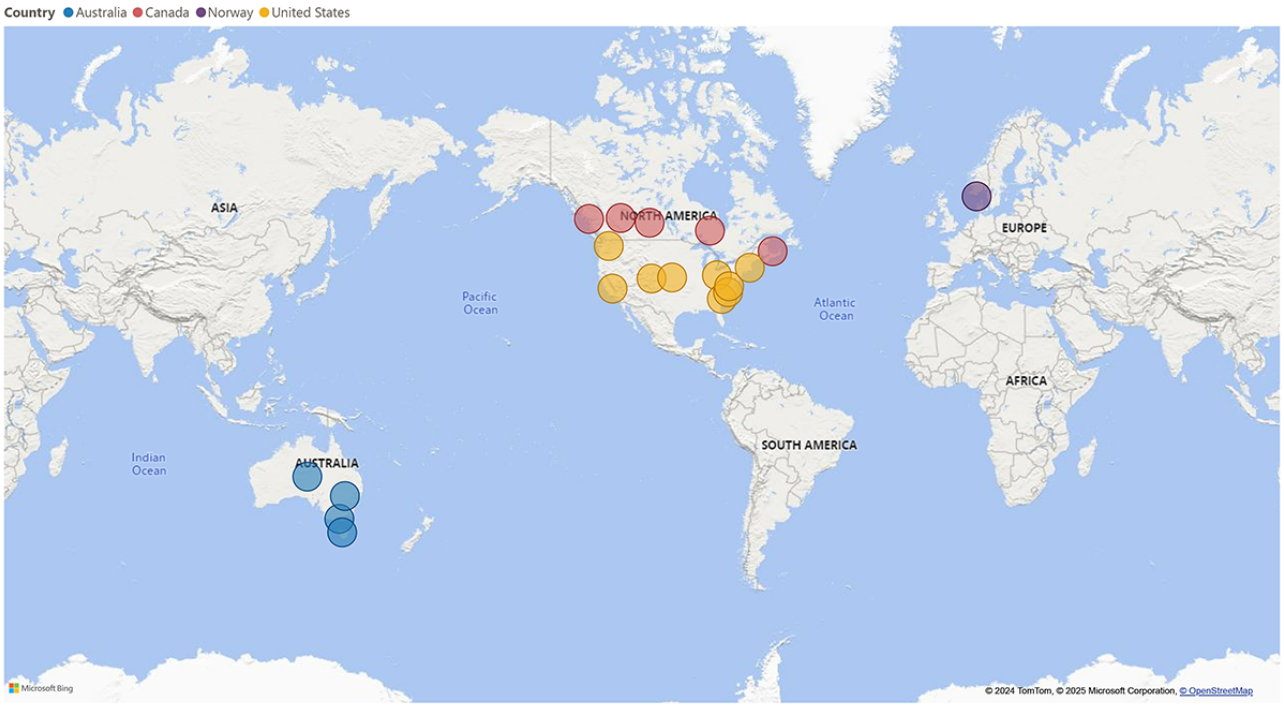
[g]ECE: early care and education.

[h]TRiPS: Teacher Tolerance of Risk in Play Scale.

[i]N/A: not applicable.

[j]WE PLAY: Wellness Enhancing Physical Activity for Young Children.

[k]MVPA: moderate-to-vigorous physical activity.



[l]ECEC: early childhood education and care.

[m]HOPPEL: Healthy Online Professional Program for Early Learners.

[n]EPAO: Environmental Policy Assessment and Observation.

[o]In Ward et al [25], the study included both in-person and online intervention groups. Our review focused only on extracting data from the online intervention group.

Figure 3. Country of study from eHealth research identified in the white literature and gray literature.

XSL•FO
RenderX

eHealth Tool Characteristics

The 30 research articles included in the review identified 19 unique eHealth tools, with 12 categorized as intervention-based and 7 as both assessment and intervention tools. The characteristics of these eHealth tools identified in the white literature are summarized in Table 2, with additional details available in Multimedia Appendix 4. Among the 7 eHealth tools incorporating an assessment component, only 1 underwent evaluation of its psychometric properties. All eHealth tools were delivered via a web-based modality (7/7, 100%).

The characteristics of the eHealth tools identified in the gray literature are summarized in Table 3, with additional details provided in Multimedia Appendix 5. Of the 7 eHealth tools identified, all were intervention-only tools (7/7, 100%). Of these, 6 (86%) were delivered via a web-based modality, while 1 (14%) was delivered as a mobile phone app.

Table 3. Characteristics of eHealth tools from included studies identified in the gray literature.

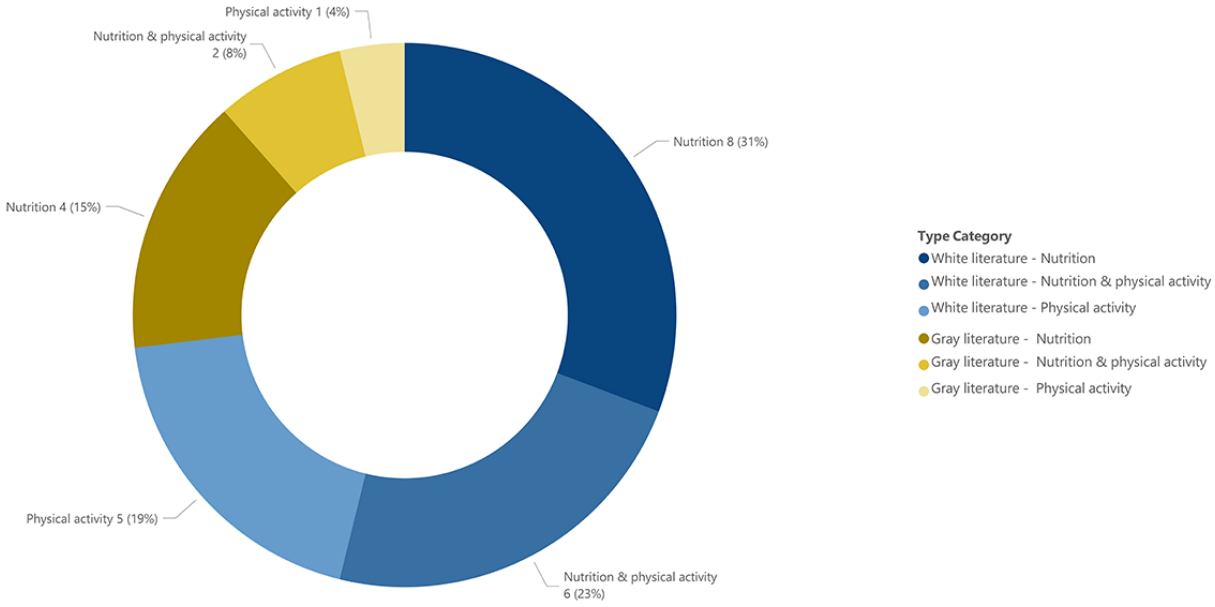
eHealth tool	Author/organization	Country: year	Participant information	Type of eHealth tool	eHealth modality[a]	Target of eHealth tool	eHealth tool description	Length of intervention
A Balanced Day: Tips and Guideline for Child Care Providers	Hastings Prince Edward Public Health	Canada: NR[b]	Childcare providers	Intervention	Web based	Physical activity	Online interactive modules (videos) on physical activity, sedentary behavior, sleep, and health messages for caregivers.	15 minutes
Boston Healthy Childcare Initiative	The Boston Public Health Commission	United States: NR	Early childhood educators	Intervention	Web based	Nutrition and physical Activity	Online training on evidence-based nutrition and physical activity best practices in early learning environments.	NR
Child Care Healthy Eating and Active Living Guidelines Training	Ottawa Public Health	Canada: 2015	Supervisors, childcare providers, and municipal cooks	Intervention	Web based	Nutrition and physical activity	Online training modules on healthy eating practices, environments, and physical literacy.	Part 1: Nutrition: 60 minutes; part 2: Active living: 30 minutes
Fostering Healthy Eating Habits	BC Provincial Health Services Authority—Interior Health	Canada: 2016	Childcare providers	Intervention	Web based	Nutrition	e-Learning course on healthy practices and environment.	1 hour
MyPlate on Alexa	United States Department of Agriculture	United States: 2020-2025	Everyone from parents and caregivers of babies starting at 4 months old through older adults (includes early learning professionals)	Intervention	App	Nutrition	An app that provides food and nutrition tips based on the Dietary Guidelines for Americans.	N/A[c]
Nourished and Active in Early Learning	University of Washington's Center for Public Health Nutrition and Washington State Department of Health	United States: NR	Early learning professionals	Intervention	Web based	Nutrition	Online course on healthy eating and beverages comprising 6 modules, strategies to support healthy eating, and common challenges.	NR
Nourishing Beginnings	Dairy Farmers of Canada	Canada: NR	ELCC[d] educators and directors as well as ELCC professors or program directors at colleges or universities.	Intervention	Web based	Nutrition	Online modules on healthy feeding practices	Module 1: 80 minutes; module 2: 70 minutes

[a]eHealth modality (eg, web, app, or SMS text messages).

[b]NR: not reported.

[c]N/A: not applicable.

[d]ELCC: early learning in childcare.



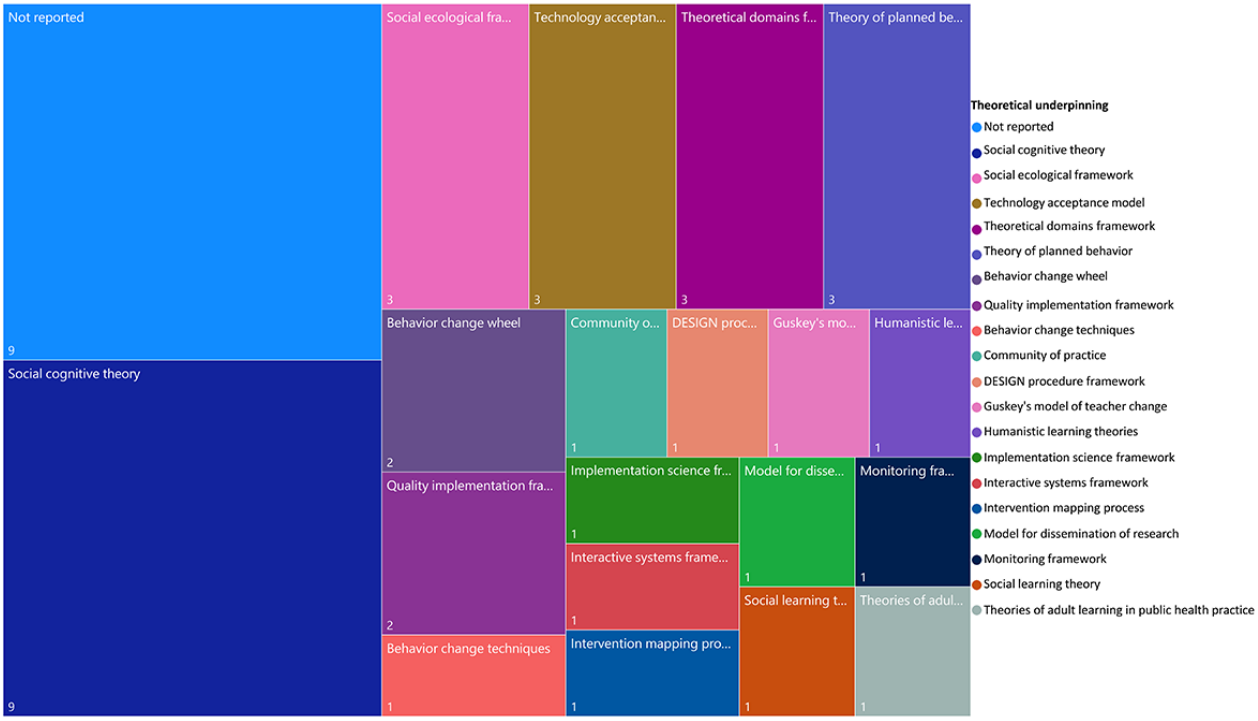
Practices Targeted

The majority of eHealth tools identified in the white literature (8/19, 42%) targeted nutrition practices, 6 of 19 (32%) targeted both nutrition and physical activity, and 5 of 19 (26%) exclusively addressed physical activity (Figure 4). The duration of intervention implementation ranged from 3 minutes to 12 months. The majority of eHealth tools identified in the gray

XSL•FO
RenderX

literature targeted nutrition (4/7, 57%), followed by tools targeting both nutrition and physical activity (2/7, 29%), and 1 focused solely on physical activity (Figure 4). For both the white (Table 2) and gray literature (Table 3), eHealth intervention tools targeting nutrition primarily addressed best nutrition and feeding practices, healthy eating or beverage practices, and menu planning. eHealth tools targeting physical activity mainly focused on best physical activity practices, outdoor play, and the reduction of sedentary behaviors.

Figure 4. Target of eHealth tool for white and grey literature.



Theoretical Framework of the eHealth Tools

Of the 30 research studies identified in the white literature, 21 reported the use of theoretical models (Multimedia Appendix 4). The most commonly cited theories include Social Cognitive Theory, Social Ecological Model, Theoretical Domain Framework, Theory of Planned Behavior, Behavior Change Wheel, and Quality Implementation Framework (Figure 5). None of the eHealth tools identified in the gray literature reported a theoretical underpinning (see Multimedia Appendix 5).

XSL•FO
RenderX

Figure 5. Theoretical underpinning from studies identified in the white literature search. DESIGN: decide target behavior, explore determinants, select theory-based model, indicate objectives, generate education plans, and nail down the evaluation.

Discussion

Principal Findings

The purpose of this scoping review was to explore the available eHealth tools developed to assess or deliver interventions aimed at improving the nutrition or physical activity environments in ECEC settings. The results of this review provide insights into the digital tools available, outlining their methodological approach and characteristics.

Mapping the included white and gray literature identified 26 eHealth tools, highlighting a growing interest in leveraging digital tools to enhance nutrition and physical environments in early learning settings. Notably, all tools were web based except for 1 delivered via a smart device application. This finding is striking, given the widespread adoption of mobile health apps in health promotion interventions [69,70]. A likely explanation is that the nature and timing of the intervention may influence the choice of eHealth modality. Mobile apps are typically utilized in interventions requiring rapidly changing data and real-time feedback, such as step tracking or patient self-care and symptom management [71,72]. By contrast, interventions targeting nutrition and physical activity practices in educational settings often focus on gradual changes implemented over extended periods. Additionally, mobile apps are generally more expensive to develop and maintain than web-based tools and require regular updates [73]. Furthermore, most educational settings rely on web-based systems and have access to computers and the internet, making web-based platforms a more convenient option for educators while facilitating the implementation of interventions. Lastly, mobile-based interventions are often more prevalent among youth populations (children and adolescents) due to their capacity to incorporate gamification—a popular and engaging approach for health promotion interventions within this demographic [74].

The identified eHealth tools employed diverse approaches and strategies to enhance nutrition and physical activity practices. Most tools focused on professional development, offering online modules and self-paced training with both synchronous and asynchronous components to improve educators' knowledge and behaviors related to best practices in nutrition and physical activity. Most of these tools (21/26, 81%) included educational videos to create engaging and interactive content, while just over half (15/26, 58%) incorporated quizzes or evaluation questions to reinforce learning and assess understanding. Additionally, a smaller proportion (10/26, 38%) provided technical support from experts or facilitators to offer guidance and enhance educator engagement. Research suggests that such human support can improve compliance and foster the adoption of new behaviors [75,76]. However, relying on human support may not be a sustainable approach due to the significant resources required and the challenges it poses for scalability [77]. A smaller proportion of tools (3/26, 12%) emphasized menu planning and provided tailored support to aid in the creation of healthier menus. Tools targeting physical activity primarily addressed best practices, highlighted the importance of outdoor and risky play, and aimed to reduce sedentary behaviors. Nutrition-focused tools concentrated on promoting best practices for nutrition and feeding while optimizing eating environments.

Less than one-third (8/26, 31%) of the identified eHealth tools addressed both nutrition and physical activity together. Evidence suggests that multibehavior interventions, which target multiple health behaviors simultaneously, are often more effective in driving meaningful change compared with interventions focused

XSL•FO
RenderX

on a single behavior [78]. Given the interconnected nature of nutrition and physical activity, these behaviors play a crucial role in health and well-being [79,80] and are recognized as leading modifiable factors in the prevention of major chronic diseases [1,2]. Knowing that nutrition and physical activity tend to cluster together, addressing these behaviors collectively might enhance the effectiveness of interventions [11,81-84]. It has also been found that targeting both nutrition and physical activity behaviors can lead to synergistic effects on health outcomes [85-87]. Therefore, tools aimed at improving educators' nutrition and physical activity practices or the nutrition and physical activity environments in early learning centers should target determinants of both behaviors simultaneously.

Another key finding is that, among the 7 eHealth tools incorporating an assessment component, only 1 reported psychometric properties testing. Psychometric evaluations, such as reliability and validity testing, are crucial as they indicate the quality of the tools, ensure their effectiveness for the intended purpose, and support their reproducibility and replicability [88]. The lack of reported psychometric testing may be due to some tools originally being developed in a pen-and-paper format before being adapted to an online format. In the original articles describing the pen-and-paper versions, psychometric testing was reported [89]. However, it is important to recognize that tool validity and reliability are not static characteristics; rather, they are assessments of the tool's instrument scores within the context in which they have been evaluated [90]. It is therefore recommended to conduct and report updated psychometric testing when tools are adapted into digital formats to ensure that the validity and reliability of the results are maintained [91,92].

Among the 30 studies identified in the white literature, the majority (21/30, 70%) incorporated a theoretical framework in their design. The most frequently cited theory was the Social Cognitive Theory, which is commonly used in behavior change interventions, aligning with findings from other reviews [93-95]. A theoretical underpinning is a critical consideration when developing health promotion interventions. It serves as a blueprint for the study, structuring and guiding the intervention planning process, and also helps in understanding the factors that might influence behavior change and need to be targeted [96,97]. Previous reviews have indicated that health interventions grounded in theory are more effective [28] and are associated with positive significant outcomes, larger effect sizes [23,94,98], and the maintenance of behavior change [99]. Hence, future research designing eHealth tools should prioritize the use of theoretical underpinnings to increase effectiveness and ensure replicability. Regarding the gray literature findings, no reports on the theoretical underpinnings or reliability were identified for any of these tools. A possible reason for this could be that the gray literature often targets a general population audience, where the focus is on practical application, whereas in peer-reviewed literature, researchers look for evidence of theoretical grounding to evaluate and further refine or replicate these tools.

Implications/Recommendations

Future research involving the development and implementation of eHealth tools in ECEC settings should emphasize the integration of theoretical frameworks, consider comprehensive multibehavior intervention approaches, incorporate community perspectives in the development process, and prioritize long-term sustainability and scalability, with a focus on implementation and efficacy assessment. Theoretical frameworks provide essential guidance in identifying key determinants of behavior and mechanisms for promoting change. Incorporating theory can enhance the effectiveness of eHealth tools, ensure consistent implementation, and facilitate replicability across different contexts. Multipronged eHealth tools designed to target both nutrition and physical activity can lead to more beneficial outcomes, as these domains are interconnected. To enhance implementation and adoption, it is essential to involve a diverse range of stakeholders, such as educators, parents, and health professionals, in the development process. This ensures that the unique needs and cultural context of the targeted eHealth tool users are addressed. Additionally, researchers should prioritize long-term sustainability and scalability when designing these tools, ensuring that interventions can be maintained and expanded across various settings over time. Finally, the resulting eHealth tools should undergo rigorous testing, including pilot trials, to assess their usability, feasibility, and effectiveness in achieving the intended outcomes. This integrated approach provides a holistic strategy for fostering healthier environments in ECEC settings.

Strengths and Limitations

This review is the first to map and summarize the scope of available evidence on eHealth tools designed to assess or improve nutrition and physical activity environments in early learning settings. The findings from this review can guide future research on the use of eHealth technologies to promote healthy practices in childcare, ultimately contributing to improved children's health behaviors and outcomes. Two librarians with expertise in scoping and systematic reviews assisted in developing and refining the search strategy. The methodology employed facilitated a systematic search of both white and gray literature, ensuring a comprehensive review of available evidence. However, there are some limitations to this scoping review that should be considered. We only considered studies published in English or French, which may have led to the exclusion of relevant research in other languages. Additionally, this scoping review focused solely on full-time day care centers, excluding family-based day care and after-school programs. The primary reason for excluding family-based day cares was the lack of formalized data, and after-school programs were not included as they typically do not cater to children aged 0-5 years. Another limitation encountered during the search for gray literature was the presence of paywalls and restricted access to certain tools, which hindered our ability to fully explore available resources.

Conclusions

This scoping review explored the breadth of evidence on eHealth tools aimed at improving nutrition and physical activity environments in ECEC settings. Future research should conduct

XSL•FO
RenderX

a systematic review to assess the effectiveness of these tools and identify the specific elements that contribute to a greater impact and sustained behavior change.

Acknowledgments

This study was funded by the Government of Alberta, Children Services (ACS565189). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the paper. The authors acknowledge and thank the research librarians at the University of Calgary and Erik Christiansen at Mount Royal University for their expert advice in developing and refining the search strategy.

Abstract

Background: Congenital heart disease (CHD) is the most common birth defect, affecting 40,000 births annually in the United States. Despite advances in medical care, CHD is often a chronic condition requiring continuous management and education. Effective care management depends on children's understanding of their condition. This highlights the need for targeted health educational interventions to enhance health literacy among children with CHD.

Objective: This scoping review aims to map and explore existing health educational interventions for children with CHD. The review identifies the types of interventions, target populations, delivery methods, and assessed outcomes. The goal is to consolidate fragmented research, identify gaps, and establish future research agendas.

Methods: Comprehensive searches were conducted in February 2024 using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) framework across multiple databases: APA PsycINFO, MedlinePlus via Ovid, Web of Science, ACM Digital Library, Scopus, and EBSCOhost (CINAHL Complete, CINAHL Ultimate, Health Source: Nursing/Academic Edition, and ERIC). The search covered health care, design, and human-computer interaction disciplines to capture the interdisciplinary nature of CHD health educational interventions. There was no predefined time limit due to the limited number of relevant studies. Eligible studies were in English, published in peer-reviewed journals, and focused on primary data about educational health interventions for children with CHD. We extracted and synthesized data using thematic analysis.

Results: The review identified 11 studies: 9 randomized controlled trials and 2 observational studies. These used 6 educational strategies: 3D patient-specific models (n=3), habit formation interventions (n=2), empowerment-based health education programs (n=2), rehabilitation interventions (n=2), web-based portals (n=1), and videotape presentations (n=1). Interventions ranged from brief outpatient sessions to 1.5-year programs, with follow-up from none to 24 months. Studies aimed to improve coping, self-management, and knowledge for children with CHD and their families. The most frequently used assessment method was the independent samples *t* test (n=4) for pre- and postassessments, and all 11 studies used questionnaires, 8 of which incorporated qualitative feedback. The target participants for these interventions were children aged 13 years and older (n=3), parents (n=2), and children of various ages and their parents (n=6). Outcomes included improved children's health literacy, reduced parental burden, and increased health care provider efficiency.

Conclusions: This review underscores the critical need for tailored educational interventions for children with CHD. Current research mainly focuses on adolescents and relies heavily on parental involvement, possibly overlooking the specific needs of younger children younger than 13 years of age. It is essential to develop engaging, age-appropriate interventions that actively involve children with CHD in their health care journey. Effective health educational interventions are crucial in empowering these young patients and improving their long-term health outcomes.

Introduction

Background

Congenital heart disease (CHD) is a structural abnormality in the heart present at birth. It is the most common birth defect, affecting 1.35 million newborns worldwide and around 40,000 births annually in the United States. CHD often leads to other health complications and poses lifelong challenges to affected children, families, and health care systems [1-3]. Improved medical and surgical care have substantially increased survival rates, with up to 90% of children with CHD now surviving through to adulthood [4,5]. Despite improved medical care, CHD is more like a chronic condition that requires early diagnosis, timely treatment, and ongoing management. Figure 1 shows the worldwide prevalence of CHD from 1970 to 2017 and how survival rates in the United States since 1999 impact the need for continuing care [2,5-8]. Effective long-term care requires a comprehensive understanding of the condition by both pediatric patients and caregivers. Traditionally, health care providers have relied on parents to educate their children about their condition, assuming effective transmission of information. This approach often falls short, with parents struggling to comprehend and recall the information provided. Insufficient knowledge leads to extensive education during appointments, causing confusion and anxiety for children with CHD and their families [9-12]. Without proper education, the ability to proactively manage the condition diminishes, potentially leading to worse health outcomes, greater difficulty transitioning to adult care, and increased hospitalizations [4,13]. Accessible health information and organized educational support systems are crucial for improving health education, self-management skills, and health literacy (HL) among pediatric patients and caregivers [2,14].

Figure 1. Worldwide CHD prevalence and the effect of US survival rates on care management. Data were sourced from Boneva et al [8], Liu et al [7], Lopez et al [6]. CHD: congenital heart disease.

Prior Work

HL is defined as "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions" [9]. However, there are uncertainties about the best educational and support approaches for improving HL in pediatric patients with CHD. Learning about this complex subject at a young age presents significant challenges. Limited learning opportunities hinder adequate information delivery and understanding [10]. Moreover, current educational materials (eg, pamphlets and postvisit summaries) are often inappropriate for young children and are primarily intended for their caregivers or parents [10,12]. To tackle these challenges, health educational interventions are designed to enhance individuals' knowledge, attitudes, skills, and behaviors to manage their condition [15]. These interventions are crucial for empowering children with CHD to understand their condition, adhere to treatment plans, and navigate the health care system effectively.

Recent focus has highlighted the importance of involving children with CHD and their caregivers in developing and executing their care plans through health educational interventions [10,12]. Despite this, the literature on educational interventions for children with CHD remains limited. To our knowledge, no systematic or scoping reviews have been conducted on this topic. Only a few scoping and systematic studies have attempted to understand the experiences of children with CHD, their families, and health care providers in managing CHD [2,16-18]. Furthermore, some studies focus on the coping mechanisms of parents and families of children with CHD rather than on the children themselves [19-21]. Therefore, a scoping review is necessary to consolidate fragmented research, identify existing gaps, and establish a future research agenda [22].

Purpose and Objectives

This scoping review systematically maps and explores existing educational interventions for children with CHD to identify intervention types, target populations, delivery methods, and assessed outcomes. Textbox 1 presents the PICOTS (population, intervention, comparator, outcome, timing, and setting) framework for educational interventions for children with CHD. PICOTS helps clarify and organize research questions. The key questions (KQs) addressed are:

XSL•FO
RenderX

KQ1: What types of educational interventions are available for children with CHD?

KQ2: What are the study designs, target populations, and the roles of various stakeholders in these educational interventions?

KQ3: What outcomes are assessed, and what approaches are used for assessment?

KQ4: What gaps exist in the current literature regarding educational interventions for children with CHD, and what areas require further exploration?

Figure 2 presents the analytical framework for the scoping review. It outlines a structured approach to address KQs concerning CHD and educational interventions for pediatric patients. The review covers intermediate outcomes, including intervention details, study design, stakeholder involvement, and assessed outcomes. The primary outcomes are improved children's HL, reduced parental burden, and enhanced efficiency of health care providers. Suboutcomes related to children's HL enhancement include understanding CHD, self-management or habits, coping or quality of life, empowerment, health care use, and health outcomes. The review also focuses on providing educational, emotional, caregiving, and financial support to reduce parental burden. Additionally, it considers suboutcomes related to saving time or effort, treatment adherence, care coordination, shared decision-making, and patient or family satisfaction to enhance the efficiency of health care providers.

Textbox 1. PICOTS (population, intervention, comparator, outcome, timing, and setting) framework for key questions on health educational interventions for children with congenital heart disease (CHD).

Population

- Children diagnosed with CHD <18 years.

Intervention

- Educational interventions targeting health literacy improvement among children with CHD.

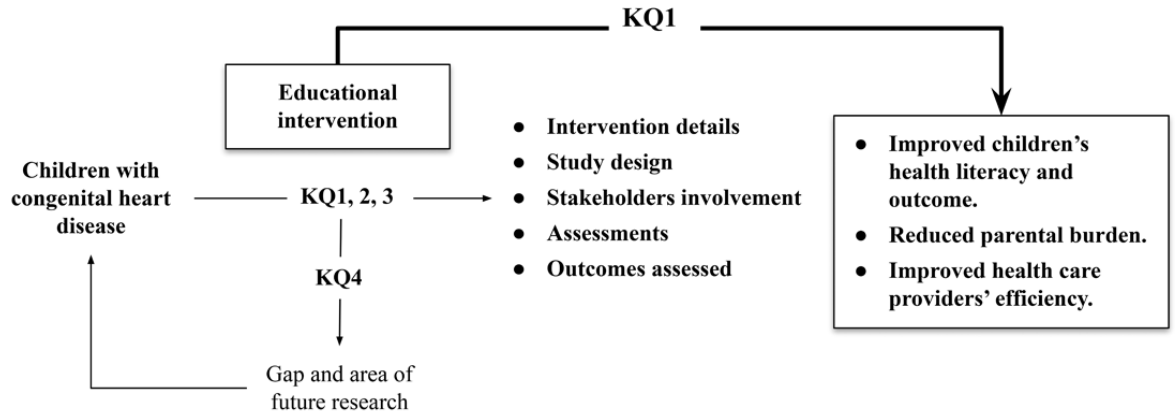
Comparators

- Any comparator (as this is a scoping review).

Outcomes

- Engagement (use and satisfaction).
- Improved health literacy in children with CHD (understanding of CHD, self-management or habits, coping or quality of life, empowerment, health care use, and health outcome).
- Reduced parental burden through effective educational support (educational support, emotional support, and financial support).
- Enhanced health care efficiency by minimizing education needs during medical appointments (saving time or effort, treatment adherence, care coordination, shared decision-making, and patient or family satisfaction).

Timing



- No restrictions.

Setting

- All types of studies (as this is a scoping review), including various health care (eg, hospitals and clinics), nonhealth care (eg, school and support community), and home settings.

Methods

Literature Search Strategy

This study used a scoping approach guided by the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) framework [23]. Scoping reviews provide an overview of emerging evidence without aiming to appraise and synthesize results for a specific question. They are useful when it is still unclear what specific research questions a systematic review can address. Additionally, scoping reviews help inform and identify current research practices and methodologies in emerging research fields [22-25]. This research process was structured using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework, including four stages: (1) identification of relevant literature searches on various databases using specific keywords, (2) screening the title and abstract of the identified studies, (3) eligibility—full-text review of screened results to eliminate studies outside our intended scope, and (4) inclusion, helped extract relevant data that met the defined criteria [26]. The PRISMA-ScR checklist is available in Multimedia Appendix 1.

Eligibility Criteria

To be included in the review, studies must be written in English and published in a peer-reviewed journal to ensure accessibility and credibility. We only considered studies with a methods section, focusing on primary data and analyses rather than studies like systematic reviews. Our focus was on CHD in pediatric patients younger than 18 years of age, and the studies addressed educational interventions for this demographic, not just HL. We excluded studies that solely targeted parents or caregivers, focused only on health care providers, or related to transition care from pediatric to adult health care, as these areas fall outside our specific review scope. However, we included studies involving parents only when their participation aimed to improve the child's health outcomes, focusing on enhancing the children's educational experience rather than the parents. This selection process ensured that the included studies were directly relevant to pediatric CHD and educational health interventions.

Information Sources and Search

We conducted comprehensive searches across the following bibliographic databases during February 2024 to identify potentially relevant studies without a predefined time limit. Given the initial research indicating a scarcity of relevant studies, we maintained an open search time frame. We gathered relevant studies from APA PsycINFO and MedlinePlus via Ovid, Web of Science, ACM Digital Library, Scopus, and EBSCOhost, including CINAHL Complete, CINAHL Ultimate, Health Source: Nursing/Academic Edition, and ERIC. These databases cover health care, psychology, education, design, and human-computer interaction disciplines. They were selected to reflect the interdisciplinary nature of CHD health educational interventions.

Three main concepts were identified based on the research questions: HL, pediatric, and CHD. Synonyms and related concepts were incorporated to ensure a comprehensive search for related terminologies used in the literature. For example, synonyms of "pediatric" included "child," "children," "toddler," and "preschool," while related concepts like "boy" and "girl" were also included. Given the cross-disciplinary database search, listing each concept's relevant ideas and terms was important. MeSH terms and keywords were tailored to each database's specifications, as detailed in Multimedia Appendix 2. Boolean search strings were formulated using the OR operator for synonyms of the main concepts (ie, "children" OR "child" OR "pediatric") and the AND operator to combine the 3 main concepts (ie, "health literacy" AND "congenital heart disease" AND "pediatric"). The terms were refined through multiple iterations by adding new terms and synonyms or adjusting specificity to enhance the quality of results. For instance, recognizing that the term "health literacy" may be omitted in studies involving health education interventions, alternative terms such as "healthcare knowledge," "health awareness," and "health education" were included. Additionally, we intentionally avoided using "intervention" as a synonym for "health literacy" to ensure that studies focusing on clinical and surgical interventions in CHD were not included (Table 1).

XSL•FO
RenderX

Table 1. Boolean search strings in categories.

Categories	AND or NOT	Boolean search string
Health literacy	AND	("Health Literacy" OR "Healthcare Literacy" OR "Medical Literacy" OR "Health Understanding" OR "Health Education" OR "Healthcare Education" OR "Health Information Literacy" OR "Medical Comprehension" OR "Healthcare Knowledge" OR "Health Knowledge" OR "Health Proficiency" OR "Health Awareness" OR "Medical Awareness" OR "Health Competency" OR "Health Communication" OR "Information Literacy" OR "Patient Education" OR "Health Promotion" OR "Health Teaching")
Pediatric	AND	(Children OR Child* OR Kid OR Kids OR Girl* OR Boy OR Boys* OR Toddler* OR Childhood OR Preschool* OR Pre-school* OR Kindergarten* OR School OR Minors OR Pediatric* OR Paediatric*)
Congenital heart disease	AND	("Congenital Heart Defects" OR "Child Heart Disease" OR "Heart Defects" OR "Congenital Heart Disease" OR "Pediatric Cardiology" OR "Paediatric Cardiology" OR "Cardiac Defect*")

The first author (NB) and a collaborator independently screened the titles and abstracts using the PICO Portal, reaching a consensus on selections for full-text screening and consulting the health librarian for final decisions in disagreements. Before and during the screening process, the first (NB), second (JYS), and last authors (CAL) held weekly meetings to clarify the selection of databases, concepts, and criteria as well as to draft an internal guideline. For example, following our discussions, we added the ACM Digital Library database to broaden our search to include technology-mediated solutions. These meetings continued during data charting and thematic analysis. We also sought guidance from a medical expert, a public health expert, and 2 librarians throughout the review. We used Zotero (Corporation for Digital Scholarship) for reference management and Google Sheets and Microsoft Excel for data abstraction. We established decision rules to guide the coding process and ensure consistency in cases requiring subjective interpretation.

The research team abstracted data on study characteristics: (1) study identification (ie, ID, author or year, country, title, study design, date of study, setting, and objective or purpose), (2) participant details (ie, target population, intervention tested on, sample size, demographic, inclusion or exclusion criteria, and CHD severity), (3) intervention specification (ie, intervention, format, description, comparison, stakeholders' roles, duration, and follow-up), and (4) outcome specification (ie, outcome measures, results, and statistical analysis). Abstraction tables are shown in Tables S1-S5 in Multimedia Appendix 3 [27-37].

Data Synthesis

Due to the heterogeneous nature of the data, the research team used a qualitative approach using affinity diagramming and thematic analysis [38,39]. This approach enabled us to explore the data without predetermined frames and uncover emerging themes to answer our scoping review questions and objectives. We began by categorizing the studies based on the types of interventions they covered. We then performed open coding on all 11 papers to identify the specifications of educational interventions (ie, objectives, strategies, stakeholder involvement, and outcomes) for children with CHD. Through constant comparison and iterative coding, thematic categories emerged. Initially, open coding of studies yielded 43 discrete codes. Subsequently, these codes were iteratively aggregated based on commonalities, resulting in 15 representative codes. Next, affinity diagramming was used to cluster these 15 codes according to similarity, difference, and hierarchy relationships.

This process allowed us to establish high-level themes, refined through constant comparison and iterative coding. The key themes that emerged from the data include (1) types of educational interventions, (2) study design and stakeholder involvement, and (3) evaluation methods and outcome objectives. Each main theme was further divided into 2 subthemes (Textbox 2). This thematic synthesis provided a clear and structured understanding of the educational interventions for children with CHD, covering their implementation and evaluation.

Textbox 2. Identified themes and subthemes.

Types of educational interventions

- Educational strategies and objectives (eg, engaging sessions and disease education)
- Intervention duration (eg, duration and frequency of educational interventions)

Study design and stakeholder involvement

- Study design (eg, observational and randomized controlled trial)
- Target age groups and stakeholder involvement (eg, children and parents)

Evaluation methods and outcome objectives

- Assessed outcomes (eg, health literacy and health outcome)
- Data collection and analysis techniques (eg, questionnaires and interviews)

Results

Selection of Sources of Evidence

The literature search identified 864 records across 5 databases: APA PsycINFO (n=3), MEDLINE (n=235), Web of Science (n=102), ACM Digital Library (n=25), Scopus (n=473), CINAHL Complete (n=11), CINAHL Ultimate (n=11), Health Source: Nursing/Academic Edition (n=3), and ERIC (n=1). After removing 280 duplicates and supplemental materials, 584 records remained for abstract screening. Following abstract and title screening by the research team, 480 records were excluded for not meeting the review criteria. The full texts of the remaining 104 reports were assessed for eligibility. Of these, 93 reports were excluded for various reasons: 31 due to the population mismatch (ie, focusing on parents or caregivers or health care providers, participants aged >18 years, or studying general heart disease), 26 because the intervention was not relevant (ie, no interventions implemented, assessments used as interventions, or noneducational interventions), and 36 were excluded based on the wrong study design (ie, focusing on transitions to adulthood or objectives aimed at parents or health care providers). Finally, 11 reports met all the inclusion criteria and were selected for inclusion in the scoping review. Figure 3 illustrates the results of the literature search and screening. We used the PICO Portal review software to support the screening process. The reasons for exclusion at each stage were clearly documented, ensuring transparency and adherence to the PRISMA guidelines. References for papers excluded in the full-text review can be found in Multimedia Appendix 4.

Figure 3. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram of the literature review process.

Characteristics of Sources Evidence

From 1982 to 2023, 11 studies were reviewed, focusing on educational interventions for pediatric patients with CHD [27-37] (Figure 4). There was a gap in the selected studies from 1982 to 2015. After that, 1 study was published every year until 2023, except for 2016, which had 2 studies [31,34]. Two studies were from the Netherlands in 2017 and 2018 [29,36], while 3 were from the United States in 1982, 2021, and 2022 [33,35,37]. Among these studies were 9 randomized controlled trials (RCTs) [27-32,34-36], with 1 covering both a pilot and RCT [29]. Additionally, 2 were observational studies [33,37]. Even though we searched design, human-computer interaction, and health databases, the studies were published in 9 medical and health-related journals. Two of the reviewed studies were published in the *International Journal of Cardiology* [27,31].

Results of Individual Sources of Evidence

Overview

In exploring educational interventions for children with CHD, the first emergent theme is "types of educational interventions," with subthemes of "educational strategies and objectives" and "intervention duration." Educational strategies and objectives refer to the strategies used to support children with CHD and how these interventions address specific objectives, like disease education. Duration presents the timing and duration of these interventions, whether they are 1-time sessions, have follow-ups, or are repeated over time. This theme and its subthemes address KQ1: What types of educational interventions are available for children with CHD?

Educational Strategies and Objectives

Across the reviewed studies, 6 educational strategies were used to support children with CHD and their families (Figure 5). These strategies include the use of 3D patient-specific models, habit formation interventions, empowerment-based health education programs, rehabilitation interventions, a web-based portal, and videotape presentations.

3D patient-specific models are anatomical models created from medical imaging data like computed tomography or magnetic resonance imaging scans, providing a detailed representation of a child's heart. They help visualize and understand complex cardiac structures and treatment plans. Three studies used these models to educate about cardiac anatomy and treatment plans. These models were accompanied by engaging discussions and supplemented with diagrams or images, clarifying complex anatomical structures and treatment options. One of these studies specifically targeted adolescent patients, combining 3D models with tele-education. These interventions offered a visual understanding of the heart's structure and treatment procedures, including cardiac catheterization [28,33,37]. Habit formation interventions aim to instill healthy habits in children with CHD through structured programs. These interventions often involve multiple components, such as printed materials, toolkits, websites, and counseling sessions, to encourage and support the development of these beneficial habits. Two studies focused on these interventions. One aimed at promoting physical activity through a multifaceted intervention, including printed materials, a physical activity toolkit, and a website. The other focused on oral health promotion through counseling, distributing oral hygiene products, and providing written information [30,32].

Figure 5. Educational strategies, objectives, and intervention durations [27-37]. CHD: congenital heart disease; NR: not reported.

Studies	Strategies	Objectives	Purpose	Duration	Follow-up
Biglino et al (2015) Zablah et al (2021) Liddle et al (2022)	3D patient-specific models	- Disease education	Provide a visual understanding of cardiac anatomy and treatment procedures, such as cardiac catheterization.	- Routine outpatient visits - Routine outpatient visits - 30-minute tele-education	- NR - NR - NR
Lemire et al (2020) Karikoski et al (2023)	Habit formation interventions	- Self-management skills	Promote physical activity and oral health—2 important habits—among children with CHD.	- 6 months (3-day workshop, conference call each month) - 1.5 years (sessions at 6, 12, 18 months)	- 6 months - 24 months
Ni et al (2016) van der Mheen et al (2018)	Empowerment-based health education programs	- Coping strategies - Disease education	Improve caregiving knowledge, caring behaviors, and self-efficacy of parents caring for children with CHD.	- 40 minutes + 3 monthly each 10 minutes - One-day workshop	- 1 month + 3 months after surgery - 6 months
Amedro et al (2019) Klausen et al (2016)	Rehabilitation interventions	- Self-management skills - Coping strategies	Enhance the quality of life, physical fitness, and health-related quality of life in adolescents and young adults with CHD.	- 12 weeks - 52 weeks	- 12 months - 12 months
Etnel et al (2017)	Web-based portal	- Disease education - Physician-patient communication	Improve patient knowledge and involvement and support physician-patient communication in the management of CHD.	- No limit	- 1 month
Uzark et al (1982)	Videotape presentation	- Coping strategies - Disease education	Enhance children's knowledge and coping during hospitalization for cardiac catheterization through visual education.	- 16 min	- 4 to 6 weeks after hospital discharge

Empowerment-based health education programs empower parents and family members by enhancing their knowledge, caregiving behaviors, and self-efficacy in managing a child's CHD. They typically include face-to-face education sessions, workshops, and follow-up support such as telephone calls, helping caregivers feel more confident and competent in their roles. Two studies implemented these programs to improve the caregiving knowledge, caring behaviors, and self-efficacy of parents or family members caring for children with CHD. One offered face-to-face education sessions and follow-up telephone calls, while the other conducted workshops [34,36]. Rehabilitation interventions aim to enhance the physical and psychological well-being of children and adolescents with CHD. These include structured cardiac rehabilitation programs (center or home-based) and eHealth interventions that use technology to improve physical fitness, activity levels, and overall health-related quality of life over an extended period. Two studies explored these interventions. One evaluated the impact of a combined center- and home-based cardiac rehabilitation program on the quality of life of adolescents and young adults with CHD. The other assessed the effects of a 52-week eHealth intervention on physical fitness and health-related quality of life in adolescents with CHD [27,31].

Web-based portals are digital platforms that enhance patient education, engagement, and communication. They provide accessible information about CHD, treatment options, and self-management strategies. These portals also facilitate communication between patients, families, and health care providers, ensuring continuous support and information exchange. Only 1 study assessed the effectiveness of these interventions in improving adolescent patient knowledge and involvement and supporting physicians in communicating with their patients [29]. Videotape presentations prepare children and their families for medical procedures and hospital stays. The videos use engaging, playful, and child-friendly formats, such as fictional or animated characters and stories, to simplify complex medical concepts and make them less intimidating. In 1982, a study evaluated the impact of a 16-minute videotape presentation on children's knowledge and coping skills during cardiac catheterization. The study featured a fictional lion who presented the videotape to guide hospitalized children through the events, sights, sounds, and sensations associated with the cardiac catheterization procedure [35].

Of the 11 studies reviewed, 7 offered disease education using the following methods: 3D patient-specific models, empowerment-based health education programs, web-based portals, and videotape presentations [28,29,33-37]. Four studies

XSL•FO
RenderX

focused on improving self-management skills using 2 strategies: habit formation interventions and rehabilitation interventions [27,30-32]. Five studies aimed to teach coping strategies using 3 approaches: empowerment-based health education programs, rehabilitation interventions, and videotape presentations [27,31,34-36] (Figure 5). It is important to note that some studies addressed more than 1 aspect, which is why the numbers overlap across different categories.

Intervention Duration

The duration of educational interventions varied across the studies, as shown in Figure 5. Some interventions were brief sessions within routine visits, while others lasted up to 1.5 years. Follow-ups also differed. Some interventions had no follow-ups, while others included assessments at intervals of 1 month, 6 months, 1 year, or 2 years.

In total, 2 of 3 studies using 3D patient-specific models were integrated into routine outpatient visits without a specified duration. Another study used digital 3D heart models during a 30-minute tele-education session instead of in person. After the session, patients received a USB drive containing a video of their 3D heart and digital files for potential self-learning, with no follow-up mentioned [28,33,37]. In contrast, habit formation interventions, such as the oral health promotion intervention and a multifaceted physical activity intervention, spanned extended periods. Oral health promotion intervention lasted 1.5 years with sessions at baseline, 6, 12, and 18 months, followed by a 24-month follow-up. The multifaceted physical activity intervention spanned 6 months, including a 3-day workshop and monthly conference calls, with a follow-up period of 6 months [30,32].

As part of the empowerment-based health education program, 1 study included a 40-minute face-to-face education session with individualized instructions on the second day after surgery. There were also 2 monthly 10-minute telephone calls after the discharge to discuss the child's care and modify action plans. Subsequent assessments were conducted at 1 month and 3 months after surgery. Another study, the Congenital Heart Disease Intervention Program-Family intervention, involved a 1-day workshop and a 6-month follow-up session and assessment [34,36]. Using the rehabilitation interventions strategy, 1 study implemented the QUALI-REHAB cardiac rehabilitation program, consisting of a 12-week program with 5 days of hospitalization at the rehabilitation center and home-based training. Recall sessions were held every 3 weeks at the center, with a final evaluation at the end of week 12 and a 12-month follow-up period for outcome measurements. Another program, the Paediatric Rehabilitation for Vanguard in Lifeskills (PReVaiL), lasted 52 weeks, with a follow-up assessment conducted after 1 year. Patients received group-based health education sessions lasting 45 minutes and individual counseling sessions lasting 15 minutes [27,31].

Additionally, 1 study introduced a web-based portal during outpatient visits that could be used anytime, with follow-up assessments conducted 1 month after the visit [29]. Finally, 1 study conducted a 16-minute videotape presentation session 1 day before procedures, with a follow-up undertaken 4 to 6 weeks after discharge from the hospital [35]. In total, 3 studies had a 1-month follow-up timeline, while 2 had 6 months and 2 had 1 year.

Study Design and Stakeholder Involvement

Overview

The second emergent theme is "study design and stakeholder involvement," with subthemes of "study design" and "target age groups and stakeholder involvement." Study design focuses on the methodologies used in the studies and the size of participant samples. Target age groups and stakeholder involvement examines the target population's age range and impact on stakeholder roles. It analyzes whether parents, caregivers, or health care providers are involved in delivering or evaluating the intervention and identifies the target population. Together, these address KQ2: What are the study designs, target populations, and the roles of various stakeholders in these educational interventions?

Study Design

In total, 8 of the 11 studies used an RCT design, while 1 study included a pilot phase followed by an RCT [27-32,34-36]. The sample sizes in these RCTs ranged from 53 to 250, with a mean of 126.11 (SD 43.95). The intervention group size ranged from 31 to 125, with a mean of 63 (SD 25.20), and the control group size ranged from 22 to 125, with a mean of 62.78 (SD 24.60).

These RCTs varied in their approach, including prospective randomized clinical trials; questionnaire-based feasibility and acceptability studies; prospective clinical trials; single-center, single-blinded, randomized controlled trials; prospective, multicenter, randomized, controlled, parallel-arm studies; cluster randomized controlled trials; and multicenter stepped-wedge implementation trials. Additionally, 2 studies adopted observational study designs [33,37]. The observational studies explored a single-center cross-sectional study and a prospective pre-post study, with sample sizes of 46 and 22, respectively.

Reviewed studies used diverse settings for their interventions. Three studies implemented interventions across home settings, cardiac clinics, and digital or telehealth platforms [29,32,33]. Another 3 studies implemented interventions at home and children's hospitals [30,34,36]. One study used interventions in home settings, cardiac clinics, and rehabilitation centers [27]. Additionally, 1 study used home settings, rehabilitation centers, and digital or telehealth platforms [31]. In total, 2 studies were conducted at cardiac centers [28,37], while 1 was conducted exclusively at a hospital [35]. The study designs and settings are summarized in Figure 6.

Target Age Groups and Stakeholder Involvement

In the reviewed studies focusing on educational interventions for children with CHD, stakeholder involvement varied depending on the participants' age range. This variation influenced the roles played by different stakeholders, such as parents or caregivers and health care providers, within these interventions.

The primary emphasis of this review was on educational interventions tailored for children with CHD, although not all studies exclusively targeted children as participants. Several studies also included parents of children with CHD within specific age groups to enhance the overall health outcomes for these children. Among the 11 studies examined, 2 exclusively focused on parents [28,34], while 6 involved both parents and children [29,30,32,35-37]. Additionally, 3 studies specifically targeted children aged 13 to 18, 13 to 25, and 13 to 16 years [27,31,33]. The youngest participants in the studies targeting just children with CHD were aged 13 years.

In a study conducted by Uzark et al [35], the researchers assessed the impact of a videotape presentation on the knowledge and coping of children with CHD aged 3 to 12 years during hospitalization for cardiac catheterization. The study also targeted the parents of these younger children to improve outcomes for both children and parents. Another study by Biglino et al [28] investigated the effectiveness of 3D patient-specific models of CHD as a communication tool during cardiology consultations for pediatric patients aged 6 to 18 years and their parents. The age range of parents included in this study was 35 to 51 years.

Lemire et al [32] studied children with CHD aged 5 to 17 years and their parents. The intervention aimed to assess whether providing resources and protocols would enable clinicians to counsel about physical activity during every pediatric cardiology appointment. In another study, Karikoski et al [30] targeted children with CHD up to 24 months old and their parents to investigate the effectiveness of repeated counseling provided by a dental hygienist in improving oral health behavior during the first 1000 days of life. They aimed to improve parental hygiene habits with the expectation that it would also enhance young children's hygiene habits.

XSL•FO
RenderX

Ni et al [34] evaluated the effectiveness of an empowerment-based health education program for parents caring for children aged 1 month to 5 years who had undergone corrective surgery for CHD. Their goal was to improve the health outcomes for the children and not the parents. Van der Mheen et al [36] assessed the effects of a program on parental mental health and the psychosocial well-being of children with CHD aged 4 to 7 years. This program also involved siblings to help normalize the child's CHD position within their family dynamic.

In all 11 studies, key stakeholders—children, parents or caregivers, and health care providers—actively participated in the interventions. In total, 8 studies involved all these stakeholders [27,29-32,35-37], while 2 involved parents and health care providers [28,34], and 1 included children and health care providers [33]. The age ranges in these studies varied widely, from birth to 25 years. However, the age range for parents was not consistently provided across the studies. Only 1 study specified the age range for parents as 35 to 51 years, with children aged 6 to 18 years [28]. Figure 6 provides details of population specification, including stakeholder involvement, age ranges, and sample sizes across the reviewed studies.

Evaluation Methods and Outcome Objectives

Overview

Theme 3, "evaluation methods and outcome objectives," includes 2 subthemes: "assessed outcome" and "data collection and analysis techniques." Assessed outcomes discusses the specific objectives and goals the interventions aimed to achieve. Data collection and analysis techniques examines the methods and approaches used to gather and analyze data. Together, these subthemes address KQ3: What outcomes are assessed, and what approaches are used for assessment?

Assessed Outcomes

The outcomes assessed represent the specific objectives the reviewed studies measure to evaluate the effectiveness of their interventions. This scoping review categorized assessed outcomes into three main categories: (1) improved children's HL and outcome, (2) reduced parental burden, and (3) improved efficiency of health care providers. Figure 7 summarizes these categories, demonstrating the varied impacts of interventions on children with CHD, their parents or caregivers, and health care providers.

Improving children's HL involves various suboutcomes. These include understanding CHD, self-management and habits, coping and quality of life, empowerment, health care use, and health outcomes. Two studies evaluated the understanding of CHD, and both reported increased knowledge following the intervention [33,35]. Meanwhile, 3 other studies are still under investigation [29,32,36]. Three studies were conducted on self-management and habits. In total, 2 showed positive impacts [30,35], while 1 showed no change or impact [31]. Furthermore, 1 study found a relationship between the intervention and self-management and habits, indicating a need for further investigation in future studies [33]. Ongoing research is being conducted in 3 more studies under investigation [27,32,36].

Two other studies assessed coping and quality of life, one showing no change after intervention [31], and one showing improvement [35], while ongoing investigations continue in 4 studies [27,29,32,36]. Regarding empowerment, 2 studies showed improvement [33,35], with ongoing investigations in 2 more studies [29,36]. Health care use was evaluated once, with no observed difference [30]. Health outcomes were assessed in 2 studies, one indicating improvement [34] and the other showing no change [31]. Additionally, 2 studies without assessments reported a relationship between health outcomes and the intervention [30,35], while ongoing investigations are underway in 2 studies [27,36].

Reducing parental burden focused on various suboutcomes, including educational, emotional, caregiving, and financial support. In total, 4 studies assessed educational support, with 3 showing improvement [30,34,37] and 1 showing no change [28]. Two studies evaluated emotional support, both indicating improvement [34,35]. One study identified a relationship between intervention and emotional support without formal assessments [28], while 2 studies are under investigation [29,36]. Three studies assessed caregiver support, all of which showed improvement [30,34,37]. Similarly, 3 studies identified a relationship that needs further assessment [28,33,35], and 2 are still under investigation [29,36]. Financial support was not assessed in any of the reviewed studies.

Furthermore, regarding enhancing the efficiency of health care providers, one study assessed saving time and effort but found no significant time savings [28], while another study on this topic is still ongoing [32]. Treatment adherence was not directly assessed in any reviewed study, although 1 study noted a relationship without formal assessment [37]. Two studies evaluated care coordination, one indicating improvement [37] and another showing no change [30]. In total, 3 studies identified a relationship between the intervention and care coordination but did not conduct formal assessments [28,33,34], and 1 study is currently under investigation [32]. Shared decision-making and patient or family satisfaction were each assessed in 1 study, both showing improvement [33]. However, another study still investigates shared decision-making [29]. Additionally, 3 studies found a relationship between the intervention and shared decision-making [28,34,37], while 1 reported a relationship with patient or family satisfaction [28]. These findings suggest avenues for future research to assess these relationships more deeply.

Data Collection and Analysis Techniques

Across the 11 reviewed studies, various assessment methods and statistical analyses were used to evaluate the effectiveness of interventions for children with CHD. These methods and analyses provided comprehensive insights into the outcomes measured and the statistical rigor applied.

As a statistical software, SPSS (IBM Corp) was predominantly used in 5 studies [30-32,34,37], reflecting its widespread utility for quantitative data analysis in health care research. Data collection methods varied, with all studies using questionnaires, often administered before and after the intervention. In total, 3 studies relied solely on questionnaires and quantitative methods [28,35,37], while 5 studies integrated questionnaire data with qualitative feedback from in-person or digital interviews, calls, or focus groups [29-31,33,36]. Two studies incorporated medical records or devices alongside questionnaires [27,32], and 1 used all 3 methods, including questionnaires, qualitative feedback, and medical records or devices [34].

Statistical analyses used in the reviewed studies to analyze the data included a wide range of methods. The most frequently used statistical analysis method was the independent samples *t* test, used in 4 studies primarily as pre- and postassessments [28,30,34,35]. Other common analyses included repeated measures ANOVA [32,34,36], analysis of covariance analysis [31,32,35], Mann-Whitney *U* test [30,32,37], and chi-square analysis [28,34,35], each used 3 times to assess various outcomes. Several studies have also applied regression analysis techniques such as stepwise regression [35], simple logistic regression [30], multiple logistic regression [30], and logistic regression [31,32].

Among the 11 studies, 2 statistical approaches were used in 3 studies [31,33,37]. Notably, 1 study in 1982 used 6 statistical

XSL•FO
RenderX

techniques, including analysis of covariance analysis, independent samples *t* test, chi-square analysis, stepwise regression, correlation analysis (*r*), and cluster analysis [35]. Figure 7 provides an overview of the statistical approaches used across the studies, highlighting a range from 2 to 6 approaches per study.

The reviewed studies used various methods and statistical techniques, indicating no single approach to achieving their objectives. The frequent use of quantitative methods, primarily involving stakeholders other than children with CHD, suggests the need for tailored methods and techniques for this patient demographic.

Discussion

Principal Findings

Overview

This scoping review identified 11 studies conducted between 1982 and 2023, focusing on educational interventions for children with CHD. The studies included 9 RCTs and 2 observational studies. These studies used various intervention strategies, durations, study designs, and evaluation methods, offering a comprehensive overview of current research in this field. Six primary types of educational strategies were identified: 3D patient-specific models (n=3), habit formation interventions (n=2), empowerment-based health education programs (n=2), rehabilitation interventions (n=2), web-based portals (n=1), and videotape presentations (n=1). These interventions varied in duration, ranging from brief sessions during outpatient visits to programs lasting up to 1.5 years. Follow-up periods also varied, with 3 interventions having no follow-up, 2 having a 6-month follow-up period, 3 having follow-ups ranging from 4 to 6 weeks, and 1 study having a follow-up period of 24 months. The primary goals of these interventions were to improve the quality of life and coping strategies, self-management skills, and knowledge of children with CHD and their families. Among these studies, 3 interventions specifically targeted children above 13 years of age, 2 focused on parents, and 6 involved both children and parents. The primary statistical method used was the independent samples *t* test, used in 4 studies for pre- and postassessments. Outcome assessments focused on children's HL, reducing parental burden, and improving the efficiency of health care providers. These findings reveal the potential and the limitations of current health educational interventions, highlighting the need for more child-centric approaches to engage younger patients with CHD.

Limited Interventions for Children With CHD

This scoping review highlights the potential of educational interventions to significantly improve chronic care management for children with CHD and their families, aligning with previous findings [10-13,40-45]. Existing research indicates that well-informed pediatric patients can delay or prevent secondary illnesses, enhance their quality of life, and reduce health care costs [46-50]. However, many children with chronic conditions lack sufficient understanding of their illnesses, leading to confusion, anxiety, and other complications [51-54]. One contributing factor is the reliance on parents by health care providers to educate their children, assuming effective transmission of information [55,56]. Additionally, the development of interventions has mostly neglected children's perspectives, focusing primarily on feedback from health care providers and parents. Younger children face barriers to participation due to limited attention spans, difficulty understanding abstract concepts, and challenges in expressing their needs [57,58]. As a result, interventions typically depend on parental feedback as a proxy for testing and design insights [59].

The review also found that educational materials were predominantly designed for teenagers or parental caregivers, lacking age-appropriate and engaging solutions for children younger than 13 years of age. Among the 11 studies reviewed, only 3 [27,31,33] exclusively targeted children, focusing on those aged 13 years and older, likely due to usability challenges for younger children [58,60-62]. This is the case despite the review's specific focus on educational interventions for children with CHD. The concept that "children are not small adults" is widely acknowledged in pediatric care. It emphasizes that children represent a unique population with their own culture, norms, and complexities [63-65]. This understanding underscores the necessity for developing more inclusive and age-appropriate educational interventions for younger children with CHD.

Limited Engaging Strategies

Among the reviewed studies, 3D modeling emerged as a prominent strategy for educating pediatric patients and their families about CHD [28,33,37]. This approach offers engaging learning and improves communication between families and health care providers. However, despite its interactivity, 3D modeling and the other 5 strategies examined in this review lack engaging, playful interactions. Earlier educational tools, such as videotape presentations featuring friendly and playful characters like a fictional lion, effectively engaged young patients by making complex medical procedures more understandable and less intimidating through storytelling [35].

Playful strategies naturally engage children and facilitate learning through play. By communicating complex health information in an age-appropriate and engaging manner, they make a painful and tedious subject more approachable. In the 1920s, nurses Nightingale and Erikson first recognized the importance of systematizing play sessions to improve children's hospitalization experience and adherence to medical procedures [66-73]. Since then, strategies like pretend play [74,75] and serious games [76,77] have been used for chronic care management, educating children about their conditions, and helping them manage their fears. However, these strategies are rarely used for children with CHD. The evolution of educational interventions from videotape presentations in 1982 to patient-specific 3D printing indicates significant technological advancements. Integrating engaging and playful approaches into current interventions could substantially boost their effectiveness by involving children directly in their health care journey through their own language: play.

XSL•FO
RenderX

Enhancing Methodological Approaches

The majority of the reviewed studies used RCTs [27-32,34-36], reflecting robust methodologies for evaluating educational interventions for children with CHD. However, except for 1 [33], many studies primarily assessed parental outcomes as proxies without adequately evaluating specific outcomes for pediatric patients themselves [28-30,32,34-37]. This highlights a gap in HL measures tailored for children with CHD. While parental involvement is essential, directly assessing children's HL, coping mechanisms, and overall well-being is equally vital.

One notable strength of these studies was the involvement of various stakeholders in intervention delivery, including pediatric patients, parents or caregivers, and health care providers. Eight studies involved all stakeholders, ensuring a comprehensive approach [27,29-32,35-37]. Nevertheless, there is a need for more extensive engagement, particularly with pediatric patients, throughout the intervention's ideation, design, and implementation phases. Early involvement of stakeholders, including children as design partners, enhances the integration of interventions into routine care, ensuring practicality, feasibility, and alignment with clinical needs [58,78-82].

While most studies used questionnaires supplemented by qualitative feedback, there is a major focus on quantitative approaches. Incorporating more qualitative studies in the initial stages could help identify challenges, barriers, and desires more effectively. Unlike quantitative methods, qualitative methods aim to explore, narrate, and explain phenomena, making sense of complex realities. Health interventions could develop as an outcome of qualitative research [83,84]. Statistical analyses were diverse, with the independent samples *t* test being the most commonly used method, typically involving defined objectives and pre- and postassessment measures. Despite the rigorous methodologies, there was a lack of long-term longitudinal studies to assess the sustained effectiveness of the interventions [85]. Most studies had follow-up periods ranging from 1 month to 1 year, with only 1 study extending to 24 months [30]. This highlights the need for future research to include extended follow-up periods to understand the long-term impact of educational interventions on children with CHD and their families.

By addressing these methodological gaps and expanding stakeholder engagement, particularly with pediatric patients, we can enhance the effectiveness of health educational interventions. Designers, health care providers, and policymakers should prioritize developing and implementing solutions with all stakeholders, not just for them. This collaborative approach can enhance care quality, coordination, and outcomes for children, families, and health care providers.

One effective strategy is to integrate engaging learning tools—both digital and physical—through play. For example, a playful, educational toy similar to Rufus the Bear with Diabetes (Empath Labs), used in diabetes education, can help children manage their health. A comparable toy featuring a simplified heart model allows children to explore their anatomy and medical routines through hands-on play, making complex concepts more accessible. Designed to meet developmental needs, these tools can reduce anxiety, foster independence, and help children manage fears through pretend play. By prioritizing children's needs rather than relying on parents to convey information, we ensure that health information remains relatable and engaging. Ultimately, these child-led strategies empower families to build the knowledge and resilience necessary for effectively managing CHD. Such efforts could improve health outcomes during the transition to adulthood, enhance autonomy in managing CHD, and streamline education and health care delivery.

Limitations

This scoping review has offered valuable insights but has limitations. First, the search was limited to English-language publications, which may have excluded relevant studies published in other languages. Second, despite efforts to conduct a comprehensive search, it is possible that some relevant studies were missed, thus introducing selection bias. Finally, the inclusion criteria were restricted to published peer-reviewed studies, which means that relevant gray literature and unpublished studies were excluded, introducing publication bias. It is essential to consider these limitations while interpreting the findings of this scoping review. Additionally, the limited number of studies meeting the inclusion criteria highlights the scarcity of research that focuses specifically on educational interventions for children with CHD. Moreover, the variability in study designs, intervention types, outcome measures, and follow-up periods across the included studies has limited the ability to conduct a meta-analysis and draw definitive conclusions about the effectiveness of educational interventions for children with CHD.

Research Directions

Educational interventions have shown promise in enhancing the quality of life, self-management skills, and knowledge of children with CHD and their families. However, there is a pressing need for further research to develop and evaluate HL-focused pediatric care interventions tailored specifically for patients with CHD younger than 13 years of age. Drawing from successful interventions in this review, such as the approach by Uzark et al [35] that engaged both pediatric patients and parents to enhance understanding and coping during hospitalization, offers a promising framework for younger children with CHD. This playful approach significantly improved HL, empowerment, and self-management skills. While this study focused exclusively on children with CHD and health educational interventions, future research could draw insights from playful interventions designed for other pediatric conditions like cystic fibrosis and diabetes. As part of our multiphase research project, this comparative approach will inform the iterative development of our health education intervention for younger children with CHD and their families.

Additionally, since no studies included in this review used qualitative approaches such as co-design, our research would prioritize integrating such methodologies to involve all stakeholders, including children, early on. This would enhance the relevance and effectiveness of the interventions. Acknowledging challenges and working with all stakeholders toward finding solutions is essential, as simply ignoring the problem will not lead to progress. Involving children as design

XSL•FO
RenderX

partners, despite all the barriers, can ensure that the interventions are engaging, relevant, and effective in meeting the unique needs of children with CHD.

Conclusions

Educational interventions promise to enhance the quality of life, self-management skills, and knowledge of children with CHD and their families. However, insufficient evidence to support educational interventions for this pediatric population highlights a significant gap in the literature. While this scoping review aimed to identify these gaps, the scarcity of evidence highlights the need for further research. Advocating for such research is crucial to guide designers, health care providers, and policymakers in delivering effective interventions tailored to the specific needs of children with CHD. There is a clear need for more research explicitly addressing pediatric care interventions for children with CHD, focusing on developing age-appropriate, engaging, and engaging educational interventions. Improving HL in pediatric patients can reduce parental educational burden and increase health care provider efficiency by improving communication and patient empowerment.
