Our trial recorded a very high attendance rate (~95% of sessions attended) for parents randomized to REDCHiP and ATTN. We think the telehealth format of our treatments was likely the main contributor to our high session attendance. Parents could participate from home, thereby eliminating typical barriers to traditional, in-person behavioral health sessions (eg, transportation, childcare, and time off from work) [19,21,22]. However, it is possible another contributor to our high attendance rate may be parents' keen interest in receiving support for the emotional and behavioral challenges of managing T1D in their young child. Indeed, our telehealth format allowed us to recruit nationally, potentially reaching families who may not have access to behavioral health care through their local diabetes center [40]. Thus, it appears REDCHiP's telehealth format helped enhance feasibility and engagement in this trial and may provide preliminary evidence to support its broader dissemination and integration into pediatric diabetes care through existing telehealth infrastructure.

Though we did not find support for our main hypothesis, our trial builds on previous research that suggests that parents of young children with T1D may be particularly vulnerable to FH [3,6]. Parents in this trial reported baseline levels of FH that were comparable to levels reported in published studies [6]. We think this is notable in the context of our sample's high rate of personal CGM (151/183, 83%) and automated insulin delivery (AID; 93/183, 51%) use. Within the larger literature, the results are mixed as to whether CGM and AID use are associated with lower FH in parents of young children [11,41-43]. Thus, our data may further support the notion that some parents require treatment specifically focused on their fear to experience any improvements [36]. We also think it is notable that REDCHiP parents experienced an absolute mean reduction in FH (−8.22)

XSL•FO
RenderX

that was comparable to our previous REDCHiP pilot trial (−9.02) [12]. This may suggest that REDCHiP is still an effective treatment in helping parents to learn the skills to manage FH, even though the reduction was only slightly and non-significantly greater than among ATTN parents.

Our trial examined reductions in parents' diabetes distress using 2 approaches, as a continuous variable and as a dichotomous variable based on clinically elevated versus nonelevated diabetes distress. We examined distress as a continuous variable to provide a precise estimate of treatment effects and calculate effect sizes. We conducted a sensitivity analysis using the dichotomous measure to assess clinical significance, whether parents moved from elevated to nonelevated distress, a threshold clinics would likely use to guide referral and treatment decisions. Results suggested that REDCHiP had a small effect on parents' diabetes distress when analyzed continuously, with an absolute mean reduction (−12.88) comparable to our pilot trial (−11.11) [12]. This suggests REDCHiP helped parents manage diabetes distress, even if the treatment-specific effect was attenuated by the ATTN group. However, when analyzed dichotomously, exposure to REDCHiP was associated with a lower occurrence of elevated distress over time compared to ATTN, suggesting REDCHiP may help parents achieve clinically meaningful reductions in diabetes distress. This finding may be particularly relevant for clinical practice.

It is important to recognize the impact of a parent report of elevated depressive symptoms on FH and diabetes distress. At every assessment point and regardless of treatment group, parents with elevated depressive symptoms reported significantly higher FH and diabetes distress than parents without depressive symptoms. Unfortunately, we conducted this trial during the COVID-19 pandemic, a time when depressive symptoms were on the rise and parents of children vulnerable to COVID-19 were more likely to report depressive symptoms than adults prepandemic [44]. While not formally recorded, many parents in our trial described limiting social behaviors or not enrolling children in childcare or preschool. Many parents reported challenges in balancing working from home with parenting secondary to the COVID-19 pandemic. Moreover, some parents described additional concerns specific to COVID-19 and its potential added risk in youth with chronic illness. In our earlier REDCHiP pilot, we did not observe a change in parents' depressive symptoms after exposure to the intervention [12]. We believe this may be because REDCHiP focuses specifically on changing parents' unhelpful thoughts and behaviors related to fear. Nevertheless, the data from this trial suggest that parents with elevated depressive symptoms may require a different treatment approach. Therefore, a future direction could be to adapt REDCHiP to incorporate strategies specifically targeting depressive symptoms, such as behavioral activation [45], to better support parents experiencing depressive symptoms and FH.

While our trial demonstrated a small but nonsignificant reduction in child HbA_{1c} related to parent exposure to either REDCHiP or ATTN, this outcome may be expected. In our REDCHiP pilot, we only observed a small change in HbA_{1c} among young children who started the trial with an HbA_{1c} that was above the clinical target [12]. In the current sample, nearly one-third of young children had a baseline HbA_{1c} <7%. This suggests the possibility that we may have encountered a floor effect; there was simply not enough variability in young children's HbA_{1c} to detect a meaningful change. In the future, it may be helpful to use young children's CGM data to explore any glycemic changes related to their parents' exposure to REDCHiP or stratify enrollment by baseline child HbA_{1c} to better detect glycemic effects.

Limitations

Our use of a large national sample may enhance the generalizability of our results, though as a limitation we acknowledge that our sample was majority non-Hispanic White and that future research should explore the efficacy of REDCHiP in a more racially and ethnically diverse sample. Related, we acknowledge a limitation in that our trial primarily recruited mothers versus fathers and other caregivers. Because less is known about FH in fathers and other caregivers of young children with T1D [4], it is important that future research explore these other caregivers' experience with FH and response to treatment. We acknowledge a limitation in that we did not restrict our sample to only include families of children with an above-target HbA_{1c}. We made this decision based on past data showing moderately high levels of FH even among parents of young children with an HbA_{1c} at or below their target [6]. Nonetheless, to see any child glycemic effects related to parents' exposure to REDCHiP, it may be important for future trials to limit enrollment to families of young children with an above-target HbA_{1c}. Because this trial included multiple outcomes and 1-sided *P* values without adjustment for multiplicity, we acknowledge the risk of type 1 error. We made these analytic decisions to prioritize clinical relevance and to explore treatment effects in this Phase 2b trial. Nevertheless, future studies should confirm these findings using more conservative approaches. As important strengths of the trial, we highlight the high rate of CGM and AID use among young children, our use of a central laboratory to analyze children's HbA_{1c}, our acceptable retention rate, our high attendance rate (~95% of sessions), our relatively low rate of data missingness (<10%) [46], and our rigorous trial design that included an attention control condition [38] and an assessment of treatment fidelity.

Conclusions

In summary, even with uptake of CGM and AID in young children with T1D, some parents continue to experience FH and diabetes distress and may require specialized treatment. REDCHiP is a telehealth-delivered intervention to reduce FH in parents of young children with T1D. Though our trial shows treatment-slope effects that only slightly and nonsignificantly favored REDCHiP parents with respect to FH and diabetes distress, we remain optimistic with respect to REDCHiP's potential treatment impact. We found that parents' exposure to REDCHiP was associated with a lower occurrence of elevated diabetes distress over time than ATTN. Also, we observed that parents exposed to REDCHiP reported high treatment satisfaction. REDCHiP aligns with broader trends in pediatric

XSL•FO
RenderX

digital behavioral health with its remote delivery, personalization, and integration of evidence-based strategies from cognitive behavioral therapy and behavioral parent training into parents' daily T1D care [19]. Moreover, because of its telehealth format, it is possible REDCHiP could be integrated into pediatric diabetes care as a first-line treatment, leaving more intensive in-person treatment for families with more complex needs [40]. Future refinements and adaptations of REDCHiP will aim to increase its treatment effect, especially for parents experiencing comorbid depressive symptoms and young children with elevated HbA_{1c}. We also intend to explore ways to tailor REDCHiP for other caregiver populations, including fathers, grandparents, and teachers. Finally, future adaptations of REDCHiP will explore how to incorporate other digital health delivery methods, such as asynchronous content for self-paced learning and mobile app integration to track and reinforce skill learning to further promote its scalability and implementation.

Acknowledgments

We thank the families who participated in the trial. We also acknowledge the contributions of Ms Amy Milkes, Ms Emily Shaffer, Ms Bailey Tanner, Ms. Ashlee Ernst, Mr Andrew McConville, Dr Alexandra Monzon, Dr Paige Trojanowski, Dr Alicia Pardon, Dr Cheyenne Reynolds, and Dr Sara Wetter-Wren whose efforts made the trial possible.

Funding

The trial was supported by a grant (PI: SRP) from the National Institutes of Health/National Institute of Diabetes and Digestive and Kidney Diseases (R01 DK118514).

Data Availability

Data supporting the findings of this trial are not publicly available due to participant privacy and institutional restrictions. Deidentified data may be made available upon reasonable request to the corresponding author, contingent on appropriate data use agreements and ethical approvals.

Authors' Contributions

Conceptualization: SRP
Formal analysis: DDW
Writing – original draft: SRP
Writing – review & editing: SRP, DDW, NK, HO, KD, MC

Conflicts of Interest

SRP reports receiving grants from the National Institutes of Health; honorarium from the American Diabetes Association; and serving on a Clinical Advisory Board for Glooko, Inc. MC is Chief Medical Officer of Glooko, Inc, and has received research support from Dexcom and Abbott Diabetes Care. HO is a consultant at Sanofi. All other authors declare no conflict of interest.

Abstract

Background: Caregivers of children with cerebral palsy (CP) encounter unique challenges that are not common in typical families. The distress of these families starts in the diagnosis period, which is marked by a "wait and see" approach, and continues because of the lack of a clear prognosis.

Objective: This study aimed to identify the level of perceived ease of care faced by families of children with CP in Kuwait and its effect on their satisfaction with daily activities.

Methods: This cross-sectional study recruited caregivers of children with CP aged 5 to 16 years. The Ease of Caregiving for Children (ECC) scale, the self-care domain of the Child Engagement in Daily Life Measure (CEDLM), and the Satisfaction with Daily Occupations (SDO) questionnaire were used.

Results: Fifty-three caregivers participated (mean age 39.77, SD 7.56 years; children's mean age 8.04, SD 2.57 years; Gross Motor Function Classification System: level I, n=18; level II, n=10; level III, n=13; level IV, n=5; and level V, n=7). ECC score was significantly correlated with SDO score (P=.03) and the participation score in the self-care scale of the CEDLM (P=.001).

Conclusions: Challenges of caring for a child with CP are positively correlated with caregivers' satisfaction with daily activities and the child's self-care abilities. Regular check-ins with caregivers and the establishment of support groups for caregivers would help with providing help sooner. Qualitative assessment is needed to explore these challenges in this region.

KEYWORDS

cerebral palsy; caregivers; self-care; satisfaction

Introduction

Cerebral palsy (CP) is a group of permanent, nonprogressive disorders that affect the infant and fetal brain, hindering the development of movement and posture [1,2]. Children with CP may experience impairments such as sensory disturbances, cognitive disabilities, communication limitations, behavioral disorders, epilepsy, and secondary musculoskeletal problems [2,3]. Other comorbidities reported in children with CP include pain, bladder control problems, blindness, sleep disorders, and hip displacement [3,4].

Caregivers of children with CP encounter unique challenges that are not commonly seen among caregivers in typical families. The distress of these families starts with the diagnosis period, which is marked by a "wait and see" approach, and continues because of the lack of a clear prognosis [4,5]. The exploratory journey that is required to discover the type of comorbidities children with CP exhibit is another demanding task for caregivers [6]. Later on, caregivers of children with CP are confronted by the constant challenges displayed by their child and the ever-present need to engage in problem-solving [2,4,6]. Families of children with CP also express concern about the transition to adolescence and, later, adulthood for these children and the level of independence they can achieve [7]. This roller coaster takes a toll on caregivers of children with CP as individuals and on the family unit as a whole [8-10]. In a recent systematic review exploring the lived experience of caregivers, the burden of caring for a child with CP was positively correlated with feelings of depression [8]. Other factors that were associated with increased caregiver burden in this group were self-efficacy and anxiety among caregivers [11,12]. Interestingly, despite the degree of depression and anxiety leading to burden, feelings of resilience have also been explored and were found to be moderately negatively correlated with caregiver burden [10].

Literature exploring burden has primarily highlighted the impact of caregiver-related factors on caregiver burden but has rarely included child-related factors (eg, child functional level or cognitive level) [8]. It is therefore imperative to include the child's behavior, family function, and caregiving demand when exploring caregiver burden, given that they have been noted to be key predictors for caregivers' well-being [13,14].

Despite the abundance of current literature that has greatly contributed to our understanding of the dynamics of the burden experienced by caregivers of children with CP, most of these studies have been conducted in high-income countries (ie,

XSL•FO
RenderX

Canada, South Korea, and Spain). Although Kuwait is a high-income country, the information available in the literature on caregivers' burden in Kuwait is scarce. Cultural differences in the region call for the need to explore these variables. Examining these variables (ie, caregiver burden) would allow for better tailoring of interventions to meet the needs of families with children with CP. Kuwait, similar to its surrounding region in the Arabian Peninsula (ie, Kingdom of Saudi Arabia and United Arab Emirates), has a cultural structure that is very different from that of the Western world. The family-centered culture and the availability of hired, live-in domestic caretakers [15] present a distinctive combination of advantages and disadvantages, which merits further exploration.

This study aimed to identify (1) the level of perceived ease of care faced by families of children with CP aged 5 to 16 years in Kuwait, (2) the child factors (demographics and level of independence) that influence this perceived level of burden, and (3) the relationship between the perceived level of burden and Satisfaction With Daily Occupations (SDO) score among caregivers of children with CP in Kuwait. The age range was chosen based on the cutoff used for children with CP in pediatric rehabilitation departments in Kuwait.

Methods

Ethical Considerations

This project was approved by the ethics committee at the Ministry of Health in Kuwait (2021/1865). The study adhered to the Declaration of Helsinki. Electronically signed informed consent forms were obtained from all participants.

Design

This cross-sectional study used a web-based questionnaire to assess the level of perceived ease of care faced by families of children with CP aged 5 to 16 years. Inclusion criteria were (1) being a caregiver of at least one child aged 5 to 16 years with a documented diagnosis of CP, (2) residing in and receiving care in Kuwait (ie, working or studying), and (3) being able to communicate effectively (ie, read and write) in either Arabic or English. A purposive nonprobability sampling method was used to recruit participants. Study flyers were distributed in waiting rooms of rehabilitation clinics throughout Kuwait to inform parents of children with CP about the study. Interested parents contacted the research team. After screening for the inclusion and exclusion criteria, parents were sent an electronic form to complete.

Procedure

Health care professionals in rehabilitation clinics around Kuwait working with developmental disorders were contacted by the research team and asked to inform their clients about the study using the study flyer. Participants who agreed to take part in the study were screened for the inclusion and exclusion criteria, then sent a link to the web-based form. Participants were asked to complete an electronic form about the demographics of the caregivers and the child with CP for whom they were providing care. Caregiver-related variables included age, gender, educational level, marital status, working hours, and the number of other caregivers. Child-related variables included age, gender, topographic type, Gross Motor Function Classification System (GMFCS) level, hand function (ie, independent, partially dependent, or totally dependent), height and weight, and schooling situation. Next, participants scored their experience using (1) the Ease of Caregiving for Children (ECC) measure, (2) participation in the self-care domain of the Child Engagement in Daily Life Measure (CEDLM), and (3) the SDO measure. The language in which each of the tools was presented was based on the participant's preferences.

Instruments

ECC is a self-reported tool developed to examine the physical demands of caring for a child with CP [16]. Caregivers were asked to rate their perceived level of physical demands associated with caring for children using 12 items relating to mobility, positioning, and self-care. The level of demand was rated using a 5-point Likert scale (1="very difficult" to 5="no help is needed"). Higher scores (maximum 60) indicate greater ease of care perceived by the caregiver (ie, less burden of caregiving) [17]. Both English and Arabic versions were reliable (intraclass correlation coefficient [ICC] >0.69) and valid [17,18]. Cultural adaptation was established in Arabic [17].

The self-care domain of the CEDLM is an 18-item caregiver-reported measure that assesses the caregivers' perceptions of the child's level of independence with their self-care activities (eg, toileting, dressing, feeding, drinking, and grooming) [17]. The level of independence is rated using a 5-point Likert scale (1="does not do the activity" to 5="does the activity independently most of the time"). A high level of independence with self-care activities is indicated by a higher score (maximum 90) [17]. Both English and Arabic versions of the scale were reliable (ICC=0.96) and valid [17,19]. Cultural adaptation was established in Arabic [17].

The SDO is a self-reported tool that was used to assess caregivers' satisfaction with daily activities. This tool explores different daily activities where a higher score indicates a higher level of participation and satisfaction across the constructs of work (4 items), leisure (3 items), home management (4 items), and self-care (3 items) [20,21]. This 14-item tool examines level of performance (range 0 - 14) and the level of satisfaction (range 14 - 70) [20,21]. Reliability (ICC=0.93) and validity of both Arabic and English versions of the scale were established [20,21]. Cultural adaptation was established in Arabic [20].

Data Analysis

The data were analyzed using SPSS Statistics for Windows (version 27.0; IBM Corp). The statistical significance level was set at α=.05 and normality of all variables was explored using the Shapiro-Wilk test. Normally distributed variables were assessed using parametric tests, whereas variables that did not follow a normal distribution were assessed using nonparametric tests. Descriptive variables were expressed as mean and SD for continuous variables and as count (n) and percentage (%) for categorical variables. BMI was calculated and presented according to the classification presented by Hurvitz et al [22].

For both the ECC and self-care domain of the CEDLM, the scaled scores (using the conversion tables) [16] were calculated. The chi-square test was used to assess whether the prevalence

XSL•FO
RenderX

of the CP burden, the independence of the child, and the satisfaction of the caregiver differed across categories of sociodemographic factors. Because cutoff scores were not established for these questionnaires, a 50% cutoff was used for all the tools (scaled score of ECC ≤40=substantial burden; scaled score of CEDLM ≥50.2=independent child; score of SDO ≥56=satisfied with daily occupation). These suggested cutoffs were used to establish categorization for each tool and enhance interpretation of the tools. The established criteria enabled comparison between scales. Regarding the self-care domain of the CEDLM and ECC items, the independent 1-tailed *t* test, and Mann-Whitney *U* test were used to assess the difference in means across the questionnaire items. The relationship between the total score of each of the tools (ie, ECC, the self-care domain of the CEDLM, and SDO) was evaluated using Pearson correlation coefficients.

Results

A total of 53 caregivers (n=40, 75.5% female) participated in this study with a mean age of 39.77 (SD 7.56) years (Table 1). The mean age of the children with CP was 8.04 (SD 2.75) years (GMFCS: 1: level I, n=18; level II, n=10; level III, n=13; level IV, n=5; and level V, n=7).; Table 2). All participants chose to use the Arabic forms of the assessment tools.

[b]*P* values calculated using the chi-square test.

The ECC mean raw score for all caregivers was 38.17 (SD 11.62; 95% CI 34.97 - 41.37) and the mean scaled score was 48.78 (SD 16.18; 95% CI 44.33 - 53.25), which showed that the entire sample had some degree of perceived burden. With further analysis using suggested cutoff scores (scaled score ≤40=substantial burden), 32.1% (17/53) of caregivers scored as having a significant perceived burden (Table 1). Two demographic factors were correlated with higher levels of perceived burden, the child's functional level with hands (*P*=.001) and the number of people involved in childcare (*P*=.03; Table 2). Cross-tabulation of the questions of the self-care domain of the CEDLM with ECC cutoff scores (significant burden vs insignificant burden) showed that all questions were negatively correlated (ie, children of caregivers with perceived significant burden were more dependent; Table 3).

The mean score for the self-care domain of the CEDLM was 48.60 (SD 23.09; 95% CI 42.24 - 54.97), whereas the scaled score for this tool was 43.60 (SD 23.53; 95% CI 35.81 - 48.79), which indicated that our sample scored near the lower end of the scale (Table 2). When suggested cutoff scores (scaled score ≥50.2=independent child) were used, the self-care domain of the CEDLM was positively correlated with the child's functional level with hands (P=.001) and school enrollment (P=.004). Cross-tabulation with the questions of the ECC and self-care domain of the CEDLM cutoff scores revealed that all the questions but one (ECC 7: "to put on or take off an orthosis or brace"; P=.23) were negatively correlated (ie, the caregivers of independent children had less perceived burden; Table 4).

Table . Ease of Caregiving for Children (ECC) items.

		Child Engagement in Daily Life Measure (self-care domain)			Satisfaction With Daily Occupations		
	Total sample, mean (SD)	Independent, mean (SD)	Dependent, mean (SD)	*P* value	Yes, mean (SD)	No, mean (SD)	*P* value
ECC 1: to move at home and in the community?	2.74 (1.14)	3.24 (1.23)	2.29 (0.85)	.002	3.25 (1.22)	2.59 (1.10)	.08
ECC 2: to position for sleeping?	3.42 (1.21)	3.96 (1.10)	2.93 (1.12)	.002	4.00 (1.28)	3.24 (1.6)	.04
ECC 3: to position for feeding?	3.47 (1.20)	3.96 (1.06)	3.04 (1.17)	.006	3.83 (1.27)	3.37 (1.18)	.18
ECC 4: to position for bathing?	2.83 (1.72)	3.40 (1.12)	2.32 (0.98)	.001	3.33 (1.16)	2.68 (1.15)	.07
ECC 5: to position for playing?	3.21 (1.41)	3.80 (1.29)	2.68 (1.34)	.004	4.08 (1.31)	2.95 (1.36)	.01
ECC 6: to put on or take off clothing?	2.98 (1.16)	3.40 (1.00)	2.61 (1.19)	.01	3.58 (1.08)	2.80 (1.15)	.05
ECC 7: to put on or take off an orthosis or brace?	2.81 (1.09)	3.00 (1.00)	2.64 (1.16)	.23	3.42 (1.17)	2.63 (1.02)	.03
ECC 8: to bathe, clean, and tidy?	2.85 (1.11)	3.20 (1.16)	2.54 (0.99)	.03	3.33 (0.99)	2.71 (1.12)	.07
ECC 9: to use the potty or toilet, or for you to change his or her diapers?	2.87 (1.27)	3.44 (1.16)	2.36 (1.16)	.002	3.83 (1.12)	2.59 (1.18)	.003
ECC 10: to eat?	4.04 (1.16)	4.40 (1.00)	3.71 (1.21)	.03	4.58 (0.90)	3.88 (1.19)	.06
ECC 11: to drink?	4.13 (1.11)	4.64 (0.70)	3.68 (1.22)	.003	4.58 (0.90)	4.00 (1.14)	.10
ECC 12: to get in and out of a car, van, or bus?	2.83 (1.22)	3.36 (1.19)	2.36 (1.06)	.003	3.33 (1.30)	2.68 (1.17)	.12
Total	—[a]	56.46 (17.28)	41.93 (11.64)	—	56.96 (12.88)	46.39 (16.40)	—

[a]Not applicable.

Finally, the mean satisfaction score for SDO was 9.49 (SD 2.87; 95% CI 8.70 - 10.28), indicating that the children participated in most daily occupations, and the mean satisfaction score with their activity level was 45.15 (SD 13.17; 95% CI 41.52 - 48.78), which showed that the participants were somewhat satisfied with their daily occupations. Further analysis with established cutoff scores of the SDO (score ≥56=satisfied with daily occupations) showed that economic security and living space were negatively correlated with their SDO scores (ie, perceived mediocre or poor economic security and living in an apartment were linked with low SDO score; Table 1). Cross-tabulation with the questions of the ECC and SDO cutoff scores showed that some of the questions (questions 2, 5 - 7, and 9) were negatively correlated with the perceived ease of care reported by the caregivers (ie, caregivers who had higher SDO scores had a perception of less caregiving burden; ECC 2: to position for sleeping; P=.04; ECC 5: to position for playing; P=.01; ECC 6: to put on or take off clothing; P=.05; ECC 7: to put on or take off an orthosis or brace; P=.03; ECC 9: to use the potty or toilet, or for you to change his or her diapers; P=.003; Table 4).

XSL•FO
RenderX

ECC scaled scores were positively correlated with the self-care domain of the CEDLM (r=0.64; P<.001) and the SDO (r=0.29; P=.03; Table 5). On the other hand, the self-care domain of the CEDLM was not correlated with the SDO score.

Table . Correlations among tools.

Comparison	Pearson coefficient (r)	P value
ECC[a] vs self-care domain of CEDLM[b]	0.641	.001[c]
ECC vs SDO[d]	0.298	.03[e]
Self-care domain of CEDLM vs SDO	0.195	.16

[a]ECC: Ease of Caregiving for Children.

[b]CEDLM: Child Engagement in Daily Life Measure.

[c]Correlation is significant at the .01 level.

[d]SDO: Satisfaction With Daily Occupations.

[e]Correlation is significant at the .05 level.

Discussion

Principal Findings

To the best of our knowledge, this is the first study to explore the challenges faced by families of children aged 5 to 16 years with CP in Kuwait, including the perceived level of ease of care, caregivers' satisfaction with daily activities, and the associations of these outcomes with other possible factors. Analyses showed that caregivers of children with CP in Kuwait reported an average level of ease of care and an above-average satisfaction level with their performance of different life activities. The analyses also showed that the higher perceived ease of care was only associated with the child's hand functional level and the number of people involved in childcare. The level of perceived ease of care reported in the current study was similar to that reported by caregivers in different regions of the world (ie, Poland and Turkey) [9,23]. This demonstrated that despite cultural and socioeconomic differences, the burden of caring for a child with CP was comparable [4]. On the other hand, the number of people involved in childcare being a significant factor can provide insights into a unique element of the culture in Kuwait and the surrounding region, where extended family and domestic workers [24] are involved in childcare and can affect the level of burden of care. This is a testament to the "village" families create to care for their children, which shows resilience and the coping measures taken to help care for children with CP.

Additionally, around half of the samples in this study scored at levels I and II of the GMFCS, which represents a higher functional capacity of the child. Nevertheless, the self-care domain of the CEDLM was toward the lower end of the scale as a total score and for individual items in our sample. This could be caused by a lack of focus on building independence (ie, performing self-care activities), which would reduce the number of tasks falling under the caregiver's responsibility. Factors such as children's hand functional level, their self-care abilities, and the number of people involved in childcare were found in previous studies to be variables that decreased the perceived level of caregiver burden for children with CP [9,10,23].

Contrary to expectations, this study did not find any significant difference in caregivers' ease of care level according to the child's BMI or CP subtype, which does not align with findings presented in the literature [9,23]. This finding may be explained by the characteristics of the children with CP, the majority of whom were at GMFCS levels I to III (41/53, 77.4%) while previous research was conducted with children at higher GMFCS levels. Additionally, the dyskinetic type of CP (34/53, 64.2%) was the most common type in our study; therefore, a lack of heterogeneity in the types of CP may have contributed to the findings [9,23].

A distinctive parameter that this study investigated was caregiver satisfaction with their daily life activities, and the literature suggests that the level of burden impacts caregivers' quality of life [8,25]. Our findings demonstrated that caregivers were active participants in most of their children's daily activities and were somewhat satisfied with their daily occupations. The current investigation also found that the higher the perceived ease of care, the more satisfied the caregivers were. This might be explained by an indirect association between the extensive care required when having a child with CP and the perceived burden of care that could hinder caregivers from being active members of the community [10].

A qualitative study conducted among parents of children with CP in Saudi Arabia revealed that caregivers expressed being under stress and experiencing challenges in navigating health and educational services [26]. These parents also emphasized the role of Islamic values expressed through religious practices in helping them cope with stress and perceived burden. The Kuwaiti population shares similar values to the Saudi Arabian population. Although it produced different data from the current study, that work showed trends similar to those exhibited in our study. These findings showed the need for further exploration of the population in the Arabian Peninsula region.

Given the differences identified in the present study compared with the published literature on caregiver burden among this patient population, it could conceivably be suggested that caring for children with CP in Kuwait should not rely on Western evidence alone. In a recent systematic review on the epidemiology of CP in Arabic-speaking countries, no articles referencing this population were found in Kuwait [27]. Given

XSL•FO
RenderX

the scarcity of research in this region, normative data should be established for this population as it is crucial for different communities to understand their populations to tailor treatments to their communities' specific needs.

As is the case with every scientific endeavor, this study is not without its limitations. The main limitation is the small sample size recruited, which also limited further investigation of some possible related factors, such as lower GMFCS levels or different CP subtypes. The nature of the cross-sectional study design limits the establishment of causal relationships or changes over time. Another limitation is self-report bias, which limits the interpretation of the results. The recruitment of participants from rehabilitation clinics may have introduced selection bias, which could have excluded caregivers of children with a high functional level and children with a very low functional level. Future studies should focus on adapting these classification systems for Arabic-speaking individuals to enable the use of these tools for upcoming research studies on children with CP and their caregivers. Further exploration of the individuals involved in caring for children with CP is warranted in future studies, especially differentiating between hired help and family members.

Conclusions

CP is a lifelong health condition that requires special management and care throughout an individual's life, impacting not only the individual with CP but also their family and primary caregivers. Caregivers might experience high levels of burden due to their assigned responsibilities, which could affect their life satisfaction. The preliminary perceived level of burden among caregivers of children with CP in Kuwait was correlated with caregivers' daily activities satisfaction and the child's self-care abilities. The findings of this study can inform practice in Kuwait and guide research advances in the region to improve care for caregivers of children with CP. Regular check-ins with caregivers and the establishment of caregiver support groups would help provide support sooner. Future studies with larger sample sizes and across multiple lifelong conditions would provide a clearer picture. Mixed methods strategies are encouraged in future studies to identify other contributing factors that may be unique to the region.

Abstract

Background: Home monitoring has the potential to enable early detection of disease progression in pediatric lung diseases such as asthma and cystic fibrosis (CF). There is minimal evidence regarding the opinions of caregivers and children on home monitoring.

Objective: This study aimed to explore children's and caregivers' perspectives on home monitoring.

Methods: This multicenter, mixed methods study included children aged 6 to 18 years with asthma or CF and their caregivers. Participants were recruited from Juliana Children's Hospital and Erasmus MC Sophia Children's Hospital between September 2023 and June 2025. Participants completed a structured questionnaire assessing experiences, attitudes, and potential barriers and facilitators to home monitoring. Fourteen children and their caregivers took part in in-depth interviews. Conventional content analysis was applied to both open-text and interview data.

Results: A total of 113 caregiver-child dyads (62 [54.9%] asthma and 51 [45.1%] CF) participated in this study. Willingness to use home monitoring was high among both children (asthma: n=47, 83.9%; CF: n=30, 62.5%) and caregivers (asthma: n=54, 87.1%; CF: n=44, 86.3%). Children with asthma and their caregivers showed significantly greater willingness to use the proposed types of home monitoring than children with CF and their caregivers. Caregivers who expressed difficulty with symptom interpretation were significantly more motivated to use home monitoring. Key barriers included time demands, usability, device size, and concerns about maintaining personal contact with health care providers. Facilitators included compact, user-friendly devices, clear instructions, and improved disease understanding.

Conclusions: High willingness to adopt home monitoring was observed among children with asthma and children with CF, but preferences and perceived barriers differ. Tailoring device choice and implementation strategies to patient needs, minimizing burden, and integrating medical oversight are important for successful uptake.

Introduction

Asthma and cystic fibrosis (CF) are chronic diseases in the pediatric population, characterized by recurrent pulmonary exacerbations that may lead to hospital visits and admissions. These exacerbations are associated with a higher perceived disease burden, a decline in pulmonary function, and higher health care costs [1]. Effective control of asthma and CF is crucial for reducing the clinical burden and adverse outcomes associated with exacerbations. Ideally, it would be possible to predict pulmonary exacerbations to start treatment in a timely manner before symptoms have progressed. Remote health care, digital biomarkers, and home monitoring offer the potential to recognize exacerbations early, minimizing both acute complications and long-term damage while also reducing health care costs [2].

In the pediatric population, assessing disease activity and predicting exacerbations are especially challenging. Young children find it difficult to perceive and express their symptoms, causing difficulty in parental recognition of symptoms [3], which home monitoring may help alleviate [4-9]. Real-time data may be necessary to effectively monitor disease activity using objective measurements. Devices such as smartwatches, spirometers, and other home monitoring devices have been used previously. However, the compliance of patients significantly decreases when the duration and frequency of home monitoring assessments increase [10]. In contrast, evidence suggests that patient empowerment and patients' capacity to understand and interpret their health-related data facilitate sustained engagement with digital health tools [11]. Despite these findings, most studies on home monitoring primarily focus on clinically relevant outcomes, while the patient perspective, particularly the pediatric perspective, is underrepresented [12]. It is essential to understand children's and caregivers' views and motivations regarding home monitoring tools to successfully implement them. Therefore, this exploratory study aims to assess the perspectives of children and caregivers regarding home monitoring and to identify barriers and facilitators to its use and implementation. In addition, preferences for different home monitoring methods and devices are investigated, as well as the circumstances under which home monitoring would be considered acceptable.

Methods

Study Design

This study was conducted at Juliana Children's Hospital (Haga Teaching Hospital, The Hague, the Netherlands) and Erasmus MC Sophia Children's Hospital (Rotterdam, the Netherlands). Data were collected between September 2023 and June 2025.

Ethical Considerations

This study was submitted to the Medical Ethics Committee Leiden Delft Den Haag (Zuid-Holland, the Netherlands), which concluded that the study did not fall under the Dutch Medical Research Involving Human Subjects Act (Wet Medisch-Wetenschappelijk Onderzoek Met Mensen [WMO]). The study protocol was reviewed and approved by the institutional review board of the Haga Teaching Hospital (T23-050). Written informed consent was obtained from caregivers and children aged ≥12 years, while children aged <12 years provided verbal assent.

Recruitment

Participants were recruited from the outpatient clinics and inpatient wards to include children with different disease severities. Participants were informed about the study by their treating pediatrician. If they were interested in participating, the researcher subsequently provided further information about the study. Eligible participants were aged 6 to 18 years with a confirmed diagnosis of asthma (per Global Initiative for Asthma [GINA] guidelines) or CF (confirmed by genetic testing). The only exclusion criterion was insufficient proficiency in Dutch, based on the caregiver's indication that the child was able to understand the questionnaire independently. A formal power calculation was not performed due to the exploratory nature of the study. The target sample of 120 participants (60 with asthma and 60 with CF) was considered sufficient to allow meaningful subgroup comparisons and thematic saturation.

Study Procedures

This study followed a convergent mixed methods design, combining quantitative survey data and qualitative interviews to explore and contextualize participants' perspectives. The study was reported in accordance with the Good Reporting of A Mixed Methods Study (GRAMMS) recommendations (Multimedia Appendix 1) [13]. The mixed methods approach was used to quantify preferences regarding home monitoring while also exploring the underlying reasons, barriers, and facilitators that could not be fully captured through predefined questionnaire responses alone. Participants were asked to complete a structured questionnaire, developed for this study, assessing experiences and attitudes toward home monitoring. At the start of the study, participants were also invited to participate in a semistructured interview to explore these themes in greater depth after completing the questionnaire. Completing the questionnaire took approximately 30 minutes and consisted of 2 sections. One section was to be completed by the caregiver first, and subsequently, a shorter section was completed by the child. Questionnaires were administered using multiple methods to accommodate participant preferences: electronically or on paper. The digital questionnaire could also be completed at home; the paper questionnaire was completed in the hospital. Research staff were available for assistance.

Incomplete caregiver questionnaires were excluded from analysis at the case level. The first item of the pediatric questionnaire asked caregivers whether their child was able to understand and answer the questions independently. This was included to account for differences in age and level of comprehension among the participating children. Participants were not excluded based on this item because caregiver-reported data were available regardless of whether the child was able to complete the questionnaire.

Instruments

The questionnaire (Multimedia Appendix 2) was specifically developed for the purpose of this study and was not based on a

XSL•FO
RenderX

previously validated instrument. The questionnaire was reviewed and informally pretested by members of the research team, laypersons, children, parents, and medical specialists to assess the quality of the questions, ensuring they did not imply or use unclear terminology that could potentially influence the participants. On the basis of several rounds of feedback, the wording and structure of the questions were refined before study initiation.

Most questions had a 5-point Likert scale outcome or a yes or no outcome. All questions had a text box option to elaborate on the answers provided. The questionnaire consisted of 5 categories. The first category included demographic and clinical characteristics of the participants. The second category assessed whether caregivers had prior exposure to digital monitoring tools. The third category explored caregivers' attitudes toward various monitoring devices, including smartwatches, lung function meters, cough detectors, smart inhalers, air quality monitors, medication reminders, and symptom questionnaires. A smart inhaler is a small electronic device attached to an inhaler that automatically detects and time stamps inhaler use. These monitoring devices were selected based on previous literature [14-18]. The fourth category focused on the conditions under which caregivers would consider using such devices. The final category included open-ended questions about potential barriers and facilitators to the implementation of home monitoring systems.

The semistructured interviews addressed the themes mentioned in the questionnaire and were conducted by 1 researcher. The interviews were audio-recorded and transcribed verbatim by 2 researchers without the use of transcription software. Member checking was not performed. Data saturation was reached after 14 interviews.

Data Analysis

All analyses were performed using RStudio (version 4.4.2; R Foundation for Statistical Computing). Participant characteristics were analyzed descriptively. To summarize participants' overall attitude toward home monitoring, a cumulative device score was calculated. For each proposed monitoring modality, willingness to use the device was scored as +1, unwillingness as –1, and a neutral or "no opinion" response as 0. Neutral and "no opinion" responses were both assigned a value of 0 because neither reflects a definitive driver of, nor a barrier to, device adoption. All modalities were weighted equally to capture broad technological acceptance, rather than being weighted by patient burden or clinical utility, which was beyond the scope of this exploratory measure. A score of –7 means that a participant had a negative attitude toward every type of device, and a score of +7 means that a participant had a positive attitude toward all devices. The children with CF and their caregivers could reach a maximum of 6 points, as most children with CF did not use inhalers. No normalization of the cumulative device score was performed.

Normally distributed variables are reported as mean (SD), and nonnormally distributed variables are reported as median (IQR). Categorical variables were summarized as absolute numbers and percentages. Comparative analyses were performed to assess differences between the asthma and CF groups. Likert scale questions were analyzed using the Mann-Whitney *U* test. Categorical variables were compared between the asthma and CF groups using the chi-square test. Associations between ranked variables were evaluated with the Spearman rank correlation coefficient. A 2-sided $P<.05$ was considered statistically significant. As this was an exploratory study, no correction for multiple testing was applied.

Qualitative open-text responses and interview transcripts were analyzed using conventional content analysis to identify key barriers and facilitators to home monitoring adoption [19]. The data were coded inductively without the use of a predefined coding framework. As new concepts emerged from the data, new descriptive codes were created, and similar codes were grouped into broader categories representing the main barriers and facilitators. For both data sources, 1 researcher performed the initial analysis, and a second researcher subsequently reviewed the data, coding, and resulting interpretation. The final coding framework and categories were then discussed within the research team and refined where appropriate.

Quantitative and qualitative data were analyzed separately and integrated during the interpretation of the findings, in accordance with the convergent mixed methods design. The quantitative questionnaire data were used to identify general patterns in participants' responses regarding home monitoring, while the qualitative data from open-text responses and interviews were used to provide context and explain the reasons underlying these response patterns.

Results

Participant Characteristics

Of the 131 parent-child dyads who provided informed consent, 113 parent-child dyads (Juliana Children's Hospital: n=86, 76.1%; Sophia Children's Hospital: n=27, 23.9%) completed the questionnaire. One parent-child dyad was excluded from the analysis because the caregiver questionnaire was incomplete. Seventeen dyads did not return the questionnaire. These children were all diagnosed with asthma, had a median age of 13.0 (IQR 10-15) years, and had been approached during an outpatient clinic visit. No further clinical information or information on the reasons for noncompletion was available. Of the 113 children with completed questionnaire data, 54.9% (n=62) were diagnosed with asthma, and 45.1% (n=51) were diagnosed with CF. A total of 9 children (n=6 with asthma and n=3 with CF) did not complete the pediatric part of the questionnaire due to an inability to understand the questions. The mean pediatric age was 10.5 (SD 3.2) years in the asthma group and 12.7 (SD 3.6) years in the CF group. A total of 23 (20.4%) caregivers described the disease burden of their child as very or somewhat heavy.

Of the 113 caregivers, 46 (40.7%) reported lung complaints as the most burdensome aspect of their child's disease, while 39 (34.5%) caregivers indicated that daily medication caused the greatest disease burden. Caregivers of children with asthma more frequently attributed the disease burden to lung complaints than did caregivers of children with CF (n=38, 61.3% vs n=8, 15.7%; $\chi^2_1=22.3$; $P<.001$). In contrast, caregivers of children

XSL•FO
RenderX

with CF more often identified daily medication use as the main contributor to disease burden than caregivers of children with asthma (n=24, 47.1% vs n=14, 22.6%; χ^2_1=6.5; *P*=.01). Additional participant characteristics are presented in Table 1.

Table 1. Participant characteristics (N=113).

Characteristics	Total participants	Participants with asthma (n=62)	Participants with cystic fibrosis (n=51)
Age (years), median (IQR)	11 (8.0-14.0)	10 (8.0-12.8)	13 (10.0-16.0)

Home Monitoring Experience

A total of 42 (37.2%) caregivers reported that their child had used home monitoring previously (n=18, 29% caregivers of children with asthma vs n=24, 47.1% caregivers of children with CF; χ^2_1=3.2; *P*=.08). Among children with CF, the most commonly used device was a handheld spirometer, which was reported for 20 (39.2%) children. Among children with asthma, pulse oximeters were most commonly reported (n=13, 21%). According to caregivers, most children (n=30, 71.4%) primarily used home monitoring devices during symptomatic episodes rather than incorporating them into a routine for regular monitoring. Caregivers stated that reasons for discontinuing home monitoring included unreliable measurements, perceived lack of necessity, and the added uncertainty it caused. One caregiver of a child with CF stated, “it was useful in the past, it is not necessary anymore with the new medication,” indicating the availability of newer CF transmembrane conductance regulator (CFTR)–modulating therapies.

Willingness to Use Home Monitoring

Most caregivers (98/113, 86.7%) expressed willingness to use home monitoring. About 77% (n=87) of caregivers would use home monitoring if it resulted in fewer outpatient visits. Of the 113 caregivers, 99 (87.6%) would use home monitoring if it led to fewer admissions, while 96.5% (n=109) would use it if it led to less lung damage. Summarized responses are displayed in Table 2. There were no associations between the age of the participants, diagnosis, use of home monitoring in the past, or perceived disease severity and the willingness of caregivers to use home monitoring (Multimedia Appendix 3).

XSL•FO
RenderX

Of all children, 74% (77/104) indicated willingness to use home monitoring in general. Children with asthma were significantly more willing (Likert scale score: median 2.0, IQR 1.0-2.0) than those with CF (Likert scale score: median 2.0, IQR 2.0-3.0; Mann-Whitney *U* test, *P*<.001). Age did not influence children's willingness to use home monitoring (Multimedia Appendix 3).

Table 2. Willingness to use home monitoring.

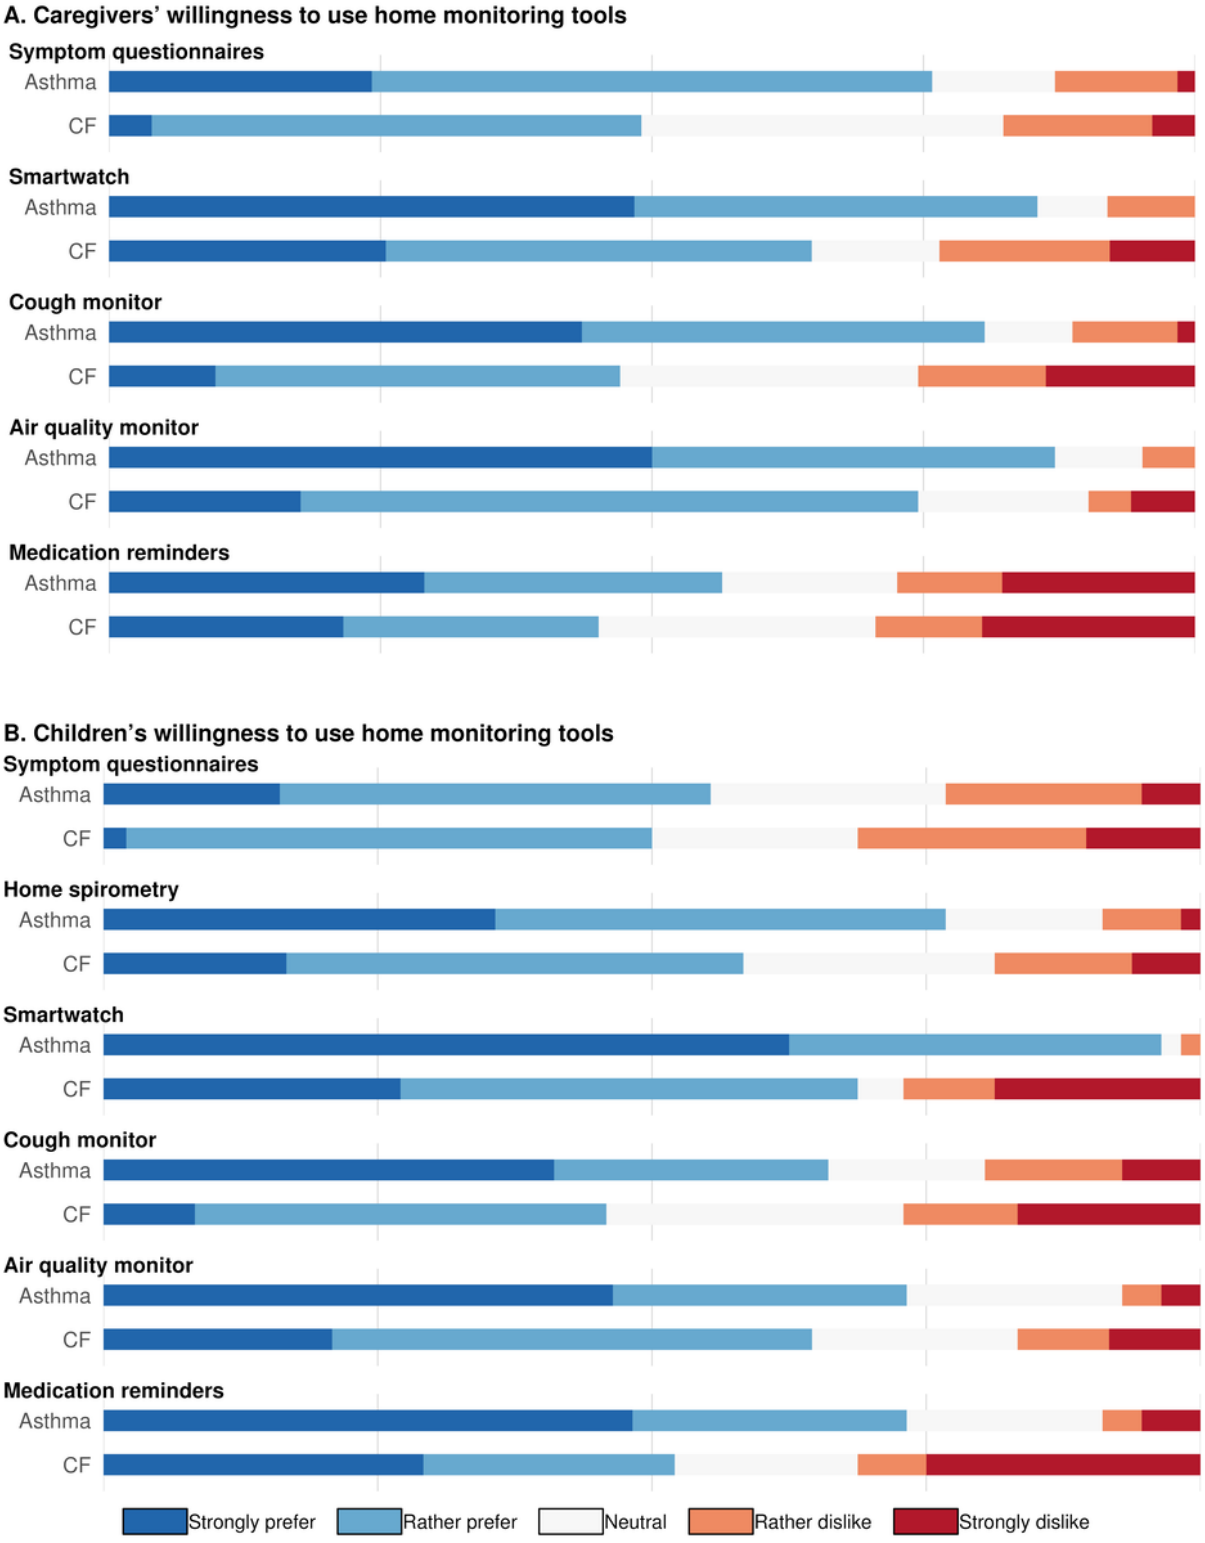
Willingness to use home monitoring	Participants with asthma, n (%)	Participants with cystic fibrosis, n (%)	*P* value
Caregivers' perspective[a]			
If it was available	54 (87.1)	44 (86.3)	.99
If it resulted in fewer outpatient visits	48 (77.4)	39 (76.5)	.99
If it resulted in a telephonic consultation instead of an outpatient visit	50 (80.6)	36 (70.6)	.30
If it led to fewer hospital admissions	55 (88.7)	44 (86.3)	.92
If it led to a decrease in long-term lung damage	60 (96.8)	49 (96.1)	.99
Children's perspective[b]			
If it was available	47 (83.9)	30 (62.5)	<.001[c]
If it resulted in fewer outpatient visits	45 (80.4)	36 (75)	.36
If it led to fewer hospital admissions	54 (96.4)	46 (95.8)	.99

[a]Caregiver responses were based on 62 participants with asthma and 51 participants with cystic fibrosis. The questions required yes or no responses. Differences were assessed using the chi-square test.

[b]Child responses were based on 56 participants with asthma and 48 participants with cystic fibrosis. The questions used a 5-point Likert scale, and participants were considered willing if they selected "I would like to use" or "I would be fine to use." Differences were assessed using the Mann-Whitney *U* test.

[c]*P*<.05 was considered statistically significant.

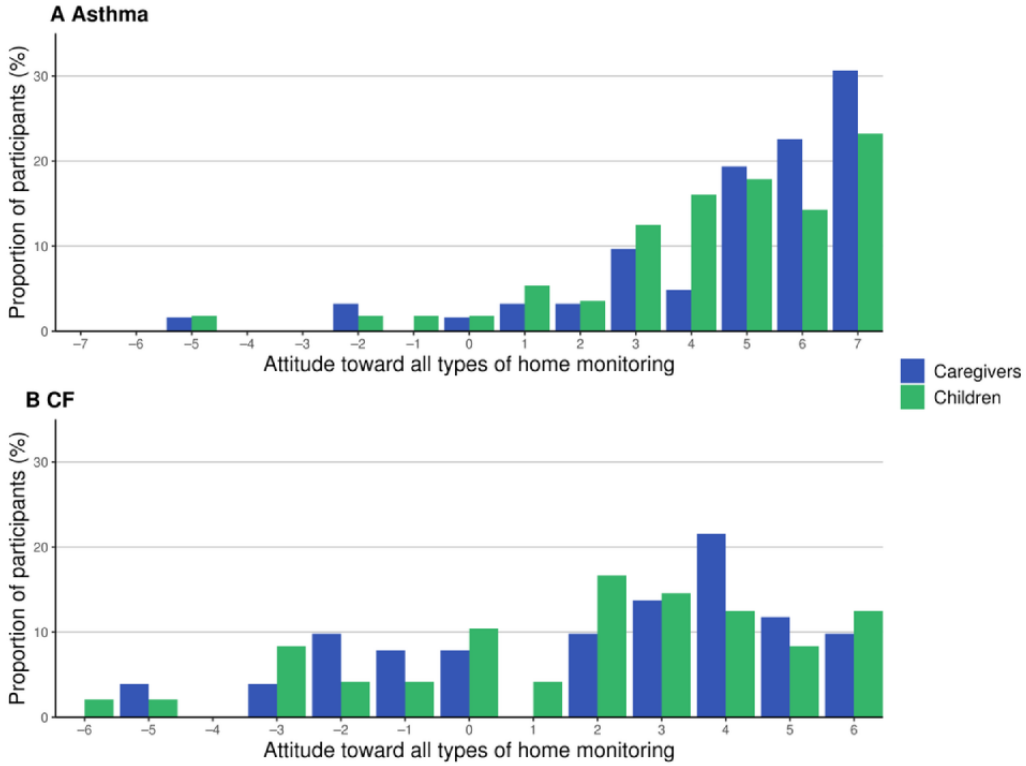
Home Monitoring Tools



Figures 1A and 1B present caregivers' and children's willingness to use different home monitoring devices, respectively. Overall, caregivers' willingness was highest for air quality meters (91/113, 80.5%), followed by daytime smartwatches (86/113, 76.1%), nighttime smartwatches (83/113, 73.5%), cough monitors (74/113, 65.5%), symptom questionnaires (72/113, 63.7%), and medication reminders (59/113, 52.2%). A total of 61 (98.4%) caregivers of the children with asthma would use an additional meter on the inhaler. Overall, children showed the greatest willingness to use a smartwatch during the daytime (87/104, 83.6%), whereas symptom questionnaires were the least preferred option (55/104, 52.8%). Acceptance of the other monitoring devices included a nighttime smartwatch (76/104, 73.1%), a spirometer (71/104, 68.2%), a cough monitor (68/104, 65.4%), an air quality meter (66/104, 63.5%), and medication reminders (65/104, 62.5%). The additional meter on the inhaler was acceptable for 78.6% (44/56) of children with asthma.

Among both children and caregivers, all devices were significantly more often preferred by participants with asthma, except for symptom questionnaires in the pediatric population and medication reminders in the caregiver population (Multimedia Appendix 4). Previous use of home spirometry in the pediatric population was not associated with willingness to use a spirometer in this questionnaire (Likert scale score median 2.0, IQR 2.0-3.0 vs median 2.0, IQR 1.0-3.0; Mann-Whitney *U* test, *P*=.50).

To summarize caregivers' and children's overall attitudes across the different home monitoring modalities, a cumulative device score was calculated and displayed in Figures 2A (asthma) and 2B (CF). Higher scores represent greater overall willingness to use the proposed home monitoring modalities. A higher subjective disease burden was significantly associated with a higher cumulative device score in both asthma caregivers (Spearman rank correlation coefficient ρ=0.29; *P*=.02) and CF caregivers (Spearman rank correlation coefficient ρ=0.40; *P*=.003).



XSL•FO
RenderX

Figure 1. Willingness to use home monitoring tools. (A) Caregivers' willingness to use different home monitoring tools for children with asthma and cystic fibrosis (CF) and (B) children's willingness to use different home monitoring tools.

XSL•FO
RenderX

Figure 2. Distribution of the cumulative device willingness score among caregivers and children with (A) asthma and (B) cystic fibrosis (CF). For each applicable home monitoring modality, willingness to use the modality was scored as +1, unwillingness as –1, and a neutral response or no opinion as 0. The maximum possible cumulative score was 7 in the children with asthma and 6 in the children with CF.

Symptom Interpretation

Symptom recognition was generally comparable between the asthma and CF groups (Multimedia Appendix 5). A total of 69 (61.1%) caregivers reported an accurate assessment of disease symptoms. About 42.5% (48/113) of caregivers reported that when they first noticed symptoms, they believed those symptoms had already been present for >1 day. Caregivers who expressed difficulty with symptom interpretation were significantly more motivated to use home monitoring in general (Spearman rank correlation coefficient ρ=–0.19; *P*=.04) and had a higher cumulative device score (Spearman rank correlation coefficient ρ=–0.272; *P*=.004). This correlation was not significant in children who expressed difficulty with symptom interpretation (Spearman rank correlation coefficient ρ=–0.18; *P*=.07). Multimedia Appendix 5 shows the ability of caregivers and children to notice disease-specific complaints.

Data Interpretation

Of the 113 caregivers, 82 (72.6%) would only use home monitoring if insight into the results was provided (n=42, 67.7% caregivers of children with asthma vs n=40, 78.4% caregivers of children with CF; χ^2=1.1; *P*=.30), while 72.6% (n=82) would only use home monitoring if a physician reviewed the results regularly (n=46, 74.2% caregivers of children with asthma vs n=36, 70.6% caregivers of children with CF; χ^2=0.05; *P*=.83). Only 38.1% (n=43) of caregivers would follow algorithmically generated treatment advice before discussing the results with their physicians, although the asthma cohort was significantly more willing to follow algorithmically generated treatment advice without consulting a medical specialist than caregivers in the CF cohort (n=30, 48.4% vs n=13, 25.5%; χ^2_2=6.4; *P*=.04).

Barriers and Facilitators

In total, 14 children (n=8 with asthma and n=6 with CF) and their caregivers also took part in an interview to elaborate on their answers. A total of 88 (77.8%) caregivers answered the open-ended question about expected barriers, and 79 (69.9%) caregivers answered the question about expected facilitators.

Responses were generally similar between the asthma and CF groups. Content analysis of barriers and facilitators identified the following themes: time commitment, ease of use, safety, and motivation, as displayed in Figure 3. The main barrier was the perceived time burden of home monitoring (n=23). Other caregivers highlighted the importance of user-friendly, compact devices that minimally disrupt the child's daily life (n=19). The child's motivation (n=6) was another possible barrier to the use of home monitoring. Adoption of devices would be enhanced by clear instructions before use and education on the interpretation of the results (n=15). Caregivers also expressed concerns about device safety, privacy, and electromagnetic exposure (n=8), emphasizing the importance of trust in the equipment. Finally, worries about reduced patient-physician interaction (n=6) were accentuated by the desire for continued contact with physicians or specialized nurses to interpret results and maintain a human-centered approach to care (n=6). In addition, several caregivers (n=12) indicated that home monitoring could enhance their understanding of their child's illness and help them anticipate clinical deterioration.

XSL•FO
RenderX

Figure 3. Content analysis of barriers and facilitators of home monitoring. Four main themes—time commitment, safety, ease of use, and motivation—are illustrated with representative participant quotes.

Discussion

Principal Findings

Home monitoring may support early detection of disease activity in pediatric lung disease, but its implementation in clinical practice remains limited [20-23]. This study explored perspectives, barriers, and facilitators related to home monitoring in pediatric pulmonology and showed that 86.7% (98/113) of caregivers and 74% (77/104) of children expressed a general willingness to use home monitoring. Several important factors were identified that should be addressed in future research, development, and implementation of home monitoring.

Caregivers were particularly motivated to use home monitoring if it could reduce long-term lung damage or lead to fewer hospital admissions. In addition, access to data and physician involvement were shown to be important factors for caregivers. Associations with a positive attitude toward multiple home monitoring modalities were found for caregivers of children with a higher disease burden and lower proficiency in symptom recognition, while age did not appear to be a significant factor. These results suggest that researchers should focus on gathering evidence that consistently shows whether home monitoring systems may improve long-term outcomes. However, previous studies on this subject have demonstrated that home monitoring did not achieve better long-term outcomes [24-27]. Additionally, it appears that children and caregivers value having access to their own health data and guidance in interpreting these results, as this may support symptom recognition and enhance their sense of control. This observation is in line with previous literature showing that access to personal health data can improve illness perception [28-31].

The qualitative component of this study provides context for the generally high willingness observed in the quantitative results by identifying important barriers to the implementation of home monitoring in practice. In line with previous literature, time commitment and sustained motivation were key barriers to implementation [32,33], as well as ease of use. Therefore, future research should focus on passive monitoring with "dummy proof" devices and minimize active measurements as much as possible. Caregivers also stressed the need for continued physician involvement in this section of the questionnaire. These barriers may help explain the gap between the apparent willingness to use home monitoring and its limited uptake in current clinical practice [34,35]. Home spirometry is a well-studied example: although widely investigated [36,37], long-term use is hampered by declining measurement quality [38] and reduced motivation over time [10].

XSL•FO
RenderX

Several notable differences between the asthma and CF groups were found in this study. These differences should be interpreted with caution, as the groups also differed in several participant characteristics, including age, sex, distance from the hospital, and previous experience with home monitoring, which may have contributed to the observed differences. In both children with asthma and their caregivers, home monitoring of pulmonary symptoms seemed to align well with patient needs, while caregivers and children in the CF group showed less interest in monitoring focused specifically on pulmonary symptoms. This may partly reflect the introduction of modern CFTR modulators, which have substantially improved lung function and symptom control in people with CF [39]. This may also be explained by the more variable and episodic nature of symptoms in asthma, which can develop rapidly, whereas exacerbations in CF are often preceded by a more gradual onset of symptoms.

A strength of our study is that, to our knowledge, it is one of the largest cohorts to examine the perspectives of children and caregivers on home monitoring. Including both perspectives provides a broader understanding of preferences and expectations. In addition, participants represented a range of ages and disease severities, improving the representativeness of the sample. Finally, the combination of quantitative and qualitative data provided a deeper understanding of motivations, concerns, and needs relevant to implementation in pediatric pulmonary care. The main limitation of this study is that it relied on self-reported data via a questionnaire that was not previously validated in other studies, which may have induced recall bias or social desirability bias. However, the questionnaire was developed through several feedback loops to improve face validity, clarity, and relevance for the target population. The sample in this study was drawn from 2 large urban hospitals in the Netherlands, which may limit the generalizability of the findings to broader, more diverse, or rural populations. Moreover, 51 parent-child dyads were included in the CF group rather than the planned 60, as the rarity of the disease limited the achievable sample size within the recruitment period. The relatively small sample size, particularly within subgroup analyses, may have limited the ability to detect significant associations. Despite not reaching the predefined target, the collected data were sufficient to provide a comprehensive overview. No correction for multiple testing was applied, as the analyses were exploratory in nature. In addition, as interviews were conducted in a subset of participants, selection bias cannot be excluded for this analysis, and the qualitative findings may not capture the full range of perspectives within the study population. Further research with a more diverse sample and a longitudinal design may lead to a better understanding of the implementation of home monitoring programs for children with asthma and children with CF. Finally, future work with a quantitative or qualitative approach should gather insights from children with other lung diseases.

Conclusions

Interest in home monitoring is high among children with asthma and CF and their caregivers, particularly in families with poorer symptom recognition. To translate this interest into clinical practice, home monitoring strategies should demonstrate clear clinical benefit, minimize patient burden through user-friendly or passive systems, and be integrated into routine care with active physician involvement.

Abstract

Background: Being active benefits children and their parents, but there is a lack of co-designed resources that support families to engage in physical activity (PA) together.

Objective: This exploratory co-design study aimed to identify ways to optimize guidance resources intended to assist in being active together, and to evaluate the co-design approach it used.

Methods: Physiotherapist-researchers with experience and expertise in family PA drafted 2 evidence-informed prototypes. One prototype informed families about the holistic benefits of being active together, while the other helped families to plan their episode of PA. Twelve parents from 9 rural families and their neurodiverse or developmentally diverse children (n=13) were recruited as co-designers to ensure a wide range of considerations. Family co-designers took part in 2 to 3 workshops. They trialed the prototypes, telling researchers what worked well and how to improve them. Child and adult advisory groups oversaw the co-design approach. Each group met 3 times, with the child advisory group meeting prior to the adult advisory group. A child voice facilitator and advocate was used to support the child advisory groups and facilitate communication between child and adult advisory groups.

Results: Sixty-two changes were made to the prototypes in response to feedback from families and researcher observations. Key changes to resources recommended by children, parents, and researchers to increase user acceptability and usability included changing the ordering of the planning resource to reflect the way that most families used it, adding a "*hard words*" section to improve readability, support to normalize that no-one wins all the time, additional examples to cover each section of the resources, and encourage negotiation among families to ensure that the planned PA was mutually desirable. All families used the resources to successfully complete, or adapt, their planned session of PA together. Overall, co-designers and advisory group members perceived the co-design approach to be appropriate and responsive. However, the researchers identified a possible gap in final communication with the children regarding dissemination of results of the project which were provided to families via parents' email.

Conclusions: The co-design approach used in this study supported families, including neurodiverse and developmentally diverse children, to trial and provide feedback on PA resources. The large number of changes made to the resources from co-designer suggestions and researcher observations highlights the importance of gaining user feedback for consumer resources. Future research is needed to evaluate how these co-designed resources may impact family PA behavior and identity. The transparent co-design approach and evaluation highlighted limitations for research communication to children, which require careful consideration in future similar studies.

Introduction

The widespread benefits from regular physical activity (PA) are dose related, with the greatest health benefits observed among those who go from inactive to active [1,2]. National and international guidelines for PA emphasize minimum recommendations for PA volume and intensity [3-5]. Yet, despite decades of public health messaging on PA, regular child PA participation remains low worldwide [6]. For example, a 2022 report from the Active Healthy Kids Global Alliance graded 10 indicators related to PA across 57 countries. Aggregate grades include D for overall PA grade, C+ for PA engagement at school, and C− for family and peer PA engagement [6]. Low child PA participation rates are concerning, given the widespread health and well-being benefits childhood PA affords children throughout their childhood and adult life [7,8]. Children who are neurodiverse and developmentally diverse are at an even greater risk of inactivity due in part to slower development of fundamental movement and prosocial skills [9-11]. These populations include children with conditions such as autism, attention deficit hyperactivity disorder, and developmental coordination disorder, as well as those who are not meeting their developmental milestones. Diagnosis of conditions takes time, and many families, particularly those in rural areas, endure long waiting lists to access developmental assessments [12].

Parents shape their children's PA behaviors, which underlines the importance of supporting their endeavors. For example, medium-sized correlations have been found in studies of parental support behaviors and child PA [13,14]. There is general consensus in the literature that the following parental behaviors assist child PA: encouragement and talking about PA, logistical support, and cross-generational PA (X-gen PA; ie, parents or carers being active with their children) [13]. In 2022, Active Healthy Kids Australia suggested increasing child and parent engagement in PA *together* to provide modeling opportunities for children and reduce risks of chronic diseases (ie, diabetes) while increasing both populations' opportunities for a healthy life [15].

Research has found that X-gen PA provides more than physical and psychological health benefits [16]. For example, X-gen PA has been identified by both children and parents as an important instrument through which they can connect to each other socially and emotionally [16]. It facilitates communication, in a nonconfrontational context, and provides a bonding experience, even in contexts where verbal communication is not feasible (eg, high-intensity activity), possibly via mirroring of similar repetitive movements [16]. Parents view the support they provide during X-gen PA as much broader than just assisting their child's PA [16]. For example, they use it to teach their children how to work with other people and build resilience by getting through physically challenging circumstances together, as well as to role model healthy behavior and help their children to gain and practice sporting skills [16].

X-gen PA is a reciprocal partnership to which children, as well as parents, contribute [17,18]. Children may influence the commencement of an episode of PA with their parents, which requires consensus from all those involved [18]. For example, children may initiate episodes of PA with their parents by bringing their siblings with them to augment their request or ask to join in their parent's PA session [18]. It is evident that X-gen PA is a complex bidirectional phenomenon when viewed through the lens of socioecological models, such as those described by Bronfenbrenner [19] and James and Prout [20]. Yet, X-gen PA is often considered in PA research through a unidirectional model as one aspect of parental support for child PA [21,22]. This unidirectional model, where children's influence is not acknowledged and parents are considered the sole *gatekeepers* of family PA, may have contributed to the lack of children's voices in family PA research [18] and the narrow focus of PA promotion by targeting parents only [23].

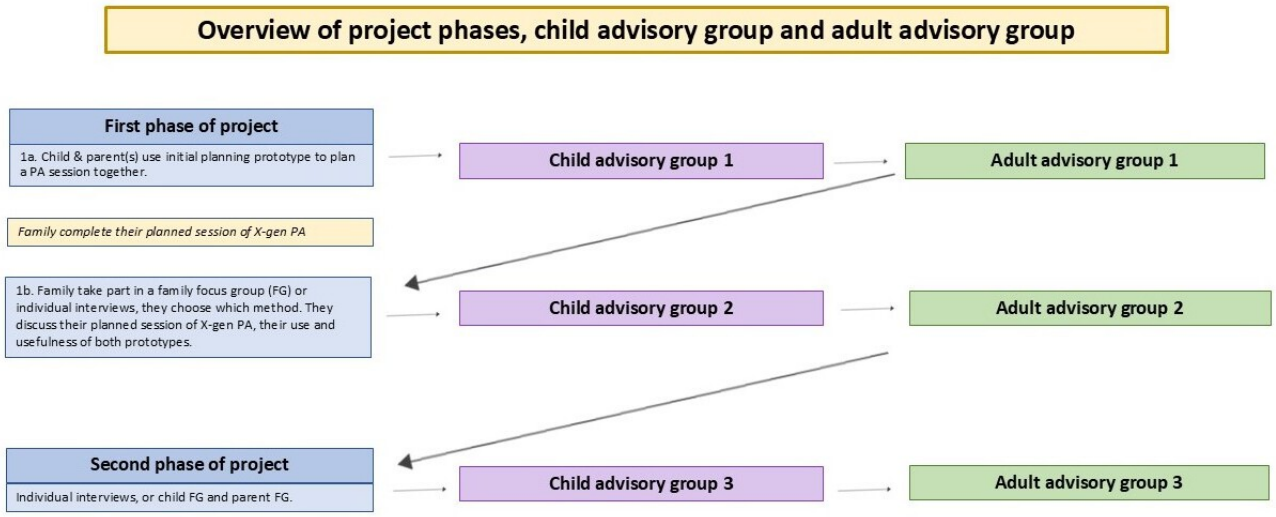
A recent systematic review identified a lack of co-designed holistic resources that support families to engage in PA *together*, including among families with neurodiverse and developmentally diverse children [23]. This oversight is surprising as co-designing with end users ensures that resources are suitable for the populations they are targeting. In addition, co-designing with end users is recognized as one way of increasing health equity and literacy [24].

Family-centered practice describes another socioecological model that supports health professionals and researchers to work in partnership with families to enhance developmental outcomes for children [25]. It is strengths-based, acknowledging that all families have strengths that can be built upon, including that they are the experts on their *own* family [1,26]. Lundy's model of participation [27] was developed to help operationalize Article 12 of the Charter on the Rights of the Child [28], which states that children have a right to be heard on issues that affect them. The model describes 4 chronological elements that should be considered to support children's participation: space, voice, audience, and influence [27].

Children living in rural areas in Australia exhibit greater developmental vulnerability. For example, an overview of the 2021 Australian Early Developmental Census identified that only 55% of children in the geographic setting for this study were developmentally on track across all 5 domains: physical health and well-being, social competence, emotional maturity, language and cognitive skills (school-based), and communication skills and general knowledge [29].

The primary aim of the research was to identify ways to improve the usability and acceptability of guidance resources intended to increase knowledge of how to plan and engage in X-gen PA among rural families, including those with children who are neurodiverse and developmentally diverse. The secondary aim was to explore the authenticity of the co-design approach by evaluating the approach through the voices of children and parent co-designers, child and adult advisory groups, and researchers.

Methods



Overview

The research was conducted within a critical realism paradigm, which acknowledges both the existence of objective reality

XSL•FO
RenderX

(ontological realism) and that co-designers' and researchers' understanding of that reality is situated and relative (epistemological relativism) [30]. The study used an exploratory, sequential, participatory research design [31,32] using multiple methods to iteratively inform resource co-design. The co-design process involved physiotherapist-researchers with experience and expertise in X-gen PA, along with neurodiverse or developmentally diverse children and the parents of these children. The physiotherapist-researchers contributed to the co-design process knowledge of considerations regarding X-gen PA gleaned from families more broadly based on prior research with families [16,18] with their own families' lived experiences with X-gen PA and their professional experiences. Participation and contributions of neurodiverse and developmentally diverse children and their parents in the co-design process enabled consideration of a range of additional issues for X-gen PA that may not have been as prevalent or as strongly recognized in many of the families involved in prior X-gen PA research. Children and parent co-designers attended 2 to 3 co-designer workshops where they trialed and provided feedback and suggestions on key elements of 2 X-gen PA prototype resources that were initially drafted by the physiotherapist-researchers, based on their prior understanding of X-gen PA (Figure 1). Additionally, child and adult advisory groups were established to provide guidance and feedback on the co-design approach (Figure 1). Both quantitative data (from surveys of participants) and qualitative data (child and parent co-designer suggestions and researcher observations) from workshops were collected and analyzed in this multimethod co-design research.

Figure 1. Co-design phases and advisory groups.

Setting

This study took place in a rural Local Health District (LHD) in NSW, Australia. Co-design workshops and child advisory group meetings were held in local library meeting rooms, while the adult advisory group meetings were online.

Drafting of Evidence-Informed Prototype X-Gen PA Guidance Resources

As a first step in the sequential co-design process undertaken in this study, 2 evidence-informed prototype X-gen PA guidance resources were drafted by the physiotherapist-researchers (KF, KA, and RP) in the research team. These drafts provided families participating in the co-design study with evidence-based prototypes to trial and critique, thereby facilitating a sequential approach to co-design in which the initial contributions of the practitioner-researchers, resulting in prototypes, provided a foundation for the contributions of children and parents and subsequent contributions of the researchers. Similar sequential approaches to co-design, which integrate research evidence and clinical and expert experience with lived experiences of consumers through a sequential co-design process, have been described elsewhere, for example, the Framework for Co-Design of Clinical Practice Tools [31]. A further example is the bidirectional strategy used in the co-design of a self-compassion mobile health intervention for people with cancer, which enabled the merging of "top-down" (research evidence based and clinical expertise based) and "bottom-up" (lived experience based) inputs in the co-design process [32].

In this study, the drafted prototypes took the form of booklets that provided families with guidance on building family capacity for planning and adapting PA to the X-gen PA context. Drafting of the prototypes was informed by evidence accumulated from previous research [16,18] and the following frameworks and behavior change theories: the International Classification of Functioning, Disability, and Health [33], family-centered practice [25], self-determination theory [33], socioecological frameworks [20], and strengths-based practice [1].

The first of these prototype resources, *Doing Physical Activity Together,* described the purposes behind X-gen PA and experiences of children and parents with X-gen PA, discussed current evidence of the benefits of being active together, and provided examples of types of PA that families might try doing together. The second prototype resource, *Planning Physical Activity Together,* covered aspects families might consider when planning a PA session together. It also guided families through a postsession review, through which they could identify aspects of the X-gen PA session that each participant liked and aspects they might wish to change in future PA sessions.

XSL•FO
RenderX

The prototype resources sought to assist autonomous experiences by supporting children's and parents' rights to take part in planning and choosing aspects of X-gen PA [34]. Competence was addressed in the *Planning Physical Activity Together* prototype [33], which stepped co-designers through every aspect of planning an episode of PA together. In addition, the prototypes provided families with a common language to plan and discuss their X-gen PA. It was anticipated that this planning process would enable children to be active participants in decision-making and that the resources would build capacity for planning and adapting PA across both generations, which would be mutually reinforcing. Three quotes from children and parents involved in preceding X-gen PA research and suggestions from that prior research for X-gen PA were included in *You might like to try* sections of the prototypes to provide ideas for families and promote norms for X-gen PA. Two Australian First Nations mothers were paid as consultants to examine the initial proposed text in the 2 X-gen resource prototypes and provide feedback on their cultural appropriateness. No changes were identified as being needed by the 2 Australian First Nations mothers. This suggested that the prototypes were culturally safe for use by Australian First Nations families, should they choose to participate in the co-design process.

Child and parent co-designers subsequently commenced engagement with the prototype resources by using the planning resource to plan a session of PA together. This approach allowed all co-designers, irrespective of their experience of X-gen PA, to take part in the co-design study, as there was no requirement for previous experience of X-gen PA. Further details are provided below of the extensive involvement and contributions of children and parents in the subsequent stages of the co-design process.

Researchers, Partner Organizations, and Child Voice Facilitator and Advocate

Two researchers (KF and KA) facilitated all co-design workshops involving children and parents. Both were experienced physiotherapists, with more than two decades of experience working with children and families, as well as experience conducting research workshops and focus groups and with X-gen PA. The study involved a partnership with the Pediatric Department of an LHD, a private rural pediatric clinic, and a primary health network. The partners assisted with recruitment and provided advice for the project through representatives in project planning and on the adult advisory group. An experienced primary school learning support officer was recruited into the role of child voice facilitator and advocate (CVFA). The CVFA was a dual role created to provide both independent (nonresearcher) facilitatory support to the child advisory group and an advocacy role for the child's voice at adult advisory group meetings.

Child and Parent Co-Designers

Purposive sampling was used to invite and secure the participation of a diverse group of families who would likely use the co-designed resources. Pediatricians identified neurodiverse or developmentally diverse children aged between 5 and 12 years who also met other eligibility criteria for participation. The parents and carers of these children were subsequently informed about the study, and both the parents (or carers) and children were invited to participate. Exclusion criteria were those with a health condition that severely limited PA participation and family members who required an interpreter to take part. Parent consent and child assent for participation were obtained.

To acknowledge their time and expertise, child co-designers were given a suitable piece of PA equipment, and parent co-designers and CVFA received a credit card voucher following participation in each workshop or advisory group.

Co-Design Workshops

The co-design research approach was chosen to ensure that both child and parent voices, reflecting their lived experiences, contributed to the final X-gen PA guidance resources, together with the evidence-based understandings and lived experiences of X-gen PA among the researchers. Lundy's model of participation, encompassing the 4 elements of *space, voice, audience,* and *influence*, was used to inform the co-design research approach [27]. The checklist developed by Ireland's Department of Children and Youth Affairs [35] was used by the researchers to aid reflexivity on all elements of the approach (Multimedia Appendix 1).

Data collection periods involving participating children and families were determined by co-designers' preferences and availability and occurred during the first 3 school holiday periods in 2024 (Table 1), with phase 1 occurring in January, phase 2 in April, and the final child and adult advisory group meetings (Table 2) occurring during the July 2024 holiday period.

Study phase and activity	Participants	Description
Phase 1: January school holidays		
Initial questionnaires	Child and parent co-designers	Children completed a paper questionnaire about intergenerational physical activity (X-gen PA[a]), with researcher assistance where appropriate. Parents completed a paper questionnaire on X-gen PA and demographic information (eg, age, gender, and health conditions).
Workshop 1: planning	Child and parent co-designers working together	Co-designers provided feedback while working through the Planning Physical Activity Together prototype. Researchers observed and documented suggestions for improvement. Families left with their completed plan, both prototypes, and an agreed date for the second interview. Families completed their planned physical activity session together.
Workshop 2: reflecting	Child and parent co-designers working together	The session began with opportunities for co-designers to reflect on their experiences of completing the plan through drawing and writing activities. Beginning with child participants, co-designers described their physical activity session and provided further critique of the planning prototype and initial feedback on the Doing Physical Activity Together prototype.
Phase 2: April school holidays		
Workshop 3: doing	Child and parent co-designers separately	Children played a board game in which landing on a specific color corresponded to a section of the Doing Physical Activity Together prototype. Colored cards contained questions about each section. Parents reviewed the prototype one page at a time, suggested improvements, identified gaps, and highlighted aspects they liked.
Post–X-gen PA questionnaires	Child and parent co-designers	Children completed a paper questionnaire, with researcher assistance where appropriate. Parents completed a paper questionnaire.
Evaluation of co-design	Child and parent co-designers	Participants completed questionnaires based on the Lundy rights-compliant model [27]. The child questionnaire was adapted from the evaluation questionnaire in the Government of Ireland Participation Framework for Children and Young People Participation in Decision Making [36]. Parents completed a corresponding questionnaire.

[a]X-gen PA: cross-generational physical activity.

Table . Summary of child and adult advisory group meetings.

Meetings	Child advisory group	Adult advisory group
Meeting 1	1. Introductions and game. 2. Discussion with researchers covering: What do child advisors do? What is research? Why should research hear from children? How would you like to tell us what you think? 3. Brainstorming and discussion on how child advocates can support the group. How do the children want the child advocate to inform the adult advisory group what they think?	1. Introductions. 2. Presentation of project. 3. Co-design approach and evaluation. 4. Draft terms of reference for the adult advisory group. 5. Briefing on the child advisory group from the child advocate. 6. Agree feedback to child advisory group (sent to child advisory group members via parent email). 7. Feedback invited from group on project.
Meeting 2	1. Introductions and game. 2. Review adult advisory group feedback. 3. Briefing on first phase of project. Watch video of researchers explaining some of the changes made to resource in response to child and adult advice. Score and provide feedback on how well researchers have listened. 4. Brainstorm what children want adult advisory group to know.	1. Introduction and attendance. 2. Review terms of reference of group. 3. Briefing and feedback invited on co-design during first phase of project. 4. Briefing on child advisory group from child advocate. 5. Agree feedback to child advisory group (sent to child advisory group members via parent email). 6. Discuss co-design approach in phase 1.
Meeting 3	1. Introductions and game. 2. Review adult advisory group feedback. 3. Researcher invited into group to remind group and discuss why hearing from children is important. 4. Briefing on second phase of project. Watch video of researchers explaining some of the changes made to resource in response to child and adult advice. Score and provide feedback on how well researchers have listened. 5. Brainstorm what children want adult advisory group to know. 6. Present children with participation certificates, thanking them for being child advisors.	1. Introduction and attendance. 2. Review terms of reference of group. 3. Briefing and feedback invited on co-design second phase of project. 4. Briefing on child advisory group from child advocate. 5. Agree feedback to child advisory group (sent to child advisory group members via parent email). 6. Where to from here? Brainstorming translation of project. 7. Group invited to contribute to evaluation of co-design approach.

Parents completed a short demographic survey at the beginning of workshop 1. The child and parent co-designers used the initial planning prototype *Planning Physical Activity Together* to plan a session of PA together, while a researcher observed and provided advice where appropriate. Child and parent co-designers left with copies of both prototypes. They returned following the implementation of their plan for an X-gen PA session. Achievements reported by the child and parent co-designers in completing X-gen plans were recorded, along with their initial experiences of using the resources and impacts they reported the resources had on their understandings of planning and doing PA together. Child and parent co-designers then provided feedback and gave their suggestions on the 2 prototypes. In phase 2, separate concurrent child and parent workshops were conducted, and co-designers were asked, as part of a small post–co-design survey, if using the resources had changed the ways they (parents and children) were active together and to evaluate the co-design approach (Table 1).

Child and Adult Advisory Groups

All child and parent co-designers were invited to join either the child or adult advisory group, respectively, to oversee the project and provide advice on the co-design approach (Table 2). Three child advisory group meetings were held during the research period. Adult advisory group meetings were held after each child advisory group meeting. Child advisory group meetings were facilitated by the CVFA (with online support from a project officer). The CVFA also attended adult advisory group meetings in their advocacy capacity, telling the adult advisory group what the child advisors wanted them to know and providing independent, nonresearcher representations of the child's voice, as requested by the children in the child advisory group. The CVFA reported back from the adult group to the child group via the children's parents' email addresses. Adult advisory group meetings included a parent co-designer, the CVFA, a pediatrician, a data support officer from the primary health network, and the physiotherapist-researchers involved in the project.

XSL•FO
RenderX

Advisory group members were invited, during the second and third advisory group meetings, to comment on changes made to the prototype resources in response to data gathered in the co-design process. Child advisors watched a short video of how researchers had responded to changes suggested by child co-designers. The CVFA invited child advisors to then score how well the changes matched what child co-designers had told researchers, using a 5-point smile rating scale. They were then invited to say why they had given those scores.

Adult advisory group members were provided with tables, which listed *all* comments from all co-designers and all observations from researchers, together with the results of initial data analysis and any related changes made to the prototype resources. Subsequently, a brief overview of key changes made to the prototypes was provided during adult advisory group meetings before the advisory group members were invited to comment and ask questions. Adult advisory group members (excluding the physiotherapist-researchers) were invited to evaluate the co-design approach via a survey after the last advisory group meeting.

Reporting of Co-Design Approach

A reporting checklist was used to ensure that there was comprehensive reporting of the co-design approach while noting that exact replication is not an aim in the reporting of participatory approaches because they should be adapted to the specific context [23] (Multimedia Appendix 2).

Data Analysis

All co-design workshops were audio recorded and transcribed. All co-designers' suggestions and researchers' observations were tabulated and counted. Researchers met regularly during the data collection period to discuss all suggestions and observations, reaching a consensus on amendments to be made to the prototype resources in response to this feedback. Conventional content analysis (as described by Hsieh and Shannon [37]) was used to group suggestions and observations of all co-designers into themes, and a thematic analysis was completed on transcripts of workshops to identify key themes from participants' experiences, recommendations, and discussions, using the 6-phase approach to thematic analysis as described by Braun and Clarke [38]. Reflexivity during content and thematic analyses was supported by regular meetings between researchers, which allowed consideration of themes and alternate explanations. Demographic and evaluation surveys were analyzed using descriptive statistics and content analysis, as described earlier.

Co-Designed Resources

At the end of the study, co-designed versions of the resources were finalized, and a graphic designer was used to compile the final co-designed resources. An infographic was created to provide feedback to participants and distribute information about the study [39], and a website [40] was created to house and make publicly available the final co-designed resources and gather further feedback on them.

Ethical Considerations

Ethical approval for this study was obtained from the Sydney Children's Hospital Network Human Research Ethics Committee (HREC) (protocol 2023/ETH00995) and Charles Sturt University HREC (protocol H23804). Consent and child assent were obtained from all co-designers, including consent for publication.

Results

Child and Parent Co-Designer Demographics

Thirteen neurodiverse and developmentally diverse children (girls: n=6, 46.2% and boys: n=7, 53.8%, age range 5 - 11, mean 8.6 y, SD 1.79 years) and 12 parents (mothers: n=9, 75% and fathers: n=3, 25%) from 9 families took part in the co-design study. Ten (83%) of the 12 parents answered a prestudy survey. All parents reported that they had never previously been given resources or advice on being active with their child. Further demographic information is listed in Table 3.

None	8
Yes	2
Additional issues identified by parents as limiting engagement in physical activity with their child[d]	4 responses

[a]X-gen PA: cross-generational physical activity.

[b] Open-text comment: “Chronic fatigue, limits my energy levels.”

[c]Open-text comments: “Just need to be careful as he has a connective tissue disorder which means his joints are unstable. No hard contact sports, just gentle activities” and “No energy to be active. Gets tired easily.”

[d]“ADHD: boredom, hyperfixation and transitioning hinders us both.” “Work/school schedule especially during winter.” “[name of child] is no fun to play with eg, listening, sticking to rules, needs to control everything.” and “I need to lose weight to feel like doing more.”

What Were Families’ Experiences of Using the Prototype Resources?

All child and parent co-designers reported they were able to complete their planned session of X-gen PA. A parent said:

> *I liked how it [the planning prototype] was all set out and how we ended up with a really good plan of what to do.*

Families noted the prototype planning resource helped them to organize X-gen PA and gave them a structure and language to debate what the episode would look like by considering all aspects of it. A father described how the prototype resource was used successfully as a reference to cease the frequent rule changes that their child tended to impose:

> *It was so good, to have a reference, to be able to say "hang on a minute, this is what we decided." Game-changing actually.*

A couple of families had to adjust their plans, and they reported that these adjustments were accommodated without difficulty. For example, a mother said:

> *The planning tool helped us even when there was some adjustment in timing. There was no arguing, there was no ’yeah, but!*

There was consensus that the prototype resources were useful and user-friendly:

> *It’s good, it‘s really easy for [child name] to understand and fill in. I found it pretty user friendly. [Parent]*

Families noted that the prototype resources included aspects of X-gen PA they had not considered, such as *physical and emotional safety* and *stopping* in the prototype planning resource. And a parent noted the following about the prototype *doing* resource:

> *I thought this resource included things that I hadn' t consciously thought about. Like supporting child development for things like problem solving, social skills, communication... It puts a positive emphasis on trying to get out and do more activity together. Reading something like this reminds us why we should do it.*

Children said they “liked planning” and that the prototype resources were “good” as they gave them “different ideas of what to do.” The prototype *planning* resource encouraged co-participation in PA, as evidenced by one parent who observed that:

> *if we hadn‘t planned this, I would have just sat down and watched them.*

There was consensus among families that using the prototype planning resource allowed children to know exactly what was happening. Using the resource reduced confusion and questions from children, which allowed all child and parent co-designers to have a better experience. For example, one mother said:

> *I think it helped to stop a lot of the questioning that we get when we say we' re going to go and do something. We set it out, they know what they' re doing. … This allowed us to say it all at the beginning*

XSL•FO
RenderX

> *and then it allowed for a calmer results because they were part of the process.*

Children concurred, for example, one child said:

> *It was really good because we had everything planned. I knew what we were doing.*

Some elements of X-gen PA covered in the prototype resources families had not considered planning before. For example, *how* to do the activity, *managing emotions*, and *stopping*. Families noted that planning improved their engagement and experience:

> *We usually just get in and just do it. And not thinking about how and what the word ' how' meant in that context. Normally if we go for a walk, it's just come on let's go for a walk but we haven' t really thought about it, we just do it. Thinking about how makes you think about what obstacles you do need to overcome to doing it.*
>
> *[Parent]*

And a child said: "I like having rules because then we argue less." Parents agreed, noting that planning enhanced their enjoyment by reducing arguments and allowing them to go "at a pace that works for them."

In the second co-design workshop, some children also demonstrated an appreciation of how managing emotions could be used during other PA. For example, a child said:

> *When I played handball at school, a boy lost and got really angry and bounced the ball really hard and hit his leg. He did not have a plan for keeping safe for big emotions.*

Likewise, child and parent co-designers commented that they found the *stopping* section useful but had not considered discussing or planning this aspect before. For example, a parent said:

> *Talking about stopping beforehand is a great idea because we were able to plan what it would look like.*

The importance of planning this aspect was underlined by the wide variation between child and parent time expectations. For example, a child said: "I could spend the whole day doing this." Parents noted how having an end point that was clear helped their children. One parent noted that it helped their child engage in the activity for longer periods, and another said:

> *[Child name] is autistic and he can be rigid and things need to be in a certain order, and change does not come easily. So that stopping one ... is huge for him, cause you heard him, "3 overs each at 6 balls."*

Parents also observed that knowing when PA will end helped them engage more fully with their children and the "confidence that it will end before everyone becomes tetchy and tired." This allowed the activity to end on a positive note, without conflict.

What Changes Were Made to the X-Gen PA Guidance Resources?

In total, 62 changes were made to the prototype guidance resources during the co-design process. Tables in Multimedia Appendices 3 and 4 detail the 35 changes suggested by child and parent co-designers and 27 changes made based on researcher co-designer observations. Textbox 1 provides a summary of the key changes from among these.

XSL•FO
RenderX

Textbox 1. Summary of key changes made to resources based on co-designer contributions.

1. Planning resource was changed to reflect the order most families addressed their planning in

For example, *Where* and W*hat* were combined into one section and moved up to after *Who*

2. Suggestions of activities were added to sections that did not have them

- "The bits of the resource which have lots of suggestions are awesome ... because it triggers ideas and helps us get more out of planning with him" (Parent).

3. Examples were added to sections to help understanding

- Some children found some of the ideas hard to grasp. For example, *Managing emotions*, they talked about being sad if they got hurt. Amended resource to provide examples of why emotions may become big.

4. Negotiation in planning needed additional support

- Several aspects in resource amended. For example, emphasized importance of hearing from both children and parents in *who* section. In *Reviewing together*, encouraged participants to work with their activity partner to help improve each other's experience.

5. Support was required not just for planning the activity but considering the preparation too

- For example, packing swimming bag, remembering goggles.

6. Resource was amended to remind families of a simple definition of PA

- "I wouldn''t have thought that just handball was physical activity because to me physical activity is walking, running, swimming, anything that they label as fitness. So that was even an eye-opener, oh this is quite fun, and it's easy to do, and it's still being active!" (Parent)

7. Resource was amended to remind families that PA didn't need to take a long time

- Parents reported that using this resource helped them appreciate that being active with their child need not take a long time after some commented that the time to engage was more achievable than they had realized.

8. Simplified some language that children identified as hard

- "I think you can improve it by getting rid of some of the big words so it's easier for other children to read." (Child)
- For example, changed *routine* to *everyday*

9. Added *Hard Words* section

- Children showed very variable ability to read and understand some words but resources are for families to read together. Retained some *hard words*, eg, *agility, self-esteem*, they were highlighted in orange in the resource and an explanation provided in the *hard words* section at the end of the resource to support parents to explain them

10. Parents advised that they would like to normalize that no-one wins all the time

- Added to *Some families compete and measure against each other*
- I think it's really important just to remind them that "It's okay if you don't win, as long as you're better at—getting better within yourself."

Has Using the Resources Changed the Way That You and Your Parent or Child Are Active Together?

Five children and 3 parents (n=8) answered a post–co-design survey. Six of these co-designers (children: n=3, 37.5%, parents: n=3, 37.5%) answered *yes* to the abovementioned question. One child answered *no*, and one child answered *don't know*. Child and parent co-designers were invited to tell us more. Table 4 provides the themes and related examples arising in responses from child and parent co-designers.

XSL•FO
RenderX

Table . Has using the resources changed how you are active together? Themes and examples based on responses from child and parent co-designers.

Themes	Child responses	Parent responses
Shared themes	*Do it more together (n=3)* • *We do more with them* (n=3).	*Do it more together* (n=1) • *I try to be more involved and play with them instead of just sending them to play on their own*
Child and parent only themes	*Plan PA more* (n=1) • *We talk about it more. I know what we are going to do.*	*Greater insight into child's interests* (n=1) • *It helped me see that what I consider a fun activity is not what [name of child] likes to do. That didn't occur to me.* *Increased child agency* (n=1) • *The kids feel like they have more agency over the activities we do together when we plan, rather than me picking the activity and us doing that.*

Was the Co-Design Approach Authentic?

Feedback From Advisory Groups During Co-Design

Child advisors during the second and third advisory group meetings were predominantly positive about the changes made to the prototype resources in response to child feedback. However, some changes attracted more approval than others, and scores given by child advisors ranged from 5 (a big smiley face) to 2 (a slight frown). For example, child advisors rated the addition of a suggestion that children and parents swap roles, and the child takes on the role of teacher or coach, in the *Being active together supports child development* section of the *Doing Physical Activity Together* prototype resource, with big smiley faces. A child advisor wrote: "This is because I understand this and it makes me want to say this to my parents."

They reported less enthusiasm for other changes. For example, making more space for writing in the blank plan by making it 2 pages instead of 1 was rated neutral to smiley face (3-4) by child advisors. A child advisor wrote: "It's not a big change but it is still a good change." Changes were made to simplify language and provide a small dictionary of *hard words* in response to child and parent feedback. One child advisor did not like the changes made to simplify the language that *they* understood. They scored this change with a slight frown (2), noting:

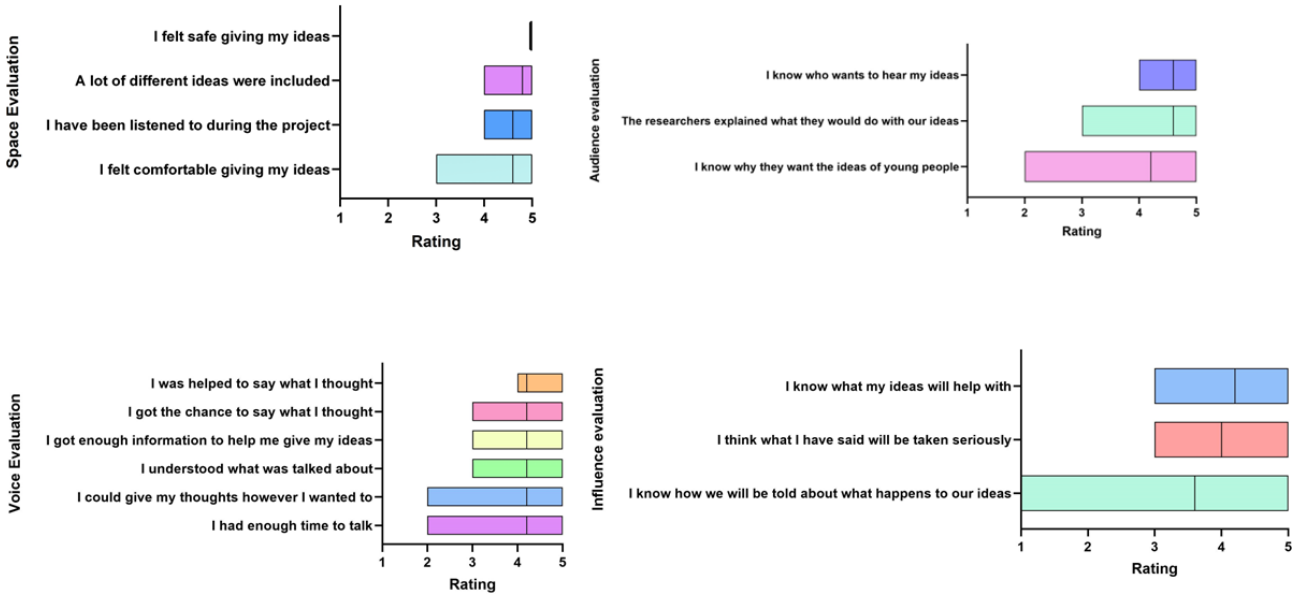
> *Because some of the words like "bonding" I know about and to me it's unfair that I know a word and you take it out.*

Likewise, support for changes made to the prototype resources was received from the adult advisory group members during the research. While adult advisers reported they appreciated this transparent approach, no additional advice or commentary was received from them.

Feedback Post Co-Design Process

All children who participated in the third co-design workshop answered the co-design evaluation survey (n=5), providing a score of 1 to 5 stars for each of 16 statements. Figure 2 shows the findings from the survey, in which questions were based on Lundy's framework of participation [40]. The statement, *I felt safe giving my ideas*, was scored 5 stars by all child co-designers. Only one statement received an average score lower than 4 stars. The statement, *I know how we will be told about what happens to our ideas*, scored an average of 3.6 stars (range 1 - 5).

The bars in the figure depict the lower and higher limits of the range of scores, and the line that dissects each bar indicates the mean of the scores.



Questionnaire adapted from the Government of Ireland Participation Framework for Children and Young People Participation in Decision Making (Government of Ireland, 2021).

Three of 12 (25%) parent co-designers took part in the co-design evaluation at the end of the project (Textbox 2).

Three of 5 eligible adult advisory group members (60%) completed the questionnaire provided to them as part of the evaluation of the co-design process (Textbox 3).

XSL•FO
RenderX

Figure 2. Child co-designer evaluation of co-design process (mean scores and range).

Textbox 2. Parent co-designer evaluation of co-design process (n=3).

1. All parent co-designers ranked the following statements on a 5-point Likert scale: 5=strongly agree

- I was given enough information to allow me to form a view about co-design
- I was given the experiences needed to form a view about co-design
- I was given enough time to express myself during co-design
- I felt comfortable giving my opinions about co-design
- I have been listened to by the researchers during the project
- I know what will happen to my opinions

2. What worked well in your co-design experience?

Two themes were found

- Co-design experience provided opportunities to share their experiences and opinions. One parent co-designer said, “I felt the whole process was valuable and gave me the ability to share my experiences and opinions. The resources worked well and it gave me some great ideas to bring to home life.”
- Two parent co-designers identified that the context and approach to co-design worked well. For example, a parent co-designer said, “Two way conversations and easy explanations.”

3. What could be improved from your co-design experience?

Nothing (n=3)

XSL•FO
RenderX

Textbox 3. Adult advisory group evaluation of co-design process (n=3).

1. Did the study provide opportunities for children and parents to participate in co-design?

100% (n=3) replied Yes

Two themes identified invitation to comment on the answer above

- Engagement with children and parents (n=2)
- "Children involved in the advisory group were treated with respect and engaged with in a friendly manner. They appeared very comfortable to give their opinions and ideas."
- Multiple rounds of co-design (n=1)
- "There were several rounds of co-design sessions. This enables the refinement of themes from the sessions."

2. How much influence were the children and parents able to exert upon the co-design of the resources?

5-point Likert scale (1=*not much influence*, 5=*a lot of influence*).

33% (n=1) scored 4

66% (n=2) scored 5

3. What impact do you think the co-designed approach had upon the PA resources?

User-friendly end product (n=2)

Tailored to the study population (n=1).

4. What worked well with the co-designed approach? (Two respondents provided more than one answer).

Structured, user-friendly approach (n=1)

Time to allow children to fully engage (n=1)

Child advisory group well supported by child voice facilitator and advocate (n=1)

Transparent approach (n=1)

Communication between adult and child advisory groups (n=1)

5. What could be improved from your co-design experience?

Nothing (n=3)

Research Team Reflections Upon Co-Design Approach

The research team identified 2 elements of the co-design methodology that may have impacted child engagement in the study: the amount of information provided to child advisors and challenges in communicating with child advisors outside face-to-face sessions.

First, the purpose of doing the research and the importance of hearing from children were discussed with child advisors during the first child advisory group meeting but omitted from the second meeting of the child advisory group. This resulted in a child advisor voicing uncertainty to the CVFA during the second meeting about why adults wanted to hear their thoughts on the changes that were being made to the resources. Upon reflection, the researchers realized that while we included a brief recap of terms of reference at the beginning of each adult advisory group meeting, we had neglected to support child advisors in this way at the second child advisory group meeting. Thus, at the beginning of the third meeting of the child advisory group, a researcher was invited to join the group and facilitate a further discussion with child advisors about why their views were important.

Second, child advisors were sent an email update from the CVFA after each adult advisory group meeting. The intent of this communication was to close the communication loop and ensure that child advisors did not experience the frustration children have previously highlighted, that they are not informed about research progress and outcomes [27]. The email update was sent to each child's parent's email address to inform the child advisors of what the adult advisory group wanted to feed back to the child advisory group. Communicating with primary school children via their parents' email addresses was considered an important ethical approach, which ensured that parents were aware of and had control over interactions between the researchers and their children. However, it was found at the second child advisory group meeting that not all parents had shown their children this email or child advisors could not remember seeing or hearing about it. To address this issue, the feedback provided in the emails was reviewed with the child advisors at the beginning of the second and third child advisory group meetings. However, this finding does identify that the researchers had no way of knowing whether child co-designers were shown other emailed communication, such as the infographic sent to all families, via parents' email addresses, at the end of the project.

Discussion

Principal Findings

This exploratory co-design study identified ways to increase usability and acceptability of guidance resources intended to increase family knowledge of how to plan and engage in PA together and evaluated the co-design approach it used. An asynchronous approach to co-design was taken to allow the development of theory-informed prototypes for families to trial and critique [41]. Key changes recommended by children, parents, and researchers to optimize the resources included changing the ordering of the planning resource to reflect the way that most families used it, adding a *hard words* section to aid readability, support to normalize that no-one wins all the time, additional examples of the types of PA families could do together, and assistance for negotiation among families to ensure that the planned PA was mutually desirable.

The secondary aim of the study was to evaluate the co-design approach. Overall, child and adult evaluators perceived the co-design approach to be appropriate and responsive and identified several elements of the co-design methodology that facilitated child and parent voices and increased methodological rigor. For example, the use of a CVFA to facilitate child advisory groups enabled safe spaces for children to contribute and evaluate changes made to the resources while ensuring independence and transparency of this aspect of the evaluation. Findings from the child evaluation and researcher observations resulted in 2 suggestions for co-design researchers to consider when conducting co-design research with children, which are discussed further later in this section.

Previous research has found that parents are already convinced about the physical health benefits of regular PA for their child but that has not changed their behavior in supporting their child's PA [42], and PA participation rates in children are still low worldwide [6]. It is also likely that some parents, who are not regularly active themselves, may not have the PA vocabulary necessary to enable, and undertake, successful episodes of PA with their children. Parent co-designers in this study discussed how the resources encouraged them to consider aspects of doing PA with their child that they had not considered before, such as how engaging in PA together supported their child's emotional and social development. It is hypothesized that the final co-designed resources [40] may provide families with greater insight into the wide range of health and well-being benefits of being active together. The resources were also written for both PA partners (children and their parents) to use together, as it is further hypothesized that planning and talking about PA together may influence family PA behavior and support for PA within families. However, both hypotheses will require further investigation with larger numbers of participants.

None of the participating families had previously received resources or advice on parents being active together with their neurodiverse and developmentally diverse children. The small sample size of this study means that this finding should be interpreted with caution, but it nonetheless is concerning because PA is an important intervention for these child populations [10]. Social PA interventions, such as X-gen PA, not only provide opportunities to practice physical skills and gain physical health benefits but also offer opportunities to practice prosocial skills, such as communication skills, taking turns, and self-regulation [10,43]. Provision of information to support families with neurodiverse and developmentally diverse children to take part in positive X-gen PA experiences is required. Development of paper-based or online resources, such as those created in this study, provides one possible way to deliver this support. Some families suggested that accessing the information via an interactive app would be fun, but it is acknowledged that the development cost and subsequent subscription costs of such an app might limit equitable access by excluding lower-income families [44].

The findings of this study suggest that the planning resource may help families consider together what obstacles they need to overcome to be active together. Importantly, parents reported they enjoyed their subsequent planned episodes of X-gen PA, indicating their children asked fewer questions and were more receptive to stopping PA at the end of an episode as planned, allowing for calmer experiences of X-gen PA and greater confidence that episodes would end without conflict. Basic psychological needs theory [45] may provide further explanatory insights into these experiences of success. The resources addressed all 3 needs that underpin the sustainment of intrinsic motivation for a behavior—relatedness, autonomy, and competence [45]. For example, planning stopping meant that children and parents gained insights into the often substantial differences between child and parent time expectations, resulting in conversations to plan mutually agreed-upon time frames for X-gen PA. Stopping of episodes of X-gen PA has previously been noted in the literature as an aspect of X-gen PA that children who were neurotypical found frustrating due to greater parental control over the cessation of a PA episode [18]. Creating a structured environment for children with neurodiversity, such as planning PA, has been identified as a key strategy to help children with neurodiversity manage their behavior [46]. Planning stopping also gave children with neurodiversity knowledge and preparation time to transition from one activity to another, which can help children with neurodiversity manage their emotions [46].

Previous parenting research has found that planning PA opportunities was identified as a key self-regulation strategy that parents who identify as an active parent perform for their family [47]. Research suggests that both role and social identities play a part in maintaining health-enhancing behaviors such as PA [44,48]. Role identity research has found a positive link between PA frequency and having a strong exercise identity [49]. Social identity theory acknowledges that people identify themselves by both their personal identity *and* a wide variety of social identities [49]. Thus, it is hypothesized that encouraging and supporting children to have both a voice and influence over the child-parent PA partnership may positively influence both a child's identity as an active person and foster a shared "active family" identity more than resources directed solely toward parents and carers, in which children are assumed to be the passive recipients of parental decision-making.

Two recommendations for family co-design have emerged from the process evaluation of our exploratory co-design study. First,

XSL•FO
RenderX

it is important to remind child advisors at the beginning of each child advisory group meeting why children's voices are important to hear [27,28] and of the purpose behind the child advisory group (eg, terms of reference). We note that establishing agreed terms of reference has been identified in recent research on co-design studies as one factor that may enhance co-designer cooperation and understanding of their roles as co-designers [50]. Second, this study found that communicating to children via their parents' email addresses did not ensure that child advisors were provided with information about research progress and thus we are unable to determine whether child co-designers saw the infographic depicting the research outcomes that was written for families [39]. The HREC approved the researchers to communicate with the child co-designers via their parents' email addresses, and we acknowledge the importance of ensuring children's safety and privacy. However, not closing the communication loop with children has been identified in previous research as a source of frustration by children [27]. Our study suggests there may still be a role in sending out research summaries by mail, perhaps addressed to the whole family, to increase the likelihood of children accessing research outcomes. Previous research has found that children enjoy receiving research outcomes in the mail and suggest sending research in multiple formats, such as summaries, coloring books, and posters [51].

Limitations

The small number of co-designers and advisory group members in this study was recruited from a single rural Australian LHD, using a purposive sampling approach. We acknowledge that readers will need to determine the transferability of our findings to other populations; thus, we have provided detailed methodology, including descriptions of settings and participants. We hope our transparent approach will allow readers to consider the relevance of the study's findings to other populations and contexts.

Fewer child and parent co-designers took part in the second phase than in the first phase of the study. A gap of two and a half months (school term) between phases is likely to have contributed to this reduction in numbers. In future research, we recommend, where possible, recruiting more child and parent co-designers to reduce the impact of attrition [51] and completing studies without such long time gaps to maintain momentum and interest. However, it should be noted that we used holiday periods because parents informed us in this study that engagement was more likely during holidays, as term-time schedules are too busy. As this study was conducted in Australia (southern hemisphere), it was not possible to conduct the study in one (summer) holiday period due to the impact of Christmas during this time, but conducting the study over a continuous 6-week period would have been ideal. It should be noted that the reduction in engagement in the second phase of the study subsequently impacted the number of children and parents who provided an evaluation of the co-design approach at the end of the study, as child and parent co-designers were invited to complete paper-based evaluations at the end of the second phase workshop. Future studies could also consider a continuous evaluation approach through the use of a short survey at the end of each workshop. Finally, the possibility of desirability bias should be noted. Steps were taken to address this risk by empowering co-designers and advisory group members, such as by employing a nonresearcher (the CVFA), doing activities that promote collaboration to disrupt power hierarchies (eg, playing games and anonymous feedback) [52], and use of multiple methods to provide different ways for co-designers to collaborate and express themselves.

The final co-designed resources are freely available under a Creative Commons License [40]. Further research is needed to test the usefulness of the co-designed X-gen resources in a broader rural population. It is suggested that such research could examine the impact of the resources on family PA literacy, family cohesion, and PA identity, and their use during holidays rather than their impact on an individual's weekly PA total.

Conclusions

In this study, child and parent co-designers provided multiple suggestions to improve the usability and acceptability of guidance resources that had been compiled by experienced physiotherapists, underlining the importance of consumer involvement in resource design. The co-design methodology supported discussion and planning of X-gen PA among rural families with neurodiverse and developmentally diverse children. Future research is needed to evaluate whether these resources can positively impact family PA behavior in the longer term and across broad populations. Evaluating co-design approaches is an important way to provide transparency of the processes involved and to protect consumers against tokenistic co-design approaches. This study highlighted the need for consideration of how to convey study findings to child co-designers.

Acknowledgments

The authors would like to thank all the children and parents who took part in the co-design workshops and advisory groups; Mrs. Julie Rafter and Mrs. Karen Paxton for research support during advisory groups; Mrs. Rebecca Barker (Yorta Yorta and Duduroa) and Mrs. Rebecca Willis (Wonnarua) who gave advice on the cultural appropriateness of the original prototypes; and pediatricians from Murrumbidgee Local Health District and Riverina Pediatrics who helped with recruitment of families.

Funding

This work was supported by Three Rivers Department of Rural Health, Charles Sturt University. Three Rivers is funded by the Australian Government under the Rural Health Multidisciplinary Training Program. The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Abstract

Background: Physical activity (PA) is essential for the healthy development of children. However, the pervasive presence of digital technologies has made digital gaming (DG) a prominent part of children's everyday lives. As children grow up immersed in these digital environments, concerns about reduced PA have intensified. Given that adults, particularly parents and guardians, play a central role in guiding children's behavior, their understanding of children's motivational drivers for both PA and DG is of particular relevance.

Objective: This study aimed to explore the motivational differences underlying children's engagement in either PA or DG. Specifically, the study investigated five distinct motivational scales (recreation, social interaction, coping, competition, and skill) to determine which motives primarily drive behavior in each context. Also, it assessed whether adults accurately perceive these motives in children.

Methods: Data were collected during events using an on-site questionnaire based on the Videogaming Motives Questionnaire. Both children and their accompanying adults completed parallel assessments regarding motives for PA and DG. The final sample included 94 participants forming 49 parent-child pairs. A 3-way mixed ANOVA with group as a between-subjects factor and activity and motive as within-subjects factors was conducted to examine group, activity, and motive effects and their interactions. To further explore these effects, a series of 2 × 5 repeated measures ANOVAs were conducted to examine the interaction between activity type and motivational dimension across groups, followed by separate multivariate tests per motive.

Results: A significant interaction effect between activity type and motivational dimension emerged in the children's data ($F_{4,45}$=3.93, P=.008, partial η^2=.259). Further analyses showed that motive competition was rated significantly higher for DG than for PA ($F_{1,48}$=4.38, P=.04, partial η^2=.084). Among adults, separate multivariate tests for each motivational dimension revealed the largest difference in perceived motive coping ($F_{1,48}$=4.72, P=.01, partial η^2=.123), with PA rated higher than DG. Additionally, a significant difference emerged for motive competition ($F_{1,48}$=4.10, P=.05, partial η^2=.079), indicating higher ratings for DG compared to PA.

Conclusions: The findings emphasize the complexity of children's motivational profiles, suggesting that engagement in DG is not necessarily a sign of diminished interest in PA but rather reflects alternative, equally compelling motivations. This nuanced understanding challenges simplistic dichotomies and supports the need for balanced perspectives on children's activity preferences. Importantly, no statistically significant differences were detected between children's self-reported motives and adults' perceptions of their children's motives, suggesting a general tendency toward similar ratings rather than clear evidence of alignment. These insights can inform the development of more tailored strategies for promoting both physical and digital engagement in a healthy and complementary manner.

Introduction

Overview

Children and adolescents are not only the custodians of future societies but also key to achieving sustainable development. Investing in their health, education, and well-being is essential for ensuring economic stability, social cohesion, and environmental resilience in the decades to come [1]. Physical activity (PA) is widely recognized for its numerous health benefits, particularly in childhood and adolescence [2]. Regular engagement in PA has been shown to improve cardiovascular health, enhance cognitive development, and foster social well-being [3,4]. Moreover, recent research further supports the cognitive benefits of PA in children, showing that structured sport-based interventions (eg, decision-making drills) can significantly enhance problem-solving and creative thinking abilities in young athletes [5]. Additionally, participation in sports contributes to lifelong physical literacy, encouraging active lifestyles into adulthood [3,6]. Nowadays, the increasing presence of electronic devices has made them an integral part of our daily lives and especially of children and young people, who grow up surrounded by these "new" technologies [7]. Smartphones, tablets, and computers are commonplace, and most young people use them for a variety of purposes, including digital gaming (DG) [7]. Indeed, large national datasets show that sedentary behavior, which often includes screen time, accounts for a significant proportion (around 50% - 60%) of children and young people's waking hours [8]. The widespread daily use of electronic devices and regular participation in DG form a crucial context for understanding parental concerns about potential negative effects, such as addiction and reduced PA [9]. Given the significant time invested in sedentary screen-based activities, understanding and promoting engagement in PA is increasingly important for the health and well-being of the young age groups [10,11]. Recent findings among physically active university students demonstrate that even short-term interventions can enhance both physical and cognitive performance, underscoring the enduring interplay between activity, recovery, and cognitive function beyond adolescence [12]. With the rise of digital technologies, children's leisure activities have evolved, and DG has become an integral part of contemporary youth culture. While DG has often been scrutinized for its association with sedentary behavior, with some research linking excessive DG to negative health outcomes, such as increased obesity risk and decreased PA levels [13], emerging research suggests potential positive cognitive, emotional, and social effects [14-16]. Indeed, Granic et al [14] argue for a more balanced perspective on video games, suggesting that their increasingly complex, varied, realistic, and social nature may offer real-world psychosocial benefits. They summarize research suggesting benefits across cognitive domains, such as improved attention and visual skills, as well as motivational, emotional, and social gains from DG experiences.

Research by Barnett et al [17] highlights a contrast in perspectives between parents and children, particularly regarding active video games (AVGs) and basic movement skills. While parents often held skeptical views, perceiving AVGs as not a substitute for "the real thing" and having limited benefits for skill development or transfer to real life, children held a more expansive view of reality and reported using AVGs as a learning tool, perceiving skill acquisition as highly transferable [17], especially in the context of alterations needed in society over time [18]. This difference in perception of rather active digital games, wherein parents have expressed concerns regarding screen time and sedentary behavior [13] and have delineated a distinction between the "virtual" and "real" world [17], contrasts with children's perspective of DG as a meaningful social space that fosters autonomy and connection [19]. Considering the increasing complexity and interactivity of modern video games, research needs to move beyond simply labeling them as "good" or "bad" and develop equally complex models to understand their influence on players and which underlying motives contribute to their universal appeal and encourage participation of the young population.

Conflict of Leisure Time—Motivations for PA and Gaming

Understanding what drives engagement in both PA and DG is increasingly pertinent in contemporary society. Gaming in a digital form has become a dominant form of leisure behavior among youth, raising concerns about its potential to displace time that could otherwise be spent on PA. A study by Salmensalo et al [20] found that Finnish vocational students who primarily used PCs for DG were more than twice as likely to exhibit insufficient levels of moderate-to-vigorous PA, suggesting that the DG context and platform may play a role in reinforcing inactivity. Although total DG time was not significantly associated with physical inactivity, the results suggest a conflict hypothesis, which could state that time spent on digital entertainment can compete with PA pursuits. This may be particularly relevant for younger populations, such as children, who face a limited amount of discretionary leisure time. As digital games continue to evolve in complexity and immersive potential, children may increasingly be drawn to screen-based engagement at the expense of PA, creating a behavioral tension between immediate digital gratification and the long-term health benefits of active lifestyles. Related to PA, the primary motivations encompass a range of factors, including the pursuit of improved physical and psychological well-being [21,22], the experience of enjoyment and pleasure [23,24], and the desire for social interaction and support [21] or competition [25]. These motivations can vary depending on individual characteristics such as age and gender [15,21,26,27], as well as the activity undertaken [23].

Similarly, the motivations for engaging in DG are multifaceted, extending beyond mere entertainment or recreation to include the satisfaction of psychological needs such as competence, autonomy, and socialization [15]. Individuals are often driven by the sense of achievement within games [17], the opportunities for social connection and competition [28], and the potential of immersion and escapism into virtual worlds [17]. To comprehensively assess these multifaceted motivations behind DG [15], instruments like the Videogaming Motives Questionnaire (VMQ) have been developed [29] to identify and measure the various underlying motives for playing digital games. An examination of these underlying motivations is

XSL•FO
RenderX

critical for designing effective implications to promote healthy behaviors and for better understanding the profound influence of digital entertainment in our lives [23].

Divergences in Perceptions

A substantial point of divergence exists in the value and purpose attributed to nonactive DG by parents compared to children [7,9,17]. Parents often hold largely negative perceptions of DG, with concerns frequently centering around violent content and the potential for addiction. Further evidence indicates that evening blue light exposure can negatively affect sleep quality, motor function, and cognitive performance in young individuals, highlighting the potential risks of excessive screen use for children's overall well-being [30], which might be seen negatively by parents as well. This aversion can be attributed, at least in part, to what has been termed a "generational difference," which hinders parents' ability to relate to DG [9].

This perspective is in contrast to the multifaceted motivations that children have for engaging with video games. As stated, children engage in DG for the sake of enjoyment, stress reduction, social interaction, the management of boredom, and competition [31]. Martucci et al [15] further delineate a comprehensive array of DG motivations, encompassing recreation, social interaction, coping, violent reward, fantasy, cognitive development, customization, and competition. Moreover, initial findings suggest that children perceive DG as more recreational and skill-enhancing than their parents do [32]. While parents may primarily focus on the perceived negative impacts of DG, existing research highlights potential benefits of DG that parents might overlook [14,33,34]. These include improvements in cognitive skills, motivation, emotion regulation, and social domains. For instance, certain games have been shown to enhance attention and spatial reasoning skills, promote persistence, provide a secure environment for managing negative emotions, and facilitate social interaction [14,35]. Rhodes et al [36] also address a related concern, highlighting that parents perceive screen time, whether active or sedentary, as a potential substitute for other activities they deem more valuable, such as homework, socializing, and sleeping. This observation suggests a more extensive set of concerns among parents regarding the opportunity cost of time allocated to DG.

In contrast, Ng et al [37] found that for children who play sports video games, it can be an important part of their overall "Physical Activity Relationships," potentially linking to their interest in watching sports and participating in PA, for example, children who actively play soccer are also attracted to soccer simulations like EA Sports' EA FC [38]. This finding suggests that some children may perceive a connection between the virtual world of sports-gaming and the real world of sports, a link that parents may not fully recognize or value. Although previous studies have examined differences in perceptions between parents and children in the contexts of DG and PA, these domains have largely been investigated in isolation. For example, Franzò et al [39] identified a discrepancy between how parents and children perceive the emotional impact of DG, with parents expressing more concern and children reporting a more nuanced view. Similarly, Kutner et al [40] found that while children view DG as a socially meaningful activity, parents tend to emphasize its potential negative effects, such as interference with academic performance and reduced socialization. In the realm of PA, Tay et al [41] explored children's motivations for engaging in PA, noting that parental support and access are crucial factors. Ostermeier et al [42] further highlighted parental concerns about decreased PA levels during the COVID-19 pandemic and the importance of peer influence in children's reengagement with active routines. Despite the value of these findings, there remains a notable gap in the literature: to date and to the best of our knowledge, no study has systematically investigated how parent-child perception differences operate simultaneously across both DG and PA domains. Given the increasing relevance of both behaviors in youth development and health, integrative studies bridging these perspectives are warranted [42].

While parents often perceive DG as excessive, violent, or potentially addictive, and thus harmful to their child's well-being [9], children are more likely to see it as a meaningful part of their social world, offering opportunities for autonomy, social connection, and identity development [19].

In conclusion, the perceptions of DG and PA might differ significantly between parents and children. While parents often express concern about DG, focusing on its potential negative impacts, lack of "real-world" value compared to PA, and a generational gap in understanding—children tend to be motivated by fun, social interaction, and skill development. They may also perceive a stronger connection between virtual and real-world PAs. We hypothesize that children are expected to show similar motivational patterns for PA and DG, with only minor differences across specific motives, as the structure of the motives for both activities appears to be similar. Moreover, we hypothesize that parents will perceive higher motivational relevance for PA compared to DG in their children, particularly in dimensions related to PA or social engagement. Lastly, certain motivational dimensions—such as coping or competition—will be rated significantly higher for DG than for PA by children. This study seeks to investigate these divergent perceptions by examining whether parents underestimate the potential positive aspects of DG and how children view both DG and PA as integral parts of their daily lives. By exploring these possible perception discrepancies, this study aims to contribute to a better understanding of DG's role in child development. Based on the hypotheses, two research questions (RQs) were formulated.

RQ1: Do children report different motivational patterns for engaging in PA compared to DG, and which motivational dimensions are more strongly associated with each activity type?

RQ2: To what extent do parents' perceptions of their children's motives for PA and DG align with the children's self-reported motives?

Methods

Recruitment

Participants were recruited at two separate events: the Frühjahrsmesse (spring fair) 2024, held from March 14-17, 2024, in Innsbruck, Austria, and Gamers Heaven, which took

XSL•FO
RenderX

place on September 21-22, 2024, in Telfs, Austria. The aim was to collect data from a broad and diverse sample representing Tyrolean society. The Frühjahrsmesse is an established annual fair featuring exhibitors and family-oriented attractions, while Gamers Heaven was held for the first time and specifically targeted individuals interested in DG. In total, 162 participants participated in the questionnaire on-site using a Samsung Galaxy Tab A (T515) for data collection due to its portability. The complete questionnaire is available in Multimedia Appendix 1 (original-German) and Multimedia Appendix 2 (translated-English), and the item-level statistics are provided in Multimedia Appendix 3. After excluding incomplete or unmatched responses, the final analytical sample comprised 94 participants (49 children and 45 adults), with four adults each participating with two children, resulting in a total of 49 parent-child pairs. The demographic characteristics of the analyzed sample are presented in Table 1. It should be noted that the child sample showed a substantial gender imbalance, with boys comprising the clear majority of participants, which should be considered when interpreting the motivational patterns reported.

Table . Demographic description of the sample.

	Age (y), mean (SD)	Gender, n (%)	PA[a]>5 h/wk, n (%)	DG[b]>5 h/wk, n (%)
Children (n=49)	12.6 (2.9)	10 (20.4) female	14 (28.6)	32 (65.3)
Adults (n=45)	44.4 (5.7)	25 (55.6) female	8 (17.8)	—[c]

[a]PA: physical activity.

[b]DG: digital gaming.

[c]Not applicable.

To link responses from children and adults, both were instructed to enter a matching code at the beginning of the questionnaire. This code was based on a combination of letters and numbers derived from shared personal information: the first letter of the place of birth, the first and last letters of the mother's surname, the first letter of the father's surname, and the sum of birth day and birth month. If an adult accompanied more than one child, their responses were matched with each respective child's data set. The average time to complete the questionnaire was 23.8 (SD 16.9) minutes.

Since this study aimed to explore motives across both domains, the questionnaire was built upon the VMQ [29], which was adapted for PA. The VMQ is a validated tool for assessing DG motivations. Prior studies have indicated the presence of psychological drivers, such as competition, skill development, and enjoyment, that are relevant to PA and DG activities [43]. This study adapts the VMQ to measure children's self-reported motivations for PA and DG, as well as their parents' perceptions, offering a dual-perspective approach to better understand these behavioral patterns. Based on the VMQ, children completed assessments that evaluated 5 psychological scales related to their engagement in PA and DG: recreation, social interaction, coping, competition, and skill. The questionnaire was independently translated from English to German by three researchers. Discrepancies in wording were subsequently discussed collaboratively to reach a consensus, ensuring that the meaning and intent of each question remained as close to the original as possible. Validated for video gaming [29], the questionnaire was modified to PA by replacing the word "video gaming" in the questions with "sport," as a child-friendly synonym for PA. It should be noted that the term sport was deliberately used in place of PA to ensure conceptual comparability with DG, as both represent structured, goal-directed, and voluntarily chosen activities. Hence, the motive scales were designed to be quasi-identical and were administered separately for PA and DG contexts, respectively, to allow for consistent and comparable measurement across the two domains. Moreover, parents were asked to report their perceptions of their children's motivations regarding PA and DG, specifically in relation to the underlying motives driving these behaviors. This allowed for comparisons between both children and parents within each activity type and within each group across the two activity types. The questions were presented in a randomized order within the items, with the starting sequence also varied; for example, some participants began with the PA section followed by the DG section, while others completed the sections in the reverse order.

Ethical Considerations

Prior to participation, written informed consent was obtained from all parents. Participants were informed about the study procedures, the voluntary nature of participation, and their right to withdraw at any time without providing a reason and without any negative consequences. Data were collected anonymously using a tablet-based survey. To allow withdrawal of data after survey completion without recording identifiable information, participants generated a self-created identification code based on predefined rules (eg, initials of parental names and calculated birth date components). This code was not linked to any personal identifiers and could not be traced back to individual participants by the research team. Confidentiality of all participant information was strictly maintained. Participants did not receive any financial or material compensation for their participation. The study was approved by the Board for Ethical Questions in Science at the University of Innsbruck (Certificate 44/2021). All taken procedures were performed in accordance with the Declaration of Helsinki (1964).

Statistical Analysis

Data were collected from children and their parents, with paired data structures employed to ensure that individual child-parent connections could be accurately matched. This approach allowed for direct comparisons between corresponding participants within each family, facilitating more precise analyses of the relationships between PA and DG behaviors. A 3-way mixed

XSL•FO
RenderX

ANOVA was conducted with group (children vs adults) as the between-subjects factor and activity (PA vs DG) and motive (5 motivational dimensions) as within-subjects factors. This design allowed testing for overall group differences, main effects of activity and motive, as well as their 2- and 3-way interactions to examine how motivational patterns varied across activities and age groups.

Moreover, to exploratorily examine differences between children and parents across 5 motivational scales in detail, as well as activity-related differences (PA vs DG) within each group, four separate 2-way repeated measures ANOVAs (2 × 5 design) were conducted. Although a linear mixed-model approach could account for random effects of matched dyads, the ANOVA strategy was chosen due to its interpretability, established robustness with balanced designs, and the primary interest in specific within- and between-group comparisons per motivational scale. The chosen approach allowed for a clear examination of within-subject effects (activity type and scale) and between-group effects (children vs parents), while also enabling follow-up post hoc comparisons. The paired nature of the data was accounted for by conducting repeated measures designs within each group. If Mauchly's test indicated violations of the sphericity assumption, the Greenhouse-Geisser correction was applied. Moreover, all individual post hoc comparisons were corrected for multiple testing using the Bonferroni procedure, ensuring control of the family-wise error rate. To control for inflation of the Type I error rate due to multiple testing across the four ANOVAs, the α level was adjusted to .0125 using the Bonferroni correction. Partial eta-squared (η^2) was reported to quantify effect sizes, and internal consistency of each scale was assessed using Cronbach α. All analyses were performed using SPSS (version 29.0.2.0; IBM Corp).

Sample Size

To determine the required sample size, an a priori power analysis was conducted using G*Power (version 3.1.9.7) for a repeated measures ANOVA with a within-subjects design [44]. The analysis was based on an expected medium effect size of f=0.25, which corresponds to empirical estimates reported by Granic et al [14] video game intervention research, particularly regarding outcomes such as cognitive flexibility, emotion regulation, and persistence. The significance level was set at α=.05 and statistical power at 1–β=.80. The analysis assumed two measurement points (eg, DG and PA motives) and a correlation among repeated measures of 0.5. Under these parameters, the required sample size was calculated to be 34 matched pairs (ie, 68 individuals) to detect a within-subjects effect with sufficient power.

Results

Internal Consistency of Questionnaire

To assess the reliability of the scales used to measure motivational constructs in both PA and DG contexts, Cronbach α coefficients were calculated for each scale. For PA, internal consistency was acceptable to excellent across all scales, with α values as follows: recreation (7 items) α=.780, social interaction (11 items) α=.910, coping (8 items) α=.828, competition (6 items) α=.810, and skill (6 items) α=.731. Similarly, for the DG context, reliability coefficients indicated strong internal consistency: recreation (7 items) α=.841, social interaction (11 items) α=.918, coping (8 items) α=.867, competition (6 items) α=.808, and skill (6 items) α=.782. These results suggest that all subscales demonstrate adequate to excellent internal consistency, indicating reliable measurement of the respective motivational dimensions in both domains.

Comparison of Motives for PA and DG Across Children and Adults

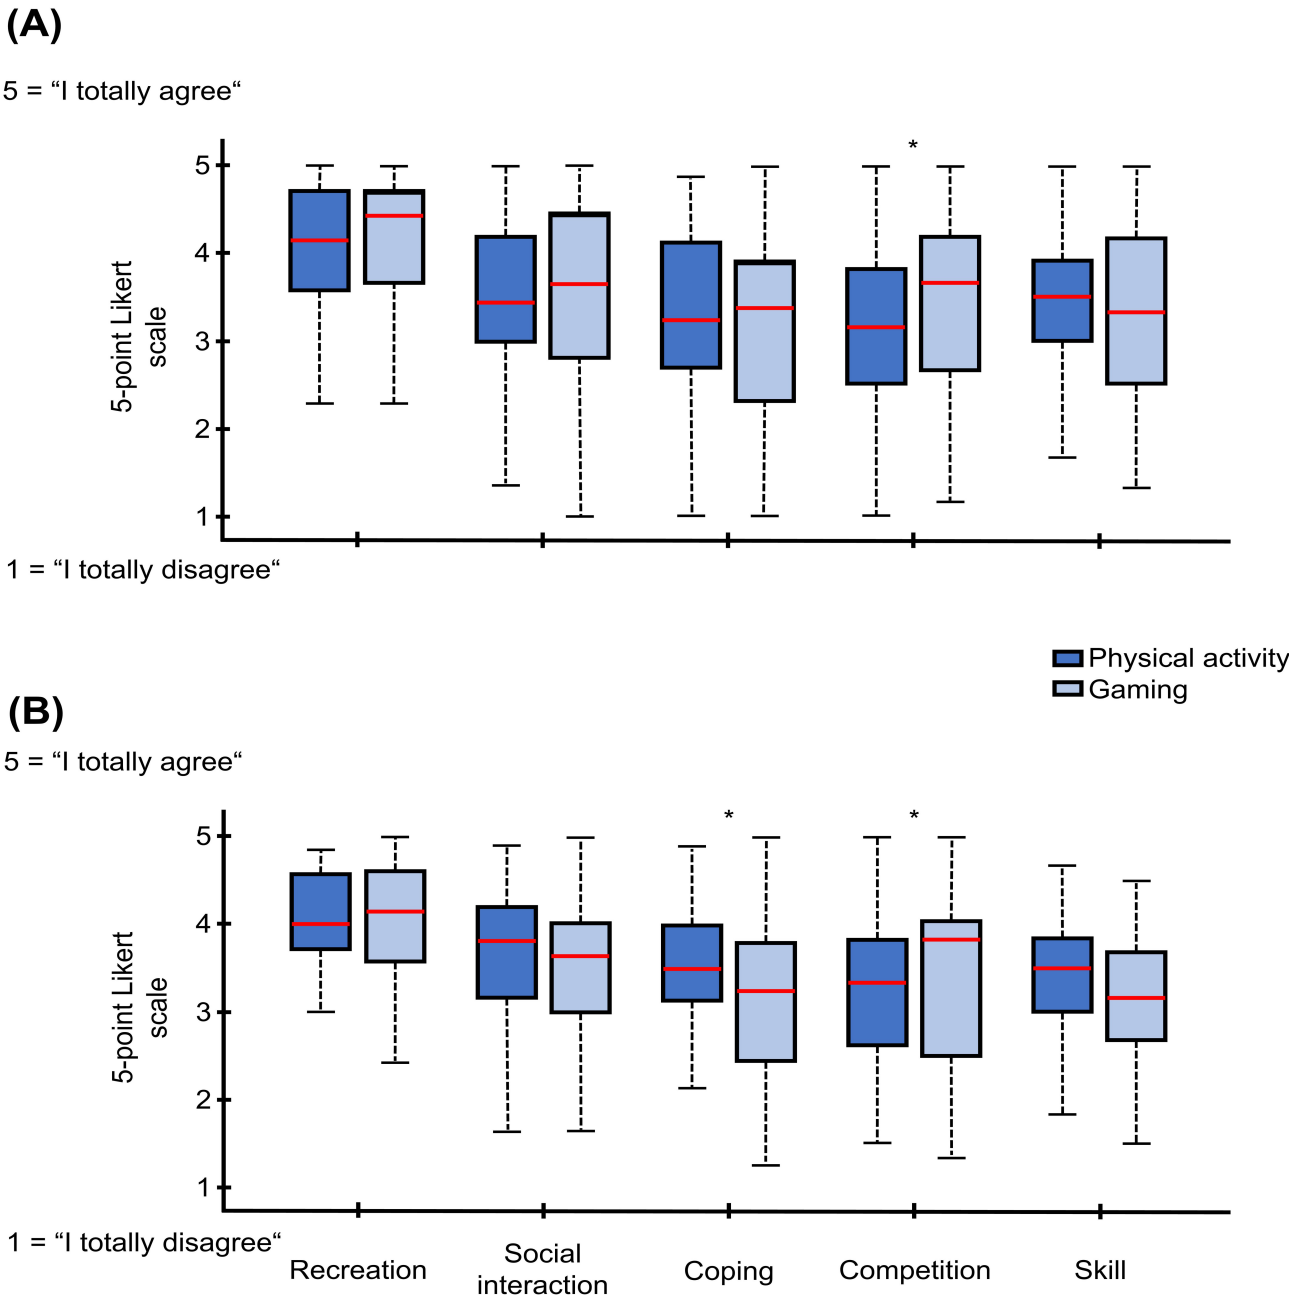
The Greenhouse Geisser-corrected 2 (group: children vs adults) × 2 (activity: PA vs DG) × 5 (motive) mixed ANOVA revealed a significant main effect of motive, $F_{3.416,327.981}$=46.93, P<.001, partial η^2=.328, indicating substantial differences across motivational dimensions. The main effect of activity was not significant, $F_{1,96}$=0.19, P=.66, partial η^2=.002, suggesting similar overall motivation levels between PA and DG.

Importantly, a significant activity × motive interaction emerged, $F_{3.474,333.540}$=7.48, P<.001, partial η^2=.072, indicating that differences in motivation between PA and DG varied depending on the specific motive. Post hoc pairwise comparisons confirmed that motives differed significantly from one another (all P<.001), with recreation and competition being rated higher than coping, social, and skill motives overall.

Neither the main effect of group ($F_{1,96}$=0.07, P=.79, partial η^2=.001) nor any interaction involving group reached statistical significance. Thus, motivational profiles were broadly similar between children and adults, both in overall intensity and in how they differentiated between PA and DG motives.

To examine the robustness of the findings across recruitment sites (Frühjahrsmesse and Gamers Heaven), separate 2 (group: child vs adult) × 2 (activity: PA vs DG) × 5 (motive) mixed ANOVAs were conducted for each location [45]. The analyses revealed highly consistent patterns, with significant main effects of motive at both sites (all P<.01) and no significant main or interaction effects involving group. The activity × motive interaction was significant at the Frühjahrsmesse but not at Gamers Heaven. Overall, the motivational structure was comparable across sites, confirming the robustness of the main results. In sum, across both age groups, participants distinguished between motivational dimensions, and these motives varied between PA and DG. However, children and adults showed comparable patterns. Because the 3-way mixed ANOVA did not yield any interactions involving the group factor, the subsequent analyses were conducted solely to provide a more detailed description of the within-group motivational patterns for PA and DG. For this purpose, separate 2 × 5 mixed ANOVAs were calculated for children and adults. These follow-up analyses are descriptive in nature and are intended to illustrate group-specific profiles. All inferential conclusions are based on the results of the abovementioned 3-way model.

Comparison of Motives for PA and DG Among Children



Multivariate tests revealed a significant main effect of motives, $F_{4,45}$=34.34, P<.001, partial η^2=.753, indicating substantial differences across motivational dimensions. The main effect of

XSL•FO
RenderX

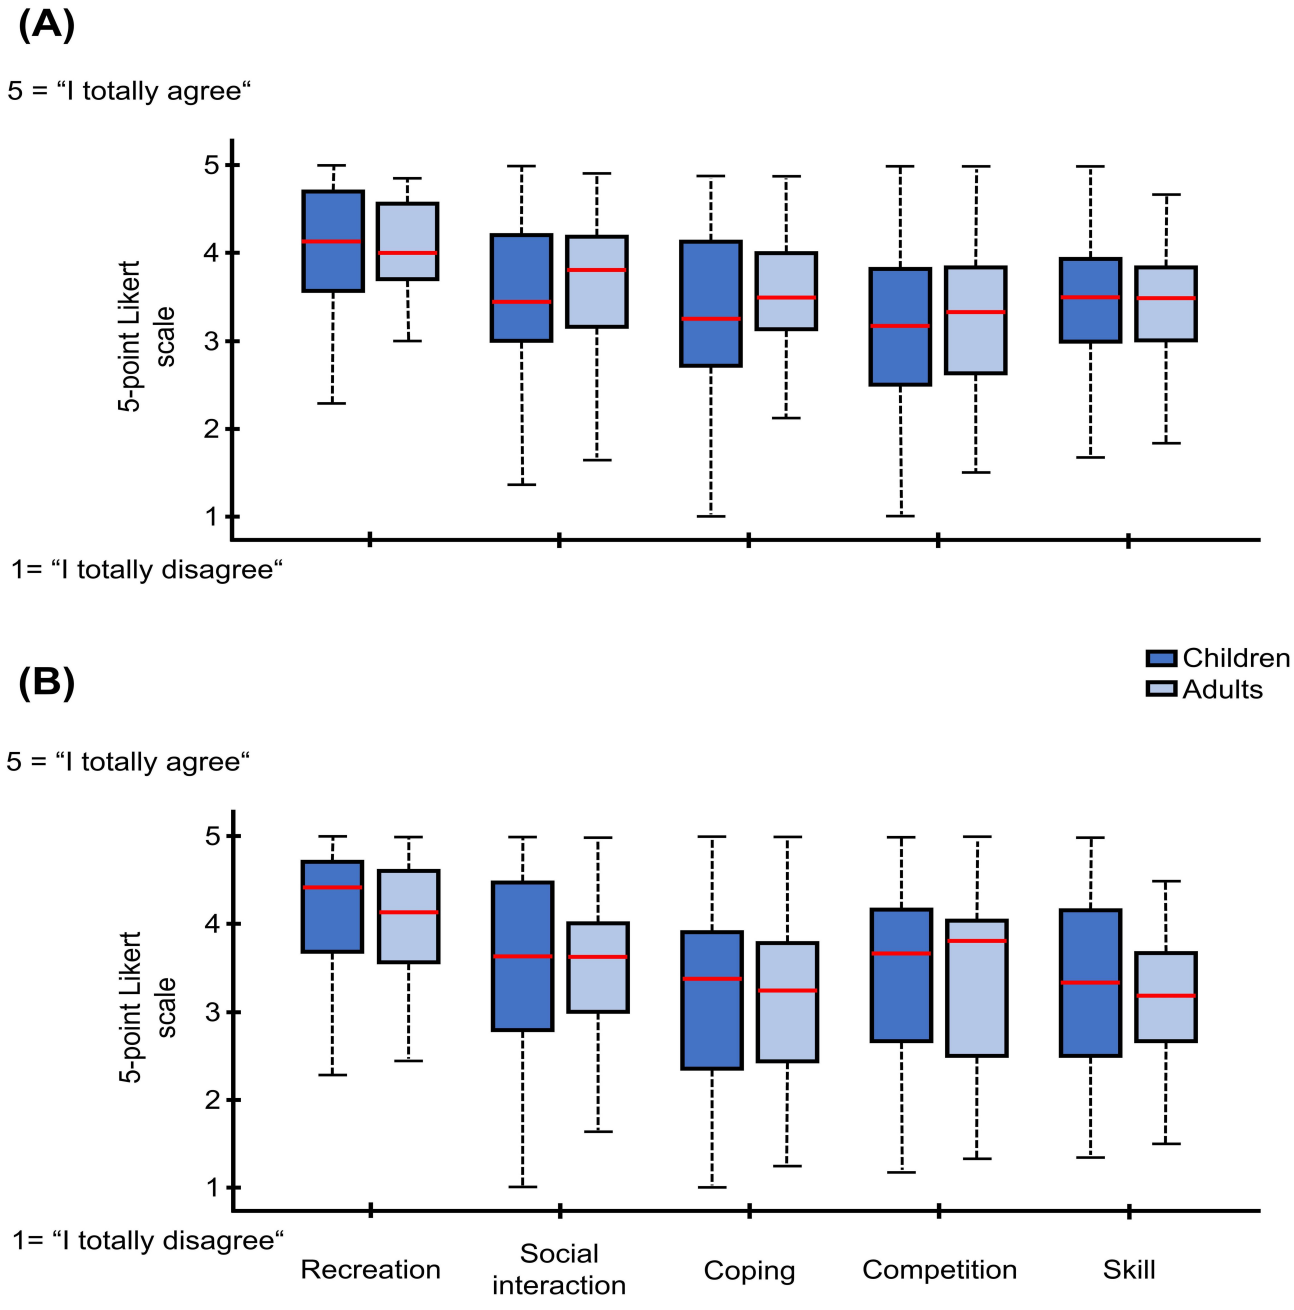
activity was not significant between PA and DG. However, a significant interaction between motives and activity emerged, $F_{4,45}$=3.93, P=.008, partial η^2=.259, indicating that the difference in motives ratings between PA and DG varied depending on the motive. The repeated measures ANOVA confirmed the significant main effect of motive, $F_{3.43,164.57}$=24.41, P<.001, partial η^2=.337. An almost significant motive × activity interaction was also observed, $F_{3.43,164.57}$=3.43, P=.02, partial η^2=.067. The main effect of activity remained nonsignificant, P=.78, across all correction methods.

Simple multivariate tests conducted for each motive revealed that only competition showed a significant group difference, $F_{1,48}$=4.38, P=.04, partial η^2=.084, as children rated DG as significantly more competition-oriented than PA. The results are demonstrated in Figure 1A.

Figure 1. Differences between physical activity (dark blue) and digital gaming (light blue) in relation to the motives recreation, social interaction, coping, competition, and skill are displayed. (A) The differences of children are presented. (B) The results of the adults. Answers to the questions of each motive were given on a 5-point Likert scale. The asterisks (*) indicate significant differences of the post hoc results, which failed to reach significance after Bonferroni correction.

Comparison of Motives for PA and DG Among Adults

For adults, multivariate tests revealed a significant main effect of motives, $F_{4,45}$=20.68, P<.001, partial η^2=.648, indicating substantial differences across motivational dimensions. The main effect of activity was not significant, $F_{1,48}$=1.40, P=.24, partial η^2=.028. Importantly, the interaction between motive and activity was significant, $F_{4,45}$=6.23, P<.001, partial η^2=.356. This suggests that the difference in motivation between PA and DG depends on the specific motive being assessed. The within-subject tests confirmed the main effect of motive,



XSL•FO
RenderX

$F_{3.06,146.71}$=23.36, P<.001, partial η^2=.327. The interaction effect was also significant, $F_{3.37,161.71}$=4.78, P=.002, partial η^2=.090, indicating that motives varied across domains between PA and DG. The main effect of activity remained nonsignificant (P=.24). Separate multivariate tests for each individual scale showed that the largest difference for adults between PA and DG occurred in perceived coping, $F_{1,48}$=4.72, P=.01, partial η^2=.123. Additionally, a significant difference was found for perceived competition, $F_{1,48}$=4.10, P=.05, partial η^2=.079. Other scales did not show significant group differences (all P.15). The results are displayed in Figure 1B.

Comparison of PA Motives Between Children and Adults

Related to PA, multivariate tests revealed a significant main effect of motives, $F_{4,45}$=29.19, P<.001, partial η^2=.722, indicating substantial differences in motives across the five domains. In contrast, the main effect of group was not significant, $F_{1,48}$=0.21, P=.65, partial η^2=.004. The motive × group interaction also did not reach statistical significance, $F_{4,45}$=1.97, P=.12, partial η^2=.149. To further explore potential group differences on individual motivational scales, multivariate tests were conducted separately for each scale. None of the 5 motivational dimensions showed statistically significant differences between children and adults. A visualization of the results is shown in Figure 2A.

Figure 2. Variances between children (dark blue) and adults (light blue) in relation to the motives recreation, social interaction, coping, competition, and skill are demonstrated. (A) The differences related to PA are presented. (B) The results of DG. Answers to the questions of each motive could be given on a 5-point Likert scale.

XSL•FO
RenderX

Comparison of DG Motives Between Children and Adults

By investigating whether motivational profiles differ between children and adults across DG, a significant multivariate main effect of motive was observed, $F_{4,45}$=43.16, P<.001, partial η^2=.793, indicating substantial differences across motivational dimensions. The main effect of group was not significant, $F_{1,48}$=0.95, P=.334, partial η^2=.019. Moreover, the interaction between motive and group also failed to reach significance, $F_{4,45}$=0.32, P=.88, partial η^2=.026. Separate multivariate tests were conducted to explore potential differences between activity types for each motivational scale individually. None of the 5 scales reached statistical significance. The results are demonstrated in Figure 2B.

Discussion

Principal Results

The present study aimed to explore motivational differences in children's engagement in PA versus DG and the extent to which parents accurately perceive these motivations. Drawing on 5 distinct motivational dimensions—recreation, social interaction, coping, competition, and skill—we addressed two research questions concerning motivational patterns, intergenerational perception alignment, and differential associations of specific motives with activity type.

A notable and unexpected finding of the present study was that the analyses did not detect evidence of discrepancies between children's self-reported motives and their parents' perceptions, despite prior literature suggesting meaningful gaps between self- and proxy-reports [7,9,17]. In contrast to this established work, our results showed no statistically reliable divergence between self- and parent-reported motives across activity domains. Importantly, this pattern should not be interpreted as evidence of true parent-child alignment. Following the principles of null hypothesis significance testing, the finding represents an absence of statistical evidence for a difference—not confirmation of equivalence in motivational understanding.

To examine whether this result might reflect a sampling artifact (eg, parents at a gaming-focused event like Gamers Heaven being more attuned to DG), we conducted sensitivity analyses [45] separately for the Frühjahrsmesse and Gamers Heaven subsamples. The motivational patterns were highly consistent across locations: both subsamples showed strong main effects of motive and, critically, no group-related main or interaction effects. The activity × motive interaction presented to be significant at the Frühjahrsmesse but not at Gamers Heaven, which is likely attributable to reduced statistical power due to the much smaller number of matched pairs at the latter site. However, an equally plausible interpretation is that the gaming-affine Gamers Heaven sample may differ systematically from the spring fair sample in ways that influence motivational patterns. In general, this consistency indicates that the absence of parent-child differences should not be attributed solely to recruitment-site characteristics or increased parental familiarity with DG. Nonetheless, several contextual factors may have contributed to the lack of detectable divergence, including shared situational cues during data collection, relatively high parental involvement in the activities assessed, and the inherently observable nature of motives such as recreation or competition. At the same time, subtle differences may exist but remain undetected due to measurement limitations, shared method variance, or limited statistical power for small effects [46]. These considerations emphasize the need for cautious interpretation: the present results indicate that no discrepancies were detected within this sample, but they should not be taken as evidence of robust parent-child congruence in motivational perceptions.

Motivational Aspects of PA and DG

Regarding RQ1, if children report different motivational patterns for engaging in PA compared to DG, the results indicate that children do not report systematically different motivational patterns across the 5 dimensions when comparing PA to DG. However, some tendencies emerged that warrant attention. In particular, competition was rated more strongly as a motive in relation to DG than PA, suggesting it may play a distinct role in driving DG activities. This suggests that the motive of competition—known to be relevant in both PA [25] and DG [28]—may be more strongly fulfilled in DG contexts than in PA settings for children. A possible underlying explanation is the accessibility of modern networked play against human opponents, as seen in formats such as Battle Royale games (eg, "Fortnite") [47] or competitive modes like the Weekend League in "EA FC" [48]. While attending local area network parties back in the days used to require considerable effort, including transporting DG hardware to physical venues, today's competitive DG experiences can be accessed conveniently from home. While the relatively small sample size may limit the generalizability of the findings, the presence of statistically significant effects even under conservative testing procedures indicates that the observed differences are unlikely to result from random variation alone. Thus, although caution is warranted in interpreting marginal effects or visual trends, the detected significant results can be considered meaningful within the scope of the present design and sample characteristics.

Interestingly, the majority of motivational means of children were in general slightly higher for DG across the board, except for motives skill (Figure 1A) and recreation (Figure 2A), which showed reverse patterns. The gaming industry designs games to be highly engaging and, arguably, even addictive [48-50], potentially addressing psychological motives such as recreation and coping. However, while game mechanics can be programmed, genuine social interaction cannot—yet it showed a higher mean value, albeit without reaching statistical significance. The ability to communicate with peers in real time while playing may further enhance the appeal of DG by strengthening social motives. In summary, games have evolved rapidly in recent years, offering a wide variety of experiences that fulfill a range of important psychological needs. Notably, recreation, interpreted as a general intrinsic or personally valued motivation, consistently received the highest ratings across both activities and groups. This supports the notion of a possible "leisure time conflict," where both active and passive behaviors are motivated by similarly strong internal drivers, potentially competing for the child's limited free time [20]. These findings

XSL•FO
RenderX

point to the complexity of children's motivational structures and emphasize that DG as an activity may not necessarily arise from a lack of motivation for PA but from competing, equally compelling motives.

Finally, we examined whether certain motivational dimensions were more strongly associated with either activity. Again, the motive competition emerged as the most activity-specific, being more strongly endorsed for DG by both children and parents. This aligns with prior research suggesting that DG behavior is often motivated by comfort, ease, or relaxation [51,52]. The convergence between generational views on competition adds confidence to this interpretation and underscores its relevance as a potential target for interventions aiming to reduce DG time. Other motives showed relatively balanced activation across PA and DG, further supporting the idea of overlapping and competing motivational structures in leisure contexts. The findings highlight the potentially overlapping nature of children's motivations for PA versus DG activity. The general alignment between children's self-perceptions and their parents' beliefs is promising for family-based intervention approaches. Importantly, the consistently high endorsement of intrinsic motivations like recreation across both activity types reinforces the idea that children are not necessarily passive recipients of screen-based content but are actively motivated by various factors—factors that may also be leveraged to promote PA if carefully aligned.

Focusing on RQ2, to what extent do parents perceive their children's motives for PA and DG correctly, the analysis did not detect statistically significant differences between children's self-reported motives and their parents' perceptions. While this indicates a lack of evidence for systematic discrepancies, it should not be interpreted as evidence of full alignment. The overall pattern suggests that parents' perceptions broadly resembled children's self-reports, though the degree of correspondence may vary across motives, which was not anticipated in that form based on existing literature [7,9,17]. We could not find results, which suggests that parents in the tested sample are generally detached from the reasons why children engage in either activity. In the context of PA, parents are generally considered to be fairly accurate in understanding their children's motives and behaviors [53]. It is plausible that this may also apply to the context of DG, suggesting that parents might be able to perceive and interpret the reasons why their children engage in video games with a comparable level of insight. This could be particularly true for more observable or socially shared motives, such as competition or social interaction, which are easier for parents to recognize. However, some nonsignificant trends pointed to potential perceptual differences. Specifically, the motives of social interaction, coping, and skill were perceived by parents as more relevant for PA than indicated by the children's self-reports, although these differences did not reach statistical significance. This trend may reflect generational assumptions or aspirational biases—parents might attribute more socially or developmentally valued motives like social interaction or skill development to active behavior [9,54]. Although not statistically robust, these trends merit further exploration, especially considering their potential impact on parental support for children's activities and a better understanding of parents related to DG nowadays.

Limitations

Several limitations should be acknowledged. First, although the VMQ [29] was originally validated for video gaming contexts, it was applied to both DG and PA settings in this study. This decision was made as the questionnaire closely aligned with the research questions, and the included motives overlapped substantially with those known to be relevant in PA. It should be noted that the term "sport" was used instead of "physical activity" to ensure conceptual comparability with DG, as both represent structured and intentionally chosen activities. However, this substitution narrows the construct to organized or leisure sport and does not capture the full range of everyday PA (eg, active play, active transport, unstructured movement). As such, the present findings primarily reflect motives for sport participation rather than PA in a broader behavioral sense. Future studies should therefore complement this approach by assessing motivation across the full spectrum of children's PA behaviors. Moreover, the motivational scales used in this study were not validated against objective behavioral measures. Thus, while the results reflect participants' self-reported motives, future research should examine how these relate to actual behavioral engagement in PA and DG. However, future research should aim to validate the VMQ across both contexts. Second, while the sample size was relatively modest, it closely matched the a priori power analysis, which indicated that 68 participants would be sufficient to detect moderate effects. The use of ANOVA and the observed moderate effect sizes (eg, partial η^2) further support the robustness of the findings, especially after Bonferroni-corrected alpha level. Third, a potential sampling bias cannot be entirely ruled out, as data were also collected at the "Gamers Heaven" event, which is an event for analog and DG-affine people. However, efforts were made to minimize bias by approaching a broad and casual family audience directly on site. Finally, the study was limited to the region of Tyrol, which may constrain the generalizability of the results to other populations. However, it presents a first matched-data approach showing the potential competing motives related to PA and DG of children. Lastly, the gender distribution differed between groups, with a lower proportion of female participants among children compared to adults. This imbalance should be considered when interpreting the results, as gender-related differences may have influenced motivational patterns.

Conclusions

These findings highlight the nuanced and multifaceted nature of children's motivational structures. Rather than indicating a lack of interest in PA—or in this study, sport—DG may emerge as a response to equally compelling, but distinct, motivational drivers. This complexity underscores the importance of further investigating these trends—particularly in relation to how they shape parental support for different types of activities. A deeper understanding of contemporary DG motives may also enhance parents' ability to relate to and support their children's engagement in both digital and physical pursuits.

Acknowledgments

We would like to thank the organizers of events Frühjahrsmesse and Gamers Heaven for allowing us to collect data without requiring entrance fees. We are also grateful to Dr Martin Niedermeier for providing statistical support. Furthermore, we used the generative AI tool ChatGPT from OpenAI [55] to assist with language corrections in the manuscript. All generated content was carefully reviewed by the authors, who take full responsibility for the final version.

Funding

This project was partially funded by the Sports Research Lab Tirol and Open Access Publishing Fund of the University of Innsbruck; however, the funder had no influence on the analyses or the interpretation of the results.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to institutional data protection policies and participant privacy considerations. However, deidentified data may be made available by the corresponding author upon reasonable request.

Authors' Contributions

FW contributed to the investigation, methodology, conceptualization, data curation, formal analysis, and writing of the original draft. NG and RMA contributed to the investigation, methodology, conceptualization, and writing sections of the original draft. NG, RMA, and SK were involved in data curation, as well as in the review and editing of the manuscript. MS was responsible for funding acquisition, project administration, resource provision, and supervision. All authors critically revised the manuscript, approved the final version for submission, and agree to be accountable for all aspects of the work.

Conflicts of Interest

Abstract

Background: Anxiety and depression are among the most prevalent mental health problems affecting adolescents. Digital mental health interventions have emerged as promising means of addressing these challenges. Understanding adolescents' experiences and perspectives, and incorporating them into intervention design, can enhance their relevance, engagement, and effectiveness, ensuring interventions meet young people's needs.

Objective: This qualitative study aimed to identify how adolescents aged 16-19 years engaged with 2 distinct interventions (Bite Back [Black Dog Institute] and Project YES [Youth Empowerment & Support; Lab for Scalable Mental Health and Koko]). It explored (1) barriers and facilitators to engagement, (2) young people's preferred design features and content, and (3) perceptions of their potential usefulness and helpfulness.

Methods: Adolescents aged 16-19 years living in the United Kingdom were eligible to take part and were recruited through a university and a charity using convenience sampling. The final sample comprised 22 participants aged 18-19 years. They were asked to use Bite Back and Project YES for 30 minutes each over a 2-week period. Following this, 1-hour semistructured online interviews were conducted between January and March 2025. Anonymized transcripts were managed in NVivo (version 14; Lumivero) and analyzed using a pragmatic, inductive thematic analysis.

Results: Seven themes were identified that captured young people's views on factors influencing engagement, preferred design features and content, and the perceived usefulness of digital mental health interventions. Participants' views were shaped by whether the content felt age-appropriate, culturally relevant, and relatable, and by how clear and transparent the interventions were. Interactive, visually appealing, and tailored features were generally preferred. Although most participants found Bite Back helpful, useful elements were identified in both interventions.

Conclusions: This study contributes to the growing understanding of how young people engage with digital mental health interventions by identifying a set of interconnected factors that influence young people's experiences. It highlights the importance of designing interventions that align with young people's stage of life, culture, and experiences. Even small age differences appeared to influence how relevant the interventions felt to the individual. Furthermore, involving young people in co-design and ensuring clear, accessible communication may support trust and engagement, ultimately enhancing the benefits of such interventions.

Introduction

Background

The prevalence of mental health problems is estimated at almost 14% among individuals aged 15-19 years, representing the highest rate across all age groups up to 24 years [1]. According to the Global Burden of Disease study by the Institute for Health Metrics and Evaluation (IHME), anxiety and depression account for approximately 40% of these cases [2]. Adolescents with anxiety or depression often experience persistent sadness, irritability, low energy, or hopelessness [3-7], which can lead to social withdrawal, school avoidance, poor academic performance, and various health-related challenges [8-11]. When such difficulties occur during adolescence, a period of critical developmental changes, including identity formation, emotional regulation, and evolving social relationships [12-18], they can negatively shape future well-being. Without appropriate support, these challenges may persist into adult life, negatively affecting employment opportunities, interpersonal relationships, and overall quality of life [19-25].

Early intervention is essential, both to prevent the worsening of symptoms and to reach young people during a critical developmental stage, particularly as an increasing number of adolescents are experiencing anxiety and depression [26-30]. However, public mental health services frequently involve long waiting times [31,32]. In the United Kingdom at the end of 2023, only about one-third of adolescents with referrals to Child and Adolescent Mental Health Services (CAMHS) were able to access support within a year [33]. These delays highlight a gap between the growing demand for mental health services and the limited capacity of available professionals [34], creating barriers to accessing care. This problem can disproportionately affect individuals from ethnic minority groups or disadvantaged socioeconomic backgrounds, who may be more likely to experience such mental health difficulties [35,36]. Digital mental health interventions offer a promising avenue to bridge this gap, reduce inequalities, and deliver timely, accessible support to those who need it most.

The widespread use of digital devices, with as many as 96.5% of young people aged 12-17 years owning a smartphone in the United Kingdom [37], has paved the way for new approaches to delivering mental health support. Among these, digital interventions have emerged as valuable tools for helping young people manage anxiety, depression, and other mental health challenges [38]. Such tools can further offer the privacy, convenience, and flexibility that many young people seek [39-41], making mental health support more accessible. In addition to meeting the needs of young people, digital mental health interventions also offer a cost-effective approach [42] that could help alleviate the burden on mental health services by complementing existing care. By improving mental health literacy, these tools can also equip adolescents with skills required to better manage their symptoms and recognize when to seek professional help [43,44].

A wide range of digital mental health interventions has been developed in recent years, including those targeting anxiety and depression in adolescents [45-49]. These interventions are primarily delivered through mobile apps (eg, We Click [UNSW Sydney Brain Sciences] [50], CARE [Child and Adolescent Research in Emotion Lab] [51], and MoodHwb [Cardiff University] [52]), websites (eg, Grasping the Opportunity [53], An Enhanced Psychological Mindset Session [54], and MoodGYM [55]), or online platforms (eg, BetterHelp and Thriveworks). They draw on a variety of theoretical frameworks, such as positive psychology (eg, Bite Back [Black Dog Institute] [56]), mindfulness (eg, CARE [51], Tita [University of Turku] [57]), and growth mindset (eg, Project YES [Youth Empowerment & Support; Lab for Scalable Mental Health and Koko] [58] and Shamiri [Shamiri Institute] [59]), among others, but cognitive behavioral therapy (CBT; eg, Stressbusters [team from Manchester, The Institute of Psychiatry, London and Australia] [60], CATCH-IT [Competent Adulthood Transition with Cognitive Behavioral, Humanistic, and Interpersonal Training; University of Chicago] [61], and SPARX [The University of Auckland] [62]) remains the most commonly used framework. Digital interventions can address a broad spectrum of mental health challenges, such as eating disorders [63], posttraumatic stress symptoms [64], or sleep problems [65,66]. Some tools are intended for individuals with neurodevelopmental disorders [67] or chronic diseases [68], whereas others are aimed at the general population or at individuals experiencing elevated symptoms, as a form of prevention [69] or early support [70]. Some serve as a medium for delivering conventional therapy [71] or are designed to complement traditional approaches by offering additional resources or activities between sessions (eg, ChilledOut Online [Macquarie University] [72]), whereas others are intended to function independently, without direct support from a mental health professional [73].

Despite the growing number of such interventions, there remains a significant gap between their development, rigorous evaluation, and application in real-world settings. While many digital mental health interventions are publicly accessible, a substantial number have not undergone empirical evaluation [45,74,75], raising concerns about their effectiveness and safety. At the same time, few digital interventions targeting anxiety and depression that have been evaluated in research studies are actually implemented or widely accessible outside research settings [69,73,76]. Additionally, such interventions are still seldom developed with the involvement of the target population, which may limit their effectiveness [77-80]. This highlights a need for co-designed, practical interventions that are both evidence-based and accessible to adolescents beyond controlled research environments.

While assessing the effectiveness of an intervention is crucial, the success of digital mental health interventions also depends on how adolescents engage with them in real-world contexts. Even the most well-designed tools can fall short if they fail to capture users' attention, meet their needs, or resonate with their lived experiences. Research has shown that adolescents often disengage from digital interventions due to issues such as limited interactivity, concerns about privacy, or unclear and unrelatable content [81-83]. Engagement itself is a complex construct that goes beyond simple metrics such as usage frequency or duration. It is important that user interactions with the intervention are

XSL•FO
RenderX

meaningful and sufficient to support positive behavior change [84]. Therefore, investigating targeted user experiences with the interventions is essential to ensure that digital mental health interventions are effectively engaging and consequently beneficial for those experiencing mental health difficulties [85].

Existing qualitative evidence has highlighted that adolescents value interventions that feel relevant to their age, culture, and experiences [81-83,86,87]. Interactive and personalized features, ease of use, privacy, flexibility, and confidentiality further support engagement with interventions [82,83,87,88]. Concerns about privacy and perceptions that interventions are overly text-heavy or too clinical have been identified as barriers to engagement [82,89]. This supports the view that qualitative research plays a vital role in understanding adolescents' experiences and perspectives on digital mental health interventions. User feedback obtained through qualitative methods helps ensure that interventions remain engaging, relevant, and responsive to the specific needs of adolescents [90]. Thus, understanding individual perspectives can provide deeper insights into what makes digital interventions acceptable, meaningful, and helpful, and further inform the refinement of intervention content and design beyond what quantitative measures alone can capture.

This qualitative study aimed to examine young people's views and experiences of 2 distinct digital mental health interventions (Bite Back [56] and Project YES [58]) designed to address anxiety and depressive symptoms. Both interventions were used as reference points for adolescents and were not directly compared to one another because they differ considerably in design and content. The study explores key factors that influence how young people in the United Kingdom interact with these interventions, including specific features and content they may find beneficial or unhelpful, their preferences, and perceived usefulness and effectiveness. By examining the views of users who differ slightly in age and culture from the original target user population, this study seeks to contribute to our understanding of potential barriers to implementation and the need for adaptation of user-centered digital mental health interventions, supporting efforts to enhance their accessibility, relevance, and impact for a wider range of young people.

Research Questions

This study was guided by the following research questions: (1) What are the barriers and facilitators to engagement with 2 distinct interventions (Bite Back and Project YES) among UK users aged 16-19 years? (2) What are young people's preferred design features and content when comparing Bite Back and Project YES? (3) What are young people's perceptions of the potential usefulness and helpfulness of Bite Back and Project YES for their mental health?

Methods

Ethics and Preregistration

Ethical approval was granted by the University of Bristol ethics board (reference number 21829), and the qualitative study protocol was registered on the Open Science Framework (OSF) [91]. This paper adhered to the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist [92].

Participants

This qualitative study explored participants' experiences of 2 distinct mental health interventions through 1-hour semistructured online interviews, analyzed using pragmatic thematic analysis. Adolescents aged 16-19 years living in the United Kingdom, with access to a smartphone or laptop and an internet connection, were eligible to take part in the study. Twenty-two adolescents aged 18-19 years were included in the final sample. Those who reported experiencing mental health symptoms that severely impacted their lives or who had ever been hospitalized due to mental health–related reasons were excluded from the study. These criteria were chosen primarily to complement the "Sleep Well" study, which recruited a nonclinical sample of mostly 16-18-year-olds. This age range was slightly expanded to include young people just above the age range in which Bite Back and Project YES had previously been evaluated, to explore how these interventions were experienced by slightly older adolescents.

Procedure

Convenience sampling was implemented due to recruitment challenges, and as a result, purposive sampling based on age and ethnicity was not feasible. Most recruitment was facilitated through a university's experimental-hours scheme, through which psychology students can earn course credit for participation in research. Five mental health charities working with adolescents were approached; only 1 agreed to assist with recruitment, while the remaining charities were unavailable. Interested adolescents first completed an online eligibility questionnaire. Those who met the inclusion criteria were invited to a brief video call with the researcher (via Microsoft Teams). During this call, which was not recorded, participants verified their nationality and age by presenting a valid photo ID. Eligible participants then received a Qualtrics (Qualtrics International Inc) link to the consent form and additional well-being, anxiety, and depression questionnaires. No relationship with participants was established prior to the start of the study. Participants received a £20 (£1=US $1.26 as of March 2025) Love2shop voucher or 2 experimental hours credits to compensate them for their time spent using the interventions and participating in the interview.

Participants provided consent and completed questionnaires (see Standardized Measures section) before they gained access to the interventions. They were then invited to engage with Bite Back and Project YES for a total of approximately 1 hour (30 minutes with each intervention) over a 2-week period, in the order they preferred. This duration was chosen to ensure that all participants had comparable exposure to both interventions while taking into account their academic commitments and the single 30-minute-session design of Project YES. As both interventions were freely available external programs, the actual time spent using the interventions was not formally tracked. Following this 2-week period, participants took part in a 1-hour, semistructured online interview that explored their views and preferences regarding these interventions.

XSL•FO
RenderX

Sample Size Justification

To determine a sample size for this study, the concept of "information power" was applied [93]. This study incorporates relatively narrow aims and a fairly specific sample, focusing on UK adolescents aged 16-19 years and their views and experiences of 2 distinct digital mental health interventions. However, the use of convenience and purposive sampling to recruit participants may limit how targeted the sample could be. In addition, the study is not guided by a single established theoretical framework. Although the data were generated through 1-hour semistructured interviews that support rich interview data, both PK and MC were novice interviewers with some prior interviewing experience. Inductive thematic analysis is used to identify patterns across participants' accounts. Taken together, these factors indicate that a sample size of 20 participants was considered adequate to provide the necessary information power to fully address the research questions.

Interventions

Bite Back and Project YES were chosen through a systematic review [73] that was conducted as part of the "Sleep Well" study (ISRCTN14480620) [94], which focused on creating stepped care that aimed to help adolescents with their sleep, anxiety, and depressive symptoms. Within this review, both Bite Back and Project YES were identified as promising interventions based on effectiveness, risk of bias, and real-world applicability, and were the only freely available options in this category [73]. This evaluation was conducted independently, with none of the authors having any investment in either intervention.

Bite Back

Bite Back is a web-based positive psychological program developed at the Black Dog Institute in Australia. This interactive and self-guided 6-session program was designed to promote well-being and enhance resilience among young people aged between 12 and 18 years. Bite Back was not originally developed in collaboration with its intended user group. This intervention was openly accessible and has been evaluated through randomized controlled trials, demonstrating significant improvements in well-being, resilience, and life satisfaction as well as reductions in anxiety and depression symptoms in a nonclinical sample [56]. The Black Dog Institute in Australia offers further information about the Bite Back program on its website [95]. However, following completion of the study, the program itself is no longer accessible.

Project YES

Project YES is a freely available web-based program created by researchers at the Lab of Scalable Mental Health at Northwestern University, United States. This self-guided program comprises 4 single sessions, approximately 30 minutes in duration: Project Personality, the Action Brings Change (ABC) Project, Project CARE, and Project RISE. The sessions were based on the growth mindset, behavioral activation, self-compassion, and minority stress theories and were developed to support the mental health of young people aged 11-17 years. A recent randomized controlled trial demonstrated significant reductions in symptoms of anxiety and depression, hopelessness, and restrictive eating [58]. While the original version of the intervention was not developed with input from the target user group, subsequent adaptations of the intervention have been co-designed with young people [96]. More information about Project YES, which remains openly accessible, can be found on the Lab for Scalable Mental Health website [97].

Data Collection

Overview

Data collection took place between January and March 2025 and was conducted by 2 female researchers (PK and MC). Interviews were automatically recorded via Microsoft Teams. Participants took part in a one-hour, one-to-one semistructured online interview guided by a topic guide (Multimedia Appendix 1), which was developed by the research team based on the research questions and content of both interventions. The topic guide was refined after the first few interviews to ensure clarity and relevance. Participants were initially asked about their experiences with Bite Back, followed by questions about Project YES. The topic guide comprised open-ended questions exploring participants' experiences using the interventions, including engagement, usability, perceived helpfulness, and suggested improvements. If time permitted, an additional think-aloud component was included, in which participants were presented with screenshots of selected pages from the interventions and prompted to spontaneously verbalize their thoughts and impressions. This component aimed to elicit additional insights into specific elements of the interventions that participants might not have recalled spontaneously but could discuss when visually prompted. Recorded interviews were transcribed, and all identifiable information was removed to ensure participant anonymity. Following transcription, video and audio recordings were securely deleted.

Standardized Measures

Standardized questionnaires administered at baseline, before participants engaged with the interventions, along with demographic data (ie, age, gender, ethnicity, and parents' highest level of education) were used to better understand and describe the study sample. This information allowed us to contextualize participants' views and experiences of the interventions and to indicate the range of mental health presentations represented within the sample. The following measures were used:

Well-Being

Mental well-being was assessed using the Short Warwick-Edinburgh Mental Wellbeing Scale (SWEMWBS) [98,99]. The SWEMWBS is a short version of the Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS). The SWEMWBS is a self-administered questionnaire consisting of 7 items that assess mental well-being using a 5-point Likert scale. Higher scores suggest more positive mental well-being. A reliability of α=.86 was reported for 16-19-year-olds [99].

Anxiety and Depression

Anxiety and depression symptoms were assessed using the Revised Children's Anxiety and Depression Scale–25 (RCADS-25) [100]. The RCADS-25 is a short version of the RCADS. The RCADS-25 is a self-administered questionnaire

XSL•FO
RenderX

consisting of 25 items that assess anxiety and depressive symptoms using a 4-point Likert scale (never, sometimes, often, and always). A higher score indicates more severe symptoms, with a cutoff point of 65 suggesting borderline clinical symptoms. A reliability of α=.86 was reported for 6- to 18-year-olds [101]. Although traditionally validated for individuals aged 8-18 years [100], emerging research has demonstrated its validity in 19-year-olds, supporting its appropriateness for this study population [102]. Thus, to maintain methodological consistency across the entire sample of 16- to 19-year-olds, this tool was selected as the sole measure.

Data Analysis

An inductive thematic analysis [103] using a pragmatic epistemological approach was adopted, allowing the researcher to actively construct themes from qualitative data while ensuring that the findings reflected participants' perspectives without using a preexisting framework. The themes remained closely grounded in participants' views and experiences and, consistent with a pragmatic approach, focused on findings of practical relevance for intervention development and improvement. Data analysis was conducted independently by the primary researcher (PK), who had prior training in qualitative research methods. All authors were involved in discussing and refining the coding framework to enhance the credibility of the findings. The process followed the step-by-step approach to thematic analysis outlined by Braun and Clarke [103]. This involved familiarization with the transcripts, development of initial codes, and an iterative process of grouping and refining patterns across the dataset until the final themes were established. NVivo (Lumivero) software was used to manage the data [104].

As a researcher with a background in psychology and an interest in improving young people's mental health, the primary researcher (PK) approached this study with a strong belief in the potential benefits of digital interventions. While PK had no affiliations with the digital mental health tools studied in this project, her personal interests may have influenced how she interpreted participants' experiences, particularly if she unintentionally elicited or prioritized positive feedback. PK strove to balance her personal interest in improving mental health with an open-minded approach to understanding young people's views and preferences. The potential influence of the researcher's positionality, prior assumptions, and values about the topic was addressed through ongoing reflection, grounding interpretations in the interview data, and actively looking for examples that did not fit the developing patterns.

Results

Participants' Characteristics

The results are based on 22 interviews. Most participants were White (n=16, 73%), 5 (23%) identified as Asian or Asian British, and one (5%) identified as having a mixed ethnic background. Participants were either 18 years old (n=8, 36%) or 19 years old (n=14, 64%). The majority were women (n=18, 82%), and most had no prior experience with online mental health interventions (n=15, 68%). Almost all participants had low-severity scores for depression (n=19, 86%), anxiety (n=20, 91%), and total RCADS-25 (n=19, 86%) scores, indicating that symptom levels were within the nonclinical range. Participants' mean SWEMWBS score was 23.35 (SD 3.13), with higher scores indicating more positive mental well-being [105]. Detailed participant characteristics are presented in Table 1.

Theme 1: Relatability

Relatability refers to whether participants felt that the interventions were relevant to their age, personal experiences, and the cultural references used within the content. Interventions targeted at younger audiences, those containing culturally mismatched information, or those failing to reflect participants' lived experiences could affect young people's engagement. See Figure 1 for an overview of all identified themes.

Figure 1. Visual representation of themes.

Participants frequently reflected on whether the tone, language, and content of the interventions felt appropriate for their stage of life. Many felt that some parts were targeted toward a younger audience, such as secondary school students. They reported that the information was overly simplified or that the language felt too basic. While most participants found this off-putting, others appreciated content that was accessible, clear, and welcoming to a range of age groups. A few described how more complex or mature content would have made it feel more suitable for them and encouraged them to continue using the intervention.

> *So just felt like it was aimed at someone much younger than me who might need help understanding certain terms.* [Participant 19, female, 19 years old, about Project YES]

> *I mean, I can imagine maybe people like my age or slightly older will probably be the age where people start thinking, oh, this is a bit childish, but for me personally, I liked it.* [Participant 15, female, 19 years old, About Project YES]

> *I think it might have been slightly younger than my age demographic, maybe by a few years, but that didn't make it boring or anything. I still thought it was quite good.* [Participant 12, female, 19 years old, about Bite Back]

> *Cause of how simply they were trying to describe things like your strengths or like your social connections, […] like defining everything and then that's what made it seem like less age appropriate.* [Participant 19, female, 19 years old, about Bite Back]

Familiarity with cultural references also influenced how relatable participants found the interventions. Some individuals found it difficult to connect with content that included Australian or US-based brands, examples, or language rather than references that felt familiar within a UK context. However, not all participants mentioned such cultural discrepancies.

> *It's very I think Australian, not British. And lots of the token things where you could choose which brands you liked. I don't think I recognized any of the brands.* [Participant 11, female, 18 years old, about Bite Back]

> *Like it's targeted toward, like, an American audience like it asked: Are you in high school? […] Are you this and I'm not. So, it did obviously feel a bit […] distance from that!? It's like I did feel like it wasn't*

XSL•FO
RenderX

> *made for like a tailored British audience.* [Participant 8, male, 19 years old, about Project YES]

Some participants indicated that other people's experiences made the intervention feel more personal. However, others pointed out that, although the stories felt like a valuable component of the intervention, they became less impactful when unrelated to their current stage of life.

> *I think it makes it a bit more specific, and it also gives you actual real-world examples of it instead of just concepts that are floating about. […] But then because there was so many of them and a lot of them were very similar, they were all in like kind of a similar setting, similar situations that got a bit repetitive and boring* [Participant 1, male, 18 years old, about the personal stories in Project YES]

> *Some stories I probably connected to, and I understood, whereas other ones that I was less connected to, I got bored so […]. Yeah, but the relevance of the story to my own experiences was a big factor in whether I felt engaged with it* [Participant 8, male, 19 years old, about Project YES]

> *Maybe if they used like examples that were a bit more relevant to someone who's older.* [Participant 9, female, 19 years old, about both interventions]

Some participants queried the inclusion of questionnaires at the beginning of the interventions. They expressed uncertainty about their purpose and how, or whether, the responses were used. For these participants, the questionnaires felt unnecessary and uninformative. Although questionnaires in both interventions were not used for tailoring, Bite Back users received some feedback depending on their scores, which some participants valued. However, most participants did not question the relevance of these questionnaires.

> *It was sort of like you just did the quiz at the start and then it was not mentioned again. Yeah, 'cause, I think it would provide more relevance to you actually having to do it at the start rather than just doing the quiz and then like forgetting about it* [Participant 12, female, 19 years old, about Project YES]

> *One part I liked about the Bite Back one was that they did give you a quiz at first and then gave you a score. So, I think Project YES could probably do something like that. I liked it because it kind of gave me an idea about like how I was about like each specific topic and then from that, I can like move on to the activities and the videos* [Participant 3, female, 18 years old, about both interventions]

Theme 2: Transparency

Transparency relates to the clarity of instructions, openness about participants' data use, and the reliability of the interventions' content. A lack of clarity around what the tasks involved or where participants' information was going could affect adolescents' willingness to fully engage with the interventions.

A few participants highlighted that the statistical content provided in Project YES made the information feel more legitimate and helpful. This was the only aspect of either intervention that participants specifically identified as contributing to a sense of reliability.

> *I kind of like the statistics. I think 'cause it made it kind of seem more legitimate when they added all of that.* [Participant 9, female, 19 years old, about Project YES]

> *Like I think it can make you feel a lot like, […] say if you're doing this and you think you're a minority or you think you're like really strange or something and then you see statistics that like, oh, most people think this or most people are in the same boat. I do think it makes you feel more like you're not just a weirdo* [Participant 1, male, 18 years old, about Project YES]

Several participants expressed uncertainty about what would happen to the information they shared. Some felt uneasy when the intervention did not clearly explain how their responses would be used or stored. This lack of clarity could lead to discomfort, which might act as a potential barrier to engagement.

> *During the session, it didn't really explicitly say where the information was going, and that was quite off putting* [Participant 11, female, 18 years old, about Project YES]

> *I had to put like I don't know like my post code and all these other information. Why does a mental health intervention need me to make an account and put my address and my phone number in. So yeah, it put me off* [Participant 8, male, 19 years old, about Bite Back]

A few participants suggested that clearer guidance on how to begin and navigate the interventions would be helpful. They described moments of uncertainty about how to start tasks or move through sessions. These suggestions highlight the importance of having explicit, well-structured instructions to support smoother engagement.

> *[What could have made it easier to use?] Perhaps making it more clear like that is going to be over a few weeks and what it's actually trying to do and how it's going to help you.* [Participant 14, female, 19 years old, about Bite Back]

> *Perhaps like for example with the name thing again, like it might have been a bit easier if there was like instructions at the top saying like oh, only put one name.* [Participant 13, female, 18 years old, about Bite Back]

Theme 3: Design and Usability

Design and usability refer to the structure, presentation, and navigation of the interventions. Adolescents commented on the visual appeal, clarity of layout, and how easy it was to use and understand the content. A user-friendly layout, inviting appearance, and clarity of delivery could influence how adolescents interacted with the interventions.

Participants addressed the tone and presentation of the interventions. Bite Back was generally described as inviting,

XSL•FO
RenderX

welcoming, and engaging, while Project YES was occasionally seen as more like a formal survey or test. Some participants who described feeling this way about Project YES also noted that it made them feel bored. A welcoming and well-structured website may influence the level of user participation.

> *I felt quite a nice, like, warm, like, welcoming feel to it.* [Participant 13, female, 18 years old, about Bite Back]
>
> *I felt like I was just doing a survey, but how it was like structured, it felt like a test rather.* [Participant 19, female, 19 years old, about Project YES]

Participants commented on the formatting and structure of the interventions. Bite Back was described by some as professional and well-designed. A few participants noted that the weekly format and content organized in smaller chunks made the sessions feel shorter and easier to follow. A few also noted that the weekly format made it easy to forget about the intervention. One participant said they would have preferred that the content take up more space on the screen.

> *It wasn't just like reading words, there was audios and interactive activities with the typing and everything.* [Participant 12, female, 19 years old, about Bite Back]
>
> *It had the weeks, so it was like the sections that you could do. I thought it was nice because it organized them into little chunks.* [Participant 4, female, 19 years old, about Bite Back]
>
> *I think it was quite good. I quite like the reading because it wasn't like that much to read. While sometimes you might find yourself like having to read like an entire page and then you get lost. I liked how concise the information was.* [Participant 19, female, 19 years old, about Bite Back]

In contrast, participants described Project YES as having a simpler design. Some said the platform was not user-friendly and mentioned that scrolling through pages was a long process. The presentation was occasionally compared to a textbook or "Wikipedia" page, and some felt that the large number of slides with minimal information elongated the experience. Suggestions included reducing the amount of text and making it more interactive.

> *I feel like it's just plain black and white, it has like a little photo. It gives very for me textbooky or like Wikipedia vibe.* [Participant 9, female, 19 years old, about Project YES]
>
> *I think it was quite focused on like questionnaires and things like that. I think it would have been, it could have been more interactive.* [Participant 12, female, 19 years old, about Project YES]

Both interventions were described by many participants as easy to use. Bite Back was reported as having clear instructions, a straightforward interface, and short, accessible activities. Some said it was easy to start using and to return to the page if they had to leave. However, a few participants mentioned that logging back in required effort, and one noted that signing up took time. Others described needing to refresh the website or listen again to audio to be able to move to the next week's session when the connection was lost.

> *I thought the interface, was very easy to use. It wasn't too, like overwhelming with information or anything like that.* [Participant 2, female, 18 years old, about Bite Back]
>
> *It wouldn't let me click on to the next page like, even though I listened to the whole audio, I clicked to go to the next page and it wouldn't let me on. So I had to listen to audio again.* [Participant 8, male, 19 years old, about Bite Back]

Several participants said Project YES was easy to start using because no login was required, and some described the interface as clear and the navigation as straightforward. Others, however, said it was less easy to use, with one reporting difficulty navigating through the sessions and another stating it took more effort to use than Bite Back. A few participants also mentioned that getting through the sessions was a long process. Difficulties with logging in or navigating could create barriers to participants' engagement with the interventions.

> *I think it was easy. I don't remember having to go through the same login process as I did with Bite Back, so that was good.* [Participant 11, female, 18 years old, about Project YES]
>
> *It was quite easy once you like started doing the session. So then it's kind of like, there's not much to like, accidentally click on. It's like you just go next, next.* [Participant 19, female, 19 years old, about Project YES]

Visual elements such as colors, fonts, and images contributed to how appealing and approachable the interventions felt. Participants described the colors and variety of fonts as uplifting and inviting. Images, especially cartoons or symbolic visuals, were positively received when they complemented the session content.

> *I like the colors, it just makes it seem less depressing.* [Participant 19, female, 19 years old, about Bite Back]
>
> *I think Project Yes doesn't really have that much kind of like colors or things that you know really attract a person. The visual elements are really important.* [Participant 6, female, 18 years old, about Project YES]

Participants expressed mixed views on the content of both interventions. Some described the content in both interventions as familiar or "common sense," reporting that it often felt like a repetition of information they already knew. While a few participants found this repetitive or not educational, others appreciated the opportunity to revisit known material and considered it a helpful reminder. Several participants mentioned that the concepts were explained using simple language. For some, this contributed to perceptions that the content was overly simplified or infantilizing. However, there were some participants who valued the inclusion of psychological concepts that were explained simply or described the content as scientific.

> *I thought it just covered like the generic, like mental health advice type of stuff you would see on like*

XSL•FO
RenderX

> *YouTube or in assemblies in school.* [Participant 9, female, 19 years old, about Bite Back]
>
> *It's still very useful information. It, I believe, would help a younger individual because when we're younger we see things a lot differently and I believe that it would help them.* [Participant 22, female, 18 years old, about Project YES]

Theme 4: Autonomy and Personalization

Autonomy and personalization refer to features that allow participants the freedom of choice, control, and flexibility within the interventions. Participants referred to existing features such as selecting sessions, receiving feedback, and viewing progress. Suggestions to save progress and comments on format preferences reflected a desire for greater control over when and how they interact with the material.

Most participants liked or were positively surprised by the feature that allowed them to choose which session to work on in Project YES. Some said that having this choice made the intervention feel more tailored to them.

> *It felt like a more personalized approach rather than just forcing everyone to do the same activity, you can pick whichever one you think suits you.* [Participant 12, female, 19 years old, about the choice of sessions in Project YES]
>
> *You can choose whether you want to do this one or this one. It depends on how you're feeling. I like that a lot.* [Participant 8, male, 19 years old, about Project YES]

Participants described the use of scores and ratings in Bite Back as a reflective and engaging feature. Several reported that receiving a score helped them learn more about themselves, visualize their progress, or feel more motivated to continue. Questions were generally viewed as clear, age-appropriate, and easy to use. However, one participant noted that receiving a low score could potentially be demotivating for some users.

> *Like this it can maybe put someone down and not want to carry on, because if they answer no, I'm not thankful. I'm not thankful and they see 5 out of 25 as the score. They're not particularly going to be happy with that.* [Participant 14, female, 19 years old, about Bite Back]
>
> *It kind of tells you how you're doing in that sort of environment. Like for example, I was doing really good in like the friends one but I'm not really good at like, the mindfulness one. […] I like how that was like, personalized.* [Participant 8, male, 19 years old, about Bite Back]

Participants referred to Bite Back's progress bar as a feature that helped them track their progress through a session. While not all participants mentioned it, those who did described it as helpful and motivating. Some said it gave a clear sense of progression and an end point to work toward. A few mentioned missing a similar feature in Project YES.

> *It's nice to know how far through you are, it's good motivation to keep going.* [Participant 11, female, 18 years old, about the progress bar in Bite Back]
>
> *I feel like it's always nice to see when you're making progress on something, even if it's like small. So I thought that was quite nice to see because I was like, oh, look at me, I'm doing well.* [Participant 13, female, 18 years old, about Bite Back]

Some participants suggested that the ability to save their responses to tasks could improve their experience with the interventions. A few mentioned that it would be helpful to revisit previous answers as a way to reflect on or recall how they felt at a particular time.

> *I feel like I would have also liked if they like, sent it to you. Obviously if they kept anonymous, but it would just be nice to have it there saved.* [Participant 9, female, 19 years old, about the activities in Project YES]
>
> *I think it would have been maybe nice to just have it like saved somewhere so you have the option of going back, because then maybe if you were […] having like a really bad day, you could go back to it and be like OK, […] what was I?! I'm having a bad day today. What was I grateful for at that time. It can give you a nice little reminder.* [Participant 1, male, 18 years old, about the activities in Bite Back]

Participants expressed varied preferences for how information was delivered. Some preferred reading text over listening to audio or watching videos, noting that reading was quicker, easier to process, or better suited to their learning style. However, many participants appreciated having multiple formats available, such as audio, video, and text, and described this as helpful or accessible. The ability to revisit the same content in different formats, such as having text that repeated video content, was seen by some as useful, while others felt that such repetition should be avoided. Several participants mentioned that bullet points would make the text easier to follow, particularly if they missed parts of a video.

> *A text that came after, it just repeated the video, and I would much prefer to skim over the text than watch the video.* [Participant 11, female, 18 years old, about Bite Back]
>
> *I quite liked the little audios that were there that you could like, listen to as you're reading along, was just easier.* [Participant 9, female, 19 years old, about Project YES]

Theme 5: Patterns of Engagement

Patterns of engagement describe how participants interacted with the interventions over time. This theme includes when and how they used the content, which sessions they continued with or disengaged from, and how they perceived the interventions in terms of accessibility and commitment.

Participants described varying patterns in when and how long they engaged with the interventions. Some completed multiple sessions in one sitting, often influenced by having free time or

XSL•FO
RenderX

wanting a distraction. Others reported using the interventions in response to specific emotional states, such as feeling stressed, down, or frustrated. The time spent on each session ranged from 20 to 40 minutes, which many participants viewed as an appropriate or optimal duration. A few appreciated the short and manageable structure of both interventions.

> *When the website was used] It was in the morning just to sort of set myself up for the day. By practicing something different, because that's […] when my anxiety peaks. And so it was nice to have, like, a routine in the morning with something to do, to practice, just to sort of like, take the time for myself and chill out.* [Participant 2, female, 18 years old, about Bite Back]

> *Used the website] when I had nothing else to do, like it wasn't really like something I picked up to do because I needed like a break.* [Participant 19, female, 19 years old, about Bite Back]

Participants noted that not all sessions were equally appealing, and some expressed a desire for more flexibility in how they moved through the interventions, as this influenced how far they progressed. Several mentioned wanting to skip sessions they found less engaging, particularly the mindfulness session in Bite Back, which was sometimes seen as requiring a specific mindset. A few participants reported stopping their use of the intervention when they reached this session, suggesting that being unable to move past less preferred content could discourage continued engagement.

> *I wanted to unlock Level 3 without having to do 10 minutes of meditation.* [Participant 11, female, 18 years old, about Bite Back]

> *Like they're forced to fill in the sentences to move on.* [Participant 3, female, 18 years old, about Project YES]

A few participants described the interventions as low-commitment or a more accessible alternative to more formal support services, such as university counseling.

> *It's much like lower commitment than trying to like get a hold of the university counseling service.* [Participant 11, female, 18 years old, about Bite Back]

> *It's an easy thing to get into because it's like not asking for huge commitments. You can just do one week if you want or you can do like multiple of the like the week modules. Which I think's good.* [Participant 7, female, 19 years old, about Bite Back]

Theme 6: Interactive and Motivational Elements

Interactive and motivational elements refer to intervention features that could encourage engagement and support a more active experience. This theme includes both the elements present in Bite Back and Project YES, as well as participants' suggestions for enhancing interactivity and motivation. It encompasses subthemes such as the unlocking feature, activities, gamification, an app version, and notifications.

Participants expressed mixed views about the unlocking structure of sessions in Bite Back. Several described it as motivating, noting that progressing through the weeks felt like achieving small goals or even like playing a game. Some said it encouraged consistency and ensured they moved through the content gradually. However, a few participants preferred having all sessions available from the start so they could choose content most relevant to them. One participant noted that the unlocking structure shortened their time spent using the intervention.

> *I think I'd rather have access to all of the weeks because there were certain weeks that for me I quite liked like the I think there was mindfulness, one which was really good, but then maybe on a specific day, I didn't really want to be doing the, say, gratitude one. If I was in a specific mood and I wasn't really feeling that. So I think it would be nice if they all were. Maybe if you were encouraged to do them in order, but they weren't locked.* [Participant 4, female, 19 years old, about Bite Back]

> *I did enjoy the whole concept of unlocking like a new week or like you couldn't start one before. I felt like I was almost playing a game, but then it was like a fun game, like AI. Well, I've done this now and now I've been rewarded with next week's and like a star.* [Participant 13, female, 18 years old, about Bite Back]

Participants expressed a range of views about the activities included in both interventions. Many found the interactive components engaging and reflective, with some describing them as encouraging deeper thinking about personal experiences or relationships. Activities involving giving advice were often highlighted as particularly engaging and meaningful, though a few participants noted that these tasks could feel irrelevant when based on scenarios they had not personally experienced. In Bite Back, short, varied activities were generally well received, with participants appreciating their manageable length and real-life applicability. In contrast, some participants felt the tasks in Project YES became repetitive, overly focused on writing, or difficult to complete. Suggestions included incorporating a greater variety of scenarios and making the tasks more general so that more people could relate to them.

> *So the activities were all very like, made me reflect and stuff like that.* [Participant 9, female, 19 years old, about Bite Back]

> *I quite like the thing about […] giving the advice cause although it was effortful, I feel like it's almost like encouraging you to give advice to yourself if you were in that situation. So, I think that did stand out.* [Participant 12, female, 19 years old, about Project YES]

Some participants suggested that incorporating game-like features could make the interventions more engaging. One participant said that receiving a reward at the end of a session would feel motivating and similar to playing a game.

> *Maybe including something like a game where you do the interventions and then it progresses through like a game sort of thing and then you get rewarded at the end or something like that.* [Participant 12, female, 19 years old, about Bite Back]

XSL•FO
RenderX

Several participants suggested that having access to the interventions through a dedicated mobile app would improve convenience and usability. An app-based format was seen as a way to encourage more consistent use by reducing barriers such as having to log in via a browser or remembering to return to the website after taking a break.

> *An app form would be quite interesting. I think an app like if it's just on your phone, could be more accessible to people.* [Participant 9, female, 19 years old, about Bite Back]

> *I think an app would be convenient so that I don't have to keep going back on my laptop and then opening it, and I can just use it on my phone.* [Participant 3, female, 18 years old, about Bite Back]

Most participants identified notifications as a potentially helpful feature for supporting consistent engagement with the interventions. They suggested that reminders could encourage them to return to the platform regularly, helping them stay on track with sessions and avoid forgetting about the program over time.

> *Like they said to have those activities to like repeat them every week or every day, if they had like a little maybe reminder like notification option, I think that could be useful.* [Participant 9, female, 19 years old, about challenges in Bite Back]

> *Just notifications on your phone and then it will remind you because obviously we're all human. Like we're forgetful, people are going to forget and stuff.* [Participant 15, female, 19 years old, about Project YES]

Theme 7: Perceptions of Usefulness

Perceptions of usefulness capture participants' reflections on how the interventions supported their mental health and well-being. Adolescents discussed overall helpfulness, impact on mood, and how the interventions encouraged positive habits.

Most participants perceived Bite Back as more helpful than Project YES. Many said they would be willing to recommend it to younger friends or family members. However, there were some participants who found Project YES beneficial, while others felt that both interventions offered useful elements. A few expressed a desire to revisit Bite Back to explore additional sessions.

> *It's kind of like an easier way of like grounding yourself compared to like other forms.* [Participant 19, female, 19 years old, about Bite Back]

> *It's easier to like actively engage in, whereas the other one [Project YES] was just like […] reading quite a few stories and things. Whereas the other one [Bite Back] was more like relating it to your own life, if that makes sense. So that was more engaging.* [Participant 5, female, 19 years old, about Bite Back]

> *[Which platform did you find more helpful?] Overall Project YES, but I think some of the activities in Bite Back were really good. I think if you could transport them then Project Yes would be perfect.* [Participant 4, female, 19 years old, about Project YES]

Several participants mentioned that using Bite Back made them feel calmer and more positive afterward and indicated that the intervention was a good starting point for improving their well-being. Some also reported positive changes after using Project YES.

> *There was definitely a more sense of like calm, I guess.* [Participant 19, female, 19 years old, about Bite Back]

> *Yes, after I used it, I did feel like a sense of accomplishment because of giving the advice and helping others.* [Participant 6, female, 18 years old, about Project YES]

When recommending Bite Back to others, some participants emphasized its potential to support the development of positive daily habits, even though not all reported forming these habits themselves.

> *I probably just tell them that it's good for keeping those like positive habits.* [Participant 9, female, 19 years old, when recommending Bite Back to a friend]

Discussion

Principal Findings

This qualitative study used 2 distinct and widely available digital mental health platforms (Bite Back and Project YES) to help understand what supports or hinders young people's engagement, what design features they prefer, and how useful they find these interventions. Participants frequently reflected on whether the tone, language, and content of the interventions felt age-appropriate, culturally relevant, and connected to their personal experiences. Clarity of instructions, transparency around data use, ease of navigation, and flexibility in how the interventions could be used also appeared to influence engagement. Participants generally preferred features that were interactive, visually engaging, and personalized, and many valued being able to track progress or choose content. Bite Back was often described as helpful, although some participants also found Project YES beneficial and identified useful elements in both interventions. These findings highlight a number of factors that may influence how young people engage with and perceive digital mental health interventions.

Facilitators and barriers to engagement were shaped by multiple, interconnected factors. Relatability and transparency were among these, with participants preferring interventions that used culturally relevant, age-appropriate content that aligned with their stage of life, supporting previous research emphasizing the value of content that resonates with adolescents' lived experiences [81-83,86,87]. It is important to note that although participants in this qualitative study were only slightly older than the intended user age group, many described the content and design of both interventions as age-inappropriate. This indicates that even small age differences may affect perceived relevance and adds to existing research showing that developmental stage matters in digital mental health intervention design [106,107]. This highlights the need to involve young

XSL•FO
RenderX

people across different adolescent age ranges in intervention development, especially when designing interventions targeting broader age groups. Although tailoring content to very narrow age bands may enhance relevance, this is not always practical in real-world settings. A more feasible approach may involve developing interventions that are adaptable to different developmental stages. In the future, artificial intelligence may offer scalable ways to personalize content dynamically based on age, preferences, or individual needs. Transparency regarding the purpose of the interventions, confidentiality, and instructions was of particular importance to participants, supporting previous research identifying transparency as a key factor in building trust and engagement [81]. Participants expressed a need for clear explanations on what happens to their data, how they could benefit from such interventions, and the purpose of certain tasks. The way transparency is communicated could matter, while clear information might foster trust, overly detailed or complex explanations might be overwhelming and may conversely hinder engagement. This suggests that interventions should balance providing essential information in a clear and accessible manner while avoiding information overload, ensuring young people feel informed and confident in engaging with digital mental health interventions.

Autonomy and personalization, patterns of engagement, and interactive and motivational elements were also identified as important factors influencing engagement, further aligning with previous research demonstrating their role in supporting young people's use of digital mental health interventions. Participants valued the ability to track their progress and choose the order or type of content they engaged with [82,87], supporting a sense of control and relevance. Patterns of engagement indicated a general preference for shorter sessions [82,83,87], with some participants expressing that digital mental health interventions felt less demanding and required less commitment than student counseling services. Most participants engaged with the interventions only once without returning, describing differences in motivation for when to use them, which was often shaped by their mood, available time, or daily routines. This highlights the need for interventions to allow flexible use that aligns with adolescents' lives, in line with broader research showing that ease of access and fit with everyday routines can influence how young people engage with digital mental health platforms [82,83,86,87,108]. Some participants suggested that the existing feature of session unlocking could help sustain motivation and recommended additional elements such as gamification, a mobile app version, or notification reminders to further encourage uptake and engagement. However, preferences varied, with some participants expressing the need for notifications as reminders and an app version for ease of access. Some participants preferred having all sessions unlocked to be able to choose those that were most appropriate for them, which is consistent with findings from the broader literature [82]. This reflects the importance of offering customizable interactive features to cater to individual preferences.

Participants preferred design features and content that offered clear and simple information, were easy to navigate, and featured a colorful, pleasing appearance. The ability to choose the order of sessions and to track progress was valued [82,87], which might have provided a sense of control and accomplishment. Informative content was appreciated, particularly when it was available in various formats, such as text, audio, or video, allowing participants to engage with material in ways that suited their preferences. These findings indicate that visually pleasing design, flexible use, and access to content in multiple formats are valued by young people and may further influence their engagement with digital mental health interventions. This is consistent with broader mHealth design research, which highlights navigation, presentation of information, personalization, and aesthetics as features associated with stronger user engagement [109].

Participants described the interventions as grounding and as a good starting point for improving well-being, with some expressing willingness to revisit them in the future. Participants' views on the usefulness of the interventions suggest that even when an intervention includes therapeutic, evidence-based content, this may not be enough on its own for young people to find it helpful. This aligns with previous qualitative research highlighting the importance of perceived usefulness in sustaining young people's engagement with digital mental health interventions [81,108].

All themes identified in this study are interconnected and collectively may shape how young people engage with digital mental health interventions and what they perceive as helpful within them. Design features and content preferences may influence whether young people find interventions appealing, practical, and worth returning to, which in turn may affect how much they benefit from using them. This highlights the importance of involving the target group in intervention development to ensure that interventions reflect young people's needs and preferences. Overall, the findings support a broader body of research suggesting that helpfulness and engagement are shaped not only by intervention content, but also by whether digital mental health tools feel relevant, easy to use, and trustworthy to young people in practice [110].

Strengths and Limitations

The use of a think-aloud component in an interview setting is a relatively novel approach and was generally perceived as a helpful technique for aiding recall and encouraging reflection on the interventions. Most participants noted that the prompts made it easier to remember and discuss specific aspects they might have otherwise overlooked, which could have enhanced the depth of feedback they provided. However, some participants found it challenging, suggesting that while think-aloud can enrich data collection, it should be introduced carefully to ensure participants feel comfortable sharing their perspectives.

Convenience sampling resulted in a participant pool that primarily consisted of university-educated individuals, including psychology students, who did not have elevated anxiety or depression and who might have greater familiarity with mental health concepts and digital tools, potentially shaping their perspectives. Although the study initially intended to use purposive sampling based on age and ethnicity, recruitment challenges contributed to the limited participation of individuals aged 16-17 years. As a result, 16-17-year-olds were not represented in the final sample, which meant that potential

XSL•FO
RenderX

age-related differences in preferences and engagement with digital mental health interventions could not be explored. This is particularly relevant as the examined interventions have been evaluated with slightly younger adolescents (Bite Back for aged 12-18 years, Project YES for aged 11-17 years), which may have influenced how participants perceived and interacted with the content. Furthermore, as the interventions were designed to support young people experiencing symptoms of anxiety or depression, our participants' generally low symptom levels may have affected how useful they found these interventions.

Participants were asked to use each intervention for approximately 30 minutes over a 2-week period. This decision was made to ensure consistency in the amount of time participants spent using each intervention, as Project YES was designed to be completed in a single 30-minute session, while also accommodating participants' academic schedules. While this approach allowed participants to experience and compare both interventions within the same timeframe, it provided limited exposure to Bite Back, which is designed as a 6-week program (around 10 minutes per session), and may not have allowed participants sufficient time to fully engage with its features and content. Additionally, the short engagement period within a longer timeframe may have affected participants' recall of content for both interventions, potentially influencing their perceptions and the depth of their feedback. To mitigate these limitations and aid recall, a think-aloud component was included, although it is acknowledged that the shortened engagement period may still have impacted the depth of participants' experiences with the interventions.

Implications for Development and Research

This study highlights the importance of involving young people in the co-design of digital mental health interventions to ensure content is age-appropriate, relatable, and engaging. In particular, future designs should consider the varying needs across different age ranges, as even small differences in age can affect how content is perceived and whether it feels relevant. Transparent communication about data use and the purpose of interventions should be clear and accessible while avoiding information overload. Future qualitative research could explore accessible and informative ways of communicating essential information, such as data use or the purpose of tasks, to build trust while maintaining engagement within digital mental health interventions.

Conclusion

This study contributes to the growing body of knowledge by identifying 7 interconnected themes that could shape how young people engage with digital mental health interventions. These findings emphasize that young people value interventions that feel relevant to their age, culture, and stage of life, and that are transparent about their purpose, data use, and content. Even slight differences in age appeared to influence how appropriate the interventions felt to participants, highlighting the importance of involving young people in the design process to ensure interventions reflect their needs and preferences and clearly convey information that could support their engagement.

Abstract

Background: Digital interventions for eating disorders have the potential to increase access to care and broaden the range of treatment options for adolescents. However, little is known about the characteristics of those who seek these interventions. Identifying such characteristics will help ensure that these interventions meet the needs of the target population, highlight potentially underrepresented groups, and support clinicians in assessing clinical suitability for individual patients.

Objective: This study aimed to examine the characteristics of adolescents seeking digital treatment for eating disorders within routine clinical care and to explore whether the key components of the novel digital treatment align with the characteristics of the adolescents it is designed to support.

Methods: This study used baseline data from an open feasibility trial of a novel digital treatment for eating disorders within routine clinical care. Participants were adolescents aged 15 to 18 years with a diagnosis of atypical anorexia nervosa, atypical bulimia nervosa, binge-eating disorder, or eating disorder, unspecified. Baseline assessment included demographic characteristics, eating disorder symptomatology, psychosocial impairment, emotional dysregulation, anxiety, depression, negative self-evaluation, and motivational factors.

Results: A total of 25 adolescents participated in the study, all of whom were women. The mean age was 16 (SD 0.87) years. Half of the adolescents had previously received face-to-face treatment for an eating disorder. The sample was transdiagnostic with some variation in distribution. The adolescents reported severe eating disorder symptoms, marked psychosocial impairment, emotional difficulties, elevated negative self-evaluation, and high levels of internal pretreatment motivation.

Conclusions: The findings from this study underscore the relevance of digital interventions to complement or extend traditional eating disorder care for adolescents. This study emphasizes the importance of designing digital treatments that are sensitive to normative biases, address the multifaceted nature of eating disorders, and are tailored to the needs and preferences of a transdiagnostic population. The present findings are important insofar as they may inform whether the key treatment components align with the characteristics of adolescents seeking digital treatment for eating disorders within routine clinical care.

Trial Registration: ClinicalTrials.gov NCT06306586; https://clinicaltrials.gov/study/NCT06306586

KEYWORDS

eating disorders; adolescents; digital treatment; routine clinical care; developing novel intervention; characteristics of help-seeking

Introduction

Eating disorders are a group of complex clinical conditions characterized by pathological concerns about shape and weight, as well as disturbed eating and weight-control behaviors [1]. Impaired physical health, disrupted psychosocial functioning, and reduced life expectancy are some of the severe consequences of eating disorders [2,3]. The disorders are highly prevalent worldwide, especially in adolescents [4,5], with overall estimates suggesting that approximately 1 in every 20 children and

XSL•FO
RenderX

adolescents are affected [6]. Several evidence-based treatments are available for adolescents [7], with family-based treatment and enhanced cognitive behavioral therapy having the strongest evidence base [8].

Despite the severity of eating disorders and the availability of evidence-based treatments, most individuals who meet the criteria for a clinical eating disorder do not seek help [9,10]. Eating disorders are therefore frequently undetected and untreated [3,11], with particularly low help-seeking rates among adolescents, where only 10% to 20% access treatment [12-14]. Individual barriers to help-seeking behavior include poor mental health literacy, stigma surrounding eating disorders, denial of the disorder's severity, as well as distorted body ideals enforced by social media [9,15]. Systemic factors contributing to the existing treatment gap are limited therapist availability, the cost of treatment, geographic isolation from available services, long waitlists, and poor eating disorder literacy among primary care providers [9,16]. Moreover, of those who seek help, a substantial number do not respond to the treatments currently available [17,18]. High dropout rates (29% - 73%) [19,20] and low remission rates (40% - 50%) indicate that a substantial proportion continue to exhibit high levels of eating pathology at the end of treatment [17,21]. Additional factors have been identified as contributing to the complexity of treating eating disorders. The disorders' complex interplay of psychological, biological, and social factors [15,22], the underlying mechanisms being unknown [23], and the high psychiatric comorbidity (>70%) [24] could be among the reasons. Furthermore, eating disorder treatments often have a categorical approach, despite diagnostic migration being common and diagnoses varying across individuals [25]. In addition, treatments often follow standardized protocols and manuals, which do not account for unique individual factors influencing an eating disorder [26]. As a result, individuals with eating disorders can feel alienated from treatment [27,28]. Given the aforementioned challenges in treating eating disorders, there is a pressing need to both improve access to existing evidence-based treatments and develop novel interventions that address the multifaceted nature of these conditions [17,23,26,29].

A promising approach is the use of treatments delivered via computers or smartphones, often referred to as digital interventions or digital treatments [30,31]. The accessibility of these treatments positions them as a valuable component within the spectrum of services for eating disorders, particularly considering the numerous barriers associated with traditional treatments [32]. Digital interventions can increase access to care and have demonstrated effectiveness in improving symptoms of eating disorders while also being cost-effective [7,33]. While endorsing many of these advantages, most individuals with eating disorders still prefer face-to-face treatment [34]. Moreover, despite a growing evidence base, only a limited number of digital interventions have been specifically developed for adolescents with eating disorders [31]. At present, the few available app-based interventions, such as TCApp and Recovery Record, have primarily been evaluated as adjuncts to standard treatment rather than as standalone interventions [35,36]. In addition, digital interventions also face challenges related to uptake and engagement [30,37], and one contributing factor may be expert-driven development processes that do not sufficiently reflect the preferences and goals of the intended users [38,39].

To address these challenges, there is a need to develop novel digital interventions for adolescents with eating disorders [17,31] based on the perspectives of those who will use them [37,40]. This is particularly important given that adolescents differ from adults in their developmental needs, preferences, and contexts, making simple adaptations of adult interventions insufficient [41,42]. At the same time, digital interventions may not be acceptable or suitable for all individuals, underscoring the importance of understanding which adolescents engage with such approaches and who may benefit most [34,37]. Such knowledge can also help identify underrepresented groups and inform necessary adaptations to ensure that interventions fit into adolescents' everyday lives [37,43]. The involvement of adolescents in the development of such interventions remains relatively limited, raising concerns about whether existing tools adequately reflect their needs and preferences [44,45]. Furthermore, only a small number of digital interventions have been developed and evaluated within routine clinical care, where treatments are delivered under real-world conditions with heterogeneous patient populations and varying clinical practices [16,38,46]. As a result, it remains unclear which adolescents are reached by digital interventions in these settings and whether those who engage with them correspond to the intended target population. Addressing this gap is essential for evaluating the feasibility and clinical relevance of digital treatments. Assessing sample representativeness within feasibility trials can provide important insights into whether interventions reach the populations they are designed for and help identify potential barriers to implementation. This study therefore aimed, as part of a feasibility trial of a novel digital treatment, to examine the characteristics of adolescents seeking digital treatment for eating disorders within routine clinical care and to explore whether the key components of the novel digital treatment align with the characteristics of the adolescents it is designed to support.

Methods

Study Design

An open feasibility trial of a digital treatment for adolescents with eating disorders was conducted in routine clinical care. The trial was guided by the UK Medical Research Council's framework for developing and evaluating complex interventions and followed CONSORT (Consolidated Standards of Reporting Trials) standards for feasibility trials (Checklist 1) [47,48]. In line with these recommendations, 4 key progression criteria were assessed to evaluate feasibility across multiple domains: sample representativeness, adherence, acceptability, and preliminary efficacy. In this study, we specifically report findings related to sample representativeness as an indicator of feasibility. Sample representativeness was examined in relation to overall eating disorder psychopathology to better understand which adolescents sought digital treatment and the extent to which the participants reflected the intended target population. This was assessed by analyzing baseline characteristics from the feasibility trial and evaluating how well the key components

XSL•FO
RenderX

of the intervention corresponded to the clinical profile of the sample. The study used baseline data from participants included in the feasibility trial between March 2024 and May 2025. In accordance with feasibility trial design, no formal sample size calculation was conducted.

Study Setting

Adolescents receiving the digital treatment were patients at child and adolescent psychiatric outpatient clinics in Norway, specifically within the catchment area of Haukeland University Hospital and Helse Fonna. These clinics are part of the state-funded Norwegian specialist health care system and are located within the Western Norway Regional Health Authority, serving a population of approximately 122,000 youth under 18 years [49].

Study Population

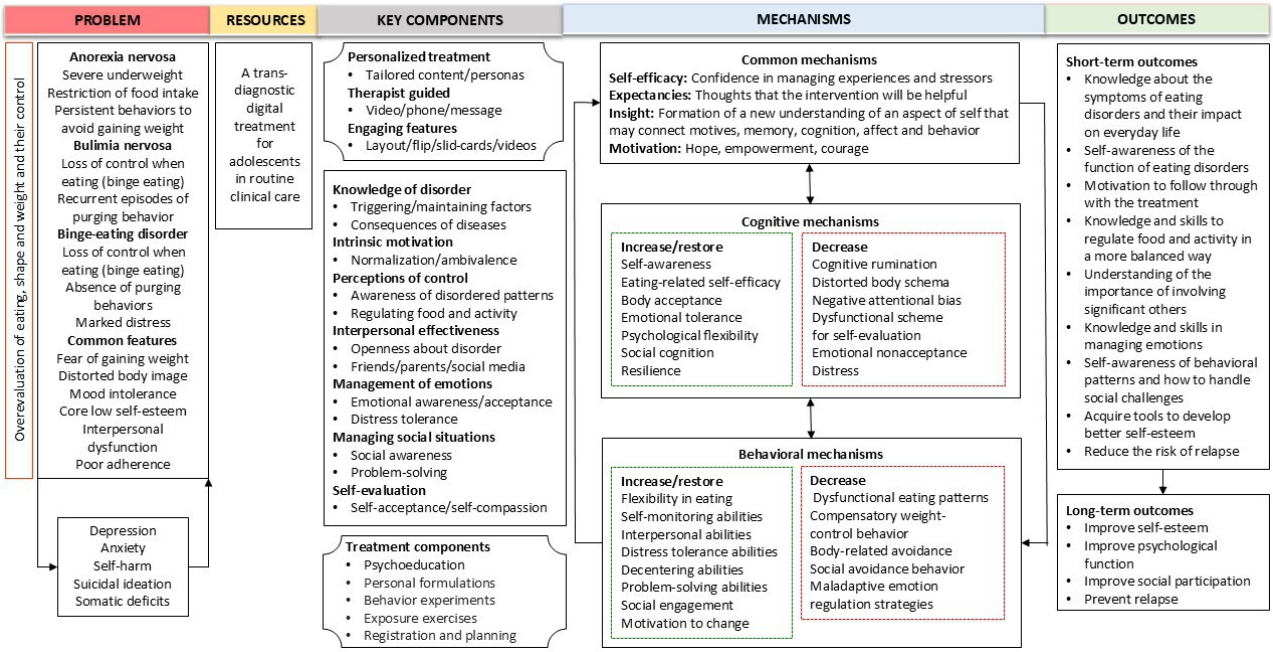
Inclusion Criteria

The following inclusion criteria were applied for the feasibility trial: (1) diagnosed with atypical anorexia nervosa, atypical bulimia nervosa, binge-eating disorder, or eating disorder, unspecified [50,51]; (2) aged between 15 and 18 years; (3) on a stable dose of medication for a psychiatric disorder for 6 weeks; (4) has a mobile phone with internet access; and (5) speaks and writes Norwegian.

Exclusion Criteria

The following exclusion criteria were applied: (1) diagnosed with anorexia nervosa, bulimia nervosa, or avoidant or restrictive food intake disorder (ARFID); (2) having a comorbid medical condition or disorder known to influence eating or weight (ie, pregnancy, cancer); (3) psychotic disorders, acute suicidality, substance abuse, substance dependence, or a severe depressive episode; and (4) receiving inpatient treatment for a psychiatric disorder or face-to-face psychological treatment. This trial was the first to examine a digital intervention for adolescents with eating disorders within routine clinical care in Norway. During the planning phase, concerns were raised about including participants with anorexia nervosa or bulimia nervosa due to the increased risk of medical instability. Although a more flexible inclusion strategy based on clinician judgment was considered, it was not implemented due to concerns about maintaining internal validity. As a result, adolescents with anorexia nervosa and bulimia nervosa were excluded from the trial. Patients with ARFID were excluded since the clinical picture is different from that of other eating disorders [50].

Procedure



Participants were recruited from 8 child and adolescent psychiatric outpatient clinics. Information about the study was disseminated through meetings with clinic managers, emails to staff, and flyers placed in waiting rooms. Interested participants were provided with a link to the study website for information about the study and a brief preliminary online screening. The online screening captured information on disordered eating, eating-related behaviors, functional impairment in daily life, as well as key inclusion criteria such as age, internet access, and language. Eligible participants were given the opportunity to leave their contact information and were contacted by telephone to confirm inclusion and exclusion criteria. A diagnostic assessment was conducted by trained clinicians within the research group using the Mini-International Neuropsychiatric Interview (MINI) [52] and Eating Disorder Assessment for *DSM-5* (EDA-5) [53]. As the *International Statistical Classification of Diseases, Tenth Revision* (*ICD-10)* is the standard diagnostic framework in Norway, final diagnoses and all inclusion and exclusion criteria were determined according to *ICD-10* [51]. While MINI was used as a diagnostic instrument, the EDA-5 served to systematically assess eating disorder symptoms and support clinical judgment, rather than as an independent diagnostic tool. In response to slow recruitment, additional promotion of the study was carried out via upper secondary schools and advertisements on social media. As the study was conducted in routine clinical care, all participants had to be eligible for specialized care in accordance with national priority guidelines [54]. Participants who were not already patients at an outpatient clinic were required to visit their general practitioner to confirm medical stability and obtain a referral. Eligible participants were given access to the native treatment application, in which they signed consent forms, with those aged 15 years required to provide additional parental consent.

Intervention

The intervention was developed in line with the person-based approach (PBA) [55]. PBA is a methodological framework for understanding the most effective way to apply appropriate behavior change techniques in the specific context of the intervention and its intended users [55]. In line with PBA, adolescents with lived experience of eating disorders [27], mental health professionals, and the existing evidence base helped us identify key issues, needs, and challenges the intervention should address. Drawing on this in-depth understanding, key components were identified and systematically embedded into the design of the intervention. A logic model was created to describe how the key components of the intervention should lead to positive behavior change and better health (Figure 1). During development, the key components were incorporated and user-tested to refine the digital treatment to meet user requirements. This model serves as background for the second aim of this study: exploring whether the following key components of the novel digital treatment align with the adolescents it is designed to support: eating disorder symptomatology, psychosocial impairment, emotional difficulties (emotion dysregulation, anxiety, and depression), negative self-evaluation, and motivational factors.

XSL•FO
RenderX

Figure 1. Logic model.

The development process resulted in a therapist-guided digital treatment delivered through a smartphone app. The intervention is based on a transdiagnostic cognitive behavioral framework targeting mechanisms that maintain eating disorders, alongside elements from emotion regulation approaches to enhance distress tolerance [56,57]. The treatment consists of eight modules delivered in a fixed sequence: (1) What is an eating disorder? (2) Motivation and change, (3) Balancing food and activity, (4) Involving others, (5) Management of emotions, (6) Managing social situations, (7) Improving self-esteem, and (8) Preventing relapse. Modules were released weekly, although 2 were designed to be completed over a 2-week period (modules 3 and 5). Adolescents received weekly clinician support through scheduled telephone consultations lasting approximately 15 to 30 minutes. In addition, they could send asynchronous messages to clinicians to address technical or practical issues. During the feasibility trial, the intervention was incorporated into the existing workflows of participating Child and Adolescent Mental Health Services (CAMHS) outpatient clinics. The clinicians delivering the intervention were employed within CAMHS and were assigned approximately 10% of a full-time position, corresponding to a caseload of around 3 patients each. Standardized guidelines were developed to support clinicians in delivering the intervention. Clinicians also received brief introductory training on the digital platform and treatment procedures. In addition, they participated in fortnightly 1-hour group supervision sessions led by an experienced clinical psychologist.

Measures

Data were collected using self-report questionnaires administered online. Sociodemographic data (age, gender, living situation, engagement at school and with friends) were gathered using a questionnaire developed specifically for this study. The selected measures have been applied in adolescent and eating disorder populations, used in evaluations of digital interventions for this group, and are consistent with international consensus recommendations on patient-centered outcome measures in eating disorders [58,59].

Eating Disorder Examination—Questionnaire Short (EDE-QS)

Eating disorder symptoms were measured using the EDE-QS [60]. EDE-QS is a 12-item questionnaire with a 4-point response scale that assesses symptom severity over the preceding 7 days. Scores range from 0 to 36, and higher scores indicate greater symptom severity. A score of 15 or above serves as a cutoff point for distinguishing between eating disorder cases and noncases [61]. The questionnaire has high internal consistency (Cronbach α=0.91) [60].

Clinical Impairment Assessment Questionnaire (CIA)

CIA was used to assess the severity of psychosocial impairment due to eating disorder features [62]. CIA consists of 16 items covering impairment in different domains of life that are typically affected by eating disorder psychopathology. Three subscales are computed, representing personal, social, and cognitive impairment that can result from eating disorders. Global scores range from 0 to 48, with higher ratings indicating a higher level of impairment [62]. A global score of 16 or above represents a cutoff for clinically significant impairment [62]. Normative data from a clinical adult female sample in Norway indicate mean scores of 14.01 (SD 4.31) for the personal impairment subscale, 9.54 (SD 3.97) for the social impairment subscale, and 8.97 (SD 3.81) for the cognitive impairment subscale [63]. In this study, the normative data have been rounded to the nearest whole number to report the number of participants with a mean score that matches the clinical sample. The questionnaire has high internal consistency (Cronbach α=0.97) [62].

Difficulties in Emotion Regulation Scale (DERS-18)

The DERS-18 was used to assess clinically relevant difficulties in emotion regulation [64]. Participants answer on a 5-point

XSL•FO
RenderX

Likert-type scale ranging from 1 (“almost never”) to 5 (“almost always”). Scores range from 18 to 90, with higher scores indicating greater emotion dysregulation [64]. DERS-18 consists of 6 subscales measuring difficulties in the flexible, multidimensional regulation of emotion: lack of awareness of one’s emotions (awareness), lack of acceptance of one’s emotions (nonacceptance), lack of access to effective emotion regulation strategies (strategies), lack of ability to manage one’s impulses during negative emotions (impulse), lack of ability to engage in goal-directed activities during negative emotions (goals), and lack of clarity about the nature of one’s emotions (clarity) [64]. DERS-18’s internal consistency is very high (Cronbach α=0.90) [65]. DERS is ideal for use in clinical research studies that require multiple assessment points and is frequently used in treatment outcome research [65]. Due to the different versions of the DERS, it is difficult to collapse findings across studies [65]. In one study from 2022, DERS scores were organized by depression subgroups [66]. For the DERS-18, total mean scores were 35.88 (SD 8.69) for normal subgroup, 42.68 (SD 10.50) for mild depression, 48.39 (SD 10.15) for moderate depression, and 56.13 (SD 10.08) for severe depression [66]. In this study, we used the same putative depressive symptomatology subgroups to organize our sample’s difficulties with emotion regulation. We used the moderate depression subgroup as a cutoff for difficulties within each domain. The reported cutoff scores have been rounded to the nearest whole number.

Generalized Anxiety Disorder-2 Scale (GAD-2)

Anxiety symptoms were measured using the 2-item version of the GAD-2 [67]. GAD-2 measures symptoms over the last 2 weeks, scored on a 4-point Likert scale ranging from 0 (“not at all”) to 3 (“nearly every day”), with a cutoff score of 3 or above [68].

Patient Health Questionnaire-2 (PHQ-2)

Symptoms of depression were measured using the 2-item version of the PHQ-2 [69]. PHQ-2 measures symptoms over the last 2 weeks and is scored on a 4-point Likert scale ranging from 0 (“not at all”) to 3 (“nearly every day”) [70]. The standard cutoff score of PHQ-2 is 3 or above; however, a cutoff score of 2 or above may represent an optimal threshold for adolescents [71].

Rosenberg Self-Esteem Scale (RSES)

The RSES was used to measure negative self-evaluation [72]. RSES measures self-competence and self-liking using 10 items, answered on a 4-point Likert-type scale—from “strongly agree” to “strongly disagree.” The scale ranges from 0 to 30, and scores between 15 and 25 are within the normal range; scores below 15 suggest low self-esteem [72]. The questionnaire’s Cronbach α was 0.92, indicating excellent internal consistency [72].

Total Burden of Symptoms

To capture the overall level of symptom burden among participants, a composite score ranging from 0 to 6 was calculated. For each standardized measure, 1 point was assigned if the participant’s score exceeded the established clinical cutoff. The total score therefore reflects the number of measures for which the participant scored above the cutoff, with higher scores indicating a greater overall symptom burden.

Treatment Motivation

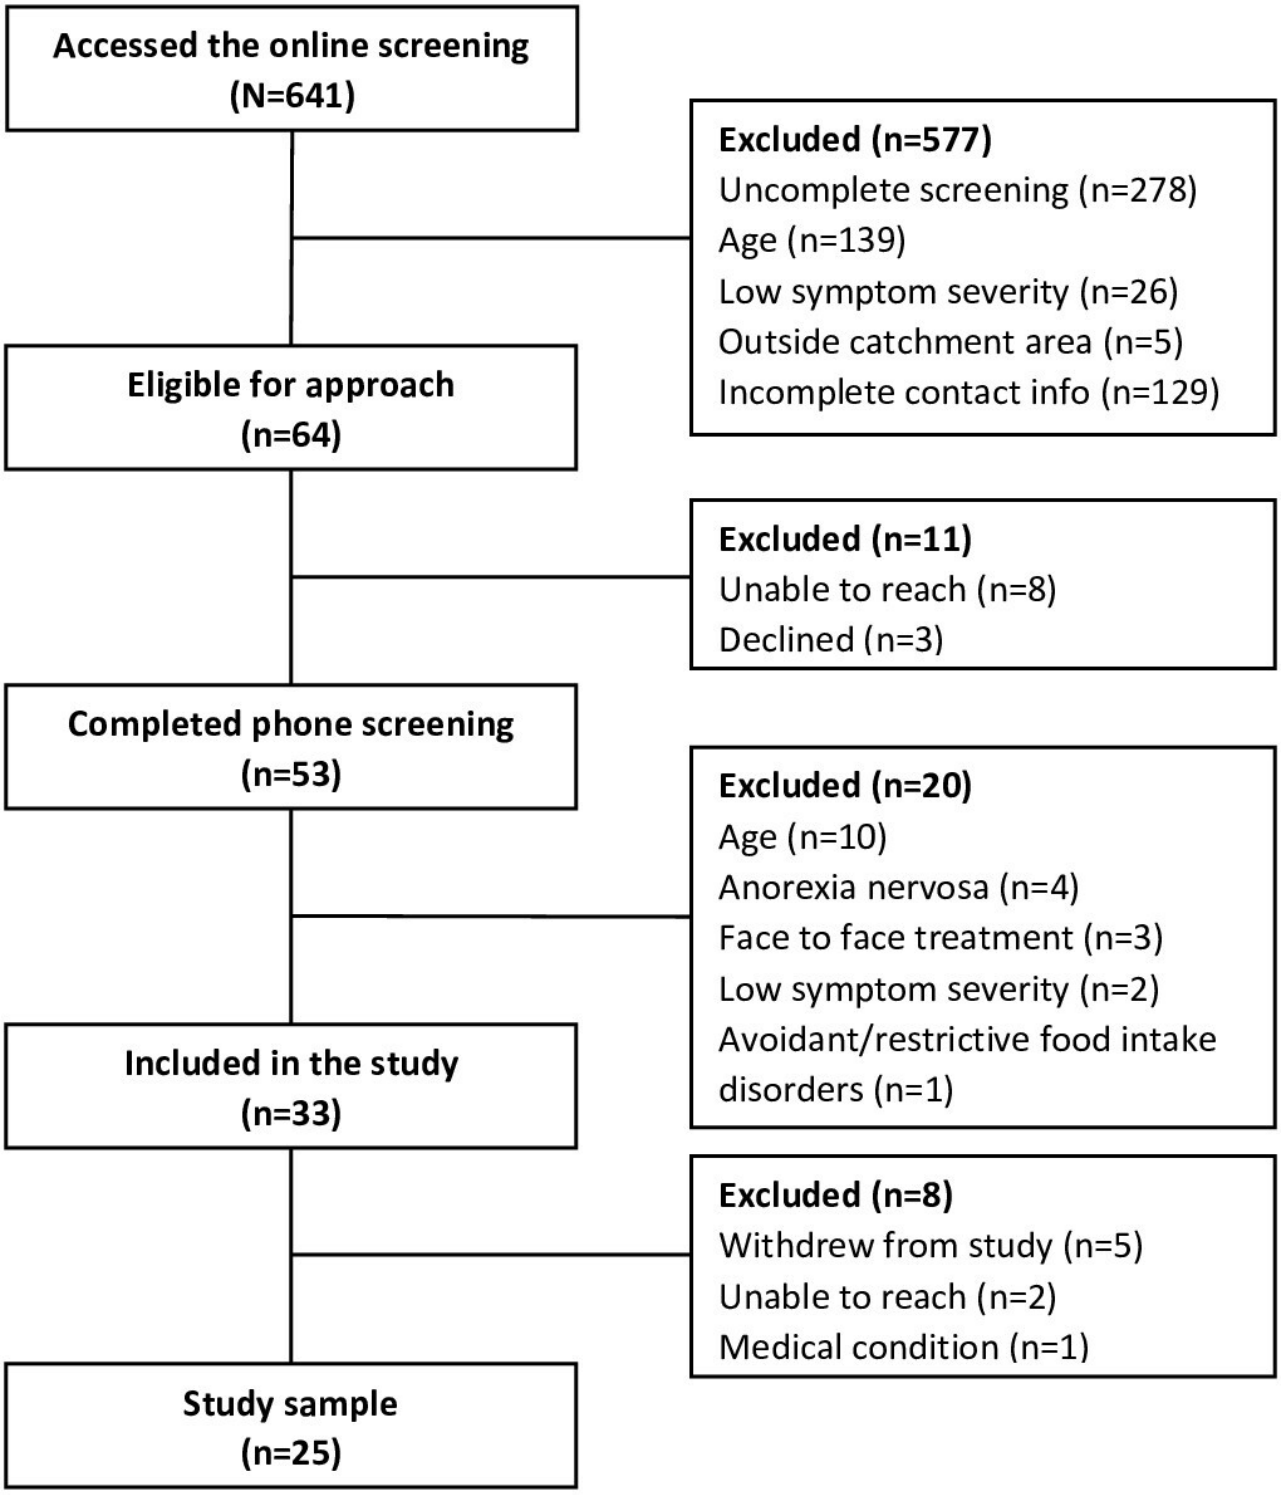
In addition to the standardized measures, the participants were given a 6-item questionnaire to explore motivational factors for participating in a novel treatment. As no suitable validated instrument was available, the questionnaire was developed specifically for this study, drawing on the Short Motivation Feedback List [73] and grounded in self-determination theory [74]. Four items were rated on a 5-point Likert scale ranging from “Strongly disagree” to “Strongly agree” and were designed to capture both the level and type of motivation (internal vs external). These items assessed reasons for participating in treatment, including intrinsic motivation (eg, wanting to engage in treatment) and externally driven motives (eg, perceived expectations from others). The remaining 2 items asked participants to rate, on a scale from 0 to 100, how much effort they expected to invest in the treatment and the extent to which they would involve others for support when needed.

Data Analysis

Data were analyzed using SPSS (version 29). Given the descriptive nature of this study, data are presented in terms of frequencies, percentages, means, and standard deviations.

Ethical Considerations

This study was approved by the Regional Committees for Medical and Health Research Ethics in Norway (REC-639031). In addition, the study was conducted in line with the Haukeland University Hospital’s guidelines for ethics and privacy considerations. Informed consent was obtained via the smartphone app.



Results

Recruitment

Following 14 months of recruitment, baseline data were used for this study as the project neared completion. A total of 641 individuals accessed the online screening portal (Figure 2) between March 2024 and May 2025. Of these, 577 individuals were ineligible due to incomplete screening, being outside the age range, not meeting diagnostic criteria for an eating disorder (low symptom severity), or living outside the catchment area. In addition, 129 individuals met the criteria for the online screening but could not be contacted as they did not leave their contact information. Of the 64 adolescents eligible for approach, 11 were excluded because they were unable to be reached or declined participation. Of the 53 adolescents contacted by telephone, 20 were excluded from the study due to age (n=10), a primary diagnosis of anorexia nervosa (n=4), receiving face-to-face psychological treatment (n=3), low symptom severity (n=2), or ARFID (n=1). After inclusion, 5 adolescents changed their minds regarding participation, 2 were unable to be reached, and 1 was excluded due to a medical condition. Twenty-five adolescents completed the baseline screening and enrolled in the study. These were recruited through CAMHS (n=15), upper secondary schools (n=5), and social media (n=5).

XSL•FO
RenderX

Figure 2. Recruitment flowchart.

Sociodemographic Characteristics

All participants were women (Table 1). The mean age of the study sample was 16 (SD 0.87, range 15-18) years. Over half of the sample were living with both parents (60%). All participants were engaged in school (100%), and almost all (96%) were engaged with friends on a regular basis.

Alone	1 (4)
Other living agreement	2 (8)
Engaged in education, n (%)	
Reduced time	5 (20)
Full-time	20 (80)
Engaged with friends[a], n (%)	
Daily	6 (24)
Weekly	11 (44)
Monthly	7 (28)

[a]For the sociodemographic characteristic "Engaged with friends," N=24 (96%).

Diagnoses and History of Present Illness

Most of the adolescents were diagnosed at inclusion with atypical anorexia nervosa (40%), with the second largest group being eating disorder, unspecified (28%) (Table 2). The rest of the sample was equally distributed between atypical bulimia nervosa (16%) and binge-eating disorder (16%). The mean age at eating disorder onset was 13 (SD 1.68, range 9 - 16) years. Half of the adolescents had previously received face-to-face treatment for an eating disorder (52%, 13/25).

Table . Diagnoses and history of present illness of adolescents seeking digital treatment (N=25).

Characteristics	Values
Diagnoses (inclusion), n (%)	
Atypical anorexia nervosa	10 (40)
Atypical bulimia nervosa	4 (16)
Binge eating disorder	4 (16)
Eating disorder, unspecified	7 (28)
Prior eating disorder treatment, n (%)	
Yes	13 (52)
No	12 (48)
Age of disorder onset (y), mean (SD)	13.00 (1.68)

Motivational Factors

The adolescents' motivational factors for participating in a novel digital treatment are summarized in Table 3. Most of the adolescents' responses to items 1 and 3 were in the higher categories, 4 ("agree") and 5 ("strongly agree"), indicating high internal treatment motivation. When asked to rank (0% - 100%) how much effort they would put into carrying out the treatment, the mean score was 83% (SD 14.34%), ranging from 50% to 100%. Regarding the involvement of others, the mean score was somewhat lower (52%, SD 33.18%), with a range from 0% to 100%.

Social impairment	1-15	9 (36)	7.80 (4.10)
Cognitive impairment	2-14	10 (40)	7.20 (3.52)
Difficulties in Emotion Regulation Scale-18 (DERS-18)			
Total score	32-85	17 (68)	53.72 (13.92)
Awareness	4-13	21 (84)	10.00 (2.48)
Nonacceptance	3-15	18 (72)	8.92 (3.39)
Strategies	3-15	11 (44)	7.24 (3.64)
Impulse	3-15	15 (60)	7.52 (3.68)
Goals	5-15	15 (60)	11.16 (2.88)
Clarity	3-15	15 (60)	8.88 (2.86)
Generalized Anxiety Disorder-2 Scale (GAD-2)			
Total score	1-6	17 (68)	3.44 (1.69)
Patient Health Questionnaire-2 (PHQ-2)			
Total score	0-6	20 (80)	2.60 (1.56)
Rosenberg Self-Esteem Scale (RSES)			
Total score	0-28	19 (76)	11.76 (6.33)

[a]Participants with scores exceeding the clinical cutoff on measure were identified. For the CIA subscales and the DERS-18, normative data were used due to the lack of clinically validated cutoff scores (62 and 66).

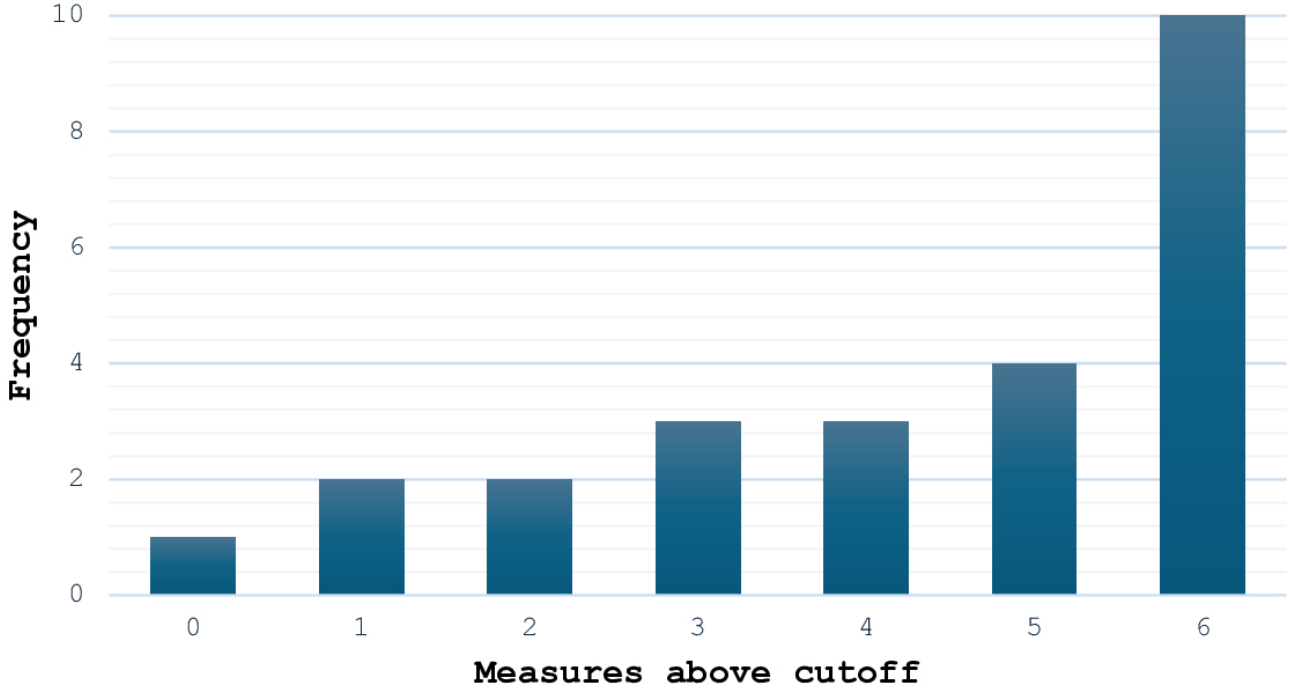
Psychosocial Impairment

The global impairment score was high at 28.08 (CIA) [62] (Table 4). The impairment subscales show difficulties across the personal, social, and cognitive domains [63].

Emotional Difficulties

To explore the adolescents' emotional difficulties, emotion dysregulation and symptoms of anxiety and depression were assessed (Table 4). The sample's abilities to regulate emotions indicate moderate to severe difficulties within this domain, with a total mean DERS-18 score of 53.72 (SD 13.92) [66]. The adolescents had difficulties in all the 6 DERS-18 subscales. In addition, they reported anxiety symptoms above the cutoff (GAD-2 score 3.44, SD 1.69) [68]. The mean score for depression was below the cutoff (PHQ-2 score 2.60, SD 1.56) [70]; however, using an optimal cutoff score for adolescents of 2 or above, the score exceeded the threshold [71].

Negative Self-Evaluation



To evaluate the sample's level of negative self-evaluation, we measured the adolescents' self-esteem (RSES mean score 11.76, SD 6.33), which was in the range indicating severely low self-esteem [72].

Total Burden of Symptoms

The total burden of symptoms was calculated (Figure 3). Median response scores ranged from 0 to 6, with the median score on 5 measures above the cutoff.

XSL•FO
RenderX

Figure 3. Total burden of symptoms above established cutoffs among adolescents seeking digital treatment (N=25). Each standardized measure exceeding its clinical cutoff contributes one point to the total symptom burden score. A score of 1 indicates one measure above cutoff, and a score of 2 indicates 2 measures above cutoff, and so forth.

Alignment Between Key Components and Adolescents' Characteristics

The second aim of this study was to explore whether the key components of the novel intervention (for more details, see Figure 1) align with the characteristics of the adolescents recruited for this study. Table 5 shows an overview of the key components, the results from measuring these characteristics, and an evaluation of the alignment.

XSL•FO
RenderX

Table . Alignment between key components of the digital treatment and adolescents' characteristics.

Key components	Measure	Result	Evaluation	Alignment
Eating disorder symptomatology	• EDE-QS[a]	Majority above clinical cut-off	Indicates that the treatment targets core symptoms relevant to the adolescent population.	Yes
Impairment	• CIA[b]	High level of global impairment	Suggests that the intervention's focus on functioning is well-matched with the sample's needs.	Yes
Emotional difficulties	• DERS-18[c] • GAD-2[d] • PHQ-2[e]	High levels of anxiety, depression, and emotional dysregulation	Supports the relevance of the treatment in addressing emotional difficulties across all these domains.	Yes
Negative self-evaluation	• RSES[f]	Severe low self-esteem	Confirms the importance of components addressing self-image and self-worth.	Yes
Motivational factors	• Six-item questionnaire	High level of pretreatment motivation	Levels observed were higher than anticipated. Variability across individuals suggests that tailored engagement strategies may still be necessary to optimize uptake and adherence.	Partial

Discussion

Principal Findings

As part of examining the feasibility of a novel digital treatment, this study assessed sample representativeness. Specifically, the study examined the characteristics of adolescents seeking digital treatment for eating disorders within routine clinical care and explored whether the key components of the novel digital treatment aligned with the characteristics of the adolescents it is designed to support. Although recruitment was not specified as a predefined feasibility criterion, the findings revealed substantial challenges in this area. Given the central role of recruitment in feasibility research, particularly for understanding whether the intended population can be reached, these challenges are addressed first in the discussion to provide important context for interpreting the remaining findings.

Recruitment

The results revealed considerable challenges in enrolling participants. Despite substantial traffic to the online screening portal, only a small proportion of adolescents progressed to study participation, suggesting a gap between initial interest and actual engagement. This pattern may reflect well-established features of eating disorders, such as ambivalence toward treatment and fluctuating motivation, which can reduce readiness to seek or accept help [3,9]. Additional challenges may be related to adolescence as a developmental stage, where factors such as stigma, reliance on caregivers, and competing demands can influence help-seeking behavior [75]. Intervention-specific and contextual factors may also have contributed. Some adolescents may have been hesitant to engage in a digital treatment format or may have preferred traditional face-to-face care [34,37]. At the same time, recruitment via social media appeared to reach individuals who had not previously accessed clinical services, indicating an unmet need for more accessible entry points to care. It should also be noted that recruitment challenges are common in clinical research [76]. In this study, such challenges may have been further exacerbated by practical constraints within clinical settings, including limited time and resources among clinicians. Together, these findings suggest that while digital interventions may lower initial barriers to help-seeking, they do not fully overcome challenges related to participation in studies and treatment.

Characteristics of Adolescents Seeking Digital Treatment for Eating Disorders

Atypical anorexia nervosa was the most frequently assigned diagnosis, which aligns with data from a Norwegian community-based prevalence study [10]. Furthermore, the adolescents' distributions of eating disorder symptoms and psychosocial impairment are consistent with the diagnostic thresholds for inclusion in this study. Moreover, their elevated levels of emotional difficulties and negative self-evaluation are in accordance with other studies examining these mechanisms among adolescents with eating disorders [77-79]. Low

XSL•FO
RenderX

self-esteem and mood intolerance are particularly pertinent in the adolescent age range [78], and anxiety and depression are the most prevalent comorbid disorders [79]. The adolescents' total burden of symptoms across domains emphasizes the sample's severity. The adolescents reported a high level of internal pretreatment motivation. The strong internal motivation may be linked to the adolescents' severe eating disorder symptoms [9] or to their being more likely to engage in the intervention due to recruitment via a self-selection process [80]. Providing adolescents with a sense of control and agency in treatment decision-making may contribute to improved adherence to therapeutic interventions [37].

The fact that none of the adolescents included in this study were men reflects the well-established gender discrepancies in the field of eating disorders [5]. Stigma associated with the disclosure of mental health issues and cultural perceptions that eating disorders are typically female disorders might influence help-seeking behaviors among adolescent boys [81]. Moreover, although individuals that identify as transgender or nonbinary are at particularly high risk for developing eating disorders [82,83], no participants in this study identified with a gender other than women. The results of this study highlight the presence of underrepresented groups within the adolescent population seeking treatment for eating disorders [17,81,83].

Alignment of Novel Interventions With Adolescents' Characteristics

The distribution of eating disorder symptoms within the sample indicates that the treatment targets core symptoms relevant to the population. In addition, the intervention's focus on functioning is well-matched to adolescents' needs. Moreover, the inclusion of a transdiagnostic sample aligns with the goal of the novel intervention to address the multifaceted and overlapping nature of these conditions. Drawing on perspectives from adolescents with lived experience of an eating disorder, the design of the digital treatment embedded emotional difficulties and negative self-evaluation as key components [27]. The results of this study show that adolescents' high levels of difficulties within these domains support the relevance of the treatment in addressing emotional dysregulation, anxiety, depression, and self-worth. This alignment may indicate that the intervention is designed for the users and contexts in which it will be implemented. Furthermore, adolescents' levels of pretreatment motivation were higher than anticipated when designing the novel intervention. Variability across adolescents highlights that tailored engagement strategies may be an important component for optimizing uptake and adherence to the digital treatment. Although the intervention was developed through a co-design process to reflect the needs of the intended target population, a one-size-fits-all approach may not fully address the heterogeneity among adolescents with eating disorders. Additional flexibility or personalization within the intervention may be needed to better accommodate individual differences and enhance engagement.

Clinical Implications and Future Directions

Half of the adolescents seeking digital treatment had previously received face-to-face treatment for an eating disorder. This emphasizes the relevance of digital interventions to complement or extend traditional care, particularly for individuals who may not have experienced sufficient benefit from prior treatment. Moreover, the adolescents' high level of internal pretreatment motivation may suggest that digital treatment can also serve as a viable alternative to face-to-face approaches for some individuals. Suitable options to traditional eating disorder treatment are urgently needed, not only because of existing treatment challenges but also to address future public health care concerns. A remarkable increase in eating disorders among adolescents since the beginning of the COVID-19 pandemic emphasizes a real challenge for health care providers [4,84,85].

Adolescents with anorexia nervosa and bulimia nervosa were excluded from participating. Given the high prevalence of adolescents who go untreated [11], future steps should be taken to offer the intervention to adolescents with these disorders within routine clinical care. A potential solution involves combining digital treatment with periodic in-person medical evaluations. This would also address the needs of those who prefer face-to-face interventions but who also endorse the advantages of digital interventions (eg, availability in times of need and the ability to address stigma associated with help-seeking) [34]. Additionally, digital platforms offer opportunities to integrate tools for monitoring symptoms that may signal medical risk, thereby enhancing patient safety and clinical responsiveness.

Although emotional difficulties are common in adolescents with eating disorders [77-79], these domains are not a primary focus of first-line eating disorder treatments [17]. In the design of mental health technologies, a shift from a top-down approach to a user-driven process necessitates new models of behavior change that move beyond traditional psychotherapy frameworks [76]. The results from this study are in concordance with other studies that address the importance of targeting emotional difficulties in the treatment of eating disorders [29].

The current findings highlight the need to increase diversity among adolescents participating in eating disorder treatment [17,82,83]. In particular, the absence of male participants and the lack of representation of gender-diverse individuals underscore well-documented disparities in help-seeking and access to care. Future research should prioritize recruitment strategies that actively engage these populations, including the use of culturally sensitive language and appropriate measurement tools [17,82,83].

Limitations

This study has important limitations that need to be addressed. Several aspects of the study design may introduce sampling bias. Recruitment was limited to adolescents eligible for specialist outpatient care within a specific catchment area, which may not reflect the broader geographical population. In addition, this recruitment approach may have constrained the extent to which the sample reflects the broader sociodemographic characteristics and contextual factors considered during the co-design process. The exclusion of those with anorexia nervosa and bulimia nervosa further narrows the sample. In addition, recruitment through self-selection options may favor adolescents who are more motivated, less burdened by barriers to help-seeking, or who already knew that the content would align

XSL•FO
RenderX

with their preferences. Moreover, the lack of a control or comparison group may introduce sampling bias, as it is unclear whether participants differ systematically from those who did not participate or from those who would have received other treatments. These factors may reduce the representativeness of the sample and limit generalizability. Another limitation is the lack of systematic reporting and evaluation of the co-design process. Even though it is reasonable to consider that user involvement in the design and development process from the start influences the extent to which adolescents' characteristics are embedded in the design, we do not know whether it was the involvement of users at a particular phase or the continuous involvement across all phases of design that offers benefits to design research.

Conclusions

The findings from this study underscore the relevance of digital interventions to complement or extend traditional eating disorder care for adolescents. Furthermore, the findings highlight the importance of enhancing diversity among adolescents participating in digital eating disorder treatments to ensure equitable access and representation. The findings emphasize the importance of designing digital treatments that are sensitive to normative biases and highlight the value of involving a diverse group of adolescents with lived experience of eating disorders in the design and development process from the start. In addition, this study highlights the importance of designing digital treatments that address the multifaceted nature of eating disorders and are tailored to the needs and preferences of a transdiagnostic population. The present findings are important insofar as they may indicate that the key treatment components align with the characteristics of adolescents seeking digital treatment for eating disorders within routine clinical care. Results from the open feasibility trial will show whether adolescents experience the novel digital treatment as acceptable, and credible, and whether the treatment reduces symptoms and increases coping skills.

Acknowledgments

The authors wish to thank the adolescents who generously participated in this study. This manuscript includes sentences that were edited with the assistance of a large language model (Microsoft 365 Copilot Chat) to improve clarity and grammar.

Funding

This research was funded by the Norwegian Research Council (NFR 331794).

Data Availability

Data generated, analyzed, and reported during this study are not publicly available but are available in a slightly shortened, deidentified form from the corresponding author on reasonable request. The protocol may be shared upon request.

Abstract

Background: The population of young individuals not in employment, education, or training (NEET) is highly diverse, but a common problem appears to be their mental health. NEETs due to illness or disability are of particular concern for social exclusion, but little is known of how young individuals who are NEET with and without disability make use of, and gain from, employment interventions. There is also a scarcity of research on psychological interventions and mental health outcomes among young NEETs. Acceptance and commitment therapy (ACT) has shown promising results in psychological outcomes in young adults.

Objective: This study aimed to expand the knowledge on the effects of an app-based intervention built on ACT on NEETs with and without disabilities.

Methods: A 2-arm randomized controlled trial was conducted in 2021, including 151 young NEETs aged 16-24 years. Participants were recruited mainly via social media platforms and through organizations working with young NEETs. The intervention group (n=77) used an app for psychological well-being with the possibility for digital group meetings for 6 weeks, and the control group (n=74) received film clips once a week. Outcomes were self-assessed through questionnaires. Statistical analyses were made using chi-square, Mann-Whitney *U* test, general linear model, and logistic regression.

Results: No differences in effects on mental health were seen between the intervention and control group, neither overall nor between young NEETs with or without disability. Usage data show that 68.8% (53/77) of the participants in the intervention group downloaded the app, and 24.7% (19/77) completed all 6 modules. Effects on employment and education levels were only seen within the intervention group, where those who had completed one or more modules had a higher likelihood of being active in terms of employment and education compared to those who did not complete modules. No significant effects were seen in employment and education levels in relation to disability status. A high proportion of the participants had a disability, few were in contact with a youth employment center, and there was an overrepresentation of young women in general. Participants with disabilities had lower self-esteem, had less frequently completed high school, had less work experience, and a larger proportion had been in the NEET situation for over a year. A higher dropout were seen among participants in the intervention group and among young men.

Conclusions: No effects of the app-based intervention were seen for psychological well-being between young NEETs with disabilities and those without, but the results showed potential effects on employment and education levels related to engagement in the intervention. NEETs with disabilities are of particular concern and might need additional efforts or other types of interventions than the one investigated in this study. Findings can be considered weak due to the low adherence and high attrition.

not in employment, education, or training; NEET; disability; intervention; app-based; psychological health; acceptance and commitment therapy

Introduction

There is a global consensus on the importance of reducing the proportion of young individuals not in employment, education, or training (NEET), as demonstrated in Sustainable Development Goal 8.6 [1]. NEET status per se can be associated with long-term detriments and disadvantages such as economic scarring [2], social exclusion [3], health scarring by impacts on mental health and health behavior [4], and preterm mortality [5]. The population of NEETs is highly diverse, and its composition and characteristics vary between European countries [3]. In the case of Sweden, there is a larger proportion of short-term unemployed NEETs (35.5% vs 25.5%), a substantially higher proportion of NEETs due to illness or disability (16.1% vs 7.1%), and a lower proportion of long-term unemployed NEETs (8.5% vs 23.1%) compared to Europe as a whole [6]. NEETs due to illness or disability (defined as "young people who are not seeking employment or are not available to start a job within two weeks due to illness or disability" including individuals who cannot do paid work due to their illness or disability) are described as of particular concern for social exclusion [3].

Leaving school early or being in the NEET situation is more common among young people with disabilities compared to those without, indicating that the transition from school to work is more challenging for young individuals with disabilities [7]. A recent Organisation for Economic Co-operation and Development (OECD) report states that 8% of 15- to 29-year-olds had a disability in 2019, with a varying prevalence around the world [7]. The incidence is on the rise due to an increasing incidence of chronic depression, particularly in the Nordic countries. This trajectory was further accelerated by the COVID-19 pandemic [8] when mental health support was disrupted, schools closed or shifted to online education, daily routines and social contact were lost, and the labor market became extremely unstable [9]. Work can be a protective factor for mental health if working conditions are adequate [10].

The potential for employment interventions directed toward the NEET population has been demonstrated in a review [11], but the number of conducted trials is few and little is known about effectiveness in relation to, for example, different types of approaches or specific subgroup populations. There is also a scarcity of research on psychological interventions, including mental health outcomes. The review calls for more research on specific aspects of interventions that work and for whom, and highlights that subgroup differences to the detriment of the most disadvantaged groups were shown in some trials in relation to both effects, recruitment, and intervention engagement [11]. The need for intervention studies increasing the understanding of the effects on different subgroups of vocational and mental health support for young people who are NEET is also highlighted in a systematic review and meta-analysis on the mental health of young people who are NEET [12]. A qualitative study on experiences from a program aiming to engage young NEET showed how different elements impacted differently on different individuals [13]. Another study focusing on psychological therapy treatment outcomes of young NEETs showed that young NEETs had worse outcomes in recovery, deterioration, and attrition compared to non-NEET individuals and that the difference between the groups grew in the first few months of the COVID-19 pandemic [14]. There were also differences in outcomes within the NEET group depending on ethnicity and level of deprivation of residential areas [14]. The same study also reports an association between attending more sessions and improved outcomes [14].

Web- and app-based interventions [15] have the potential to reach populations that are normally hard to reach. The evidence around eHealth and smartphone-based psychological interventions is yet to be concluded, but has shown small positive effects on general mental health [15], anxiety and depression [15-17], and acceptance and mindfulness skills [18], and are described as promising tools to make psychotherapy more widely available even though the effects seem to be smaller than face-to-face psychotherapy. For adolescents, the evidence of these kinds of interventions is even scarcer [15]. Web-based acceptance and commitment therapy (ACT) has shown promising results in reducing stress and increasing academic buoyancy among adolescents [19] and improving psychological, emotional, and social well-being, life satisfaction, and self-esteem, and reducing symptoms of stress and depression among university students [20]. ACT aims to increase psychological flexibility, helping individuals regulate difficult thoughts and emotions while engaging in valued actions [16]. These mechanisms may be particularly relevant for NEET youth facing uncertainty, low self-esteem, or avoidance patterns, and could theoretically support both well-being and reengagement in work or education. A meta-analysis on the efficacy of smartphone-based mental health interventions called for more research investigating which aspects of interventions are effective and for whom they are beneficial [21]. Several reviews also underline the difference in effects dependent on the choice of control group, with larger effects when using a waitlist or no treatment control compared to an active control group [15,16,18]. Adherence is another aspect to take into account, where a systematic review and meta-analysis of self-guided online acceptance and commitment therapy interventions reported that 57.6% of all participants completed all modules, with adherence data ranging from 27.5% to 94.7% in the included studies [16]. Another review focusing on web-delivered acceptance and commitment therapy for mental health and well-being reported a mean adherence of 83% in terms of completing post-assessment, ranging from 48% to 100% [17]. Using reminders has been suggested to improve adherence and subsequently the effects of the interventions [15,18].

XSL•FO
RenderX

Recruitment and attrition are indeed other problems related to intervention studies on the population group NEET. There are numerous reports of the difficulty in reaching NEETs, in particular long-term NEETs and those that are not registered at the public employment services [22]. In Sweden, where this particular study took place, young women in the NEET situation have been particularly difficult to reach with interventions [23]. Social media have shown promise as a possible way to reach hard-to-reach populations [24,25] but have mostly been used for observational or cross-sectional studies and less for clinical or interventional studies [24,25]. In terms of attrition, a recent evidence and gap map of youth employment interventions rated 73.4% of the studies to be of low quality, which was most commonly related to high attrition rates or nonreporting of attrition. Another reason for the low-quality impact evaluations was large differences between intervention and control groups in baseline characteristics [26]. Furthermore, a study on an apprenticeship program directed to young NEETs showed that younger individuals and those with worse relationships with parents were more likely to drop out, underlining the need for different support approaches considering the background of the individuals [27].

In line with the research gaps identified relating to differences in how subgroups of NEETs make use of, and gain effects from, mental health interventions, the study aimed to expand the knowledge on the effects of an app-based intervention built on acceptance and commitment therapy on NEETs with and without disabilities. The following research question was considered: How do the effects (well-being, psychological distress, and employment and education level) of an app-based intervention on psychological well-being on young NEETs in Sweden vary depending on the presence of disability and moderated by background characteristics?

Methods

Study Design

A 2-armed parallel randomized controlled trial (RCT) was conducted between March and October 2021 to assess the feasibility and effectiveness of an app-based intervention built on ACT in comparison to film clips from YouTube dealing with mental health problems. The CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines for reporting RCT [28] were used (Multimedia Appendix 1).

Inclusion and Exclusion Criteria

To be eligible for participation in the study, participants had to be 16-24 years of age, unemployed or not working or studying more than 19 hours per week. The reasons for including individuals who were active up to 19 hours per week were to include semiactive students struggling to get through high school and individuals with insecure employment. They also had to be willing and have the possibility to participate in the full intervention and have a sufficient level of Swedish to take part in the intervention. Participants who received high values on screening for depression, that is, 15 points or more on the Patient Health Questionnaire-9 (PHQ-9), were excluded and provided contact details on where to seek care. The reason for exclusion was that depression was considered to need more treatment than this study intervention could provide. The excluded participants were also offered the chance to be contacted by any of the psychologists involved in the study if they wished to have further support.

Recruitment

The recruitment of participants from all over Sweden was done in two different phases, with the first phase of the recruitment taking place in March and April 2021, with advertisements on Facebook and Instagram. At this stage, municipalities and organizations working with NEETs were contacted and asked for support to reach out by posting on their social media, informing potential participants about the study, or having the study coordinator inform at digital group meetings. The study was also advertised on the Karolinska Institutet website, “Research subjects wanted.” When a participant declared interest in participating in the study at this stage, she or he received an email with a link to a participant information and consent form, followed by a baseline questionnaire. Despite the efforts made to reach out broadly to the target group, recruitment went slowly, which is why a new take on the recruitment strategy had to be made. Phase 2 of the recruitment started in May 2021, when the developer of the app that was tested in the study helped to create a short recruitment video that could be posted on other social media sites such as Snapchat, TikTok, and YouTube. Snapchat became the primary recruitment source. Those who declared interest in this phase were sent a text message where they were asked if the study coordinator could contact them by phone to give them more information about the study or if they preferred to be emailed. All advertisements and information regarding the study contained the logo of Karolinska Institutet.

Randomization

Randomization was performed continuously when 20 new participants had been recruited. This number was twice the number of participants that were required for a full potential group for the digital group meetings in the intervention group (described below). Randomization was performed 1:1 by the study coordinator using the statistical program IBM SPSS by inserting the study ID of the participants and using the command “Random sample of cases,” requesting that exactly 10 out of 20 be selected. The randomization was performed 3 times, and the third randomization was used for all randomization rounds. Due to logistical reasons related to the timing of the group meetings, randomization was sometimes performed before reaching 20 new individuals. In those cases when an uneven number of individuals had been recruited, one additional person was requested to be assigned to the intervention group.

Participants

A total of 590 young individuals declared interest in participating in the study. Of those, 193 individuals consented to participate in the study and filled in the baseline questionnaire. Due to high scores on the screening for depression, 42 individuals were excluded from the study and provided contact details for where to seek care. A total of 151 participants were randomized into either the intervention group (n=77) or the control group (n=74) and started the study.

XSL•FO
RenderX

The Intervention

The active intervention was a youth program for increased self-compassion, self-care, mindfulness, and value-based behaviors, delivered in the 29k app (29k Foundation) [29]. The 29k app was developed by the nonprofit foundation 29k to make evidence-based tools for mental health available to as many as possible in a user-friendly manner. The youth version used in the study was in Swedish, had been piloted on young people with different backgrounds and experiences, and consisted of 6 modules that were to be used during 6 weeks. The modules included interactive material and exercises on stress, self-compassion, gratitude, relationship skills, recovery, and mindfulness exercises. In the app, additional modules were freely available for the participants to use, but no updates to the app were made, so the content remained the same throughout the trial. Participants randomized to the intervention group received individual, unique links to download the app. Participants were provided with contact details for the research team in case they needed support concerning the use of the app. Participants in the intervention group were invited to participate in weekly digital group meetings led by a trained facilitator. The facilitators did not need to be mental health professionals and got 1.5 hours of training in how to facilitate the groups. The meetings were 45 minutes long. Participation in the digital group meetings was voluntary, and the participants could choose to participate in one or several meetings or decide to use the app program on at least a weekly basis by themselves without participating in the meetings. Reminders were emailed for group meetings, and those reminders were also planned to work as reminders for using the app.

The Control Condition

The control intervention consisted of YouTube film clips where young adults were discussing stress, mental health problems, self-esteem, and the meaning of life (Multimedia Appendix 2). An active control was chosen to reduce expectancy effects and ensure that both groups receive a structured weekly engagement. This design provides a conservative test of intervention-specific effects. Links to the film clips were sent out via email once a week for 6 weeks, and the clips were between 4 and 8 minutes long. The participants were asked to watch the video that was provided in the link and reflect for themselves. A reminder was sent out three days after the link was sent.

Data Collection and Measures

Overview

Data were collected using self-assessed electronically distributed questionnaires at three timepoints: baseline (t1), postintervention (t2), and 6 months after randomization (t3). The secure web platform REDCap (Research Electronic Data Capture; Vanderbilt University) was used for overall project management and for data collection by sending out links to the questionnaires as well as reminders when the questionnaires were not completed. The questionnaire included background questions on age, sex, country of birth, physical or psychological disability or diagnosis, years of schooling, work experience, relationship with parents, trust in different societal institutions, trust in general, and how they found out about the study. The follow-up questionnaires (t2 and t3) also contained 3 free-text questions on whether the study had affected motivation, supported knowing what to do in life, and affected how the participant cares for, or commits to, others or the environment. Furthermore, the following outcome measures were included in the questionnaire.

Self-Esteem

Self-esteem was measured with the Swedish version of the Rosenberg self-esteem scale [30], consisting of 10 items to be answered with a 4-grade scale stretching from “strongly agree” to “strongly disagree.”

Well-Being

The Swedish version of the World Health Organization-Five Well-Being Index (WHO-5) [31] was used to assess well-being among the participants. The WHO-5 has five items to be answered on a 6-grade Likert scale ranging from “all the time” to “at no time.”

Stress

Stress was measured with the Swedish version of the Perceived Stress Scale (PSS-10) [32,33], consisting of 10 items to be answered with a 5-grade Likert scale representing the range from “never” to “very often.”

Anxiety

The Swedish version of the Generalized Anxiety Disorder 7-item scale (GAD-7) [34] was used to assess anxiety among the participants. The instrument consists of seven items to be answered with a 4-grade Likert scale ranging from “not at all” to “nearly every day.”

Depression

Depression was measured using PHQ-9 [35]. The PHQ-9 is used in Swedish health care as a screening instrument for depression and consists of 9 items to be answered with a 4-grade Likert scale representing the range from “not at all” to “nearly every day.”

Career Adaptabilities

Career adaptabilities are individual resources for coping with occupational challenges and tasks. The outcome was measured with a translated version of the Career Adapt-Abilities Scale - Short Form [36]. The scale consists of 12 questions that are to be answered using a 5-point Likert scale ranging from 1=“not a strength” to 5=“greatest strength.”

Employment or Education Status

The outcome was measured by questions on whether the participant was working, in education, or in training (3 different questions). The total time that the participants responded that they were either in employment, education, or training was compiled. A total of 20 hours or more per week was considered “active,” less than 20 hours a week was regarded as “not active.”

For the intervention group, data on app downloads, registration, and completed lessons were collected. Participation in the digital group meetings was noted by the facilitators. Given the design of the study, neither the participants nor the group leaders could be blinded to the intervention conditions. Participants received

XSL•FO
RenderX

information about the 2 conditions (intervention and control) and to which group they were assigned. Group leaders provided parts of the intervention and feedback on why they were aware of the condition. Researchers had access to the assessments made online.

Data Treatment and Analyses

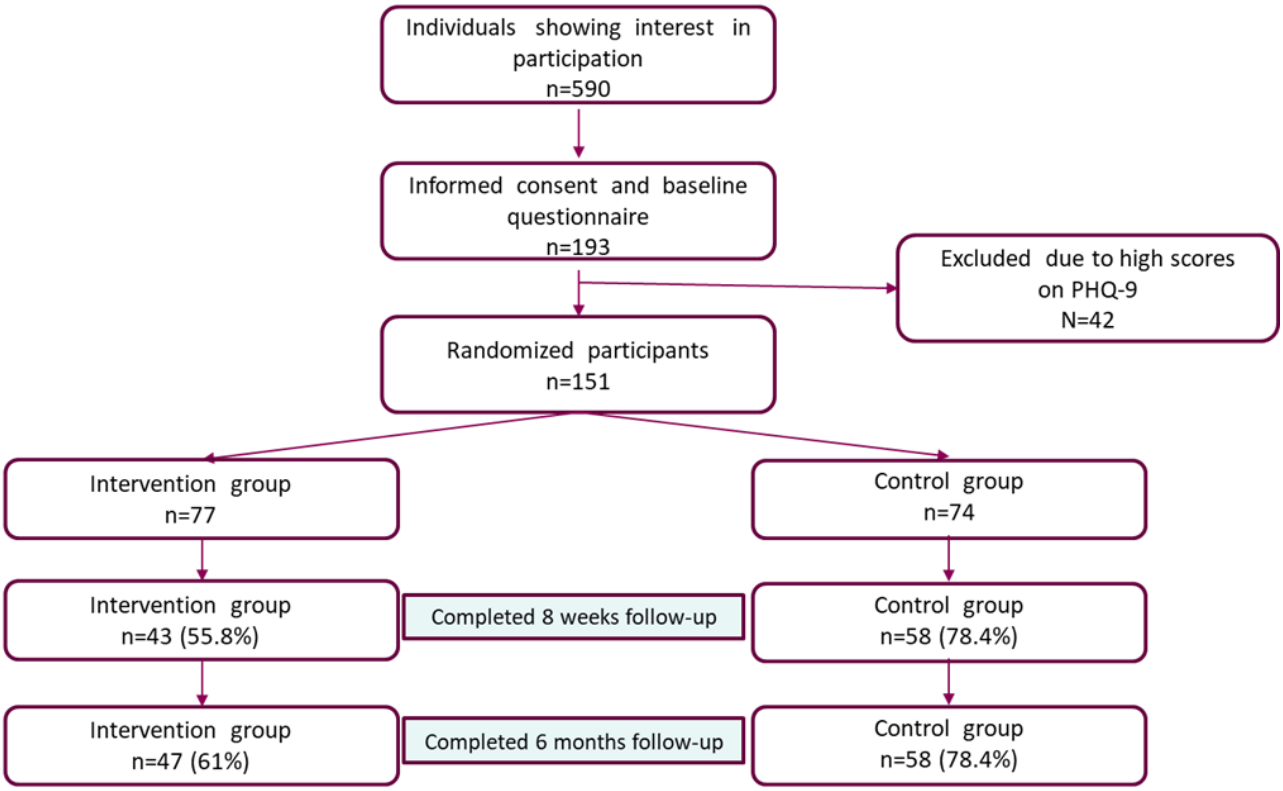
Sample size was compiled based on a power of .80 and α=.05 for a moderate effect in an analysis of variance with two groups, resulting in a sample of 64 participants in each group [37]. The aim of recruitment was 180 participants to allow for a dropout of about 25%.

Differences in background data of the participants in the intervention and control groups were tested with the chi-square for categorical variables and the Mann-Whitney *U* test for continuous variables due to nonnormality of the variables. The Pearson correlation test was used to assess the correlation between the total score of the Career Adapt-Abilities Scale and completion of modules in the app for the participants in the intervention group.

Composite scores were compiled for the outcomes "well-being" and "psychological distress" using *z*-scores. For well-being, the *z* scores from the instruments WHO-5 and the Rosenberg self-esteem scale were summed into one composite variable. For psychological distress, the *z* scores from the instruments GAD-7, PSS-10, and PHQ-9 were summed. Composite scores were chosen to reduce the number of statistical tests.

A general linear model (GLM) was used to analyze the differences between t1 and t2 for the composite scores of well-being and psychological distress. Analyses were made using both per protocol (PP) and intention to treat (ITT) approach, where missing values in the ITT analysis were replaced with series means of the intervention and control group. The ITT approach assumed data were missing at random at the level of the treatment group. Differences in well-being and psychological distress (t2-t1), respectively, were used as dependent variables in each model. Group, gender, and disability were used as fixed factors in the GLM model. The interaction effect between those variables was included in the tables. Country of birth was not included as a fixed factor since the number of participants born abroad was small. Binary logistic regression was used for the analyses of employment and education status at t3. IBM SPSS (version 28) was used for all analyses.

Ethical Considerations



The study was approved by the Swedish Ethical Review Authority (Dnr 2020-03952). All participants were informed about the study and their rights and signed a digital informed consent form before participation. Data collected are stored in secure databases at Karolinska Institutet and presented at the group level to minimize the risk of identifying specific participants. Participants were reimbursed with a gift card of 750 SEK after completing the final questionnaire to cover the time used for the study.

Results

Of the 151 participants who participated in the study (Figure 1), almost three-quarters were young women (Table 1). The mean age of the participants was 20 (SD 2) years, and 9 out of 10 were born in Sweden. Almost half of the participants responded that they had a physical or psychiatric disability or diagnosis (hereafter mentioned as "disability"). More than half of those had several different disabilities, and the most common ones were psychiatric disabilities such as attention deficit hyperactivity disorder (ADHD; n=35), depression (n=25), generalized anxiety (n=20), and autism (n=15). The majority of the participants had passed ninth grade, and about 6 out of 10 had completed high school. Participants came from all parts of Sweden, about half from the middle part, a third from southern Sweden, and the rest from the northern part of Sweden. The largest proportion of participants came from large cities or municipalities nearby, followed by medium-sized towns and nearby municipalities, while 18.5% (28/151) of participants came from small towns or rural municipalities. Slightly more than half of the participants had been outside of employment, education, or training for 3-12 months. Only 21.9% (33/151) were in contact with a youth employment center or other activity directed to NEET youths. No significant differences in terms of background characteristics were found between the intervention and the control group.

[a]*P* values were calculated by chi-square or Mann-Whitney *U* tests.

[b]Analysis only including women or men categories.

[c]Not displayed as n<5.

[d]Not applicable.

[e]NEET: not in employment, education, or training.

Some statistically significant differences were found in background characteristics between those who reported a disability and those who did not (Table 1). A lower proportion of those with a disability had completed high school and had previous work experience compared to those without disability. Participants with disabilities also had a higher proportion of 13 months or more with NEET status.

There were no significant differences between the intervention and the control group in self-reported health at baseline (Multimedia Appendix 3). The participants had a mean value of 45.7 in the instrument WHO-5, which can be regarded as relatively low considering that values below 52 points indicate further investigation when used in health care [31]. The mean value of the participants on self-esteem, 14.5 points, was on the limits of low and normal self-esteem. About half (74/151, 49.7%) of the participants had values indicating mild anxiety, while 27% (41/151) had values indicating moderate or severe anxiety. The stress levels of the participants were classified as moderate in 74.8% (113/151), and 11.9% (18/151) had values indicating high stress levels. About 57% (86/151) had moderate depressive symptoms, and the remaining participants had either no, minimal, or mild depressive symptoms (those with more severe symptoms had been excluded).

The participants who reported a disability had a significantly lower mean score on self-esteem compared to those without disability (12.0 vs 16.1). No other significant differences were observed (Multimedia Appendix 3).

Table 2 shows that about 30% (46/151) of the participants did not complete the final questionnaire at 6 months and were considered to have dropped out. There was a significantly higher dropout in the intervention group compared to the control group, and among young men compared to young women. There was also a higher proportion of those born outside of Sweden who dropped out, but the difference was not significant. No difference in dropout was found in the other background factors. Looking further into the intervention group, a significantly higher share of the young men dropped out compared to the young women in the intervention group (12/77, 15.6% vs 18/77, 23.4%; χ^2_1=.03). No other significant differences were found in terms of dropout in the intervention group related to age, country of birth, or disability status.

[a]Chi-square analysis only including women and men categories.

Usage data from the app show that about 7 out of 10 participants in the intervention group downloaded and registered in the app (Table 3). Of those that registered, about 87% (46/53) consented to having their usage followed. Slightly more than half of the participants did not complete any modules in the app. About 27% (21/77) of the participants completed 4 or more modules, and the same percentage participated in one or several digital group meetings. There were no significant differences in usage between those with disabilities and those without disabilities. Multimedia Appendix 4 displays some background and health-related characteristics of the participants who completed any modules in the app and those who did not complete any. Among those who did not complete any modules, there was a higher proportion of participants born outside of Sweden, a lower proportion of participants reporting that they trust other people in general, and a higher proportion who were in contact with a youth employment center or other activity toward young NEETs. No significant differences were seen for the other characteristics. A sensitivity analysis examining the correlation between the score on the Career Adapt-Abilities Scale from the participants in the intervention group at the beginning of the study and whether they completed modules or not resulted in a significant negative correlation (Pearson correlation coefficient r=–.31; P=.01). Hence, participants who completed modules tended to score lower on the scale than those that had not completed modules. In terms of time dedicated per week for

XSL•FO
RenderX

the study, 28.4% (21/74) of the participants in the control group did not answer the question, 33.8% (25/74) answered that they had used 1-15 minutes per week, 24.3% (18/74) had used 16-30 minutes per week and 13.5% (10/74) had used more than 30 minutes per week. In the intervention group, 49.4% (38/77) did not answer, 9.1% (7/77) of the participants answered 1-15 minutes, 11.7% (9/77) had used 16-30 minutes per week, and 29.9% (23/77) had used more than 30 minutes per week for the study.

Table 3. Usage of the app in the intervention group, total, and depending on disability status.

	Intervention (n=77), n (%)	Disability (n=41), n (%)	No disability (n=36), n (%)	Chi-square (*df*)
Registered				.17 (1)

Completed all 6 modules				.26 (1)
Yes	19 (24.7)	8 (19.5)	11 (30.6)	
No	58 (75.3)	33 (80.5)	25 (69.4)	
Participation in group meetings				.68 (1)
Yes	21 (27.3)	12 (29.3)	9 (25)	
No	56 (72.7)	29 (70.7)	27 (75)	

Comments in the free-text answers were similar for the participants with and without disabilities in the intervention group. Some comments were raised about using the app, which made them feel less alone, as it was comforting to hear others having similar thoughts and feelings. Other comments were that they appreciated the discussions with the group leaders during the group discussions and the exercises to work on in between. Some participants also described how they valued the exercises provided in the app, such as meditation, and that some exercises had triggered self-reflection and awareness about how they feel. Other participants expressed that they did not perceive that the app had changed their motivation. A few participants wished for a longer duration of the intervention.

The GLM analyses made PP showed no significant differences for improvement of psychological distress or well-being between the intervention and the control group, irrespective of disability status or gender (Table 4). The ITT analysis on change in well-being indicated a tendency (P=.08) where the intervention group had a more positive change in well-being between baseline and directly after the intervention compared to the control group. No interaction effects were observed.

When focusing on the intervention group and their exposure to the intervention using both PP and ITT analysis, there were no significant differences between those who completed one or several modules in the app compared to those who did not complete any (Table 5). Similar results were observed when looking at those who participated in the group meetings (Table 6).

The analyses regarding employment and education level of the participants 6 months after randomization did not yield any significant results when including the full sample, nor when comparing the control group to those in the intervention group that had completed any modules in the app (Table 7).

The analyses regarding employment and education level of the participants 6 months after randomization did not yield any significant results when including the full sample, nor when comparing the control group to those in the intervention group that had completed any modules in the app (Table 7).

Discussion

Principal Findings

The study aimed to expand the knowledge on the effects in terms of well-being, psychological distress, and employment and education level of an app-based intervention on NEETs with and without disabilities. The main findings of the study are that no differences were seen overall between the intervention and control groups, irrespective of whether the participants had completed a module in the app or not. No significant differences were found regarding the effect of being active in terms of employment or education, 20 hours or more per week, 6 months post randomization, except within the intervention group, where those who had completed one or several modules in the intervention were more likely to be active compared to those who did not complete any.

The findings could be related to those described in the review of Mawn et al [11], showing varying results from the interventions, and where high-contact interventions seemed to be most effective. Participation in the digital group meetings offered to the intervention group was low in general, and it might be worth considering if other formats would suit the target group better, in particular for participants with a disability. Other studies have presented differences in effects related to, for example, gender, ethnicity, and age [11,14]. Only gender was tested in this study since the material did not allow for examining ethnicity, and the age group was too narrow, but the results on intervention effects did not differ across gender. When reflecting about the effects of the app, it is important to keep in mind that the app is health promotive in the sense that it is developed to enhance the participant's well-being rather than to treat depression or anxiety and the target group excludes those with symptoms of severe depression, all of which are factors that could make it more difficult to detect positive effects of the intervention. Likewise, being a health-promotive app, it was not designed specifically for the purpose of getting young people into employment or education and was not intended as a stand-alone solution to replace traditional employment services but rather as a complement to other services. Indeed, several reviews emphasize the need for multicomponent strategies to cover the complex needs of the diverse population of NEETs [11,38,39]. Digital innovations could be a way to provide scalable and flexible support to young NEETs as an add-on to other activities, both focusing on psychological support and skills acquisition. One example of that is a clinically integrated online platform for young NEETs with mental health difficulties in Australia that showed positive work and study outcomes. The participants appreciated not having to travel and described the online mode as less confronting compared to in-person support, although some would have preferred meeting in-person

XSL•FO
RenderX

[40]. Other studies have shown promising results from digital interventions such as the use of social media as a platform for skill acquisition [41] and a game-based positive psychology intervention [42] to support and engage young NEETs. A meta-analysis of the effectiveness of gamified interventions for mental health promotion showed positive effects on both mental wellness and psychological symptoms [43]. However, several studies on NEET emphasize the role of a mentor to handle challenges that arise [44,45], in particular for NEETs with mental health challenges or NEETs experiencing other vulnerabilities, where often more intensive strategies are needed [38]. A sustainable contact with a qualified practitioner where the relationship is built on trust and close collaboration with the young NEET and where interventions include psychological support and social skills development are identified as important features for the transition into employment for NEETs with additional vulnerabilities [38]. A Swedish study on workplace-oriented rehabilitation found, on the other hand, a model with personnel-intensive support with a clear and early focus on work to be more effective in getting young NEETs into employment compared to another personnel-intensive support model with a more holistic approach [46]. The diversity of NEETs and the complex flora of needs and interventions provides an additional argument for why digital interventions could be more suitable as a complementary intervention, enhancing other types of contacts and interventions when multicomponent interventions are recommended [38]. Some of the qualitative feedback that came from the participants in the intervention group mentioned how the use of the app made them feel less alone by knowing that others have similar thoughts and feelings. Others mentioned the importance of the discussion with the group leader during the digital group meeting. The feedback shows the potential for digital innovations to provide psychological support in a suitable manner for some participants, appreciating the digital format as a complement to the face-to-face-format although other participants described that the app did not result in any change. Whether this preference could be related to specific disabilities among the participants remains unclear, but participants with and without disabilities brought up similar issues in the free text. The heterogeneity of disabilities among the participants and the fact that the majority of those with disabilities had multiple diagnoses in our study make it difficult to draw any conclusions from the findings on the appropriateness across diverse disabilities. Further studies of a more specific nature in terms of target group and specific diagnoses could increase understanding in this area.

A previous study looking at psychological treatment outcomes found an association between improved outcomes and attending more sessions [14]. In this study, no differences in psychological outcomes were found related to completing modules in the intervention or not. However, there was a higher likelihood of being in employment or engaged in studies 6 months post randomization in this study for those in the intervention group who completed modules in the intervention compared to those who did not. This finding can indicate the importance of further completing the intervention, or at least motivating the participants to give it a try. It is also possible that the results in this study could be related to differences in participant characteristics in the sense that characteristics facilitating completing the intervention, such as, for example, motivation, could also facilitate the process of seeking employment or studies. Motivation was not measured among the participants, but career adaptability has been associated with career motivation [47]. The results from the correlation analysis between career adaptabilities and completion of modules showed a negative correlation, where those with high scores on the career adaptabilities scale tended not complete modules to a higher extent and vice versa, which was a bit surprising. These findings should be interpreted with caution, but a possible explanation could be that the group with high career adaptability had expectations on the app that were not met. Another interpretation is that the app could be a good complement to those with lower career adaptability. The data at hand and the small sample of the intervention group restrict the possibilities to examine the underlying reasons for this further, and it is an area for future research. No significant differences in being active in terms of employment or education, 20 hours or more per week, were found between the intervention and the control groups. Keeping in mind that a meta-analysis of 3 high-intensity interventions directed toward NEETs resulted in a very low increase in employment for the intervention group [11], the intervention studied in this paper is of a lower intensity and, as mentioned previously, was not designed specifically to get people into employment. Additionally, this study had an active control group, which could make it more difficult to detect intervention effects compared to having a waitlist or passive control group, as has been mentioned in previous research [15,16,18,43]. In the same vein, our choice of having the cut-off at 20 hours per week as both inclusion criteria for the study (19 hours or less per week) and as an outcome for being active (20 hours or more per week) could be debated. Similar cutoffs have been used earlier in combination with other measures [48,49], but the diverse flora of outcome measures used in studies focusing on NEETs underline the need to develop standardized outcome measures for reengagement [50]. In Sweden, like in many other countries, poor school results or high absence from school are risk factors for becoming NEET, and insecure employment is common among young individuals [51]. Having a “generous” inclusion criterion that also includes young semiactive individuals embeds for capturing individuals early on in their career in a health-promotive approach. It can also be underlined that the majority of participants in our study were at the extremes in terms of the outcome of being active, three out of four were either active 0 hours or 30 hours or more per week, 6 months post intervention.

Focusing on the participants that were recruited, the larger proportion were young women. This was a bit surprising since the gender division of NEETs in Sweden is relatively equal, with a slightly higher representation of men [6], and women have previously been reported to be difficult to recruit [23]. Young men were also overrepresented among those who dropped out. A scoping review of the use of social media for recruitment to medical research studies did not find a gender difference in the recruited participants [25], and Snapchat, which was the primary recruitment channel during the second recruitment phase when the majority of the participants were recruited, has a relatively equal use over genders [52]. However, a review of digital mental health interventions found that men

XSL•FO
RenderX

were less likely to complete interventions compared to women and calls for interventions catering to the interests of young men [53]. It is possible that the intervention or the advertisements were more appealing to young women, even though the app and the short recruitment video were designed to appeal to all genders. Gamified interventions have shown promise for promoting mental health across genders, with an even greater potential effect on the reduction in anxiety symptoms in samples with a higher proportion of young men [43]. It is possible that using a gamified type of intervention could have resulted in increased recruitment and attainment of young men.

There was also a substantial proportion of those recruited who had a disability (about half), which is much higher than the general prevalence of 8% stated in an OECD report [7] and higher than the estimated 16% among NEETs in Sweden [6]. This high proportion of participants with a disability could imply that the type of intervention is particularly appealing to those with a disability, even though some adjustments have to be made for it to have an effect. As mentioned above, the heterogeneity of disabilities, as well as the high proportion of participants with multiple disabilities, complicated the interpretation of the findings in relation to disability status. The group of participants with a disability had nevertheless less frequently completed high school, which confirms the previous reports of a higher risk for school dropout among persons with, for example, depression, anxiety, or ADHD [54]. Previous reports of a difficult transition from school to work among individuals with disabilities [7] are also echoed in the findings of this study, where fewer participants with disabilities had previous working experience, and a larger proportion had been in the NEET situation for over a year. Participants with disabilities also had significantly lower self-esteem compared to those without. These findings call for further investigation of how the education system can be adjusted to meet the needs of all children and young people to lay the ground for a successful transition from school to work life. Working toward good health irrespective of disability status should be a priority in a society where all people should be entitled to be included and given possibilities for an engaged and rich life.

Overall, only 1 out of 5 participants had contact with an employment center, and it might be that this type of intervention, in combination with recruitment via social media, facilitates reaching populations that are normally difficult to reach with conventional interventions directed toward NEETs. Self-selection bias is a well-known risk when recruiting based on the fact that participants have volunteered for the study, and it might be that the recruitment strategy also attracted technology savvy participants. Furthermore, the recruiting procedure using both social media and affiliated organizations could also imply selection biases, but most probably of different kinds since the two approaches are likely to reach slightly different target groups. A large proportion of those recruited via social media had not been in contact with employment centers or similar activities, whereas those recruited via affiliated organizations had been informed about the study due to the contact they already had. The use of different approaches for recruiting was chosen to broaden the variety of young NEETs and to increase the possibility of also reaching those who had not been in contact with employment centers. Reaching participants at the beginning of their NEET journey could be a window of opportunity to prevent them from staying in the NEET situation for a long time, since research shows that individuals starting their career as unemployed are more likely to become unemployed later [55].

A major problem in the study was adherence, where slightly more than half of the participants in the intervention group did not complete any module in the app. Among those who did not complete any modules, there was also an overrepresentation of participants born outside of Sweden, a lower proportion of participants reporting that they trust other people in general, and a higher proportion being in contact with youth employment centers. In terms of time dedicated to the study per week, the intervention group had larger proportions on the "extremes" with a large proportions of participants who did not answer, but also a larger proportion of participants who had used more than 30 minutes per week for the study compared to the control group. Just by looking at what was required by the participants from the start, the time for the control arm each week was considerably shorter compared to the intervention arm, with the film clips being 4-8 minutes long. The higher time burden in the intervention arm compared with the control condition likely contributed to lower adherence and should be viewed as a structural feature of the design. Adherence is a problem seen in other similar studies based on smartphone or online interventions [16,56]. To improve adherence to mental health apps, actions such as involving end users in the development and thorough usability testing, as well as including clinician or peer support, have been suggested [56]. The apps that were tested in this study were developed with continuous feedback and input from end-users and underwent usability testing. It also included the digital group meetings that were intended to provide peer support, although these were not used much by the participants and sometimes even seemed to scare some of the participants off. The anonymity of the online context is indeed an appreciated feature that needs to be considered and balanced with the advantage of including social support or interaction with health professionals within an app [53].

High dropout is a common problem in both digital mental health interventions [56] and youth employment interventions [26]. In this study, 3 out of 10 participants did not complete the follow-up questionnaire 6 months post randomization, which is a relatively expected share given the target group, although slightly above the expected 25%. Efforts were made from the start to increase retention by using reminders as well as providing reimbursement for participation in the study, actions that have been suggested to reduce attrition [56]. We also changed the recruitment procedure along the way to have a mixed recruitment procedure involving both online registration, text message, and phone contact, but many participants actually chose to only use the online registration because they did not feel comfortable talking on the phone. Apart from a higher dropout among young men (discussed above), there was a higher dropout among participants in the intervention group. This has been seen in other studies using inactive control group but, to our knowledge, not in studies using active control groups [56],

XSL•FO
RenderX

such as this particular study. The high drop-out in the intervention group is likely related to the experienced higher demand and the need to dedicate more time to the intervention compared to the control arm. All participants in the intervention group were also invited to participate in digital group meetings that, even though they were described as voluntary, could have put further pressure on the participants. Keeping all that in mind, an app tailored for the target group of young NEETs may contain shorter modules to not appear excessively demanding.

Strengths and Limitations

Among the strengths of the study is the use of an RCT design using an active control group, which lay ground for an investigation of potential additional benefits of the specific app. The downside of having an active control group is that it makes it more difficult to detect effects [15,16,18]. Furthermore, the analyses made with both the PP and ITT approaches to handle missing data in the material due to high dropout resulted in similar results in all analyses. The power of the study was affected by the fact that recruitment had to close before reaching 180 participants due to logistical reasons. In addition, the dropout exceeded the expected 25%, which further lowered the power of the study. The online format also limited the possibilities to further explore the reasons for dropping out. Apart from a high dropout, there were also problems with low adherence to the intervention and low participation in the digital group meetings. About 1 in 10 participants were born outside of Sweden, which is about half the share compared to the Swedish setting, where 1 out of 5 in the age group is born outside of Sweden [57], and the numbers are too small in this sample to allow for assessing the effect of ethnicity which could have provided additional insights of the app's effects. The recruitment strategy with potential participants volunteering to participate limits the generalizability of the findings due to the risk of self-selection bias. Another limitation is related to the lack of blinding in the trial, which could not be done due to the design of the study. Furthermore, the fact that limited qualitative data were collected limits the possibilities of providing explanations of the use and nonuse of the app or for potential reasons for dropping out.

Conclusion

The findings of the study showed no differences in the effects of an app-based intervention for psychological well-being between young NEETs with disabilities and those without, although low adherence and high attrition make the conclusions weak. No effects were, however, seen between those using the app and those receiving film clips. The findings about a higher likelihood of being in employment or education among those who completed modules in the app compared to those who did not call for more research about the potential reasons. The study managed to reach a wide variety of young NEETs, reaching groups that often are hard to reach, such as participants with disabilities and young women. Many were also relatively new to the NEET situation and were not in contact with other activity initiatives, embedding for early interventions. There might be a need to include other social media sources for recruitment and to adjust the app and its content to increase the chances of including and retaining young men, since they were both underrepresented in the study population and overrepresented among those who dropped out. The heterogeneity of disabilities among the participants makes it difficult to conclude the findings, and more studies are needed to assess the appropriateness of digital interventions across diagnoses. NEETs with disabilities are of particular concern and might need additional efforts or other types of interventions than the one investigated in this study.

Acknowledgments

We would like to express our sincere gratitude to the participants of the study. We would also like to thank the people working in municipalities or organizations meeting young NEET individuals who supported the outreach to potential participants.

Funding

We would like to thank the Swedish Research Council for Health, Working Life and Welfare (Forte) who funded the study (2015-01136). The funders had no role in the design of the study or the reporting of the results.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available because the informed consent did not include a statement that the data would be made public. However, subsets of the data can be made available from the corresponding author on reasonable request and with permission from the Swedish Ethical Review Authority.

Authors' Contributions

LB, JR, FL, and LL contributed to the conceptualization of the study. LB and LL were in charge of data management and analysis and drafted the manuscript. FL and JR contributed to the conceptualization of the study and to revising the manuscript. LB, JR, FL, and LL took part in revising the manuscript and have approved the final version of the manuscript.

Conflicts of Interest

FL and JR hold positions at Karolinska Institutet and the nonprofit foundation 29k, which developed the app and its content. Neither FL nor JR participated in data analysis, and 29k had no role in study design decisions or interpretation of results.

Abstract

Background: Nonsuicidal self-injury (NSSI) is common among adolescents with depressive disorders and is associated with substantial clinical burden. Machine learning may assist in identifying multidimensional patterns associated with NSSI, although its incremental value beyond direct clinical assessment remains uncertain.

Objective: This study compares 7 supervised machine learning model variants for classifying past-year NSSI status among adolescents with depressive disorders and conducts detailed analyses of interpretability, sensitivity, subgroup performance, and clinical utility using a random forest model as the focal exploratory model.

Methods: We retrospectively identified 437 adolescents aged 10-19 years who received inpatient or outpatient psychiatric care at 4 hospitals in Zhejiang Province, China, between January 2021 and December 2023. A total of 410 eligible participants were included, of whom 274 reported NSSI during the preceding year. The primary analysis included 67 assessment-time sociodemographic, physiological, biochemical, and clinical-behavioral features. The sample was divided into a training set (287/410, 70%) and an untouched held-out test set (123/410, 30%) using stratified random sampling. Hyperparameters were optimized using 5-fold cross-validation within the training set. Performance was evaluated using discrimination, classification metrics, calibration, and decision-curve analysis. Random forest model behavior was examined using Gini importance, permutation importance, and Shapley Additive Explanations (SHAP).

Results: The radial basis function support vector machine achieved the highest mean cross-validated area under the receiver operating characteristic curve (AUROC) in the training set (0.720), whereas the random forest showed the highest observed AUROC and area under the precision-recall curve (AUPRC) and the lowest Brier score in the held-out test set. The random forest achieved an AUROC of 0.681 (95% CI 0.583-0.778), an AUPRC of 0.808 (95% CI 0.741-0.874), an accuracy of 0.667 (95% CI 0.585-0.748), a sensitivity of 0.720 (95% CI 0.622-0.817), a specificity of 0.561 (95% CI 0.415-0.707), and a Brier score of 0.212 (95% CI 0.188-0.236). Its calibration slope was 1.013. Pairwise AUROC differences between the random forest and alternative models were not statistically significant after Holm correction (Holm-adjusted *P* values ranged from .17 to .81). The full random forest model did not outperform a suicidal-ideation-only model (AUROC 0.701), whereas excluding suicidal ideation and previous suicide attempt reduced the AUROC to 0.540. A biochemical-only model showed near-chance discrimination (AUROC 0.513). Decision-curve analysis indicated that the random forest provided greater net benefit than the assess-all and assess-none strategies

XSL•FO
RenderX

across threshold probabilities of approximately 0.51-0.80. Suicidal ideation showed the most consistent importance across Gini, SHAP, and permutation analyses.

Conclusions: The random forest had the highest observed AUROC and AUPRC and the lowest Brier score in the held-out test set among the evaluated algorithms, although the pairwise AUROC differences were not statistically significant after correction for multiple comparisons. Suicidality-related information contributed substantially to model discrimination, whereas routinely collected biochemical variables did not demonstrate clear incremental value. Because this was a retrospective cross-sectional classification study, the findings do not establish prospective risk prediction. External and prospective temporal validation is required before clinical implementation.

nonsuicidal self-injury; depressive disorders; adolescents; machine learning; biopsychosocial approach

Introduction

Depressive disorders are among the most common mental health conditions during adolescence and are associated with substantial impairments in emotional well-being, academic functioning, interpersonal relationships, and daily life [1]. Adolescents with depressive disorders are also particularly vulnerable to nonsuicidal self-injury (NSSI), defined as the deliberate and direct injury of body tissue without suicidal intent [2]. Meta-analytic and epidemiological studies suggest that NSSI affects a substantial proportion of adolescents, with prevalence estimates generally higher in psychiatric and depressive-disorder samples than in community populations [3-6]. Although NSSI is conceptually distinguished from suicidal behavior by the absence of an intention to die, it is associated with greater psychiatric severity, repeated self-harm, suicidal thoughts and behaviors, and increased demand for mental health care [7-9]. Consequently, accurate identification and comprehensive assessment of recent NSSI among adolescents with depressive disorders represent important clinical priorities.

The clinical assessment of NSSI remains challenging because self-injurious behavior is heterogeneous and may vary in frequency, methods, functions, medical severity, and persistence [6,10,11]. Adolescents may also conceal NSSI because of shame, fear of stigma, concerns about confidentiality, or uncertainty about how parents and clinicians will respond [12,13]. Direct inquiry regarding NSSI and suicidal thoughts therefore remains essential. However, multidimensional clinical information may help clinicians identify patterns associated with recent NSSI and determine which patients require a more comprehensive, structured assessment [2,12]. Importantly, models based on concurrently or retrospectively measured variables can classify current or previous NSSI status, but they cannot establish temporal precedence or predict future NSSI onset unless they are evaluated prospectively using longitudinal data [14-18].

NSSI is understood as a complex behavior arising from interactions among psychological distress, behavioral vulnerability, interpersonal experiences, family context, and biological or physiological characteristics [19,20]. Established clinical correlates include younger age, female sex, greater depressive severity, emotional dysregulation, suicidal ideation, previous suicide attempts, and other forms of self-directed or interpersonal aggression [6,9,21,22]. Family-level factors are also particularly relevant during adolescence. Parental psychopathology, family conflict, adverse childhood experiences, limited perceived parental support, maladaptive parenting practices, and difficulties in parent-adolescent communication have all been associated with adolescent NSSI [23-25]. These factors may operate as vulnerabilities, protective resources, or moderators of the relationship between emotional distress and self-injurious behavior.

Physiological and biochemical characteristics have also been explored in relation to depression and self-injurious behavior, including inflammatory markers, thyroid function, metabolic indicators, liver and renal function, and neuroendocrine measures [26,27]. Such routinely collected variables may contain information that is not fully captured by symptom-based assessments and may contribute to nonlinear or interactive model structures [28]. Nevertheless, evidence that individual laboratory markers provide clinically meaningful information beyond established clinical variables remains inconsistent [18]. Laboratory measurements may reflect current depressive severity, medication exposure, nutritional status, physical activity, comorbid conditions, or consequences of recent behavior rather than antecedent mechanisms of NSSI. Accordingly, biochemical variables identified by a cross-sectional model should be regarded as potential model correlates and hypothesis-generating findings rather than independent causal biomarkers [18,19].

Despite the relevance of family context, family-level information is frequently underrepresented in routinely collected electronic medical records. Variables such as family psychiatric history or household residence may be available, whereas standardized assessments of parental mental health, family conflict, parenting practices, perceived support, parent-adolescent communication, and adverse childhood experiences are often absent. This limitation is particularly important in pediatric settings, where parents or caregivers are not only sources of clinical information but also potential partners in safety planning, treatment engagement, and relapse prevention [29]. At the same time, communicating model-derived findings to parents requires careful attention to adolescent autonomy, confidentiality, uncertainty, and the risk of stigmatizing labels [12,30]. Parent-facing information should therefore be accessible, probabilistic, and nondeterministic, and should be communicated within a clinician-mediated assessment rather than through automated alerts or isolated risk scores.

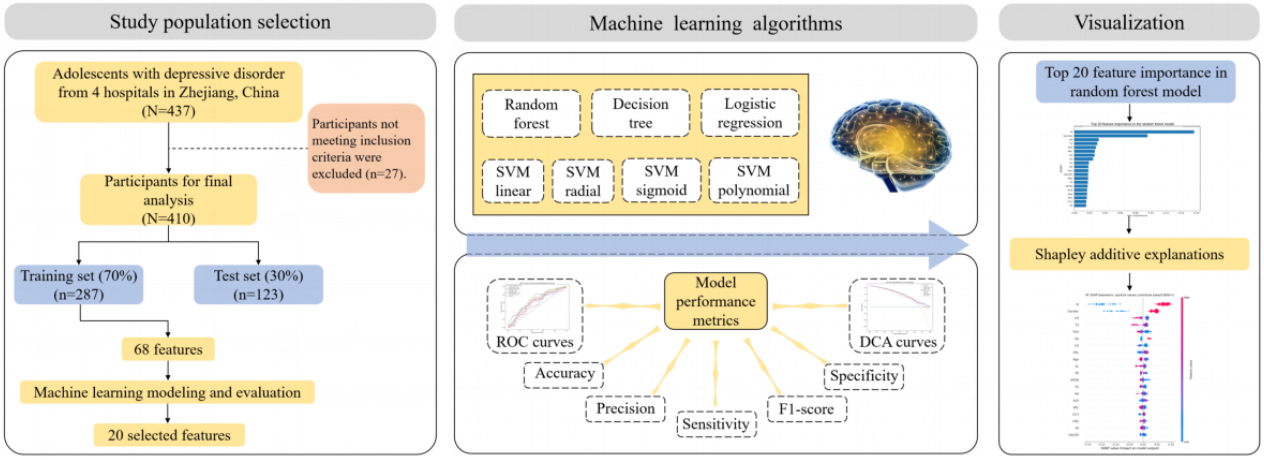
XSL•FO
RenderX

Machine learning has increasingly been applied to the study of NSSI and related self-harm outcomes using questionnaire data, clinical records, behavioral information, digital phenotyping, neuroimaging, and biological measures [31-34]. Compared with conventional regression approaches, some machine learning algorithms can accommodate complex nonlinear relationships and higher-order interactions [28,35]. Random forests are particularly suitable for modeling heterogeneous clinical data and allow complementary examination through impurity-based importance, permutation importance, and Shapley Additive Explanations (SHAP) [36]. However, algorithmic complexity does not necessarily ensure clinical usefulness. Most published NSSI models have been internally evaluated in cross-sectional or geographically restricted samples, whereas fewer studies have examined future NSSI occurrence using longitudinal designs [17,18,31-33]. Additional limitations include small event-to-feature ratios, inadequate control of information leakage, insufficient reporting of hyperparameter optimization and missing-data procedures, limited assessment of calibration, absence of external validation, and failure to compare complex models with simple clinical screens [30,35].

Model interpretability is particularly important when machine learning is applied in mental health care [30]. SHAP can quantify the contribution of a feature to an individual model output and summarize the magnitude and direction of contributions across a sample [36]. Nevertheless, SHA*P* values explain the predictions of a fitted model rather than the underlying causal process. A high SHAP or Gini ranking does not demonstrate that a feature is independently associated with NSSI, nor does it establish that changing the feature would alter clinical outcomes. Interpretation should therefore be supported by calibration, sensitivity analyses, subgroup performance, comparisons with simpler models, and alternative importance measures such as test-set permutation importance [30,36].

Accordingly, this retrospective multicenter cross-sectional study aimed to compare 7 supervised machine learning model variants for classifying past-year NSSI status among adolescents with depressive disorders using routinely collected sociodemographic, physiological-biochemical, and clinical-behavioral information. We evaluated discrimination, classification performance, calibration, and clinical net benefit in an untouched, held-out test set. As suicidal ideation is both a strong clinical correlate of NSSI and an immediate assessment priority, we examined whether the multidimensional models provided incremental information beyond suicidal ideation and other basic clinical variables. We also evaluated performance after excluding suicidality-related variables and examined sex- and residence-specific performance. The random forest was used as the focal exploratory model for detailed analyses of Gini, permutation importance, and SHAP. Finally, we considered the limited availability of family-context variables and the implications of model-assisted assessment for future parent- and adolescent-involved clinical communication. Given the concurrent and retrospective measurement of the candidate features and outcome, this study was designed to evaluate internal classification rather than prospective prediction of future NSSI.

Methods



Study Design and Participants

This retrospective multicenter cross-sectional study screened the electronic medical records of adolescents aged 10-19 years with depressive disorders who received inpatient or outpatient psychiatric care at 4 hospitals in Zhejiang Province, China, between January 2021 and December 2023. The study was designed to classify past-year NSSI status rather than to predict the future onset or recurrence of NSSI. Participants were retrospectively identified through systematic screening of electronic medical records and screened for eligibility. The inclusion criteria were as follows: (1) age between 10 and 19 years; (2) a clinical diagnosis of depressive disorder according to the International Classification of Diseases, 10th Revision (ICD-10); and (3) availability of the clinical assessment and laboratory information required for this analysis. The exclusion criteria were as follows: (1) bipolar disorder, schizophrenia-spectrum disorder, or another severe psychiatric disorder; (2) intellectual disability or cognitive impairment that could prevent a reliable clinical assessment; (3) severe or unstable physical illness or a chronic medical condition likely to substantially affect physiological or biochemical measurements; and (4) substance use disorder.

After the initial screening of the electronic medical records, 2 senior psychiatrists independently evaluated participant eligibility. Disagreements were reviewed with a third psychiatrist and resolved through discussion. A total of 437 records were screened, of which 27 were excluded because of severe psychiatric disorders (n=12), intellectual disability or cognitive impairment (n=2), severe or unstable physical illness (n=5), or substance use disorder (n=8). The remaining 410 participants were included in the final analytic sample. The participant-selection and modeling procedures are presented in Figure 1. Missing data within the included dataset were addressed using multiple imputation.

Figure 1. Study flowchart. AA: amylase; ALP: alkaline phosphatase; APOB: apolipoprotein B; CC3: complement component C3; CK: creatine kinase; CR: creatinine; DCA: decision curve analysis; FA: free fatty acid; FBG: fasting blood glucose; HSCRP: high-sensitivity C-reactive protein; IBIL: indirect bilirubin; PRL: prolactin; PS: previous suicide attempt; RF: random forest; ROC: receiver operating characteristic; SA: suicide attempt; SHAP: Shapley Additive Explanations; SI: self-injury; SL: aspartate aminotransferase-to-alanine aminotransferase ratio; SVM: support vector machine; T3: total triiodothyronine; T4: total thyroxine; TG: triglyceride; TSH: thyroid-stimulating hormone.

Ethics Approval

The Ethics Committee of Kangning Hospital, affiliated with Wenzhou Medical University, approved the study (ethical approval number KNLL-20211011002). The study was performed in strict accordance with the ethical principles of the Declaration of Helsinki (1975).

Data Collection

Outcome Variable

Past-year NSSI status was assessed during clinical interviews conducted independently by 2 senior psychiatrists. Participants were asked, "During the past year, have you intentionally injured yourself without intending to die, for example, by cutting, scratching, burning your skin, or hitting yourself?" Responses were recorded as "yes" or "no," with NSSI coded as 1 and non-NSSI coded as 0. Any disagreement between the 2 psychiatrists was reviewed by a third psychiatrist and resolved by consensus.

The binary outcome represented the presence or absence of broadly defined NSSI during the preceding 12 months. It did not constitute a diagnosis of NSSI disorder or capture NSSI frequency, persistence, methods, medical severity, functions, or associated impairment.

Candidate Features

Overview

Candidate features were identified through expert consultation and a review of the relevant literature. The processed dataset contained 71 candidate feature columns. Three fields that were not consistently defined in the original manuscript or source coding—SS, number of hospitalizations, and creatine kinase muscle-brain isoenzyme—were excluded from the manuscript-matched feature set. Completed length of stay was excluded from the primary model because it was not available at the index assessment and could have been affected by subsequent clinical management. The primary assessment-time model therefore contained 67 candidate features, grouped into sociodemographic and lifestyle features, family and social-context features, physiological and biochemical features, and clinical and behavioral features. The complete feature list is provided in Table S1 in Multimedia Appendix 1.

Sociodemographic and Lifestyle Features

Sociodemographic and lifestyle information was systematically collected during routine psychiatric consultations. The variables included sex, age, education level, BMI (kg/m^2), place of residence, smoking status, drinking status, family psychiatric history, and religious belief.

Family and Social-Context Features

The family and contextual variables available in the routinely collected electronic medical records were family psychiatric history and place of residence. Family psychiatric history indicated whether a psychiatric disorder had been documented among family members. Place of residence was classified according to the urban-rural coding used in the source records and was considered a contextual indicator rather than a direct measure of family functioning.

Standardized assessments of parental psychopathology, family conflict, perceived parental support, parent-adolescent communication, parenting style, and adverse childhood experiences were not systematically collected across the 4 participating hospitals and were therefore unavailable for model development.

Physiological and Biochemical Features

Blood samples were collected from the antecubital vein by trained nursing staff after overnight fasting (≥8 hours) between 7 and 9 AM upon hospital admission, ensuring standardized preanalytical conditions. Blood coagulation function was assessed by measuring D-dimer using a latex-enhanced immunoturbidimetric assay (Sysmex CS-5100). Thyroid function was evaluated by measuring thyroid peroxidase antibodies, thyroid-stimulating hormone (TSH), free

XSL•FO
RenderX

triiodothyronine, free thyroxine, total triiodothyronine (T3), and total thyroxine (T4) using a chemiluminescence immunoassay (Siemens ADVIA Centaur XP). Liver function was assessed by measuring alanine aminotransferase, aspartate aminotransferase, the aspartate aminotransferase-to-alanine aminotransferase ratio, total protein, albumin, globulin, albumin-to-globulin ratio, alkaline phosphatase, gamma-glutamyl transferase, total bilirubin, total bile acid, direct bilirubin, and indirect bilirubin using automated enzymatic methods (cobas c702; Roche). Serum prealbumin was determined using an immunonephelometric assay (Siemens BN ProSpec), while alpha-L-fucosidase was quantified using a spectrophotometric assay (Hitachi 7600). Markers of glucose and lipid metabolism, including fasting blood glucose, triglycerides, total cholesterol, high-density lipoprotein, low-density lipoprotein, apolipoprotein A, apolipoprotein B, lipoprotein a, and free fatty acids, were assessed using an enzymatic colorimetric assay (cobas c702).

Renal function was evaluated by measuring blood urea nitrogen, creatinine, and uric acid using an enzymatic method (cobas c702). Myocardial and muscle enzyme activities, including creatine kinase, creatine kinase isoenzymes (muscle-brain isoenzyme), and lactate dehydrogenase, were analyzed using an enzymatic assay (cobas c702). Plasma homocysteine levels were measured using an enzymatic cycling assay (cobas c702). Electrolyte balance was assessed by measuring potassium, sodium, chloride, calcium, magnesium, and phosphorus levels using an ion-selective electrode method (cobas c702).

Biochemical markers included serum ferritin, measured using an immunoturbidimetric assay (cobas c702), and cholinesterase, assessed using a butyrylthiocholine substrate method (cobas c702). Inflammatory response was evaluated by measuring high-sensitivity C-reactive protein using a latex-enhanced immunoturbidimetric assay (cobas c702). Complement system activity was assessed by measuring complement component C3 and complement component C4 using an immunonephelometric assay (Siemens BN ProSpec). Lastly, amylase was analyzed using an enzymatic assay (cobas c702), and the prolactin level was determined using a chemiluminescent immunometric assay (Siemens ADVIA Centaur XP).

Clinical and Behavioral Features

Data on length of hospital stay (days), disease course (months), and first episode were obtained from electronic medical records. The depression grade and psychotic symptoms were systematically assessed through structured clinical interviews conducted by trained psychiatrists. The depression grade was classified as mild, moderate, or severe according to ICD-10 criteria based on clinical assessments of symptom intensity, functional impairment, and distress levels. Psychotic symptoms were evaluated based on DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition) diagnostic criteria, with patients systematically assessed for depressive hallucinations and depressive delusions, and symptoms recorded as either present or absent. Suicidal ideation was assessed according to DSM-5 criteria, with patients asked, “In the past month, have you seriously considered ending your life?” Suicide attempt history was assessed using the question, “Have you ever made an actual suicide attempt in your lifetime (eg, overdosing or cutting your wrists with suicidal intent)?” Participants were asked to respond “Yes” or “No.” Aggressive behaviors were documented through both direct clinical observation and structured interviews with caregivers and patients. Verbal aggression was assessed using a single question: “Has the patient recently exhibited hostile, insulting, or aggressive language toward others?” Physical aggression was assessed using the question: “Has the patient exhibited any aggressive physical behavior (eg, hitting, pushing, or fighting) in the past month?” Participants were asked to respond “Yes” or “No.”

Patient and Parent Involvement

Adolescents and parents or caregivers were not involved in the original study design, candidate-feature selection, model development, interpretation of the findings, or preparation of the manuscript. Written informed consent was obtained from participants and their legal guardians as part of the ethical procedures but did not constitute patient or parent involvement in research co-design.

Future prospective implementation studies should involve adolescents, parents or caregivers, and clinicians in determining how model outputs, uncertainty, privacy, and the distinction between NSSI and suicidal intent should be communicated. Any parent-facing use of model-derived information should occur within a clinician-mediated assessment rather than through an automated alert or an isolated risk score.

Statistical Analysis

Descriptive Analysis and Data-Quality Assessment

The revised statistical and machine learning analyses were conducted in Python (Python Foundation) using pandas, NumPy, SciPy, statsmodels, scikit-learn, imbalanced-learn, and SHAP. All statistical tests were 2-sided, and a P value of <.05 was considered statistically significant.

Continuous variables were summarized using medians and IQRs and compared between the NSSI and non-NSSI groups using 2-sided Mann-Whitney U tests. Categorical variables were summarized using counts and percentages. Pearson chi-square tests were used for categorical comparisons, except for 2×2 tables with expected cell counts below 5, for which Fisher exact tests were used. These univariable comparisons were descriptive and were not used to screen or select features for model development.

Automated range checks and category-level audits were conducted before model fitting. Potentially implausible numerical values and unexpected category codes were flagged for verification against the source records. No values were corrected automatically. Any correction was required to be supported by the source record and documented in an auditable correction file before the complete analysis was rerun.

Sample-Size Considerations

All eligible records available during the predefined study period were included; therefore, no prospective sample-size calculation was performed. The primary model contained 67 candidate

XSL•FO
RenderX

variables and generated 88 model inputs after one-hot encoding. The analytic sample included 274 participants with NSSI and 136 without NSSI, corresponding to 4.09 NSSI cases and 2.03 non-NSSI cases per candidate variable. After one-hot encoding, there were 3.11 NSSI cases and 1.55 non-NSSI cases per model input. These ratios indicated a substantial risk of overfitting and model-selection instability; therefore, the modeling analyses were considered exploratory.

Model Development

The 410 participants were divided by stratified random sampling into a training set (287/410, 70%) and a held-out test set (123/410, 30%), using a random seed of 46. The training set contained 287 participants, including 192 with NSSI and 95 without NSSI. The held-out test set contained 123 participants, including 82 with NSSI and 41 without NSSI. The test set was not used for preprocessing estimation, hyperparameter tuning, resampling, or model fitting. The synthetic minority over-sampling technique was applied to address class imbalance and enhance the representation of the minority class [37].

Categorical features were imputed within the modeling pipeline using the most frequent category and subsequently one-hot encoded. Continuous variables were imputed using the median within the pipeline. Continuous features were standardized for logistic regression and support vector machine models using parameters estimated only from the corresponding training data or cross-validation fold. Continuous features were not standardized for decision tree or random forest models. All preprocessing procedures were incorporated into the model pipelines to prevent information leakage.

Seven prespecified supervised machine learning model variants were evaluated: logistic regression, decision tree, random forest, and support vector machines with linear, radial basis function, polynomial, and sigmoid kernels. Class weights were balanced in the primary analysis to address the unequal frequencies of NSSI and non-NSSI. Synthetic oversampling was not applied before the training-test split or to the held-out test set.

Hyperparameters were optimized using randomized search with stratified 5-fold cross-validation exclusively within the training set. Area under the receiver operating characteristic curve (AUROC) was used as the optimization metric. Up to 30 hyperparameter configurations were sampled for each model; when a search space contained fewer than 30 possible combinations, all possible combinations were evaluated.

The selected random forest configuration used 1500 trees, a maximum tree depth of 15, a minimum of 5 observations required to split an internal node, a minimum of 12 observations per terminal leaf, 44 of the 88 (50%) available model inputs considered at each split, the Gini impurity criterion, bootstrap sampling, and balanced class weights.

The SVM with a radial basis function kernel achieved the highest mean AUROC during training-set cross-validation. After all 7 optimized models were evaluated on the held-out test set, the random forest showed the highest observed test-set AUROC and area under the precision-recall curve (AUPRC) and the lowest observed Brier score. The random forest was therefore designated post hoc as the focal exploratory model for detailed calibration, decision-curve, subgroup, sensitivity, and interpretability analyses. This focal designation did not imply statistically significant superiority over the alternative models.

Model Performance, Calibration, and Formal Comparison

Model discrimination was evaluated in the held-out test set using the area under the receiver operating characteristic curve and the area under the precision-recall curve. At the prespecified probability threshold of 0.50, accuracy, sensitivity, specificity, positive predictive value, negative predictive value, and F_1-score were calculated. NSSI was defined as the positive class.

The 95% CIs for AUROC, AUPRC, accuracy, sensitivity, specificity, positive predictive value, negative predictive value, F_1-score, and Brier score were estimated using 2000 stratified bootstrap resamples of the held-out test set.

Calibration was evaluated using the Brier score, calibration intercept, calibration slope, and calibration plots based on quantile-grouped predicted probabilities. Ideal calibration was represented by a calibration intercept of 0 and a calibration slope of 1.

The random forest was compared with each of the other 6 model variants using paired DeLong tests based on predictions from the same held-out test participants. Holm correction was applied to account for multiple pairwise comparisons. Model rankings based solely on observed test-set AUROCs were not interpreted as evidence of superiority when the adjusted comparisons were not statistically significant.

Clinical utility was assessed through decision curve analysis to quantify the net clinical benefit of model-based decision-making relative to other strategies (eg, treating all or treating none) across a range of threshold probabilities [38]. Feature importance was assessed using mean decrease in Gini impurity, an impurity-based measure commonly used to quantify variable importance in random forest models [39]. Additionally, SHAP was used to enhance model interpretability by quantifying the contribution of individual features to model predictions [36]. The SHAP approach offers both global and individual-level explanations, improving the transparency of the model and facilitating interpretation in clinical applications.

Decision curve analysis was performed over threshold probabilities from 0.01 to 0.80 to quantify net benefit relative to strategies of assessing all participants and assessing no participants. The modeled clinical action was referral for a more comprehensive, structured assessment of NSSI rather than automatic diagnosis, hospitalization, or treatment.

RF-Focused Incremental-Value and Sensitivity Analyses

A series of RF-focused analyses was conducted to examine the incremental contribution of different feature domains and the potential dominance of suicidality-related variables. These analyses included an RF model using suicidal ideation alone; an RF model using suicidal ideation and previous suicide attempt; a basic clinical RF model; a clinical-only RF model; a biochemical-only RF model; an RF model using only the

XSL•FO
RenderX

available family and contextual variables; a full RF model excluding suicidal ideation and previous suicide attempt; a full RF model excluding sex; a full RF model excluding residence; a full RF model excluding family psychiatric history and residence; and a full RF model including completed length of stay.

Logistic regression models using suicidal ideation alone and suicidal ideation together with previous suicide attempt were additionally fitted as simple clinical benchmarks. For the RF ablation analyses, the RF hyperparameters were fixed at the values selected for the full RF model and were not retuned separately for each reduced feature set.

The full RF model was formally compared with the reduced and benchmark models using paired DeLong tests, with Holm correction for multiple comparisons. These analyses were used to determine whether the multidimensional RF model provided incremental discrimination beyond the direct assessment of suicidal ideation and other basic clinical information.

As a class-imbalance sensitivity analysis, the RF was refitted using the Synthetic Minority Over-Sampling Technique for Nominal and Continuous (SMOTENC). SMOTENC was applied exclusively to the training data, with 5 nearest neighbors, and was never applied to the held-out test set. The RF hyperparameters were fixed at those selected in the primary training-set search.

Subgroup Analyses

RF performance was evaluated separately within the sex and residence subgroups represented in the held-out test set. Within each subgroup, AUROC, AUPRC, accuracy, sensitivity, specificity, positive predictive value, negative predictive value, F_1-score, Brier score, and corresponding bootstrap CIs were calculated when both outcome classes were present.

The subgroup analyses were exploratory and were not used to select separate subgroup-specific models or classification thresholds. Hospital-specific performance and leave-one-hospital-out validation could not be evaluated because the processed analytic dataset did not contain a hospital-site identifier.

RF Model Interpretation

The focal RF model was interpreted using 3 complementary approaches: Gini impurity–based feature importance, test-set permutation importance, and SHAP. Gini importance was aggregated from one-hot-encoded inputs to the corresponding original variables.

Permutation importance was calculated in the held-out test set using AUROC as the scoring measure and 100 repeated permutations per feature. A positive value represented a reduction in test-set AUROC after a feature was permuted, whereas a value near or below 0 indicated a limited or unstable contribution to held-out discrimination.

SHA*P* values were calculated using TreeExplainer and observations from the held-out test set. SHA*P* values were aggregated from encoded inputs to their original variables. Mean absolute SHA*P* values were used to summarize feature importance magnitude. Beeswarm plots were used to display the direction and distribution of feature contributions, with positive SHA*P* values indicating contributions toward the NSSI class. Dependence plots were generated for high-ranking continuous features to examine possible nonlinear and threshold-like patterns.

The agreement between Gini and mean absolute SHAP rankings was assessed using Spearman rank correlation. Gini, SHAP, and permutation importance were compared to identify variables with relatively consistent importance across methods. Model-specific feature importance and SHA*P* values were interpreted as descriptions of fitted-model behavior and not as evidence of independent association, causality, temporal precedence, or treatment targets.

All 67 candidate features remained in the full RF model. The 20 variables displayed in the Gini and SHAP figures represented only the 20 highest-ranked variables for visual clarity and did not constitute a separately selected 20-feature model.

Results

Participant Characteristics

A total of 437 electronic medical records were screened. After application of the eligibility criteria, 27 records were excluded, leaving 410 adolescents with depressive disorders in the final analytic sample. Of these participants, 274 (66.8%) reported NSSI during the preceding 12 months and 136 (33.2%) did not. Stratified random sampling allocated 287 participants to the training set, including 192 with NSSI and 95 without NSSI, and 123 participants to the untouched held-out test set, including 82 with NSSI and 41 without NSSI.

The processed analytic dataset contained no missing values, and all 410 participants were included in the complete-case analysis. The primary assessment-time model contained 67 candidate variables and generated 88 model inputs after one-hot encoding. This corresponded to 4.09 NSSI cases and 2.03 non-NSSI cases per candidate variable, and 3.11 NSSI cases and 1.55 non-NSSI cases per encoded model input.

The median age of the overall sample was 15 (IQR 13-16) years, and 320 of the 410 (78.1%) participants were female. Participants with NSSI were younger than those without NSSI (median 14 years, IQR 13-16 years vs median 15 years, IQR 14-16 years; $P<.001$). The proportion of female participants was also higher in the NSSI group than in the non-NSSI group (232/274, 84.7% vs 88/136, 64.7%; $P<.001$). Education-level distribution differed between the groups ($P=.008$). Smoking was uncommon but was reported by 11 participants in the NSSI group and none in the non-NSSI group (11/274, 4% vs 0/136, 0%; $P=.02$). No statistically significant between-group differences were observed for BMI ($P=.72$), place of residence ($P=.36$), drinking status ($P=.06$), family psychiatric history ($P=.84$), or religious belief ($P=.21$). Other sociodemographic characteristics are presented in Table 1.

[a]NSSI: nonsuicidal self-injury.

[b]Italicized values are statistically significant (*P*<.05).

Physiological and biochemical characteristics are presented in Table 2. Among the continuous physiological and biochemical variables, participants with NSSI had lower creatinine concentrations than those without NSSI (median 59 µmol/L, IQR 52-65 µmol/L vs median 63 µmol/L, IQR 54-72 µmol/L; *P*=.001), lower creatine kinase concentrations (median 64.5 U/L, IQR 51-82 U/L vs median 76 U/L, IQR 55-94.8 U/L; *P*=.005), and lower fructosamine concentrations (median 1.97 mmol/L, IQR 1.86-2.11 mmol/L vs median 2.04 mmol/L, IQR 1.92-2.17 mmol/L; *P*=.009). No other continuous variable showed a statistically significant between-group difference. In particular, high-sensitivity C-reactive protein did not differ significantly between the NSSI and non-NSSI groups (*P*=.19). These univariable comparisons were descriptive and were not used for feature selection or model development.

Clinical and behavioral characteristics according to past-year NSSI status are summarized in Table 3. Suicidal ideation and previous suicide attempt showed different distributions between participants with and without past-year NSSI. Suicidal ideation was reported by 221 of 274 (80.7%) participants with NSSI and 66 of 136 (48.5%) participants without NSSI (*P*<.001). A previous suicide attempt was reported by 88 (32.1%) participants with NSSI and 20 (14.7%) participants without NSSI (*P*<.001). The distribution of psychotic-symptom categories differed between the groups (*P*=.04), whereas depression-severity categories did not (*P*=.52). First-episode status (*P*=.11), illness duration (*P*=.08), verbal aggression (*P*=.26), and physical aggression (*P*=.62) also did not differ significantly between the groups.

Model Development and Held-Out Test-Set Performance

In training-set cross-validation, the SVM with a radial basis function kernel achieved the highest mean AUROC (mean AUROC 0.720, SD 0.046). This was followed by logistic regression (mean AUROC 0.716, SD 0.049), SVM linear (mean AUROC 0.716, SD 0.025), decision tree (mean AUROC 0.709, SD 0.054), random forest (mean AUROC 0.703, SD 0.050), SVM sigmoid (mean AUROC 0.702, SD 0.062), and SVM polynomial (mean AUROC 0.680, SD 0.037). The relatively small differences in mean AUROC and overlapping cross-validation variability did not indicate clear separation in model performance during development. Detailed cross-validation results and optimized hyperparameters for all evaluated models are provided in Table S1 in Multimedia Appendix 1.

In the untouched held-out test set, the random forest had the highest observed AUROC and AUPRC among the 7 evaluated machine learning models (Table 4). Its AUROC was 0.681 (95% CI 0.583-0.778), and its AUPRC was 0.808 (95% CI 0.741-0.874). At the prespecified probability threshold of 0.50, the random forest had an accuracy of 0.667 (95% CI 0.585-0.748), sensitivity of 0.720 (95% CI 0.622-0.817), specificity of 0.561 (95% CI 0.415-0.707), positive predictive value of 0.766 (95% CI 0.703-0.835), negative predictive value of 0.500 (95% CI 0.395-0.622), and F_1-score of 0.742 (95% CI 0.671-0.810). The corresponding confusion matrix contained 59 true-positive, 23 false-negative, 23 true-negative, and 18 false-positive classifications.

Table 4. Performance of the 7 machine learning models in the untouched held-out test set.[a]

Model	AUROC[b] (95% CI)	AUPRC[c] (95% CI)	Accuracy (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)	PPV[d] (95% CI)	NPV[e] (95% CI)	F_1-score (95% CI)	Brier score (95% CI)

[a]All metrics were evaluated in the same held-out test set (n=123) at a probability threshold of 0.50, except AUROC, AUPRC, and Brier score, which are threshold-independent. CIs were obtained from 2000 stratified bootstrap resamples.

[b]AUROC: area under the receiver operating characteristic curve.

[c]AUPRC: area under the precision-recall curve.

[d]PPV: positive predictive value.

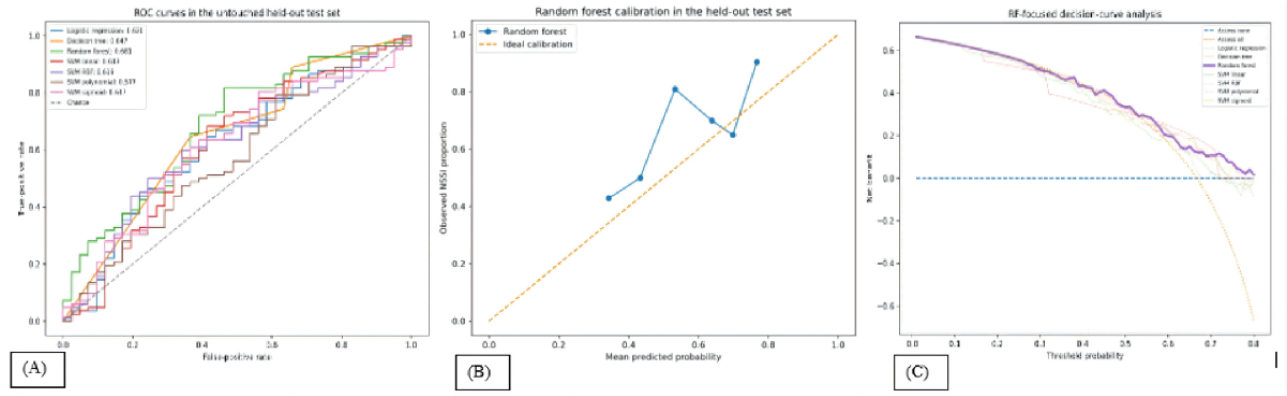
[e]NPV: negative predictive value.

[f]SVM: support vector machine.

[g]RBF: radial basis function kernel.

The decision tree showed the second-highest observed test-set AUROC at 0.647, followed by logistic regression (0.620), support vector machine with a radial basis function kernel (SVM-RBF; 0.619), SVM sigmoid (0.617), SVM linear (0.613), and SVM polynomial (0.577). Several SVM variants had higher sensitivity but lower specificity at the 0.50 threshold. Sensitivity ranged from 0.878 to 0.902 among the 4 SVM models, whereas specificity ranged from 0.049 to 0.244. In comparison, the random forest had a sensitivity of 0.720 and specificity of 0.561 at the same threshold.

Although the random forest showed numerically higher test-set AUROCs than the alternative models, none of the 6 pairwise comparisons remained statistically significant after Holm correction (Holm-adjusted P values ranged from .17 to .81). The largest observed difference was between the random forest and SVM polynomial (AUROC difference 0.104, 95% CI



XSL•FO
RenderX

0.011-0.197; unadjusted *P*=.03; Holm-adjusted *P*=.17). The difference between the random forest and the SVM-RBF model, which achieved the highest cross-validation AUROC during model development, was 0.062 (95% CI –0.027 to 0.152; unadjusted *P*=.17; Holm-adjusted *P*=.81). Therefore, the random forest was selected as the focal exploratory model for subsequent interpretation based on its overall held-out test-set performance and suitability for nonlinear interpretation; these comparisons did not demonstrate statistical superiority. Full pairwise AUROC comparisons between the random forest and alternative models are presented in Table S2 in Multimedia Appendix 1.

Calibration and Decision-Curve Analysis

Calibration performance of the random forest model is summarized in Table 4 and illustrated in Figure 2B. The model achieved a Brier score of 0.212 (95% CI 0.188-0.236), with a calibration intercept of 0.457 and a calibration slope of 1.013. The calibration slope was close to the ideal value of 1, indicating that the spread of predicted probabilities was generally consistent with the observed outcomes. However, the positive calibration intercept suggested that the model tended to underestimate the overall observed probability of past-year NSSI. Across the 6 calibration groups, mean predicted probabilities ranged from 0.343 to 0.767, whereas the corresponding observed NSSI proportions ranged from 0.429 to 0.905.

Figure 2. Performance evaluation and clinical utility analysis of the machine learning models. (A) Receiver operating characteristic (ROC) curves for the 7 model variants in the untouched held-out test set. (B) Calibration plot for the focal random forest model. (C) Decision curve analysis, with the random forest model highlighted. The modeled clinical action was referral for a comprehensive, structured nonsuicidal self-injury (NSSI) assessment rather than automatic diagnosis or treatment. RBF: radial basis function kernel; SVM: support vector machine.

Decision-curve analysis of the random forest model is shown in Figure 2C. The random forest demonstrated greater net benefit than both the assess-all and assess-none strategies across the main continuous threshold-probability range of approximately 0.51-0.80. At the prespecified threshold probability of 0.50, the net benefit of the random forest was approximately equivalent to that of the assess-all strategy. Compared with the other evaluated models, the random forest had the highest model-specific net benefit only within selected threshold intervals rather than across the entire probability range. These intervals included 0.01-0.10, 0.12-0.26, 0.34, 0.37-0.38, 0.45-0.46, 0.50-0.52, 0.56, 0.72-0.73, 0.76-0.77, and 0.79-0.80. Overall, the random forest had the highest model-specific net benefit at 40 of 80 (50%) evaluated threshold probabilities, indicating potential usefulness for identifying adolescents who may benefit from further structured NSSI assessment rather than serving as a standalone diagnostic tool.

RF Incremental-Value and Sensitivity Analyses

Incremental-value and sensitivity analyses of the focal random forest model are summarized in Table 5. The suicidal-ideation-only logistic regression benchmark achieved an AUROC of 0.701 (95% CI 0.616-0.780), which was numerically higher than the AUROC of 0.681 for the full multidimensional random forest model. However, the difference between the full random forest and the suicidal-ideation-only benchmark was not statistically significant (AUROC difference –0.020, 95% CI –0.079 to 0.038). A benchmark model including both suicidal ideation and previous suicide attempt achieved an AUROC of 0.697 (95% CI 0.594-0.790).

[a]AUROC: area under the receiver operating characteristic curve.

[b]AUPRC: area under the precision-recall curve.

[c]SI: suicidal ideation.

[d]RF: random forest.

[e]SA: suicide attempt.

[f]FH: family psychiatric history.

[g]SMOTENC: Synthetic Minority Over-Sampling Technique for Nominal and Continuous.

Removing suicidality-related variables reduced model discrimination. The random forest without suicidal ideation and previous suicide attempt achieved an AUROC of 0.540 (95% CI 0.429-0.655), compared with 0.681 for the full model (AUROC difference 0.141, 95% CI 0.045-0.237; Holm-adjusted *P*=.048). This finding indicated that suicidality-related variables contributed substantially to the full model's discrimination of concurrent NSSI status in this sample, while also highlighting the close conceptual relationship between NSSI and suicidality-related clinical features.

Domain-specific sensitivity analyses showed that the clinical-only random forest achieved an AUROC of 0.682 (95% CI 0.573-0.781), which was comparable with that of the full multidimensional model (AUROC difference –0.001). The basic clinical random forest achieved an AUROC of 0.676 (95% CI 0.559-0.778). By contrast, the biochemical-only model achieved an AUROC of 0.513 (95% CI 0.409-0.622), and the available family/context-only model achieved an AUROC of 0.488 (95% CI 0.396-0.579). The full random forest model showed higher discrimination than the biochemical-only and available family/context-only models after Holm correction (adjusted *P*=.048 and .03, respectively). These findings did not demonstrate measurable incremental discrimination from adding the available biochemical variables to the clinical features.

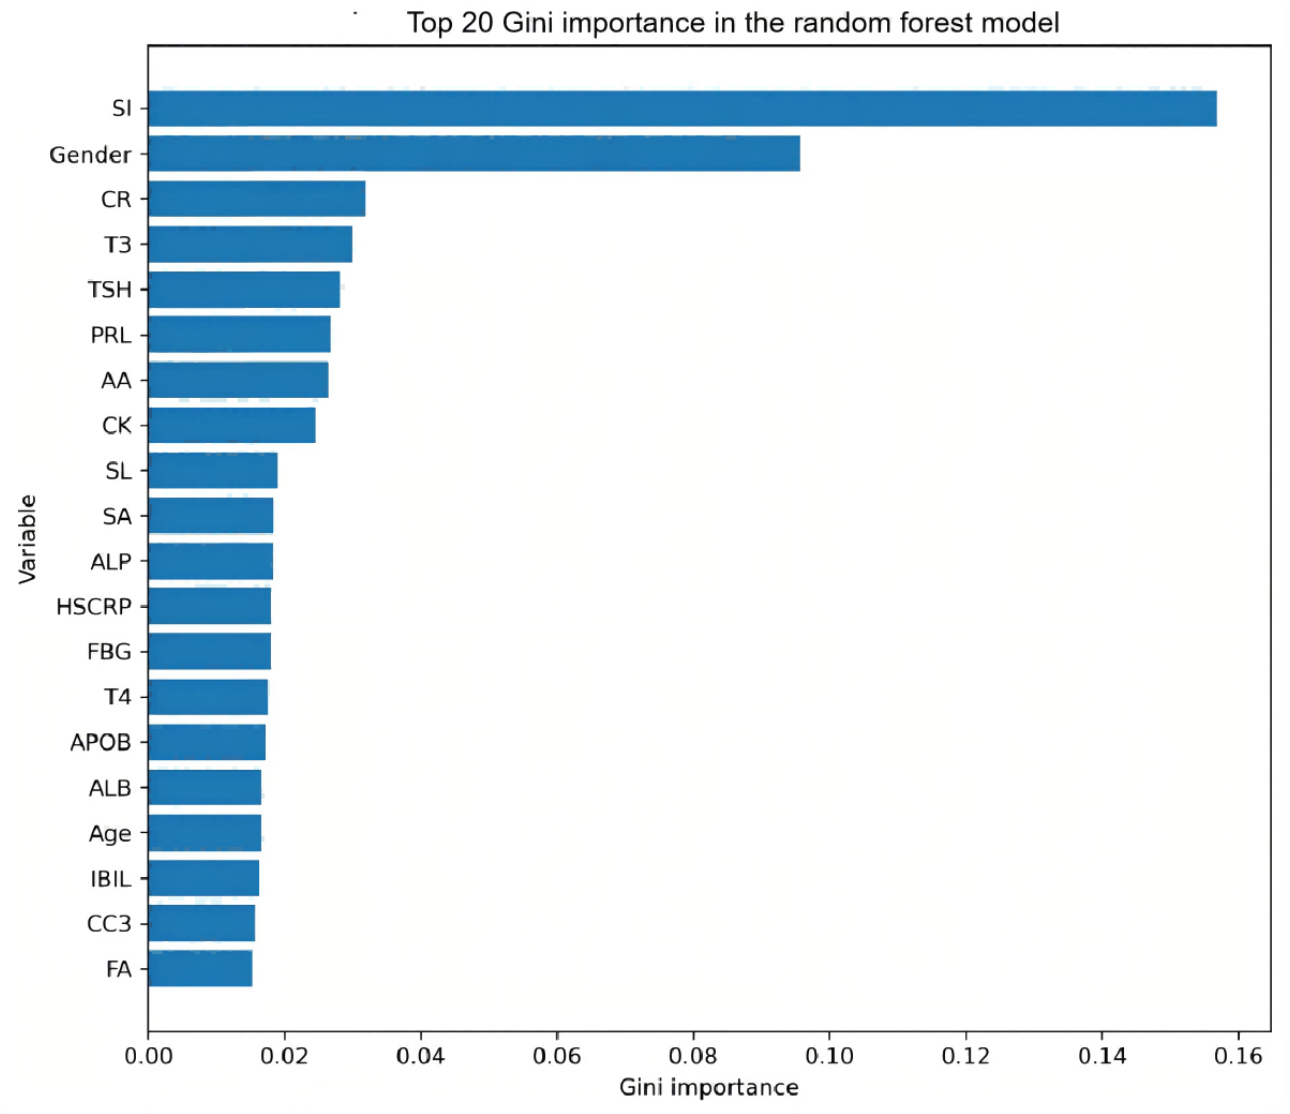
Sensitivity analyses addressing potential demographic and contextual influences showed minimal changes in model performance. Excluding sex resulted in an AUROC of 0.692, excluding residence resulted in an AUROC of 0.678, and excluding both family psychiatric history and residence resulted in an AUROC of 0.676. Adding completed length of stay also did not improve discrimination (AUROC 0.677). These results indicated that excluding sex, residence, available family-context variables, or completed length of stay had limited effects on model discrimination in our sample.

In the class-imbalance sensitivity analysis, SMOTENC was applied exclusively within the training data. The resulting random forest achieved an AUROC of 0.697 (95% CI 0.593-0.798), an AUPRC of 0.805 (95% CI 0.735-0.879), an accuracy of 0.675, sensitivity of 0.707, specificity of 0.610, and Brier score of 0.212. The calibration slope was 0.959. These results were broadly consistent with those of the primary class-weighted random forest model, indicating that the observed model performance was not substantially altered by the approach used to address class imbalance. The AUROC distributions of these incremental-value and ablation analyses, with bootstrap CIs, are additionally presented in Figure S1 in Multimedia Appendix 1.

Sex- and Residence-Specific Performance

Exploratory subgroup analyses according to sex and residence are summarized in Table S3 in Multimedia Appendix 1. Among male participants in the held-out test set (n=26; 15 with NSSI and 11 without NSSI), the random forest had an AUROC of 0.776 (95% CI 0.576-0.945). At the 0.50 threshold, sensitivity was 0.267 and specificity was 1.000. Among female participants (n=97; 67 with NSSI and 30 without NSSI), the AUROC was 0.665 (95% CI 0.548-0.777), sensitivity was 0.821, and

XSL•FO
RenderX



specificity was 0.400. The wide CI among male participants and the markedly different sensitivity-specificity profiles indicated substantial uncertainty in the subgroup-specific performance estimates.

Among participants coded as urban residents in the held-out test set (n=74; 50 with NSSI and 24 without NSSI), the random forest had an AUROC of 0.718 (95% CI 0.587-0.835), sensitivity of 0.660, and specificity of 0.667. Among participants coded as rural residents (n=49; 32 with NSSI and 17 without NSSI), the AUROC was 0.619 (95% CI 0.445-0.778), sensitivity was 0.813, and specificity was 0.412. The CIs overlapped, and removal of residence from the full model resulted in minimal change in overall AUROC. Hospital-specific performance and leave-one-hospital-out validation could not be evaluated because the processed analytic dataset did not contain a hospital-site identifier.

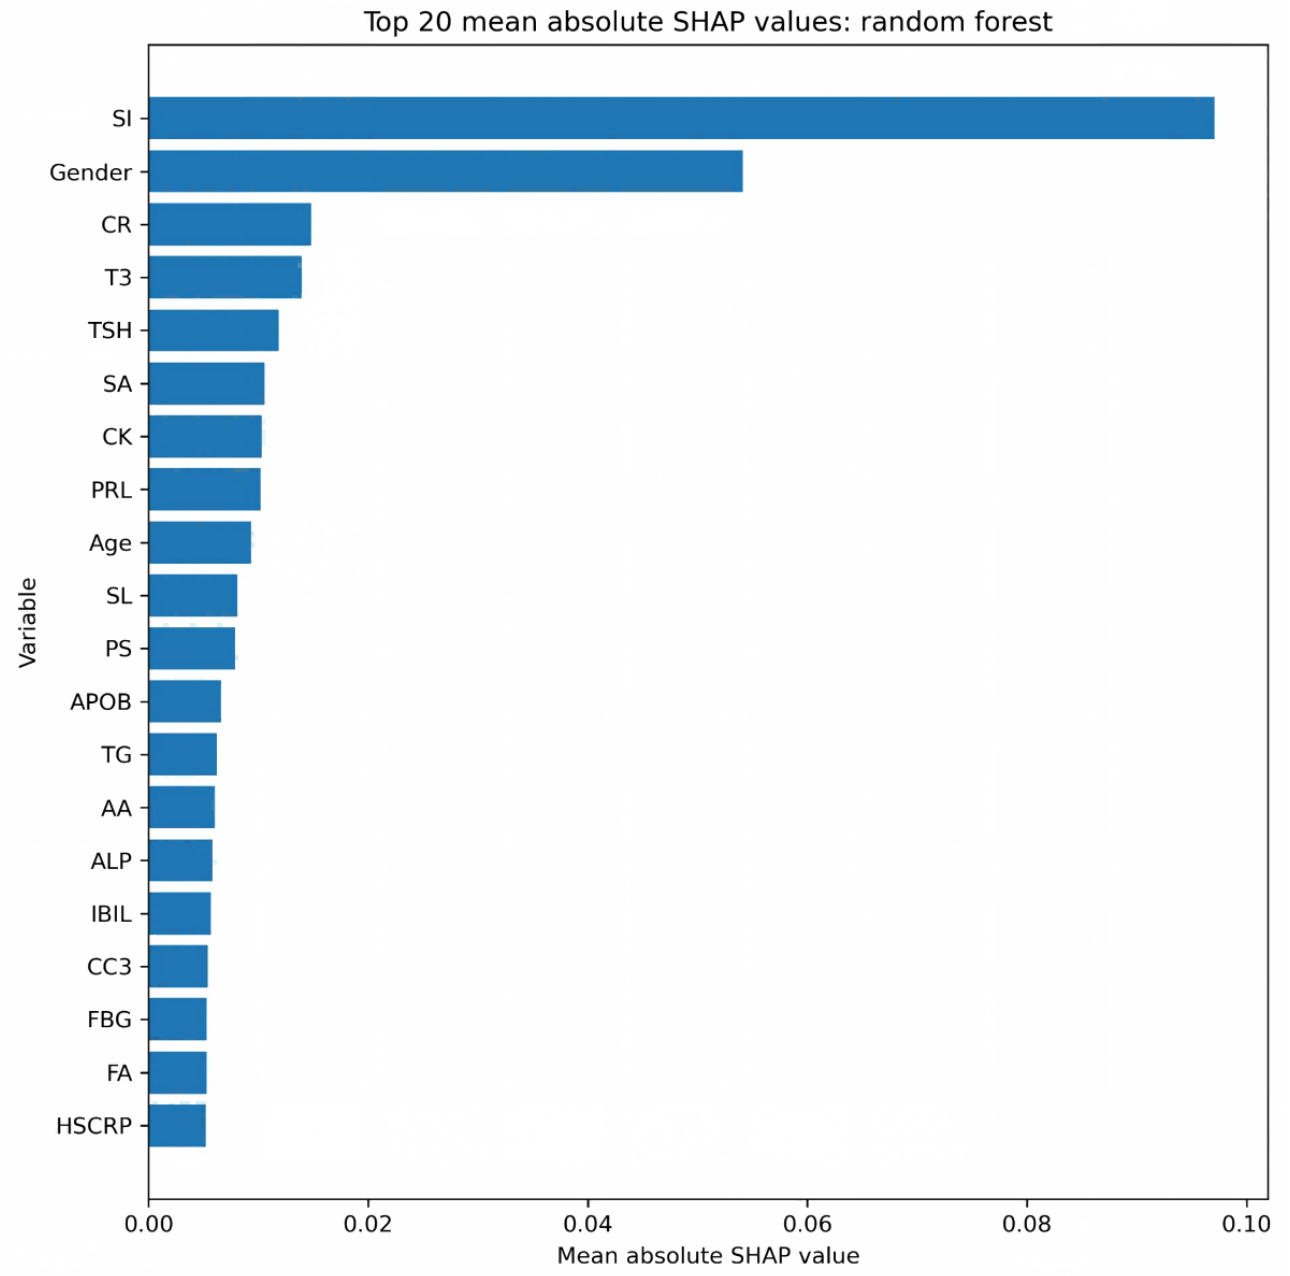
Random Forest Model Interpretation

According to Gini impurity–based importance, the 5 highest-ranked variables in the focal random forest model were suicidal ideation, sex, creatinine, T3, and TSH. Their corresponding Gini importance values were 0.157, 0.096, 0.032, 0.030, and 0.028, respectively. Previous suicide attempt ranked 10th, high-sensitivity C-reactive protein ranked 12th, and age ranked 17th among the 67 candidate variables. All candidate variables remained included in the fitted random forest model; Figure 3 displays the 20 highest-ranked variables according to Gini importance for visual clarity. Gini importance reflects the contribution of each variable to impurity reduction within the fitted tree ensemble and should not be interpreted as evidence of a causal relationship.

Figure 3. The 20 highest-ranked variables according to Gini importance in the focal random forest model. The fitted random forest included all 67 candidate variables; only the 20 highest-ranked variables are shown for visual clarity. AA: amylase; ALB: albumin; ALP: alkaline phosphatase; APOB: apolipoprotein B; CC3: complement component C3; CK: creatine kinase; CR: creatinine; FA: free fatty acid; FBG: fasting blood glucose; HSCRP: high-sensitivity C-reactive protein; IBIL: indirect bilirubin; PRL: prolactin; SA: suicide attempt; SI: self-injury; SL: aspartate aminotransferase-to-alanine aminotransferase ratio; T3: total triiodothyronine; T4: total thyroxine; TSH: thyroid-stimulating hormone.

Mean absolute SHAP values showed a broadly similar ranking pattern. Suicidal ideation, sex, creatinine, T3, and TSH were again among the 5 highest-ranked variables, followed by previous suicide attempt, creatine kinase, prolactin, age, and

XSL•FO
RenderX



the aspartate aminotransferase-to-alanine aminotransferase ratio. The Gini importance and mean absolute SHAP rankings were strongly correlated (Spearman ρ=0.917, *P*<.001), showing substantial agreement between the 2 model-specific importance measures. A detailed comparison of variable rankings across Gini importance, SHA*P* values, and permutation importance is provided in Table S4 in Multimedia Appendix 1. However, differences in individual rankings were observed, reflecting that Gini importance and SHA*P* values capture different aspects of variable contribution within tree-based models.

Test-set permutation importance provided a more conservative assessment of feature contribution on unseen data. Permuting suicidal ideation resulted in the largest reduction in test-set AUROC (mean decrease 0.134), which was substantially greater than the reductions associated with amylase (mean decrease 0.014), age (mean decrease 0.006), previous suicide attempt (mean decrease 0.005), free thyroxine (mean decrease 0.004), and creatine kinase (mean decrease 0.004). Although sex, T3, and TSH ranked highly according to Gini importance and SHA*P* values, their mean permutation importance values were negative (–0.002, –0.011, and –0.003, respectively; Figure 4). High-sensitivity C-reactive protein ranked 12th according to Gini importance and 20th according to SHA*P* values but also showed negative permutation importance. These findings indicated that suicidal ideation showed the most consistent model-specific contribution across the interpretation approaches, whereas the apparent contribution of several physiological variables varied depending on the interpretation method.

The SHAP beeswarm plot further characterized the direction and distribution of variable contributions within the fitted random forest model (Figure 5). The presence of suicidal ideation generally showed positive SHA*P* values, indicating a shift in model output toward classification as NSSI=1. Female sex also tended to contribute positively toward the NSSI class. In the continuous-feature dependence analyses, feature values were inversely correlated with SHAP contributions for creatinine (Spearman ρ=–0.909), T3 (Spearman ρ=–0.758), TSH (Spearman ρ=–0.901), age (Spearman ρ=–0.896), and creatine kinase (Spearman ρ=–0.692), whereas prolactin values showed a positive correlation with SHAP contributions (Spearman ρ=0.767). Within the fitted model, lower creatinine, T3, TSH, age, and creatine kinase values tended to shift predictions toward NSSI classification, whereas higher prolactin values tended to shift predictions toward NSSI classification. The creatine kinase pattern was interpreted cautiously because its distribution in the held-out test set was heterogeneous (range 24-3935 U/L). These SHAP-based patterns describe fitted-model behavior and should not be interpreted as causal or prospective effects.

Discussion

Principal Findings

In this study, we evaluated 7 supervised machine learning models for classifying past-year NSSI status among adolescents with depressive disorders using multidimensional clinical, behavioral, and biochemical variables. The support vector machine with a radial basis function kernel achieved the highest mean AUROC during training-set cross-validation, whereas the random forest had the highest observed AUROC and AUPRC and the lowest Brier score in the untouched held-out test set among the evaluated models. However, the random forest did not demonstrate statistically significant superiority over alternative algorithms after correction for multiple comparisons. The discrepancy between training-set and held-out test-set rankings suggests that algorithm rankings may be unstable in relatively small clinical datasets.

Previous applications of machine learning to suicidal and self-injurious outcomes have demonstrated the potential of these approaches for classification and prediction [40]. However, systematic reviews have also identified methodological limitations, including inconsistent reporting and a lack of validation in external samples [41]. Recent longitudinal work has applied machine learning to identify clinical predictors of persistent NSSI trajectories among adolescents [37], while other NSSI-focused studies have reported favorable internal classification performance using machine learning algorithms [42]. Nevertheless, independent validation remains essential before such models can be considered for clinical implementation. Transparent reporting of model development and validation is important for evaluating the reliability and reproducibility of clinical prediction research [43], while careful assessment of risk of bias and applicability is required to identify potential methodological limitations [44]. The most consistent contributor to discrimination in the focal random forest model was suicidal ideation. The suicidal-ideation-only logistic regression benchmark achieved discrimination comparable to that of the random forest, whereas removal of suicidal ideation and previous suicide attempt substantially reduced random forest performance. These findings indicate that direct suicidality-related information accounted for a considerable proportion of the model's classification ability in this sample. Longitudinal evidence has shown that adolescents engaging in NSSI or nonsuicidal self-harm are at increased risk of subsequent suicide attempts [45]. Prospective evidence further suggests that the co-occurrence of NSSI and suicidal ideation may identify adolescents at particularly elevated risk of subsequent suicide attempts [46]. Nevertheless, NSSI is conceptually distinguished from suicidal behavior by the absence of suicidal intent [47]. NSSI may serve multiple psychological and interpersonal functions, including regulation of negative affect and other intrapersonal or interpersonal functions [48]. Real-time monitoring studies further demonstrate substantial between-person and within-person variability in the functions of NSSI over time [49]. Person-centered analyses likewise support substantial heterogeneity in NSSI presentations and behavioral patterns [50].

Therefore, the prominent contribution of suicidal ideation in our model should not be interpreted as indicating that NSSI can be reduced to suicidality-related variables. Rather, our findings reinforce the importance of directly assessing suicidal ideation and previous suicidal behavior while maintaining a separate and comprehensive assessment of NSSI characteristics. In clinical practice, models incorporating suicidality-related information could potentially help organize complex patient information and identify adolescents who may warrant more comprehensive assessment, but they should complement rather than replace clinical judgment.

By contrast, biochemical variables did not demonstrate clear incremental discrimination beyond the available clinical information. Although creatinine, T3, TSH, creatine kinase, and prolactin appeared among the higher-ranked variables according to Gini importance or SHA*P* values, their contributions were less consistent in permutation-based analyses. Previous research has identified differences in inflammatory and immune-related biomarkers between adolescents with depression and healthy controls, although findings remain heterogeneous [51]. Peripheral biological correlates have also been investigated in relation to suicidality among children and adolescents, but their clinical utility remains uncertain [52]. More specifically, emerging research has suggested a possible role of inflammatory processes in adolescent depression accompanied by NSSI [53]. Neuroendocrine mechanisms may also be relevant, with studies reporting associations between NSSI and variations in testosterone and cortisol levels [54]. Alterations in the hypothalamic-pituitary-thyroid axis have similarly been reported among adolescents with major depressive disorder and NSSI [55]. However, these findings remain insufficient to establish clinically reliable biomarkers. In this study, high-sensitivity C-reactive protein did not differ significantly between participants with and without NSSI despite appearing among the higher-ranked variables in some model-interpretation analyses. This discrepancy illustrates an important limitation of interpreting variable importance in complex machine learning models: a variable that contributes to model discrimination does not necessarily represent an independent biological mechanism or causal risk factor [56]. Explainability methods may provide information about model behavior, but they should not be assumed to ensure trustworthy patient-level decision support or to substitute for rigorous model validation [57]. Tree-based algorithms can capture nonlinear relationships, interactions, and conditional dependencies that may not be apparent in conventional univariable comparisons. Accordingly, the physiological variables identified in this study should be interpreted as contributors to fitted-model behavior rather than as established biomarkers or causal determinants of NSSI.

The random forest demonstrated acceptable calibration characteristics and potential clinical usefulness within selected threshold ranges in decision-curve analysis. However, these findings do not justify automated diagnosis, treatment selection, hospitalization decisions, or direct risk labeling of adolescents. Evaluation of clinical prediction models should extend beyond discrimination alone and include calibration, validation, and assessment of potential clinical usefulness [58]. Decision-curve analysis provides a framework for estimating net clinical benefit

XSL•FO
RenderX

across different threshold probabilities [59]. Nevertheless, favorable decision-curve results cannot substitute for prospective evaluation of whether use of a model actually improves clinical outcomes. Similarly, although explainability methods can provide information about how a model generates its predictions, such explanations should not be assumed to ensure trustworthy patient-level decision support or to substitute for rigorous model validation [57]. Translation of AI from retrospective model development into clinical practice therefore requires staged and rigorous evaluation of real-world performance and clinical utility [60]. Trustworthy implementation also requires attention to robustness, fairness, transparency, usability, and potential unintended harms throughout the model life cycle [61]. Importantly, meaningful clinician oversight should remain central when AI is used to support decisions in complex and high-stakes psychiatric settings [62].

Another important consideration is the limited representation of family and broader social-contextual factors in the present model. Family dynamics have been consistently associated with self-harm and suicidality among children and adolescents [63]. Peer relationships, including interpersonal difficulties and social experiences, may also contribute meaningfully to the development and maintenance of self-harm thoughts and behaviors [64]. As the available dataset contained relatively limited information regarding family functioning, peer relationships, interpersonal stressors, social support, and adverse experiences, the model may not have fully captured important developmental and interpersonal pathways associated with NSSI. Future models may therefore benefit from incorporating more comprehensive psychosocial assessments alongside clinical and biological information. Standardized measures of family functioning, peer relationships, emotion regulation, adverse experiences, and social support could help determine whether these variables provide meaningful incremental value beyond readily available clinical indicators. In addition, clinical evaluation of AI systems should consider whether the information provided by a model is understandable, actionable, and compatible with real-world clinical workflows [60]. Broader frameworks for trustworthy health care AI also emphasize the importance of human-centered development and stakeholder involvement when models are intended for clinical use [61]. Involving adolescents, caregivers, and clinicians in future model development and evaluation may therefore improve the clinical relevance and acceptability of prediction tools.

Overall, our findings suggest that machine learning can integrate multidimensional clinical information to assist in identifying adolescents with depressive disorders who report past-year NSSI. However, the substantial contribution of suicidal ideation and previous suicidal behavior indicates that much of the model's discriminatory ability was derived from established clinical indicators rather than from biochemical information. The comparable discrimination achieved by the suicidal-ideation-only benchmark further suggests that the incremental value of a more complex multidimensional model should be interpreted cautiously. Nevertheless, machine learning may provide a means of integrating heterogeneous information and capturing complex patterns that may not be readily identified using conventional approaches. Rather than replacing standard clinical assessment, interpretable machine learning may be most appropriately positioned as an adjunctive tool for organizing multidimensional information, identifying patterns that warrant further evaluation, and supporting comprehensive clinician-led assessment.

Limitations

Several limitations warrant consideration. First, the sample size was relatively small and drawn from psychiatric clinical settings in Zhejiang Province, which may limit the generalizability of the findings. Second, the cross-sectional design precludes causal inferences; therefore, future longitudinal studies involving larger and more diverse populations are needed to externally validate and refine these models and to evaluate their prospective performance. Lastly, incorporating self-reported psychosocial data, such as family dynamics and peer relationships, alongside clinician-assessed information could provide a more comprehensive representation of the psychosocial factors relevant to NSSI.

Implication

This study provides clinical and research implications for understanding the clinical characteristics associated with NSSI among adolescents with depressive disorders. By integrating demographic, physiological, biochemical, and behavioral variables, this study demonstrates the potential of combining multidimensional information to characterize clinical profiles associated with NSSI. The interpretable machine learning approach may assist in identifying adolescents with past-year NSSI and provide information to support comprehensive assessment. Importantly, the model should be considered a decision-support tool rather than a replacement for clinical judgment. Future studies incorporating larger samples, longitudinal designs, external validation, and richer psychosocial information are warranted to further evaluate the robustness, generalizability, and clinical applicability of such models. These findings may contribute to the development of more individualized assessment strategies and support the identification of adolescents who may benefit from comprehensive evaluation and targeted clinical support.

Conclusions

This study demonstrates the potential utility of integrating multidimensional clinical, behavioral, and biochemical data with interpretable machine learning approaches to classify past-year NSSI status among adolescents with depressive disorders. The findings suggest that machine learning models integrating heterogeneous information may provide complementary support for comprehensive clinical assessment. However, further validation in larger and independent cohorts, particularly using longitudinal designs, is required before clinical implementation. Ultimately, interpretable machine learning models may serve as useful adjuncts to clinician-led assessment and may contribute to improving the identification and evaluation of adolescents with NSSI.

Abstract

Background: Adolescents and young adults (AYAs) with type 1 diabetes (T1D) face a heightened risk of care gaps and preventable complications during the transition from pediatric to adult care. AYAs from low-income families are more likely to experience poor outcomes. Care guidelines for T1D now recommend a transition program beginning several years prior to anticipated independence. However, existing transition programs often require substantial resources, limiting their scalability and accessibility.

Objective: We used a human-centered design approach to develop and refine a low-cost, virtual intervention to support T1D transitions among publicly insured AYAs.

Methods: Guided by the "3I" model (inspiration, ideation, implementation) of IDEO, we conducted semistructured interviews with 26 providers and staff across 4 University of California medical centers to identify challenges and opportunities for improving transition care. We then completed customer discovery interviews with 36 adopters and influencers, including AYAs, endocrinologists, and diabetes educators, to identify priorities and needs and create value propositions. The resulting intervention was tested with 3 cohorts (n=25) of publicly insured AYAs aged 17 to 21 years receiving pediatric diabetes care at an academic medical center. The intervention consisted of two 75-minute virtual group sessions led by a diabetes educator and peer mentors with lived experience. Feasibility, acceptability, and appropriateness were assessed via validated surveys and qualitative interviews.

Results: Core functions of the intervention included education and discussion on "adulting with diabetes" and navigating the health care system, interactive creation of a transition plan, mentors sharing their experiences with diabetes, open discussion among peers, opportunities to ask questions, and provision of resources based on individual needs. Facilitators and mentors reported high feasibility (mean 4.25, SD 0.52) and appropriateness (mean 4.43, SD 0.53). Qualitative interviews highlighted peer support and lived-experience mentorship as core drivers of engagement. Attendance was highest among participants enrolled closer to session dates. Participant feedback informed ongoing adaptations to content and delivery across cohorts, including timing of the intervention, use of the chat function, multiple text reminders before intervention sessions, and specific topics of interest.

Conclusions: This human-centered virtual transition intervention addressed priorities identified by AYAs, peer mentors, and clinicians, including peer support, judgment-free discussion, and self-advocacy. While engagement and attendance varied across cohorts, findings support further refinement and evaluation of the intervention in diverse settings.

Introduction

Type 1 diabetes (T1D) is a serious medical condition that affects more than 300,000 children and adolescents in the United States [1]. T1D poses a significant burden on patients and families in terms of health-related quality of life, missed school days, missed work days, and health care costs [2-4]. Previous research suggests that increased independence and a desire for autonomy during adolescence and young adulthood may lead to reduced adherence to medications and other self-care strategies, as well as lapses in communication with health care providers [5-9]. The transition from adolescence to young adulthood has been identified as a particularly vulnerable stage for lapses in care; up to one-third of patients with T1D fail to complete an initial visit with an adult endocrinology provider within 12 months after their final pediatric endocrinology visit [10,11]. For patients with T1D, the transition phase is associated with high rates of hospitalization due to diabetic ketoacidosis (DKA), a life-threatening complication that can be prevented with appropriate management [9,12]. Patients from low-income families are the most vulnerable to these lapses in care and subsequent hospitalizations; intervening in the transition period is therefore essential to prevent the widening of disparities into adulthood [12,13].

Current guidelines from the American Diabetes Association suggest that the transition process from pediatric to adult specialty diabetes care should begin at least 1 to 2 years prior to the actual transfer of care to allow for a gradual increase in adolescents' self-management responsibilities and continuous education on navigating the logistical aspects of adult health care [14]. Previous T1D transition programs have demonstrated success in improving continuity of care and reducing hospitalizations using full-time transition coordinators, case management, designated young adult clinics, delaying transition until age 25 or 26 years, and shared medical appointments for adolescents and young adults (AYAs) [15-19]. However, more recent studies highlight ongoing gaps in transition preparation, including unmet psychosocial needs and variability in both transition readiness and the effectiveness of existing interventions [20-22]. In addition, transition interventions have not been systematically implemented, even at large academic medical centers, due to limited resources. We sought to design a low-resource, sustainable T1D transition intervention that could be easily implemented and scaled with existing resources within pediatric diabetes clinics. Here, we describe the human-centered design (HCD) process based on the "3I" framework of IDEO used to develop and test the transition intervention, as well as the key components we identified as essential to transition programs for AYAs with T1D.

Methods

HCD and Intervention Development Process

We used an HCD approach based on the "3I" model of IDEO, which includes 3 phases: inspiration, ideation, and implementation [23,24]. Across the 3 phases, we engaged distinct participant groups and data collection approaches, including provider and staff interviews (phase 1), stakeholder customer discovery interviews (phase 2), and intervention delivery with surveys and qualitative interviews among AYAs and mentors (phase 3). We incorporated the principles of HCD throughout, including engaging stakeholders early and throughout the design process, understanding the needs of patients, clinicians, and staff involved in diabetes care, and taking a systems approach to design [25,26]. We enhanced standard HCD steps with rigorous qualitative and customer discovery methods [27], adapted for implementation science [28], to aid in a rigorous, adopter-centered assessment of the "jobs, pains, and gains" that would be addressed by the transition intervention. Collectively, this iterative process followed best practices for designing for dissemination and sustainability and ensuring strong fit-to-context [29].

Phase 1: Inspiration

In the first phase of the project, we gathered perceptions and ideas from providers and staff involved in delivering specialty diabetes care across 4 University of California medical centers. An open-ended question about transitions from pediatric to adult care was added to a semistructured interview guide for an existing qualitative study examining telehealth use for specialty diabetes care. This study used purposive and snowball sampling to identify adult and pediatric endocrinologists, nurses, and staff involved in specialty diabetes care. Interviews lasted 1 hour, were conducted on Zoom, and were recorded and transcribed. We conducted thematic analysis using line-by-line coding in Dedoose (Sociocultural Research Consultants, LLC) [30], as fully described elsewhere [31]. Responses to the transition question were coded and analyzed separately using qualitative content analysis. The research team organized and discussed the main findings for this question.

Phase 2: Ideation

The second design phase was customer discovery, a process widely used across industries to identify intervention adopters' and influencers' "jobs, pains, and gains" and to develop value propositions tailored to different types of stakeholders (ie, adopters and influencers) involved in the clinical transition workflow [32-34]. Our process, adapted for implementation science, focused on understanding (1) adopters' and influencers' perspectives on the most important jobs to be done regarding transitions for patients with T1D, (2) the "pains" (ie, current challenges in supporting transition) and "gains" (ie, opportunities for improved experience or impact) for each group, and (3) how each group defines success [27,28,35]. We first developed a value proposition hypothesis, then conducted customer discovery to validate this hypothesis, and finally established a final value proposition statement. Value proposition statements articulate how the proposed intervention will relieve pains and create gains while carrying out the jobs to be done. Four groups of adopters and influencers were included in customer discovery: (1) people with T1D who had experienced the transition from pediatric to adult care in the past 10 years, (2) pediatric endocrinologists, (3) adult endocrinologists, and (4) diabetes educators. We recruited participants through a snowball sampling strategy, beginning with the participants from the phase 1 qualitative study. Customer discovery interviews were conducted over the

XSL•FO
RenderX

telephone and lasted between 15 and 30 minutes; the interview guide was informed by standard customer discovery questions [27]. Questions for people with diabetes included the following: (1) Can you tell me about your experience transitioning from pediatric to adult care? (2) What types of things were you most concerned about? (3) What were the main challenges and how did you deal with them? (4) Is there anything that could have made the transition easier? (5) What would an ideal transition intervention look like? (6) How would you define a successful transition? Questions for providers and staff included the following: (1) What is your role in transitions of care for patients with T1D? (2) Can you walk me through a typical transition? (3) How do you feel your health system/department/division/clinic is doing at transitions? (4) What resources are offered? (5) How do you think transitions could be improved? (6) How important do you think transitions are (for you, your colleagues, your patients, and leadership)? (7) What motivates you to want to improve transitions? Responses were captured in notes during interviews and were summarized immediately afterward.

Phase 3: Implementation

Participants

To refine the intervention components identified in phases 1 and 2, we tested our intervention with 3 cohorts of 6 to 10 AYAs. Participants were eligible for the study if they were (1) currently receiving pediatric endocrinology care at UC Davis, (2) between the ages of 17 and 21 at the time of enrollment, (3) planning to transition to adult endocrinology care at UC Davis, (4) insured under Medicaid or California Children's Services (CCS) insurance, which we used as a proxy for low-income status, and (5) able to participate in English-language video sessions. Participants were recruited by a trained clinical research coordinator both during in-person visits and through messages sent via the electronic health record (EHR). The clinical research coordinator confirmed the eligibility criteria and obtained informed consent as described below.

Intervention and Adaptations

The first of our 3 cohorts received three 75-minute group virtual sessions led by a diabetes nurse educator and supported by 2 "T1D mentors," adults aged 23 to 35 with T1D who had previously transitioned to adult endocrinology care. Initial content included modules on the following: (1) navigating the health care system, (2) "adulting" with diabetes (eg, alcohol, pregnancy, social interactions, and explaining diabetes to others), and (3) developing a transition plan. Sessions were conducted synchronously via Zoom and included a combination of facilitator-led discussion, mentor storytelling, and interactive activities. At the end of each session, we asked for feedback from participants on the intervention components, discussion topics, and meeting format. Feedback was tracked and discussed with the research team to make subsequent adaptations to sessions. Two subsequent cohorts of AYAs received the adapted intervention.

Qualitative Interviews

Following the completion of each cohort, we invited all participants and T1D mentors to participate in a qualitative interview about their experiences with the intervention. Interviews were completed via Zoom or phone, lasted approximately 30 minutes, followed a semistructured interview guide, and were audio-recorded and transcribed. Deidentified transcripts were coded line-by-line by 2 independent coders. Coders met regularly to review codes and resolve discrepancies through discussion. Final themes were discussed, categorized, and refined by the research team. Findings from interviews from the first 2 cohorts were also incorporated into intervention adaptations.

Survey Measures

All participants completed a baseline survey on demographics, employment, educational status, and time since T1D diagnosis. After completing the intervention, facilitators and T1D mentors completed 2 short validated surveys that measure perceived intervention appropriateness and feasibility on a 5-point Likert scale: the intervention appropriateness measure and the feasibility of intervention measure [36]. Participants were also asked to complete a third validated measure, the acceptability of intervention measure. Surveys were analyzed using means and SDs.

Ethical Considerations

This study was reviewed and approved by the UC Davis Institutional Review Board (approval number 1982341). Interview participants for phases 1 and 2 provided verbal consent. AYA participants in phase 3 provided written informed consent if aged 18 years or older and written assent along with written informed consent from the parent or guardian if younger. Participants who turned 18 during the study were reconsented.

Results

Phase 1: Inspiration

Qualitative study participants included 5 pediatric endocrinologists, 7 adult endocrinologists, 4 diabetes educators, 2 diabetes pharmacists, and 8 staff members involved in specialty diabetes care. We identified 3 main findings related to transitions from pediatric to adult care for persons with T1D: (1) There is a perception among all types of clinicians and staff that transitions to adult care need improvement; (2) Levels of support for transitions vary widely depending on the patient's distance from the health system; and (3) Components that may be helpful for a transition program include navigating the health care system independently (eg, insurance, appointments, pharmacy, and device companies) and a transition plan available to all members of the care team (pediatric and adult) in the EHR.

Phase 2: Ideation

We completed customer discovery interviews with 36 participants, including 16 people with diabetes, 8 pediatric endocrinologists, 6 adult endocrinologists, and 6 diabetes educators. Adults with diabetes who had previously transitioned emphasized that, during that period of their lives, their primary concern was not health outcomes per se but succeeding in broader developmental milestones, such as starting college, entering the workforce, or living independently. They described the transition as most effective when it supported their ability

XSL•FO
RenderX

to manage diabetes in a way that enabled these life goals, rather than focusing narrowly on avoiding adverse health events like DKA or hospitalization. When reflecting on what would have helped them most during the transition, participants consistently identified 3 essential components: access to peer support, a space to ask questions without judgment, and the development of strong self-advocacy skills. Table 1 summarizes the motivating gains, pains, and value proposition statements for each adopter or influencer group.

Table . Motivating "pains and gains" and value propositions by adopter or influencer group.

Group	Motivating "gains"	Current "pains"	Value proposition statement
AYA[a] with T1D[b]	More independence and confidence as they move into a new phase of life (eg, entering the workforce, attending college, living independently).	Not knowing others with T1D diabetes ("no one to talk to about it"), anxiety about navigating the health system, anxiety about asking for accommodations.	For adolescents and young adults with T1D, this intervention provides all of the information they need to transition to adult care in one place along with a supportive, judgment-free environment where they can learn from diabetes experts and peers, they can call on for help in the years to come, allowing them to focus on living their life instead of on their diabetes.
Pediatric endocrinologists	Greater ability to provide resources to ensure a smooth transition to adult care.	Emotional pain seeing patients not successfully transition, discomfort around continued insulin prescriptions after leaving pediatrics.	For pediatric endocrinologists who want to ensure the patients they have cared for for so long end up thriving after transition, this intervention provides them with an easy way to increase that likelihood and feel good about the resources being provided to their AYA patients.
Adult endocrinologists	Greater confidence that AYAs are arriving to adult care with more education and connection to resources.	High no-show rates for AYAs, which contribute to inefficient use of physician and staff time and may lead to poor outcomes for patients.	For adult endocrinologists who want to avoid poor clinical outcomes and reduce no-shows for new AYA patients, this intervention provides an easy way to help these patients transition to their care and gives them the opportunity to take advantage of the wealth of knowledge gathered on these patients over the years by their pediatric colleagues.
Diabetes educators	Having a more convenient resource available for all AYAs.	Limited time to provide individualized education and transition resources to every patient.	For diabetes educators that want to provide as much support as possible to all of their AYA patients, this intervention allows them to do this in a convenient way that will give them the opportunity to participate as much as they would like but won't place a mandatory burden on their time.

[a]AYA: adolescents and young adult.

[b]T1D: type 1 diabetes.

Across interviews with pediatric endocrinologists, adult endocrinologists, and diabetes educators, several key themes emerged about the transition from pediatric to adult diabetes care. Pediatric endocrinologists saw their primary role as initiating transition conversations and referring patients to adult care, often with support from diabetes educators. Many described significant emotional distress when patients failed to transition successfully, especially when long-term patients experienced poor outcomes. They also expressed discomfort about continuing to refill insulin prescriptions for patients who should have moved on, and they described time and resource limitations as ongoing challenges. Adult endocrinologists focused more on ensuring that young adults received the care and tools they needed to manage diabetes in adulthood. While they reported less emotional strain, given they typically meet patients after the transition, they highlighted high no-show rates and limited background information as key pain points. Diabetes educators emphasized their role in providing resources and answering questions about what to expect in adult care but noted that strict oversight of how they use their time limited their ability to support transitions more fully. They were enthusiastic about anything that could reduce the burden of 1:1 education and help more patients. Customer discovery significantly influenced the intervention design, including prompting the addition of "T1D mentors," adults who have transitioned in the past 10 years, to share their experiences and strategies, and having a specific focus on advocating for oneself (eg, explaining diabetes to others, asking for accommodations, etc). These

XSL•FO
RenderX

features created the "gains" sought by participants in terms of connecting with other people with T1D and improving confidence, and addressed the "pains" of anxiety around self-advocacy.

Phase 3: Implementation

We identified 73 eligible patients at the beginning of the study. Of these, 25 were enrolled through in-clinic recruitment and EHR messaging. Seven eligible participants declined, citing that they were either not interested in research (n=4), had a work conflict (n=1), were concerned about the time commitment (n=1), or did not feel comfortable participating in English (n=1). The remaining 41 did not respond to StudyPages (Yuzu Labs PBC) messages and were not seen in the clinic during the recruitment window. Table 2 shows the demographic and health characteristics of participants for phase 3 testing. The group was diverse, with 48% (12/25) female participants, 40% (10/25) of Hispanic or Latino ethnicity, and a variety of self-identified races. The median age of participants was 18 (IQR 18-19), and median number of years living with diabetes was 6 (IQR 4-12.5). Self-reported employment status varied, with 44% (11/25) enrolled as students (including 3/25, 12% with part-time jobs), 12% (3/25) working part-time, 4% (1/25) working full-time, and 20% (5/25) unemployed and not in school.

Table . Characteristics of participants in phase 3 user testing.

Characteristics	Values (N=25)
Sex, n (%)	
Male	13 (52)
Female	12 (48)
Race, n (%)	
White	9 (36)
Black	6 (24)
Asian	3 (12)
Native Hawaiian or Pacific Islander	1 (4)
Other	6 (24)
Ethnicity, n (%)	
Hispanic or Latino	10 (40)
Not Hispanic or Latino	15 (60)
Employment, n (%)	
Student only	8 (32)
Student also employed part-time	3 (12)
Part-time job	3 (12)
Full-time job	1 (4)
Unemployed	5 (20)
Missing	5 (20)
Age, median (IQR)	18 (18-19)
Years living with type 1 diabetes, median (IQR)	6 (4-12.5)

The intervention for the first cohort consisted of three 75-minute sessions scheduled monthly. In the first cohort, 7 out of 9 participants enrolled attended the first session, but only 3 participants attended the subsequent 2 sessions, and only 2 participants completed all 3 sessions. We subsequently adapted the intervention to 2 sessions delivered over consecutive weeks in response to feedback from cohort 1 participants. In the second cohort, 5 out of 8 participants enrolled attended session 1, and 4 also attended session 2. In the third cohort, only 2 out of 8 participants enrolled attended the first session, and only 1 attended both sessions. Attendance appeared to be influenced in part by the timing of the sessions relative to enrollment, with lower participation observed when there was a longer delay between enrollment and the session start.

After the completion of cohort 1, we also increased the use of the chat function in subsequent sessions, as many participants were uncomfortable speaking on video but actively participated in the chat when asked to do so. We also adapted the transition plan component of the intervention; rather than asking participants to fill out and share their transition plans, participants preferred to watch one of the T1D mentors fill out the transition plan template and discuss the rationale behind their choices. Table 3 shows the resulting core components and adaptive forms of the intervention.

XSL•FO
RenderX

Table . Core functions of the transition intervention, refined over 3 stages of human-centered design.

Core functions of transition intervention	Components
Education and discussion on "adulting with diabetes" facilitated by a certified diabetes educator	• Asking for accommodations at work or school • Advocating for oneself • Talking about diabetes with others • Understanding the relationships between diabetes and alcohol, drugs, sleep, stress, pregnancy, and driving • Managing diabetes while away from home • Being prepared for emergencies
Education and discussion on navigating the health care system as an independent adult with T1D[a]	• Making appointments • Asking diabetes-related questions and finding information • Filling prescriptions • Implications of insurance changes • Communicating with device companies • Obtaining additional supplies and replacement devices • Expectations for adult care
Interactive creation of a detailed transition plan	• Provide fillable online template • Talk through examples as a group
"T1D mentors" sharing experiences with T1D	• Between 2 and 4 T1D mentors during each session provide stories and differing perspectives about how they navigated the transition to adult care
Open discussion between peers with T1D	• Provide time between topics and at the end of sessions for open discussion
Opportunities to ask any questions about T1D management to peers, T1D mentors, and facilitators	• Encouragement to discuss • T1D mentors facilitate discussion and questions
Assess individual needs and provide additional resources as needed	• Facilitator and T1D mentors provide links to informational resources based on group discussion or questions • Participants were encouraged to use chat during session or to email afterwards with questions

[a]T1D: type 1 diabetes.

We completed a total of 15 qualitative interviews (9 participants, 5 T1D mentors, and 1 facilitator) during phase 3. Table 4 summarizes qualitative findings and provides illustrative quotes. Participants described the intervention as helpful, prompting them to think about aspects of managing their care they had not previously considered, and improving their confidence that they would transition successfully to adult care. The 2 components highlighted by participants as being most valuable were the T1D mentors and peer support. Many participants had not previously spoken with other people with T1D and appreciated the open discussions about challenges others had encountered and how they overcame them. These findings suggest that the core needs identified during customer discovery, particularly peer support, judgment-free discussion, and self-advocacy, were reflected in participants' experiences of the intervention. T1D mentors and facilitators also perceived the intervention to be valuable. Mentors and participants had different perspectives on session participation. While mentors were concerned that some participants were not engaged in the sessions, participants themselves noted that, although they may have had their cameras turned off or not spoken often, they were nonetheless engaged and learned from the discussions between the peer mentors and other participants. Qualitative interviews also provided insights into the intervention timing, ideal number of participants, and perspectives on topics and exercises.

XSL•FO
RenderX

Table . Key findings from qualitative interviews with adolescent and young adult (AYA) participants and type 1 diabetes (T1D) mentors and facilitators.

Finding	Illustrative quote	Implications for transition intervention
AYAs found interaction with peers with T1D to be supportive and encouraging; peer support may mitigate some of the barriers to transitioning successfully (eg, feeling discouraged or lonely).	"I think hearing from other people my age and what they deal with really helped me realize I'm not alone. We've all got to deal with it, and we are still trying to accomplish everything even though we have diabetes." [AYA participant]	Highlight this aspect of the intervention in recruitment and during sessions. Encourage further peer-to-peer support to reduce isolation and foster motivation.
AYAs found the discussion with T1D mentors, who shared their experiences managing T1D, how they overcame challenges, and strategies they use to manage health, social situations, and logistics, to be extremely valuable.	"At first, I was kind of scared because I didn't know how I was going to do everything on my own. But now I feel like I am better. I see other people who have done this and I kind of think to myself, if they can do it, I can too." [AYA participant]	Incorporate structured opportunities for mentors to share experiences and strategies (eg, structured questions, preparation in advance of sessions).
Personal stories from the T1D mentors can help make AYA participants feel more comfortable in the group setting.	"Yeah, I definitely felt comfortable because the fact that everybody had the same thing as I do and especially people sharing, like, how [one mentor] talked about how her mom was kind of micromanaging and really on her about her numbers and all that. I can relate to that. It made me kind of come forward and speak about my own experiences." [AYA participant]	Include mentor storytelling to normalize challenges and encourage peer discussion.
Navigating the health care system, including insurance, device companies, and pharmacies, will present challenges for many AYAs. Discussing prior to independence or transition may be helpful.	"Just knowing where to get your stuff, like prescription and stuff, knowing where your closest pharmacy is. I didn't even think about that because I'm going to be in charge and stuff like that now too. I might be doing things with friends and stuff, and this is all kind of going to be different." [AYA participant]	Ensure that practical content on health care navigation is covered.
The transition intervention may increase self-efficacy regarding transition.	"I've been nervous about transitioning to an adult endocrinologist. And I found it very helpful that it gave me the peace of mind that it would be easy to transition." [AYA participant]	Emphasize skill-building and reassurance to boost confidence in managing transition.
Some participants may be uncomfortable being on camera but want to participate in the discussion.	"Personally, I didn't turn on my camera because I feel like I can still stay engaged without it on. And it makes me more awkward, I guess." [AYA participant]	Allow flexible participation modes (eg, camera optional) to support comfort and engagement.
Icebreakers at the beginning of the session were helpful for improving comfort and engagement.	"I liked how they asked little questions, like what is your favorite low blood sugar snack…it gave me a feeling of like we all are dealing with the same thing and made it more comfortable to open up." [AYA participant]	Incorporate icebreakers consistently to build connection and lower barriers to participation.
Participants found that a variety of different media and activities (eg, a mix of icebreaker questions, presentation by the facilitator, structured questions, and unstructured discussion time) were helpful for staying engaged.	"I thought the slide show was great…because the information was really helpful and stuff that we need to know about. And then you could also ask questions about other things if you wanted to." [AYA participant]	Use diverse formats to maintain engagement and accommodate different learning styles.
T1D mentors were enthusiastic about sharing their experiences to help young people with T1D.	"I enjoyed it so much that I would love to do something like that again…so I think it would interest a lot of others like me to do it because it's not often that you get an opportunity to be a mentor to somebody who is experiencing something you've already experienced." [T1D Mentor]	Build sustainability by recruiting and supporting mentors who find value in contributing.

Seven facilitators and mentors (100% response rate) completed the intervention appropriateness measure and feasibility of intervention measure surveys. They rated the intervention as having good feasibility (mean 4.25, SD 0.52) and appropriateness (mean 4.43, SD 0.53). Of the 14 AYAs who participated in the sessions, only 3 completed the acceptability of intervention measure survey. These 3 participants rated the intervention as having high acceptability (mean 4.67, SD 0.29).

Discussion

This study describes the development and iterative refinement of a human-centered virtual transition intervention designed to support AYAs with T1D during the transition from pediatric to adult care. The intervention was intentionally designed to align with existing clinic workflows and resources while addressing priorities identified by AYAs, peer mentors, and clinicians.

XSL•FO
RenderX

Stakeholder input was gathered at every stage, including from patients, peer mentors, pediatric and adult providers, and educators. Across phases, we identified peer support, judgment-free education, and the development of self-advocacy skills as essential components of an effective transition program. Through iterative fit-to-context validation and refinement, we arrived at a virtual, mentor-supported intervention focused on practical concerns such as navigating insurance, managing diabetes in educational or work settings, and advocating for accommodations. While these components were consistently identified as valuable by participants, this did not necessarily translate into sustained participation, underscoring the distinction between intervention content and participant engagement.

Consistent with previous studies, participants described the transition as a time of vulnerability, not only because of elevated risk for adverse health events but also due to major life changes such as moving out, starting college, or entering the workforce [37-39]. While DKA and hospitalizations are often used as clinical indicators of a failed transition, participants in this study defined success differently. For them, successful transition meant maintaining diabetes care in ways that supported broader developmental goals. These findings highlight the importance of aligning intervention content with the real-world priorities of young adults rather than focusing solely on clinical end points [40].

Our intervention shared several elements with prior programs, including peer mentorship and a focus on building self-management skills [16,17,41-43]. However, unlike many existing models that depend on intensive resources, such as full-time coordinators or dedicated young adult clinics [44], this intervention was designed for use in settings with limited capacity. The structure of 2 virtual sessions, led by a diabetes educator and supported by trained mentors, may offer a practical approach for clinics with limited resources to support transition care. This is especially relevant for clinics serving large numbers of publicly insured patients or those with limited infrastructure to support transition care. However, efficiency is dependent on participant engagement, and low attendance may limit cost-effectiveness and scalability in practice. Prior educational and transition-focused interventions for AYAs with T1D have similarly reported mixed findings regarding engagement and retention, with some programs demonstrating strong participation and others encountering substantial challenges with sustained involvement [16,45-47]. Difficulty engaging AYAs and families in structured diabetes education has also been identified as an important implementation barrier, even in larger, well-resourced programs [48].

We also identified several important findings related to implementation. We observed lower attendance in the third cohort, which may be partially explained by the longer delay between enrollment and the start of the sessions. More broadly, engagement and retention were variable across cohorts, reflecting common challenges in delivering interventions during the transition stage. Future programs may benefit from enrolling participants closer to the intervention start date or developing strategies to maintain engagement during waiting periods. In addition, small adaptations, such as increased use of the chat function and a shift toward observational learning, were well received by participants. These changes reflect the value of responsiveness to participant preferences and highlight how flexible delivery can enhance engagement. Future adaptations may explore shorter or more flexible session formats to better align with participant preferences and competing demands.

A key strength of this study is its focus on publicly insured AYAs, a group often underrepresented in transition research and at increased risk for poor transition outcomes. AYAs from low-income households may face additional barriers, such as limited access to technology, competing work responsibilities, or less involvement from parents or caregivers. These factors can affect both participation in and the success of structured transition programs. Future research should explore how to further reduce these barriers. Potential strategies include integrating content into clinical workflows, using mobile-first platforms, or offering incentives for completion. This study has several limitations. First, the phase 3 testing was conducted at a single academic medical center in Northern California, which may limit generalizability. While some features of the intervention may support adaptation in other underserved settings (eg, the virtual format, limited number of sessions, and use of existing clinic personnel), implementation and engagement may differ in settings with fewer institutional resources, different staffing models, rural populations, or more limited access to reliable technology. Second, the phase 3 testing experienced notable attrition across sessions, with declining attendance over time. Interpretation of feasibility, appropriateness, and acceptability findings is therefore limited by low participant survey response rates and variable attendance. In addition, a substantial proportion of eligible participants were not reached or did not respond to recruitment, underscoring the challenge of engaging AYAs during the transition stage. These individuals may represent those at highest risk for care gaps, suggesting a need for alternative outreach and engagement strategies. Finally, the study focused on user testing and did not assess clinical outcomes, such as appointment attendance or hospitalization rates. Future work should evaluate the impact of this intervention on health outcomes and explore adaptation for other populations, including those in rural areas or non–English-speaking groups.

Acknowledgments

We would like to acknowledge Aaron Neinstein, Tejaswi Kompala, Leigh Ann Simmons, and Afroz Subedar for their guidance and support of this project.

Funding

The third phase of this study was supported by the National Institute of Diabetes and Digestive and Kidney Diseases and funded by the DREAMS (Diabetes Research and Engagement through Advanced Multilevel Science) Center for Diabetes Translational Research under award number P30DK092924 and by the American Diabetes Association. The first 2 phases of the study were supported by a research award from the Children's Miracle Network in association with UC Davis Children's Hospital. SCH receives support from the National Institute of Diabetes and Digestive and Kidney Diseases of the National Institutes of Health under award number 1K01DK143201. SCH and JLR also receive support from the National Center for Advancing Translational Sciences, National Institutes of Health, through grant number UM1TR005995. SSC also receives support from the National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, through grant number K23DK125671. EHM received support from the National Center for Advancing Translational Sciences, National Institutes of Health, through grant number 2UL1TR002389. The content of this manuscript is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The data generated during this pilot study are not publicly available due to their sensitive nature and the potential risk of participant identification. Participants did not provide consent for sharing qualitative data beyond the research team, and permission to share deidentified data was not obtained as part of the informed consent process. As a result, the data cannot be shared or made available upon request.

Authors' Contributions

SCH conceptualized and designed all study phases, recruited participants, collected and analyzed data, and drafted and edited the manuscript. PSR conceptualized and designed phase 3 of the study, provided continuous oversight of study activities, and contributed to drafting and editing the manuscript. SL recruited patients, collected data for phase 3 of the study, and contributed to drafting and editing the manuscript. ECH conceptualized and designed phase 3 of the study, facilitated study sessions, assisted with the recruitment for all 3 study phases, and contributed to drafting and editing the manuscript. AR conceptualized and designed phase 3 of the study, facilitated study sessions, assisted with the recruitment for all 3 study phases, and contributed to drafting and editing the manuscript. BMK conceptualized phase 2 of the study, provided feedback on the interpretation of phase 2 results, and contributed to drafting and editing the manuscript. EHM conceptualized phase 2 of the study, provided feedback on the interpretation of phase 2 results, and contributed to drafting and editing the manuscript. JLR conceptualized the study phases, analyzed phase 1 data, provided feedback on the interpretation of results for all phases, and contributed to drafting and editing the manuscript.

MS collected and analyzed data for phase 1 of the study, assisted with the interpretation of results, and contributed to drafting and editing the manuscript. AL facilitated phase 3 sessions, analyzed qualitative data for phase 3, and contributed to drafting and editing the manuscript. DP conceptualized phase 3 of the study, assisted with the recruitment for all study phases, and contributed to drafting and editing the manuscript. SSC conceptualized and designed all study phases, recruited participants, assisted with the interpretation of data, and drafted and edited the manuscript.

Conflicts of Interest

EHM has served as a consultant on issues of drug safety to Eli Lilly, i2o, Reata Pharmaceuticals, and Syneos Health, as well as to the Class Plaintiffs of the Xyrem (Sodium Oxybate) Antitrust Litigation, including United Healthcare Services, Inc, Humana Inc, Molina Healthcare, Inc, and Health Care Service Corporation, Inc, and has received compensation for these services. The terms of this arrangement have been reviewed and approved by Loyola University Chicago in accordance with its policy on objectivity in research.

Abstract

Background: Children with medical complexity experience multiple chronic conditions that demand intensive, ongoing, and highly coordinated care, often placing a burden on their parents, who serve as primary caregivers. Digital health offers a promising solution for enhancing care coordination, monitoring, and communication. However, its effectiveness depends on it being developed as a user-centered solution that incorporates feedback from parents, who are the primary decision-makers and advocates in their children's health care. By prioritizing the voices of parents, especially those from underserved communities, during the design and implementation of digital health solutions, these tools can more effectively meet their unique needs. This ensures that digital health solutions are effective in real-world caregiving scenarios.

Objective: This qualitative study explored the experiences of family caregivers of children with medical complexity, with a focus on parents from underserved communities, shedding light on the challenges they face and opportunities for future digital health innovations. Underserved communities in this study are defined as families experiencing structural barriers to accessing specialized care for children with medical complexity, often necessitating additional support from nonprofit or community-based organizations.

Methods: We conducted semistructured interviews with 19 parents of children with medical complexity from underserved communities. All interviews were conducted over Zoom and were audio recorded. We conducted an inductive, reflexive thematic analysis using an iterative codebook to support analytic transparency.

Results: The children in this study had a variety of chronic conditions, each experiencing at least 3 chronic, long-lasting medical conditions. An inductive thematic analysis revealed two broader key themes: (1) virtual care and (2) consumer mobile health (mHealth) apps. The "virtual care" theme focused on the use of remote health care services and communication with health care providers, highlighting parents' challenges and needs for enhancing virtual care. The "consumer mHealth apps" theme identified needs and challenges in the care management of children with medical complexity that could be addressed through consumer mHealth apps.

Conclusions: This study highlights several insights into the digital health needs of children with medical complexity and their family caregivers. Parents identified a clear and urgent need for telehealth features tailored to better support the unique needs of care for children with medical complexity. Despite the growing adoption of consumer mHealth apps, caregivers reported ongoing challenges, underscoring the necessity for user-centered solutions that are specifically designed with their needs in mind. Future research and development should focus on integrating user feedback to continuously refine and enhance digital health solutions. By addressing these gaps, technology can better empower caregivers and improve the overall health care experience for families of children with medical complexity. Ultimately, this study provides valuable guidance for future digital health innovations to support parents of children with medical complexity from underserved communities.

KEYWORDS

children with medical complexity; pediatric care; digital health; mobile health; mHealth; design; care coordination; underserved populations

Introduction

Children with medical complexity are individuals with multiple chronic conditions—either congenital or acquired—that often involve significant cognitive and/or physical impairments [1,2]. These children typically face functional limitations; rely on life-sustaining medical technologies; and require ongoing, intensive care across multiple body systems [3]. For instance,

XSL•FO
RenderX

a child with medical complexity might have a genetic syndrome, a congenital heart defect, cerebral palsy, swallowing difficulties, and a urologic condition [4]. Meeting the needs of children with medical complexity requires highly coordinated, specialized care delivered by a multidisciplinary team of health care professionals [5] along with continuous, collaborative engagement between families and health care providers [6]. Although there is no clear definition of children with medical complexity, they are affected by chronic, often very severe conditions for their entire life, which represents a significant cost for the health care system due to their need for continuous assistance [7]. In our study, we defined "children with medical complexity" as individuals aged 21 years or younger who have at least 3 chronic medical conditions [7].

Parents of children with medical complexity are often the foremost experts on their children's needs. They shoulder responsibility for both routine and intensive medical care, frequently under unpredictable and high-stakes conditions with few—if any—alternatives to their demanding role [8]. This unpredictability stems from the child's fragile and often unstable health status [9]. Parents of children with medical complexity perform tasks typically performed by licensed professionals, such as managing life-sustaining technologies, administering medications, and providing complex daily care [10]. As a result, the family caregivers of children with medical complexity report significantly poorer well-being than the general US adult population, including elevated levels of anxiety and impaired sleep health [11].

User-centered digital health solution design incorporating end user input increases the likelihood that digital health solutions will be seen as useful, making it essential to understand patients' and parents' access to and interest in such interventions during technology development [12]. Digital health solutions may play an essential role in improving mental and physical health outcomes [13]. The development of digital health technologies represents a rapidly growing area, offering global health care systems opportunities to enhance care and accessibility [14].

This research aimed to elevate the voices of parents of children with medical complexity by exploring their experiences with current digital health tools and gathering their insights into future innovations. As constant caregivers, advocates, and decision-makers, these parents play a central role in managing their children's complex health care needs and navigating fragmented care systems. By examining how existing technologies support—or fail to support—families of children with medical complexity, this study aimed to identify how digital health can improve care delivery for children with medical complexity and empower families in underserved communities in their caregiving roles. Ultimately, the goal was to identify needs in terms of current digital health solutions and offer actionable recommendations to develop tools that more effectively address the caregiving challenges faced by families of children with medical complexity in underserved communities.

Methods

Ethical Considerations

This qualitative study used semistructured interviews to collect data following ethics approval (2023‐006) from the institutional review board of Stevens Institute of Technology. The interview questions focused on identifying challenges and needs in digital health for the care of children with medical complexity (Multimedia Appendix 1). Participation in the study was entirely voluntary, and participants were informed that the data would be reported anonymously. Data access was strictly limited to the study researchers. Each participant was given a US $30 Amazon gift card for completing the interview. We structured our methodology in alignment with the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist to ensure transparency [15]. The study team received verbal consent from all participants.

Semistructured Interviews

This qualitative study explored parents' perspectives on how digital health technology supports them in providing care for children with medical complexity, and this study also has potential to shape the path for future enhanced digital health solutions designed for primary caregivers of children with medical complexity. Participants were recruited through the Statewide Parent Advocacy Network (SPAN) based in New Jersey [16]. SPAN is a community organization for children with special needs and children with medical complexity. It was founded by parents of children with special needs in 1987 to provide support to the families of these children and of children with medical complexity [16]. The staff has supported more than 500 families of children with medical complexity in New Jersey for many years, especially those from underserved communities. We designed a brochure and worked with SPAN members to distribute it to families of children with medical complexity from underserved communities who lacked access to medical services. Participants were family members identified as the primary caregivers for children with medical complexity; most were the children's parents. We conducted semistructured interviews with primary family caregivers of children with medical complexity from underserved communities between October 2023 and March 2024. In this study, "underserved communities" refers to families who face structural and access-related barriers to specialized care for children with medical complexity, including provider shortages, geographic constraints, fragmented health systems, and challenges navigating services [17]. These barriers are often substantial enough that families rely on nonprofit or community-based organizations (SPAN) for additional support, care coordination, and resource access beyond what is available through the formal health care system. We also used snowball sampling techniques by asking for referrals from the participants. We used the theoretical data saturation approach to determine the final sample size [18]. Data saturation occurs when further interviews do not yield new themes or reveal new subthemes within the existing themes [19,20]. All interviews were conducted over Zoom (Zoom Video Communications) and were audio recorded.

XSL•FO
RenderX

Data Analysis

An inductive, reflexive thematic analysis was conducted, with a codebook developed iteratively during analysis to support analytic transparency rather than to impose a priori coding structures. We used a constant comparative approach to collect and analyze data simultaneously. Transcripts were analyzed using inductive thematic analysis. The inductive approach focuses on identifying themes as they emerge from the data to understand the needs of children with medical complexity regarding technology preferences and challenges [21]. Inductive thematic analysis ensures that the themes are representative of participant responses and not shaped by a predefined hypothesis [22]. We used a line-by-line coding method [23]. The first author (FE) coded the data and created a codebook, which was then reviewed, refined, and validated by the second author (OA). We identified themes by comparing situations, suggestions, and experiences from the same and different individuals and gradually refined the coding schema [24]. The coding was performed using Microsoft Excel, which included both inductive analysis and participant demographics.

Results

This study included interviews with 19 family caregivers of children with medical complexity, focusing on parents of children with medical complexity from underserved communities; each interview lasted approximately 45 minutes.

Demographics

Participant demographics were documented to describe the sample. Table 1 presents a summary of the demographic characteristics of the participating caregivers and their children with medical complexity.

Most participants (15/19, 78.9%) were from New Jersey. However, through snowball sampling, in which existing participants referred others to the study, additional caregivers from California, Alaska, Colorado, and New York were included (4/19, 21.1%). Most (12/19, 63.2%) were African American, with others identifying as Hispanic (3/19, 15.8%) or White (4/19, 21.1%) individuals. Most caregivers were aged between 30 and 49 years. The study included 52.6% (10/19) female and 47.4% (9/19) male participants. All caregivers had 1 child with medical complexity except for one caregiver who had twins with medical complexity. The educational backgrounds of the participants included 10.5% (2/19) with master's degrees, 73.7% (14/19) with bachelor's degrees, and 15.8% (3/19) who had completed high school. Finally, most of the children (15/19, 78.9%) were boys. The largest age group was 12 to 14 years.

Qualitative Analysis

An inductive thematic analysis of the qualitative data revealed 2 primary themes related to current experiences with technology in the care for children with medical complexity and unmet needs that could be addressed through digital solutions. These themes were (1) virtual care and (2) consumer mobile health (mHealth) apps.

Virtual Care

The first theme, "virtual care," refers to any interaction between patients and health care providers occurring remotely, using technology with the aim of facilitating or maximizing the quality and effectiveness of patient care [25]. This theme encompasses subthemes based on parents' experiences with using virtual care for their children with medical complexity, highlighting both the challenges they encountered and their needs for improving the virtual care process. Table 2 includes the subthemes, their definitions, and supporting quotes.

XSL•FO
RenderX

Table . Subthemes, definitions, and supporting quotes for the theme of virtual care.

Subtheme	Definition	Quotes
Information and mental overload related to the parental role as mediator	Refers to the overwhelming amount of information and emotional strain while passing on information to health care providers during telehealth sessions	• "During the pandemic, it was overwhelming. We had to understand the whole process of how and what my child was going through, because it was at this point that we had to communicate with the doctors more remotely, and we had to pass out information to the service providers." [P6] • "It was just me trying to give all the information to the healthcare provider during the telehealth session, and somehow I kind of felt uncomfortable because I do not know, but I had to do it." [P5] • "You can look at the child, but things are subjective. There are these types of things. How swollen are they? My child's stomach is hard and painful. How hard is it? There is no clear answer for that. So how do we make sure that the physicians are getting a clear picture of what is happening with the child physically, based on what you see and measure." [P19]
User-friendly vocabulary	Refers to the need to clearly explain and simplify the medical language so that health information is easy to understand for parents of all levels of medical knowledge	• "There are some terminologies I came across that I did not understand. So maybe providing resources where you can actually understand some of the symptoms or what your child is going through. This can be very helpful. We have to carry out personal research. But these are some things that could be included in telehealth services. And it will actually reduce the stress." [P6]
Support for nonverbal children with medical complexity	Refers to the need to engage, comfort, and support nonverbal children with medical complexity during health care appointments by providing various communication methods based on their abilities and preferences	• "My experience is that providers should know how to communicate with a patient with autism who is nonverbal, or how to understand whether they would like to be touched or whether they have struggles waiting like having survey questions to ask the parent before you begin the telehealth session. It really helps to do those prescreening questions." [P5] • "Some service providers actually do not know how to treat kids who have a hearing impairment, because I know it might be like very tense talking to someone, and the person is finding it hard to hear you." [P7] • "The doctor asked some questions and stuff like that. But facing the screen and answering questions is a bit stressful for my child, and my child can get upset, or just leave the virtual meeting." [P2]
Child-friendly virtual waiting room	Refers to the need for a digital tool designed to engage, comfort, and entertain children with medical complexity while they wait for their health care appointments	• "In terms of the virtual aspects, like sitting, viewing a laptop, and having an appointment, waiting for the doctor. It is kind of intense and stressful for the child." [P6]

Consumer mHealth Apps

The theme "consumer mHealth apps" represents the needs and challenges of parents of children with medical complexity that can be addressed through consumer-focused mHealth features to support their caregiving experience. It explores the features and tools that parents of children with medical complexity need to be developed to manage their caregiving responsibilities effectively. Table 3 presents the subthemes, their definitions, and supporting quotes.

XSL•FO
RenderX

Table . Subthemes, definitions, and quotes for the theme of consumer mobile health apps.

Subtheme	Definition	Quotes
Digital health notebook	Refers to the need for organizing, tracking, and managing health information in an accessible format	• "I write all symptoms down. But it is always kind of hard for me, because, like, in the process of rushing to take my kid to the doctor. Sometimes, I forget to carry the book with me, so I drive back to the house to bring it." [P10] • "I think we need a milestone tracker of where they should be, or where they could be at that age. I think, if it follows them through their milestone and through their ages as they grow and develop, it could be helpful." [P16]
Medication administration	Refers to the challenges of managing medications for children with medical complexity due to having multiple medications and doses that change frequently	• "Change in medication is a big thing, because giving the child certain things at certain times of the day. And suddenly things have changed. So now you have to be able to make sure you are giving it the right time. And there are no other medications that could potentially have a negative effect on the child due to cross interactions." [P4]
Health technology synchronization	Refers to the need for integrating digital tools and systems related to the care for children with medical complexity to enhance connectivity and user experience	• "I think for us, the safety issue is being able to access medical teams that are all on the same page, who can interact, even if they are in different facilities, can communicate with each other effectively." [P19]
Supporting decision-making	Refers to supporting children with medical complexity in their transition to adult care, enabling them to make informed and confident choices in various situations	• "What they really should be learning at the earliest stages is supported decision-making and self-direction supports. Because I was not told. My kids are 12, and I really was not aware of supported decision-making and self-direction until my kids were 9, and I should have been doing this when they were 3." [P14]

Discussion

Principal Findings

Caring for children with medical complexity involves navigating an extensive network of health care providers—primary care clinicians, specialists, and nurses—across multiple settings, including the home, school, clinics, and hospitals. This fragmentation increases the risk of care gaps over time [26-28]. Prior studies have shown that parents of children with medical complexity face multiple barriers to communication and information accessibility, including difficulties scheduling appointments; coordinating among health care providers; and obtaining clear, actionable health information [29-32]. Many are also tasked with administering complex medication regimens without formal training or having children with medical complexity–specific tools to ensure accuracy [33]. These challenges are even more pronounced for families in underserved communities.

Underserved populations who lack access to proper health care infrastructure are rapidly increasing their adoption of digital health tools to address gaps in care by overcoming barriers such as language and geography [34,35]. A previous study shows that further research is needed to evaluate the effectiveness of mHealth and virtual care and their impact on health care delivery in underserved communities [36]. In addition, digital health tools for the care for children with medical complexity should be shaped by the voices and experiences of families on the front lines of care to build systems that work for children with medical complexity [37]. A unique aspect of this study is its focus on children with medical complexity in underserved communities as a first step, revealing how caregiving challenges intersect with the realities of digital health use with the goal of advancing user-centered digital health solutions for parents of children with medical complexity.

Telehealth has been suggested as a possible way to address health care disparities among underserved urban populations who are often unable to access health care in a timely manner due to low physician-to-population ratios and limited specialty care [38]. Accordingly, telehealth is viewed as a strategy for improving access to care for rural and underserved populations by connecting them with primary care providers, specialists, and mental health services [39]. While virtual care offers a promising avenue for overcoming geographic and resource-related barriers [40], our findings demonstrate that it can also shift significant responsibility onto caregivers. Parents

XSL•FO
RenderX

described the mental and emotional overload of acting as the primary information conduit between child and health care provider, particularly during remote visits.

Therefore, health literacy is essential for parents of children with medical complexity to make informed decisions and manage their children's specialized care needs [41,42]. Low parental health literacy has been associated with limited health knowledge and poorer child health outcomes [43,44]. Consistent with this, our participants emphasized that integrating user-friendly vocabulary and parent-centered resources within telehealth platforms can reduce the cognitive burden on parents by enabling them to interpret information immediately while communicating with health care providers via telehealth and actively participate in their children's care.

While parental understanding supports a child's care, providers also need to adopt strategies that allow them to communicate effectively with nonverbal children with medical complexity during telehealth appointments. A previous study reported that medical providers' communication strategies often failed to address the needs of nonverbal children with medical complexity, and that strategies such as warmly greeting patients and introducing themselves were sometimes skipped based on the false assumption that these patients could not engage in meaningful communication, which in turn diminished trust between patients and medical providers [45]. This supports our findings that telehealth tools need to be designed as child friendly and support nonverbal children with medical complexity to facilitate communication between patients and health care providers. These considerations were identified as critical for developing an inclusive telehealth tool and are often overlooked in current platforms.

In addition, mHealth is a type of digital health that refers to the use of mobile technologies to deliver health services. It is particularly valuable for improving health outcomes in patients with chronic conditions [12]. Families of children with medical complexity commonly struggle to accurately recall symptoms, clinical events, or over-the-counter medication use, highlighting the need for mHealth tools to document health events outside clinical settings [46]. Regarding caregiver needs, our participants sought mHealth solutions to reduce daily burden and empower decision-making. They envisioned tools consolidating digital health notebooks and medication management. These findings align with those of previous research on the potential of mHealth to empower patients through personalized, timely support [47,48] and integrate digital tools across home, health care, and school systems [49-52]. The desire for synchronized health technology highlights a critical gap in current systems as caregivers of children with medical complexity must repeatedly communicate the same information across providers, increasing workload and the risk of errors.

In addition to supporting day-to-day care, participants emphasized the need for digital technologies that facilitate decision-making for children with medical complexity as they transition to adult care. Few studies have examined the effectiveness of digital health interventions to assist adolescents and young adults with chronic conditions in facilitating self-management and transitioning to adult care [53,54]. There is an interest in using mHealth tools to facilitate the transition to adult care, but early co-design with users and collaboration with health care providers are needed to address varying preferences and needs [53].

Figure 1 summarizes the key challenges that parents of children with medical complexity face—managing complex needs, accessing specialized resources, and coping with emotional and physical burdens—that emerged from our findings. We also developed and listed targeted solutions and recommendations for researchers, health care providers, and software engineers to develop effective, user-friendly systems that better support families.

Figure 1. Challenges, solutions, and recommendations for enhancing care for children with medical complexity through technological and supportive interventions.

As part of the user-centered design approach, we developed key digital health functionalities to address participants' needs and bridge gaps in the care for children with medical complexity (Table 4). Effective mHealth tools begin with a user-centered design approach that engages end users throughout development to ensure functionality, usability, and relevance [55-57]. Guided by this principle, we assessed the needs of parents of children with medical complexity and translated them into recommended mHealth platforms, including a description of their functionalities to inform the development of actionable software solutions. Technology developers must also ensure compliance with HIPAA (Health Insurance Portability and Accountability Act) alongside robust security, reliability, and usability in collaboration with health care leaders and policymakers [58-60]. In addition, expanding access to digital health tools in underserved communities requires investment in telehealth infrastructure, mobile-friendly screening tools, and community outreach programs that educate caregivers on how to use these technologies effectively [61].

Table . Technological solutions to support caregivers in underserved communities.

Subtheme	Recommendation	Description
Information and mental overload related to the parental role as mediator	Centralized child-specific care app	• A personalized platform tailored to each child's unique needs, providing a database of treatments, technologies, and resources for mobility, speech, and feeding; contact information for specialists and facilities; and video tutorials and step-by-step guides on managing medical devices, administering medications, and responding to emergencies at home
Medication administration	Medication and device management tool	• An app with features providing barcode scanning for medications; automated reminders for dosage and allergy tracking; integration with medical devices to monitor use and performance; medication interaction checker (the app cross-references medications and alerts parents if there are potential interactions or adverse effects); and notifications to reorder critical medical supplies, with direct links to pharmacies or online retailers
Support for nonverbal children with medical complexity, child-friendly virtual waiting room, and information and mental overload related to the parental role as mediator	Virtual assistant and follow-up tracker	• A virtual assistant app that sets follow-up reminders after treatment; logs symptoms automatically during video consultations; provides summaries of past interactions with physicians; analyzes logged symptoms over time and provides reports, highlighting patterns or triggers for review with health care providers; automatically translates medical terminology into simple, parent-friendly language during telehealth interactions; integrates a pre–telehealth visit form to identify the child's communication preferences, including visual aids, text-based prompts, captioning, or other alternative input methods, to support nonverbal children during telehealth visits; and provides an interactive virtual waiting room with games and calming visuals to reduce children's stress while waiting for appointments
Information and mental overload related to the parental role as mediator	Medical team coordination tool	• A shared platform for health care providers that links professionals from different facilities; offers real-time updates on the child's medical condition; allows caregivers to monitor progress remotely; provides shared medical records and care plans; allows for easy access to specialists in cases of emergency; features a one-tap emergency alert button that notifies all members of the health care team and shares the latest health data; and includes a comprehensive profile that can be shared with new health care providers, including past treatments, medications, and allergies
Supporting decision-making and information and mental overload related to the parental role as mediator	Enhanced appointment and scheduling system	• A system for booking appointments that integrates with personal reminders and health care databases • Parental controls to allow older children to schedule appointments independently • Ability to set appointments and notifications in the caregiver's preferred language to accommodate diverse backgrounds

XSL•FO
RenderX

Subtheme	Recommendation	Description
Information and mental overload related to the parental role as mediator	Stress relief features for parents	• A caregiver-focused app with emotional support resources such as online counseling; guided journaling to reduce the mental load of caregiving; sleep and stress management techniques; and quick, step-by-step instructions for handling medical emergencies, with links to emergency contacts or services
Health technology synchronization	Smart integration with existing technology	• Compatibility with devices such as Alexa or Google Assistant for reminders and notifications • A mobile-friendly design that integrates seamlessly with smart home ecosystems • Hands-free voice commands to log symptoms, check schedules, or receive reminders • A shared care dashboard that syncs updates across caregivers and medical teams

Strengths and Limitations

To our knowledge, this is the first study to examine the needs and challenges related to digital health technology among parents of children with medical complexity in underserved communities. A key strength of this study is the inclusion of a relatively large sample of caregivers from underserved communities, a group that is frequently underrepresented in qualitative research on children with medical complexity. Although participants were recruited from underserved communities, the relatively high educational attainment among caregivers in our sample may limit the generalizability of the findings to caregivers with lower levels of education. Another limitation of this study is its reliance on Zoom interviews, which may have excluded participants with limited access to technology or who were uncomfortable with digital platforms. This could result in a sample that does not fully capture the experiences of parents who might prefer face-to-face communication.

Conclusions

Our study reinforces that parents in underserved communities are not resistant to digital health; rather, they are eager for solutions that are trustworthy, accessible, and tailored to the care of children with medical complexity. By addressing the intersecting barriers of medical complexity and systemic inequity, health care systems and technology developers can design digital tools that meaningfully enhance care coordination, reduce caregiver burden, and improve health outcomes. Future work should focus on co-design approaches with families of children with medical complexity, evaluation of tailored interventions, and longitudinal research to examine impacts on care transitions and health care use.

Abstract

Background: Injury is the leading cause of death among US children, with over 2700 deaths due to unintentional injuries among children aged <6 years in 2023. Many of these deaths occur in the home and involve addressable safety hazards. Evidence-based parenting programs (EBPPs), in which parents work with a provider to learn parenting skills, offer an infrastructure for disseminating home safety content. However, few programs have structured modules on home safety, with most home safety education coming from printed materials or websites. Immersive virtual reality (IVR) allows participants to engage in activities in a simulated, risk-free environment. IVR's technological affordances create a training environment that supports experiential learning and helps learners internalize and transfer knowledge more effectively to real-world situations.

Objective: This study aimed to (1) design an IVR home safety program for parents of children aged <6 years in line with our conceptual model, (2) obtain feedback from parents and EBPP providers on the initial design, and (3) test an initial prototype of the program with parents.

Methods: The prototype was developed using human-centered design principles. The team first identified key components for program content using existing research and theory. Qualitative data were then collected from EBPP provider interviews (n=5) and focus groups with parents (n=7) regarding implementation constraints, program content, barriers/facilitators for engagement, and feedback on the use of IVR. Thematic analysis was used to identify themes from the qualitative data. The initial prototype was then pilot tested with parents of children aged <6 years (n=5).

Results: The IVR program addresses knowledge and skill enhancement in three key areas: (1) home safety hazard identification, (2) hazard removal/mitigation, and (3) parental supervision. Using surveillance data, we identified leading causes of unintentional injuries in the home environment among US children aged <6 years, including sleep-related deaths, firearm injuries, and drowning. Hazards and corresponding tasks in the IVR program were developed for these leading causes. Findings from interviews with providers indicate that they are open to the use of IVR in EBPPs and envision uses for both group and individual settings. They expressed concerns about the cost of incorporating IVR into their usual programs. Parents were interested in IVR, especially if presented in brief sessions. They also noted a desire for the virtual environment to look realistic and "lived in."

Conclusions: Currently, home safety information is delivered in a didactic or pamphlet-driven format in most EBPPs, which is not ideal for behavior change. This IVR home safety program will provide unique benefits in training, including (1) real-world simulations, (2) hands-on learning, (3) a risk-free environment, and (4) IVR scenario-based assessment. This study provides support for the use of IVR in engaging parents in home safety education and presents considerations for future research.

Introduction

Background on Child Injury

Injury is a major public health issue faced by children in the United States. In 2023, over 3500 children aged 0-5 years died due to injury, amounting to 226,385 years of potential life lost. In addition to fatal injuries in this age group, there were almost 2 million nonfatal injuries that required an emergency department visit [1]. Over 3 quarters of fatalities (77.3%) among children aged 0‐5 years in 2023 were due to unintentional injuries, and these injuries predominantly occur in the home environment [2-4]. Common types of unintentional home injuries associated with the leading causes of death among young children include drowning, suffocation, poisoning, burns and scalds, falls and tip-over incidents, and firearm injuries [1].

Child Home Injury Prevention

Parents and other primary caregivers (referred to in this paper simply as “parents”) are key to the prevention of home injuries among young children. Fundamental elements of injury prevention include parents’ ability to identify safety hazards, adequately address hazards, and provide proper supervision. Parents’ knowledge of home safety is associated with reductions in observed home safety hazards [5]. Additionally, children whose parents adopt unsafe behaviors in terms of failing to address hazards and provide adequate supervision are more likely to sustain injuries [6]. Supervision is an especially important element of child injury prevention. Research has found this to be a stronger contributor to child injury prevention than simply identifying and addressing hazards [7,8]. One study noted that parents’ proximity “beyond reach” was associated with serious injuries in young children [8].

Efforts exist to educate parents on home safety in order to prevent child injury. For instance, parents may receive written and/or verbal patient education from their pediatrician at child well visits [9]. There are also organizations such as Safe Kids Worldwide [10] that connect parents with safety devices through their local health department and provide home safety and child injury prevention information online and on social media. Additionally, each year over 280,000 families participate in evidence-based parenting programs (EBPPs), which involve parents meeting with a trained program provider in an individual or group setting to learn parenting skills [11]. These programs typically focus on parent-child interaction skills for parents of young children, and many incorporate home safety in some way. However, home safety information delivered through EBPPs is primarily didactic, involving written materials and/or videos with home safety and child injury prevention information, with home safety devices provided in some instances [12]. A notable exception is SafeCare, which includes a dedicated home safety module with opportunities for home assessment by the provider, parent practice, and feedback [13].

Digital Health and Child Injury Prevention

Digital health tools have been used as a way to engage parents and enhance learning on home injury prevention. To date, this has primarily involved screen-based applications or games. A serious game developed to teach home safety skills was found to be feasible and acceptable among teenage mothers, and their reaction time was faster when they had the opportunity to play the game multiple times [14,15]. This game involved hazard identification in a screen-based virtual home environment and required mothers to maintain focus as distractions such as alarms were deployed periodically in the game [14]. Other serious games and screen-based programs have been deemed feasible and acceptable by parents learning home safety skills [16-18].

Immersive virtual reality (IVR) engages parents and enhances learning beyond what is possible through screen-based interactions. IVR incorporates immersion, embodiment, sense of presence, and interactivity, which have been positively associated with user engagement and learning outcomes [19,20]. Furthermore, IVR has been found to be effective in increasing procedural knowledge [21]. This is especially applicable to home safety education for parents, as much of the knowledge involves understanding the skills necessary and the steps required to create a safer environment. Using IVR, parents can practice skills in a virtual home environment, receiving feedback in real time. Rehearsing skills in a safe, controlled environment allows parents to refine their responses to improve the likelihood of success in the physical world during real-life scenarios.

Study Aims

The goals of this study included (1) designing an IVR home safety program for parents of children aged 0‐5 years intended for dissemination through EBPPs, (2) developing a prototype of the program, and (3) testing the feasibility and usability of the program with parents.

Methods

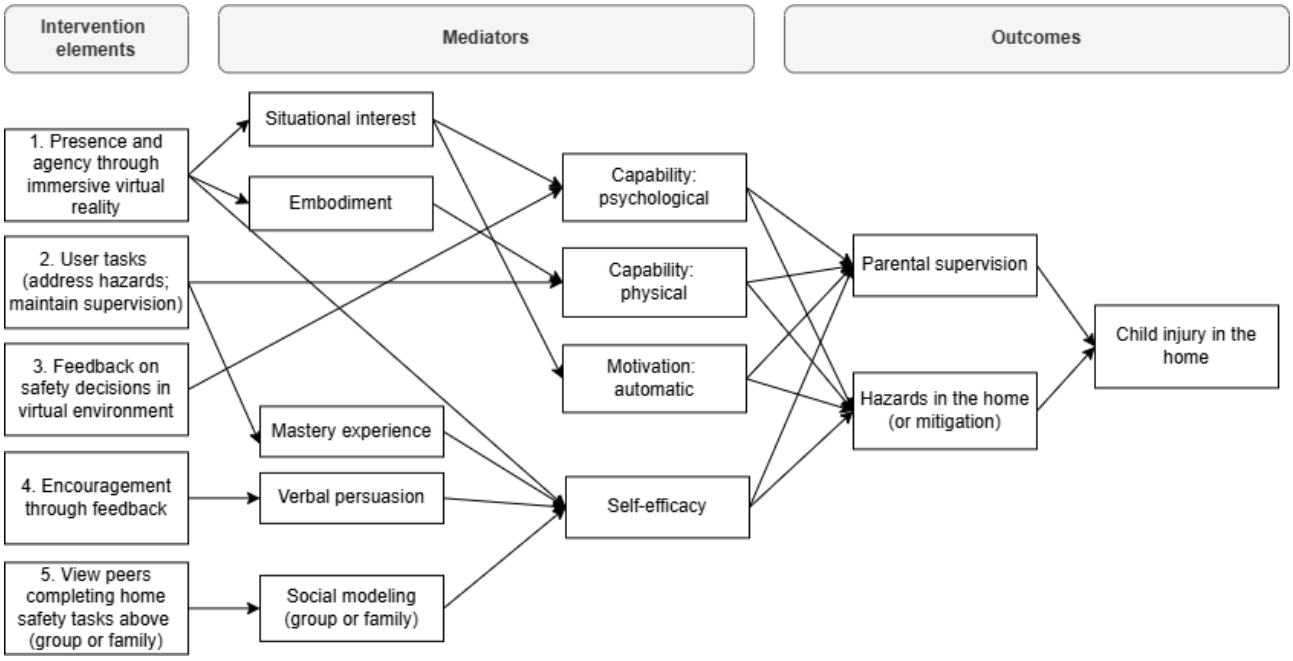
Overview

The IVR program was developed using principles of human-centered design in a discover, design/build, and test framework [22]. In Phase 1, we conducted preliminary work to identify key content areas and obtained feedback from parents on the initial design. We then developed the prototype and tested it in Phase 2. Each phase is described in more detail below. All data collection from study participants took place between November 2024 and May 2025.

Ethical Considerations

This study was approved by the Kennesaw State University Institutional Review Board (IRB-FY24-579).

Discover and Design: Phase 1



Overview

We first developed a conceptual model for the IVR home safety program (see Figure 1). It is important to note that the goal in this study was not to test this model but to provide a theoretical foundation for the program. The model integrates components of the behavior change wheel [23] and the cognitive affective model of immersive learning (CAMIL) [24]. The behavior change wheel is centered around a framework that states that capability, opportunity, and motivation lead to behavior (the COM-B system) [23]. Our model incorporates elements of capability and motivation, as this best reflects our

XSL•FO
RenderX

individual-level intervention. CAMIL is a theoretical model for understanding the mechanisms by which education and training through IVR are related to learning outcomes [24].

Figure 1. Conceptual model of ParentSHIELD-VR. Mediators are constructs from the behavior change wheel and the cognitive affective model of immersive learning.

The intervention elements are proposed to ultimately lead to the outcomes of interest (ie, parental supervision and home safety hazards and child injury) through several mediators. Figure 1 depicts these relationships. We will now describe how we propose that each intervention element is related to proximal and distal mediators and, ultimately, to the outcomes of interest. We will describe the proposed paths for each intervention element (numbered in Figure 1). First, the model posits that the sense of presence and agency afforded through IVR (Element 1) leads to increased situational interest, embodiment, and self-efficacy. These proximal mediators lead to effects on distal mediators. Specifically, increased situational interest subsequently leads to increased psychological capability (ie, knowledge) [25] and motivation [26-28]. Embodiment leads to increases in physical capability (ie, skills) [21], which has favorable impacts on the outcomes of interest. Next, the model posits that the user tasks in the program (Element 2, ie, identifying and addressing hazards; maintaining proper supervision in the midst of distractions) favorably impact outcomes through increased physical capability (ie, skills) [23]. Feedback provided to users after they address safety hazards in the virtual environment includes facts or additional context around each hazard (Element 3), and this impacts outcomes through increased psychological capability. Similarly, encouraging statements within the feedback (Element 4) affect home safety outcomes through increased self-efficacy [29]. The program is intended for use both in EBPPs that meet with families individually and those that meet in a group setting. Parents meeting in a group setting could watch other parents engaging with the program through the “cast to screen” feature (Element 5). This feature could also be used for EBPP participants who meet as a family with their provider (eg, one parent watching the other parent or caregiver engaging with the program). These situations would offer an opportunity for social modeling, which would impact self-efficacy [29]. Further details on the conceptual model for the program can be found in Figure 1.

As part of Phase 1, we also identified tasks for inclusion in the program. Our team reviewed the literature and publicly available data sources to identify key content areas. We decided to focus the program’s content areas on leading causes of death related to home injury among children aged 0 - 5 years. As such, we used data from the Centers for Disease Control and Prevention to identify the leading causes of injury in this age group [1] and considered those that occur in a home environment. The initial set of user tasks designed by the research team related to these leading causes as well as hazards of increasing concern (eg, vaping devices), as identified in recent peer-reviewed literature [30]. We included tasks related to the following hazard categories: poisons, burn/scalds, sharp objects, tip-over/crush, falls, firearms, strangulation, suffocation, and drowning.

Provider Interviews

After creating the user tasks and the initial program design in a rough prototype, we conducted qualitative interviews with EBPP providers and focus groups with parents. Specifically, we sought to recruit 5 EBPP providers based on available seed funding resources (ie, funding and timeline). While we would have preferred a sample size of 6 - 12, based on recommendations for qualitative interviews [31], we decided to maximize the number of parent voices included in the project while obtaining as much feedback as possible from providers. Inclusion criteria were providers who were currently delivering an EBPP, had been doing so for at least 1 year, and had the technology necessary to participate in a virtual interview through video conferencing software. Administrators from local social service agencies that deliver EBPPs were contacted via email

XSL•FO
RenderX

with a description of the study opportunity and a recruitment flyer. They were asked to distribute the opportunity to their providers. Interested providers were instructed to contact the principal investigator (PI; MCO) via email to confirm eligibility. Once eligibility was confirmed, the provider scheduled a virtual qualitative interview with the PI. Each interview took approximately 60 minutes, and providers received a US $35 gift card as compensation.

Qualitative interviews were conducted using an interview protocol developed by the research team. The interview began with the consent process, followed by questions about the provider's current experiences delivering home safety information to parents (eg, current content provided, areas of interest to families, parents' receptivity to safety education) and their current use of technology in program delivery. We then presented the provider with a description of the overall program concept, user tasks, and screenshots of the rough prototype. We also shared the proposed name of the program: parent safe home immersive education and learning development–VR (ParentSHIELD-VR). Following this presentation, the provider was given an opportunity to share feedback verbally. We then conducted a Roses, Thorns, and Buds activity [32] in which providers were given a link to a shared Google Sheet where they listed aspects of the program that they liked, things they did not like, and things they would change. Providers were given 5 - 10 minutes to provide feedback in this way and then were given the opportunity to expand on any written feedback. Finally, providers were asked questions related to resource constraints (ie, time and cost).

The virtual qualitative interviews were recorded and transcribed using features available through Microsoft Teams. Transcriptions were deidentified, and recordings were subsequently deleted. Google Sheets files from the Roses, Thorns, and Buds activity were also saved using a unique identification number for each participant. Following all interviews, data from transcriptions and Google Sheets were analyzed using descriptive qualitative analysis [33,34]. This approach was selected over a thematic qualitative analysis, as the questions focused primarily on program content and design and often requested discrete answers (eg, ways of incorporating home safety content and time spent on the program). Essentially, the questions elicited primarily surface-level responses, and the resulting data are better aligned to descriptive analysis rather than thematic analysis, in which underlying themes are identified [34]. The research team (ie, PI, co-investigators, and research assistants) developed a codebook based on the interview protocol, with codes reflecting each topic area. For instance, there was a code for home safety content in EBPP and subcodes for content provided and not provided. Similarly, there was a code for response to IVR use in EBPP and subcodes for positive, neutral, or negative sentiment. The interview transcripts were then coded by the PI using ATLAS.ti (ATLAS.ti Scientific Software Development GmbH). Through the descriptive analytic approach, similar ideas or responses were identified. Responses from the Roses, Thorns, and Buds activity were organized into common responses using Microsoft Excel. These findings were then shared with the research team and agreed upon before finalizing the results.

Parent Focus Groups

We sought to recruit 10 parents for focus groups to inform the program, with a goal of 5 parents per focus group. The target sample size was based on considerations for ideal focus group size, funding constraints, and study timeline. While we ideally would have included 12 parents across 2 focus groups [35], as with provider interviews, we sought to maximize the number of participants per focus group within our available resources, getting as close as possible to the sample size recommendations. Initially, the inclusion criteria for parents were as follows: at least one child aged 0-5 years, ability to read and speak English, access to the technology necessary to participate in a meeting using web-based conferencing software, and current or previous participation in an EBPP. We attempted to recruit parents through the EBPP providers who participated in qualitative interviews. However, after 2 months of attempts, we were unable to recruit any parents through EBPP providers and their agencies. We revised our inclusion criteria such that the criteria related to participation in an EBPP were eliminated. Using the new inclusion criteria, we recruited parents through an advertisement on the authors' university's Children and Family Programs website and weekly email communication.

Study procedures for parent focus groups closely mirrored those of provider interviews. Interested parents contacted the PI to confirm eligibility and sign up for a virtual focus group. Each focus group lasted approximately 60 minutes. Participants received a US $35 gift card as compensation. The focus group protocol was developed by the research team and was structured similarly to that of the EBPP providers' interviews, with questions adapted for the parent experience (eg, asking about experiences learning about home safety instead of delivering home safety information). The goal of the initial questions regarding sources of information on home safety and interests was to better understand the context in which parents approached the topic of home safety; our primary interest was around the questions asking for feedback on the use of IVR and about ParentSHIELD-VR. Each focus group had 3 - 4 participants. Analysis of qualitative data was conducted in the same manner as the provider interview data described above.

Build: IVR Program Development

Storyboards were developed to provide the initial structure of the virtual environment and the room layout of a virtual apartment. Hazard identification and supervision tasks were also outlined and added to specific scenarios. For example, in a kitchen room, hazards may include scattered knives on a tabletop, a misplaced pot with boiling water on a stove with the handle sticking out, and rotten fruits. Based on detailed scenarios with hazard identification and supervision tasks and room layout descriptions, the development team created a fully immersive virtual environment (VE) using the game engine "Unity." The VE consisted of a living room, kitchen, 2 bedrooms (parent and child), and a bathroom. Interactivity with virtual objects in the VE and supporting virtual hand-based 3D user interfaces (3DUI) were also added to the experience to simulate the real-world interactive experiences. Many of the interactions used Earnest Robot's Auto Hand–VR interaction package, which enhanced the experience with automatic hand posing. The IVR experience

XSL•FO
RenderX

was intended for use with the Meta Quest 3 mixed reality (MR) headset and controllers, a midtier VR system available on the market with a large user population. The full experience included a tutorial session, which taught participants how to travel in the virtual home and interact with virtual objects, followed by the training session. Users were tasked with identifying and resolving hazards in the VE. Within the training session, players received feedback via 3DUI upon attempting to address each hazard. See Figure 2 for screenshots of the VE. In the top panel of Figure 2 is an example of a firearm hazard in the primary bedroom. The middle panel depicts the kitchen in ParentSHIELD-VR. Participants can see the number of hazards that need to be resolved. Two hazards can be seen in Figure 2: a pot of boiling water and a knife (on the counter next to the stove) within reach. The bottom panel depicts an example of a supervision scenario in ParentSHIELD-VR. When the parent places the baby in the bathtub, they are presented with a situation in which the older child calls for them in another room. The parent is asked to select a response to this scenario.

XSL•FO
RenderX

Figure 2. Screenshots from parent safe home immersive education and learning development–virtual reality (ParentSHIELD-VR).

Test: Phase 2

Study Design and Procedures

Following prototype development, we sought to conduct prototype testing with 10 parents of children aged 0 - 5 years, based on recommendations of 5 - 10 individuals for usability testing [36,37]. Parents were recruited through flyers at local community organizations (eg, local libraries and social service agencies) and the authors' university weekly email communications. Interested parents contacted the PI to confirm eligibility and schedule a research assessment at the university. At the research assessment, participants first completed a survey (pretest), then went through ParentSHIELD-VR, and finally completed a second survey (posttest). Measures in the pretest and posttest are described in more detail below. While we use the terms "pretest" and "posttest," the study aims primarily focused on feasibility and usability data, which were collected at posttest. Secondarily, we aimed to collect data on the research

XSL•FO
RenderX

process and to pilot measures related to home safety and child injury to be used in a future large-scale trial. When participants tested ParentSHIELD-VR, members of the research team were present to orient them to the headset, answer questions, and remain present for the session. Each research assessment took approximately 90 minutes, and participants were compensated with a US $99 gift card.

Measures

The pretest was administered using Qualtrics (Qualtrics International Inc) and included sociodemographic information, injury history, and a safety hazards knowledge assessment. Data from the latter 2 categories were collected as part of piloting measures in preparation for future studies examining injury outcomes. Sociodemographic items captured data on parents' age, race, ethnicity, household income, and child's age. Two items asked about child injury history in the past 3 months. First, parents were asked about the frequency of injuries that were treated at home: "In the past 3 months, how many accidental or unintentional injuries did your child have that you treated at home (eg, with an ice pack, bandages, etc)? This could be from a fall, scrape, burn, or any other injury that occurred and that you cared for at your home but did not require a visit to the doctor, hospital, or urgent care." Then they were asked about the frequency of injuries that required treatment by a medical provider: "In the past 3 months, how many accidental or unintentional injuries did your child have that occurred at your home and required you to take them to seek care from a medical provider (eg, at the hospital, urgent care, or doctor's office)?" Finally, participants' knowledge of home safety hazards was assessed through a task in a physically simulated home environment in the authors' university simulation center. A simulation space typically used for nursing home health simulations was transformed into a home with a young child and their family. Nine safety hazards were placed in the room by the research team. Participants were given 10 minutes to walk through the physical space and list the hazards in the Qualtrics survey.

The posttest included items on the research process, program usability, feedback on the program, and a safety hazards knowledge assessment. Specifically, items in the research process related to recruitment source, motivation to participate, and satisfaction with compensation. Program usability was assessed with the User Experience Questionnaire (UEQ) [38], a 26-item measure asking participants to rate the program using a 7-point Likert scale with bipolar anchors representing various elements of usability and experience. For instance, one item asks respondents to rate the program in terms of how annoying (1) or enjoyable (7) it is. Several items (3, 4, 5, 12, 23, 24, and 25) were reverse-coded such that 7 indicated the favorable side of the scale. However, note that some UEQ items do not necessarily have one favorable side (eg, fast to slow), and the open-ended items provided participants the opportunity to expand on the aspects of the program that they favored. Participants were given the Roses, Thorns, and Buds activity that was used in Phase 1, but it was completed via open-ended items in the Qualtrics survey. Finally, participants returned to the physical home simulation space and were given 10 minutes to assess the space for hazards.

Analytic Plan

Quantitative data (ie, sociodemographic information, the UEQ, and research process items) were summarized using descriptive statistics. Given the small sample size, UEQ items are presented as frequencies by category and range. As in Phase 1, qualitative data were analyzed using descriptive analysis. Data from the safety hazards knowledge assessment were examined in terms of the feasibility of using the physical simulation space to assess parents' home safety knowledge rather than to assess knowledge itself. That is, we sought to determine whether assessing parents' knowledge in this way was practical and to identify any barriers to collecting data in this way.

Results

Phase 1

EBPP Providers

Five EBPP providers (4 women and 1 man) were recruited for qualitative interviews. They represented 4 different EBPPs. Four of the 5 providers (80%) delivered programs that focused on parent-child interaction but incorporated home safety information; one provider delivered a program that had a dedicated home safety module along with parent-child interaction and other content. All providers incorporated home safety information in some way. The 4 providers who delivered an EBPP that did not have a dedicated home safety module all said that their approach to incorporating the content involved discussion of written information or videos, with some agencies providing parents with home safety devices. For example, one provider stated, "Yes, we do have some handouts, and then we give them to the parents...." Another provider said, "...we have a video we review. We provide a book that we review...as well as their worksheets and that kind of stuff in the book." The one provider delivering the EBPP with a dedicated home safety module said she typically begins with that module if the family has been referred to the program based on allegations of safety concerns. When asked about home safety topics of interest to families, providers, interestingly, initially provided responses related to a range of safety topics, not necessarily related to in-home safety. For instance, 2 providers discussed families' interest in learning how to avoid violence from strangers, one mentioned the importance of emotional safety, and one cited parents' concerns about children's physical health after a recent environmental crisis that occurred in their community in which toxins were released in the air. When prompted specifically about home safety topics that parents would benefit from, providers noted safe sleep, car seats, and "child proofing" (eg, cabinet locks and outlet covers). Four of the 5 providers in the sample reported limited use of technology for program delivery.

> *I have a computer to enter my [hours spent with families], but I don't use it when I go to do my home visits. I just take papers.* [Provider C]

Some used their mobile phones or the parents' phones to share videos during sessions (eg, "I take my phones and show them videos...."). While 2 providers reported that their EBPP had an app, they reported inconsistent use.

XSL•FO
RenderX

> *I mean, the app is only used with some people, honestly, if they want to see those handouts [digitally] or if they don't want me to physically give them a copy, but we don't use a lot of technology.* [Provider B]

All providers had an overall positive response to the idea of using IVR in EBPP sessions and thought it would be engaging to parents (eg, "I think that'll be great," "...it's another great way to present the program and have parents explore," "...it could be really powerful to do"). Questions and concerns about the use of IVR related to logistics (eg, who brings the headset and would Wi-Fi be required) and cost.

> *The families that we serve do not have a lot of access to things, so a lot of things may not have Wi-Fi. I have families that use only Text Now numbers, so they're not even able to receive phone calls or see videos like that.* [Provider E]

This provider also noted that some parents may be "more receptive to it [IVR] than others just because of age." Regarding ParentSHIELD-VR, providers also had an overall positive reception to the concept and name. One provider noted that the name may cause some parents to think of a popular movie franchise, but they did not think that was a negative thing. Providers suggested more realism in terms of the graphics (ie, higher-quality graphics) and the look of the VE. Of note, the rough prototype used to develop screenshots shared in Phase 1 featured a home setting with a bright, clean look, new appliances, and few imperfections. Providers suggested that there should be typical imperfections, such as piles of laundry, to make the house appear like a realistic family home and therefore more relatable to the average family they serve, with one provider especially emphasizing this issue.

> *My only worry would be like making it more real-ish for our parents because none of our parents has a clean—you know...they have more than just a knife on the counter.* [Provider B]

While the suggested time spent on the program ranged from 15 minutes to an hour, most providers said they would spend an hour. Two providers suggested incorporating the program into community events that their programs participate in, such as parent seminars that are held on a regular basis. Some suggested breaking up the experience across multiple sessions. Providers had questions about cost, and while the study participants did not make budgetary decisions in their respective organizations, 3 providers wondered if small grants or existing funds could be used to purchase IVR equipment.

> *...we're pretty much federally funded. So, I guess it would have to go back to whether they deemed it something that we could use that'd be beneficial.* [Provider A]

Another said, "I think in the past we have had, like, a technology fund for a certain amount."

Parents

In total, 7 parents (6 women and 1 man) were recruited for Phase 1 across 2 focus groups. Parents reported car seat installation, "baby proofing" their home, and safe sleeping as main safety topics of interest, with car seats mentioned most frequently. They reported a range of sources consulted when seeking home safety information, including professionals, their own social network, and internet sources. Professionals from whom parents received home safety information included pediatricians, health care professionals at the hospital postdelivery, and certified car seat installation technicians at local fire departments.

> *I think we received, like, a huge amount of pamphlets when he was born from the hospital, and I think we have gotten things from our pediatrician.* [Parent C]

They also sought information from friends and from other parents in social media parent groups. Parents reported searching for home safety topics using online search engines, YouTube (Google), apps, and ChatGPT (OpenAI). Online search engines (ie, Google) and YouTube were the most common sources used when seeking information about home safety on their own (ie, without a professional or another individual in their social network), with 3 participants reporting use of each of these approaches. One parent described the usefulness of online search engines, saying, "So usually when I'm needing information, it's, like, quick and in the moment, and I'm just Googling." Another parent said, "I Google a lot – like, a lot." Some parents also reported that home safety topics appeared in their social media feeds, and it could be confusing to identify reputable sources and sort through conflicting information.

> *I feel like what comes to my mind initially is just Instagram. And sometimes it's like a blessing and a curse. There's a lot of information out there, so sometimes it makes me a little paranoid.* [Parent D]

> *I feel like I have to do a lot of research myself just to figure out how trust those online YouTube video and things on Instagram are. Very confusing and very time consuming too.* [Parent F]

> *Yeah, I think I would just echo I feel like I see a lot of conflicting information also on social media where there's accounts that are like about safe sleep habits and like preventing SIDS, but then there's accounts of 'you can totally co-sleep safely; it's your family's choice,' so it's just very, like, differing opinions and not necessarily people who are coming from, like, a research mindset. It's usually their own personal experience.* [Parent G]

Parents in the focus groups had an overall positive response to the use of IVR to learn about home safety and to ParentSHIELD-VR, describing it as "fantastic" and "something I wish I had when I was a first-time mom." One parent pointed out the element of skill practice that IVR offers, saying, "I like that because I do learn better personally by doing." As none of the parents had participated in an EBPP, they had suggestions for places where they would like to encounter the program, including prenatal visits, pediatrician visits, and use of the program on their own at home. They noted that first-time parents may be more receptive to the information and have more time to spend on it.

> *If you're at the pediatrician's office you have your kid there with you...But if you're at the OB/GYN*

XSL•FO
RenderX

> *before you have a kid, that's a different story.* [Parent E]

As with providers, parents thought that the program would be improved with more realism in terms of the graphics and the look of the VE. Regarding graphics, one parent said "...it looks like a Minecraft game." That parent also commented on the look and feel of the VE saying, "It was also super clean...That is not realistic." One parent suggested adding a "kid's-eye view." This parent said that she had been given advice to:

> *get on the kid's level to see the hazards. So, is there a way in your program to get on the kid's level and see not just at the adult standing level but...on the ground with the kids, so you're at kid eye level...?*
>
> *[Parent A]*

One parent suggested adding a feature to assess their own home for hazards through augmented reality.

> *It would be amazing if you could maybe, like, do integrated reality as I'm looking around my actual kitchen and then you put, like, a virtual knife on the counter, similar to what you did, but it's, like, my home, so then it means more to me.* [Parent B]

In terms of time spent on the program, parent responses ranged from 5 to 60 minutes, with most saying they would spend 20 - 30 minutes on it. One parent noted that she would have been able to spend more time on such a program when her children were younger.

> *I would say 20 to 30 minutes would probably be my max, but that's just 'cause I have two kids so I don't have a lot of extra time, but when they were little [sic], I could probably do, like, 30 to 45.* [Parent B]

One parent suggested participating in the program in segments rather than in one encounter.

Phase 2

Following Phase 1, refinements were made to the program based on participant feedback, including the development of a tutorial, the addition of a child's bedroom, and addressing comments about realism through the use of a more modest, relatable home environment (eg, dust and dirt in high traffic areas, miscellaneous objects on side tables, and modest appliances and fixtures). Five parents participated in Phase 2 prototype testing. These parents were recruited through flyers distributed via a social service organization (n=2, 40%), university email communications (n=2, 40%), and the local public school system (n=1, 20%). They identified as non-Hispanic White (n=2, 40%), non-Hispanic Black (n=1, 20%), Hispanic White (n=1, 20%), and non-Hispanic multiracial (n=1, 20%), with a mean age of 30 (SD 2.12) years. Most reported an annual household income of <US $50,000 (n=3, 60%). While we did not formally collect data on prior IVR use, the research team noted through informal conversations with participants that they reported little exposure to IVR, with some having never used it before and one having used it for job-related training. In terms of injury history, all participants reported at least one injury treated at home in the past 3 months, and one reported a single injury requiring treatment by a medical professional.

The results of the UEQ indicated that participants found the program to be highly creative (median 7, IQR 4.5-7), innovative (median 7, IQR 6.5-7), and organized (median 6, IQR 6-7). There was variability in ease of learning (median 5, IQR 3-6.5) and predictability (median 5, IQR 3-5.5). See Table 1 for UEQ results. Participants provided free text responses to the Roses, Thorns, and Buds activity. Elements of the program that participants liked included learning about home safety, the use of IVR to learn about home safety, and learning how to respond to hazards that may not be in their own home (eg, considering what to do with button batteries when you have not encountered them before). Elements that participants did not like included some program elements that did not function during testing (eg, doors that were difficult to open), experiencing motion sickness, time to become accustomed to the technology, and a lack of realism (eg, "some things don't look too real which makes them hard to identify"). Regarding the lack of realism, in observation notes taken during assessments, research team members identified items in the VE that parents asked about, including cleaning products, bath soap bottles, and a button battery pack, that were difficult to identify. Finally, elements that participants wanted to add to the program were hazards outside the home (eg, pool) and an in-person component.

26: Conservative to innovative	0	0	0	0	0	1	4

[a]UEQ: user experience questionnaire.

[b]Items were reverse coded.

As with Phase 1 parents, parents in Phase 2 were not recruited through EBPPs and had suggestions for alternative dissemination routes, including high school early childhood classes. Parents also provided general feedback on ParentSHIELD-VR and on research participation in an open-ended question. One participant said that she had learned about a new thing.

blinds and putting the strings up. My current blinds don't have them but I can definitely see that causing issues for a small child. [Parent I]

I've learned a lot about safety hazards through traditional methods...but this concept made me think about ways to show those hazards to new parents or caregivers.... [Parent K]

XSL•FO
RenderX

Finally, regarding research participation, a parent noted, "I learned that there is [sic]people looking after child safety, and ways to help parents achieve it, which is great." Three parents specifically noted that the program was "fun," "enjoyable," and/or "cool" in their responses.

Discussion

Principal Findings

This proof-of-concept study found that an IVR home safety program was positively received by parents and EBPP providers, and they identified key areas for further development. While this is a small proof-of-concept study and more research is needed, this IVR approach shows promise as a child injury prevention strategy. Parents appreciated a unique opportunity for interactive and immersive learning on home safety, and EBPP providers saw the possibilities of increased engagement through IVR. Parents had a range of prior experience with and ease of learning in using IVR. Future work on ParentSHIELD-VR will incorporate approaches that bypass challenges in acclimating to the VE and reducing cognitive load. Prior research has found that, despite the many benefits of IVR, it can increase cognitive load, which has implications for learning outcomes [39,40]. This can be addressed with careful attention to design, including just enough details to maintain representational fidelity without overstimulating the user or requiring a great deal of cognitive processing [24]. For instance, in the virtual home environment in ParentSHIELD-VR, interior doors could remain open, eliminating the need for the user to open them. This could be done using additional interaction techniques based on the design of virtual hands. Future iterations of ParentSHIELD-VR will incorporate this approach.

In addition to cognitive load, other elements of parents' interaction with IVR may impact their engagement with or outcomes associated with the program. First, prior experience using IVR could have an effect. Parents who have had the opportunity to acclimate to the VE and are more confident using the IVR equipment (ie, headset and controllers) may feel more comfortable engaging with the program. This could impact their experience of the program and their openness to learning, as has been found in prior research [41,42]. While we did not collect data on prior experience with IVR, this is an area for future research. Furthermore, cybersickness (ie, experiencing motion sickness, such as nausea and dizziness, during IVR use) may affect parents' experiences with the program. One participant in our study reported motion sickness as a "thorn," or an area of the program in need of revision. The estimated extent to which cybersickness affects IVR users varies, but some studies suggest that over half of users experience cybersickness when using head-mounted display-based IVR, and a greater proportion of women report it compared with men [43]. Cybersickness can be influenced by factors including postural instability, approach to moving in the VE (eg, use of joystick locomotion as opposed to real walking in the physical space), prior experience with IVR, and individual susceptibility to motion sickness [44-46]. For instance, use of teleportation and sitting (as opposed to standing) are approaches to moving in the virtual space that are associated with reduced risk of cybersickness [44]. Additionally, novice users and those who are susceptible to motion sickness in the physical realm are at increased risk for cybersickness symptoms [45,46]. Guidance on various options for moving through the VE (ie, real walking, joystick locomotion, and teleportation) was included in the ParentSHIELD-VR tutorial in an effort to reduce the risk of cybersickness. However, the implications for cybersickness may not have been made explicit. The primary cause of cybersickness in our prototype may be the constant virtual movement required to complete the tasks. We can mitigate this risk through 3 design changes. First, we can encourage users to choose teleportation instead of continuous locomotion. Teleportation is already available as an alternative movement option in the prototype, but the tutorial should explain its benefits more clearly and show users how to switch to it if they begin to feel sick. Second, we can apply a tunnel vision effect during continuous locomotion. Temporarily reducing the user's field of view while they are moving can help minimize cybersickness. This technique has been available in the Unity VR template project and many commercial VR experiences involving virtual movement. Third, we can map the virtual environment to the available physical space. This would allow users to navigate the virtual environment by walking naturally in the real world, reducing their reliance on artificial locomotion.

ParentSHIELD-VR was designed to be implemented within the context of EBPP. Results of this proof-of-concept study shed light on potential issues related to implementation in this setting, which should be explored further. EBPP providers had questions about the costs of an IVR program. The providers in our study were not involved in budgetary and administrative decisions. However, they wondered who would be paying for the VR headset and noted that their organizations sometimes apply for small grants to purchase new technology. They also suggested implementing the program with parents who already own a VR headset. This could have the added benefit of engaging parents who are already familiar with and motivated to use IVR. Of note, some providers brought up concerns regarding lack of Wi-Fi in some families' homes. ParentSHIELD-VR would come loaded on the VR headset, preventing the need for an internet connection. Ultimately, while we propose that this program could benefit all EBPP families, it may be the case that when EBPP agencies have limited technology available, ParentSHIELD-VR should be targeted to families who would most benefit. For instance, families who have been reported to child welfare for allegations of neglect related to safety practices have a clear need for home safety education. One of our provider participants noted that she begins with home safety education when working with such families. Also, families who are already engaging in IVR and therefore have already overcome the common barriers, such as cybersickness or difficulty learning how to operate the equipment, may be most receptive to the program and derive the most benefit from it. However, more work is needed to determine approaches for identifying families who would benefit most and the contexts in which IVR is most effective [47]. Research on virtual reality in mental health and behavioral health settings has found cost to be an implementation barrier, despite clinician or provider acceptance of the technology [48]. In one study, 2 substance use disorder treatment clinics shared a VR headset to save costs, but this

XSL•FO
RenderX

resulted in inefficiencies in scheduling patients [48]. In mental health treatment, concerns around security and patient privacy have arisen as barriers to implementing telehealth or VR therapy [49]. While this has not been studied explicitly among EBPP providers, they may share these concerns, and future work should explore this potential barrier. There is also an indication that adoption of IVR in mental health treatment settings follows organizational norms around adopting innovative practices in general (ie, technological or otherwise), and some organizations may be slower to implement new practices than others [49,50]. The potential resource constraints associated with implementing IVR programs in EBPP are an area in need of research.

Limitations

The findings in this proof-of-concept study should be interpreted in the context of several limitations. Phase 1 and Phase 2 participants were primarily from the Southeastern United States (94%), and there may be regional differences in preferences for safety and parenting information that would be identified with a sample from multiple geographic regions. Additionally, while Phase 2 parent participants represented a diverse set of races, ethnicities, and socioeconomic backgrounds, all identified as women. Gender differences may exist with regard to the receptivity of home safety education and interactions with technology. Relatedly, no sociodemographic information was formally collected on Phase 1 participants. Thus, while we have information on participant gender based on research team member interview notes, we cannot report detailed sociodemographic information that would assist in assessing sample representativeness for Phase 1. The study has limitations regarding sample size. In Phase 1, our sample sizes were slightly below recommended sizes for qualitative research due to funding constraints and challenges with recruitment, which may have resulted in some points not being identified, although studies have found that few new concepts are identified after the fifth or sixth interview [31,51]. The Phase 2 sample consisted of only 5 participants. While this is in line with conventional recommendations for usability testing using heuristic evaluation [36,37], we acknowledge the discussion regarding the need for larger sample sizes in usability testing [52,53]. Further testing (ie, beyond proof-of-concept) is needed to obtain expanded perspectives on the usability and acceptability of ParentSHIELD-VR. Finally, parents in the study were not recruited from EBPPs, as intended, which could limit generalizability to the population of EBPP participants. This was especially true with regard to Phase 1 parents, all of whom were ultimately recruited from the university environment. Data from evidence-based home visiting programs (a subset of EBPP) indicate that a substantial proportion of parents participating in these programs (21%) do not have a high school diploma, and 84% have children who are on public insurance [11]. Parents referred to EBPP are often (but not always) experiencing family stressors such as financial stress or violence in the home. These characteristics (ie, low socioeconomic status and family-level stressors) may bring unique challenges or perspectives that were not captured among our parent participants, who reported higher levels of income and education. While Phase 2 parents were not from EBPPs, 60% reported an annual family income of <US $50,000, and those parents may be similar to the average EBPP participant in that regard. Additionally, responses from Phase 1 providers often incorporated the ways they anticipated that parents might respond to the program or potential challenges, but we recognize that this is not a replacement for learning directly from parents in EBPP. Future research should include the voices of parents in EBPP, addressing recruitment challenges through strong collaborations with EBPP agencies.

Conclusion

In this proof-of-concept study, ParentSHIELD-VR emerged as a potentially feasible way to engage parents of young children in home safety education. This study was proof-of-concept, and refinements and additional testing are needed to address user recommendations for the program and to assess its efficacy in addressing outcomes related to parent behavior and child injury. Our team has begun program refinements, including the use of improved graphics and clear labels to improve the realism of products in the VE. While ParentSHIELD-VR is in the early stages of development and testing, the approach has the potential to be translated to additional populations, such as parents of older children and teenagers. As children age, new hazards and concerns emerge, and these could be incorporated into a future iteration of the program. As one provider noted in Phase 1, many families have a “wide age range” between children, and they may be experiencing multiple developmental phases simultaneously. Future development and research could explore the potential benefits and opportunities of more recent technological advancements, such as the integration of AI into the IVR system through, for example, tailored, responsive feedback throughout the program to create a more adaptive and personalized training experience. IVR opens up a range of unique opportunities to engage parents in home safety education to prevent child injury.

Acknowledgments

The authors wish to thank the research assistants, Javier Haro and Umesh Perni, and the study participants. The authors wish to thank the KSU Libraries and the Office of Research for their support in the publication of this work.

Generative AI was not used at any state of the preparation of this manuscript.

Funding

This study was funded through the Interdisciplinary Seed Grant opportunity from the Office of Research at Kennesaw State University, the authors’ institution for US $9500. The funders had no role in the study design; collection, analysis, and interpretation of data; writing of the paper; or decision to submit this study for publication.

Abstract

Background: Childhood asthma places substantial burdens on caregivers, particularly in communities facing structural barriers to health care access. Patient portals, the patient-facing component of electronic health record systems, are primarily designed for clinical workflows, limiting their usefulness for caregivers managing their child's asthma.

Objective: This qualitative study aimed to elicit primary caregivers' perspectives on managing childhood asthma and their experiences with patient portals to inform the development of a community-centered and family-centered medical platform.

Methods: The authors conducted a qualitative study using in-depth, semistructured interviews between July and October 2024 with 15 Black primary caregivers of children with asthma living in the Greater Philadelphia area. Participants were recruited through purposive sampling in partnership with Philly Thrive, a community-based organization. Interviews were conducted both in person and virtually and lasted 30 to 90 minutes. A semistructured guide with 3 core questions explored experiences with managing childhood asthma, interactions with medical documentation and patient portals, and recommendations for redesigning patient portals. The number of interviews was determined by data richness and fulfillment of study aims. Data were analyzed using reflexive thematic analysis, guided by the Standards for Reporting Qualitative Research.

Results: Two themes were generated. Theme 1, lived experiences of managing childhood asthma in families and communities, revealed that caregiving involves profound emotional work, daily routines, and community knowledge sharing that health systems largely do not recognize or support. Theme 2, caregivers' perceptions and experiences of navigating patient portals for childhood asthma, revealed that caregivers used portals selectively at key care moments rather than routinely. Persistent barriers included confusing medical terminology, outdated medication records, and limited communication channels. Caregivers recommended direct provider messaging, integration of environmental trigger data, streamlined medication refill processes, and age-appropriate portal features to support children's gradual self-management.

Conclusions: Effective childhood asthma management requires information systems that honor caregiver expertise, provide transparent and accurate documentation, and actively work to reduce epistemic injustice. Community-centered platform design should integrate caregiver knowledge, environmental data, and child-appropriate tools to support equitable asthma care.

Introduction

Background

Childhood asthma affects approximately 4.9 million children in the United States and is one of the most common chronic conditions in childhood, as well as a leading cause of missed school days and health care usage [1]. Globally, the condition affects approximately 10% of children and is characterized by symptoms such as wheezing, coughing, and shortness of breath that disrupt daily activities [2]. While asthma cannot be cured, it can be managed through ongoing treatment that requires consistent daily care, both inside and outside clinical settings.

The majority of childhood asthma management occurs outside clinical settings. Primary caregivers take responsibility for monitoring symptoms, administering medication, and coordinating care [3]. Recurrent exacerbations, emergency department visits, and disruptions in school attendance place emotional and practical burdens on families [4]. These challenges are frequently more pronounced in Black and Hispanic communities, which bear a disproportionate burden of asthma morbidity rooted in structural racism, including residential segregation, exposure to poor housing conditions, and disproportionate proximity to environmental pollutants that worsen air quality and increase asthma risk [5,6]. Pediatric asthma is defined as a chronic inflammatory condition of the airways characterized by variable airflow limitation and respiratory symptoms, including wheezing, coughing, and shortness of breath [7]. Current management encompasses a stepwise pharmacological approach, from inhaled corticosteroids to biological therapies, including omalizumab and dupilumab, for children with severe or poorly controlled disease [8,9].

Although effective treatments exist, many children continue to experience poorly managed symptoms in real-world settings, contributing to ongoing disease burden and health care usage [10]. Effective management depends on more than treatment availability. Collaboration between caregivers and providers, including clear communication about treatment plans, is essential for ensuring families can manage symptoms and medications at home [11].

The electronic health record (EHR), an evolving technology with widespread use, supports communication and shared decision-making between families and providers; however, limited caregiver engagement signals persistent barriers to its use [12]. EHR systems are primarily designed for clinical practice rather than patient or caregiver involvement. This design gap limits accessibility and has been described as a form of epistemic injustice: a harm done to someone specifically in their capacity as a knower [13,14]. These gaps suggest that EHR systems, designed primarily for clinical workflows, may be misaligned with the realities of how caregivers implement and navigate asthma management. Interdisciplinary and community collaboration offers a path toward addressing these barriers by reimagining how medical documentation is designed to better integrate community knowledge to meet caregiver needs [15,16].

These design gaps are compounded by health literacy challenges: caregivers who already struggle to understand medical information face additional barriers when EHR interfaces require them to navigate complex clinical terminology without support [17,18]. Variability in how clinical information is documented across systems further limits caregivers' ability to build a coherent picture of their child's health [19]. These inequities extend into the digital health environment, where patient portals designed primarily for clinical workflows may further disadvantage Black caregivers by failing to support the realities of their caregiving context [20,21]. This study, therefore, centers the perspectives of Black primary caregivers as those most affected by these intersecting inequities and least served by current portal designs.

Despite growing recognition of these disparities, qualitative research examining how Black primary caregivers specifically experience and navigate patient portals in the context of managing childhood asthma remains limited [12,20,22,23]. This study addresses that gap by centering caregivers as domain experts whose lived experiences are essential to designing health information systems that work for the communities most burdened by asthma.

Objective

This qualitative study aimed to elicit primary caregivers' perspectives on managing childhood asthma and their experiences with patient portals (the patient and caregiver-facing system of an EHR) in their child's care and to inform the development and implementation of a community-centered and family-centered medical platform.

Methods

Study Design

We conducted a qualitative study using in-depth, semistructured interviews with 15 caregivers of children with asthma, focusing on their experiences with patient-facing portal interfaces rather than clinician-facing EHR systems, as these tools present distinct design challenges for caregiver engagement. The aim was to generate community-informed insights into caregivers' information needs and their interactions with clinical documentation systems.

Participants

All participants were Black female caregivers of a child with asthma living in the Greater Philadelphia area. For this study, a primary caregiver was defined as an adult who identified as the person primarily responsible for the day-to-day health management of a child with an asthma diagnosis. Recruitment was conducted in partnership with Philly Thrive, a community-based organization serving the region. This partnership considered caregivers as domain experts whose lived experience was central to understanding asthma management, health information needs, and the limitations of current patient portal systems. We focused on Black primary caregivers because Black children experience disproportionately high asthma morbidity in the United States, and Black caregivers often manage asthma within conditions shaped by structural racism, environmental inequity, and unequal health system responsiveness [5,6]. Centering this population allowed the study to examine patient portal design and EHR documentation

XSL•FO
RenderX

in asthma management from the perspective of caregivers most affected by these intersecting inequities. Asthma diagnoses were caregiver-reported and ranged from intermittent to persistent; the study did not collect formal spirometry or medical record data on asthma classification.

The sample consisted of 15 caregivers with an average age of 41.7 (SD 7.28, range 27‐55) years, each managing the treatment of at least one child with an asthma diagnosis. The participants included single primary caregivers (n=13) and married primary caregivers (n=2). Primary caregivers had between 1 and 8 children (mean 3.87, SD 2.03). All participants reported English as their primary language and accessed care for their child with asthma through various pediatric health systems in the Greater Philadelphia.

Procedure

In-depth one-on-one interviews were conducted between July 2024 and October 2024. The number of interviews was determined by data richness and by the fulfillment of study aims, which were assessed through ongoing review of transcripts [24]. AOO, a social work student trained in qualitative research methods with experience in health equity, conducted all interviews. All interviews were audio-recorded and video-recorded and transcribed verbatim. Primary caregivers received a US $100 gift card in recognition of their time and contributions to the research. We recognize that participants from marginalized communities contribute not only their time but also their expertise and the emotional labor of sharing lived experiences of health inequity; future community-based research should consider compensation structures that more fully reflect this contribution.

A semistructured interview guide was used to explore participants' experiences with clinicians and with medical documentation regarding their child's asthma. The guide included the following questions: (1) What was your first conversation with your clinician about your child's asthma? (2) Tell us about instances you can remember learning about your child's asthma through medical documentation and what you understood from these documents. (3) What would you do if you had the opportunity to redesign medical documentation concerning your child's asthma? Interviews were conducted in person and via Zoom and lasted 30 to 90 minutes. Quotations presented in the "Results" section were lightly edited for readability (eg, removal of false starts and filler words) while preserving the speaker's meaning and voice.

Ethical Considerations

The study received approval from the University of Pennsylvania Institutional Review Board prior to data collection (protocol number: 23‐1810). Participants provided informed consent before participation, and all transcripts were deidentified to protect confidentiality. To further protect participant privacy, all names reported in this paper are pseudonyms assigned by the research team; no real names are used. Participants were informed of the sensitive nature of the research topic and their right to withdraw at any time.

Data Analysis

Reflexive thematic analysis was conducted in 3 stages to generate key themes and categories [25,26]. This study followed the SRQR (Standards for Reporting Qualitative Research) reporting guideline [27] (Checklist 1). Drawing on Braun and Clarke's framework for quality in reflexive thematic analysis, we prioritized reflexivity, rigor, and thick description as ongoing analytic practices rather than criteria to satisfy [25,26]. Reflexivity was central to the process: AYL is a social worker and health informatics researcher whose prior work on EHR design and marginalized communities shaped the study questions, theoretical framing, and interpretive lens. AOO is a social worker with experience working with marginalized communities facing health disparities, and LAS is a nurse and doctoral student with clinical experience caring for people living with chronic conditions across the lifespan. Both researchers maintained reflexive discussions throughout data collection and analysis to examine how their subjectivities and assumptions actively shaped the interpretive process. Thick description of the study context, participant characteristics, and analytic process is provided throughout to support readers in assessing the relevance of findings to other settings. In stage 1, AYL and AOO engaged in deep familiarization with the data, repeatedly reading all interview transcripts as an active interpretive process rather than a neutral scan of content. Consistent with Braun and Clarke's reflexive approach, this stage foregrounded the researchers' subjectivities as resources rather than sources of bias, acknowledging that engagement with data is always shaped by the researcher's perspective [25,26]. Using Dedoose (SocioCultural Research Consultants, LLC), a qualitative software platform, both researchers independently coded 2 identical transcripts, attending to meaning and interpretive possibilities rather than surface content. Codes were compared and discussed within the research team to surface interpretive differences, refine the coding approach, and develop a working code set. In this phase, we constructed codes such as "Lived experience with managing asthma" and "Perceptions about patient portals."

In stage 2, the remaining transcripts were coded with active reflexive engagement, and codes were continuously interrogated and revised in relation to the dataset as a whole. Rather than mechanically sorting codes into predetermined groups, AYL and LAS worked to identify patterns of shared meaning across the data, constructing candidate themes that represented coherent interpretive accounts of caregivers' experiences. Throughout this nonlinear process, codes and themes were added, collapsed, or reconsidered as interpretations developed. LAS, a doctoral student in nursing, joined the analytic team in stage 2 after AOO completed data collection responsibilities. LAS reviewed the stage 1 codebook in full, discussed the rationale for each code with AYL, and conducted independent verification coding on 2 transcripts before proceeding to stage 2 analysis. Analytic decisions and interpretive choices were documented and discussed as a team throughout. For example, the initial code "Routine usage of patient portal" was examined to understand whether and how caregivers used patient portals. This analysis led to 2 new codes: "Positive experiences with patient portal" and "Negative experiences with patient portal," which were

XSL•FO
RenderX

grouped into the category "Accessing health records for care needs."

In stage 3, the research and community team collaboratively reviewed and defined each theme, ensuring that it told a coherent and grounded story in relation to the dataset as a whole. Theme names were developed as interpretive acts, chosen to be vivid and analytically meaningful rather than simply being descriptive. For example, the candidate themes "The emotional and practical work of asthma care" and "Building understanding to support asthma management" were brought together and defined as the central theme "Lived experiences of managing childhood asthma in families and communities," capturing the relational and community-embedded nature of caregiving that ran across both themes.

Results

Overview

Two themes were generated from the analysis: (1) lived experiences of managing childhood asthma in families and communities, encompassing the emotional, practical, and social dimensions of asthma caregiving; and (2) caregivers' perceptions and experiences of navigating patient portals for childhood asthma, capturing how caregivers access patient portals and medical records, the barriers they encounter, and their recommendations for improvement.

Theme 1: Lived Experiences of Managing Childhood Asthma in Families and Communities

This theme highlights how managing a child's asthma is an emotional, relational, and practical process embedded within family life and community (Table 1). A distinct type of fear runs through many caregivers' accounts, arising from watching their child struggle to breathe, intensified by the reality that children may not fully understand or communicate the seriousness of their symptoms (Q1-Q2). This emotional burden is inseparable from the practical, everyday work of asthma care. Toni's account—constantly reminding her son to take his medications, laying them out each morning before she leaves for work, and rehearsing inhaler technique with him the night before—makes this interplay of vigilance and routine concrete (Q3).

XSL•FO
RenderX

Table . Theme 1: Lived experiences of managing childhood asthma in families and communities.

Subthemes	Illustrative quotes
Emotional and practical work of asthma care	• Q1: *As a parent, to see your children struggle, oh my god. That's a different type of fear*. [Natasha] • Q2: *The advice that I would like to give is to be mindful, always be alert. I think it's vitally important to be alert, mindful, and watchful, especially when watching a child, because children are so innocent and may not fully understand the seriousness of certain things*. [Laura] • Q3: *I constantly speak, talk to him, and let him know it is very important that he takes his medication. Make sure that his medication is laid out on the sink each morning, as I leave home before he leaves for school. And so, in case my daughter, who takes him to school, forgets, I make sure that each night the medication is laid out and remind him in the morning before I leave: "Make sure you shake your pumps up before you take them." And so basically, I have these talks quite often*. [Toni]
Building understanding to support asthma management	• Q4: *They (health workers) talked to me. They broke it down and explained exactly what asthma is, what can cause flare-ups, how to treat it, and how to manage it*. [Maya] • Q5: *I had asthma classes. Asthma studies. I think that's really good 'cause you learn more and more about your child's health, which can help decrease the number of times you have to go to the hospital*. [Katherine] • Q6: *If you're going into the hospital, I would think maybe flyers would be more effective because your appointment is only for a specified amount of time. However, if you're going into schools, webinars will most certainly be of interest to parents, allowing them to sit, watch, and learn. It might be more interesting than just hearing somebody speak*. [Denise] • Q7: *I want the medical field to take asthma a whole lot more seriously. Because you have parents at home, that's literally just like losing their mind. The child feels like they're losing their life, and the mom or the dad feels like they're losing their mind. I never in life had to make this decision, but I did last week, and I was just like you're going to go home with daddy because I have to go to work, and if you're home with me, I have to be up all night and still get up for work at 6:00 o'clock. And my baby screamed and hollered and cried and looked me in my eyes and said, you need to tell them your child is sick*. [Natasha]
Confidence through shared experience and support	• Q8: *When my 14-year-old had her first asthma attack at the age of three, because I have asthma, I knew the signs and symptoms*. [Keesha] • Q9: *It was easier because she knew (grandmother) what to do because both my sister and my dad had it (asthma), so it definitely killed my nervousness or anxiety*. [Gabby] • Q10: *So everyone in my support system knows what to do, what to look for. We are basically familiar with this asthma thing. It's unfortunate, but we're just on point with it*. [Toni]

Building understanding through clear and accessible information was central to effective asthma management. Caregivers valued plain-language explanations from health workers and participation in asthma education programs, which some believed reduced hospital visits (Q4-Q5). When asked how information could be better delivered, caregivers offered format-specific suggestions based on the demands of different settings: flyers might work better in time-pressured hospital appointments, while webinars could allow parents in school settings to learn at their own pace (Q6). These accounts reflect caregivers' active pursuit of knowledge and the considerable effort it requires. Natasha's account makes the weight of that effort concrete: she describes the medical field's failure to take asthma seriously as something felt in the body, in sleepless nights, and ultimately in an impossible choice between her child's safety and her livelihood (Q7). Work and caregiving demands do not simply compete; they reveal the structural and economic pressures that make asthma management far harder than any educational program alone can address.

For many participants, personal and family experience with asthma served as a source of confidence and readiness. Those who had asthma themselves or had family members with the condition felt better equipped to recognize early warning signs and respond quickly (Q8-Q9). This shared knowledge extended to broader support networks, with participants ensuring that

XSL•FO
RenderX

everyone involved in their child's care knew what to look for and what to do during an episode (Q10). Such collective familiarity, though born of difficult circumstances, provided reassurance that children would be safe even when caregivers were absent. In this sense, the practical knowledge caregivers have accumulated over years of managing asthma within their families constitutes a form of clinical familiarity that is neither captured in nor recognized by existing documentation systems.

Theme 2: Caregivers' Perceptions and Experiences of Navigating Patient Portals for Childhood Asthma

This theme captures how primary caregivers access, interpret, and respond to patient portals and medical documentation, as well as the challenges they encounter in doing so (Table 2). Engaging with the patient portal was a selective, need-based practice, shaped by time constraints, trust in existing systems, and the immediacy of care demands. Rather than consulting records routinely, Denise relied on automated processes such as prescription refills, accessing documentation only when changes arose or when clarification was needed (Q11). Gabby used the portal to verify clinical information following appointments, particularly when co-parenting arrangements limited direct communication about what had been discussed with the doctor (Q12). Katherine described using the portal to send a doctor's note directly to her child's school, eliminating the need to print and hand-deliver paper documentation (Q13). Alicia highlighted a specific limitation of current portal systems: records from visits to different hospitals or health systems are not automatically consolidated in one place, and her suggestion that all visits from any provider appear in a single portal reflects the reality that patients who receive care across multiple institutions must navigate fragmented records that do not follow them from provider to provider (Q14).

XSL•FO
RenderX

Table . Theme 2: Caregivers' perceptions and experiences of navigating patient portals for childhood asthma.

Subthemes	Illustrative quotes
Accessing health records for care needs	**Q11:***I'm very busy, I don't have time to go in and look for stuff. But I'll refer when I need to refer to anything. But his (child) prescriptions have been with his doctor and his pharmacy forever, so they're like on automatic refill unless he runs out or the dosage changes. So, there's really no need for me to keep doing all of that because they do it*. [Denise]
	Q12:*I normally just compare his progress or their progress. I look from last year to this year. Make sure it's nothing I missed since I don't take him to the doctor. His dad is not really good at explaining what the doctors say. I work in healthcare, and I can kind of figure some things out. But I just like to go in there to read and make sure the paperwork matches what's in the portal*. [Gabby]
	Q13: (Caregivers) *Send a note through your medical record to give to your teacher*. [Katherine]
	Q14:*I would suggest they put everything onto the portal. In case you lose the papers, you can still see everything (all medical information across medical institutions and settings). All visits from whatever doctor that patient sees should all be in one place*. [Alicia]
Barriers to understanding and accuracy	**Q15:***They have to remove it (old prescriptions) because it is still there. When she gets other medicines, they just add up. And I have to go and tell 'em like, you gotta take that off and that off because she doesn't take that anymore. So I don't want them to think that that's what she takes*. [Alicia]
	Q16:*It's so much. It's not easy. It's a lot. You have to figure out what....If it's an app or a website, I want it to be easy to understand. I don't have patience for figuring it out when my child is sick*. [Natasha]
	Q17:*I honestly, in my opinion, feel like there are things that the medical professional knows and is knowledgeable of that we don't....That they don't share with us, for whatever reason. So, I definitely would appreciate and love to take advantage of an AI's assistance when it comes to helping me review notes, charts, and gain an understanding of what's going on*. [Laura]
	Q18:*I had to do too much to get certain diagnoses when I already knew what the problem was. No parent should have to go through that. You had to jump through hurdles to get results*. [Jill]
Caregivers' recommendations for improving patient portals	**Q19:***I would also like to reach out to the physicians on the app, instead of waiting for a phone call, or having to constantly call and call*. [Christina]
	Q20:*Every day, I'm looking at the pollen levels for him. Every day, because it's like, okay, if the pollen levels are high, we cannot go outside*. [Nicole]
	Q21:*So, say if my child was having symptoms that I'm unfamiliar with, I think I should be able to go on the app and search those symptoms, and then I think the app should have a contact where the doctor or nurse, whoever reviews it, is able to get in contact with you. Like we, as the parent, get to leave our information so the professionals can get back to us*. [Toni]
	Q22:*When you are diagnosed with asthma, you should be able to get a refill for your child's asthma pump as soon as possible. You should not have to set up a doctor's appointment. They already have the diagnosis, so it should just be sent to the pharmacy*. [Shonte]
Fostering autonomy in children living with asthma	**Q23:***I told my daughter to download it. You can send messages to your doctor yourself at 13. You've got a problem, go to your doctor. I can always see it. But you can go to your doctor on your own. So, he's turning 18 soon, he's gonna have access to his own chart, and they better not limit me, but I think they will*. [Gabby]
	Q24:*I actually think the health portal should be easy for anybody. I use it for myself too. I recently had blood work done and was able to look at the results with definitions right there. I believe children could use it the same way*. [Simone]
	Q25:*Now that she's getting older, I'm starting to tell her what's what and how it means for her, or how to take care of herself in regard to that. Now, more because I feel like she understands more now*. [Maya]

XSL•FO
RenderX

Many participants described having to exert substantial effort to obtain accurate information, correct errors, and secure recognition of what they already knew about their child's condition. Alicia described having to actively advocate for the removal of outdated medications from her child's record concerned that persistent errors could lead to clinical mistakes (Q15). Many participants expressed frustration that critical information was not always fully shared or explained to them (Q16). Laura felt excluded from aspects of her child's care and expressed interest in AI-assisted tools to help interpret medical notes and bridge the knowledge gap between herself and providers (Q17). Jill described having to fight repeatedly to secure her child's diagnosis, reflecting a broader pattern in which caregivers must exert significant effort simply to be heard (Q18).

Participants offered concrete recommendations for improving the patient portal, grounded in their daily experiences. Direct messaging with physicians was a consistent priority, with Christina describing frustration with having to wait for phone calls rather than sending a message through the app (Q19). Nicole described checking pollen levels daily to inform decisions about her child's outdoor activity (Q20). While environmental data are available through weather applications, integrating them directly into the patient portal may allow caregivers to connect real-time trigger information to their child's documented symptoms and medication use. Toni proposed a symptom-search feature that would allow parents to look up unfamiliar symptoms and receive clinical follow-up (Q21). Shonte highlighted unnecessary friction in medication refills, arguing that a confirmed diagnosis should be sufficient to authorize a prescription without requiring a new appointment (Q22).

Several participants described gradually involving their children in managing their own asthma care. Gabby encouraged her daughter to use the patient portal independently starting at age 13, sending messages to her own doctors while still keeping a parental view of the account (Q23). Simone noted that the health portal should be accessible and easy for anyone to use, including children, pointing to its potential for youth engagement with health information (Q24). As Maya explained, she began sharing more details about asthma management as her daughter grew older and could better understand what it meant for her health (Q25). Taken together, these accounts suggest that caregivers view the patient portal not only as a tool for adult management but also as a scaffold for children's gradual development of health self-agency—a function that current portal design does not explicitly support.

Discussion

Principal Findings

This qualitative study offers several insights from Black primary caregivers about their lived experiences managing childhood asthma and their interactions with EHR-generated information, patient portals, and medical documentation. These perspectives contribute to the development of a community-centered and family-centered medical platform that addresses caregivers' information needs while reducing epistemic injustice in health care systems [13]. Two primary themes illustrate how caregivers navigate childhood asthma care and engage with health information systems. The first illuminates the lived experience of childhood asthma caregiving, encompassing the emotional weight, daily routines, and community knowledge that sustain management outside clinical settings. The second turns to caregivers' engagement with patient portals, revealing patterns of selective use, persistent barriers to accurate and accessible information, and a set of grounded recommendations for redesign.

Caregivers described the emotional and practical day-to-day work of asthma care as an ongoing process that extends beyond the provision of medication. They articulated a distinct type of fear associated with watching their child struggle to breathe, intensified by the reality that children may not fully understand or communicate their symptoms. The ongoing work involves establishing daily routines, preparing medications, and providing reminders to ensure treatment adherence. These findings are consistent with prior research documenting caregiver burden associated with childhood asthma [3,4] and underscore opportunities for technology to reduce the informational and logistical burden of daily asthma management, particularly for caregivers navigating care largely outside clinical settings.

Caregivers consistently described clear, accessible information as central to their ability to manage their child's asthma confidently. They valued plain-language explanations from health workers and participation in asthma education programs, which some believed had reduced hospital visits. These findings support previous research on health literacy and asthma management [17,18] and add specificity regarding preferred educational formats. Caregivers suggested that flyers may be more effective in busy hospital settings, while webinars may be useful in school contexts, as they allow parents to learn at their own pace. These preferences suggest opportunities to integrate multimodal educational content that adapts to different caregiving contexts.

Managing childhood asthma is inseparable from the conditions of daily life. When work obligations and caregiving responsibilities collide, caregivers face choices that no health information system can resolve, yet that directly shape their ability to manage their child's condition. These tensions are consistent with research documenting the compounding demands faced by caregivers, particularly Black caregivers, who disproportionately face employment precarity and insufficient institutional support when managing chronic illness in their children [5,6]. Platform design should therefore support caregivers not only in understanding medical information but also in navigating the broader competing demands of daily life.

Families' lived experience with asthma created expertise in managing the condition. Caregivers with a personal or family history of asthma felt better equipped to recognize early warning signs and respond quickly. These findings align with prior research on caregiver knowledge in pediatric chronic illness management and extend this work by demonstrating how family knowledge and lived experience serve as strengths in childhood asthma management [3,4]. Lived experience represents a form of domain expertise that is often unrecognized in health

XSL•FO
RenderX

information systems, suggesting opportunities to enhance the sharing of experiential knowledge alongside professional medical knowledge.

Caregivers did not describe patient portals as resources for routine, everyday asthma management. Rather, they used them selectively at times when documentation was needed for coordination, verification, or urgent decision-making, such as reviewing what was discussed at appointments, sharing information with schools, confirming medications, or referencing medication details during emergency care visits. Seen this way, selective use reflects not low engagement but the limited usefulness of current systems for the day-to-day work of asthma care [12,20,21]. This pattern is consistent with evidence from a study of diverse caregivers of children with asthma showing that limited digital health app engagement reflects barriers related to design and accessibility rather than caregiver willingness or motivation [22].

Caregivers described encountering records that were outdated, difficult to understand, and sometimes incomplete. Medication lists retained prescriptions their children no longer took, requiring caregivers to intervene directly to prevent errors. Clinical terminology left caregivers searching elsewhere for explanations, and many felt providers did not share the full picture of their child's condition. These findings reflect broader patterns of medical mistrust among Black patients, which research has linked to histories of discrimination and perceived asymmetries in clinical encounters [28]. This dynamic extends into digital communication channels: research demonstrates that portal messages from Black patients receive physician responses at lower rates than those from White patients, a structural disparity that may compound the trust deficit caregivers described [29]. Caregiver perspectives on AI-assisted interpretation of medical notes were mixed, reflecting both interest in tools that could bridge the clinical knowledge gap and concern that AI may be too general to address a specific child's needs, a tension that warrants attention in future platform design. These findings extend prior work on documentation inconsistencies [15] by demonstrating that documentation problems directly affect caregiver trust and engagement. These documentation barriers may constrain caregivers' ability to engage with and act on health information, a process prior research has linked to poorer asthma outcomes [10,17]. Rather than indicating individual disengagement, participants' accounts point to EHR design as an underexamined factor shaping the gap between treatment availability and everyday asthma management. Addressing these barriers requires both technical solutions and a shift in how caregiver knowledge is recognized within health records [15].

Caregivers' perspectives reflect knowledge emerging at the intersection of health and lived experiences, and their suggestions underscore that community-informed design is essential for addressing asthma disparities rooted in structural racism and environmental injustice, particularly for Black caregivers in urban settings like Philadelphia [6]. While the findings are specific to this population and context, they offer insights relevant to other marginalized caregiver communities managing pediatric chronic illness through health information systems designed primarily for clinical use. Improvements to EHR systems based on day-to-day experiences, including direct messaging with physicians, integration of environmental data such as pollen levels, the ability to search for symptoms with clinical follow-up, and improved medication refill processes, signify opportunities to enhance EHR design. The integration of their recommendations aligns with emerging frameworks for shared decision-making in asthma care [11] and broader efforts to develop patient-centered clinical decision support tools [16,30] to advance better outcomes.

Finally, caregivers described efforts to involve their children in managing their asthma care, including engaging them with their health records. However, existing systems often do not support age-appropriate engagement or youth-centered design [31]. These findings point to opportunities to develop interfaces and features that facilitate meaningful child participation and acknowledge young people's distinct lived experiences with chronic illness.

Implications for Developing a Community- and Family-Centered Medical Platform

Without structural changes to patient portal design, existing disparities in asthma management are likely to persist despite advances in clinical care. Platform design should integrate community knowledge alongside professional medical expertise rather than treat caregiver experience as supplementary. When caregivers access their patient portal, their documented observations and concerns should be visible alongside clinician notes, creating a shared record that positions caregiver knowledge as a legitimate input rather than a supplement [15].

Key platform features directly requested by participants include easy-to-understand translations of medical terminology, direct messaging with physicians, symptom-search functionality with clinical follow-up, and streamlined medication refill processes. The research team also proposes design directions informed by but extending beyond the data: AI-assisted interpretation of medical notes, integration of environmental data such as pollen levels, and caregiver-facing tools for annotating or correcting records. These represent researcher-generated extrapolations rather than direct caregiver recommendations, and they should be co-designed with community members before implementation [30]. Integrating environmental data, such as air quality and pollen counts, can help families identify and respond to environmental triggers [32]. Child-friendly interfaces could support developmental transitions toward independence by offering age-appropriate education and tools that help young people gradually assume self-management responsibilities.

Platforms should also facilitate peer-to-peer knowledge sharing through moderated community forums where caregivers exchange insights on managing asthma, identifying environmental triggers, and navigating care systems [33]. Customizable views can show only relevant information to different stakeholders while allowing caregivers to control what gets shared across the distributed network of parents, children, family members, and schools involved in asthma care [34].

Although this study centers on childhood asthma, these findings may extend to other pediatric chronic conditions in which caregivers carry substantial responsibility for coordination,

XSL•FO
RenderX

monitoring, and interpretation outside clinical settings. More broadly, they suggest that patient-facing health information systems should treat caregiver knowledge as essential rather than peripheral.

Limitations

This research has several noteworthy limitations. First, we interviewed only primary caregivers from one region in the United States; future research should include caregivers from diverse geographic locations to gain broader perspectives. Additionally, asthma diagnoses were caregiver-reported rather than clinically verified, and the distribution of intermittent versus persistent diagnoses was not systematically recorded, which limits the specificity of clinical context available for interpreting caregiver experiences. Second, all participants were Black female caregivers. Future studies should include fathers, grandparents, other guardians, caregivers from diverse racial and ethnic backgrounds, and children and adolescents with asthma themselves. Third, this qualitative study does not allow generalization to all caregivers of children with asthma. Because the recommended platform features have not yet been developed, caregiver suggestions reflect proposed rather than validated interventions. Future research should use participatory design methods to develop and evaluate these features with community members. Fourth, participants received a US $100 gift card incentive, which may have influenced willingness to participate and introduced self-selection bias; caregivers who chose to participate may differ systematically from those who did not in ways that shaped their portal experiences and perspectives.

Implications for Future Research

Additional research is needed in four areas: (1) expanding participant diversity to include different caregiver types, children and adolescents with asthma, and multiple geographic locations and health care systems; (2) using participatory design to translate caregiver recommendations into platform features and testing whether these reduce caregiver burden, improve health outcomes, and advance health equity; (3) examining how health information systems intersect with environmental and health justice, and whether technology designed with community input reduces epistemic injustice by shifting power dynamics and enhancing caregiver agency; and (4) examining whether the community-centered, caregiver-as-expert model developed here is transferable to other pediatric chronic conditions in which caregivers carry primary responsibility for coordination, monitoring, and interpretation outside clinical settings.

Conclusions

This study elicited Black primary caregivers' perspectives on managing childhood asthma and their experiences with EHR-generated information and patient portals to inform the development of a community- and family-centered medical platform. In this study, participants described the profound emotional and practical work of asthma management, emphasized the importance of accessible health information and education, and articulated how family and community knowledge supports their confidence. When engaging with EHR-generated information and patient portals, the majority of primary caregivers used these systems selectively and strategically, identified barriers related to accuracy and medical terminology that undermined trust, and offered meaningful recommendations for improvement.

Our findings show that effective childhood asthma management requires more than clinical treatment. It requires information systems that honor caregiver expertise while reducing burden, provide transparent and accurate documentation, integrate environmental and social context, and actively work to reduce knowledge inequities. By centering caregivers' voices through a partnership with a community organization, this research contributes to the design of platforms that advance health equity rather than perpetuate existing disparities.

Abstract

Background: Research on children's media use has traditionally focused on risks and negative outcomes. However, screen-based media may also provide opportunities for learning and curiosity-driven exploration. As young children increasingly engage with digital media within family contexts, parental media literacy may represent an important competency associated with children's media experiences and developmental outcomes.

Objective: This study examined the associations between parental media literacy and children's epistemic curiosity during screen-based media use. Specifically, it investigated how 4 dimensions of parental media literacy—technological use, critical understanding, self-expression, and norm compliance—were associated with 2 dimensions of children's epistemic curiosity: interest-type and deprivation-type curiosity.

Methods: Between July 31, 2024, and August 21, 2024, we conducted an online cross-sectional survey of 1020 parents of children aged 7 to 9 years in South Korea, including 340 parents in each age group. Household income, parental media literacy, and children's epistemic curiosity were assessed using validated 5-point Likert scales. Separate structural equation models were estimated to examine the direct associations between parental media literacy and children's epistemic curiosity and the indirect associations between household income and children's epistemic curiosity through parental media literacy.

Results: Technological use was positively associated with both interest-type (β=.32; *P*<.001) and deprivation-type (β=.18; *P*<.001) curiosity. Critical understanding, self-expression, and norm compliance were also positively associated with both interest-type (β=.20 to .26; *P*<.001 in all cases) and deprivation-type (β=.21 to .23; *P*<.001 in all cases) curiosity. Household income showed significant indirect associations with interest-type curiosity through all 4 dimensions of parental media literacy (β=.005 to .009; *P*<.05 in all cases), whereas indirect associations with deprivation-type curiosity were observed only through critical understanding (β=.007; *P*=.003), self-expression (β=.011; *P*<.001), and norm compliance (β=.004; *P*=.03).

Conclusions: The findings suggest that parental media literacy may extend beyond an individual competency and be associated with children's curiosity-driven engagement with digital media. By highlighting parental media literacy as a potentially modifiable factor, this study underscores the importance of supporting parents as active participants in children's digital learning environments.

Introduction

Parental Media Literacy and Children's Epistemic Curiosity in Screen Media Use

In the pervasive and rapidly evolving digital environment, parents play a pivotal role in shaping young children's media use, bearing primary responsibility for guiding their engagement with digital media [1]. Children's early exposure to digital technology is influenced by multiple family-level factors [2], including socioeconomic status (SES) and parental educational level [3], parents' expectations of and attitudes toward children's media use [4], and everyday patterns of family interaction with digital technologies [5]. These factors shape children's media experiences and may affect their developmental and social outcomes. Although parental factors have been widely studied across environmental, social, and emotional domains, the interpersonal and dynamic aspects of parent-child interactions around media use—particularly those related to parental competencies—remain underexplored [1].

Media literacy refers to the ability to access, interpret, evaluate, and create media messages in contemporary digital environments [6]. Previous research suggests that media literacy can reduce

XSL•FO
RenderX

negative media influences while supporting more positive and informed media experiences [7]. By fostering critical thinking, media literacy can encourage more reflective media practices and protective attitudes [8]. However, traditional media literacy studies primarily emphasize risk mitigation and self-referential effects (eg, parents' own media efficacy), often neglecting the critical impact of parental media literacy on children's positive media experiences and cognitive development. Unlike parental mediation, which refers to specific behavioral strategies used to manage children's media use, parental media literacy reflects a broader competency encompassing how parents access, understand, evaluate, and engage with media.

Rather than examining specific parental mediation behaviors, this study conceptualized parental media literacy as a broader parenting competency and investigated how it relates to children's epistemic curiosity during screen-based media use. Epistemic curiosity refers to a desire for new information that motivates knowledge acquisition and exploratory behavior [9]. In digital environments where children encounter vast amounts of information, epistemic curiosity may support learning, problem-solving, and meaningful engagement with media content [10,11].

This study was conducted in South Korea, a highly digitalized society where children are exposed to digital media from an early age and where parents face increasing responsibility for guiding children's media use. This issue may be particularly salient in South Korea, where digital media adoption is widespread and parents are increasingly expected to support children's media experiences. However, many contemporary parents grew up without formal media literacy education and must navigate rapidly evolving digital environments while helping their children engage with media. Examining parental media literacy in this context provides valuable insights into how family-level competencies relate to children's positive media experiences and learning-related outcomes in everyday digital environments.

Media Literacy: Evolution and Outcomes

Media literacy originally referred to the knowledge and skills that enable individuals to understand media critically and use it appropriately [12,13]. Early conceptualizations emphasized the ability to access, analyze, evaluate, and create media messages in various forms [14]. As media environments have become more complex, the scope of media literacy has expanded beyond protection from harmful content to include competencies related to participation, privacy management, information evaluation, self-expression, ethical engagement, and the ability to maximize opportunities while minimizing risks in digital media use [7]. Although the specific dimensions of media literacy continue to evolve alongside technological change, scholars broadly agree that media literacy supports more informed, responsible, and effective media use.

Most research on media literacy has focused on its effects at the individual level. A substantial body of literature has demonstrated that media literacy is associated with greater critical thinking, improved understanding of media messages, stronger awareness of persuasive intent, and healthier media-related attitudes and behaviors [8,15,16]. However, media use rarely occurs in isolation. Individuals engage with media within social environments where interactions with family members, peers, and other social actors shape how media content is interpreted and experienced. Consequently, media literacy may extend beyond an individual competency and function as a form of social influence, affecting not only the person who possesses it but also those with whom they interact.

Although this possibility has received limited empirical attention, there are theoretical reasons to expect that media literacy may have implications beyond the individual. Media experiences are embedded within interpersonal relationships, where people exchange information, discuss media content, model behaviors, and influence one another's interpretations of media messages. Consequently, media literacy may function not only as an individual competency but also as a form of social influence.

This possibility may be particularly relevant in family settings, where parents play a central role in structuring children's media environments and guiding their engagement with digital media. Parent-child relationships are characterized by frequent interaction and asymmetries in knowledge and experience, making them a likely context in which media-related competencies may extend beyond the individual. Young children rely heavily on their parents to interpret media content, navigate digital environments, and make decisions about media use. Examining parental media literacy, therefore, provides an opportunity to explore how media-related competencies may shape children's media experiences and learning-related outcomes.

Parental Media Literacy as a Parenting Competency

Parents play a central role in shaping children's media experiences. Existing research has primarily examined this influence through parental mediation strategies, such as restrictive mediation, explanatory mediation, and coviewing [17,18]. However, parents' influence extends beyond observable mediation behaviors. Parents shape children's media experiences through the media environments they create, the beliefs and attitudes they communicate, the resources and technologies they provide, and the ways in which they themselves engage with media [19].

For contemporary parents, these influences are particularly important in digital environments. Many parents grew up during a period of rapid technological change and did not receive formal media literacy education. Instead, they developed their understandings, habits, and beliefs through direct experiences with emerging media technologies. Paradoxically, these same individuals are now expected to guide their children's media use and help them navigate increasingly complex digital environments. As a result, parents vary substantially in their ability to critically evaluate media, support children's engagement with digital content, and foster constructive media experiences. In this study, these competencies were conceptualized as parental media literacy.

SES may further shape the development of parental media literacy. Parents with greater educational and economic resources often have broader access to digital technologies,

XSL•FO
RenderX

information resources, and learning opportunities, which may facilitate the acquisition of media-related knowledge and skills [20-22]. Higher-SES families may also be more likely to adopt and engage with emerging technologies, providing parents with greater opportunities to develop familiarity with and competence in digital environments. Consequently, SES may influence children's media experiences not only through material resources but also through its association with parents' media literacy. Examining SES alongside parental media literacy, therefore, provides a more comprehensive understanding of the family factors associated with children's media engagement and learning-related outcomes.

Much of the existing literature on children's media use has focused on risks and problematic outcomes, reflecting concerns about excessive screen time, problematic use, and exposure to harmful content. Although these concerns remain important, digital media has become an unavoidable part of children's everyday lives. Rather than viewing media solely as a source of risk, it is equally important to understand the conditions under which children experience positive and developmentally beneficial outcomes. One such outcome may be epistemic curiosity, a desire for knowledge and understanding that motivates learning and exploration. Examining whether parental media literacy is associated with children's epistemic curiosity may therefore provide insights into how family environments support constructive engagement with digital media.

Epistemic Curiosity in Digital Media Environments

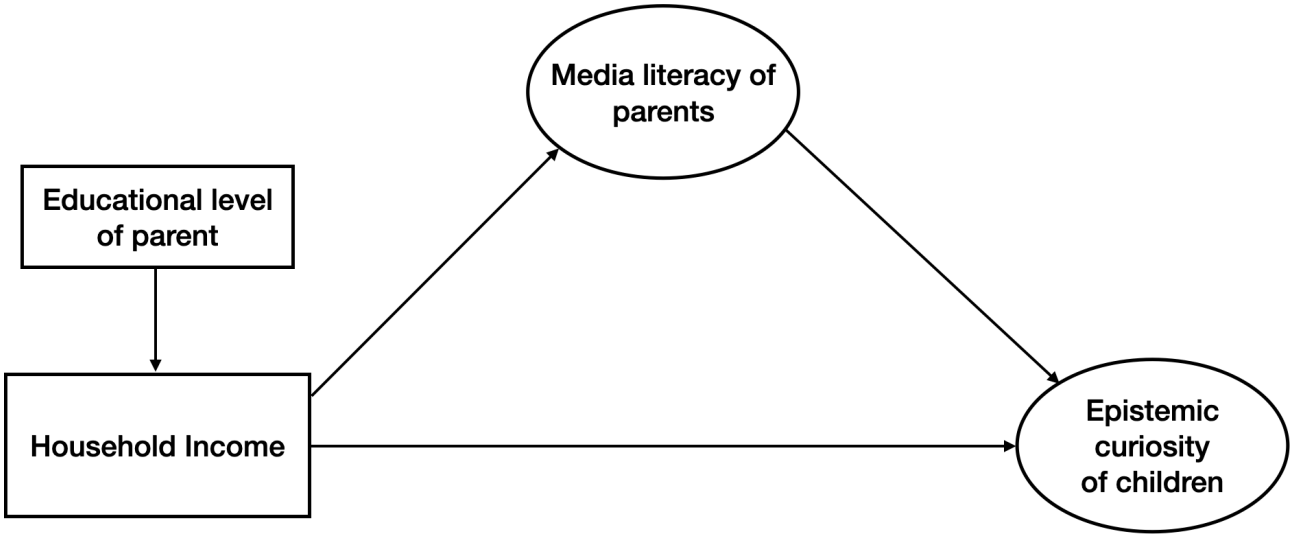
Epistemic curiosity refers to a desire for knowledge and understanding that motivates information seeking, exploration, and learning [9]. Because it encourages children to engage with new ideas, ask questions, and resolve uncertainty, epistemic curiosity is considered an important developmental outcome linked to cognitive growth and learning [23-25].

Prior research distinguishes between 2 dimensions of epistemic curiosity: interest-type and deprivation-type curiosity [26]. Interest-type curiosity reflects enjoyment of novelty and discovery, whereas deprivation-type curiosity arises from a desire to resolve gaps in knowledge or understanding [27,28]. Although these dimensions differ in motivation, both are associated with active information seeking and intellectual exploration [26,29,30].

The development of epistemic curiosity begins early in life, when children are actively constructing knowledge about the world around them. Prior research suggests that curiosity can be fostered through exposure to novel information, opportunities for exploration, and encounters with uncertainty that motivate information seeking [31-34]. Because epistemic curiosity supports learning, problem-solving, and knowledge acquisition, it is increasingly recognized as an important developmental resource during childhood.

Epistemic curiosity may be particularly relevant in contemporary digital environments. Children are routinely exposed to novel information, diverse perspectives, and new learning opportunities through screen-based media. As digital media increasingly serves as a gateway through which children encounter and learn about the world, media experiences may play an important role in stimulating curiosity and exploration. While much research has focused on the risks of digital media use, these environments may also provide opportunities for curiosity-driven learning and intellectual engagement. Given parents' central role in shaping children's media experiences, parental media literacy may be associated with how children engage with these opportunities and experience epistemic curiosity during media use.

The Current Study



On the basis of the theoretical arguments and empirical gaps discussed above, this study examined the relationships among parental media literacy, SES, and children's epistemic curiosity, including both interest type and deprivation type. Specifically, this study investigated whether parental media literacy was associated with children's epistemic curiosity during screen-based media use and whether parental media literacy may help explain the relationship between SES and children's epistemic curiosity.

Figure 1 shows the conceptual model linking household income, parental media literacy, and children's epistemic curiosity. On the basis of prior literature, parental media literacy is expected to be positively associated with children's epistemic curiosity, and SES is expected to be associated with both parental media literacy and children's epistemic curiosity. The following hypotheses were proposed:

- *Hypothesis 1*—higher levels of parental media literacy (technological use, critical understanding, self-expression, and norm compliance) will be positively associated with children's epistemic curiosity (interest type and deprivation type) during screen-based media use.
- *Hypothesis 2*—higher SES will be positively associated with children's epistemic curiosity during screen-based media use.
- *Hypothesis 3*—parental media literacy will mediate the association between SES and children's epistemic curiosity during screen-based media use.

Figure 1. Research model.

Methods

Participants and Procedure

Data were collected from a target population of 1020 primary caregiver parents of children aged 7 to 9 years in South Korea via a professional online research panel. The survey was administered between July 31, 2024, and August 21, 2024, and included 340 parents of children in each age group (7, 8, and 9 years). Most respondents (n=887, 87%) were mothers, and 13.0% (n=133) were fathers. The survey, designed for quantitative analysis, commenced with a screening question to confirm the respondent's status as the primary caregiver and included detailed measures regarding the child's media exposure, device access, use patterns, and the control variables used in the final analysis. All items were measured on a 5-point Likert scale except SES, which was measured categorically.

Ethical Considerations

This study received ethics approval from the Ewha Womans University Institutional Review Board (protocol number ewha-202103-0028-04). Participants provided informed consent through the online platform.

Measurements

All constructs were assessed using previously validated scales. Confirmatory factor analyses (CFAs) were conducted to evaluate the measurement properties of the scales. Table 1 shows the CFA results, reliability estimates, and validity indicators for all study variables.

Table . Measurement properties of the study variables[a].

Construct	Mean (SD)	Loading range	McDonald ω	AVE[b]
TU[c]	4.31 (0.52)	0.63-0.83	0.84	0.51
CU[d]	3.95 (0.56)	0.31-0.87	0.75	0.44
SE[e]	3.80 (0.69)	0.56-0.76	0.83	0.46
NC[f]	4.14 (0.54)	0.35-0.88	0.68	0.37
Interest-type curiosity	3.77 (0.55)	0.65-0.76	0.80	0.50
Deprivation-type curiosity	3.36 (0.65)	0.70-0.83	0.84	0.56

[a]The 4-factor confirmatory factor analysis provided partial support for the proposed multidimensional structure (comparative fit index [CFI]=0.87; Tucker-Lewis index [TLI]=0.85; root mean squared error of approximation [RMSEA]=0.07; standardized root mean squared residual [SRMR]=0.07), whereas the 2-factor model for epistemic curiosity demonstrated good fit (CFI=0.97; TLI=0.96; RMSEA=0.06; SRMR=0.04). Discriminant validity was considered acceptable because the squared latent correlations were lower than the average variance extracted estimates for most constructs.

[b]AVE: average variance extracted.

[c]TU: technological use.

[d]CU: critical understanding.

[e]SE: self-expression.

[f]NC: norm compliance.

For parental media literacy, a 4-factor model demonstrated modest fit (χ^2_{146}=959.8; comparative fit index [CFI]=0.87; root mean squared error of approximation [RMSEA]=0.07; standardized root mean squared residual [SRMR]=0.07). For epistemic curiosity, a 2-factor model demonstrated good fit (χ^2_{19}=85.0; CFI=0.97; RMSEA=0.06; SRMR=0.04).

XSL•FO
RenderX

Standardized factor loadings ranged from 0.31 to 0.88 for parental media literacy and from 0.65 to 0.83 for epistemic curiosity. Internal consistency was assessed using the McDonald ω.

Epistemic Curiosity

Epistemic curiosity during screen-based media use (parent reported) was measured using a 10-item scale adapted from the work by Piotrowski et al [25] that assesses children's curiosity through caregiver observation. The scale was previously translated into Korean and validated [29].

The scale consists of 2 dimensions: intellectual interest (5 items; mean 3.77, SD 0.55; ω=0.80) and informational deprivation (5 items; mean 3.36, SD 0.65; ω=0.84). A 2-factor CFA supported the distinction between interest- and deprivation-type curiosity. Standardized factor loadings ranged from 0.65 to 0.76 for interest-type curiosity and from 0.70 to 0.83 for deprivation-type curiosity. Items were measured on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree").

Parental Media Literacy

Parental media literacy was measured using a validated multidimensional scale developed by Ahn et al [35]. On the basis of their established relevance to child outcomes and parent-child mediation effectiveness, 4 key dimensions were selected for this study: technological use (5 items; mean 4.31, SD 0.52; ω=0.84), critical understanding (4 items; mean 3.95, SD 0.56; ω=0.75), self-expression (5 items; mean 3.80, SD 0.69; ω=0.83), and norm compliance (4 items; mean 4.14, SD 0.54; ω=0.68). The reliability coefficient for norm compliance was somewhat lower than those observed for the other dimensions. However, the value remained within the range often considered acceptable for established multidimensional scales in social science research, particularly when constructs encompass heterogeneous behavioral indicators. Accordingly, the scale was retained to preserve the theoretical breadth of the parental media literacy framework.

A 4-factor CFA generally supported the multidimensional structure of parental media literacy. Standardized factor loadings ranged from 0.63 to 0.83 for technological use, 0.31 to 0.87 for critical understanding, 0.56 to 0.76 for self-expression, and 0.35 to 0.88 for norm compliance. Items were measured on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree").

Household SES and Control Variables

SES was operationalized using 2 parent-reported measures. Household income, the primary SES proxy for the main hypothesis (hypotheses 2 and 3), was measured using a 10-point categorical scale (from less than KRW 2.5 million to more than KRW 10.5 million, with intervals of KRW 1 million [KRW 1=US $0.00072 as of August 20, 2026]). For the analysis, this categorical variable was treated as a continuous ordinal variable. Parental educational level, categorized into 5 options (eg, high school graduate and bachelor's degree), was measured to serve as a control variable in the analysis. The gender of the primary caregiver (mother=0; father=1) was also included as a control variable.

Analysis Plan

Prior to hypothesis testing, the psychometric properties of all latent variables were rigorously assessed through CFA. Through the validated measurement models established via CFA, this study used structural equation modeling via the *lavaan* package in R (R Foundation for Statistical Computing) [36] to test the hypothesized relationships, including the mediation effect (hypothesis 3).

Because parental media literacy was conceptualized as 4 distinct dimensions and epistemic curiosity was conceptualized as 2 theoretically distinct outcomes (interest and deprivation type), separate structural equation models were estimated for each combination of media literacy and curiosity dimensions (4 × 2 = 8 models). This approach allowed the associations between specific dimensions of parental media literacy and specific dimensions of epistemic curiosity to be examined independently, consistent with the study's aim of understanding the role of each media literacy dimension rather than evaluating their relative effects within a single model.

Given the observed nonnormal distribution of the variables and the categorical nature of SES, indirect effects were tested using 5000 bias-corrected bootstrap samples, following the recommendations of Preacher and Hayes [37].

Parental educational level was included as a covariate in all structural equation models. This decision was made because the educational level was observed to influence both household income and parental media literacy and the sample exhibited a skew toward highly educated parents. The primary caregiver's gender was also included as a covariate in all models.

Results

Descriptive Statistics

A total of 1020 completed questionnaires were collected and statistically analyzed. The age range for participating parents was 27 to 56 years. Mothers' ages ranged from 27 to 51 years (mean 40.37, SD 3.72 years), and fathers' ages ranged from 27 to 56 years (mean 41.41, SD 3.97 years). The sample exhibited a higher educational attainment compared to the national average (41% with higher education), with 92.5% (n=944) having an associate college degree or higher. Specifically, 21.8% (n=222) had an associate college degree, 57.5% (n=586) had a bachelor's degree, and 13.3% (n=136) had a graduate degree or higher. Only 0.2% (n=2) had not completed middle school, and 7.3% (n=74) were high school graduates. The sample also reported relatively high household incomes (mean KRW 5.5 million to 6.5 million, SD KRW 2.13 million). The distribution was near normal (skewness=0.25; kurtosis=–0.62), with 46.3% (n=472) reporting a household income exceeding KRW 6.5 million.

Correlations between all study variables were examined and are shown in Table 2. Findings indicated statistically significant correlations among most variables except between parental educational level and 2 dimensions of media literacy: technological use and norm compliance.

Parental Media Literacy and Children's Epistemic Curiosity

The results of the structural equation models with interest-type epistemic curiosity as the dependent variable are shown in Table 3. Model fit indexes for interest-type epistemic curiosity as the dependent variable indicated acceptable fit across all dimensions of parental media literacy (technological use: χ^2_2=7.5, *P*<.001, CFI=0.97, RMSEA=0.05, and SRMR=0.02; critical understanding: χ^2_2=11.9, *P*<.001, CFI=0.94, RMSEA=0.07, and SRMR=0.03; self-expression: χ^2_2=4.8, *P*=.09, CFI=0.98, RMSEA=0.04, and SRMR=0.02; norm compliance: χ^2_2=1.4, *P*=.50, CFI=1.00, RMSEA=0.00, and SRMR=0.00). All structural equation models were estimated under the same analytical framework and included the same set of covariates. The models were overidentified (df=2), allowing model fit to be evaluated using conventional fit indexes.

Table . Interest-type curiosity results.

PML[a] dimension	Income→PML, β	PML→interest-type curiosity, β	Income→interest-type curiosity, β	Indirect effect, β
TU[b]	.02[c]	.32[d]	.02[d]	.006[c]
CU[e]	.03[d]	.24[d]	.02[c]	.007[c]
SE[f]	.05[d]	.20[d]	.02[c]	.009[d]
NC[g]	.02[c]	.26[d]	.02[d]	.005[c]

[a]PML: parental media literacy.

[b]TU: technological use.

[c]*P*<.05

[d]*P*<.001.

[e]CU: critical understanding.

[f]SE: self-expression.

[g]NC: norm compliance.

Consistent with hypothesis 2, the direct effect of household income on children's interest-type epistemic curiosity was statistically significant across all 4 dimensions of parental media literacy (β=.02; *P*<.05). This finding suggests that higher household income is consistently associated with greater experience of interest-type epistemic curiosity in children during media use.

Regarding the mediation hypothesis, the indirect effect of parental media literacy significantly mediated the relationship between household income and interest-type epistemic curiosity across all 4 parental media literacy dimensions, supporting hypothesis 3 for interest-type curiosity. The standardized indirect effects were significant through technological use (β=.006; *P*=.02), critical understanding (β=.007; *P*=.003), self-expression (β=.009; *P*<.001), and norm compliance (β=.005; *P*=.005).

XSL•FO
RenderX

Although statistically significant, the indirect effects were small in magnitude.

The results of the structural equation model with deprivation-type epistemic curiosity as the dependent variable are shown in Table 4. The model fit indexes for all 4 models suggested an adequate fit (technological use: χ^2_2=14.0, *P*<.001, CFI=0.91, RMSEA=0.07, and SRMR=0.04; critical understanding: χ^2_2=15.0, *P*<.001, CFI=0.91, RMSEA=0.08, and SRMR=0.04; self-expression: χ^2_2=8.2, *P*=.02, CFI=0.96, RMSEA=0.06, and SRMR=0.03; norm compliance: χ^2_2=5.8, *P*=.06, CFI=0.97, RMSEA=0.04, and SRMR=0.02).

Regarding the direct effect of household income (hypothesis 2), the relationship with deprivation-type epistemic curiosity was statistically significant for 3 dimensions of parental media literacy: critical understanding (β=.03; *P*=.005), self-expression (β=.02; *P*=.01), and norm compliance (β=.02; *P*=.002). However, the direct effect was not significant for the technological use dimension (β=–.00; *P*=.79). This finding partially supports hypothesis 2.

Regarding the mediation hypothesis (hypothesis 3), the indirect effect of household income on deprivation-type epistemic curiosity mediated by parental media literacy was significant for critical understanding (β=.007; *P*=.003), self-expression (β=.011; *P*<.001), and norm compliance (β=.004; *P*=.03). In contrast, the indirect effect through technological use was not statistically significant (β=.00; *P*=.74). This finding partially supports hypothesis 3 concerning deprivation-type curiosity. Although these indirect effects were statistically significant, their magnitudes were small and should be interpreted with caution.

Table . Deprivation-type curiosity results.

PML[a] dimension	Income→PML, β	PML→deprivation-type curiosity, β	Income→deprivation-type curiosity, β	Indirect effect, β

Discussion

Principal Findings

This study examined the role of parental media literacy in children's epistemic curiosity during screen-based media use. In contemporary digital environments, children are routinely exposed to diverse information and learning opportunities through screen-based media, making it increasingly important to understand the factors that shape how they engage with these experiences. Across the 4 dimensions of parental media literacy, higher levels were generally associated with greater epistemic curiosity among children during media use. Although the magnitude of the associations varied across dimensions, the findings suggest that parental media literacy may be linked to children's curiosity-driven engagement with digital media. Among the 4 dimensions, technological use showed a distinct pattern: it was directly associated with both interest- and deprivation-type curiosity, but the indirect association between household income and deprivation-type curiosity through technological use was not statistically significant.

Parental Media Literacy and Children's Epistemic Curiosity

Critical understanding, self-expression, and norm compliance were positively associated with both interest- and deprivation-type curiosity. Technological use was also positively associated with both forms of curiosity, although its association with deprivation-type curiosity was relatively weaker than that observed for interest-type curiosity.

One notable finding was that technological use showed a different pattern from those of the other dimensions of parental media literacy. While critical understanding, self-expression, and norm compliance demonstrated significant indirect associations linking household income to deprivation-type curiosity, technological use did not. Although technological use was directly associated with both interest- and deprivation-type curiosity, its indirect association between household income and deprivation-type curiosity was not statistically significant.

Technological use may increase children's opportunities to encounter novel content and diverse information, thereby stimulating interest-based exploration (interest-type curiosity). One possible explanation is that deprivation-type curiosity, which reflects a desire to resolve uncertainty and knowledge

XSL•FO
RenderX

gaps, may depend more heavily on higher-order competencies such as critical understanding, self-expression, and reflective engagement with media.

This distinct pattern warrants further investigation. Future research should examine why technological media skills appear to support children's curiosity directly but do not function as a significant pathway linking household income to deprivation-type curiosity.

Parental Media Literacy as a Pathway Linking SES and Epistemic Curiosity

The findings also suggest that parental media literacy may represent one potential pathway through which socioeconomic resources are associated with children's media-related experiences. Household income was positively associated with parental media literacy, and indirect effects emerged across several dimensions of epistemic curiosity. These findings are consistent with those of previous research showing that families with greater socioeconomic resources often have increased access to educational opportunities and digital technologies that may support the development of media-related competencies.

The association between household income and parental media literacy may be particularly understandable for dimensions such as technological use, which often requires access to digital devices, platforms, and opportunities for hands-on engagement with emerging technologies. In contrast, competencies such as critical understanding, self-expression, and norm compliance may be more amenable to educational interventions and learning opportunities.

Importantly, unlike socioeconomic resources, parental media literacy represents a potentially modifiable competency. Although the present findings do not imply that media literacy can eliminate socioeconomic disparities, they suggest that parental media literacy may be one factor associated with children's positive engagement with digital media regardless of family income. From this perspective, media literacy education may represent a promising avenue for supporting families as they navigate increasingly complex digital environments.

Although the indirect associations were statistically significant, their effect sizes were small in magnitude. Consequently, parental media literacy should be viewed as one of several factors that may be associated with the relationship between socioeconomic resources and children's epistemic curiosity.

Implications for Media Literacy Education

The present findings highlight the potential value of parental media literacy education. Contemporary parents are increasingly expected to guide children's media use, yet many developed their own media practices through personal experience rather than formal media literacy training. As digital environments continue to evolve, parents face growing challenges in helping children navigate complex media ecosystems. The present findings suggest that parental media literacy may be associated with children's curiosity-driven engagement with media, underscoring the importance of supporting parents as active participants in children's digital learning environments.

Notably, parental media literacy represents a competency that can potentially be strengthened through education and intervention. Although media literacy education cannot eliminate broader socioeconomic inequalities, it may provide parents with practical tools to support children's engagement with digital media. Educational programs that promote critical understanding, self-expression, and responsible media use may help parents create media experiences that encourage exploration, learning, and curiosity.

Given the importance of epistemic curiosity for children's learning and development, future research should continue to explore how parental media literacy education may support positive media experiences and learning-related outcomes in childhood.

Limitations

This study has several limitations. First, the data were cross-sectional, preventing conclusions regarding the direction of the associations observed. Although the findings suggest that parental media literacy is associated with children's epistemic curiosity during screen-based media use, future longitudinal research is needed to better understand how these relationships develop over time.

Second, children's epistemic curiosity was assessed through parent reports rather than direct observations or child self-reports. Although parent reports are commonly used when studying young children, they may not fully capture children's subjective experiences during media use. In addition, because both predictor and outcome variables were obtained from the same respondent, shared method variance may have inflated some of the observed associations. Future research should incorporate multiple sources of data, including child reports, behavioral measures, observational approaches, and longitudinal designs.

Third, this study was conducted in South Korea, a highly digitalized society characterized by widespread media use and strong parental involvement in children's education. In addition, participants were recruited through an online panel, which may have resulted in a sample with relatively high levels of parental engagement. Furthermore, mothers constituted most respondents. Although mothers often serve as primary caregivers for children in the target age group for this study, future research would benefit from including a more balanced representation of fathers to examine potential differences in parental media literacy and children's media experiences.

Conclusions

In conclusion, this study contributes to the growing literature on media literacy by examining parental media literacy in relation to children's epistemic curiosity during screen-based media use. The findings suggest that parental media literacy may extend beyond an individual competency and be associated with children's media-related experiences within family contexts. By highlighting parental media literacy as a potentially modifiable factor linked to children's curiosity-driven engagement with digital media, this study underscores the importance of supporting parents as they navigate increasingly complex media environments. Future research should continue

XSL•FO
RenderX

to explore how parental media literacy can be fostered and how it may contribute to positive media experiences and learning-related outcomes in childhood.

Abstract

Background: Over the past decade, smartphones have become an integral part of family life, shaping both daily routines and parent-child interactions. Although parental smartphone use in the presence of children is frequently framed as harmful through concepts such as phubbing and technoference, these constructs emphasize disruptive smartphone use and may bias interpretations toward negative effects. Moreover, most previous research has relied on cross-sectional self-report data, limiting insight into how parental smartphone use relates to children's well-being in everyday life.

Objective: This study examined the associations between parental smartphone use in the presence of the child and children's affective well-being, as well as perceived threats to children's fundamental needs, using both self-reported and device-logged measures of smartphone use.

Methods: Individual parents (N=131) participated in a 10-day daily diary study. Each evening, parents reported their smartphone use in the presence of a selected target child, their child's positive and negative affect, and perceived threats to their child's fundamental psychological needs. In addition, Android users who provided consent installed a mobile sensing app that continuously recorded objective smartphone use throughout the study period. Multilevel models were used to examine both within-person (day-to-day fluctuations) and between-person associations separately for mothers and fathers while controlling for day of study, weekday vs weekend, and daily working hours.

Results: Higher parental smartphone use was largely unrelated to children's affective well-being. However, mothers who, on average, reported greater overall smartphone use perceived greater threat to their child's fundamental needs. Similarly, on days when fathers reported using their smartphones more than usual, they also perceived greater threats to their child's fundamental needs. In regard to positive affect, no significant associations were found for children's positive affect perceived by their parents, indicating that parents who, on average, used their smartphones more frequently around their child did not report lower child positive affect. Regarding negative affect, fathers who reported higher overall smartphone use also reported higher child negative affect. Additionally, on days when mothers used their smartphone more than usual, they perceived their child as displaying more negative affect. None of these associations emerged when parental smartphone use was assessed using device-logged data.

Conclusions: Taken together, these findings suggest that perceived child need threat may be linked to parents' subjective perceptions and interpretations of their smartphone use rather than to their digitally traced smartphone behavior. This discrepancy underscores the importance of distinguishing between subjective and objective assessments of parental smartphone use and highlights the need for future research that integrates children's perspectives and interactional context to clarify when and how parental smartphone use may impact children's well-being.

child well-being; parental phubbing; parental smartphone use; parent-child bonding; parent-child interaction; technoference

Introduction

Overview

Over the past decade, smartphones have inevitably become part of family life, shaping both daily routines and leisure activities. While this connectivity offers many benefits, growing evidence suggests that parental smartphone use in the presence of a child may have negative consequences, as parental attention is diverted from the child to the device [1]. In the present literature, parental smartphone use is often used interchangeably with phubbing and technoference. Phubbing—a blend of "phone" and "snubbing"—refers to instances in which an individual ignores another person in a social setting by directing attention to their smartphone [2], whereas technoference refers to interruptions in social interactions resulting from smartphone use in the presence of others [3]. However, both phubbing and technoference carry a negative connotation and may, as a result of this connotation, bias interpretations, as parental smartphone use may not inherently be negative [4]. In addition, most prior studies use self-report and a cross-sectional design that only allows comparisons between people [5]. Therefore, this study leverages longitudinal self-report and mobile sensing data to obtain a more nuanced understanding of the association between parental smartphone use in the presence of children and children's affective well-being.

Parental Smartphone Use and Its Effects

Through the lenses of phubbing and technoference, prior work suggests that parental smartphone use in the presence of a child should have a detrimental effect on the child's well-being [6]. Studies on phubbing indicate that phone use in the presence of a child is associated with the development of unhealthy screen habits and behaviors in the child, with especially strong implications for younger children [7,8]. These detrimental consequences may extend into children's future lives, underscoring the importance of raising parental awareness and reducing habitual phone use in the presence of children. In line with this research, other studies found that higher levels of phubbing by one or both parents are associated with children experiencing more negative emotions and feeling disconnected from their parents [9]. Phubbing has also been linked to lower maternal happiness, which in turn predicts reduced child happiness and poorer self-regulation skills in children [10]. Meanwhile, from the perspective of technoference, higher technoference in parent-child contexts is linked to greater externalizing and internalizing behaviors [11,12], such as depressive symptoms [13] and anxiety [14], along with lower prosocial behaviors [15] and problematic smartphone use [16] among children. Furthermore, parental technoference was associated with lower self-esteem [17], higher incidence of cyberbullying [14], and higher levels of smartphone addiction [13] in adolescents. Taken together, these findings suggest that parental smartphone use in the presence of children appears to be consistently linked to poorer child well-being.

In the literature on phubbing and technoference, this detrimental effect is often explained through 2 perspectives. First, parental smartphone use in the presence of a child is thought to displace parental attention, leading to a disruption in parent-child attachment. This displacement hypothesis suggests that when parents spend more time on their smartphones, they displace the quality time they could otherwise spend with their children, which is important for fostering a secure parent-child attachment [18]. Secure attachment is often considered the hallmark of a healthy parent-child relationship [19], as it has consistently been linked to positive outcomes such as higher academic achievement, better comprehension, enhanced cognitive functioning, and stronger socioemotional competence compared to less secure attachment styles [20,21]. Consistent with the displacement hypothesis, past work suggests that children's perceptions of parental neglect, arising from parents' phubbing behavior, were negatively associated with the quality of parent-child attachment.

Second, the potential negative effects of parental smartphone use on children's affective well-being can be understood through the fundamental need-threat framework proposed by Williams [22]. According to this framework, the use of a smartphone in the presence of others elicits ostracism, reflecting feelings of being invisible and/or excluded that threaten individuals' fundamental psychological needs, thereby decreasing positive affect and increasing negative affect. Accordingly, parental smartphone use may undermine children's affective well-being by threatening the fulfillment of children's fundamental needs and through feelings of ostracism [23,24]. In contrast, parental engagement can fulfill children's fundamental needs (eg, need for belonging, need for self-esteem, and sense of meaningful existence) and prevent feelings of ostracism [25-28]. Together, the displacement hypothesis and fundamental need-threat framework highlight that parental smartphone use may have tangible psychological consequences for a child, particularly when the child's needs become unfulfilled.

A critical limitation of the above frameworks is that they are heavily derived from the phubbing and technoference literature. Both phubbing and technoference are often presented as highly negative concepts, thus biasing the overall narrative toward the idea that any parental phone use in the presence of a child will be detrimental [4]. Most measures of phubbing and technoference are negatively framed, often inquiring about moments when smartphone use was experienced as disturbing. As a result, these studies primarily capture situations in which smartphone use is indeed perceived as disruptive, which—unsurprisingly—are also associated with negative outcomes. Such framing thus fails to capture the many moments in which smartphone use is neutral or even integrated into positive interactions [5,29]. Using more neutral approaches, which do not frame parental smartphone use as phubbing or technoference, we see that the association between parental phone use and child well-being is more nuanced. On the one hand, the detrimental consequences of parental smartphone use may still be present. For instance, one study showed that

XSL•FO
RenderX

child-observed parental phone use was associated with children experiencing increased anger and sadness as a result of less parental attention [30]. On the other hand, one study showed that self-reported parental smartphone use had only minimal effects on parental listening qualities, so that meaningful child-parent interactions were still possible [31]. Meanwhile, another study suggested that higher levels of social connectedness were found when parents used their phones to complement the interaction with their children [32]. Taken together, the current body of literature may thus present a skewed perspective of parental smartphone use. To obtain a more comprehensive understanding of the influence of parental smartphone use on child well-being, it may be advantageous to adopt more neutral measures that allow us to capture the full spectrum of smartphone use, including its potentially neutral or beneficial aspects.

A second limitation of prior work is its overreliance on cross-sectional data [33]. Cross-sectional studies only allow between-person comparisons, which reflect stable differences in child outcomes across parents with different levels of smartphone use. This allows us to differentiate whether higher or lower parental smartphone use is differentially linked to child well-being. However, previous research and theoretical frameworks suggest that a within-person perspective might give more insight into the processes underlying parental smartphone use. Parental smartphone use likely varies on a day-to-day basis—the same parents are likely to experience days with higher or lower smartphone use, and these fluctuations are likely to have different influences on child well-being. Consistent with this notion, one study demonstrated that there is substantial variability in daily parental smartphone use, altering the associations between parental smartphone use, technoference, and the perception of child restlessness (within-person) [5]. Another study showed no differences in parental engagement with their children between parents with higher and lower smartphone use (between-person), but higher parental smartphone use was associated with higher parental engagement at a later time (within-person) [34]. Therefore, to obtain a more comprehensive portrait of the influence of parental smartphone use on child well-being, it is beneficial to not only capture stable between-person differences but also the effects of day-to-day fluctuations in parental smartphone use.

A final limitation of past studies is that parental smartphone use has almost exclusively been measured using self-reported data [33]. Studies have shown that self-reported smartphone use data is a poor representation of actual, "objective" smartphone use data [35]. That is, findings based on self-reported amounts of smartphone use can be unreliable, as participants may misremember or underreport their behavior (eg, to appear socially acceptable). Interestingly, one of the first pioneering studies using objectively measured parental smartphone use found no association between the duration or frequency of parental smartphone use and parents' perceptions of child restlessness [5]. Combining self-report measures with more objective markers (eg, phone logs, observer ratings, and mobile sensing) may thus yield more nuanced insights into the effects of parental smartphone use on children.

Study Objectives

Based on these limitations, there is a recognizable need for further research that more precisely conceptualizes parental smartphone use and its interaction with children, using an objective and unbiased approach in the measurement of smartphone use [36]. Building on prior research and in response to the limitations described above, this study aims to examine the association between parental smartphone use in the presence of the child and the child's affective well-being.

Our study makes the following contributions: first, through its intensive longitudinal, ecological momentary assessment (EMA), our study allows us to compare effects between parents and at the same time also offers insight into the (within-person) effects of day-to-day fluctuations in parental smartphone use on the child's outcome. Second, using mobile sensing data, our study was able to compare the subjective self-report data with device-logged data. Third, by examining both parents, our study extends prior research that has predominantly focused on primary caregivers and, consequently, largely reflects the maternal perspective. Based on the above framework, this study aims to investigate the following preregistered hypotheses concerning both within-person and between-person associations between parental smartphone use in the presence of the child and children's well-being (the preregistration is available on the Open Science Framework (OSF) [37].

At the within-person level (H1), we expected that day-to-day fluctuations in parental smartphone use would be meaningfully related to children's affective well-being. Specifically, on days when parents used their smartphones more than usual in the presence of their child, we expected children to be rated as experiencing greater fundamental need threat, higher negative affect, and lower positive affect compared to their own average levels. This hypothesis reflects the idea that momentary increases in parental smartphone use may interfere with ongoing parent-child interactions and be associated with short-term changes in children's affective well-being.

At the between-person level (H2), we expected that stable differences in parental smartphone use across the study period would be associated with differences in children's overall affective well-being. That is, parents who, on average, reported higher levels of smartphone use in the presence of their child were expected to report greater fundamental need threat, higher negative affect, and lower positive affect in their children compared to parents with lower average levels of smartphone use. This hypothesis captures the assumption that more frequent exposure to parental smartphone use may be linked to more enduring differences in children's well-being.

Finally, we additionally explored whether these associations differed between mothers and fathers, given potential differences in parenting roles, expectations, and perceptions related to smartphone use. While our preregistration referred to the construct as "parental phubbing," we revised the terminology to "parental smartphone use" to ensure a more neutral and objective operationalization.

Methods

Sample

A total of 70 romantic parental couples (N=140 individuals) took part in the study. Parents were recruited via (social) media (eg, radio podcasts, a popular German psychology magazine, and social media posts), distribution of flyers in shopping malls, daycare centers, and doctoral practices, and through snowball sampling. Eligibility criteria included (1) being 18 years of age or older, (2) understanding and speaking German fluently, (3) owning a smartphone, (4) being in a romantic relationship for at least 6 months, (5) both partners agreeing to take part in the study, and (6) having a child aged 1 to 16 years. A total of 9 partners did not complete any questionnaires and were therefore not included in the analyses. This resulted in a final sample of 131 individual parents (n=61 parental couples and n=9 individual parents without a participating partner), aged between 26 and 61 years (mean 37.34, SD 6.02). The age of the target children ranged between 1 and 16 years (mean 6.59, SD 3.95, including 60/131, 46%, girls). On average, partners had been in a relationship for 10.6 (SD 6.22) years. The majority of participants were married, including 77% (50/65) of mothers and 71% (47/66) of fathers. Our compliance rate for the daily reports ranged between 83% and 86%. Additional social demographics separately for mothers and fathers are shown in Table 1.

Table 1. Demographic characteristics of the study sample.

Demographics	Mothers		Fathers	
	Mean (SD; min-max)	n (%)	Mean (SD; min-max)	n (%)
Parent's age (years)	36.5 (5.41; 26-53)	65 (100)	38.1 (6.50; 27-61)	66 (100)

Procedure

Data were collected as part of the larger experience-sampling project eMotion, which combines an intensive longitudinal EMA design with mobile sensing to investigate the well-being of romantic couples in an increasingly digital world. Data collection took place between 2022 and 2025. Parents could sign up for the study online by filling out a contact form. Those who did not fulfill the inclusion criteria were automatically screened out. Those who were eligible for the study could sign up for an intake procedure, in which a trained recruiter provided information and instructions about the study. Subsequently, parents were asked to select one target child for whom the questionnaires were completed and filled out an intake questionnaire, providing informed consent and responding to demographic and trait measures. This survey took about 30-45 minutes. Couples were screened out if one or both partners did not fill out the questionnaire by midnight the day before the start of the experience sampling method (ESM) period. Then, over a period of 10 days, both parents were simultaneously beeped 5 times per day between 9:30 AM and 9:00 PM. The parents received an SMS text message with the link to the questionnaire programmed in formR [38]. An additional sixth beep included a short evening questionnaire (administered at 9:30 PM), with several (other) questions about the entire day. For this study, we only used the data from the evening questionnaire. At the end of the ESM period, parents answered a final questionnaire, including several postmeasures (ie, a few trait scales), and questions about their experience with the study. To reduce the likelihood of parents changing their target child during the study, each evening questionnaire included a reminder before the child-related questions: "When answering the

XSL•FO
RenderX

following questions, please refer to the child you selected at the beginning of the study." For the mobile sensing component, participants with Android smartphones who provided additional consent installed the movisensXS app, which continuously recorded smartphone trace data throughout the 10-day study period. At the end of the study, participants completed a final questionnaire assessing additional trait measures, were thanked and reimbursed. Furthermore, they could receive individualized feedback on their personality, burnout, emotions, emotion regulation strategy use, sleep quality and mood, partner contact and relational well-being.

Ethical Considerations

The study procedure was approved by the ethics committee of the Psychology Department of the University of Münster, Germany, with approval number 2021-81-AM.

Written informed consent was obtained from all participants as part of the eMotion study prior to data collection. The consent covered the collection of questionnaire and smartphone sensing data and permitted the use of these data for secondary analyses. Participants were informed that participation was voluntary and that they could withdraw from the study at any time without consequences.

The data used in these analyses were deidentified prior to analysis. Participant confidentiality was maintained throughout the study, and all data were stored securely in accordance with applicable data protection regulations.

Parents received financial compensation on a pro rata basis with a maximum reimbursement of €118 (US $132.91) per person, including a €10 (US $11.26) bonus for all parents who completed more than 80% of the experience-sampling prompts. Alternatively, participating students could opt for course credit.

Measures

Overview

All variables used in this project were part of the evening questionnaire and were thus answered once a day in the evening by both parents during the 10-day study period. We implemented different ways to estimate the internal consistency of our self-reported measures. For multi-item EMA measures, we first estimated Cronbach α separately for each study day. We then report the average of daily α values as a pragmatic indicator of reliability. For 2-item measures, we report mean daily interitem correlation and Spearman-Brown reliability. For single-item measures, where internal consistency is not applicable, we instead report intraclass correlation coefficient (ICC) across days.

Child Fundamental Need Threat

Child fundamental need threat was measured by asking participants to reflect on the extent to which their child felt "rejected" (Belonging), "it had the situation(s) under control," "irritated" (Control), "at ease" (Self-Esteem), "invisible" (Meaningful existence), and "excluded" (Ostracism) because of their smartphone use that day. Participants rated these statements on a 7-point scale (1: "not at all"; 7: "very much"). An average of these 6 items was calculated to obtain an aggregate measure of child fundamental need threat, with higher scores reflecting higher need threat due to smartphone use. Mean daily α suggested that the internal consistency for the child fundamental need threat items was good (α=.84).

Child Positive Affect

Child positive affect was measured by averaging the 2 items ("My child was happy today" and "My child was relaxed today"). Before reporting on any child-related smartphone use items, parents were asked to rate these statements on a 7-point scale (1: "not at all"; 7: "very much"), with higher scores reflecting more positive affect. Mean daily interitem correlation and Spearman-Brown coefficients suggested that the internal consistency of the 2 items was acceptable (r=0.55; r_{SB}=0.71).

Child Negative Affect

Child negative affect was assessed by averaging the following 6 items per day: "My child was sad today," "My child was upset today," "My child was worried today," "My child was exhausted today," "My child was stressed today," and "My child was down today." Before reporting on any child-related smartphone use items, parents rated these statements on a 7-point scale (1: "not at all"; 7: "very much"), with higher scores reflecting more negative affect. Mean daily α suggested that the internal consistency for the child negative affect items was acceptable (α=.75).

Self-Reported Parental Smartphone Use in the Presence of a Child

Parental smartphone use in the presence of a child was assessed using one self-report item ("To what extent did you use your smartphone today in the presence of your child? (Not counting answering the questionnaires on the smartphone)"). Both parents rated this item separately on a 7-point scale (1: "not at all"; 7: "very much") every evening, with higher scores reflecting more parental smartphone use. The ICC for this item was relatively modest ($ICC_{adjusted}$=0.41), suggesting that participants' patterns of phone use in the presence of their child tended to vary over time.

Overall Device-Logged Parental Smartphone Use

Device-logged parental smartphone use was assessed using a mobile sensing app (movisensXS [39]). The app recorded when a participant's smartphone screen was turned "on" and when it was turned "off" throughout the entire ESM period. Similar to the procedure used in Denecker et al [5], we calculated 2 separate parental smartphone use indicators per day: "screen frequency" represents the number of times per day a participant's phone screen was turned on. "screen duration" reflects the total amount of time (in hours) per day participants' devices were in use. It should be noted that while parental smartphone use was captured via device-logging, we did not collect information on whether the child was present during these logged episodes. Device-logged parental smartphone use was added as an additional predictor after the completion of the preregistration. Hence, analyses including screen duration or frequency must be considered exploratory.

XSL•FO
RenderX

Data Analysis

Our analysis plan was preregistered on OSF [37]. As preregistered, in a first step, we tested whether the same target child was chosen by both parents by matching the target child's gender and age in both parental reports. Despite being instructed otherwise, 22% (n=29) of the parents did not choose the same target child. Hence, we refrained from using double intercept actor-partner-interdependence models to analyze our intensive longitudinal data (preregistered Strategy A). We therefore followed preregistered Strategy B, where traditional multilevel models with random intercept and random slopes for all time-varying effects would be computed separately for mothers and fathers, and for each outcome. As a result, no partner effects could be tested.

The daily evening reports constituted level 1 (L1, within-person level) and were nested within individuals at level 2 (L2, between-person level). Parental smartphone use was entered into the model as within-person (L1) and between-person (L2) components. To calculate the within-person component of parental smartphone use (L1), the variable parental smartphone use was person-mean centered. A deviation from zero can thus be interpreted as a deviation from the individual's own average level of parental smartphone use. The between-person component (L2) was extracted by (gender-specific) grand-mean centering the within-person means of parental smartphone use. By entering this between-person component into the model, we controlled for deviations of an individual's average level of parental smartphone use from the mean level across all mothers or fathers, respectively. The outcome variables were neither transformed nor centered. To account for potential (linear) trends of the outcome over time, we included day as a control variable, recoded such that day=0 reflected the first day of the study. We also controlled for weekday (0) or weekend day (1), to account for the possibility that parental smartphone use would differ between weekdays and weekends, since we assume that parents have more time available for their children. Additionally, hours worked in a paid job (assessed every evening) were included as control variables on level 1 (within-person centered) and level 2 (between-person centered), to account for time (not) spent with the child. Primary analyses were run using the *lme4* [40] and *lmerTest* [41] packages in R.

During the review process, the question arose whether child age might qualify our findings, as it was suggested that parental smartphone use may have more detrimental effects on younger children. Therefore, we decided to include the target child's age as a moderator in the models. For significant interactions, we conducted simple slope analyses to further examine how the association between variables varied across different levels of children's age. This analysis was not preregistered and should be considered exploratory. The original tables of our preregistered analysis can be found in Tables S1.1-S1.6 in Multimedia Appendix 1.

Results

Descriptive Statistics

Means, SDs, and zero-order correlations for all variables were calculated for the within- and between-level (separately for mothers and fathers). To test for potential differences between mothers and fathers, paired-sample t tests were conducted for all variables of interest (Tables 2 and 3). These tests revealed that mothers reported higher self-reported smartphone use in the presence of the child than fathers. Device-logged smartphone use, reflected through screen duration and screen frequency, did not significantly differ between mothers and fathers.

Table 2. Descriptive statistics and paired-samples t tests comparing mothers and fathers (baseline)[a].

Variable	Mothers, mean (SD)	Fathers, mean (SD)	*t* test (*df*)	*P* value	Cohen *d*
Child fundamental need threat	3.13 (1.39)	2.63 (1.04)	1.72 (34)	.09	0.29
Child positive affect	5.01 (1.10)	5.08 (1.10)	–0.48 (51)	.63	–0.07

[a]Sample sizes ranged from 31 to 60. Mothers' correlations are below and fathers' correlations are above the diagonal; intercorrelations between mothers and fathers are on the diagonal. The correlation is significant at the .05 level (2-tailed).

Parental Smartphone Use and Children's Emotional Well-Being

Below, we present the results of the different models on the association between parental smartphone use and child emotional well-being outcomes. We first present our findings for self-reported parental smartphone use, disentangling between- and within-person associations among mothers and fathers. Finally, we summarize the additional exploratory analyses linking device-logged parental smartphone use and child emotional well-being.

Self-Reported Parental Smartphone Use and Child Fundamental Need Threat

Overview

Key model estimates of the association between self-reported parental smartphone use and parental perceptions of child fundamental need threat are presented in Table 4, while a complete list of model estimates can be found in Table S2.1 in Multimedia Appendix 1.

Screen frequency[c] × child age	0.00 (–0.00 to 0.00)	.96	0.00 (–0.00 to 0.00)	.56
Screen frequency[d] × child age	0.00 (–0.00 to 0.00)	.10	0.00 (–0.00 to 0.00)	.60

[a]In all models, time, work hours, and weekday/weekend were included as control variables.

[b]In the presence of the child.

[c]Within-person level.

[d]Between-person level.

Between-Person Associations

At the between-person level, self-reported parental smartphone use predicted higher levels of perceived child need threat for mothers (*b*=1.13, 95% CI 0.56-1.70; *P*<.001), but not for fathers. Crucially, the interaction between maternal smartphone use and the target children's age was significant. Simple slope analyses indicated that higher maternal self-reported smartphone use was associated with higher perceived need threat for younger children (–1 SD; *b*=0.922, SE 0.213, 95% CI 0.496-1.349) but not for older children, although the slope remained positive (*b*=0.320, SE 0.142, 95% CI –0.042 to 0.682; Table S3.1 in Multimedia Appendix 1). Overall, this pattern of findings suggests that mothers who reported higher smartphone use tended to perceive greater need threat in their children compared to mothers with lower smartphone use, and that this association became less relevant for older children.

Within-Person Associations

Self-reported smartphone use was linked to child need threat for fathers (*b*=0.22, 95% CI 0.03-0.42; *P*=.03), but not for mothers. This pattern of findings thus suggests that on days when fathers reported greater smartphone use than usual, they perceived their child to display greater need threat. No statistically meaningful interaction effects of target child's age were found for either parent.

Self-Reported Parental Smartphone Use and Child Positive Affect

Overview

Key model estimates of the association between self-reported parental smartphone use and parental perceptions of their child's positive affect are presented in Table 5, while a complete list of model estimates can be found in Table S2.2 in Multimedia Appendix 1.

XSL•FO
RenderX

Table 5. Fixed-effect estimates for within- and between-person predictors of parents' reports of child positive affect[a].

Predictors	Positive affect maternal report		Positive affect paternal report	
	Estimates (95% CI)	*P* value	Estimates (95% CI)	*P* value
Self-reported smartphone use [b,c]	–0.10 (–0.27 to 0.06)	.21	–0.09 (–0.27 to 0.08)	.30
Self-reported smartphone use [c,d]	–0.15 (–0.58 to 0.28)	.48	–0.16 (–0.67 to 0.36)	.55
Self-reported smartphone use [b,c] × child age	0.01 (–0.01 to 0.03)	.32	0.01 (–0.01 to 0.03)	.35
Self-reported smartphone use [c,d] × child age	–0.01 (–0.06 to 0.05)	.78	0.03 (–0.03 to 0.09)	.33
Screen duration[c]	–0.01 (–0.20 to 0.18)	.90	–0.04 (–0.17 to 0.08)	.53
Screen duration[d]	0.20 (–0.14 to 0.55)	.24	0.07 (–0.16 to 0.29)	.55
Screen duration[c] × child age	0.01 (–0.02 to 0.03)	.63	0.01 (–0.01 to 0.03)	.26
Screen duration[d] × child age	–0.02 (–0.05 to 0.01)	.21	–0.01 (–0.04 to 0.01)	.29
Screen frequency[c]	0.00 (–0.01 to 0.01)	.85	–0.00 (–0.01 to 0.01)	.84
Screen frequency[d]	0.01 (–0.01 to 0.03)	.21	–0.00 (–0.01 to 0.01)	.99
Screen frequency[c] × child age	0.00 (–0.00 to 0.00)	.69	0.00 (–0.00 to 0.00)	.96
Screen frequency[d] × child age	–0.00 (–0.00 to 0.00)	.13	–0.00 (–0.00 to 0.00)	.59

[a]In all models, time, work hours, and weekday/weekend were included as control variables.

[b]In the presence of the child.

[c]Within-person level.

[d]Between-person level.

Between-Person Associations

At the between-person level, self-reported parental smartphone use was not significantly associated with perceived child positive affect for both parents. Further, no significant interactions between self-reported smartphone use and target child age were found. Overall, this pattern of findings suggests that parental perceptions of child positive affect did not differ between mothers and fathers with differing levels of smartphone use.

Within-Person Associations

At the within-person level, day-to-day fluctuations in self-reported parental smartphone use were also not significantly associated with perceived child positive affect for both parents. Similarly, no significant interactions between self-reported smartphone use and target child age were found. This suggests that parental perceptions of child positive affect were not contingent on day-to-day differences in parental smartphone use.

Self-Reported Smartphone Use and Child Negative Affect

Overview

Key model estimates of the association between self-reported parental smartphone use and parental perceptions of their child's negative affect are presented in Table 6, while a complete list of model estimates can be found in Table S2.3 in Multimedia Appendix 1.

XSL•FO
RenderX

Screen frequency[d]	–0.16 (–0.43 to 0.11)	.24	0.03 (–0.15 to 0.21)	.76
Screen frequency[c] × child age	–0.01 (–0.02 to 0.01)	.57	–0.01 (–0.02 to 0.01)	.45
Screen frequency[d] × child age	0.02 (–0.00 to 0.05)	.11	0.00 (–0.02 to 0.02)	.96

[a]In all models, time, work hours, and weekday/weekend were included as control variables.

[b]In the presence of the child.

[c]Within-person level.

[d]Between-person level.

Between-Person Associations

At the between-person level, self-reported parental smartphone use was significantly associated with perceived child negative affect in fathers (*b*=0.45, 95% CI 0.06-0.85; *P*=.03), but not for mothers. In addition, the interaction between paternal self-reported smartphone use and target child age was statistically significant: simple slope analyses revealed a significant positive association between paternal self-reported smartphone use and their perceptions of negative affect among younger children (–1 SD; *b*=0.320, 95% CI 0.027-0.613), but not older children (+1 SD; *b*=–0.073, 95% CI –0.315 to 0.169; Table S3.1 in Multimedia Appendix 1).

Within-Person Associations

Conversely, at the within-person level, self-reported parental smartphone use was significantly associated with perceived child negative affect in mothers (*b*=0.20, 95% CI 0.06-0.35; *P*=.006), but not in fathers. In addition, the interaction between maternal smartphone use and target child age was significant, suggesting that this association was prominent for younger target children (–1 SD; *b*=0.149, SE 0.052, 95% CI 0.046-0.251), but was attenuated among older target children (+1 SD; *b*=–0.010, SE 0.054, 95% CI –0.117 to 0.096). Thus, this pattern of findings suggests that on days when mothers reported higher smartphone use than usual, they perceived more negative affect in their children, but that this association became less prominent when target children were older.

Self-Reported vs Device-Logged Smartphone Use

We additionally investigated whether the above associations between self-reported parental smartphone use and child emotional well-being outcomes could be replicated using device-based measures of parental smartphone use, namely screen time frequency and duration. At the between- and within-person levels, these analyses revealed that neither screen time frequency nor duration were significantly associated with parental perceptions of child fundamental need threat, child positive affect, or child negative affect. This pattern of nonsignificant associations was consistent for both parents, irrespective of target child age. Key model estimates of the association between device-logged smartphone use and parental perceptions of children's emotional well-being can be found in Tables 4-6, and a complete list of model estimates is documented in Tables S2.4-S2.6 in Multimedia Appendix 1.

Discussion

Summary

This study examined the association between parental smartphone use in the presence of a child and the child's emotional well-being, using a multimethod approach that combines self-reported measures and device-based log data. By examining several indicators of child emotional well-being, our findings provide partial support to the notion that daily fluctuations in parental smartphone use are meaningfully associated with children's well-being. For mothers, our findings show that higher-than-usual self-reported smartphone use was associated with higher child negative affect. Notably, this

XSL•FO
RenderX

association was evident only among mothers with younger children, suggesting that younger children may be particularly sensitive to maternal smartphone use in their presence. Meanwhile, for fathers, higher-than-usual smartphone use was associated with greater perceived child need threat, regardless of their children's age. Next, our findings provide partial support to the idea that stable differences in parental smartphone use are associated with differences in child emotional well-being. Mothers reporting higher smartphone use reported greater perceived child need threat, compared to mothers with lower smartphone use, and this association was particularly noticeable among mothers with younger children compared to older children. On the other hand, fathers reporting higher smartphone use reported greater perceived negative affect in their children compared to fathers with lower smartphone use. Lastly, our exploratory findings suggest that the above self-report findings are not replicable using objective, device-logged smartphone use measures. Together, this pattern of findings suggests that the association between parental smartphone use and child emotional well-being is more nuanced than presented in recent studies. Specifically, our findings suggest that parents' subjective perceptions of their own smartphone use may be more closely related to their children's emotional well-being than their actual, objectively recorded smartphone use.

Between vs Within-Person Effects

By distinguishing within-person (daily fluctuations from a parent's own average) and between-person (stable differences between parents) effects, this study scrutinizes the displacement theory and technoference framework in a daily-life setting. Displacement theory posits that time spent on smartphones reduces opportunities for parent-child interaction, thereby undermining child well-being. Similarly, technoference and phubbing research view technology-related interruptions as relational stressors that disrupt attentional availability and responsiveness [12], evoking feelings of being ostracized [23,24].

Based on these frameworks, it is reasonable to expect that these mechanisms operate at the micro level: on days when parents use their smartphones more than usual in their child's presence, children should show lower positive affect or higher negative affect. We found this to be true for mothers in terms of negative affect. Particularly, young children are perceived as having more negative affect on days when mothers use their smartphones more than usual in their presence.

This finding is in line with observational studies documenting increased child frustration or bids for attention when parental attention is diverted to smartphones [42]. However, these findings suggest that these short-term associations are neither universal nor consistent across parents. Specifically, daily increases in smartphone use were associated with greater child negative affect only for mothers, and only among mothers with younger children. One possible explanation is that mothers, on average, spend more time in direct caregiving and emotionally salient interactions with young children than fathers. Consequently, temporary reductions in maternal attentional availability may be more noticeable to young children and may therefore be reflected more strongly in maternal perceptions of children's affective experiences. This finding is in line with experimental research showing that interruptions due to smartphone use can temporarily reduce parental responsiveness and elicit increased bids for attention from young children, reflecting children's sensitivity to disruptions in caregiver availability [43]. Notably, Braune-Krickau et al [43] found that similar responses were observed following nondigital interruptions (ie, paper-and-pencil tasks), suggesting that the critical mechanism is not smartphone use itself but the temporary disruption of responsive parent-child interaction. This interpretation is consistent with developmental research using the still-face paradigm, which demonstrates that even brief interruptions in caregiver responsiveness evoke distress and attempts to reengage with the caregiver [44,45].

In addition to children's affect, we examined children's perceived fundamental need threat. Here, a different pattern emerged. On days when fathers reported higher-than-usual smartphone use in their child's presence, they also perceived greater threats to their child's needs (eg, belonging, meaningful existence, and control). This association was not observed for mothers and was not moderated by child age. One possible explanation is that fathers may be more likely to perceive the relational implications of their smartphone use (ie, children's threatened fundamental needs) than immediate changes in children's affect. While negative affect reflects observable emotional states, perceived need threat might represent a broader interpretation of the quality of the parent-child interaction. Importantly, perceived need threat was assessed immediately after smartphone use reports and explicitly framed as attributable to that use. The temporal proximity and explicit causal framing may activate self-evaluative processes, particularly in light of prevailing societal narratives that portray parental smartphone use as problematic. Under such conditions, fathers may infer need threat as a consequence of their behavior independent of observable changes in the child's affect. In contrast, children's positive and negative affect were assessed prior to smartphone use reports and were not explicitly framed as consequences of that use. This temporal and conceptual separation may therefore have reduced the likelihood that affect ratings were influenced by immediate reflections on fathers' own behavior.

At the between-person level, associations emerged between mothers' smartphone use and perceived threat to their child's fundamental needs, and between fathers' smartphone use and perceived child negative affect, particularly among young children. The differing patterns for mothers and fathers may reflect differences in caregiving roles and the contexts in which mothers and fathers use their smartphones. Given that mothers, on average, take over a larger share of daily caregiving [46,47], their habitual smartphone use may more frequently coincide with emotionally salient caregiving interactions. Over time, stable patterns of reduced availability may align more closely with displacement-based mechanisms, potentially shaping the relational climate of the dyad. This interpretation is consistent with research highlighting the central role of maternal interaction quality in children's emotional adjustment [18,48]. By contrast, the association with fathers' smartphone use was observed for children's negative affect rather than perceived need threat. One possible explanation is that negative affect may be more readily

XSL•FO
RenderX

observable than underlying threats to children's fundamental psychological needs.

Children's Age as a Moderator

An important finding of this study was that several associations between parental smartphone use and child emotional well-being were evident only among younger children. These findings suggest that child age represents an important developmental context that shapes parental perceptions of children's susceptibility to their smartphone use. This notion is consistent with previous research showing that the detrimental effects of parental smartphone use are particularly pronounced during early childhood [7,8]. One explanation is that younger children require more direct parental care, supervision, and emotional responsiveness than older children. During early childhood, parents remain children's primary source of emotional coregulation, social interaction, and need fulfillment. Consequently, temporary reductions in parental attentional availability due to smartphone use may be perceived by parents as particularly salient and disruptive for younger children. In contrast, as children grow older, they become increasingly autonomous, develop more advanced emotion regulation skills, and rely more heavily on peers than on parents for social interaction and support. Older children may therefore be better able to compensate for temporary reductions in parental attention, rendering them less susceptible to the immediate effects of parental smartphone use. Together, these findings suggest that displacement and technoference processes do not operate uniformly across development but are likely to be strongest during developmental periods characterized by greater dependence on parental attention and responsiveness.

Self-Report vs Device-Logged Smartphone Use

This study used 2 distinct operationalizations of smartphone behavior: contextualized self-reports of smartphone use in the child's presence and device-logged measures of overall smartphone use independent of context. Prior work suggests that parental smartphone use in the presence of a child—often framed in terms of technoference or parental phubbing—is inherently detrimental to children's well-being [12,30]. However, device-logged overall use was unrelated to child affect and perceived need threat. The divergent findings between self-reported and objectively device-logged smartphone use may reflect psychological appraisal processes: awareness of one's own smartphone use—regardless of the actual device-logged use—may increase the perception of its potentially harmful consequences for the child, thus leading to more negative ratings of child well-being. Further, greater overall smartphone use (as indexed by device-logged data) does not necessarily imply more frequent interruptions of emotionally salient parent-child interactions—particularly, given that it is not differentiated between the child being present or not. Consequently, total smartphone use may be a relatively poor proxy for the interactional processes through which smartphone use is hypothesized to affect children's well-being.

Gender differences further underscore the importance of measurement mode. Mothers reported higher smartphone use in their child's presence than fathers, whereas no gender differences emerged in device-logged overall use. This discrepancy suggests that mothers and fathers may use their smartphones for similar total durations, yet differ in the contextual cooccurrence of smartphone use and caregiving. Because mothers typically spend more time in direct interaction with children, their smartphone use may more frequently overlap with caregiving contexts and thus be more likely to be perceived as technoference. Moreover, stronger societal norms regarding maternal attentiveness may heighten mothers' sensitivity to perceive their smartphone use as "phubbing" behavior, contributing to stronger associations between self-reported use and perceived need threat. In line with this interpretation, parental phubbing has been linked to negative maternal emotions [10], consistent with guilt-based or norm-based self-evaluative processes.

Taken together, the findings indicate that the impact of parental smartphone use depends critically on how smartphone behavior is operationalized. Device logs provide objective indicators of overall use but lack contextual information about whether use occurred in the presence of the child. Self-reports capture relational context but also incorporate subjective interpretation and cultural meaning. Integrating both approaches is therefore essential for avoiding overgeneralized claims about the effects of parental smartphone use on children's affective well-being. Most importantly, future research should also integrate children's self-reports and independent observational indicators of affect to disentangle perceived from actual need threat and to more precisely assess the role of parental reporting biases. Incorporating interactional context and multi-informant data will be essential for clarifying when and for whom parental smartphone use meaningfully relates to children's well-being.

Limitations, Strengths, and Future Directions

Several limitations need to be considered, offering opportunities for future studies. First, the generalizability of our findings is limited by the characteristics of our sample. We included romantic parental couples in relatively stable relationships (ie, an average relationship duration of 10 years), which may not reflect the experiences of more diverse family structures or dynamics. Moreover, parents reported, on average, high levels of positive affect and low levels of negative affect in their children, indicating a generally high level of affective well-being. This restricted range likely reduced variability in key outcome measures, thereby limiting our ability to detect associations between parental smartphone use and children's affective responses. Importantly, children's high affective well-being—characterized by elevated positive affect and low negative affect—may function as a resilience factor, enabling them to cope more effectively with brief disruptions in parent-child interactions [49]. As a result, parental smartphone use may be less detrimental in this sample than suggested by previous research. In contrast, children growing up in more stressed family contexts or with lower baseline affective well-being may be more vulnerable to smartphone disruptions, potentially leading to stronger associations between parental smartphone use and child affect. Future studies should therefore examine whether similar patterns emerge in samples characterized by higher parental stress, greater relational strain, or lower child affective well-being.

XSL•FO
RenderX

Next, we did not directly assess whether parental smartphone use actually resulted in interruptions of parent-child interactions, nor whether smartphone use had immediate effects on children's positive or negative affect. Only perceived need threat was smartphone use explicitly assessed in direct relation to smartphone use in the presence of the child. Moreover, the device-logged measures reflect overall daily smartphone use rather than smartphone use specifically during interactions with the child. While higher overall usage increases the likelihood that smartphone use occurred in the child's presence, this approach introduces substantial measurement error and does not capture the quality, timing, or interactional context of smartphone use. This distinction is particularly important given that secondary distractions are a normative part of everyday parenting. Although parents are often judged for using their smartphones as a distraction, such use may be comparable to other routine interruptions, such as attending to household chores. As Knitter and Zemp [29] noted, it may therefore be critical to differentiate between parental smartphone use that occurs during quality parent-child interactions and smartphone use during more arbitrary moments. Without this differentiation, overall measures of smartphone use may conflate potentially disruptive "phubbing" with benign or unavoidable everyday distractions. Similarly, different smartphone activities are likely to vary in the extent to which they interfere with parent-child interaction. For example, passively scrolling through social media may reduce opportunities for responsive engagement more than engaging in a video call with family members in which the child can actively participate. Consequently, the absence of associations between device-logged smartphone use and children's well-being should not be interpreted as evidence that digitally traced smartphone use is unrelated to child well-being. Rather, it highlights the need for more context-sensitive assessments that distinguish between smartphone use occurring outside the child's presence, smartphone use during everyday shared activities, and smartphone use that disrupts emotionally salient parent-child interactions. Future research should therefore distinguish between different smartphone activities and their interactional context to better understand which forms of parental smartphone use are most relevant for children's emotional well-being. In addition, future studies could combine device-based smartphone logs with proximity-sensing technologies (eg, Bluetooth beacons), observational methods, or EMAs to capture not only the timing and duration of smartphone use but also its interactional context and its immediate implications for children's lived experiences.

Another limitation refers to our use of parental report instead of self-report. We acknowledge that children's self-reports are generally considered the preferred source for assessing subjective emotional well-being whenever developmentally appropriate [50]. However, parent-proxy reports are widely used in developmental and child psychology research, because parents are often the primary informants of children's emotional and behavioral functioning [50]. Therefore, our findings should be interpreted as reflecting parents' perceptions of their children's emotional well-being rather than children's subjective experiences. Consequently, we do not know how children themselves experienced their parents' smartphone use, as all measures of child well-being relied on parental reports. Future research should incorporate children's self-reported experiences to examine whether parental judgments accurately reflect children's subjective perceptions. To more precisely assess when and how parental smartphone use affects children, future studies could combine device-based smartphone logs with proximity-sensing technologies (eg, Bluetooth beacons), observational methods, or EMAs, allowing for a more fine-grained analysis of interactional context and children's lived experiences.

Another limitation of our study concerned the interpretation of the device-logged smartphone data. Although device logs provide an objective estimate of smartphone use and are not subject to recall bias, they do not provide information about the context in which smartphone use occurred, nor do they provide information on the reason for the smartphone use. The absence of associations between device-logged smartphone use and child well-being should therefore not be interpreted as evidence that objectively measured smartphone use is unrelated to children's well-being. Instead, this may indicate the need for more nuanced objective measures to distinguish between smartphone use that occurs outside the child's presence and smartphone use that takes place together with the child and is therefore not necessarily perceived as negative by the child.

A further limitation is that we relied on parents' adherence to the target-child instruction throughout the EMA period. Although reminders were provided before child-related questions, we were unable to independently verify whether parents consistently reported on the same child across all assessments. Therefore, some uncertainty remains regarding whether target-child switching may have influenced the results.

Finally, we did not assess parental characteristics, including neuroticism and psychological distress that may influence parental reports [51]. As these parental characteristics were not measured, we cannot determine the extent to which they influenced the observed associations. Future studies would benefit from including measures of parental psychological functioning alongside child self-reports of emotional well-being to provide a more comprehensive assessment.

Despite these limitations, this study contributes to the growing research on parental smartphone use around children by incorporating several key strengths. First, we included both mothers and fathers, addressing the persistent underrepresentation of fathers in prior research on parental smartphone use. This inclusion is particularly important given that our findings revealed differential associations for mothers and fathers, suggesting that parental smartphone use may play distinct roles within family dynamics and child-rearing contexts, with potentially different implications for children's well-being. Second, by integrating daily diary self-report data with device-logged data, this study provides both ecologically valid and more objective indicators of parental smartphone use. This multimethod approach reduces common-method bias and allows for a more robust examination of smartphone use across measurement modalities. Importantly, the daily diary design enabled the distinction between within-person (day-to-day fluctuations) and between-person (stable individual differences)

XSL•FO
RenderX

effects, offering a more nuanced understanding of how parental smartphone use relates to children's emotional well-being over time. Notably, the relatively limited evidence for negative effects of parental smartphone use on children's well-being—particularly at the between-person level—may be related to how parental smartphone use was operationalized in this study. Rather than framing smartphone use as inherently problematic through negatively connoted constructs such as phubbing or technoference, we adopted a neutral and descriptive approach that aimed to reflect the everyday digital context in which families live. This broader perspective may have captured a wider range of everyday smartphone behaviors than measures focusing exclusively on phubbing or technoference, thereby contributing to a more nuanced understanding of how parental smartphone use relates to children's well-being. At the same time, this approach aligns with our call for a more nuanced examination of parental smartphone use by allowing for a more fine-grained assessment of how routine smartphone use naturally occurs in family life and how it relates to different dimensions of children's well-being. Furthermore, we assessed multiple dimensions of child well-being, including positive affect, negative affect, and fundamental need threat. This comprehensive measurement approach allows for differentiation between distinct affective and psychological outcomes, highlighting that parental smartphone use may be more strongly related to certain aspects of children's well-being than others.

Finally, previous research investigating child age as a moderator of the association between parental smartphone use and child well-being is limited [6]. While the majority of studies have been conducted with younger children [6], evidence regarding whether younger children are indeed more susceptible to the effects of parental smartphone use remains scarce. Our inclusion of a broader child age range therefore represents a strength of this study, as it enabled us to examine age-related differences in these associations. However, the number of adolescents in our sample was relatively small. Future research should include larger samples of older children and adolescents to further investigate developmental differences in the effects of parental smartphone use. Practically, our findings suggest that parental smartphone use should not be viewed as inherently detrimental. Parents should not fear that any smartphone use in the presence of their child is inherently harmful. Rather, potential negative effects may arise from specific patterns of use, such as reduced responsiveness or interference with parent-child interactions. Our findings may help reduce parental guilt by highlighting that their smartphone use is not necessarily harmful in itself, particularly when in the presence of younger children. However, potential negative effects may arise when parental smartphone use repeatedly interferes with responsive parent-child interactions.

Conclusion

This study examined the association between parental smartphone use in the presence of the child and children's affective well-being using both parental self-reports and device-logged data. Taken together, our findings suggest that parental smartphone use is not uniformly or inherently detrimental to children's well-being. Stable differences between parents who, on average, use their smartphones more frequently around their children were largely unrelated to children's affective well-being, indicating that higher habitual smartphone use does not necessarily coincide with poorer child outcomes. In fact, our results point to a more nuanced, situational pattern: momentary increases in parental smartphone use were associated with less favorable child outcomes in some cases. This suggests that the impact of parental smartphone use may depend less on overall use in the child's presence and more on the timing and context of use within parent-child interactions, potentially shaped by psychological processes such as parental guilt. More broadly, these findings challenge prevailing narratives that portray parental smartphone use as categorically harmful. In line with calls for a more balanced and objective perspective [4,29], our results highlight the importance of moving beyond moralized framings of technology use in families. Smartphones are embedded in daily family life and serve both disruptive and facilitative functions. Understanding their role in parent-child relationships therefore requires approaches that acknowledge this complexity rather than assuming uniformly negative effects. In sum, advancing research on parental smartphone use will require a shift toward more nuanced, context-sensitive, and theoretically grounded perspectives that distinguish between habitual use and situational dynamics, and that better reflect the realities of contemporary family life.

Abstract

Background: An important strategy to decrease infant morbidity and mortality is timely initiation of breastfeeding (TIBF), which is defined as putting the newborn to the breast within 1 hour of delivery. Delayed initiation of breastfeeding may contribute to high neonatal and infant mortality in sub-Saharan Africa.

Objective: This study assessed the prevalence of TIBF and associated factors using recent Demographic and Health Survey data from 20 sub-Saharan African countries.

Methods: Using recent Demographic and Health Survey data from sub-Saharan African countries, a cross-sectional study was conducted. Data were accessed on January 27, 2026. The analysis included 177,988 children after application of sampling weights. The hierarchical structure of the data was taken into consideration by conducting a multilevel logistic regression analysis. Results were presented using adjusted odds ratios (AORs) with 95% CIs. To evaluate cluster-level variance, random-effects measures such as the median odds ratio and intraclass correlation coefficient were reported.

Results: Among 177,988 weighted samples, 59.05% (95% CI 58.82%-59.28%) initiated breastfeeding within 1 hour of birth. TIBF was more likely among rural residents (AOR 1.25, 95% CI 1.21 - 1.28), mothers with primary (AOR 1.48, 95% CI 1.45-1.52), secondary (AOR 1.22, 95% CI 1.19-1.26), and higher education (AOR 1.22, 95% CI 1.15-1.28), institutional delivery (AOR 1.40, 95% CI 1.36-1.43), multiparous (AOR 1.19, 95% CI 1.15-1.23), and grand multiparous mothers (AOR 1.10, 95% CI 1.05-1.14). Lower odds were observed among cesarean births (AOR 0.31, 95% CI 0.30-0.33), twin births (AOR 0.87, 95% CI 0.82-0.92), delayed antenatal care initiation (AOR 0.84, 95% CI 0.82-0.85), female children (AOR 0.90, 95% CI 0.88-0.91), and mothers with a history of child death (AOR 0.90, 95% CI 0.86-0.94).

Conclusions: TIBF remains suboptimal in sub-Saharan Africa and is influenced by maternal, obstetric, and health care factors. Enhancing antenatal counseling and postnatal breastfeeding support, particularly after cesarean delivery and among vulnerable groups, may improve timely initiation practices.

Introduction

Timely initiation of breastfeeding (TIBF) is defined as placing the newborn to the breast within the first hour of delivery. This practice is strongly recommended by the World Health Organization (WHO), as it plays a vital role in promoting optimal infant and young child feeding. This behavior is favorable for the provision of colostrum to the infant, which contains high concentrations of immunoglobulin and other bioactive constituents, including growth factors that are essential for optimal neonatal nutrition, growth, development, and the establishment of passive immunity [1,2]. During the first 6 months of life, breast milk is the primary and most appropriate source of nutrition for newborns. It should be initiated within the first hour after birth, ideally even before the placenta is delivered, in line with recommendations from the WHO [2-4]. TIBF has the following advantages for infants: it decreases upper respiratory tract infections, promotes the development of dentition, enhances cognitive development, and reduces childhood obesity [5]. TIBF helps to reduce the risk of postpartum hemorrhage by promoting uterine contraction and faster uterine involution, supports quicker physical recovery after delivery, and strengthens mother-infant bonding [3,5,6]. It stimulates breast milk production and helps transfer protective antibodies to the infant, strengthening early immunity. For mothers, it reduces the risk of postpartum hemorrhage and supports quicker uterine recovery. It also promotes emotional attachment and strengthens the mother-child bond [7].

The Baby-Friendly Hospital Initiative (BFHI), established by the WHO and United Nations Children's Fund (UNICEF) in 1991, developed a platform of 10 steps to improve maternal and neonatal care in health care institutions and promote optimal breastfeeding practices, including TIBF [8].

Worldwide, the magnitude of TIBF ranged from 17.7% to 98.4%, with an average magnitude of 57.6%. A global study demonstrated that an estimated 78 million newborns were not put to the breast within the first hour of delivery, based on a joint report by the UNICEF and the WHO [3,8]. A pooled analysis of Economic Community of West African States countries found that the magnitude of TIBF was 43%, highlighting notable differences in breastfeeding practices across the region [9].

Delayed initiation of breastfeeding (DIBF) is highly practiced, and reports have highlighted that it is linked with increased neonatal morbidity and mortality, particularly in low- and middle-income countries [10]. The 2019 mini-demography health survey of Ethiopia revealed that the prevalence of TIBF was 73.6% [11]. Evidence from sub-Saharan African countries from the 2013 Demographic and Health Survey (DHS) revealed that the prevalence of TIBF was 57% [12] and 34.7% [13], which were below the recommendations.

Maternal complications during pregnancy and cesarean delivery were associated with DIBF. Health facility deliveries that adhered to postnatal care protocols promoted TIBF among mothers [8,9,12]. Antenatal care attendance, having female infants, urban residence, multiparity, larger birth size, maternal unemployment status, and belonging to wealthier households were significantly associated with TIBF [9,11,12].

Although there are different recommendations by the WHO and UNICEF about the importance of TIBF within 1 hour, many newborns are not put to the breast within the recommended time [14]. Nowadays, different evidence demonstrates that TIBF reduces infant mortality by 22% [15]. Countries in sub-Saharan Africa had an infant mortality rate of 52 per 100 live births, which is higher than the global level, and this could be reduced by TIBF [12].

While the national policies and recommendations in Africa advocate and promote timely breastfeeding initiation, countries are not adhering to these recommendations [6,7,13,16]. There are other programs that promote TIBF in African countries, such as the national policy on infant and young child feeding, the WHO, and the Community-Integrated Management of Childhood Illness [2,17].

Reports from previous studies on the continent demonstrated that TIBF is complex and shaped by many factors, notably maternal sociodemographic characteristics like age, education, and residence, as well as use of maternal health services, including antenatal care visits and place of delivery [18].

Countries in sub-Saharan Africa continue to face high neonatal and infant mortality rates, and one contributing factor could be the DIBF after birth. There is a need to determine the updated pooled estimate level of TIBF and its key determinants at the continent level. Recent DHS data from 20 sub-Saharan countries can provide important information to estimate the magnitude and identify factors. Therefore, the aim of this study was to assess the prevalence of TIBF and to identify factors associated with this among women who delivered in the last 5 years preceding the survey in the selected countries, using data from the recent DHS.

Methods

Study Design and Setting

The study included 20 countries in sub-Saharan Africa that had recent Demographic and Health Survey data available. The countries were selected based on the availability of recent DHS datasets and included Angola, Burkina Faso, the Democratic Republic of the Congo, Côte d'Ivoire, Gabon, Ghana, The Gambia, Kenya, Liberia, Lesotho, Madagascar, Mali, Mauritania, Mozambique, Nigeria, Rwanda, Sierra Leone, Senegal, Tanzania, and Zambia.

Data Source and Extraction

We obtained the required authorization to access the dataset online after submitting a request for the data via the DHS online platform, accompanied by a detailed explanation of the study's objectives and research methodology. The data were accessed using the following login link [19].

Populations

The study population comprised children aged 6 to 59 months from 20 sub-Saharan African countries with available DHS data conducted between 2019 and 2024. We used the DHS Kids'

XSL•FO
RenderX

Recode files for the analysis. The countries included in the study, their respective regions, DHS survey periods, and sample sizes are presented in Table 1. Countries were eligible for inclusion if they had a DHS conducted from 2019 onward and the available dataset contained the variables required for the present analysis. Countries without an eligible DHS conducted during the study period, including those whose most recent DHS was conducted before 2019, were excluded.

Table . Countries, regions, Demographic and Health Survey periods, and sample sizes included in the analysis.

[a]DHS: Demographic and Health Surveys.

[b]Not applicable.

Sample Size Determination and Sampling Procedure

Sample Size Determination

The sample size for this study included all children who were born within the last 5 years preceding the survey and were documented in the dataset. After eliminating and adjusting for relevant variables and applying sampling weights, a total weighted sample of 177,988 was extracted and included in the analysis.

Sampling Procedure

The DHS used a stratified 2-stage sample design. Stratification was achieved by separating each of the countries' states and the Federal Capital Territory into urban and rural areas. Samples were selected independently in every stratum via a 2-stage selection. The first stage involved selecting sample points (clusters) consisting of enumeration areas. Enumeration areas were drawn with probability proportional to their size within each sampling stratum.

Variables of the Study

Dependent Variable

The primary outcome variable of the study is the magnitude of TIBF in 20 sub-Saharan African countries.

XSL•FO
RenderX

Independent Variables

These were categorized as individual-level factors and community-level factors, as described below:

- Individual-level factors: maternal age, educational level of the mother, media exposure (mass media and print), parity, wanted the last child, sex of household head, ever had died children, wanted pregnancy, getting permission to visit a medical health facility, transport cost, respondent's occupation.
- Health sector–related factors: mode of delivery (delivered by cesarean section or vaginal birth), ever had history of terminated pregnancy (abortion)
- Community-level factors: residence, distance from health facility, and wealth index

Operational Definition

TIBF

It was defined as the proportion of children aged 0 to 59 months who were put to the breast within the first hour of delivery [20].

Parity

This is the total number of live births that a woman has given birth to. It was classified as primiparous (1 birth), multiparous (2 - 5 births), and grand multiparous (>5 births), consistent with prior DHS analyses [21].

Media Exposure

If a woman reads, listens to, or watches mass media (radio, TV, and newspaper) at least once a week, she is considered to have media exposure [22].

Data Management, Processing, and Analysis Methods

Secondary data obtained from the DHS survey were used, and the extracted dataset was analyzed. The data were obtained from an online source. They were cleaned, recoded, and analyzed using Stata (version 17; StataCorp). In line with DHS survey recommendations, sampling weights were applied to adjust for sampling probabilities and nonresponse, ensuring nationally representative and statistically reliable estimates before analysis.

Bivariable logistic regression followed by multivariable logistic regression analyses was conducted. Variables with a *P* value less than .25 in the bivariable regression were considered for inclusion in the multivariable logistic regression model. Both crude odds ratios and adjusted odds ratios (AORs) with 95% CIs were calculated. Variables with *P* values less than .05 were considered statistically significant. Three models were constructed: Model I included individual-level variables, Model II included community-level variables, and Model III (final model) included both individual- and community-level variables simultaneously. Multicollinearity among independent variables was assessed using the variance inflation factor (VIF). A VIF value greater than 10 was considered evidence of multicollinearity. To obtain statistically valid regression coefficient estimates, clustering information was used.

A multilevel analysis was employed to account for both person-level and community-level predictors, with a random effect for variations between clusters. Model I included individual-level factors, Model II included community-level factors, and Model III included both individual- and community-level factors. The significance of the random intercept variation was assessed using the likelihood ratio test. Measures of variation for the random effect between clusters were determined using the intraclass correlation coefficient (ICC), proportional change in variance, and median odds ratio (MOR).

Ethical Considerations

Ethical approval for data collection was obtained from the relevant institutional review boards overseeing the DHS Program in each participating country. Permission to use the dataset was requested from the DHS Program, and approval was obtained. The institutional review board–approved procedures for DHS public-use datasets do not in any way allow respondents, households, or sample communities to be identified. There are no names of individuals or household addresses in the data files. This study analyzed publicly available, deidentified secondary data and was therefore exempt from further ethical review. All analyses were conducted in accordance with established ethical standards of the Declaration of Helsinki.

Results

Sociodemographic and Other Factors

A total of 177,988 weighted samples were extracted and included from the DHS Kids' Record dataset. The mean age of the respondents was 28.90 (95% CI 28.86 - 28.93) years. Among the study participants, 64,260 (36.1%) were from urban residences. The majority of households were male-headed (n=140,983, 79.21%), and regarding age distribution, 70.59% (n=125,642) of women were in the age group of 20 to 34 years. Concerning media exposure, more than half (n=90,233, 50.7%) had media exposure (Table 1).

The largest contribution to the pooled sample came from Nigeria (NG8), accounting for 12.66% (22,542/177,988) of the total population, with 14,106 late initiations and 8436 timely initiations. This was followed by the Democratic Republic of the Congo (CD8), which contributed 9.65% (17,173/177,988) of the sample, including 7387 late and 9786 timely initiations. In contrast, Lesotho (LS8) contributed the smallest proportion (1548/177,988, 0.87%) with 442 late initiations and 1106 timely initiations (Table 2).

The Magnitude of TIBF Among Sub-Saharan African Countries

The magnitude of TIBF was 59.05% (95% CI 58.82% - 59.28%) within 1 hour of delivery.

Factors Associated With the TIBF

All included individual- and community-level variables were candidates for multivariable logistic regression as they had a *P* value less than .25. Individual-level and community-level factors were entered into separate regression models initially, followed by a final model (Model III) in which both sets of factors were included simultaneously. The analysis identified several factors associated with the TIBF. In the final model (Model III), type of place of residence, sex of head of household, sex of the child, women's educational level, media exposure, respondents' occupation, respondents' age, place of delivery, getting permission to seek medical help, distance to a health facility, initiation of first antenatal care, parity, twin status of the child, delivery by cesarean section, and history of child death were significantly associated with TIBF (*P*<.05).

Mothers living in rural areas had higher odds of TIBF compared with urban residents (AOR 1.25, 95% CI 1.21 - 1.28). Maternal education showed a positive association, where women with primary education had 48% (AOR 1.48, 95% CI 1.45 - 1.52) compared to no education, secondary education has 22% (AOR 1.22, 95% CI 1.19 - 1.26), and higher education and above had 22% (AOR 1.22, 95% CI 1.15 - 1.28) more likely to initiate breastfeeding timely compared with women with no education. Mothers who delivered by cesarean section had reduced odds of TIBF (AOR 0.31, 95% CI 0.30 - 0.33). Similarly, mothers of twin births had significantly lower odds of TIBF compared with singleton births (AOR 0.87, 95% CI 0.82 - 0.92). Multiparous and grand multiparous mothers were more likely to timely initiate breastfeeding (AOR 1.19, 95% CI 1.15 - 1.23 and AOR 1.10, 95% CI 1.05 - 1.14, respectively). Mothers who initiated their first ANC visit late had lower odds of TIBF (AOR 0.84, 95% CI 0.82 - 0.85), while mothers who delivered at a health institution had higher odds of TIBF (AOR 1.40, 95% CI 1.36 - 1.43) (Table 3).

XSL•FO

Total	72,879	105,108	100

Random Effects and Model Comparisons

In the empty (null) model, the ICC revealed that variations between cluster areas accounted for 8.3% (ICC 0.083) of the overall variation in TIBF after delivery, while individual differences accounted for the remaining 91.7% of the variability (Table 4). In the null model, the odds of TIBF differed between higher- and lower-risk clusters by a factor of 1.68 (MOR 1.68).

Model fitness was assessed using the Akaike information criterion, Bayesian information criterion, and deviance statistics. The model with the lowest deviance value was considered the best-fitting model. Accordingly, the final model (Model III) had the lowest deviance (230,786.96) compared with the null model (236,767.84), Model I (231,114.1), and Model II (236,494.74), indicating better model fitness for identifying factors significantly associated with TIBF among children born within the 5 years preceding the DHS survey. Similarly, Model III had the lowest Akaike information criterion (230,833) and a relatively lower Bayesian information criterion (231,065.8) compared with the other fitted models.

In the final model (Model III), the cluster-level variation in TIBF remained at 8.3% (ICC 0.083), suggesting the presence of unobserved community-level factors influencing breastfeeding initiation practices. The MOR slightly decreased from 1.69 in Model I to 1.68 in Model III, indicating persistent but relatively stable cluster-level heterogeneity after controlling for both individual- and community-level factors. The proportional change in variance indicated that the variables included in the final model explained only a minimal proportion of the variation (−0.01%) in TIBF compared with the null model. In addition, the mean VIF (1.74) in Model III suggested no evidence of problematic multicollinearity among explanatory variables (Table 5).

Discussion

Pirncipal Findings

The analysis in these 20 sub-Saharan African countries showed that 59.05% (95% CI 58.82% - 59.28%) of children initiated breastfeeding within the first hour of delivery, indicating suboptimal TIBF. This finding was slightly higher than the pooled estimate of 58.3% reported from 35 sub-Saharan African countries between 2008 and 2019 [23]. This similarity could reflect persistent regional barriers, including inadequate breastfeeding counseling [24], limited access to maternal health care services [25], and sociocultural practices that delay timely breastfeeding initiation [26]. This increment might also be attributed to gradual improvements in maternal and child health services and breastfeeding promotion programs across the region, including BFHI programs, increased antenatal counseling, and expanded awareness campaigns emphasizing the importance of initiating breastfeeding within 1 hour of birth. These initiatives are known to improve mothers' knowledge and attitudes toward timely breastfeeding [8,16,17].

The finding from the analysis in the included countries revealed that the magnitude of TIBF is lower than that reported in studies conducted in many sub-Saharan African countries. Higher magnitudes were reported in Ethiopia (73.6% from Mini DHS 2019), Burundi (85%), Uganda (71.6%), Malawi (76.9%), and Mozambique (75.03%) [11,13,27-29]. This variation may be attributed to the inclusion of pooled data from 20 sub-Saharan African countries with differences in health care systems, socioeconomic contexts, and breastfeeding promotion strategies, which could influence the overall estimate. Conversely, findings from individual countries may reflect more favorable maternal health services and country-specific progress in breastfeeding practices [13,30]. Higher rates of TIBF in some countries could be attributed to better implementation of maternal health care services, particularly skilled birth attendance and institutional delivery care [8]. Effective integration of breastfeeding promotion into antenatal care and immediate postpartum support, particularly early skin-to-skin contact and adherence to BFHI guidelines, contributed to significant improvements in the initiation of breastfeeding within 1 hour of delivery [10,31]. In settings where health facilities provide consistent postpartum breastfeeding support within the first hour of birth, higher rates of TIBF have been reported, highlighting the importance of strengthening immediate postnatal care practices across health facilities [32].

Community-based health promotion activities may explain the differences. Countries with strong community health worker programs that deliver breastfeeding counseling after delivery tend to achieve a higher magnitude of TIBF [33,34]. In contrast, poor counseling quality, shortages of trained health professionals in breastfeeding counseling, and absence of postnatal care can delay its initiation.

In contrast, the magnitude in the current study is higher than that in Guinea (16.6%), Congo-Brazzaville (24%), and Chad (23%) [13]. Such variations have also been documented in previous sub-Saharan African analyses, which show substantial between-country differences in TIBF, largely due to disparities in maternal health care access, socioeconomic status, and cultural practices influencing newborn feeding behaviors. Differences in study design, sample size, and sociodemographic composition may also contribute to these inconsistencies [17,30].

In this study, women from rural residences had higher odds of TIBF (AOR 1.25) compared with their counterparts. The higher odds of timely breastfeeding initiation among rural women may be attributed to urban health facilities, which may also have greater formula exposure and weaker adherence to Baby-Friendly practices. In addition, urban mothers are more

XSL•FO
RenderX

likely to be influenced by modern feeding beliefs, face employment-related constraints, and experience inconsistent breastfeeding counseling despite better access to health services [17].

The present study findings reported that women with higher educational levels were more likely to initiate breastfeeding in a timely manner. This is supported by evidence from Ethiopia Demographic and Health Survey analyses, which show that mothers with secondary or higher education have significantly increased odds of timely breastfeeding initiation compared with uneducated women [25].

Women with media exposure demonstrated significantly decreased odds of TIBF in the current study. This finding is inconsistent with the study conducted in pooled sub-Saharan African countries using DHS data, which identified media exposure as a strong enabler of early initiation of breastfeeding [9,13]. This inconsistency may be due to differences in the type of media content accessed in the study setting, where exposure may include formula marketing or mixed infant feeding messages that discourage immediate breastfeeding. In contrast, in settings covered by DHS analyses, mass media often delivers coordinated public health campaigns promoting TIBF. Variations in media regulation and the effectiveness of breastfeeding promotion messages may therefore explain the differing associations [35].

Age of the mother was also a significant factor in TIBF. Women aged 20 to 34 years and 35 to 49 years had higher odds (AOR 1.07 and 1.26, respectively) compared with those aged 15 to 19 years, indicating an age-related disparity in TIBF. The possible reason for this is that young women could have relatively poor knowledge of the importance of timely breastfeeding and may not have received antenatal care or institutional delivery, which have a direct or indirect effect on TIBF [36]. This finding is similar to that of a study conducted in Nigeria [37]. Additionally, older women, particularly multiparous mothers, may rely on previous childbirth experience and perceived knowledge, which may positively influence TIBF. However, this pattern contrasts with studies reporting that younger mothers demonstrate higher timely breastfeeding behavior, possibly due to targeted maternal health programs, perceived vulnerability, and stronger exposure to health promotion messages [38].

Women who reported difficulty obtaining permission to seek medical care had lower odds of TIBF. This may be because restricted autonomy limits access to antenatal care, institutional delivery, and postnatal breastfeeding counseling, all of which positively influence timely breastfeeding initiation.

Women who delivered in health facilities were more likely to initiate breastfeeding timely than those who delivered at home. This finding is consistent with a study conducted in Ethiopia [39], which reported that institutionally delivered women had about 2 times higher odds of TIBF. This may be because health facility delivery provides access to skilled birth attendants, immediate breastfeeding counseling, and postpartum support, including early skin-to-skin contact, which facilitates breastfeeding within the first hour after birth [40].

The findings of this study indicated that multiparous and grand multiparous women were more likely to initiate breastfeeding within 1 hour of delivery compared with nulliparous mothers. This may be because first-time mothers often have limited experience and knowledge regarding breastfeeding, may feel uncertain about proper positioning of the baby, lack confidence to initiate breastfeeding immediately after birth, and require more guidance on breastfeeding techniques. They also experience stress and anxiety during labor and can delay skin-to-skin contact and breastfeeding initiation within the recommended hour. Nulliparous women may rely heavily on family advice, which is not always supportive of immediate breastfeeding. Elders may prioritize other newborn practices before breastfeeding, and misconceptions about colostrum may delay initiation of breastfeeding. This evidence is similar to that from studies conducted in Nepal, Bangladesh [41], Ghana, and Ethiopia [13]. This similar report could be because of the similarity in cultural perceptions and sociodemographic factors.

In this study, twin children had DIBF compared with singletons. This is because twin pregnancies are more likely to have preterm birth, low birth weight, and high fetal complications, more likely to have an elective cesarean section. These mentioned unfavorable outcomes lead for the DIBF [42,43].

Employed women had lower odds of TIBF compared with unemployed women. This may be related to work-related stress, fatigue, and competing responsibilities, which may reduce preparedness for immediate breastfeeding. Employed mothers may also be more exposed to formula-feeding alternatives and concerns about balancing breastfeeding with future work demands.

Women with a history of child death had lower odds of TIBF. This may reflect previous adverse birth experiences, maternal psychological distress, or underlying health and socioeconomic vulnerabilities that negatively influence maternal care practices, including timely breastfeeding initiation.

Limitations

Some subnational areas had relatively small sample sizes, requiring cautious interpretation of findings. As a secondary analysis of DHS data, important factors such as cultural beliefs, psychosocial influences, partner preferences, and qualitative maternal perspectives were unavailable. In addition, breastfeeding initiation was self-reported for births occurring within the 5 years preceding the survey, which may introduce recall bias. Finally, the cross-sectional nature of the data limits causal inference between explanatory variables and TIBF.

Conclusion and Recommendations

The TIBF according to the DHS survey in sub-Saharan African countries remains suboptimal. Although this reflects a modest improvement compared with previous surveys, it demonstrates inconsistent national progress toward global breastfeeding targets recommended by the WHO and United Nations Children's Fund. Individual-level and community-level factors were regressed together in the final model, and place of residence, women's educational level, media exposure, wealth index, age of the respondent, mode of delivery, wanted child,

XSL•FO
RenderX

getting permission to go to a health facility, parity, and type of pregnancy were significantly associated with TIBF.

The substantial cluster-level variation suggests the influence of contextual and health system factors. Strengthening implementation of the BFHI, improving access to skilled delivery and postnatal counseling, particularly in rural areas, and promoting maternal education and social protection mechanisms are critical to enhancing timely breastfeeding practices in the country.

Rural-urban disparities highlight the need for expanded access to skilled birth attendance, quality antenatal counseling, and timely postnatal support in rural settings.

Educational and socioeconomic disparities observed in this study suggest that policies promoting female education, male partner involvement, media-based health promotion, and financial risk protection (including health insurance coverage) may enhance timely initiation practices. Strengthening family planning services may further contribute by reducing unintended pregnancies, which were associated with DIBF.

Acknowledgments

We would like to thank the Demographic and Health Surveys Program, which provided us with the dataset and allowed us to use it for this research. ChatGPT (GPT-5.6 Luna; OpenAI) and Grammarly were used to assist with language editing, grammar, and improving the clarity and readability of the manuscript. The authors reviewed and verified all suggested edits and remain fully responsible for the accuracy, integrity, and final content of the manuscript.

Funding

All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

The data used in this study are from the Demographic and Health Surveys (DHS) Program. DHS data are publicly available upon reasonable request and approval from the DHS Program. The datasets analyzed during the current study are available from the DHS Program data repository [44] after registration and submission of a data access request. Due to data use restrictions, the datasets cannot be shared publicly by the authors. Information generated or analyzed during this research is included in the main manuscript for publication, and if further information is needed, it could be available upon request from the corresponding author.

Authors' Contributions

TDK conceptualized the study, conducted data extraction and statistical analysis, and drafted the Methods and Results sections. GG, MDB, AAA, and AAE contributed to data extraction, data analysis, and manuscript editing. TS, MG, and MS contributed to writing the Background section of the manuscript. MGM and DME drafted the Discussion section. TWW and AAM critically reviewed and edited the manuscript. All authors read and approved the final manuscript.

Abstract

Background: AI-enabled chatbots and related conversational systems can facilitate human–computer interaction through natural language, personalization, and automated support. In pediatric health promotion, these tools have the potential to provide scalable and flexible approaches to support physical activity (PA) and related lifestyle behavior change within family contexts. However, evidence regarding AI and chatbot-supported interventions for PA and obesity-related lifestyle behaviors among children and adolescents remains limited, and the extent to which these interventions involve parents, caregivers, or families has not been clearly characterized.

Objective: This scoping review aimed to provide an up-to-date overview of how AI and chatbot-supported interventions are designed, delivered, and evaluated for PA and obesity-related lifestyle behaviors among children and adolescents, with attention to technology characteristics, family involvement, delivery platforms, outcomes, and research gaps.

Methods: In accordance with PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guideline, 7 databases (PubMed, Web of Science, APA PsycINFO, Academic Search Complete, CINAHL Ultimate, IEEE Xplore, and Scopus) were searched through February 2026. Two reviewers independently conducted title and abstract screening, followed by full-text screening in Rayyan (Qatar Computing Research Institute). Eligible studies involved children, adolescents, or families; evaluated an AI-enabled chatbot, conversational agent, or related digital system; and addressed PA, exercise, sedentary behavior, screen time, obesity, overweight, or weight management. Diet, sleep, and other lifestyle outcomes were extracted when reported within otherwise eligible studies. Data were extracted and synthesized narratively in accordance with research objectives.

Results: Of 2730 records identified, 14 studies met inclusion criteria. Most were published in 2023 or later (n=12, 85.7%) and spanned 10 countries. Mobile app delivery was most common (n=9, 64.3%). AI approaches included rule-based chatbots, hybrid personalization systems, generative AI, and single studies using recommender systems or computer vision. A total of 10 studies (71.4%) included a specific parent, caregiver, or family component. Common intervention features were personalized feedback (n=10, 71.4%), self-monitoring (n=9, 64.3%), and education (n=9, 64.3%). PA was the most common target behavior, often within broader obesity or healthy lifestyle interventions. Among 8 studies reporting direct PA or fitness outcomes, 4 showed significant improvement, 2 found no significant change, and 2 reported mixed or indirect findings. Feasibility, acceptability, usability, and engagement findings were generally favorable across studies, but cultural tailoring was reported in only one study.

Conclusions: AI and chatbot-supported interventions for pediatric PA and obesity-related lifestyle behaviors represent a rapidly emerging but still early-stage field. Family involvement varies considerably across interventions and should be more clearly conceptualized and evaluated in future studies.

Introduction

Childhood physical inactivity (PA) and obesity are persistent, high-impact challenges across the life course and often cluster within families through shared environments, routines, and resources [1]. World Health Organization (WHO) guidelines recommend that children and adolescents accumulate an average of at least 60 minutes per day of moderate-to-vigorous PA, while also reducing sedentary time [2]. Yet recent global surveillance indicates that PA levels remain low across childhood and adolescence. Global Matrix 4.0 data from 57 countries suggest that only about 27%-33% of children and adolescents aged 5-17 years meet recommended activity levels [3], and the WHO reports that 81% of adolescents aged 11-17 years are insufficiently active worldwide [4].

Pediatric overweight and obesity also represent a growing global public health challenge. In 2022, more than 390 million children and adolescents aged 5-19 years worldwide were living with overweight, including more than 160 million living with obesity. The prevalence of overweight, including obesity, among children and adolescents aged 5 - 19 years increased from 8% in 1990 to 20% in 2022, while the prevalence of obesity alone increased from 2% to 8% [5]. Important regional differences are also evident. Latin America and the Caribbean, the Middle East and North Africa, and North America have among the highest prevalence of overweight, while the largest numbers of affected children and adolescents are concentrated in East Asia and the Pacific, Latin America and the Caribbean, and South Asia [6]. These patterns reflect broader behavioral, environmental, and structural determinants of health and reinforce the need for accessible and scalable approaches to support healthy behaviors among children, adolescents, and families [1].

Families play a central role in shaping children's health behaviors [7]. Caregivers influence opportunities for PA through role modeling, encouragement, co-participation, transportation, and the organization of routines [8]. Therefore, family-based approaches are widely recognized as an important strategy for supporting healthy lifestyle behaviors and pediatric obesity prevention and treatment [7]. At the same time, participation in intensive family-based programs can be difficult to sustain because of barriers such as cost, scheduling demands, transportation, workforce limitations, and unequal access to care [7]. These challenges are particularly relevant for underserved families and have increased interest in more flexible and scalable approaches to family-centered behavior change support.

Digital health and mHealth have rapidly expanded as a delivery channel for behavior change interventions, supported by widespread mobile device access and increasing interest from health systems in scalable, low-cost approaches [9,10]. Within this broader digital health landscape, conversational tools such as chatbots and virtual agents represent one emerging delivery format that may support health promotion through interactive communication, tailored prompts, and ongoing engagement [9,10]. However, for pediatric PA and relevant lifestyle behaviors, the literature remains scattered across diverse populations, platforms, intervention designs, and outcomes.

AI has further expanded the potential of digital health interventions for children and families by enabling more tailored, interactive, and responsive (ie, real-time) support [11,12]. In contrast to static digital content, AI-enabled systems such as chatbots and conversational agents may help deliver intervention components based on user input, preferences, or real-time data [13]. In pediatric lifestyle interventions, these features may be especially relevant because children's PA and related behaviors are shaped by changing routines, developmental needs, and family context [12]. However, the evidence base remains fragmented across platforms, target behaviors, and outcome measurement strategies [14].

Despite growing interest in AI-enabled digital health tools, few studies have synthesized the current evidence on AI and chatbot-supported interventions for pediatric PA and obesity-related lifestyle behaviors while examining the extent and nature of family involvement [10,12,13]. Previous reviews have examined conversational agents in health care broadly, chatbot-supported lifestyle interventions across age groups, or the feasibility and acceptability of chatbots for nutrition and PA promotion among adolescents [10,12,13]. However, these reviews often aggregate adult and pediatric populations, emphasize individual-level interventions, or examine digital health more broadly without distinguishing AI-driven systems from traditional mobile apps [10,12]. Moreover, family engagement within digital interventions is inconsistently conceptualized and operationalized, ranging from passive caregiver monitoring to active, dyadic, or multigenerational participation [12]. Questions also remain regarding cultural responsiveness, equity considerations, accessibility for underserved families, and safeguards related to data privacy, algorithmic bias, transparency, and accountability [12]. To address these gaps, the present review focuses specifically on AI and chatbot-supported interventions for pediatric PA and related lifestyle behaviors, with particular attention to family engagement, technology characteristics, cultural tailoring, and implementation gaps.

Given the rapid evolution of AI technologies and the heterogeneity of study designs, including pilot feasibility trials, randomized controlled trials, and early-stage implementation studies, a scoping review is warranted. Thus, the objective of this scoping review was to map and characterize AI and chatbot-supported interventions targeting pediatric PA and obesity-related lifestyle behaviors. Priority areas of focus are (1) technology type and AI features, (2) delivery platforms and intervention components, (3) definition and operationalization of family engagement, (4) cultural tailoring and bilingual delivery strategies, and (5) the characteristics of the existing evidence base, including study designs, outcomes, and gaps to inform future research and equitable implementation.

Methods

Study Design

A formal review protocol was not prospectively registered. Before screening began, the research team developed the review objectives, eligibility criteria, search strategy, screening procedures, and standardized data-extraction form. The complete

XSL•FO
RenderX

database search strategies are provided in Multimedia Appendix 1, and the completed PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist is provided in Checklist 1 [15]. The review aimed to map and synthesize the existing literature on AI and chatbot-supported interventions targeting pediatric PA and obesity-related lifestyle behaviors, with particular attention to the extent and nature of family involvement.

Search Strategy

Information Sources

A comprehensive literature search was conducted across 7 electronic databases, including PubMed, Web of Science, APA PsycINFO, Academic Search Complete, CINAHL Ultimate, IEEE Xplore, and Scopus. The final search was performed on February 8, 2026. Searches were limited to English-language peer-reviewed publications published within the past 10 years. This timeframe was selected to capture contemporary AI-enabled and chatbot-supported technologies relevant to current practice, given the rapid evolution of conversational-agent platforms, natural language processing, adaptive personalization, wearable integration, and generative AI. Earlier digital interventions may be less comparable with the systems currently used in pediatric health promotion. The search was limited to peer-reviewed publications indexed in the selected databases. A formal gray-literature search and supplementary backward or forward citation tracking were not conducted.

Search Terms

Search strategies were developed to capture three primary domains: (1) AI-enabled conversational technologies, (2) PA and obesity-related outcomes, and (3) child and family populations. Terms for AI technologies included chatbot*, chat bot*, conversational agent*, virtual agent*, relational agent*, virtual assistant*, AI coach*, ChatGPT (OpenAI), large language model*, LLM*, and generative AI. Health-related terms included physical activity*, exercise*, obese*, obesity, overweight, weight management, obesity prevention, sedentary, and screen. Population terms included child*, adolescent*, youth, teen*, pediatric*, family*, parent*, caregiver*, family-based, and parent-based. Database-specific syntax adjustments were applied as needed, including title and abstract field restrictions and wildcard limits. The detailed search history was provided in supplementary material (Multimedia Appendix 1).

Review articles, systematic reviews, scoping reviews, and meta-analyses were excluded during the search process where possible using database filters.

Eligibility Criteria

Eligibility criteria were guided by the population, intervention, comparator, outcomes, and study design (PICOS) framework. Studies were included if they: (P) involved children or adolescents aged 0 - 18 years or parents, caregivers, or families supporting the health behaviors of a child or adolescent within this age range; (I) evaluated an AI-enabled chatbot, conversational agent, or related digital system designed to support PA or obesity-related lifestyle behaviors; (C) included any comparator, such as usual care or an alternative intervention, or no comparator; (O) reported outcomes related to PA or exercise, sedentary behavior or screen time, obesity, overweight, or weight management; and (S) reported empirical quantitative, qualitative, or mixed methods findings.

Studies were eligible if they involved children or adolescents or parents, caregivers, or families supporting the health behaviors of children or adolescents. Direct parent or caregiver involvement was not required because family involvement was examined as an analytic dimension rather than an eligibility criterion.

Studies were excluded if they described general digital health tools without an automated conversational, chatbot, AI-enabled, adaptive, or personalized support component, were purely technical development papers without behavioral outcomes, or were nonempirical publications such as editorials, commentaries, protocols, or review articles. Only studies published in English were included.

Study Selection

All retrieved records were imported into Rayyan (Qatar Computing Research Institute), a web-based systematic review management platform [16]. Rayyan was used to manage records, identify potential duplicates, and support blinded title and abstract screening. Potential duplicates identified through bibliographic metadata were manually reviewed and confirmed before removal. Final eligibility decisions were made by the reviewers rather than by the software. Title and abstract screening were conducted independently by 2 reviewers (DP and SA), who were blinded to each other's decisions during the initial screening phase. At this stage, records were excluded if they were clearly unrelated to pediatric, adolescent, or family populations; did not involve AI-enabled chatbots, conversational agents, or related automated digital systems; did not address PA, obesity, sedentary behavior, weight management, or related lifestyle behaviors; or were clearly nonempirical publications. Records were retained for full-text review when eligibility could not be determined from the title and abstract alone. Full-text screening was then conducted independently by 2 reviewers (DP and SA) using the complete eligibility criteria. At this stage, specific reasons for exclusion were recorded. Articles were excluded during full-text review if they did not report PA or related lifestyle outcomes, did not include children, adolescents, parents, caregivers, or families, did not include an AI-enabled or chatbot-supported intervention component, or provided insufficient information to determine eligibility. Disagreements were resolved through discussion, and unresolved disagreements were adjudicated by a third reviewer (QJ). Interrater reliability was assessed using Cohen kappa (κ=0.81).

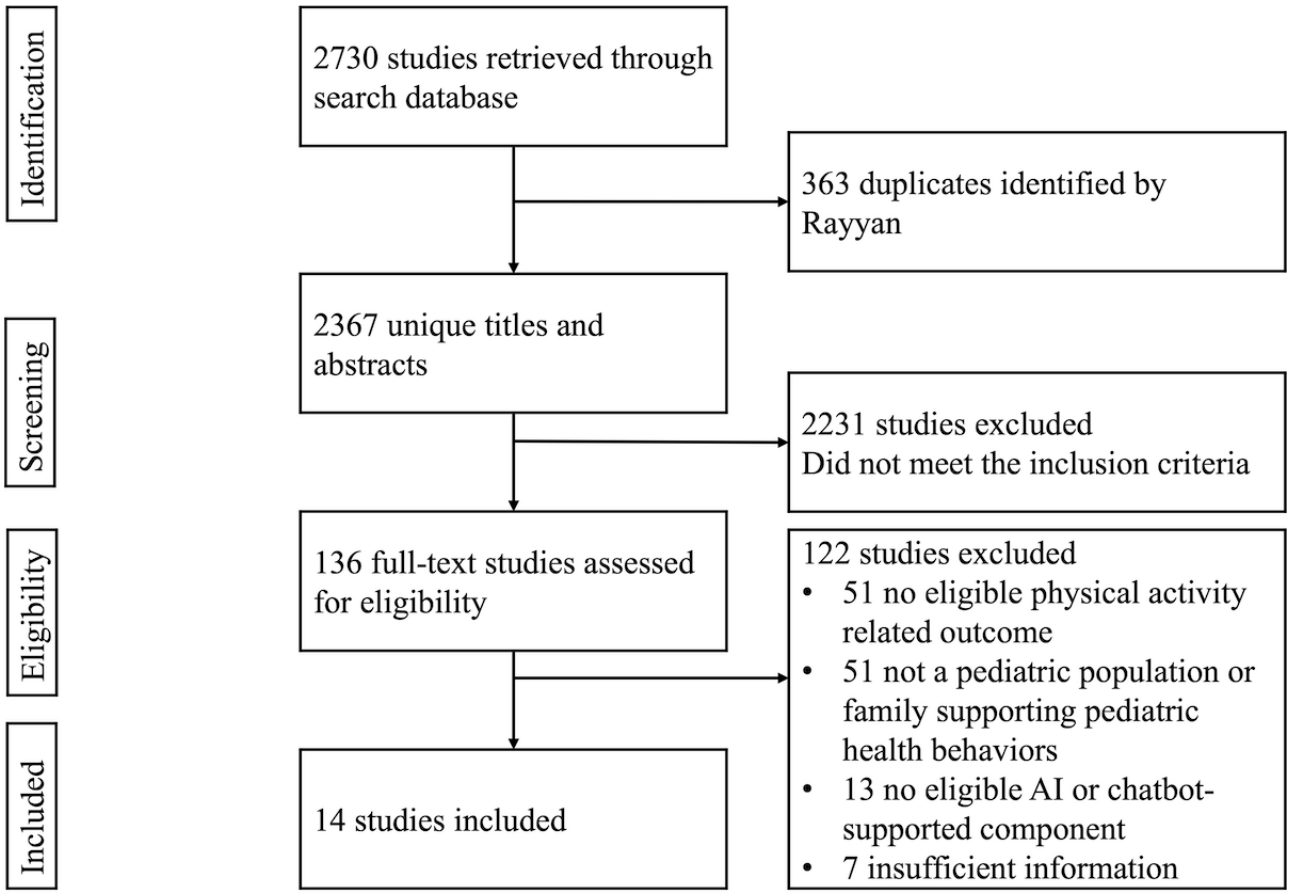
Data Extraction and Synthesis

Data were extracted using a standardized form developed for this review. Extracted variables included publication and study characteristics (author, year, country, design, and sample size); participant characteristics (target population, age, sex, and family involvement); intervention characteristics (intervention type, delivery platform, duration, comparator, wearable or sensor

XSL•FO
RenderX

use, and behavior change components); AI-related features (AI or automation role, intervention system or platform, reported AI technique or automation logic, input data type, and AI tasks or outputs); theoretical foundations; and reported outcomes, including feasibility, acceptability, usability, engagement, PA, and related lifestyle outcomes, secondary outcomes, and key findings. Extracted data were synthesized narratively to characterize the scope of the evidence and identify patterns across study design, intervention delivery, AI functionality, family engagement, and outcomes.

Critical Appraisal



A formal critical appraisal or methodological quality assessment was not conducted. The purpose of this scoping review was to map the characteristics, applications, and gaps within an emerging and heterogeneous evidence base rather than to assess the certainty of evidence or estimate pooled intervention effects.

Results

Overview

Figure 1 presents the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. The initial database search identified 2730 records. After removing 363 duplicate records, 2367 unique articles remained for title and abstract screening. Of these, 2231 were excluded because they were clearly outside the review scope. A total of 136 full-text articles were assessed for eligibility. During full-text review, 122 articles were excluded for the following primary reasons: no PA or related lifestyle outcome, not child-, adolescent-, parent-, caregiver-, or family-focused, no AI-enabled or chatbot-supported component, or insufficient information to determine eligibility. Ultimately, 14 studies met the inclusion criteria and were included in the final sample (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for study selection process.

Study Overview

A total of 14 original studies were included in this scoping review [17-30] (Table 1). The studies were published between 2021 and 2026, with 12 of the 14 published in 2023 or later. The 14 studies were conducted across 10 countries. The United States and South Korea were the most frequently represented settings (n=3 each), followed by one study each from Turkey, Spain, Italy, the United Kingdom, Belgium, Switzerland, Greece, and Canada. Although the included studies were geographically diverse, all were conducted in middle- or high-income contexts.

XSL•FO
RenderX

Table . Characteristics of included studies.

Study and year	Country	Study design	Sample size
Aydemir (2025) [17]	Turkey	Pre-post feasibility study with intervention and control groups	26 parent-child dyads (13 intervention and 13 control)
de Arriba Muñoz et al (2026) [18]	Spain	Prospective single-arm observational pre-post study	40 families or pediatric patients
Emerson et al (2026) [30]	United States	Three-phase qualitative adaptation study	22 total (phase 1: n=6; phase 2: n=4; phase 3: n=12)
Heerman et al (2024) [19]	United States	Multicenter randomized clinical trial	900 parent-infant pairs
Larizza et al (2023) [22]	Italy	App development+pilot usability or acceptability study	13 children
Moore et al (2024) [23]	United Kingdom	Co-design study with mixed methods evaluation	9 co-design participants; 46 evaluation participants
Oh et al (2022) [24]	South Korea	Randomized controlled trial	24 adolescents
Peuters et al (2024) [25]	Belgium	Quasi-randomized controlled trial+process evaluation interviews	279 adolescents; interviews n=13
Stasinaki et al (2021) [26]	Switzerland	Randomized controlled trial	41 recruited; analysis n=31 at baseline after exclusions or dropout
Tan et al (2026) [27]	United States	Single-arm pilot feasibility study	172
Zarkogianni et al (2023) [29]	Greece	Feasibility pilot trial	50 children
Kim et al (2025) [20]	South Korea	User-centered design or development and usability study	Needs survey n=96; interviews n=30; UI usability n=76
Kang et al (2026) [21]	South Korea	Descriptive comparative cross-sectional survey study	160 total (80 childhood or adolescent cancer survivors >80 parents)
Willms and Liu (2024) [28]	Canada	Autoethnographic feasibility case study or development paper	No human participants; content development case study

Among included studies, 3 studies were randomized controlled trials [19,24,26], one was quasi-randomized [25], one was a pre-post feasibility study with a comparison group [17], and 3 were single-arm or uncontrolled pilot or pre-post studies [18,22,27]. The remaining 6 were noneffectiveness-focused designs, including one qualitative adaptation study [30], one co-design mixed methods study [23], 2 development or usability studies [20,28], one cross-sectional survey [21], and one autoethnographic feasibility or development paper [29]. Sample sizes ranged from 9 to 900 participants, with most studies enrolling relatively small samples; only one large, randomized trial included more than 500 participants [19].

Participant and Family Characteristics

The 14 studies targeted a broad range of pediatric populations, including infants, school-aged children, and adolescents (Table 2). Most studies focused on school-aged children or adolescents, whereas one large trial focused on infants from birth to 24 months [19]. Several studies targeted specific clinical or high-need populations, including youth with autism spectrum disorder (n=2) [17,30], children or adolescents with obesity or overweight (n=5) [18,22,24,26,29], childhood or adolescent cancer survivors (n=1) [21], and adolescents facing barriers to PA or living in under-resourced settings (n=2) [23,27].

XSL•FO
RenderX

Table . Participant and family characteristics of included studies.

Study and Year	Target population or unit of Intervention	Population characteristics or special group	Child age	Parent age	Sex (female), n (%)	Language	Cultural tailoring
Aydemir (2025) [17]	Parent-child dyads	Children with autism spectrum disorder (ASD)	• Intervention: mean 14.38 (SD 3.06) • Control: mean 13.92 (SD 3.52)	• Intervention: mean 42.84 (SD 7.70) • Control: mean 44.07 (SD 7.95)	• Children: intervention 6/13 (46%), control 8/13 (62%) • Parents: intervention 5/13 (38%), control 4/13 (31%)	Likely Turkish / ChatGPT (OpenAI)-supported text prompts	NR[a]
de Arriba Muñoz et al (2026) [18]	Family (caregiver+ child or adolescent)	Children or adolescents with obesity receiving GLP-1[b] therapy	• Mean 14.05 (SD 1.04) years	NR	• 25/40 (62.5%)	Spanish	NR
Emerson et al (2026) [30]	Youth with ASD and caregivers; providers or therapists	Youth with autism spectrum disorder at risk of obesity	• Youth with ASD; exact ages not reported in abstract	NR	• NR	English	NR
Heerman et al (2024) [19]	Parent-child dyads	Infants from racially and ethnically diverse US families	• Birth-24 months follow-up	Adults ≥18 years	• Children: intervention: 243/449 (54.1%) • Control: 233/451 (51.7%) female	English and Spanish	Yes; all content translated into Spanish and assessed for cultural appropriateness
Larizza et al (2023) [22]	Child and parent	Children with obesity	• Age: 6 - 12 years • Mean 9.3 (SD 1.3) years	NR	• 5/13 (38.5%)	Italian context	NR
Moore et al (2024) [23]	Adolescents	Adolescents facing barriers to physical activity	• 11 - 13 years (co-design) • Adolescents in evaluation	NR	• Co-design group 5/9 (56%)	English	Personalization emphasized; no cultural tailoring reported
Oh et al (2022) [24]	Adolescents	Adolescents with obesity	• 10 - 17 years • Mean 13.2 (SD 3.6)	NR	• 4/24 (16.7%)	Korean context	NR

XSL•FO
RenderX

Study and Year	Target population or unit of Intervention	Population characteristics or special group	Child age	Parent age	Sex (female), n (%)	Language	Cultural tailoring
Peuters et al (2024) [25]	Adolescents	General population adolescents aged 12 - 15 during COVID-19 restrictions	• 12 - 15 years	NR	• NR	Dutch	Human-centered development; no explicit cultural tailoring
Stasinaki et al (2021) [26]	Youth or adolescents	Youth with overweight or obesity receiving specialist obesity care	• 10 - 18 years • Median baseline age 13.6 years (range 10.9 - 16.9)	NR	• 13/31 (41.9%)	German/Swiss context	NR
Tan et al (2026) [27]	Children or adolescents	Primarily sixth-grade students in socioeconomically disadvantaged schools	• Mostly 12 years • Range 11 - 15 years	NR	• 96/172 (55.8%)	English	NR
Zarkogianni et al (2023) [29]	Child and parent	Overweight or obese children	• Mean 10.5 (SD 2.00) years	NR	• 26/50 (52%)	Greek context	NR
Kim et al (2025) [20]	Adolescents + parents + school health teachers	Middle school adolescents in school-based health management context	• First-year middle school students or adolescents	Range 30 - 59 years	• Students 23/36 (65%) • Parents 25/40 (83%) • Teachers 30/30 (100%)	Korean	Designed for Korean school context
Kang et al (2026) [21]	Childhood or adolescent cancer survivors and parents	Childhood or adolescent cancer survivors (aged 10 - 16 years) recruited via the Korean Pediatric Cancer Foundation; survivor-parent perspectives	• Mean 12.1 (SD 2.0) years • Eligibility 10 - 16 years	Mean 44.7 (SD 4.2) years	• CACSs[c] 41/80 (51.2%); • Parent respondents 76/80 (95.0%)	Korean	South Korean childhood cancer survivorship context; no explicit cultural tailoring intervention because no chatbot program was deployed
Willms and Liu (2024) [28]	Parents supporting child physical activity (intended target)	Family-based PA[d] content development for children aged 8 - 12 and parents	• Intended target: children 8 - 12 years	NR	• NR	English	NR

[a]NR: not reported.

[b]GLP-1: glucagon-like peptide-1.

[c]CACS: childhood or adolescent cancer survivor.

[d]PA: physical activity.

XSL•FO
RenderX

Ten [17-21,25,26,28-30] of the 14 studies included a parent, caregiver, or family component in the target population or intervention design, such as parent-child dyads, family-based obesity management, or studies collecting both child and caregiver perspectives. The remaining 4 [22-24,27] were primarily youth-focused, although family influence was acknowledged as an important contextual factor. The degree of family involvement varied considerably, ranging from minimal parental support or consent to parent-mediated delivery, co-participation in activities, shared monitoring, and parent-facing intervention interfaces.

Reporting of demographic and contextual characteristics was inconsistent. Child age was available in all 14 studies. While parents' age was reported in only 4 studies [17,19-21]. Female participation or sex distribution was reported in 11 studies [17-24,26,27,29]. Among studies reporting child sex distribution, the proportion of female participants ranged from 16.7% to 65.0% [20,24]. Language or linguistic context could be identified in all 14 studies. However, cultural tailoring was reported in only one study [19], and 4 additional studies [20,21,23,30] described some form of contextual, linguistic, developmental, or population-specific tailoring.

Intervention Design and Delivery Characteristics

Intervention design and delivery characteristics were presented in Table 3. Mobile app– or smartphone-based delivery was the most common format, appearing in 9 studies [17-19,22,24-27,29]. Six studies [19,20,23,28-30] incorporated a clearly web-based component, such as a dashboard, web platform, online interface, or browser-based system. Other delivery modes included chatbot-supported platforms, WhatsApp (Meta)-supported programming, SMS text messaging or responsive text messaging, serious games, metaverse-supported systems, and hybrid platforms integrating child-, parent-, and clinician-facing tools.

XSL•FO
RenderX

Table . Intervention design and delivery characteristics.

Study and year	Intervention type	Platform or delivery mode	Intervention duration	Wearable or sensor used	Family involvement	Comparator or Control	Intervention components or behavior change features
Aydemir (2025) [17]	ChatGPT (OpenAI)-delivered, parent-mediated home PA[a] intervention	ChatGPT+parent training+WhatsApp (Meta) support	4 weeks; 40 min/session; 3 days/week	None	High; parents implemented activities and could involve siblings or family	Non-ChatGPT control group	Parent training; home PA plans; warm-up, main, or cool-down; co-participation; WhatsApp support; rewards
de Arriba Muñoz et al (2026) [18]	Family digital support program adjunct to semaglutide	Adhera Caring Digital Program mobile app (Adhera Health, Inc.)	10-month active intervention; interim results at 150 days	Fitbit Inspire 3 (Google LLC)	High; caregiver-focused education, behavior support, and monitoring	None	Education; motivational messaging; progress feedback; wearable monitoring; psychometrics
Emerson et al (2026) [30]	Adaptation of WeChat (Tencent Holdings Limited) chatbot for ASD[c] accessibility	Text or email chatbot concept; interviews or focus groups	Not an intervention trial; exploratory qualitative study	Not central; some participants discussed Fitbit or Apple Watch use	High; family-centered care identified as essential	None	SMART[b] goals; SDOH[d] screening; health resources; adaptation recommendations; branching logic
Heerman et al (2024) [19]	Digital obesity prevention added to primary care counseling	Responsive text messages+web dashboard+clinic counseling	24 months	None	High; parents were the direct intervention users	Clinic-only counseling group	Goal setting; self-monitoring; tailored feedback; dashboard; growth charts; health literacy materials
Larizza et al (2023) [22]	mHealth[e] lifestyle improvement app	Smartphone app+physician or admin dashboard+chatbot	2-week home pilot after training	None	High; parents register child, enter data, monitor trends, support use	None	Goals; education; success stories; monthly questionnaires; diaries; badges; quizzes; avatar; chatbot
Moore et al (2024) [23]	Conversational agent to overcome PA barriers	Web or text-based conversational agent	Prototype evaluation; not long-term intervention	None	Low or minimal	None	Barrier identification; confidence and motivation modules; social dialogue; links or resources; personalization
Oh et al (2022) [24]	AI-based interactive home exercise exergame	Smartphone-based gesture-recognition game versus Nintendo Switch Ring Fit (Nintendo Co., Ltd.)	3 weeks; 30 min/session, 5 days/week	Camera or computer vision gesture recognition	Low or minimal	Nintendo Switch exercise game	Gamified exercise; real-time visual or auditory feedback; alarms; posture feedback

Willms and Liu (2024) [28]	JITAI[f] content development using ChatGPT	ChatGPT-3+ Pathverse no-code mobile app builder	10-week planned JITAI; development process over 2 months	Intended JITAI used child MVPA[g] minutes as decision input; no specific wearable evaluated in case study	High; parent supports child PA	None	Tailored lessons; decision-tree personalization; family PA challenges

[a]PA: physical activity.

[b]SMART: Specific, Measurable, Achievable, Relevant, and Time-bound.

[c]ASD: autism spectrum disorder..

[d]SDOH: Social determinants of health

[e]mHealth: mobile health.

[f]JITAI: Just-in-Time Adaptive Intervention.

[g]MVPA: moderate to vigorous physical activity.

Nine studies [17-19,22,24-27,29] reported a defined intervention or exposure period, with durations ranging from 2 weeks to 24 months. Four studies [17,24,25,27] had relatively short intervention periods of 2-4 weeks, 3 [22,26,29] lasted approximately 8-12 weeks, and 2 [18,19] extended beyond 5 months, including one 24-month randomized trial and one 12-month obesity management program. The remaining 5 studies [20,21,23,28,30] were qualitative, developmental, survey-based, or case-based and therefore did not involve a conventional intervention period.

Most interventions were multicomponent and incorporated established behavior change strategies. Self-monitoring or tracking components were present in 9 studies [18-22,25-27,29], personalized feedback or adaptive content in 10 studies [17-20,23,25-27,29,30], and education or informational support in 9 studies [18,19,21-23,25-27,30]. Goal setting or challenge-based components were identified in 7 studies [19,22,25-28,30], gamification or reward-related elements in 7 studies [17,20,22,24-26,29], and social support, co-participation, or human-supported features in 8 studies [17-20,23,25,29,30]. Reminders or prompts were described as a distinct feature in 4 studies [17,24,26,27]. Although all studies were relevant to PA, only 5 [17,23,24,27,28] focused primarily on PA or exercise promotion; the remaining 9 [18-22,25,26,29,30] embedded PA within broader obesity-management, lifestyle, rehabilitation, or healthy living interventions.

Wearable devices, sensor-based inputs, or objective digital monitoring were reported in 6 studies [18,24,25,27-29]. These included Fitbit (Google LLC) devices, accelerometers, computer vision–based gesture recognition, smartphone- or app-linked monitoring, and planned smartwatch integration. However, most studies still relied partly or primarily on self-reported behavior, questionnaires, or user-entered information.

AI Features and Functional Characteristics

The included studies varied substantially in the sophistication and reporting of their AI and automation features (Table 4). To improve clarity, we distinguished the named intervention system or platform from the reported AI technique or automation logic. Three studies [17,27,28] used generative AI or large language model–based approaches directly in intervention delivery or content development. Several studies used scripted, predefined, or automated chatbots and tailoring functions based on structured pathways, branching logic, or automated rules [19,22,25,26,30]. Moore et al [23] described natural language understanding for intent recognition and dialogue routing. The study by de Arriba Muñoz et al [18] used a hybrid personalization engine, Zarkogianni et al [29] used a machine learning–based recommendation system, Oh et al [24] used computer vision and deep learning for gesture recognition, and Kim et al [20] described a broader integrated chatbot-supported digital health ecosystem.

XSL•FO
RenderX

Table . AI features and functional characteristics of the included interventions.

Study	Year	AI or automation role	Intervention system or platform	Reported AI technique or automation logic	Input data type	AI task	AI contribution/claimed benefit	AI explainability/transparency reported
Aydemir [17]	2025	Generates individualized home physical activity plans and answers parent follow-up questions	ChatGPT-4 (OpenAI)	Generative AI using a large language model	Parent text prompts; child age; and ASD[b] status	Text generation; PA[a] recommendation; instructional clarification	Low-cost, home-based, scalable PA guidance for ASD families	Limited; prompts described but model logic not detailed
de Arriba Muñoz et al [18]	2026	Personalizes caregiver support content	Adhera AI Precision Digital Companion (Adhera Health, Inc)	Hybrid personalization engine; specific algorithm not fully reported	App engagement data; psychometrics; wearable metrics; clinical data	Personalization; feedback; progress support	Complement pharmacotherapy with scalable caregiver support and monitoring	Limited
Emerson et al [30]	2026	Delivers health prompts, screening questions, and resources	WE CHAT (Wellness Education to Create Healthy Habits and Actions to Thrive)	Predefined chatbot pathways or branching logic; underlying algorithm not fully reported	User responses to prompts; provider recommendations for adaptation	Goal support; screening; resource/referral prompts	Potential to support obesity prevention for youth with ASD if adapted for variability and caregiver burden	Moderate; logic and use described conceptually
Heerman et al [19]	2024	Provides automated tailoring and adaptive feedback	Greenlight Plus digital platform (Vanderbilt University Medical Center)	Automated tailoring using predefined logic; no machine learning model or large language model reported	Parent surveys; goal progress self-ratings; child anthropometrics	Tailored messaging; adaptive feedback; dashboard tracking	Frequent asynchronous support and scalable tailored obesity prevention	Moderate; tailored logic described
Larizza et al [22]	2023	Collects responses and provides practical advice through a virtual coach	V-care app (University of Pavia) with Google Dialogflow chatbot	Task-oriented conversational agent using Dialogflow natural language processing and predefined workflows	Profile, questionnaires, quizzes, daily/weekly behavior diary, BMI updates	Questionnaire administration; coaching; advice; engagement	Increase compliance and reduce dropout in pediatric obesity management	Good technical description of architecture; limited algorithmic detail beyond workflow
Moore et al [23]	2024	Identifies physical activity barriers and delivers tailored relational support	Phyllis conversational agent (Sheffield Hallam University); Google Dialogflow and MindBehind (MindBehind Inc) engine	Natural language understanding for intent recognition and dialogue routing	Open-text user barrier input; conversation responses	Intent recognition; routing; tailored dialogue; persuasive coaching	On-demand personalized support to overcome PA barriers	Moderate; NLU[c] training and F_1-score reported
Oh et al [24]	2022	Recognizes body movements and provides exergame feedback	Super Kids Adventure (Funrehab)	Computer vision and deep learning using a convolutional neural network (CNN)	Video/image-based body movement data	Gesture recognition; exercise scoring; real-time feedback	Low-cost motivational home exercise alternative	Basic model type reported (CNN), limited technical detail

Willms and Liu [28]	2024	Generates intervention content for a just-in-time adaptive intervention	ChatGPT-3 and Pathverse (Pathverse Ltd) no-code mobile app builder	Generative AI using a large language model for content development; predefined decision rules for intervention tailoring	Researcher prompts with theory, target behavior, and intervention structure	Content generation	Rapid, scalable creation of tailored mHealth[d]/JITAI[e] content	Prompting process described; acknowledged hallucination/privacy limits

[a]PA: physical activity.

[b]ASD: autism spectrum disorder.

[c]NLU: natural language understanding.

[d]mHealth: mobile health.

[e]JITAI: Just-in-Time Adaptive Intervention.

Across studies, the most common role of AI was to support personalization and automated interaction rather than diagnosis or prediction. Tailored feedback, adaptive support, or personalized recommendations were described in 10 studies [17-20,22,23,25-27,29]. Chatbot-based or conversational coaching features were present in 8 studies [17,21-23,25-27,29], activity generation or exercise recommendation in 4 studies [17,24,28,29], and monitoring or self-management support in 6 studies [18,19,22,25,26,29].

Input data were most commonly participant- or caregiver-entered, including text prompts, questionnaires, goal selections, behavior logs, profile information, or interaction history. Six studies [18,24,25,27-29] incorporated wearable, sensor, image, or other objectively tracked data as part of the AI-supported system. Technical reporting of AI methods was often limited. Seven studies [20,21,23,27-30] provided only limited, conceptual, or partial descriptions of AI logic or architecture, whereas 6 [17-19,22,24,25] provided at least moderate detail about system workflow, personalization logic, or model type. One study [21] did not evaluate a live AI system but instead assessed attitudes toward a proposed future chatbot.

Theory, Implementation, and Outcome Findings

Theoretical frameworks were identified in most studies (Table 5), including Social Cognitive Theory [19]; the capability, opportunity, motivation, and behavior (COM-B) model; the Theoretical Domains Framework [23]; the Health Action Process Approach; the Elaboration Likelihood Model; Persuasive Systems Design [25]; Self-Determination Theory [27,29]; the Health Promotion Model; the Technology Acceptance Model [21], and the Multi-Process Action Control (M-PAC) model [28]. Other studies referenced broader approaches such as cognitive-behavioral principles, family-centered care, or user-centered design, whereas Aydemir [17] and Oh et al [24] did not report an explicit theoretical framework.

XSL•FO
RenderX

Table . Theoretical foundations, implementation outcomes, and behavioral/health outcomes.

Study and year	Theoretical framework	Feasibility/acceptability/usability/engagement	Primary PA[a] outcomes	Secondary outcomes	Key findings/effect Size
Aydemir (2025) [17]	NR[b]	High parent satisfaction; 92% participated in WhatsApp (Meta) discussions	Leisure Time Exercise Questionnaire (LTEQ)	Parent feasibility feedback	LTEQ increased from 6.69 to 34.00 in intervention versus 7.46-7.23 in control; interaction F=353.07; P<.001; ηp^2=.936
de Arriba Muñoz et al (2026) [18]	Cognitive-behavioral principles	SUS[c] score 72; exploratory trends between higher engagement and better fat loss	Wearable-recorded PA/biometric metrics collected, but main reported outcomes were clinical obesity measures	BMI, weight, body fat %, muscle mass %, waist circumference, usability, and engagement	At Day 150: BMI –4.51 kg/m²; weight –11.42 kg; body fat –5.63%; waist –8.69 cm; muscle mass 4.47% (all P<.001)
Emerson et al (2026) [30]	Family-centered care- or user-centered adaptation	Qualitative evidence of interest and need; branching logic and family support emphasized	NR	Feasibility, acceptability, accessibility needs, and adaptation recommendations	No efficacy outcomes; key themes were ASD[d] variability, perceived value of mHealth[e], family-centered care, and interdisciplinary support
Heerman et al (2024) [19]	Social Cognitive Theory; health literacy-informed design	High retention: 86.3% primary outcome at 24 months	No direct PA primary outcome; PA support behaviors embedded in program	Weight-for-length trajectory; BMI z score; overweight/obesity prevalence	Weight-for-length at 24 mo was lower by –0.33 kg/m (95% CI –0.57 to –0.09); BMI z score −0.19; obesity 7.4% versus 12.7% (aRR[f] 0.56)
Larizza et al (2023) [22]	Psychological/behavioral change theories; goal-based behavioral intervention	Overall friendliness 85%; perceived utility 100%; chatbot acceptable to 69%; all average scores >3/5	No quantitative PA outcome reported in pilot	Usability, acceptability, friendliness, and utility	High usability and perceived utility; chatbot section scored lower than other features but remained >3/5
Moore et al (2024) [23]	COM-B[g]; Theoretical domains framework; behavior change techniques; theory of planned behavior for confidence module	61 conversations; positive UX[h]; 73% definite intention to use; F_1-score about 80%	Perceived confidence and motivation to engage in PA	Acceptability, usability, recommendation likelihood, and barrier coverage	Significant increase in self-reported confidence and motivation after interacting with Phyllis (Sheffield Hallam University); 73% would use future version
Oh et al (2022) [24]	NR	Postquestionnaire on motivation, fun, perceived exercise effectiveness	Calorie expenditure; VO_2max[i]; 6MWT[j]; RPE[k]; BMI	Motivation, fun, and perceived exercise effectiveness	SUKIA (Funrehab) showed superior calorie consumption, VO_2max, and RPE versus Nintendo Switch (Nintendo Co, Ltd); authors report better cardiopulmonary function and energy expenditure

XSL•FO
RenderX

Study and year	Theoretical framework	Feasibility/acceptability/usability/engagement	Primary PA[a] outcomes	Secondary outcomes	Key findings/effect Size
Peuters et al (2024) [25]	Health action process approach; elaboration likelihood model; persuasive systems design	High nonusage attrition: 18% never used app; 30% stopped by week 2; interviews highlighted rewards and self-regulation as helpful	PA (ENMO[l]/MV-PA[m]) and sedentary behavior from accelerometers	HRQoL[n], mood, peer support, sleep quality, sleep routine, and breakfast	Beneficial effects for PA (χ^2=4.36; *P*=.04), sedentary behavior (χ^2=6.44; *P*=.01), sleep quality (χ^2=6.11; *P*=.01), and mood (*P*=.02); effects moderated by COVID restrictions
Stasinaki et al (2021) [26]	Behavior change techniques; obesity counseling framework (no single explicit theory emphasized)	Average daily app usage 71.5%; no side effects observed	Physical capacities (strength, agility, and endurance) via modified Dordel-Koch test	BMI-SDS[o], fat mass, muscle mass, waist-to-height ratio, BP[p], pulse, and stress markers	BMI-SDS decreased significantly in controls at 5.5 months, not in PathMate2 (PathMate Technologies GmbH); both groups improved muscle mass, strength, and agility by 12 months; PathMate2 reduced fat mass at T1/T2
Tan et al (2026) [27]	Self-Determination Theory; Self-Regulation Theory	Mean 8.9 behavior entries, 30 reflections, 33.5 AI feedback messages; 63.8% of daily goals achieved	Self-reported PA hours	Screen time, fruit/vegetable intake, sleep, engagement, and sentiment	PA did not significantly change (2.5-2.4 h/day; *P*=.20); screen time decreased by 0.93 h/day (*P*<.001); fruit/veg intake decreased by 0.50 servings (*P*=.02); sleep unchanged
Zarkogianni et al (2023) [29]	Self-Determination Theory	Adherence tracked by usage frequency; activity tracker use correlated with BMI improvement	Activity tracker usage / PA patterns (minutes of activity; steps/day)	BMI *z* score, diet quality, screen time, sleep duration, and usability/adherence	Mean BMI *z* score reduction –0.21 (SD 0.26); *P*<.001; tracker usage correlated with BMI *z* score improvement (*r*=−0.355; *P*=.02)
Kim et al (2025) [20]	MASUN[q] framework/user-centered design methodology	Students/parents prioritized PA and sleep tracking; reward systems rated promising; teachers rated effectiveness/usefulness/usability highly	NR	User needs, usability ratings, and preferred features	No efficacy outcomes; stakeholders favored PA measurement, rewards, and integrated monitoring across student-parent-teacher interfaces

XSL•FO
RenderX

Study and year	Theoretical framework	Feasibility/acceptability/usability/engagement	Primary PA[a] outcomes	Secondary outcomes	Key findings/effect Size
Kang et al (2026) [21]	Health Promotion Model and Technology Acceptance Model	Positive perceptions of chatbot use in both groups; mean A-uC[r] scores were above 4/5 overall, with parents showing higher intention to use	No intervention PA outcome; PA was one healthy lifestyle subdomain and a commonly reported unmet need	Overall healthy lifestyle score and subdomains; awareness of chatbot use (perceived usefulness/ease, value, empathy, reliability, professionalism, intention to use); topic-modeled unmet needs	No significant group differences in overall healthy lifestyle score (CACSs[s] mean 3.16, SD 0.80 vs parents mean 3.18, SD 0.36; *P*=.74) or PA subscale (mean 2.55, SD 0.89 vs mean 2.53, SD 0.81, *P*=.91). Parents had higher intention to use chatbots (mean 4.21, SD 0.68 vs mean 3.94; SD 0.90; *P*=.03). Common unmet areas were exercise, healthy diet, and regular lifestyle.
Willms and Liu (2024) [28]	Multi-Process Action Control (M-PAC)	Researchers found ChatGPT acceptable and easy to use for producing 13 lessons	NR	Feasibility, acceptability, and ease of use of AI-generated content process	ChatGPT (OpenAI) was judged acceptable and easy to use for creating 13 PA JITAI[t] lessons, but expert review remained essential due to the risk of inaccurate references/content

[a]PA: physical activity.
[b]NR: Not Reported
[c]SUS: system usability scale.
[d]ASD: autism spectrum disorder.
[e]mHealth: mobile health.
[f]aRR: adjusted risk ratio.
[g]COM-B: capability, opportunity, motivation, and behavior.
[h]UX: user experience.
[i]VO_2 max: maximal oxygen uptake.
[j]6MWT: 6-minute walk test.
[k]RPE: rating of perceived exertion.
[l]ENMO: Euclidean norm minus one.
[m]MVPA: moderate to vigorous physical activity.
[n]HRQoL: Health-related quality of life.
[o]BMI-SDS: body mass index standard deviation score.
[p]BP: blood pressure.
[q]MASUN: Method of App Selection based on User Needs.
[r]A-uC: Awareness of the Use of Chatbots.
[s]CACS: childhood or adolescent cancer survivor.
[t]JITAI: Just-in-Time Adaptive Intervention.

Outcome assessment approaches varied across studies (Table 5). Six studies [18,19,24,25,27,29] included an objective or performance-based PA-related measure, such as accelerometer-assessed activity, Fitbit-derived metrics, step counts, calorie expenditure, physical fitness testing, or device-recorded movement patterns. Four studies [17,21,23,26] relied primarily on self-report or parent-report PA-related measures, including exercise questionnaires, activity hours, or perceived confidence and motivation for PA. The remaining 4

XSL•FO
RenderX

studies [20,22,28,30] did not directly assess intervention-related PA outcomes.

The studies frequently examined outcomes beyond PA alone. Anthropometric or weight-related outcomes, including BMI, BMI *z* score, body fat, waist circumference, or obesity-related indicators, were reported in 6 studies [18,19,22,24,26,29]. Diet- or nutrition-related outcomes were reported in 4 studies [18,19,21,29], screen time or sedentary behavior in 3 studies [19,25,27], and sleep-related outcomes in 3 studies [19,21,25]. Psychosocial, motivational, quality-of-life, and usability-related outcomes were also commonly reported, suggesting that many AI-supported family-based interventions were conceptualized as broader healthy lifestyle or obesity-management programs rather than narrowly focused PA interventions.

Among the 8 studies that reported direct PA-, exercise-, movement-, or fitness-related outcomes, 4 [17,23-25] reported significant improvements in PA participation, exercise performance, movement-related behavior, or fitness-related indicators. Two studies [26,27] reported little or no statistically significant improvement in PA despite favorable findings for engagement or other health outcomes. One study [18] collected wearable-based PA data but reported stronger clinical obesity-related effects than PA-specific effects, and one additional study [19] described PA-related findings as part of a broader multibehavior framework without demonstrating a clearly significant PA effect.

All 14 original studies reported at least one feasibility-, acceptability-, usability-, or engagement-related outcome (Table 5). Five studies [20,21,23,28,30] were primarily qualitative, developmental, survey-based, or case-based in design and therefore emphasized user preferences, accessibility needs, perceived usefulness, desired features, implementation barriers, or design priorities rather than behavioral efficacy. These studies generally reported favorable perceptions of AI-supported tools, particularly when interventions were viewed as personalized, interactive, and supportive of family routines or youth autonomy.

Among the intervention-oriented studies, quantitative implementation indicators were commonly reported. Examples included high parent satisfaction and 92% participation in WhatsApp discussions in one parent-mediated ChatGPT study [17]; a System Usability Scale score of 72 in one obesity-management intervention [18]; 86.3% retention at 24 months in the large primary care trial; 85% friendliness, 100% perceived utility, and 69% acceptability in one pediatric obesity app pilot [22]; 61 total chatbot conversations and 73% definite intention to use in one conversational-agent co-design study [23]; average daily app usage of 71.5% in one obesity management trial [26]; and a mean of 8.9 (SD 7.6) behavior entries, 30 reflections, and 33.5 AI feedback interactions in one school-based chatbot study [27]. One quasi-randomized trial reported substantial nonuse attrition, with 18% of participants never using the app and 30% stopping use by week 2 [25].

Discussion

Principal Findings

This scoping review explored the emerging evidence on AI and chatbot-supported interventions targeting PA and obesity-related lifestyle behaviors among children and adolescents, with attention to family involvement. Across the 14 studies included, the evidence indicates that AI-supported interventions are being used in increasingly diverse ways to support PA, obesity management, and related health behaviors in pediatric populations, but the literature remains varied in terms of intervention design, AI capabilities, family involvement, and outcome measurement.

Complex AI Features Across Studies

Across the included studies, AI features span a continuum of complexity, from rule-based scripted chatbots and automated tailoring systems (eg, structured coaching or tailored text messaging) to hybrid systems that incorporated limited natural language understanding or personalization. AI was most commonly used to support personalization, user interaction, and ongoing behavioral support, rather than for diagnostic, predictive, or decision-making purposes. Many studies provided only high-level or conceptual descriptions of system functionality, with limited detail on model architecture, training data, validation procedures, or performance across subgroups. This lack of transparency makes it difficult to assess reproducibility, evaluate potential bias, or determine whether AI-driven personalization meaningfully contributes to outcomes beyond standard digital tailoring approaches. These gaps are particularly important given the increasing integration of more complex AI systems, which introduce additional concerns related to accuracy, safety, and algorithmic bias. Future research should adopt AI-specific reporting standards and explicitly document how AI outputs are validated, monitored, and updated over time across diverse populations.

Delivery Platforms and Intervention Components

Regarding the delivery platform and intervention components, most interventions embed common behavior change functions, including self-monitoring, goal setting, education, feedback, and rewards, within various platforms. These platforms range from low-burden text messaging and web dashboards to multiapp family–clinician ecosystems, wearable-linked systems, higher-complexity immersive environments, and sensor-rich exercise apps. Engagement strategies also include gamification, relational dialogue, narrative content, and school- or family-embedded routines. Within this structure, AI primarily serves as a delivery and personalization mechanism that shaped how these components were implemented. AI enabled more dynamic forms of support, such as routine coaches, on-demand assistants, and interactive educational or motivational agents [23,25,28]. In this sense, AI modifies the timing, intensity, and responsiveness of intervention delivery rather than fundamentally changing its core behavioral content.

Extent and Operationalization of Family Engagement

A central contribution to this review is the characterization of family involvement, which was important but inconsistently

XSL•FO
RenderX

operationalized. In some studies, parents were critical to implementation, such as delivering activities at home, receiving caregiver education, or interacting with the digital system directly [17-19,29]. In others, youth were the primary users and family influence was acknowledged but not fully integrated into the intervention structure [23,24,27]. This variability suggests that the field has not yet converged on a clear definition of what constitutes a "family-based" AI intervention. Importantly, most studies do not measure family engagement systematically enough to test whether caregiver involvement mediates or moderates intervention effects. More precise conceptualization of whether caregivers are intended as co-users, facilitators, role models, or targets of behavior change may improve both intervention design and interpretation of outcomes.

Limited Cultural Tailoring and Bilingual Intervention

With respect to cultural tailoring and bilingual delivery, evidence remains limited. One large randomized clinical trial embedded bilingual delivery (English/Spanish) and cultural appropriateness processes in a racially and ethnically diverse population [19]. Although all studies could be situated within identifiable linguistic or contextual settings, specific cultural adaptation was rare, and the evidence base was entirely in middle- and high-income countries. This limits the transferability of current findings to lower-resource contexts and to culturally diverse family populations whose routines, values, digital access, and barriers to health behavior change may differ substantially. The lack of consistent reporting on cultural tailoring, bilingual adaptation, and structural access issues also limits understanding of how well current interventions align with the realities of underserved families. These limitations introduce broader concerns in digital health that technologies may inadvertently reinforce inequities if they are developed primarily in well-resourced settings without sufficient adaptation for different social and cultural contexts [31].

Exploratory Feasibility and Efficacy Findings

Consistent with the aims of this review, PA emerged as the most prominent target behavior, either as a primary intervention focus or as part of broader multibehavior lifestyle and obesity-management programs. Several studies focused directly on PA promotion, home exercise, or movement-related confidence and performance [17,23,24,27], whereas others addressed PA within broader interventions targeting obesity prevention, rehabilitation, or healthy lifestyle routines [18,19,25,26,29]. This pattern likely reflects both the importance of PA in pediatric health promotion and the broader reality that children's movement behaviors are closely associated with diet, sleep, sedentary behavior, and family routines. Rather than treating PA as an isolated outcome, many of the included studies positioned it within a more comprehensive family lifestyle framework.

The reviewed studies also indicate that AI-supported interventions were generally more consistent in demonstrating feasibility, acceptability, and engagement than in behavioral efficacy. These findings align with previous youth-focused syntheses emphasizing that chatbots and AI-supported tools are often perceived as appealing and acceptable when they are interactive, personalized, and low burden [12]. However, the current review also found that favorable usability does not necessarily translate into sustained engagement or robust changes in PA participation, exercise performance, calorie expenditure, cardiopulmonary function, or confidence and motivation for PA [17,23-25], and some broader obesity-management or prevention interventions also showed favorable changes in clinical or anthropometric outcomes [18,19,29]. At the same time, findings were not uniform across studies. Tan et al [27] did not detect significant changes in PA, and Stasinaki et al [26] did not show clear superiority of the conversational-agent intervention over the comparison condition for BMI-SD score (BMI-SDS). Moreover, many included studies were feasibility, pilot, or developmental studies rather than adequately powered effectiveness trials. These findings suggest that while AI-supported interventions show promise, the current evidence remains stronger for feasibility and acceptability than for clinically meaningful and sustained improvements in PA and related outcomes.

Implications for Practice and Research

This review highlights several implications for intervention design, implementation, and future research. In practice, AI-supported family interventions may be most useful when integrated into broader family-based, school-based, or clinical programs rather than positioned as isolated tools. Their strengths appear to lie in delivering tailored education, self-monitoring support, reminders, coaching, and feedback in ways that are flexible, scalable, and responsive to daily family routines. However, the findings also indicate that intervention success likely depends on more than the presence of AI alone. Additional attention to developmental appropriateness, caregiver roles, response quality, burden of use, and contextual relevance will be essential to sustaining engagement and producing meaningful behavior change.

Future research and program development should prioritize family-centered co-design, more rigorous comparative and longitudinal study designs, and greater consistency and transparency in reporting AI features, personalization logic, and behavior change techniques. More culturally and linguistically responsive adaptation is also needed, particularly for diverse and underserved family populations. Additional work should examine implementation outcomes such as reach, adoption, maintenance, scalability, and cost, alongside behavioral and clinical outcomes. Emerging approaches such as generative AI, wearable-integrated personalization, and adaptive feedback systems may offer added value, but their safety, accuracy, transparency, and practical benefit require more careful evaluation in pediatric settings. Continued interdisciplinary collaboration will play an important role in ensuring that AI-supported family interventions are not only innovative but also ethical, accessible, and equitable.

Limitations

Several limitations should be acknowledged. First, the number of included studies was small, and the evidence base was highly heterogeneous. Further, the included studies varied widely in population, intervention modality, duration, AI sophistication, and measured outcomes, which limits comparability. In addition, many studies were pilots, feasibility studies, or usability-focused

XSL•FO
RenderX

investigations rather than adequately powered trials. Further, reporting of demographic, contextual, and technical AI details was often incomplete, making it difficult to assess generalizability or identify active intervention ingredients. The search was limited to English-language publications; therefore, relevant studies published in other languages may not have been captured, which may have introduced selection bias. Further, the search was limited to peer-reviewed publications indexed in the selected databases and did not include a formal gray-literature search or supplementary citation tracking. Therefore, relevant evidence reported in theses, reports, conference materials, policy documents, unpublished sources, or publications not indexed in the selected databases may not have been captured. A formal critical appraisal or methodological quality assessment was not conducted; therefore, the methodological rigor of the included studies was not evaluated.

Conclusion

In conclusion, this scoping review found that AI and chatbot-supported interventions for pediatric PA and obesity-related lifestyle behaviors are a rapidly emerging but still early-stage field. The existing literature suggests that these interventions are generally feasible, acceptable, and promising as scalable tools for supporting healthy behavior change among children and families. However, evidence for effectiveness, particularly for PA outcomes, remains mixed and limited by methodological heterogeneity, short follow-up, and inconsistent outcomes. The review also highlights important gaps in family-based design, cultural tailoring, equity, and evaluation of advanced AI capabilities. Future research should prioritize rigorous trials, clearer conceptualization of family engagement, objective outcome measurement, and culturally responsive development to ensure that AI-supported interventions are not only innovative but also effective, equitable, and meaningful for diverse families.

Abstract

Background: Febrile seizures, although typically benign, can cause significant emotional distress for parents. Their diverse etiological risk factors underscore the need for further research. Ecological momentary assessment (EMA) offers a cost-effective and timely method for real-time data collection. The FeverApp, an EMA-based registry for fever management, enables parents to document febrile seizures as they occur.

Objective: This study systematically investigates febrile seizure records from the FeverApp registry to assess their characteristics and explore the clinical implications of the findings. By providing real-world data on seizure management, this research demonstrates the potential of app-based EMA in pediatric care. Additionally, it offers insights for targeted interventions and improved febrile seizure management.

Methods: We used a mixed methods approach. A descriptive qualitative analysis of parental descriptions of 226 seizures belonging to 161 children was conducted. Additionally, a comparative quantitative analysis of group differences was assessed through matched-pair sampling, comparing 114 children. Statistical methods were tailored to the nature of the respective variables, which included prevalence, age, gender, health and febrile history, fever management, temperature, well-being, and parental confidence.

Results: Qualitative analyses provided detailed descriptions of seizure symptoms, seizure duration, and seizure management practices. Additionally, the data revealed a high rate of emergency consultations related to febrile seizures. However, there was underreporting of febrile seizures within the FeverApp, with a reported incidence of only 0.4% among febrile children. In a matched sample controlled for gender and age, significant differences were observed between febrile children with and those without febrile seizures in several parameters, including maximum recorded temperature (P<.001), prevalence of chronic diseases (P=.004), parental confidence (P=.01), and frequency of emergency consultations (P<.001).

Conclusions: This study offers valuable insights into the characteristics, temporal dynamics, management strategies, and parental responses to febrile seizures in children. Despite the limitation of potential underreporting in an EMA-based registry, the findings highlight the critical importance of parental education and support in managing febrile seizures. Enhancing these areas has the potential to reduce unnecessary medical consultations and improve the overall care of affected children. Furthermore, integrating improvements in the FeverApp's education and documentation system regarding febrile seizures could facilitate better management and support future research efforts.

Introduction

Theoretical Background

Febrile Seizures

Febrile seizures are among the most common pediatric neurological events, affecting 2%-5% of children aged 6 months to 5 years, with a peak at 18 months [1-5]. They occur in the context of febrile illness and are not caused by intracranial infection or central nervous system damage [6,7]. Diagnostic criteria, as defined by the World Health Organization (WHO) *ICD-11* (*International Classification of Diseases, 11th Revision*), are detailed in Multimedia Appendix 1 [8,9]. They are classified as either simple or complex, with the majority being simple (75%-80%) [7,10]. Seizures typically resolve spontaneously, with children recovering within 24 hours, especially in simple cases [4]. They usually occur within the first day of fever, are more frequent in the early evening, and peak in fall and winter [1,7].

The prognosis for children with febrile seizures is generally favorable, with brain damage or death being extremely rare [11,12]. While most children recover without complications, those with complex seizures, a family history of seizures, or younger age have a slightly higher risk of afebrile seizures or later epilepsy [13-15]. Febrile seizures recur in 30%-50% of cases, with recurrence risk increasing with additional risk factors such as lower fever or early onset after fever [7,15,16]. Despite their benign nature, febrile seizures are clinically significant due to their prevalence and potential for recurrence or later epilepsy [4].

Febrile seizures cannot be prevented with antipyretics [17]. Acute seizures can often be stopped with rectal diazepam or buccal/intranasal midazolam [1], while paracetamol and ibuprofen may relieve discomfort but are not recommended solely to reduce fever [18]. Long-term anticonvulsant therapy does not prevent recurrences or later epilepsy [1].

The exact mechanisms underlying febrile seizures remain unclear. Risk factors include a positive family history, certain genetic predispositions, young age (6 months-5 years, peak 12-18 months), developmental delay, neurological abnormalities, prolonged neonatal hospitalization, and maternal smoking [1,4,19,20]. Boys are slightly more affected [6,13,20-22]. Febrile seizures are often associated with infections and may rarely follow vaccinations [4,23-26]. Seizures are typically triggered by elevated body temperature, frequently above 39 °C, though even mild fever can provoke them. It remains unclear whether absolute temperature or the rate of increase is more critical, and seizures can sometimes occur before or after the fever spike [1].

Parental Experience and Alleviation

Febrile seizures, though generally benign, are often frightening and distressing for parents, who may fear their child is dying [5,27,28]. Reactions can include psychosomatic symptoms (eg, sleep disruption and dyspepsia) and psychological stress such as anxiety, fear of recurrence, and excessive worry. This can disrupt family life and contribute to "vulnerable child syndrome," where parents perceive their child as unusually susceptible to problems [5,29]. Despite these fears, children with febrile seizures do not use more medical resources than peers [5]. Studies indicate that many parents lack prior knowledge: in Germany, around 50% had not informed themselves, only 32% recognized a seizure during the episode, and 63% administered antipyretics at lower-than-recommended temperatures [30].

Early recognition, education, and guidance are key to alleviating parental anxiety and improving outcomes. Multimedia educational interventions about the benign nature and management of febrile seizures can further support parents [13]. Health care providers should address misconceptions, fears, and coping strategies to empower parents effectively [5].

This highlights the potential of digital health applications, which can provide real-time guidance, educational support, and data collection to assist families in managing febrile illnesses safely.

About the FeverApp

The FeverApp is one of 6 model registries funded by the Federal Ministry of Education and Research (BMBF) and launched in 2019 [31]. It serves as an ecological momentary assessment (EMA) for fever management in families, where parents can document febrile illnesses in real time and receive evidence-based information on fever management [31,32]. Initially, access to the FeverApp was only possible via codes provided by pediatricians. This approach ensured data reliability and accuracy, fostered parental trust, and secured acceptance among treating pediatricians. Since August 2022, the app has been accessible without a code as well.

It is primarily a research tool rather than a certified medical device. Its main purpose is observational, collecting longitudinal data on fever and parental management. At the same time, by monitoring their child's illness and accessing evidence-based guidance, parents learn about fever, are supported in their care decisions, and may experience reduced anxiety. Its EMA-based design provides clinicians with structured, high-resolution data that can support diagnosis and management, even though the app itself does not make medical decisions.

Technically, the app operates as a client–server system: anonymized data are stored locally in an open-source database (PouchDB) and synchronized with central CouchDB and transferred to MongoDB servers at the University of Witten/Herdecke. The app is available for iOS and Android. It is also possible to extend the functions of the app by implementing additional modules to document specific diseases. In the current app version, it is possible to document febrile seizures separately. Previous studies show that the backend reliably captures real-time data and complements outpatient care [33,34]. A comparison between different fever apps was presented in Joosen et al [35]. The authors reviewed pediatric

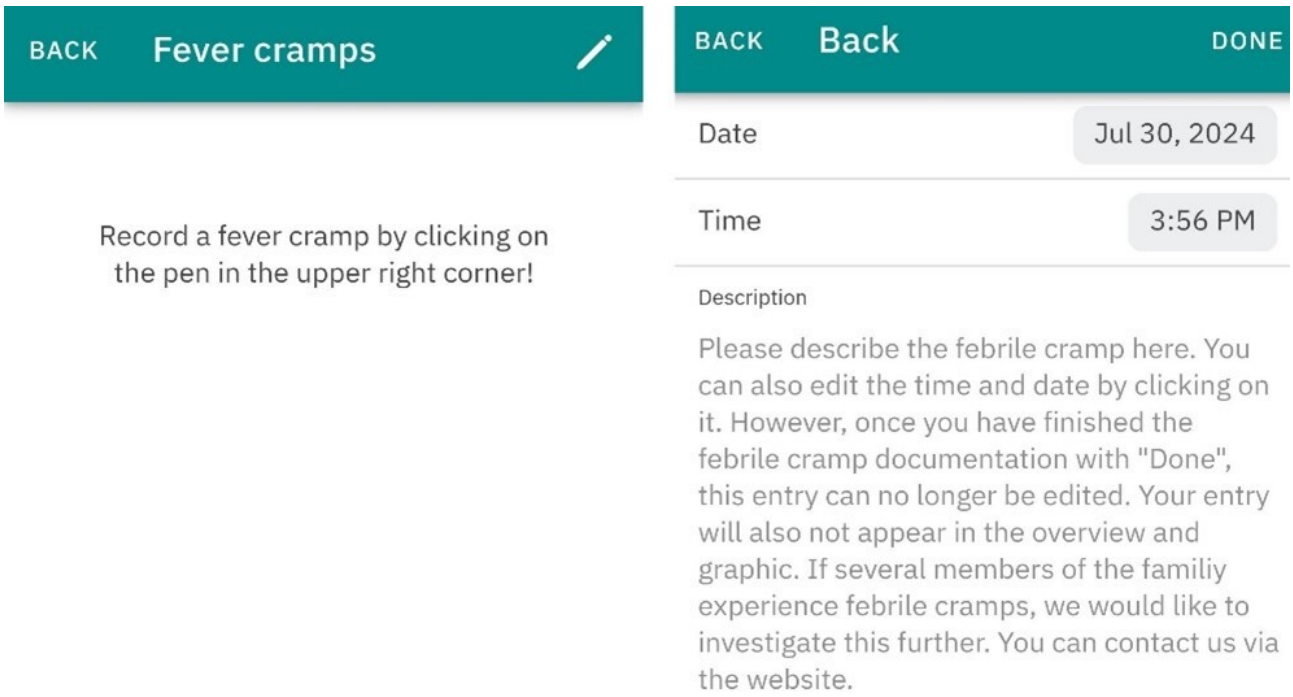
XSL•FO
RenderX

fever apps for quality and guideline adherence. Out of 878 apps, 3 were fully assessed: Kinsa and FeverApp scored highest in quality, while FeverFriend best adhered to the National Institute for Health and Care Excellence (NICE) guidelines [36]. FeverApp was originally based on the NICE Guidelines until the first author of the present publication and inventor of the FeverApp initiated and coordinated the new German S3 national guideline on fever management in children and youth [37]. The study shows few evidence-based apps exist, including the FeverApp, and highlights their potential for parental support.

Goal of the Study

Febrile seizures represent a common, most benign yet complex pediatric neurological condition with unknown, probably multifactorial etiology and can be frightening for parents. Understanding these theoretical aspects is critical for developing targeted interventions and providing comprehensive care for affected children and their families.

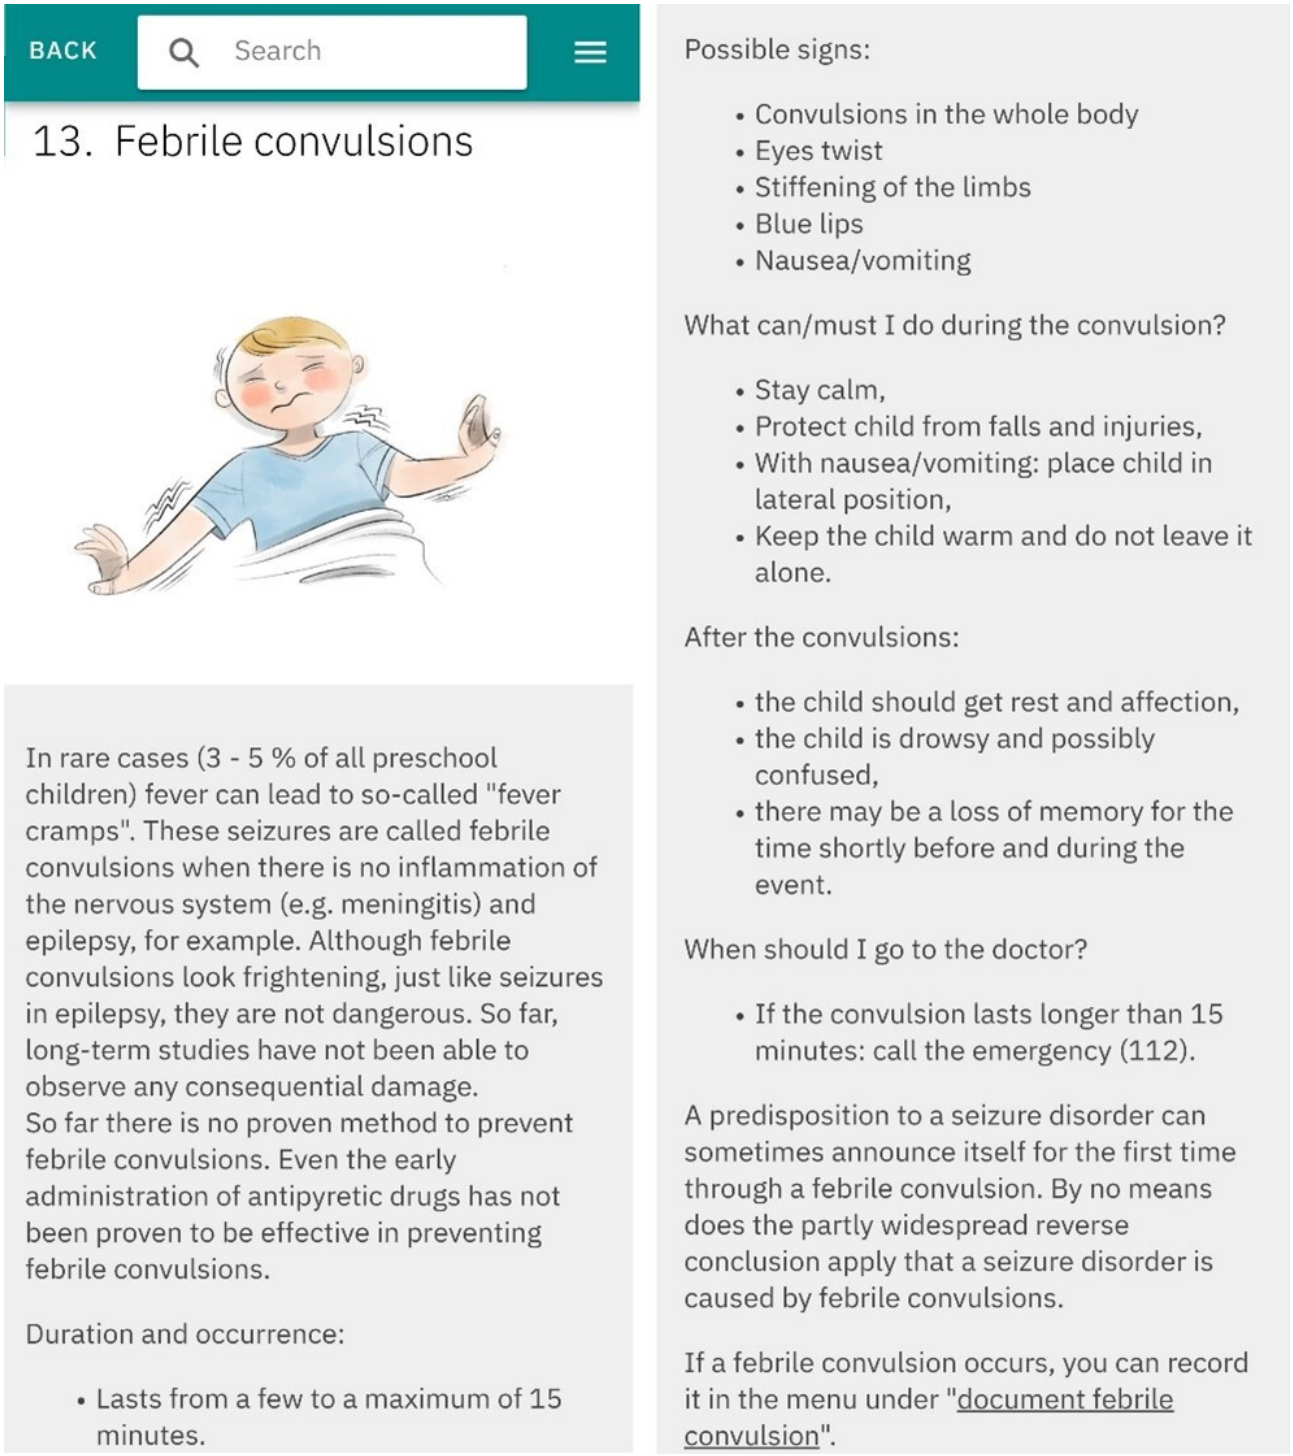
The quality of data collected is often limited due to reporting and recall bias. Therefore, immediate records are preferred in medical research. EMA is a modern method that enables timely, direct, and cost-effective data collection by allowing repeated sampling of participants' behavior in real-time environments, thus minimizing recall bias and increasing external validity [38-40].



The primary objective of this study is to investigate the FeverApp as an EMA-based registry for febrile illnesses, with a particular focus on differentiating specific conditions such as febrile seizures. Additionally, the study aims to examine febrile seizure records for their conformity with current research, assess the potential for expanding existing studies, and identify areas for improvement in EMA-based registries.

Methods

Data Source



The FeverApp serves as an EMA-based registry for fever management, enabling parents to record febrile illnesses and receive advice on managing their child's fever at home [31]. Since its launch in September 2019, the app has recorded approximately 54,300 fever episodes from around 46,600 children as of November 2024. Data are securely stored on university servers at Witten/Herdecke for scientific research purposes. The app supports various caregiver roles and allows for the creation of multiple profiles and episodes per child. A fever episode concludes either when the parent selects the "child is healthy" option within the app or, during data cleaning, when no further entries are recorded within a 48-hour period. The app collects comprehensive data, including sociodemographic details, medical history, and acute fever-related information such as parental confidence in dealing with their children's fever, the child's temperature, symptoms, well-being, and medication usage [32]. Febrile seizures are documented separately, with automatic timestamps and the option for manual adjustments to the date and free-text seizure descriptions (Figure 1). As a continuously updated registry, the completeness of the data varies. Additionally, users have access to educational resources on childhood fever, including a video and a multimedia, guideline-oriented information library with 23 chapters, one of which is dedicated to febrile seizures (Figure 2).

Figure 2. Chapter about febrile seizures in the Info Library of the FeverApp.

Recruitment and Sampling

The FeverApp registry constitutes at the beginning a convenience sample of parents who voluntarily use the app to document their child's fever episodes. Initially, access to the app was provided exclusively through pediatric offices, where physicians distributed access codes to families, ensuring reliability and authenticity of user data. Over time, the app has become publicly available, allowing any interested caregiver to participate voluntarily. Thus, data originates from a naturalistic sample of parents documenting fever episodes in real-life settings.

For this study, no additional recruitment was performed. Instead, a purposive subsample was extracted from the existing FeverApp database, consisting of all cases in which parents documented at least one febrile seizure episode. Entries were included if the seizure documentation appeared reliable, while duplicates or clearly false entries excluded (15 cases). For comparative analysis, a convenience sample of all existing fever episodes were used. In both analyses, children aged 18 years or older, parents who deleted their account, or parents aged 14 years or younger were filtered out. No further exclusion criteria, such as family history of seizures or previous seizures of the

XSL•FO
RenderX

child, were applied, as such information was not systematically available.

Data Analysis

The study followed 2 separate analyses: a descriptive qualitative analysis of parental descriptions regarding febrile seizures and a comparative quantitative analysis between children with and those without a febrile seizure.

Two datasets were used for analysis. Continuous EMA data for each entry were stored in a single large dataset, while a separate dataset was created specifically for time-lagged febrile seizure documentation. Data were subsequently cleaned, processed, and analyzed using IBM SPSS (version 28; IBM Corp).

Initial qualitative analyses focused on entries within the "seizures" dataset. A quantitative analysis of sample characteristics was performed, examining variables such as gender, age, number of febrile seizures recorded, prevalence of chronic disease, febrile disease in the past 12 months, tendency for high fever, typical fever duration, behavior during fever rise, antipyretic use in the past 12 months, time of febrile seizure, and difference between seizure date and seizure record. Some variables (age, febrile disease in the past 12 months, tendency for high fever, typical fever duration, time of the febrile seizure, and difference between seizure date and seizure record) were categorized or dichotomized. Detailed categories are provided in Table 1. Parents' free-text descriptions of seizure events were manually analyzed following an inductive thematic approach as described by Braun and Clarke [41], aiming to identify recurring patterns, words, and themes that reflected parents' observations and experiences during febrile seizures to develop categories. To support the interpretation of the qualitative themes, limited frequency indications are provided to show how often specific symptoms or parental descriptions occur. In addition, a quantitative overview of these categories was generated, indicating, for example, the frequency of specific observations such as blue lips or the involvement of emergency services. These descriptive patterns were then interpreted to highlight clinically and behaviorally relevant features of febrile seizures as perceived by parents, such as common symptom clusters, typical parental responses, and indicators of perceived severity, providing insights into both the objective and subjective aspects of seizure events as recorded in a naturalistic setting.

Quantitative analyses within the "seizure" dataset examined variables such as age, gender, number of seizures, health and febrile history (eg, previous fevers, tendency for high fever, typical fever duration, and chronic diseases), fever management strategies (eg, cooling/warming methods and use of antipyretics), timing of seizures, and the time interval between seizure occurrence and documentation.

In the subsequent step, both datasets were merged to incorporate missing variables from the seizure dataset and enable comparisons between febrile children with and those without febrile seizures. As febrile seizures can be recorded some time after they occur, data from fever episodes are not always directly connected. Therefore, seizures in which the timestamp of the entry and the reported seizure differed by more than 48 hours were excluded from the comparison. Since a single child can have multiple fever episodes, comparing children is challenging due to dependency in some entries (multiple episodes for one child) and independence in others (single episode per child). To address this, only the first fever episode for each child was selected for analysis, and in cases of children with seizures, only their first recorded seizure was considered. To control for significant differences in age and gender distribution between the 2 groups, children were randomly matched based on these variables. The analyses examined children with and those without a febrile seizure and compared variables such as age, sex, febrile history (eg, previous fevers, tendency for high fever, and typical fever duration), fever management strategies (eg, cooling/warming methods and use of antipyretics), temperature, parental confidence in dealing with their children's fever (5-point Likert scale from "thumbs down" to "thumbs up"), medical consultations, and children's well-being (5-point Likert scale from "sad face" to "happy face"). Some Variables (fever in the past 12 months, tendency for high fever, typical fever duration, and management during fever rise) were categorized or dichotomized. Statistical tests were applied as follows: the *t* test for normally distributed metric data, the Mann-Whitney *U* test for nonnormally distributed metric data (including Likert scale variables, per scale [42]), and chi-square tests for ordinal and nominal data. For 2×2 contingency tables or when cell frequencies were below 5, Fisher exact test was reported. Effect sizes were calculated for all applicable tests to quantify the magnitude of observed differences.

Reporting of this study followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology; for quantitative analyses) and SRQR (Standards for Reporting Qualitative Research; for qualitative analyses) guidelines [43,44]. Completed checklists are available in Multimedia Appendices 2 and 3 [43]. While the study includes qualitative analysis of parental free-text entries regarding febrile seizures, it does not follow traditional qualitative research design (eg, interviews or ethnography). Therefore, some items from the SRQR checklist are not applicable. The analysis was limited to the content of entries collected in the naturalistic, real-world setting of the FeverApp.

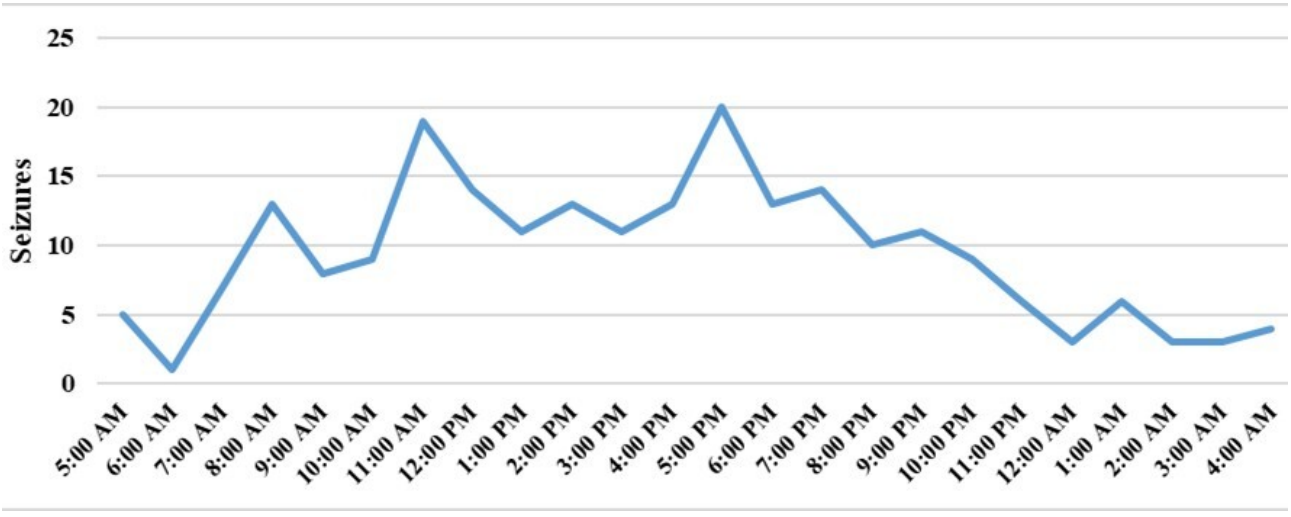
Ethical Considerations

Ethical approval for the FeverApp registry has been granted by the ethics committee of the University of Witten/Herdecke (proposal number: 139/2018).



The FeverApp Registry is registered in the German Clinical Trials Register (DRKS-ID: DRKS00016591). The registry follows the Declaration of Helsinki. Informed consent was obtained from all participants involved in the study. After installing the app, users must confirm a data privacy statement where they accept that their data are being recorded and used for scientific reasons. The FeverApp ensures privacy and confidentiality through data anonymization. Each family is assigned a randomly generated 8-character code, and all users and children are identified only by these codes. Data can be deleted at any time either via the app or by contacting the study team by email to request data removal. No compensation was provided to participants, as the study was based on data collected through the FeverApp and did not involve direct participation or intervention.

Results

Dataset of Febrile Seizures

Over a data collection period of 5 years, there were 226 registrations of febrile seizures. These belonged to 161 children, of whom 128 (79%) had only 1 febrile seizure and 33 (21%) had 2 or more febrile seizures. From 226 registered febrile seizures, 125 (60%) included detailed descriptions. Children's gender was evenly distributed. A chronic disease was present in 10% (17/156) of the children. Regarding fever history, around 81% (118/145) of children had experienced a febrile illness in the past 12 months. Most children (102/142, 72%) rarely or never have high fever, and nearly all (43/44, 98%) have a typical fever duration of up to 3 days. Parents' responses varied regarding their actions during a fever rise, with 21% (20/95 children) warming, 31% (30/95 children) cooling, and 31% (29/95 children) doing neither. In 81% (114/140) of children, antipyretics were administered within the past 12 months. Approximately 15% (24/161) of the children were aged 12 months or younger, while about one-third (51/161, 32%) were aged between 12 and 24 months. Nearly half (72/161, 45%) of the children were aged between 2 and 5 years, and approximately 8% (14/161) were aged 5 years or older. Most records of febrile seizures were between 8 AM and 8 PM (168/226, 74%), with peaks at 11 AM and 5 PM (Figure 3). In most cases (127/226, 56% records), the time between the seizure and its recording was less than 24 hours, although in around 10% (23/226 records) of cases, parents recorded the seizure more than 6 months after it happened. Additional results are provided in Table 1.

Figure 3. Seizure frequencies at different times.

Descriptive Qualitative Analysis of Parental Descriptions of Febrile Seizures

A total of 70 children had 1 detailed description, and 17 children had 2-6 descriptions of their seizures. They are reported separately because of their possible different seizure profile.

Children With 1 Seizure Report

High fever was reported in 13 of 70 cases, with temperatures ranging from 39.1 °C to 40.2 °C. Some described it as "sudden fever," "fast rising," or "from 0 to 100." Two of 70 parents reported lower temperatures from 38.0 °C to 38.8 °C. The duration of the seizures ranged from 30 seconds to 10 minutes (40/70), with the majority lasting less than 3 minutes (26/70). One parent reported that the seizure lasted for about half an hour.

Out of 70 descriptions, some parents described their child as whiny (3 cases) or restless, lethargic, clingy, and tired (2 cases each) before the seizure. During the seizure, parents frequently

XSL•FO
RenderX

reported “rolling eyes,” that is, upward gaze deviation (29 cases), cramping (25 cases), twitching (24 cases), tension or stiffness (15 cases), blue lips (15 cases), unresponsiveness (15 cases), and salivating (9 cases). Additional symptoms included a staring gaze (6 cases) and blue (5 cases) or pale (3 cases) skin color. Some parents reported rhythmic movements (5 cases) and others a limp child (4 cases). Children whimpered or cried (4 cases), screamed (4 cases), vomited (4 cases), and clenched or ground their teeth (3 cases) during the seizure. Breathing was described as gasping for air (6 cases), wheezing (3 cases), or flat breathing (2 cases). Tachycardia was infrequently reported (2 cases). In 3 cases, the seizures were described as uncomplicated and quickly resolved. One mother reported that she was “scared” and “thought he was dying.”

After the seizure, 5 out of 70 cases reported that the child was not responsive for a period or that they fell asleep immediately. In 3 cases, the child vomited afterward. Five of 70 parents reported that their child seemed very limp afterward.

In 19 out of 70 cases, an ambulance or emergency doctor was called. One parent waited and then went to the doctor the next morning. In 13 out of 70 cases, the child was taken to the hospital for overnight monitoring or a few days of observation. Diagnoses reported included kidney inflammation, tonsillitis or throat infection, ear infection, and 3-day fever.

Various measures were taken before, during, or after the seizures. In 2 out of 70 cases, antipyretics were given directly before the seizures, and in 5 of 70 cases, they were given afterward. During the seizures, diazepam was administered once, buccolam once, an “antispasmodic medication” once. Additionally, antipyretics (4/70 cases) were administered during the seizure. Other measures included calf wraps, cooling of the forehead and legs (2 cases), removing clothes (1 case), and placing the child in a stable side position (3 cases).

Overall, these reports illustrate the range and frequency of symptoms, postictal behaviors, and parental responses during single febrile seizure events, highlighting commonly observed patterns such as high fever, eye rolling, cramping, cyanosis, and emergency interventions.

Children With More Than 1 Seizure Report

The temperature ranged from 38 °C to 40.1 °C. Many cases (10/56) had a higher fever than 39 °C. Two reports described low or no fever. A fast fever rise was noted in 2 cases. The duration of the seizure ranged from 50 seconds to 30 minutes. Most seizures (20/56 cases) lasted up to 2 minutes. In 9 cases, a duration of 5 to 10 minutes was reported, and in 3 cases, a duration of 20 to 30 minutes was reported.

In some cases (6/56), parents described that their child was “not really responsive” or “not quite himself” before the seizure even started. Parents described their child as very sleepy (4 cases) and that the child had fever throughout the day (3 cases). Twitching, lots of crying, being shaky on the legs, and screaming (2 cases each), as well as restlessness and stretching (1 case each), were also reported before the seizure. One parent noted that there were no signs of fever or an infection before the seizure.

Among the 56 documented seizures, common clinical manifestations included tonic-clonic activity (cramping, 27 cases), oculogyric crisis (fixed gaze, 18 cases), perioral cyanosis (blue lips, 14 cases), postictal state or loss of consciousness (13 cases), and myoclonus or clonus (twitching, 11 cases). Additionally, a tonic gaze or ictal fear was noted in 11 cases. Less frequent findings included ictal vocalizations (screaming, 9 cases), acrocyanosis or pallor (blue or pale skin, 6 cases), and emesis (vomiting, 4 cases). Some children exhibited opisthotonos (abnormal posturing, 3 cases), rigidity or hypertonia (increased muscle tone, 2 cases), hypotonia or flaccidity (decreased muscle tone, 2 cases), or automatisms (stereotyped rhythmic movements, 1 case). Respiratory compromise was observed in several cases: apnea (cessation of breathing) or dyspnea (difficulty breathing) was reported in 3 instances, and expiratory stridor (wheezing) in another 3. One case involved significant oxygen desaturation requiring supplemental oxygen therapy. Normal respiration was explicitly documented in only 1 case. Regarding seizure characteristics, 2 episodes were described as uncomplicated (simple febrile seizures), while 3 were noted to resemble prior seizures (recurring febrile seizures). One parent expressed acute psychological distress, describing the event as “the horror.”

In 10 out of 56 cases parents reported that their child remained not responsive and required 20 to 30 minutes to be “back to himself/herself.” In 1 case it took over 45 minutes and sleep for the child to become responsive again. Two cases reported that the child was not able to talk for a while. In many cases (n=17), children were very sleepy or lethargic afterward. Parents reported that their child was vomiting (2 cases), salivating (1 case), screaming (1 case), and twitching (1 case) afterward. One noted that she had “the feeling the seizure continued.”

In 16 out of 56 cases, an ambulance was called, or they drove to the emergency room, and in 15 cases, they stayed at the hospital for observation for up to 2 days. One parent was going to a neurologist the next day. Influenza A (2 cases), a side effect of the measles vaccination (1 case), and a mild blood infection (1 case) were diagnosed in the hospital.

Paracetamol was given before the seizure in 1 case, and in 2 cases, paracetamol and ibuprofen were administered. In many cases (16/56 cases), diazepam was given during the seizure. In 2 cases, a double dose of diazepam or diazepam and additionally buccolam was administered. In 1 case it was a combination of diazepam and an antipyretic. Some children (3 cases) received paracetamol or ibuprofen afterward as well. In contrast to children with only 1 seizure or their first seizure, children with more seizures received diazepam as an anticonvulsive medication more frequently.

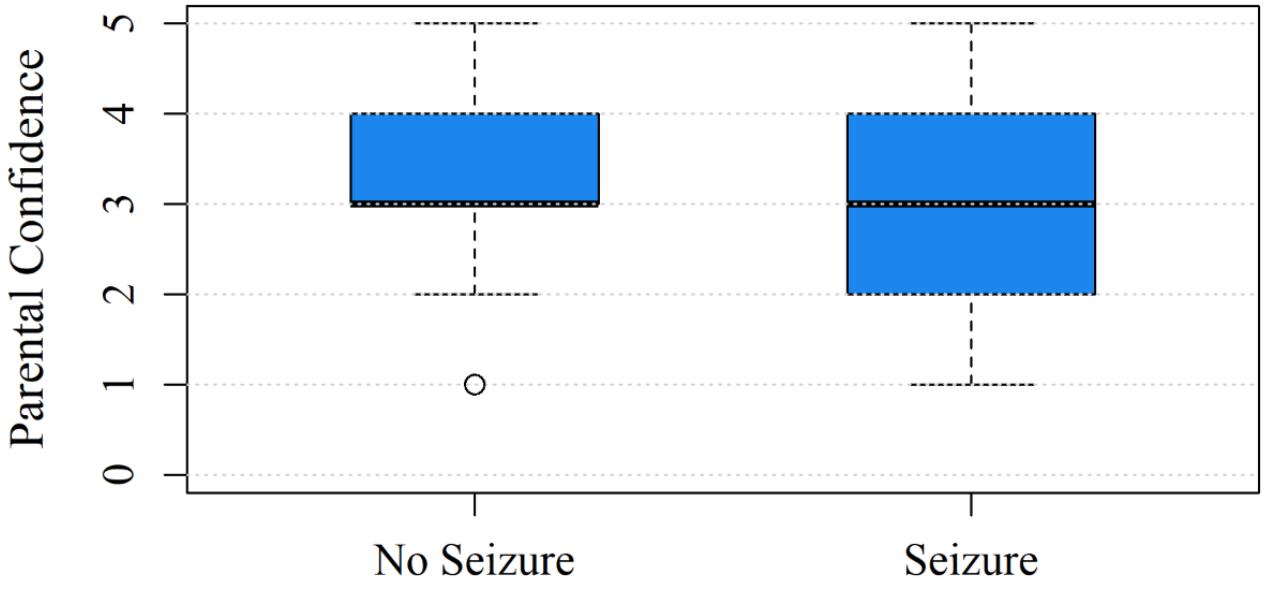
Overall, these reports illustrate the range and frequency of symptoms, postictal behaviors, and parental responses during multiple febrile seizure events, highlighting recurring patterns such as tonic-clonic activity, blue lips, postictal unresponsiveness, and the frequent involvement of emergency services or administration of diazepam.

XSL•FO
RenderX

Comparative Quantitative Analysis of Febrile Children With or Without a Febrile Seizure

Overview

Only 0.4% of all children in the FeverApp had a febrile seizure documented. Although most children with a fever were male (14,298/27,342, 52.3%), febrile seizures were evenly distributed (57 female, 57 male; total 114) around gender. The median age of children with a febrile seizure was 30 months (IQR 13-42) and without a febrile seizure was 21 months (IQR 7-36). The age distribution between the groups differed significantly in the 2-tailed *t* test (t_{27237}=–2.41, *P*=.02). After matching, each group consisted of 114 children with an identical distribution of age (mean 31.68, SD 24 months) and gender (57 male and 57 female children in each group).



Temperature

Children's mean temperature without a febrile seizure was 38.6 °C and ranged within an episode from 38.0 °C to 39.0 °C. The mean temperature with a febrile seizure was 38.7 °C and ranged from 37.9 °C to 39.5 °C. The difference was significant in the Mann-Whitney *U* test between the highest reported temperature during an episode, with a moderate effect (*U*=2915; *z*=–4.25; *P*<.001; *r*=–0.25).

Parental Confidence

A Mann-Whitney *U* test was conducted to compare the minimum and maximum reported parental confidence during an episode between parents of children with and those without a febrile seizure. Although the medians were identical in both groups (minimum median 3, IQR 3-4; maximum median 4, IQR 3-5), the average lowest reported confidence differed: parents of children with a febrile seizure reported an average minimum confidence level of 2.9, while parents of children without a febrile seizure reported an average of 3.5. The test revealed a significant difference in the distribution of minimum parental confidence with a small effect size (*U*=3657; *z*=–2.45; *P*=.01; *r*=–0.18). As illustrated in the boxplot in Figure 4, this difference may be explained by the greater spread toward lower values among parents of children with febrile seizures compared with those without.

Figure 4. Boxplot comparing the minimum parental confidence levels between the group of children with and without a seizure.

Children's Well-Being

A Mann-Whitney *U* test was conducted to compare the minimum and maximum reported children's well-being during an episode between the group of parents with children with and those without a febrile seizure. The medians for both groups ranged between 2 and 3 (low to moderate well-being) within an episode, with no significant differences. Further information is provided in Table 2.

[a]Not applicable.

Contact With a Doctor

In 59% (64/196) of cases, parents had no contact with a doctor when their child did not have a febrile seizure, whereas in the group of children with a febrile seizure, only 34% (30/196) had no contact with a doctor. In this group, 35% (31/196) had contact with an emergency service. Parents who did not have a child with febrile seizure only contacted an emergency service in around 5% (5/196) of cases. The difference was significant in the Fisher exact test, with a moderate effect (*P*<.001; Cramer V=0.401).

Vaccination in the Past 2 Weeks

About 14% (14/179) of children with no febrile seizure had a vaccination in the past 2 weeks. There was a lower percentage of recent vaccination (8/179, 11%) in the group of children with a febrile seizure, although this difference was not significant in Fisher exact test between the 2 groups.

Chronic Diseases

In the group of children with a seizure, 14% (16/203) had a chronic disease, whereas only 3 % (3/203 cases) in the group with no seizure had a chronic disease. Fisher exact test indicated that the difference was statistically significant at the conventional alpha level, with a weak effect (*P*=.004; Cramer V=0.196). Most children had asthma (5 cases), epilepsy (2 cases), or neurodermatitis (2 cases).

Fever in the Past 12 Months

Around one-third of children in the group without a seizure (31/101, 31%) and around one-fourth in the group with a seizure (24/101, 24%) had no fever in the past 12 months. Around two-thirds of children in both groups (61/101, 60% vs 62/101, 63%) had fever 1-5 times in the past 12 months. There was no significant difference in the chi-square test.

Tendency for High Fever

Almost all children in both groups (83/194, 85% vs 75/194, 78%) had a tendency for high fever "never" to "few times." There was no significant difference in the chi-square test.

Typical Fever Duration

Almost all children in both groups (24/56, 92% vs 29/56, 97%) had a normal fever duration of up to 3 days. There was no significant difference in the Fisher exact test.

Antipyretics in the Past 12 Months

Most children in both groups got antipyretics in the past 12 months (79/188, 82% vs 73/188, 79%). There was no significant difference in the chi-square test.

Cooling/Warming During Fever Rise

More parents in the group of children with a febrile seizure would cool their child during fever rise (22/106, 42%) than in the group of children with no febrile seizure (15/106, 28%). Around one-quarter of parents in both groups would warm their child during fever rise (15/106, 28% each). Around 30% (16/106) of parents in the group of children with a febrile seizure would neither cool nor warm their child, whereas 43% (23/106) of parents in the group of children without a febrile seizure would do neither. Even though there was a relevant difference in percent between the groups, these differences were not significant in the chi-square test. Table 3 shows further results from the comparison of children with and those without a seizure.

Discussion

Overview

The primary aim of this study was to assess the effectiveness of the FeverApp as an EMA registry for febrile illnesses, specifically in relation to febrile seizures. Additionally, the study sought to expand existing research and identify improvements for associated EMA registries. Our results provide valuable insights into the characteristics and management of febrile illnesses in children.

Descriptive Qualitative Analysis of Parental Descriptions of Febrile Seizures

The detailed descriptions of febrile seizures provided by parents offer critical insights into the nature and management of these events. Of 226 reported febrile seizures, a significant portion (60%) included comprehensive reports, revealing common patterns in symptoms and parental actions during these distressing episodes. These included temperature, duration, description of the seizure itself, measures that were taken, and contact with a doctor. Some parents even recorded the seizure years after it occurred, which highlights the importance in their

XSL•FO
RenderX

perception. The febrile seizure module itself is not in the normal backend of the FeverApp but in a different menu, so users must invest extra cognitive effort to record febrile seizures. This finding likewise emphasizes the importance of precise documentation and longitudinal analyses to better understand the lasting effect of febrile seizures.

Among children with a single seizure (13 out of 70 cases) and those with multiple seizures (10 out of 17 cases), many parents reported a high fever of 39.0 °C or higher immediately preceding the seizure. This observation aligns with current research indicating that 75% of seizures in children occur at body temperatures exceeding 39 °C [1]. Descriptions of the fever as "fast rising" or "from 0 to 100" in children with a single seizure (2 cases) and in those with multiple seizures (2 cases) suggest that rapid increases in body temperature may act as a trigger as well. This observation is consistent with existing literature on febrile seizure [1].

The duration of seizures varied between both groups, with most episodes lasting less than 3 minutes. This finding is congruent with related research, where seizures were reported to typically last 1-1.5 minutes. In both groups, however, seizures extended up to 10 minutes, and in 3 cases even up to 20-30 minutes. This may be due to a temporal overestimation on the part of the parents, or as an indicator that the episode constitutes a more complex seizure. Due to the highly emotional nature of seizures, especially during a child's first episode, parents' subjective time perception may often overestimate the actual duration [1,45], that is, this deviation may constitute a systematic time perception bias that warrants further investigation. It should be noted that parents who reported a longer duration consistently described the seizure with additional symptoms (ie, "teeth grinding" and "muscle cramping"). These symptoms were not halted by diazepam, which is indicative of a more complex seizure (prevalence estimated to be 20%-25%) [7,10].

Parents frequently noted a period of postictal unresponsiveness, with some children taking up to 20-30 minutes to recover (in some cases, the child fell asleep). This observation aligns with the typical postictal phase seen in febrile seizures, where children may appear disoriented or lethargic following the event [1].

The symptoms reported by parents, such as rolling eyes, blue lips (cyanosis of the lips), unresponsiveness (altered consciousness or unresponsiveness), twitching, and cramping, are characteristic of febrile seizures and are well-documented in the pertinent clinical literature [46]. The variety of symptoms like smacking, teeth clenching, and vomiting, demonstrates that febrile seizures can manifest in a wide range of symptoms.

In terms of emergency response, the descriptions show parental concern in both groups, with an ambulance or emergency doctor being called in 35 cases. The fact that 28 children were admitted to the hospital for observation can be an indicator either for medical evaluation following a febrile seizure or parent's anxiety [1]. An inpatient admission is considered depending on the age, the complexity of the seizure, the result of the clinical examination and parents' anxiety [1]. A further factor is that some hospitals encourage high admission rates for financial reasons.

Antipyretics were administered both prophylactically and reactively, reflecting their widespread use in fever management. It should be emphasized that empirical data indicate that lowering fever does not prevent the occurrence of febrile seizures [17]. In the group of children with more than 1 seizure diazepam was frequently administered. Most febrile seizures are short, typically resolve on their own, and thus do not need immediate pharmacological intervention. However, when a seizure lasts longer than 5 minutes, it may require medical treatment [47]. It is also recommended to prescribe diazepam after the first seizure in case of a relapse, but also for the feeling of security of parents [1]. However, children are often very strongly affected by diazepam, and such pharmaceutical drugs are not for parents "emotional safety." Benzodiazepines have side-effects (especially in neurosensitive children) and should only be prescribed to children as an ultima ratio [48]. Studies have shown that exposure to benzodiazepines can lead to neuronal apoptosis in the developing brain. For instance, research on neonatal macaques demonstrated that short-term exposure to these drugs resulted not only in neuronal apoptosis but also in oligodendroglial apoptosis, impaired synaptogenesis, inhibited neurogenesis, and subsequent long-term neurocognitive deficits [49]. Our understanding of how benzodiazepines affect the neurosensitive developing brain remains very limited. Research into the GABAergic and opioid systems is evolving, and the interplay between neurochemistry and cognitive development (consciousness) represents a cutting-edge area of study. It cannot be prima facie excluded that benzodiazepines may have longitudinal, and potentially epigenetic, effects on neuronal development [50,51]. This possibility underscores the importance of caution in their use and the exploration of safer and less controversial alternatives. There is a growing awareness of the risks associated with benzodiazepine use in children. The US Food and Drug Administration has updated boxed warnings for all benzodiazepine medicines to highlight the risks of abuse, misuse, addiction, physical dependence, and withdrawal reactions consistently across all drugs in this class [52].

Comparative Quantitative Analysis of Febrile Children With or Without a Febrile Seizure

The quantitative analysis showed that febrile seizures were reported in only 0.4% of cases in the FeverApp, which is likely an underreporting compared to the 2%-5% incidence documented in the literature [2-4]. While app-based registries can capture certain diseases, recording serious events seems to remain a challenge. The relevant module is in a separate menu of the FeverApp, located along with technical settings and information about the app, rather than being integrated into the main backend. Enhancing the accessibility of this module could lead to more accurate records. Additionally, the app should encourage users to distinguish more precisely between simple and complex convulsions and to note subsequent events and preperceptions which could enhance the understanding of febrile seizures. Lastly, including a video about febrile seizures in the information library could both improve the module's visibility and provide educational support, increasing user confidence in this area.

Several medical studies and resources document that the risk of febrile seizures is higher in males [13,20-22]. However, the

XSL•FO
RenderX

FeverApp shows a slight predominance of female children with febrile seizures, which may also indicate the underreporting within the app. The majority of the children in the study had only 1 recorded seizure, which speaks for a simple nature of the seizure and aligns with reports in the literature [5].

For a better comparison of the 2 groups (viz, children with and those without a febrile seizure), they were matched regarding age and gender. One of the key findings is the significant difference in the highest reported temperatures between children with and those without febrile seizures. This suggests that higher temperatures might trigger a febrile seizure, which is in alignment with current research [1]. On the other hand, children who experienced febrile seizures had a wider range of temperatures, indicating that even a relatively low fever can potentially trigger a seizure. This supports the idea that individual susceptibility plays a role in the occurrence of febrile seizures and that seizure thresholds can vary among children [1]. It has been stated that recurrent febrile seizures and a family history of febrile seizures have a lower threshold in temperature as well [4].

In managing fever, a notable difference was observed in how parents responded to the onset of fever. Parents of children with a history of febrile seizures were more likely to report cooling their child during a fever rise. In contrast, parents of children without such a history were more inclined to take no action or to warm their child during a fever rise. This disparity highlights the heightened concern among parents regarding febrile seizures and their proactive efforts to manage them through cooling. It also emphasizes the importance of providing proper education on febrile seizures and their management strategies. It is to date unclear whether cooling decreases or increases the probability of developing a febrile seizure. Tumor necrosis factor and other cytokines may lower the seizure threshold. Given that their increase in fever can, to a certain extent, be neutralized by warming the child, it has been proposed that warming in the phase of a rising fever may prevent febrile seizures [53,54].

Children with a febrile seizure were more likely to have a chronic disease (notably asthma and neurodermatitis) which is found in other studies as well. A relevant study in Taiwan found a risk of subsequent asthma in children with febrile seizures [55], and a study in Iran found that febrile seizures are associated with the number of comorbid allergic diseases in children [56]. A Turkish study found that children have a higher risk for febrile seizures when they have a chronic illness that requires continuous medication [57].

Despite the differences in temperature, the reported well-being of the children did not significantly differ between the groups. This suggests that while febrile seizures are distressing, they do not necessarily correlate with a perceived decrease in the overall well-being of the child, as assessed by the parents. This finding is important as it may help reassure parents that febrile seizures, while emotionally alarming, are generally not indicative of a more serious underlying condition affecting the child's health.

Interestingly, no significant differences were found between the groups regarding vaccination history in the past 2 weeks, despite the potential for an increased risk of febrile seizures following certain childhood vaccines, such as the diphtheria, tetanus, and pertussis vaccine, as well as the measles-mumps-rubella vaccine [4]. Similarly, there were no notable differences between the groups in terms of fever frequency, duration, or antipyretic use over the past 12 months.

The study also highlighted significant differences in health care use between the 2 groups. Parents of children who experienced a febrile seizure were more likely to seek medical attention, particularly from emergency services. This is consistent with the high level of concern febrile seizures generate, often prompting immediate medical consultation. They usually occur in the evening and thus lead to emergency consultations. In contrast, parents of children without febrile seizures were less likely to contact a doctor, reflecting greater confidence in managing routine fevers at home. This is also shown in the significant difference in confidence levels between the 2 groups. Parents of children who had experienced a febrile seizure reported lower confidence levels. This is also reported in the descriptions, where one parent noted that "it was the horror" and one parent said she was "scared" and "thought he was dying." The lower confidence and higher emergency consultations among these parents highlight the need for better education and support to help them manage future febrile episodes more effectively.

Strengths, Limitations, and Future Research

This study has limitations. First, all data were self-reported by parents through manual entry rather than automated measurement or clinical verification, which may introduce recall bias, subjectivity, or incomplete reporting, particularly regarding seizure duration and symptoms. While some physiological parameters (eg, temperature or heart rate) could potentially be captured with automated devices, febrile seizures themselves are complex, short-lived events that are initially observed by parents. Seizures are more standardized in clinical settings, but often occur at home and are initially described by caregivers, which limits full automation of data collection in real-world environments. Second, although we used a purposive sample, the relatively small number of detailed seizure descriptions (73 out of 121 cases) and general underreporting of febrile seizures among febrile children (0.4%), limits the generalizability of the findings and formal statistical inference for the broader population. Finally, early pandemic restrictions and later increases during the Omicron wave influenced app use [32,58], but these effects likely evened out across the full dataset collected through 2023.

Despite its limitations, one of the primary strengths of this study lies in the comprehensive data collected from a large cohort of children using the FeverApp, providing valuable insights into febrile seizures and their management in a real-world setting. The matching of the sample led to a more valid comparison of the 2 groups, with age and gender differences being controlled as well as accounting for underreporting in the FeverApp. The detailed parental descriptions of febrile seizures offer a unique perspective on the symptoms, duration, and immediate responses, which are often difficult to capture in clinical settings. Additionally, the study highlights the variability in fever patterns

XSL•FO
RenderX

and seizure characteristics, contributing to a more nuanced understanding of febrile seizures.

Future research could aim to further enhance the data quality of the FeverApp and clinical relevance through partial integration of automated measurements from validated medical devices (eg, temperature or heart rate sensors). Such integration could help to more precisely determine temporal relationships between fever onset, physiological changes, and the occurrence of seizures. In addition, the findings from this study could serve as a basis for developing a structured febrile seizure module with standardized questions reflecting the most frequently reported and relevant anamnestic parameters.

Conclusions

This study offers valuable insights into the characteristics, management, and parental responses to febrile seizures in children, as documented in the FeverApp registry. Its strengths include detailed parental descriptions and real-world data on fever management practices, contributing to a deeper understanding of febrile seizures. However, the findings also highlight the need for further research into the psychological impact on parents. Despite limitations such as reliance on self-reported data and the lack of clinical verification, the study underscores the critical importance of parental education and support in managing febrile seizures. Enhancing these areas could reduce unnecessary medical consultations and improve the care of febrile children. Future research should investigate the effectiveness of parental education in managing febrile seizures and evaluate whether targeted interventions can reduce reliance on emergency medical services. Additionally, improving the reporting mechanism within the FeverApp to better capture febrile seizure data is warranted, as this could address underreporting and support further research. Although video documentation was omitted due to data safety concerns, the registry-based data provides an excellent foundation for future trials on this important topic.

Acknowledgments

We thank all parents and pediatricians who helped us in this project.

Funding

The funding for the FeverApp was provided by the Software AG Foundation (20%) and a total of 80% by the German Federal Ministry of Education and Research (grant number: 01GY1905) for the years 2019–2024.

Data Availability

The datasets analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

DM and RM contributed to the conceptualization of the study. The methodology was developed by RM and EJ, while the software was handled by DM and EJ. Validation was carried out by EJ and DM, and formal analysis was performed by RM and EJ. The investigation involved contributions from DM, EJ, MG, and SS. Resources were provided by DM, and data curation was conducted by EJ. The original draft of the manuscript was prepared by DM, RM, CBG, MG, SS, and EJ, while writing, review, and editing were undertaken by DM, RM, CBG, and EJ. Project administration was managed by SS, and funding acquisition was carried out by DM and EJ. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Neonatal jaundice is a very common condition in the first week of life requiring timely recognition of the small subset of neonates at risk of developing severe neonatal hyperbilirubinemia (SNH). Total serum bilirubin, as quantified through blood testing, remains the gold standard for diagnosis, whereas screening based on visual inspection has been proven unreliable in identifying which jaundiced neonates require total serum bilirubin. Picterus Jaundice Pro (JP) is a mobile health app developed for use by health care professionals and parents to screen for imminent SNH. However, parental user experiences with Picterus JP remain largely unexplored.

Objective: This study aimed to evaluate the usability and user-friendliness of Picterus JP when used and evaluated by parents.

Methods: Between August 2023 and January 2025, we conducted a prospective mixed methods study at 3 maternity care settings: the maternity wards of 2 hospitals in the Netherlands and 1 hospital in Israel. Parents were invited to participate if their infant was near term born (gestational age of ≥35 weeks) and at least 12 hours old but still in the first week of life. Parents used Picterus JP once according to the manufacturer's instructions. Immediately afterward, usability was evaluated using the validated mHealth App Usability Questionnaire, an instrument measured on a 7-point Likert scale ranging from 1 ("strongly disagree") to 7 ("strongly agree"), and open-ended questions. A subset of parents and nurses participated in semistructured interviews and focus groups.

Results: In total, 123 parents completed the questionnaire. The median mHealth App Usability Questionnaire score was 6 (IQR 5-7) out of 7. A total of 87.7% (100/114) of the parents indicated that they would use Picterus JP at home. Parents reported that they found the app easy, quick, and convenient, although 55.8% (67/120) reported a failure on the first try. Some parents struggled to find or interpret the instructions, but most of those who tried again (79/105, 75.2%) obtained a bilirubin estimate. Additionally, 12 nurses from 2 participating maternity wards provided their observations on parents' use of Picterus JP in 2 focus groups. Thematic analysis of all combined data identified 3 themes that were considered important for the usability of Picterus JP: intention to use Picterus JP, infant well-being, and instruction and guidance.

XSL•FO
RenderX

Conclusions: Parents rated Picterus JP highly in terms of usability despite encountering difficulties during initial use. Technical improvements and more proactive guidance seem important to support successful parental use. Nonetheless, both parents and nurses were positive about the potential of Picterus JP for home screening for SNH.

KEYWORDS

bilirubin screening; clinical decision support; digital health; hyperbilirubinemia; jaundice detection; mobile health; neonatal jaundice

Introduction

Neonatal jaundice, a yellowish discoloration of the skin and sclerae, occurs in the first days of life due to excessive levels of total serum bilirubin (TSB) [1]. Neonatal jaundice affects over 80% of neonates and is generally self-limiting [2]. However, in 4% to 9% of near-term neonates, treatment is necessary to prevent neonatal jaundice from progressing to severe neonatal hyperbilirubinemia (SNH) [3,4]. Undiagnosed and untreated SNH can lead to irreversible brain damage (ie, kernicterus). Kernicterus is a preventable condition that leads to sensorineural hearing loss, vertical gaze paralysis, dystonia, or more subtle forms of kernicterus spectrum disorders [5]. Therefore, within the large group of jaundiced infants, it is paramount to detect those who develop potentially dangerous levels of TSB.

The gold standard for diagnosing hyperbilirubinemia is quantification of TSB levels through blood sampling [6]. Screening via transcutaneous bilirubin (TcB) is a reliable method to facilitate early recognition of SNH, but the costly TcB devices are not accessible to everyone everywhere every day [7]. As such, visual inspection is widely used by health care professionals (HCPs) to assess the severity of jaundice, although this has shown to be unreliable and inaccurate [8,9].

In some countries, a predischarge TSB or TcB screening is performed to ensure appropriate follow-up of neonatal jaundice [4]. However, this often occurs before the physiological peak in TSB levels, which is typically around the fourth day of life. Other strategies encompass the use of risk factors to predict the risk of developing SNH [10-12]. However, HCP home visits are typically scheduled once or a few times during the first week of life but do not occur daily. As a result, jaundiced neonates may continue to develop SNH unnoticed, placing them at risk of kernicterus and the need for intensive treatment once diagnosed [13].

To support timely diagnosis and treatment, several novel devices to screen for SNH have been developed [7,14-18]. Only a subset of these approaches uses smartphone apps, allowing for bilirubin screening using widely available smartphones rather than dedicated devices.

One of these apps is the Picterus Jaundice Pro (JP), a mobile health (mHealth) app developed to estimate bilirubin levels noninvasively. Picterus JP showed high sensitivity (94%) in detecting SNH and has obtained European CE marking [19-21]. Parents increasingly use mHealth tools for monitoring in the neonatal period [22]. However, the usability of existing apps varies widely, and usability influences use in real-world settings [22,23]. By empowering parents to use the app at home, Picterus JP could facilitate frequent screening for imminent SNH at any time. However, parental experiences with Picterus JP remain largely unexplored.

Therefore, this study aimed to determine the usability and user-friendliness of Picterus JP when used and evaluated by parents.

Methods

Study Design

We evaluated the usability and user-friendliness of Picterus JP through a prospective mixed methods study using the validated mHealth App Usability Questionnaire (MAUQ), open-ended questions, interviews, and focus groups.

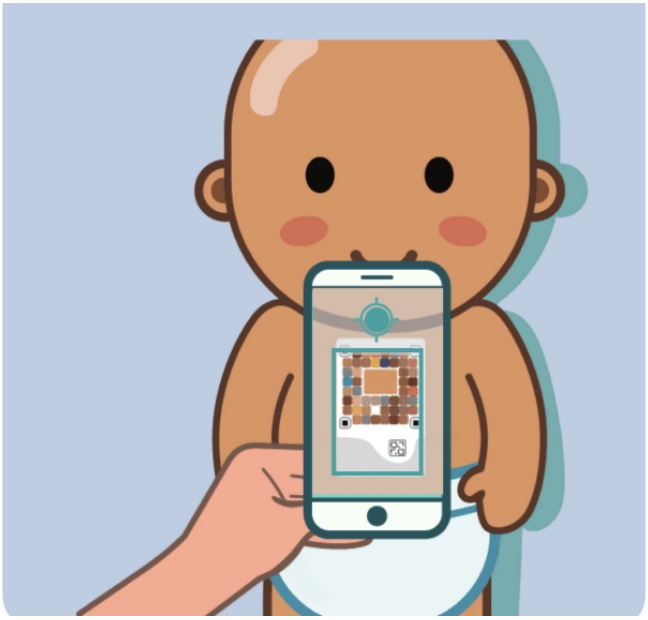
Setting and Participants

This study was part of the Jaundice@Home project conducted under the Transforming Health and Care Systems program (project number: 1477) [24]. Participants were recruited from 3 distinct real-world newborn care settings: the maternity wards of 2 hospitals in the Netherlands (Frisius Medical Center, Leeuwarden, and University Medical Center Groningen [UMCG]) and 1 in Israel (Shamir Medical Center). This study was initially conducted in the Netherlands from August 2023 to December 2023 (period 1) and extended to Israel from October 2024 to January 2025 (period 2). To ensure comparability, this study was also repeated at UMCG in the Netherlands in the second period.

Parents and/or caregivers were invited to participate if their neonates were healthy, with a gestational age of 35 or more weeks and between the age of 12 hours and 7 days. At least one parent was required to have sufficient proficiency in Dutch (in the Netherlands) or Arabic or Hebrew (in Israel).

Intervention

Parents were asked to use Picterus JP at least once during their hospital stay. Immediately afterward, parents completed a paper questionnaire about their experiences, which was collected within 24 hours. The app could only be used by parents during their hospital stay for practical and safety considerations. All participating neonates received standard care to ensure safe practice. This included visual inspection for signs of jaundice and TcB and/or TSB measurements as deemed necessary by the attending physicians or midwives. The use of the Picterus JP app did not affect standard care.



All parents received a Picterus calibration card, a download link, and the same instructions for using Picterus JP at their

XSL•FO
RenderX

convenience. The instructions consisted of a brief verbal explanation; textual instructions (via the patient information letter or app); and pictograms, which were included in the app and printed out [25]. The study team did not provide explicit demonstrations or guidance before and during app use. Nurses received a demonstration of the app at the beginning of the study period. The study team and nurses were encouraged to leave the room while parents used the app but would sometimes remain as silent bystanders. Parents either installed the app on their own smartphones (the Netherlands) or used a Samsung Galaxy A50 smartphone provided by the researchers (Israel).

When starting Picterus JP, users were instructed to place the square, colorful Picterus calibration card on the infants' bare chest (Figure 1). Picterus JP then guided users on-screen on how to correctly position their smartphone (ie, angle and distance). Once the app detected that the conditions were appropriate (ie, correct placement of the calibration card and positioning of the smartphone and sufficient ambient light), it would then automatically proceed to take 6 photos: 3 with flash and 3 without.

Figure 1. Intended use of Picterus Jaundice Pro. Figure used with permission from Picterus AS.

After capturing the images, the app either displayed a bilirubin value (in µmol/L or mg/dL depending on the setting) or issued an error message. If an error occurred, the app either stated that the measurement was unsuccessful or, if possible, provided a reason (eg, insufficient ambient light or shadows rendering the photo unsuitable for analysis). During the photo-taking phase, the app attempted to correct suboptimal conditions by offering simple on-screen instructions to the user. If image quality remained insufficient, Picterus JP stopped the standard 6-image count and either continued attempting automatic image capture or temporarily paused image capture. Image counting resumed only once image quality improved following user adjustment. If adequate image quality could not be achieved, the measurement attempt was eventually aborted and an error message was displayed, when available.

Data Collection

Quantitative Data Collection

The MAUQ was used to evaluate Picterus JP usability. This is a validated instrument specifically designed to evaluate the usability of mHealth apps [26].

The MAUQ consists of 18 statements divided into 3 subscales: ease of use, interface and satisfaction, and usefulness (Table S1 in Multimedia Appendix 1). One statement (number 17) from the original MAUQ version was omitted because it assessed offline functionality, which did not apply. The MAUQ was scored from 1 ("strongly disagree") to 7 ("strongly agree") on statements in favor of the device. Statements were translated from English into Arabic, Dutch, and Hebrew and verified via independent back translation.

Qualitative Data Collection

All parents were asked to answer 4 open-ended questions about their experiences with the app to elaborate on topics such as their general experience, child comfort, and possible malfunctioning of the app and provide additional comments.

Semistructured interviews and focus groups were conducted using a topic list covering 4 categories: general experience, instruction and guidance, possible app malfunctions, and perceived future use and suggestions for improvement. The topics encompassed 2 to 5 questions that the researcher could use to elicit further responses if participants provided limited information. The topic list can be found in Multimedia Appendix 2.

A subset of 5 participants per center was invited to take part in the semistructured interviews at the midpoint of the study period. Participants were initially approached consecutively at that time point. After the first 2 interviews, additional participants were selected to ensure representation across a broad range of MAUQ scores. The interviews lasted between 5 and 15 minutes and were conducted either in person or over the phone by local members of the study team. The interviews were generally audio

XSL•FO
RenderX

recorded and transcribed, whereas phone interviews were documented through detailed notes. Data saturation was considered to have been reached when no new codes or themes emerged from the available data.

Registered nurses in the Netherlands were invited to share their observations in focus groups held at the end of a regular work shift near the end of the study period. The number of focus groups was determined pragmatically rather than through data saturation: one in each center where nurses had observed parents using Picterus JP. Focus groups were led by 2 researchers (FT and TdV) and were recorded and transcribed. Each session lasted between 15 and 25 minutes.

Definition of Participant Characteristic Variables

Parental educational level was classified into three categories according to the self-reported highest level attained: (1) basic education (elementary school), (2) intermediate education (high school and vocational training), and (3) advanced education (college or university degree).

Postnatal age was recorded in 24-hour intervals (eg, 24-48 hours and 48-72 hours) based on the time of birth. Daily check-ins were conducted by the study team to confirm whether parents had used the app within the previous 24 hours. Exact age in hours was not documented. Infants younger than 12 hours were not enrolled due to the informed consent reflection period.

Additional demographic and clinical variables collected from infants and parents were neonatal sex, birth weight, gestational age, maternal parity, and country and hospital of recruitment. These variables were collected as per standard clinical documentation.

Limited information on health care providers was collected, including age, years of work experience, and the number of times they observed the use of the app.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki. In the Netherlands, the study was approved by the Central Ethical Review Committee of UMCG (research register number 10763). This study was classified as falling outside the scope of the Medical Research Involving Human Subjects Act. Local feasibility was confirmed by the Regional Ethics Review Committee at Frisius Medical Center (reference: RTPO 1160). In Israel, the study was approved by Shamir Medical Center Helsinki Committee (approval number 264-23-ASF). Informed consent was obtained from the parents of all participating neonates.

Data Analysis

Sample Size

A convenience sample of 120 participants was targeted across 2 study periods, with 30 participants per participating center in each period. This sample size was chosen to ensure sufficient variation in user experiences for a usability study while remaining feasible within the available study duration and recruitment capacity of the participating sites. No formal power calculation was applicable as this study did not aim to detect statistical differences but to explore usability and user perceptions.

Quantitative Data Analysis

The Likert-scale data of the MAUQ were summarized using medians and IQRs given the skewed data distribution as visually assessed via histograms. Other categorical data were represented as relative distribution (frequencies and percentages) per item. Demographic variables were assessed for normality and reported as means with SDs, medians with IQRs, or ranges depending on distribution. No formal hypothesis testing was performed; all analyses were descriptive. Microsoft Excel and SPSS Statistics for Windows (version 28; IBM Corp) were used for all analyses.

Qualitative Data Analysis

Qualitative data from focus groups, in-depth interviews, and the 4 open-ended survey questions were analyzed and systematically coded using thematic analysis [27]. Participant responses were summarized as codes (ie, keywords). Codes with similar meanings were grouped into overarching topics. These topics were either facilitators of or barriers to the use of Picterus JP.

Topics (ie, barriers and facilitators) were subsequently organized into themes. These themes could follow the structure of the open-ended questions (deductive) or emerge from the data themselves (inductive). This approach allowed for a comprehensive and integrated analysis of all qualitative sources.

Coding was independently performed by country by local researchers. Additionally, one author (FT) coded all datasets of both countries to ensure consistency across contexts and maintained a manual codebook in Microsoft Excel that was iteratively refined. Another author (TdV) reviewed a sample of the coded data and confirmed agreement with the chosen topics and thematic structure.

Quantitative MAUQ results are presented first, followed by qualitative findings that provide additional context to these results.

Results

Participants

In total, 123 parents completed the MAUQ and open-ended questions. Table 1 shows participant characteristics. The sample included both first-time and experienced parents, with a relatively high proportion (78/123, 63.4%) of participating parents having completed higher education. In total, 16 parents were approached for in-depth interviews: 12 (75%) participated after 2 reminders across the 3 centers. Data saturation was reached after approximately 5 interviews.

XSL•FO
RenderX

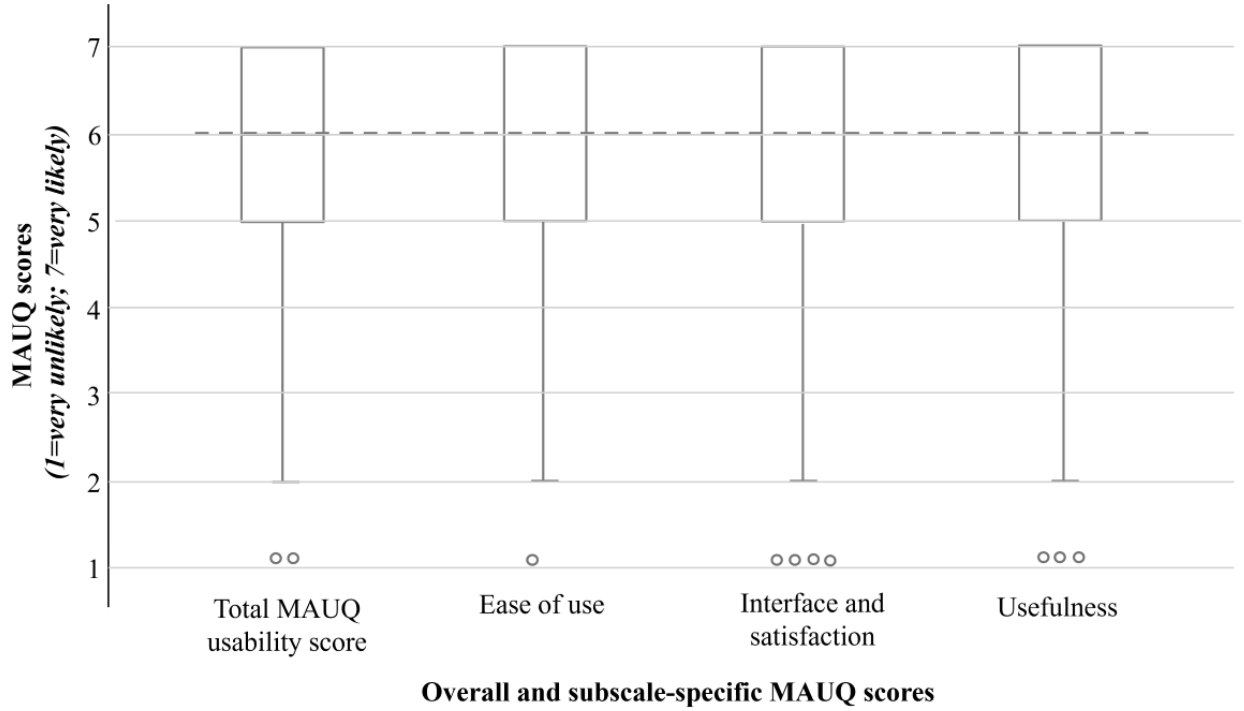
Table 1. Participant characteristics: neonate and parent dyads.

Variable	The Netherlands (n=93)	Israel (n=30)
Hospitals, n	2	1
Parents per period, n (%)		
2023	62 (66.7)	0 (0)
2024 and 2025	31 (33.3)	30 (100)
Interviews with parents, n	6	6
Gestational age (wk), median (IQR)	39 (38-40)	39 (38-40)
Postnatal age category (h), most common category (range of reported ages)	24-48 (12-144)	24-48 (12-120)
Birth weight (g), mean (SD)	3466 (570)	3552 (339)
Female sex, n (%)	44 (47.3)	14 (46.7)
Maternal parity, n (%)		
First	14 (15.1)	11 (36.7)
Second	48 (51.6)	7 (23.3)
Third or higher	31 (33.3)	12 (40)
Parent educational level, n (%)		
Basic education	1 (1.1)	0 (0)
Intermediate education	25 (26.9)	4 (13.3)
Advanced education	56 (60.2)	22 (73.3)
Unknown	11 (11.8)	4 (13.3)

The 2 focus groups included 12 nurses, all Dutch and female. Nurses had sometimes observed when parents used the app as they had been caring for mother and infant or had heard parents discuss app use afterward. Table 2 shows nurse characteristics. Overall, the nurses were relatively young and had few years of work experience.

Table 2. Characteristics of the registered nurses who participated in 1 of the 2 focus groups.

Variable	Focus group 1 (n=5)	Focus group 2 (n=7)
Location	Frisius Medical Center, Leeuwarden, the Netherlands	University Medical Center Groningen, the Netherlands
Female sex, n (%)	5 (100)	7 (100)
Age (y), median (IQR)	24 (24-26)	27 (23-34)
Work experience (y), median (range)	0.5 (0.3-15)	5 (0-12.5)
Frequency of witnessing Picterus app being used by parents, n		
1 time	1	4
1-5 times	2	3
5-10 times	1	0
≥10 times	1	0



Quantitative Usability: MAUQ

Figure 2 shows the median MAUQ usability score of 6 (IQR 5-7) on a scale from 1 to 7 on the MAUQ. Similarly, the median scores for the subscales of ease of use, interface and satisfaction, and usefulness were 6 (IQR 5-7). There were no differences in overall median MAUQ scores or MAUQ scores per subscale between the 2 countries, among the 3 hospitals, or between both study periods.

Parents expressed the most positive attitudes toward the statements that Picterus JP was easy to learn and improved their access to health care, with a median MAUQ score of 7 (IQR 6-7). All other statements had a median MAUQ score of 6. Table S1 in Multimedia Appendix 1 shows all 17 MAUQ statements and their corresponding median scores.

XSL•FO
RenderX

Figure 2. Total parental mHealth App Usability Questionnaire (MAUQ) scores and scores on the 3 subscales. The median is marked by the horizontal dotted line. The boxes are limited by the 25th and 75th percentiles. The whiskers (⊥) represent the lowest and highest irradiance within 1.5 times the interquartile distance below the box. Extreme outliers (◯) indicate participants who gave the lowest possible rating (ie, a score of 1) on the statements.

Qualitative Usability: Thematic Analysis

Themes, Facilitators, and Barriers

Table 3 shows the results of the thematic analysis. Three themes were identified: "intention to use Picterus JP," "neonatal well-being," and "guidance and instructions." The first 2 themes were deductive, corresponding to 2 open-ended questions, whereas the last theme was inductive and emerged from the interviews and focus groups but was also supported by the responses to the open-ended survey questions. Within these themes, 13 facilitators and 10 barriers were identified.

Table 3. Facilitators of and barriers to using the Picterus Jaundice Pro (JP) app: insights from parents and nurses[a].

Theme	Facilitators	Barriers
Intention to use Picterus JP	• Easy and simple to use (P[b], I[c], and N[d]) • Home access (P and I) • Feeling in control (P, I, and N) • Reassuring for extra monitoring (P and I)	• Difficulties obtaining measurements (P, I, and N) • Doubts about relevance (I and N) • Doubts about reliability (P and I) • Reminders needed (I and N)
Infant well-being[e]	• Quick (P and N) • Comfortable (P) • Safe (P) • Minimally intrusive (P) • Usable at own convenience (P and I)	• Prolonged undress (P and I) • Neonate too upset (P and I) • Camera flash (P and I)
Guidance and instructions	• Easy to understand (P, I, and N) • Self-explanatory (P, I, and N) • Quick to explain (P and N) • In-person explanation (I and N)	• Unclear for parents what to do when a problem occurs (P, I, and N) • Uncertainty among parents regarding what to do with results (P, I, and N) • In-app guidance easy to miss (P, I, and N)

[a]This table presents perceived topics divided into either facilitators of or barriers to using the Picterus JP app. Topics were grouped into 3 themes. Within themes, topics were ordered from most to least frequently mentioned.

[b]P: parents (responses from the survey; n=123).

[c]I: interviewed parents (n=12).

[d]N: nurses who participated in the focus groups (n=12).

[e]The theme "infant well-being" reflected factors related to the infant's comfort and safety as perceived by parents but did not indicate actual clinical risk that was reported during the study.

XSL•FO
RenderX

Open-Ended Questionnaire Responses From Parents

Table 4 presents the 4 open-ended questions for parents. A total of 87.7% (100/114) of the parents responded affirmatively to the first question ("Would you use the app?"). For the second question, 81.7% (98/120) of the parents reported no concerns about their infants' comfort while using the app. A common facilitator in both questions was that Picterus JP was "easy, simple, and quick to use." Common barriers included difficulty obtaining a valid measurement and specific concerns about their baby, particularly when using the app took longer than expected. Parents worried that prolonged undressing might result in hypothermia or cause the neonate to become upset. Of the 22 parents who expressed concerns, 20 (87%) reported having encountered difficulties using the app.

Table 4. Open-ended questions[a].

Question	Yes, n (%)	No, n (%)
Would you use the app? (n=114)	100 (87.7)	14 (12.3)
Concerned about neonates comfort? (n=120)	22 (18.3)	98 (81.7)
Did you encounter any difficulties using the app? (n=120)	67 (55.8)	53 (44.2)
Do you have any other comments? (n=123)	50 (40.7)	73 (59.3)

[a]Missing data were excluded from the analysis.

For the third question ("Did you encounter any difficulties using the app?"), 55.8% (67/120) of the parents reported having experienced an issue. Textbox 1 shows the reasons for difficulties, which varied between study periods and countries and were either device-related or user-related issues. Device-related difficulties referred to issues in which parents reported having received an error message. For example, when the photo quality was insufficient for analysis, Picterus JP could display a message such as "ambient light insufficient" or "difficulty focusing."

Textbox 1. Parental difficulties when using the Picterus Jaundice Pro app for the first time organized from most to least frequent.

Device-related difficulties

- Issue with focusing and/or ambient light
- Miscellaneous error messages (ie, freezing or calibration card not recognized)
- Unknown error
- Phone not compatible

User-related difficulties

- Baby factors (ie, upset or moving)
- Finding the instructions unclear
- Using the calibration card incorrectly
- Miscellaneous parental factors (ie, hand tremors)

User-related difficulties included cases in which the infant was too "uncooperative" to obtain sufficient photos or parents acknowledged incorrect use of Picterus JP (eg, displacing the calibration card).

During the first study period in the Netherlands (2023), 58.1% (36/62) of the parents primarily encountered device-related difficulties for various reasons. During the second period in the Netherlands (2024), 32.3% (10/31) of the parents reported difficulties, which were primarily user related, whereas in Israel (2025), 76.7% (23/30) of the parents reported difficulties, and these were mostly device related. In Israel, 30.4% (7/23) of these parents indicated an issue in which ambient light was insufficient. Multiple attempts were made to improve ambient light. Retrospective analysis of these photos indicated that the issues in these cases were often related to the quality of the camera and the saved file format of the specific phone model being used.

Of the 105 parents who attempted the measurement again, even though this was not required within the scope of the study, 79 (75.2%) reported that they were able to obtain a bilirubin estimate. Similarly, 70% (21/30) of the Israeli parents reported a successful measurement after further attempts.

The fourth question ("Do you have any additional comments?") resulted in 50 responses that were integrated into the thematic analysis (Table 3). Some comments addressed misunderstandings and suggestions regarding the instructions and in-app guidance (ie, correct use of the calibration card), whereas others expressed uncertainty about interpreting the results. Additionally, satisfaction with Picterus JP was expressed. All emerging topics were closely aligned with findings from the other survey questions, interviews, and focus groups.

Findings From Focus Groups With Nurses and Interviews With Parents

Because themes and topics overlapped, results from parents and nurses are presented together. The identified topics in focus groups with nurses and in-depth interviews with parents supported and further contextualized the topics previously reported by parents in the questionnaires. This led to the identification of 3 additional topics (Table 3).

An additional identified facilitator was the perceived value of receiving an in-person explanation or demonstration of the app. There were 2 additional barriers. First, parents needed reminders to use the Picterus JP app. Another issue was that in-app guidance could easily be missed, which delayed or disrupted the process. All 3 of these topics were mentioned by both nurses and parents. Table S1 in Multimedia Appendix 3 presents supporting quotes from nurses.

Theme 1: Intention to Use Picterus JP

Consistent with questionnaire findings, ease of use was frequently mentioned as a facilitator by parents and nurses (quote 1: Multimedia Appendix 3). However, more unique to this part of the data collection, both nurses and parents noted that reminders to use Picterus JP were often necessary (quote 2).

Parents appreciated the ability to monitor their neonate for jaundice themselves but questioned its added relevance alongside regular health care visits. Parents stated that it had to be very clear for them what they had to do with the results. In the interviews, they emphasized the need for clear guidance. Nurses acknowledged the relevance as well, noting that their clinical experience and recognition of early signs of jaundice served as important reminders for parents (quote 3).

Theme 2: Neonatal Well-Being

Similarly to the answers from parents, nurses mentioned that taking a photo using Picterus JP was perceived as quick and nondistressing for the neonate. Similarly to the questionnaire, parents expressed a preference for additional warnings about the camera flash to remind them to cover their neonates' eyes (quote 4). Nurses expressed no concerns about infant well-being during the use of Picterus JP when asked about disadvantages or improvements that could be made.

Theme 3: User Guidance and Instructions

User guidance and instructions were most prominently discussed during interviews and focus groups. Oral explanations were preferred over written instructions even though, in general, the latter were considered clear (quote 5). Nurses found the instructions easy to explain, and often parents agreed that understanding what to do was straightforward (quote 6).

Interestingly, as was often reported in the survey and also shown in Textbox 1, when parents were unsuccessful in obtaining a measurement, it was not always clear to them what had gone wrong (quote 7). Some parents admitted in hindsight that they had not fully paid attention to the in-app guidance or that they had misunderstood the instructions (quote 8). Some nurses reported that, at times, they were unsure why a measurement had failed. In contrast, other nurses stated that the cause of failure was often clear to them as observers, whereas parents appeared to have overlooked the in-app guidance (quote 9).

Overall, nurses in the focus groups were positive about the potential parental use of Picterus JP in the home setting (quote 10).

Discussion

Principal Results

We determined how parents perceived the usability and user-friendliness of Picterus JP, a novel smartphone app to allow for early detection of imminent SNH. Our results show that parents rated Picterus JP highly on usability, supported by a median MAUQ score of 6 (IQR 5-7) out of 7. Parents described Picterus JP as easy, simple, and quick to use.

A considerable number of parents reported either technical difficulties or movement of their baby as reasons for failing to obtain a result on the first use of Picterus JP.

Technical difficulties reported by users may be partly explained by the variation in smartphone devices used across study sites despite the fact that these devices passed Picterus JP's compatibility check. However, some phones (eg, budget models) may still be more sensitive to ambient lighting conditions. In Israel, all parents used the same midrange phone provided by the study team, whereas in the Netherlands, varied personal devices were used. This difference may explain the lower incidence of technical difficulties in the Netherlands than in Israel. Furthermore, within the Dutch sites, technical difficulties decreased in the second study period, possibly due to ongoing software improvements of Picterus JP.

In addition to technical difficulties, some parents (22/120, 18.3%) expressed concerns regarding neonatal well-being during app use. Frequent topics were concerns about the infant becoming cold or upset. Most of these parents (20/23, 87%) reported having encountered difficulty using Picterus JP on their first attempt. This may suggest a possible connection between prolonged attempts and parental concerns, but this was not formally studied.

Although parents and nurses found the Picterus JP instructions clear, they reported that instructions could be overlooked or misunderstood. It is possible that, in some cases, unsuccessful attempts were related to skipped or misunderstood instructions rather than technical failure alone. Picterus JP offers multiple instructions: symbols on calibration cards and the app launch screen, online text, and in-app pop-ups. It is tempting to speculate that passive instructional methods may not fully support parents in busy postpartum settings.

Nonetheless, most parents (100/114, 87.7%), even among those who encountered technical difficulties or had concerns, stated that they would use the app at home. This implies that, despite initial barriers, overall acceptability and perceived usefulness of Picterus JP in a home setting are high, which are both essential prerequisites for its implementation. Given the near-universal smartphone use in our study population, eventual barriers to implementation are unlikely to stem from limited access to or lack of experience with smartphones [28].

XSL•FO
RenderX

Notably, the nurses participating in focus groups were young and had limited work experience, reflecting the composition of junior and senior staff typically present during shifts. Demographic characteristics, with younger nurses potentially being more technologically savvy, may influence generalizability but also improve comparability with similarly aged parents.

Nevertheless, all nurses had experience with SNH screening and regarded Picterus JP as relevant and useful. They emphasized that parents engaged more with Picterus JP when its relevance was clear to them too. Moreover, insights from nurses helped contextualize parental responses as they frequently observed parents during the use of Picterus JP. This underlines the importance of incorporating multiple perspectives in usability studies.

Comparison With Prior Work

While many SNH screening applications have been developed over the years, our findings align with broader digital health literature showing that the main challenges of home-based screening tools lie in usability [29]. Despite the widely recognized need for accessible screening tools to detect SNH, still few clinically validated alternatives currently exist. Although noninvasive screening can be performed using TcB devices, these devices are rather costly and currently not available in home settings [7]. To save costs, 2-color and multicolor icterometers (ie, the BiliStrip and Bili-Ruler, respectively) have been developed with rather acceptable screening performances and interrater reliability [14,17]. In parallel with these icterometers, other smartphone apps to optically estimate hyperbilirubinemia have been developed and studied over the past years [7,15,16]. Except for Picterus JP, to our knowledge, none have currently published usability results or reached a clinical implementation phase and obtained a CE mark or Food and Drug Administration certification.

Our findings on the usability of Picterus JP are consistent with those of the 2 prior studies to date in which the use of Picterus JP was assessed by HCPs. HCPs perceived Picterus JP as an easy-to-use, useful, and time-saving tool in the management of neonatal jaundice [30,31]. Our study builds on previous work by including the perspectives of both HCPs and parents in high-income countries.

Usability studies are a relevant step for implementation given that apps that are considered easy to use have yielded higher acceptability and satisfaction ratings [32]. However, studies linking app usability to clinical outcomes in pediatrics remain scarce and are mainly focused on chronic disease management [33,34]. The MAUQ is a validated and reliable instrument specifically developed to evaluate mHealth apps used by patients and HCPs, unlike more general instruments such as the System Usability Scale and the Post-Study System Usability Questionnaire [26].

The MAUQ has increasingly been adopted in recent years and used for studies across diverse health care settings worldwide [35]. High MAUQ scores have been associated with proper test performance in another mHealth screening app [36] This suggests that high usability scores as measured using the MAUQ could be a relevant indicator for evaluating the feasibility of successful implementation of a screening mHealth tool such as Picterus JP.

Limitations

This study has several limitations. First, we used convenience sampling, which may limit representativeness, although saturation was observed in the open-ended responses, interviews, and focus groups. The design may have led to selection bias: participants were motivated to take part, comfortable with smartphone use, less frequently first-time parents, and noticeably highly educated on average. We did not observe a clear association between educational level and MAUQ score or between educational level and parental experience (ie, failure to obtain a measurement). This does not eliminate the concern that less technologically savvy or lower-literacy parents may have been systematically underrepresented. Future studies should, therefore, specifically evaluate usability and feasibility in more diverse populations and care settings, including lower-income countries.

Second, the observational nature of our study design limited us to reporting descriptive findings rather than statistical cross-site comparisons or adjusting for potential confounders.

Third, MAUQ scores were generally high (median 6, IQR 5-7 on a 7-point scale) but with no complete concentration at the maximum score, suggesting no clear evidence of a ceiling effect.

Finally, the app was typically used for only 1 measurement in a hospital setting, with limited instruction with the purpose of generalizing the outcomes. One in-hospital measurement with either the study team or an HCP nearby may introduce performance bias and limit ecological validity. Although the study team was not always directly present during measurements, the potential influence of supervision was not systematically assessed. It is important to note that, in real-world settings, parents are also likely to use the app in interaction with HCPs such as maternity care assistants, who provide daily postpartum care in the Netherlands, or during telehealth consultations. The intended repeated daily use of Picterus JP in variable settings might influence user experience differently. Although repeated use might expose the user to other user- and device-related difficulties, familiarity through guidance and practice may also enhance perceived parental usability of the app.

Strengths

To the best of our knowledge, this is the first study to assess the usability of a smartphone-based bilirubin screening tool from the perspective of both parents and HCPs. Furthermore, the multicenter and multicultural setting spanning 2 countries and 3 hospitals adds to the potential generalizability of the results to different health and care systems as similar usability patterns emerged across diverse user groups. In addition, we used a validated instrument (MAUQ) to evaluate usability, which enhances the reliability and comparability of our findings.

Conclusions

Our findings show that parents and nurses highly appreciated the Picterus JP app despite some device- and user-related

XSL•FO
RenderX

difficulties. Our findings highlight the importance of ongoing technological improvements, clear user guidance, and proactive support to improve usability and user experience to successfully facilitate the implementation of parental use of Picterus JP in neonatal jaundice management.

If future studies confirm the clinical accuracy and reliability of parental use of Picterus JP in different populations and health and care systems, daily noninvasive home screening could become feasible. As such, the use of Picterus JP may enable earlier detection of imminent SNH, allowing for timely intervention for at-risk neonates, reducing the emotional and logistical burden on families, and supporting clinical decision-making by HCPs.

Acknowledgments

The authors thank the participating hospitals, Frisius Medical Center, Shamir Medical Center, and University Medical Center Groningen, and their clinical teams for their invaluable support in conducting this study. They are grateful to Picterus AS for providing the calibration cards used in this study free of charge. They thank Picterus AS for granting permission to use Figure 1.

Funding

This study was funded by the Netherlands Organization for Health Research and Development; the European Partnership on Transforming Health and Care Systems; the Innovation Fund of Frisius Medical Center, Leeuwarden, the Netherlands; and the Municipality of Groningen, Groningen, the Netherlands. The authors received free calibration cards from Picterus AS. Picterus AS is a member of the Transforming Health and Care Systems consortium Jaundice@Home. However, the company had no role in the study design, data collection and analysis, or interpretation of the results.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to participant privacy and ethical restrictions but are available from the corresponding author on reasonable request. Data can be shared in fully anonymized form for noncommercial research purposes.

Abstract

Background: Positional cranial deformities are common in infancy. Smartphone-based apps are increasingly used to assess infant head shape, but evidence comparing these tools with 3D scanners across age groups in community-based settings remains limited.

Objective: This study evaluated age-stratified agreement and screening performance of a mobile app for estimating Cranial Vault Asymmetry Index (CVAI) and Cephalic Index, compared with a 3D scanner, when used by a trained examiner during routine municipal health checkups in Japan.

Methods: We conducted a cross-sectional study in Goto City, Japan, between May 2023 and March 2025. Independent, age-specific cohorts of children attending municipal health checkups at 4, 18, and 42 months were included. Paired cranial measurements were obtained by a trained examiner using a VECTRA H2 3D scanner (Canfield Scientific Inc) and the mobile app. Agreement was assessed using mean differences, 95% limits of agreement (LoA), and intraclass correlation coefficients (ICCs), with device-stratified sensitivity analyses. Screening performance was evaluated using sensitivity and specificity based on prespecified clinical thresholds. Receiver operating characteristic (ROC) analyses were secondary exploratory analyses. The primary outcome was app-based CVAI for detecting scanner-defined moderate-or-worse plagiocephaly (CVAI≥7%). Secondary outcomes were app-based Cephalic Index for detecting brachycephaly (Cephalic Index>94%) and dolichocephaly (Cephalic Index<79%).

Results: The final analytic samples comprised 262 children at 4 months, 171 at 18 months, and 216 at 42 months. Agreement for continuous CVAI was highest at 4 months (mean difference 0.14, 95% LoA −4.18 to 4.46; ICC 0.76, 95% CI 0.71 - 0.81) and lower at 18 months (ICC 0.42, 95% CI 0.29 - 0.54) and 42 months (ICC 0.49, 95% CI 0.38 - 0.59). For Cephalic Index, the app consistently overestimated values relative to the scanner, with mean differences of 3.83 SD 3.42, 3.24 SD 3.07, and 2.61 SD 3.33 points at 4, 18, and 42 months, respectively. For detecting scanner-defined moderate-or-worse plagiocephaly, app sensitivity and specificity were 84.8% and 88.0% at 4 months, 50.0% and 88.4% at 18 months, and 53.3% and 89.6% at 42 months, respectively. Device-stratified analyses showed some variation in measurement agreement and screening performance across devices.

Conclusions: Under municipal health checkup conditions with a trained examiner, app-based CVAI showed the strongest performance at 4 months and may be useful for early screening. However, performance was weaker at 18 and 42 months. App-based Cephalic Index was systematically higher than scanner-based Cephalic Index, potentially increasing false-positive classifications for brachycephaly when identical thresholds are applied. Performance varied somewhat between devices, although device effects

XSL•FO
RenderX

could not be separated from study period and accumulated examiner experience. Positive findings, particularly at later ages or for Cephalic Index–based measures, should be interpreted in the context of the child's age and broader clinical findings, with further evaluation or referral considered only when clinically indicated.

Introduction

Positional cranial deformities, including plagiocephaly, brachycephaly, and dolichocephaly, are common conditions observed during infancy. Although some cases may resolve spontaneously over time, moderate-to-severe deformities may warrant early evaluation and, when appropriate, timely consideration of cranial orthotic therapy within a critical age window during which treatment effectiveness is expected to be greater [1-3]. In Japan, parental awareness and concern regarding infant head deformities have increased, and the number of head-shape consultations has risen in recent years [4,5]. In this context, the availability of accessible and reliable tools to support timely assessment and appropriate referral decisions has become increasingly important.

Cranial shape is commonly quantified using standardized indices. For plagiocephaly, the Cranial Vault Asymmetry Index (CVAI) is widely used to quantify cranial asymmetry, whereas the Cephalic Index is used to describe head width-to-length proportions relevant to the classification of brachycephaly and dolichocephaly. In Japan, threshold-based classification systems derived from these indices are routinely applied in clinical and community settings, including the identification of moderate-or-worse deformities that may prompt specialist referral or closer clinical follow-up [6,7]. However, the application of index-based thresholds depends on the availability of measurements that demonstrate sufficient reliability and consistency under real-world conditions, particularly in nonspecialist, community-based settings.

Smartphone- and tablet-based apps that estimate cranial indices from photographs are increasingly available and widely accessible. Such apps have the potential to serve as practical screening tools; however, their accuracy may be influenced by real-world image capture conditions and may vary across different age groups [8-10]. 3D scanners are generally regarded as the reference standard for cranial shape assessment, as they reconstruct head morphology in three dimensions and derive indices in a standardized and reproducible manner [7]. Nevertheless, empirical evidence directly comparing app-based measurements with 3D scanner-derived indices in real-world populations of infants and young children—particularly across different ages and within community-based settings—remains limited.

In Japan, municipal child health checkups provide a near-universal platform for early childhood health assessment and monitoring. The 18-month checkup and the checkup for children aged 3 years to younger 4 years are mandated by law, and a 3 - to 5-month infant checkup is also widely implemented across municipalities. Recent national data indicate attendance rates of approximately 96% for the 3 - to 5-month, 18-month, and 3-year checkups [11]. Accordingly, these settings provide opportunities not only for early identification of cranial deformities during infancy but also for follow-up, parental reassurance, and guidance regarding residual head shape asymmetry in early childhood.

Therefore, this study aimed to evaluate whether this mobile app could serve as a practical screening aid under municipal health checkup conditions by (1) quantifying age-stratified agreement in continuous CVAI and Cephalic Index measurements between a 3D scanner and the mobile app and (2) assessing its screening performance relative to 3D-scanner–based reference classifications for deformational plagiocephaly, brachycephaly, and dolichocephaly.

Methods

Study Design and Setting

This cross-sectional study included infants and young children attending municipal health checkups in Goto City, Nagasaki Prefecture, Japan. The 4-, 18-, and 42-month assessments were treated as independent cross-sectional samples, with no child contributing to more than one age group. A formal a priori sample size calculation for diagnostic accuracy estimates was not conducted because all eligible participants attending the age-specific checkups during the study period were targeted for enrollment.

All measurements were obtained within routine municipal health checkup workflows under standardized conditions. The 4-month checkups were conducted at the obstetrics and gynecology outpatient clinic of Goto Central Hospital, whereas the 18- and 42-month checkups were conducted at the Fukue Comprehensive Welfare and Health Center. Reporting was guided by the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement for observational studies and the STARD (Standards for Reporting Diagnostic Accuracy Studies) 2015 guideline [12,13]. Completed checklists are provided in Checklist 1 (STROBE checklist) and Checklist 2 (STARD checklist).

XSL•FO
RenderX

Participants

Eligible participants were infants and young children, along with their parents or guardians, who attended the 4-, 18-, or 42-month municipal health checkups organized by Goto City between May 2023 and March 2025. Children were excluded if they had a diagnosed congenital cranial disorder or an obvious structural abnormality (eg, craniosynostosis).

These age-specific municipal health checkups have high population coverage, with nearly all eligible children in the target age groups attending. After routine clinical examination and anthropometric measurements, a research nurse or midwife approached parents or guardians to invite participation and obtained written informed consent prior to study-specific measurements.

Data Collection Procedures

Parents or guardians completed a self-administered questionnaire on obstetric history, the child's medical history, and daily positioning and care practices. Additional variables collected for descriptive and comparative purposes included the child's sex, mode of delivery, gestational age at birth, birth weight, and anthropometric measurements at the time of the health checkup (ie, weight, length or height [as appropriate], and head circumference), as well as the presence of muscular torticollis or limitation of hip abduction as assessed by physicians and documented in health checkup records. Information on birth-related and anthropometric variables was extracted from the Maternal and Child Health Handbook and health checkup records. The handbook is a nationally standardized, home-based record system used in Japan to document pregnancy, birth, and child health information, and is routinely referenced during municipal health checkups [14-16].

Cranial measurements were performed after fitting a standardized measurement cap and were obtained using both the mobile app and the 3D scanner during the same visit. All measurements were performed by a trained examiner following a predefined protocol. To minimize burden on children and parents and disruption to routine health checkup procedures, measurements were performed as efficiently as possible and were omitted if the child was excessively distressed or uncooperative.

Reference Standard: 3D Scanner

3D scanners are widely used as the clinical reference method for quantitative cranial shape assessment; however, they do not represent a pathological gold standard independent of measurement. We used the VECTRA H2 3D scanner (Canfield Scientific Inc), which has been used clinically for cranial shape assessment [17,18]. Each child wore a dedicated grid-pattern measurement cap to reduce interference from hair and facilitate 3D surface reconstruction. Children aged 4 and 18 months were imaged while seated on their caregiver's lap, whereas children aged 42 months were seated in a chair. Imaging was conducted by a single trained examiner with assistance from one staff member. All scans were performed throughout the study period by the same examiner, who received prestudy training using a head model.

Cranial images were captured from 7 directions for construction of a 3D cranial model. Subsequent processing and quantitative analysis of the 3D scanner data were performed by Japan Medical Company (JPMC) technical staff according to previously reported methods [7,19,20]. 3D image reconstruction was performed primarily using dedicated software, with manual refinement by technical staff as needed. Subsequent procedures included definition of measurement planes and landmarks, measurement of cranial dimensions, calculation of CVAI and Cephalic Index, and severity classification. A reference plane (0th slice) was defined by connecting the lowest point of the nasal root (ie, the sellion) and the bilateral tragion points, after which the cranium was divided into 10 equal horizontal slices, with the vertex corresponding to the 10th slice. The third slice from the reference plane was used for quantitative analysis. Cranial asymmetry (CA, mm), CVAI using the shorter diagonal as the denominator (CVAI(S), where S indicates the shorter diagonal; %), and Cephalic Index (%) were derived at this slice. CA was defined as the absolute difference between the lengths of the two 30° diagonal lines across the midline. CVAI(S) was calculated as the difference in diagonal lengths divided by the shorter diagonal, expressed as a percentage. Hereafter, CVAI(S) is referred to as CVAI. Cephalic Index was calculated as biparietal width divided by anteroposterior length, expressed as a percentage. Scanner-derived CVAI and Cephalic Index were used as the reference-standard measures for agreement and screening performance analyses.

Index Test: Mobile App

The index test was the "Akachan no Atama no Katachi SOKUTEI (Measurement of Baby's Head Shape)" mobile app, developed by JPMC as a nonmedical, smartphone- or tablet-based tool for assessing infant cranial shape for screening purposes. The app was installed on dedicated tablets. Images captured from May 22, 2023, to June 24, 2024, were obtained using an Apple iPad (sixth generation; iOS 17.5.1), whereas images captured from June 25, 2024, to March 31, 2025, were obtained using a Lenovo Tab M10 Plus (third generation; TB125FU; Android 13). The device change was not preplanned and occurred because the in-app camera function could no longer be launched on the original iPad. The Lenovo tablet was selected as the next available device confirmed to be compatible with the app. For the main analyses, data from both device periods were pooled to evaluate overall performance across the municipal screening program; device-stratified analyses were conducted as sensitivity analyses.

Although the app is intended for use by parents or caregivers as well as health care professionals, all image capture, landmark identification, and contour tracing in this study were performed by a single trained examiner. App-based measurements were performed after 3D scanning by the same examiner using the same measurement cap and positioning, with minimal delay between measurements. The vertex image of the child's head was captured using the tablet's built-in camera. The examiner premarked the positions of both ears and the nose on the measurement cap and, after image capture, identified these landmarks on the two-dimensional image and manually traced the cranial contour according to the in-app instructions (Multimedia Appendix 1). The app outputs 2 indices:

XSL•FO
RenderX

"Yugami-do" (degree of asymmetry) and "Tantou-do" (degree of brachycephaly). Based on developer information and previous validation work, these indices were operationally defined and analyzed as app-based CVAI and app-based Cephalic Index, respectively [8].

Blinding and Test Interpretation

At the time of app-based image capture and contour tracing, the examiner did not have access to the final, processed quantitative results derived from the 3D scanner. Conversely, JPMC technical staff who processed and analyzed the 3D scanner data were blinded to the app-based measurement results. However, because the same examiner performed both procedures consecutively in a fixed order under a partially shared measurement context, the measurements were not fully independent and may have been subject to measurement bias.

Definitions of Cranial Indices and Clinical Thresholds

Plagiocephaly severity was classified according to the CVAI severity criteria specified in the Japanese package insert for the Michigan-style cranial reshaping orthosis: normal (<5%), mild (5%-<7%), moderate (7%-<10%), severe (10%-<14%), and very severe (≥14%) [21].

For the primary screening accuracy analyses, moderate-or-worse plagiocephaly was defined as scanner-derived CVAI≥7%. This prespecified threshold represents clinically meaningful severity for which cranial orthotic (helmet) therapy may be considered [7].

Brachycephaly was defined as scanner-derived Cephalic Index>94% and dolichocephaly as Cephalic Index<79%, based on reference values for Japanese children and thresholds used in previous Japanese clinical studies [7,22]. These thresholds were selected to align with population-specific normative data and established clinical interpretations in Japan. Because age-specific differences in Cephalic Index have been reported among Japanese children [22], analyses were stratified by age at 4, 18, and 42 months.

Statistical Analysis

All statistical analyses were performed using SPSS Statistics (version 29.0; IBM Corp). Agreement, screening performance, and receiver operating characteristic (ROC) analyses were conducted separately within each age group, using participants with paired measurements from both methods for the relevant index. Participant characteristics were summarized as counts and percentages for categorical variables and means and SDs for continuous variables. Continuous variables were reviewed for distributional plausibility to support the use of parametric summaries.

Primary Analysis: Agreement (Continuous Indices)

Agreement between the 3D scanner and mobile app was assessed for CVAI and Cephalic Index within each age group. Differences were calculated as app−scanner, with the mean difference representing systematic bias. Positive values indicated higher measurements from the app relative to the 3D scanner.

Bland-Altman 95% limits of agreement (LoA) were computed as mean difference ±1.96×SD of the differences, and Bland-Altman plots were generated for visual inspection of agreement and potential trends across the measurement range. Systematic and proportional bias were assessed descriptively from the plots. Heteroscedasticity was assessed using Spearman rank correlations between the absolute method differences and measurement magnitude, defined as the mean of the 2 methods.

Intraclass correlation coefficients (ICCs) were estimated within each age group using a two-way mixed-effects model with absolute agreement for single measurements (ICC [1,3]) and reported with 95% CIs [23]. ICCs were interpreted according to conventional thresholds: <0.50, poor; 0.50 - 0.75, moderate; 0.75 - 0.90, good; >0.90, excellent agreement. ICCs were calculated from paired measurements only, using listwise deletion within each age group and index.

Primary Analysis: Screening Performance (Clinically Anchored Thresholds)

For screening performance analyses, 3D scanner–based classifications were used as the reference standard (plagiocephaly: CVAI≥7%; brachycephaly: Cephalic Index>94%; dolichocephaly: Cephalic Index<79%). App-based results were dichotomized using the same thresholds. For each age group, 2×2 contingency tables were constructed to calculate scanner-defined prevalence, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). For sensitivity, specificity, PPV, and NPV, 95% CIs were calculated using the Wilson score method.

Secondary Exploratory ROC Analyses

As secondary exploratory analyses, ROC analyses evaluated continuous app-based indices against scanner-defined classifications within each age group. Areas under the curve (AUCs) with 95% CIs were estimated, and optimal cutoffs were identified by maximizing the Youden index (sensitivity + specificity − 1). Sensitivity-prioritized cutoffs were also derived.

For outcomes in which higher app-based values indicated a positive state (CVAI and brachycephaly), the sensitivity-prioritized cutoff was defined as the highest cutoff achieving sensitivity≥0.90 while maximizing specificity; for dolichocephaly, in which lower values indicated a positive state, it was defined as the lowest cutoff meeting the same criterion.

For plagiocephaly, we additionally performed ROC analyses using multiple scanner-defined severity thresholds as the positive definition (CVAI≥5%,≥7%,≥10%, and≥14%). We summarized the AUC, Youden-optimal cutoff values, and the corresponding sensitivity and specificity for each threshold. Age-stratified confusion matrices were also constructed using identical classification boundaries for both methods: 5×5 matrices for plagiocephaly (normal,<5%; mild, 5%-<7%; moderate, 7%-<10%; severe, 10%-<14%; very severe,≥14%) and 3×3 matrices for cephalic shape (dolichocephaly, Cephalic Index<79%; normal, 79% - 94%; brachycephaly, Cephalic Index>94%). For both, the 3D scanner classifications were represented as rows and app classifications as columns, and cell counts, row percentages, exact agreement rates, and directions of discordance (overclassification vs underclassification relative to the 3D scanner reference) were reported.

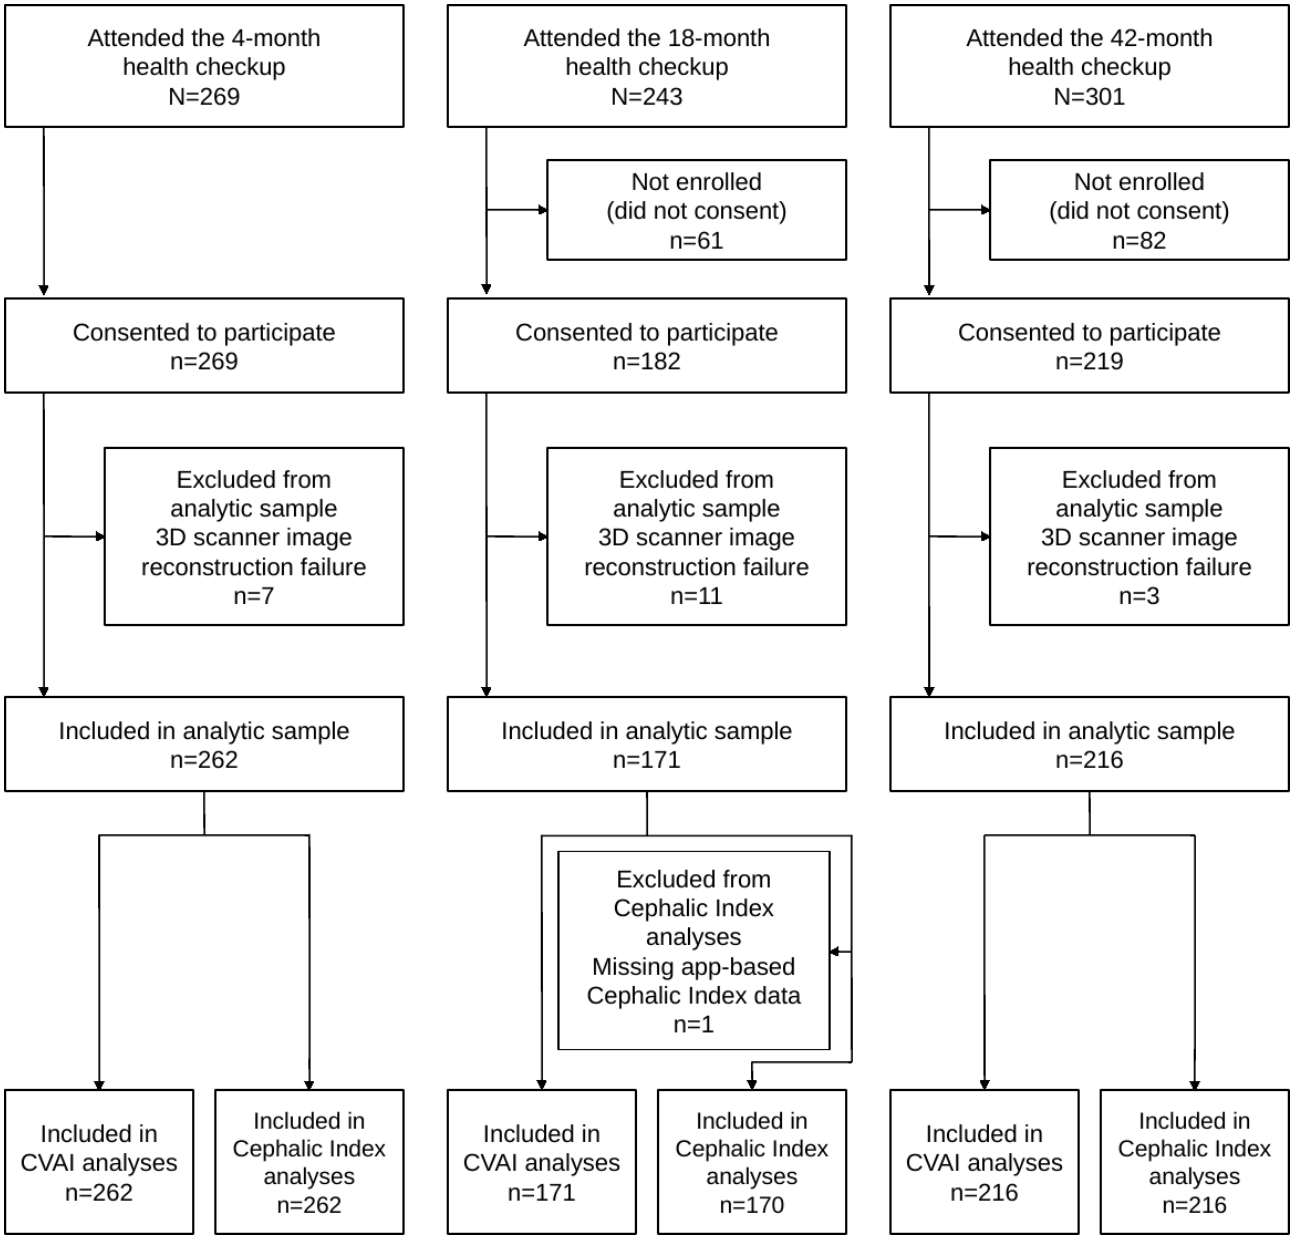
XSL•FO
RenderX

Sensitivity Analyses: Device-Stratified Analyses

To assess potential variation associated with the tablet device, sensitivity analyses were stratified by the iPad and Lenovo device periods described above. Within each device period and each age group (4, 18, and 42 months), we repeated the primary agreement analyses (mean difference [app−scanner], Bland-Altman 95% LoA, and ICC [1,3] with 95% CIs) and the threshold-based screening performance analyses (sensitivity and specificity, with 95% CIs).

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki and the Japanese Ethical Guidelines for Life Science and Medical Research Involving Human Subjects. The protocol was approved by the Ethics Committee of the Graduate School of Biomedical Sciences, Nagasaki University (approval no. 23020901‐3) and prospectively registered in the University Hospital Medical Information Network (UMIN) Clinical Trials Registry (UMIN000052342). Written informed consent was obtained from all parents or legal guardians after they received a comprehensive explanation of the study aims, procedures, potential risks and benefits, and the voluntary nature of participation, including explicit assurance that refusal or withdrawal would not affect access to health services. When results indicated severe or very severe cranial asymmetry, parents or guardians were offered referral for further clinical assessment and provided with information on specialist services, with referral facilitated as appropriate. Low-dose computed tomography (CT) cranial imaging was considered when clinically indicated.



Results

Participant Characteristics

Figure 1 shows the flow of participants through the study. Of the consenting participants, 7 of 269 children at 4 months, 11 of 182 at 18 months, and 3 of 219 at 42 months were excluded because 3D scanner images could not be successfully reconstructed, resulting in final analytic samples of 262, 171, and 216 children, respectively. Agreement and screening performance analyses were performed using paired measurements from both the 3D scanner and the mobile app for each index. At 18 months, 1 participant had missing app-based Cephalic Index data and was therefore excluded from Cephalic Index−based analyses only, while remaining included in CVAI-based analyses.

XSL•FO
RenderX

Figure 1. Participant flow diagram by age group. CVAI: Cranial Vault Asymmetry Index.

The characteristics of the participants at each assessment time point are shown in Table 1. Across all 3 assessments, the sex distribution was approximately balanced, with boys accounting for 49.6% (130/262) at 4 months, 45.0% (77/171) at 18 months, and 45.1% (97/215) at 42 months. The proportion of children born by cesarean section ranged from 13.5% (29/215) to 18.7% (32/171), indicating that the majority of participants were delivered vaginally. Mean gestational age at birth was consistent with term delivery at all time points (mean 39.1, SD 1.7, 38.9, SD 1.7, and 39.2, SD 1.7, weeks at 4, 18, and 42 months, respectively). Torticollis and limitation of hip abduction were rarely observed, with no more than 1 child affected at any assessment time point (0%-0.5%). Missing data for selected variables were minimal and are indicated in the table footnotes.

XSL•FO
RenderX

Table . Characteristics of participants at each assessment time point[a].

Characteristics	4 months (n=262)[b]	18 months (n=171)[c]	42 months (n=216)[d]
Sex, n (%)			
Male	130 (49.6)	77 (45.0)	97 (45.1)
Female	132 (50.4)	94 (55.0)	118 (54.9)
Delivery			
Vaginal delivery, n (%)	218 (83.8)	139 (81.3)	186 (86.5)
Cesarean section, n (%)	42 (16.2)	32 (18.7)	29 (13.5)
Gestation, at birth, weeks, mean (SD)	39.1 (1.7)	38.9 (1.7)	39.2 (1.7)
Weight at assessment, kg, mean (SD)	6.9 (0.8)	10.4 (1.0)	14.4 (1.8)
Height at assessment, cm, mean (SD)	62.9 (2.6)	79.5 (2.7)	94.5 (5.5)
Head circumference, cm, mean (SD)	41.6 (1.3)	47.2 (1.3)	49.8 (1.5)
Torticollis, n (%)	0 (0)	0 (0)	1 (0.5)
Limitation of hip abduction, n (%)	1 (0.4)	0 (0)	1 (0.5)

[a]Percentages were calculated using the number of participants with nonmissing data for each variable.

[b]At 4 months, data on mode of delivery were missing for 2 participants.

[c]At 18 months, data on weight and height at assessment were missing for 1 participant each.

[d]At 42 months, data on sex, mode of delivery, torticollis, and limitation of hip abduction were missing for 1 participant each.

Distribution of Cranial Indices by Age Group and Measurement Method

Figure 2 shows the age-stratified distributions of CVAI (%) obtained using the 3D scanner and mobile app. Across age groups, CVAI values were right-skewed and concentrated at lower levels, and the app tended to yield slightly higher values than the 3D scanner. For the 3D scanner, most CVAI values were distributed below the higher severity thresholds, with relatively few observations in the severe and very severe ranges.

XSL•FO
RenderX

Figure 2. Distribution of CVAI (%) by age group and measurement method (3D scanner vs mobile app). CVAI was calculated using the shorter diagonal as the denominator ([CVAI(S), where S denotes the shorter diagonal]). Vertical reference lines indicate CVAI severity thresholds, marking the cut-offs for moderate (≥7%), severe (≥10%), and very severe (≥14%) categories. CVAI: Cranial Vault Asymmetry Index.

XSL•FO
RenderX

Figure 3 shows the corresponding distributions of Cephalic Index (%), which were approximately unimodal and centered in the mid-to-high range; the app similarly showed a modest rightward shift (ie, higher Cephalic Index values) relative to the 3D scanner. For the 3D scanner, Cephalic Index values were predominantly distributed within the normal-to-brachycephalic range, whereas values in the dolichocephalic range were relatively infrequent.

XSL•FO
RenderX

Figure 3. Distribution of Cephalic Index (%) by age group and measurement method (3D scanner vs mobile app). The 2 vertical reference lines indicate the prespecified Cephalic Index cut-off thresholds (79% and 94%), corresponding to the boundaries for dolichocephaly (<79%), normal (79% - 94%), and brachycephaly (>94%).

XSL•FO
RenderX

Agreement Between the 3D Scanner and the Mobile App

Table 2 shows the agreement between the 3D scanner and the mobile app for CVAI and Cephalic Index at each assessment time point, and the corresponding Bland-Altman plots are presented in Figure 4 (CVAI) and Figure 5 (Cephalic Index).

For CVAI, at 4 months, the mean difference between the app and the scanner was small (0.14, SD 2.20), with 95% LoA from −4.18 to 4.46 and an ICC of 0.76 (95% CI 0.71 - 0.81), indicating good agreement. At 18 months and 42 months, the mean differences for CVAI remained close to zero (0.32 and 0.31, respectively), but the LoAs were wider (−5.60 to 6.23 and −4.63 to 5.25, respectively), and the ICCs decreased to 0.42 (95% CI 0.29 - 0.54) and 0.49 (95% CI 0.38 - 0.59), suggesting poor-to-moderate agreement at these later time points.

For Cephalic Index, the app consistently yielded higher values than the scanner, with mean differences of 3.83, SD 3.42, 3.24, SD 3.07, and 2.61, SD 3.33 at 4, 18, and 42 months, respectively, indicating a systematic positive bias. The 95% LoA were wide at all time points (approximately −2.88 to 10.54 at 4 months, −2.77 to 9.25 at 18 months, and −3.91 to 9.14 at 42 months), indicating substantial individual-level variability. Although ICC point estimates were similar across age groups (0.69 - 0.70), their 95% CI were wide, particularly at 4 and 18 months (4 months: 0.07 - 0.88; 18 months: 0.09 - 0.87; 42 months: 0.31 - 0.84). Therefore, the ICC point estimates should not be overinterpreted as evidence of stable agreement for Cephalic Index. In this context, the Bland-Altman mean differences and LoA, which directly quantify the magnitude and direction of systematic bias and individual-level disagreement, provide a more clinically informative summary (Table 2 and Figure 5).

Table . Agreement between 3D scanner and mobile app-derived measurements of CVAI[a] and Cephalic Index at each assessment time point.

* Measure	4 months (n=262)	18 months (n=171)[b]	42 months (n=216)
CVAI[c]			
Mean difference (app−scanner), mean (SD)	0.14 (2.20)	0.32 (3.02)	0.31 (2.52)
95% limits of agreement[d]	−4.18 to 4.46	−5.60 to 6.23	−4.63 to 5.25
ICC[e] (95% CI)[f]	0.76 (0.71 - 0.81)	0.42 (0.29 - 0.54)	0.49 (0.38 - 0.59)
Cephalic Index			
Mean difference (app−scanner), mean (SD)	3.83 (3.42)	3.24 (3.07)	2.61 (3.33)
95% LoA[d,g]	−2.88 to 10.54	−2.77 to 9.25	−3.91 to 9.14
ICC (95% CI)[f]	0.70 (0.07 - 0.88)	0.69 (0.09 - 0.87)	0.70 (0.31 - 0.84)

[a]CVAI: Cranial Vault Asymmetry Index.

[b]At 18 months, 1 participant was excluded from CI-based analyses because of missing Cephalic Index data (n=170).

[c]CVAI was calculated using the shorter diagonal as the denominator [CVAI(S)].

[d]Limits of agreement were calculated as mean difference±1.96× SD of the differences.

[e]ICC: intraclass correlation coefficients.

[f]Intraclass correlation coefficients were calculated using a two-way mixed-effects model with absolute agreement, single measures.

[g]LoA: limits of agreement.

To assess heteroscedasticity in Bland-Altman differences, we examined Spearman correlations between the absolute method differences and the measurement magnitude (defined as the mean of the two methods). For CVAI, absolute differences increased modestly with increasing measurement magnitude across all ages (ρ=0.18 - 0.29; $P \leq .004$), suggesting mild heteroscedasticity. In contrast, for Cephalic Index, the association was weak and not consistently observed across age groups (ρ=0.06 - 0.18), indicating no clear consistent pattern of heteroscedasticity across age groups.

Threshold-Based Screening Performance

Table 3 summarizes scanner-defined prevalence and screening performance, including sensitivity, specificity, PPV, and NPV, when the same clinical thresholds were applied to both the 3D scanner (reference standard) and the mobile app. Specifically, for plagiocephaly (CVAI≥7%), sensitivity was 84.8% (39/46) at 4 months and decreased to 50.0% (12/24) and 53.3% (8/15) at 18 and 42 months, respectively, whereas specificity remained stable at 88.0% (190/216), 88.4% (130/147), and 89.6% (180/201). Scanner-defined prevalence decreased from 17.6% (46/262) at 4 months to 14.0% (24/171) and 6.9% (15/216) at 18 and 42 months, respectively, with PPV decreasing correspondingly from 60.0% (95% CI 47.9 - 71.0) to 41.4% (95% CI 25.5 - 59.3) and 27.6% (95% CI 14.7 - 45.7); NPV remained high at 96.4% (190/197), 91.5% (130/142), and 96.3% (180/187).

Table . Screening performance of the mobile app relative to the 3D scanner reference standard.

Age	Prevalence, n/N (%)	Sensitivity, n/N (%)	95% CI	Specificity, (n/N) %	95% CI	PPV[a], % (95% CI)	NPV[b], % (95% CI)
Plagiocephaly[c]							
4 months	46/262 (17.6)	39/46 (84.8)	71.8 - 92.4	(190/216) 88.0	82.9 - 91.7	60.0 (47.9 - 71.0)	96.4 (92.8 - 98.3)
18 months	24/171 (14.0)	(12/24) 50.0	(31.4 - 68.6)	(130/147) 88.4	82.3 - 92.7	41.4 (25.5 - 59.3)	91.5 (85.8 - 95.1)
42 months	15/216 (6.9)	(8/15) 53.3	(30.1 - 75.2)	(180/201) 89.6	84.6 - 93.1	27.6 (14.7 - 45.7)	96.3 (92.5 - 98.2)
Brachycephaly[d,e]							
4 months	70/262 (26.7)	(64/70) 91.4	(82.5 - 96.0)	(121/192) 63.0	56.0 - 69.5	47.4 (39.2 - 55.8)	95.3 (90.1 - 97.8)
18 months	10/170 (5.9)	(10/10) 100.0	(72.2 - 100.0)	(138/160) 86.3	80.1 - 90.7	31.3 (18.0 - 48.6)	100.0 (97.3 - 100.0)
42 months	6/216 (2.8)	(6/6) 100.0	(61.0 - 100.0)	(184/210) 87.6	82.5 - 91.4	18.8 (8.9 - 35.3)	100.0 (98.0 - 100.0)
Dolichocephaly[d,f]							
4 months	11/262 (4.2)	(2/11) (5.1 - 47.7)	(5.1 - 47.7)	(251/251) 100.0	98.5 - 100.0	100.0 (34.2 - 100.0)	96.5 (93.6 - 98.2)
18 months	13/170 (7.6)	(2/13) 15.4	(4.3 - 42.2)	(157/157) 100.0	97.6 - 100.0	100.0 (34.2 - 100.0)	93.5 (88.7 - 96.3)
42 months	12/216 (5.6)	(5/12) 41.7	(19.3 - 68.0)	(203/204) 99.5	97.3 - 99.9	83.3 (43.6 - 97.0)	96.7 (93.3 - 98.4)

[a]PPV: positive predictive value.

[b]NPV: negative predictive value.

[c]Cranial Vault Asymmetry Index (CVAI) was calculated using the shorter diagonal as the denominator [CVAI(S)]. Plagiocephaly was defined as CVAI≥7% for both the 3D scanner and the mobile app.

[d]At 18 months, 1 participant was excluded from brachycephaly and dolichocephaly analyses because of missing Cephalic Index data (n=170).

[e]Brachycephaly was defined as Cephalic Index>94% for both the 3D scanner and the mobile app.

[f]Dolichocephaly was defined as Cephalic Index<79% for both the 3D scanner and the mobile app.

For brachycephaly (Cephalic Index>94%), sensitivity was high across age groups (64/70, 91.4%, 10/10, 100.0%, and 6/6, 100.0% at 4, 18, and 42 months, respectively), while specificity increased from 63.0% (121/192) at 4 months to 86.3% (138/160) and 87.6% (184/210) at 18 and 42 months. Scanner-defined prevalence decreased from 26.7% (70/262) at 4 months to 5.9% (10/170) and 2.8% (6/216) at 18 and 42 months, respectively, accompanied by a decrease in PPV from 47.4% (64/135; 95% CI 39.2 - 55.8) to 31.3% (10/32; 95% CI 18.0 - 48.6) and 18.8% (6/32; 95% CI 8.9 - 35.3), while NPV remained high at 95.3% (121/127) - 100.0% (184/184).

For dolichocephaly (Cephalic Index<79%), specificity remained≥99.5% across age groups, whereas sensitivity was low overall at 18.2% (2/11), 15.4% (2/13), and 41.7% (5/12) at 4, 18, and 42 months, respectively. PPV was 100.0% (2/2) at 4 and 18 months and 83.3% (5/6) at 42 months, whereas NPV ranged from 93.5% (157/168) to 96.7% (203/210).

As some Cephalic Index–based subgroup estimates were based on small numbers of scanner-positive cases, these sensitivity estimates—particularly those that appear high (eg, 100%)—should be interpreted cautiously. One 18-month participant with missing Cephalic Index data was excluded from the brachycephaly and dolichocephaly analyses only.

Secondary Exploratory ROC Analyses of Continuous App-Based Indices

These ROC analyses were conducted as secondary exploratory analyses to describe the discriminative characteristics of the continuous app-based indices and should be interpreted as supplementary to the primary clinically anchored same-threshold screening analyses shown in Table 3.

For scanner-defined moderate-or-worse plagiocephaly, ROC analyses showed excellent discrimination at 4 months, with lower discriminative performance at 18 and 42 months. ROC-derived cut-off values varied across age groups, and sensitivity-prioritized cutoffs at older ages required substantial reductions in specificity, reinforcing the primary same-threshold findings that screening performance was most favorable at 4 months.

For brachycephaly, ROC analyses suggested apparently high discriminative performance at 18 and 42 months; however, these estimates were based on very small numbers of scanner-positive cases and should therefore be interpreted with caution as exploratory and potentially unstable. For dolichocephaly, ROC analyses also suggested good discrimination in some age groups, but the limited number of positive cases restricted the precision and interpretability of these estimates. Detailed ROC results, including AUCs, Youden-optimal cut-off values, and sensitivity-prioritized cut-off values, are provided in Multimedia Appendices 2-4.

Agreement in Severity Classification

Additional analyses compared severity classifications derived from the 3D scanner and mobile app. Across age groups, discordance in 5-category CVAI-based plagiocephaly severity classification more often reflected overclassification by the app (App>3D scanner) than underclassification (App<3D scanner), and disagreements often occurred between adjacent severity categories. At 42 months, the observed severity range was more restricted, resulting in a 3×4 classification matrix (Multimedia Appendices 5-7). The overall direction of discordance is summarized in Multimedia Appendix 8, showing that discordance was more often in the direction of higher severity classification by the app.

Similarly, for 3-category Cephalic Index–based head-shape classifications (dolichocephaly, normal, or brachycephaly), discordance was predominantly in the direction of higher Cephalic Index–based classification, particularly toward brachycephaly, with minimal underclassification and no evidence of extreme misclassification across nonadjacent categories (Multimedia Appendices 9-11). The direction of discordance is summarized in Multimedia Appendix 12. At 18 months, 1 participant with missing Cephalic Index data was excluded from these analyses (valid n=170).

Device-Stratified Sensitivity Analyses

Device-stratified analyses showed some variation across devices (Multimedia Appendix 13). For CVAI, the mean difference was small with both devices, but the direction differed at 18 months (iPad: 0.49, SD 3.13 vs Lenovo: −0.55, SD 2.23); the Lenovo subgroup was small (n=28). For Cephalic Index, positive bias was observed with both devices but was larger during the iPad period (eg, at 4 months: 4.24, SD 3.45 vs 3.06, SD 3.25). Device-stratified screening performance also varied by device and age (Multimedia Appendix 14), although the overall pattern of higher plagiocephaly sensitivity at 4 months was observed with both devices. Several subgroup estimates, particularly at later ages, were based on few scanner-positive cases and should be interpreted cautiously.

Discussion

Main Findings

The main finding of this study was that, under standardized, trained-examiner municipal health checkup conditions, app-based CVAI showed the most favorable screening performance for scanner-defined moderate-or-worse plagiocephaly at 4 months, whereas its performance was less favorable and more variable at 18 and 42 months. This age-related pattern was consistent across both agreement and screening performance analyses. Although ICCs provided a global summary index of agreement between methods, the Bland-Altman LoA were more clinically relevant for assessing individual-level disagreement and potential interchangeability between the app and the 3D scanner [24]. However, even at 4 months, the 95% LoA (−4.18 to 4.46) indicate that app-based values could still differ from scanner-based values by several percentage points in either direction. Importantly, small average differences between methods did not necessarily translate into stable classification at clinically relevant thresholds. When values were near the 7% threshold for moderate-or-worse plagiocephaly, even modest between-method differences could shift a child across the classification boundary. Accordingly, the app may be useful as a practical screening aid in structured, examiner-administered settings, but it should not be regarded as a direct substitute for 3D scanner–based classification when making decisions for individual children.

For Cephalic Index, a distinct pattern emerged. Across all ages, the app showed a consistent positive bias (ie, higher Cephalic Index values relative to the 3D scanner) and wide LoA, indicating a tendency toward systematic overestimation with substantial variability at the individual level. This may have contributed to increased false-positive classifications for brachycephaly, particularly at lower specificity levels. In addition, the Cephalic Index–based findings should not be interpreted as establishing robust age-specific screening thresholds, but rather viewed as exploratory signals that require confirmation in larger samples with sufficient numbers of scanner-positive cases. Device-stratified analyses also showed some variation across devices, including a reversal in the small CVAI bias at 18 months and differences in Cephalic Index bias. However, sequential device use was confounded with study period and accumulated examiner experience, precluding attribution to hardware alone.

Comparison With Existing Literature

Prior validation work has largely been conducted under more controlled conditions than routine municipal health checkups. For example, Nakahari et al [8] evaluated the same app used in this study against a reference method using 3D-printed head

XSL•FO
RenderX

models under highly standardized imaging conditions and proposed ROC-based cutoffs. In contrast, our study assessed Japanese infants and young children in real-world municipal health checkup settings, where unavoidable factors (eg, movement, hair, and variability in landmark visibility and camera-to-head distance) may introduce additional measurement variability. This difference in study context is important when interpreting the observed performance patterns, particularly the finding that agreement and screening performance for CVAI were most favorable at 4 months and declined at later ages in our data.

Given this context, our findings both align with and extend existing evidence in clinically relevant ways. In exploratory ROC analyses, the Youden-optimal cutoff for detecting scanner-defined moderate-or-worse plagiocephaly at 4 months was similar to that reported previously, suggesting convergent validity under comparable age conditions. However, these ROC-derived cutoffs should be interpreted as sample-specific exploratory findings rather than as proposed clinical thresholds for implementation [8]. For Cephalic Index–based outcomes, the ROC-derived cutoffs varied across ages and measurement contexts and should not be interpreted as establishing robust generalizable age-specific screening thresholds, particularly given the small number of scanner-positive cases in some subgroups. In addition, app-based Cephalic Index values consistently exceeded scanner-based values across all ages, indicating a systematic tendency toward overestimation. Correspondingly, ROC-derived app cutoffs to reproduce scanner-defined brachycephaly (Cephalic Index>94%) were substantially higher than those reported in prior studies, suggesting that Cephalic Index thresholds may not be directly transferable across measurement contexts without local calibration. Consistent with the primary same-threshold analyses, at 18 and 42 months, achieving high sensitivity required substantial reductions in specificity, indicating that cutoff adjustment alone may not fully compensate for age-related limitations in measurement agreement beyond early infancy. This study also adds an implementation-oriented perspective by evaluating “same-threshold” use (ie, applying identical clinical thresholds to both the app and the scanner) and by describing the direction and magnitude of discordance in severity classification. These analyses demonstrate how acceptable agreement for continuous indices may not translate directly into consistent threshold-based classification, thereby highlighting the importance of considering both measurement agreement and classification behavior in real-world screening pathways.

Interpretation of Age-Related and Cephalic Index–Related Differences

Plagiocephaly

Agreement and discrimination of CVAI were strongest at 4 months but attenuated at 18 and 42 months, with corresponding reductions in sensitivity for detecting scanner-defined CVAI≥7%. This age-related pattern should be interpreted cautiously as a hypothesis-generating observation rather than a directly tested causal explanation. One possible contributor is a shift in case mix over time: CVAI may peak in early infancy and gradually improve as infants develop gross motor skills, which could shift the population distribution toward milder asymmetry at older ages [10,25,26]. In our study, the number of children with scanner-defined moderate-or-worse plagiocephaly was also smaller at older ages, particularly at 42 months, which increases statistical uncertainty in sensitivity estimates. This interpretation is consistent with the observed concentration of CVAI values in the lower range at older ages and with discordance often occurring between adjacent severity categories.

A second, nonmutually exclusive explanation relates to increased measurement difficulty under real-world image capture conditions. App-based CVAI estimation depends on accurate visualization and manual specification of key anatomical landmarks from a single vertex photograph; the app instructs users to capture an overhead image with the nose and ears visible and to annotate these landmarks, and prior validation work suggests that landmark visibility and positioning conditions can influence screening sensitivity [8]. Moreover, because prior validation studies were conducted using stationary head models without hair, performance in older infants and young children may be more susceptible to real-world capture challenges, including movement, hair coverage, and variable head positioning, which could increase landmark identification error and contour-tracing variability and reduce measurement repeatability in single-image assessments [8,27]. Our data could not determine whether the lower apparent performance at older ages was primarily attributable to changes in case mix (ie, fewer scanner-positive cases and a higher proportion of borderline values near classification thresholds) or to greater measurement difficulty under real-world conditions.

In addition to biological or case-mix differences across ages, part of the apparent age-related pattern may also reflect methodological features inherent to the measurement process. Because the 3D scanner was always used first, followed by app-based measurement by the same examiner with the same cap in place and minimal delay, the index test was performed under a partially shared measurement context with a fixed testing sequence. This design likely enhanced comparability between methods, but it may also have introduced the potential for overestimation of agreement and screening performance compared with fully independent assessments. Therefore, the observed age-related differences should not be interpreted solely as intrinsic differences in app performance across developmental stages, but rather in the context of potentially interacting biological, behavioral, and methodological factors.

Cephalic Index–Related Findings: Brachycephaly and Dolichocephaly

Across all assessment time points, the app tended to yield systematically higher Cephalic Index values than the 3D scanner, indicating a consistent positive bias. This shift may have contributed to the comparatively lower specificity for brachycephaly (scanner-defined Cephalic Index>94%) and to an increased frequency of false-positive classifications. This finding can be considered in relation to a previous smartphone-based validation study [28]. Kocabalkanli et al [28] compared smartphone-based cranial measurements with 3D

XSL•FO
RenderX

reference measurements in 71 infants and reported minimal Bland-Altman bias for both CVAI (−0.05; 95% LoA, −3.85 to 3.76) and Cephalic Index (0.08; 95% LoA, −4.18 to 4.34). Although differences in the reference systems, study populations, app, and image-capture protocols preclude direct comparison, the CVAI agreement observed in their study was similar to that observed in our 4-month cohort (mean difference, 0.14; 95% LoA, −4.18 to 4.46), whereas our Cephalic Index showed a substantially larger positive bias (mean difference 3.83, 95% LoA −2.88 to 10.54). This index-specific contrast suggests that the positive Cephalic Index bias observed in our study may not be attributable to 2-dimensional image acquisition alone. Kocabalkanli et al [28] noted the importance of positioning the camera orthogonally to the measurement plane for smartphone-based cranial measurements. Potential contributors in our study include deviation of the camera from an orientation orthogonal to the cranial measurement plane, variation in head position during image acquisition, cranial contour extraction, the algorithm used to derive Cephalic Index from the 2-dimensional image, and differences between dimensions derived from a 2-dimensional cranial contour and those measured on a defined cross-section of a 3D model. In particular, differences in the estimation of cranial width or anteroposterior length could systematically affect Cephalic Index because Cephalic Index is calculated as the ratio of these dimensions. However, the app did not output the component cranial width and anteroposterior length measurements, and these potential mechanisms could therefore not be directly evaluated in the present study.

In contrast to brachycephaly, the app showed high specificity but low sensitivity for dolichocephaly (scanner-defined Cephalic Index<79%), indicating that scanner-defined cases of dolichocephaly were frequently missed by the app. This pattern may partly reflect the underlying distribution of Cephalic Index in the study population: because Cephalic Index varies with age in Japanese children, relatively few children fell below the 79% threshold, resulting in few positive cases and limited precision in sensitivity estimates [22]. In addition, the systematic positive bias in app-based Cephalic Index values may have shifted some measurements above the lower Cephalic Index threshold, thereby contributing to the low sensitivity for dolichocephaly.

Taken together, these features also help explain the uncertainty in agreement estimates for Cephalic Index. Although ICCs for Cephalic Index were approximately 0.69 - 0.70, their 95% CIs were relatively wide, likely reflecting restricted between-child variability in Cephalic Index within this community-based sample. Moreover, the systematic positive bias indicates that disagreement between methods was not purely random. Therefore, for Cephalic Index, Bland-Altman mean differences and LoA provide a more transparent summary of the clinically relevant disagreement than ICCs alone.

Clinical Implications

Clinically, the potential role of the app appears to vary by age and clinical context. At 4 months—when early identification can guide timely counseling and referral—the app may be most useful as a screening aid when administered by a trained examiner within a structured health checkup setting. In contrast, at 18 and 42 months, agreement and/or screening performance were reduced, suggesting more limited utility for threshold-based clinical decision-making. At 42 months in particular, assessment should be interpreted as descriptive of residual cranial shape and supportive of parental reassurance and counseling, rather than as determinative of treatment eligibility. In practice, because this app is commonly used in home settings, parents may use its outputs to decide whether to seek specialist evaluation [8]. This timing is clinically important because helmet therapy outcomes are strongly age-dependent: a review recommends initiation before 6 months, reports that treatment is generally effective up to 12 months, and notes that the effect becomes limited after 12 months and poor after 18 months [2]. In addition, the Congress of Neurological Surgeons guideline recommends helmet therapy for infants with persistent moderate-to-severe plagiocephaly after a course of conservative treatment, and also for infants with moderate-to-severe deformity who present at an older age [29]. Consistent with these recommendations, delayed identification and initiation of treatment may reduce the achievable degree of correction, as older infants are less responsive to helmet therapy [7]. Therefore, incorporating app-based CVAI screening into the 4-month municipal health-checkup workflow could be pragmatically valuable, as this represents a near-universal point of contact and may facilitate early identification and timely referral for confirmatory assessment when moderate asymmetry is suspected.

At the same time, the LoA suggest that app-based measurements should not be considered directly interchangeable with 3D scanner–based classifications for individual clinical decision-making. Rather, the app appears more suitable for screening purposes—specifically, **i**dentifying children who may warrant confirmatory assessment**,** particularly when values lie, near clinically relevant thresholds, where classification may change according to the measurement method. For implementation, clear and practical operational guidance is essential to reduce avoidable variability, including maintaining a consistent camera-to-head distance, avoiding head tilt or rotation**,** and ensuring adequate visualization of key landmarks in a vertex-view photograph (ie, the nose and both ears), alongside adherence to the in-app measurement guide [8].

Finally, because app-based Cephalic Index values tended to be systematically higher than scanner-based values across age groups in this study, app-positive brachycephaly findings should be interpreted cautiously. For moderate-or-worse plagiocephaly, PPV decreased from 60.0% (39/65) at 4 months to 27.6% (8/29) at 42 months as scanner-defined prevalence declined; similarly, PPV for brachycephaly decreased from 47.4% (64/135) to 18.8% (6/32). Thus, particularly at later ages, app-positive findings may lead to additional confirmatory assessments for children who would not meet the corresponding 3D scanner–based threshold. Accordingly, positive findings at later ages require cautious interpretation in light of age, clinical context, and, when appropriate, confirmatory evaluation.

Strengths and Limitations

This study has several strengths. First, measurements were obtained during municipal health checkups with broad

XSL•FO
RenderX

population coverage, supporting the relevance of the findings to community-based screening in Japan. Second, app-based measurements were compared with a clinically used 3D scanner. Third, age-stratified analyses allowed assessment of agreement and screening performance across 3 developmental stages.

Several limitations should also be noted. First, findings may not generalize beyond the devices and OSs evaluated. Because the devices were used sequentially rather than concurrently, device type was confounded with study period and accumulated examiner experience, precluding separation of hardware effects from examiner learning or other temporal factors. Second, some subgroup analyses included very small numbers of scanner-positive cases, particularly in the 18-month Lenovo subgroup and at higher-severity plagiocephaly thresholds (CVAI≥10% and≥14%), resulting in potentially unstable estimates. Third, although JPMC technical staff were blinded to the app-based measurement results, JPMC—the developer of the index app—also performed postacquisition processing and quantitative analysis of the 3D scanner data. Therefore, the reference-standard analysis was not fully independent of the app developer and may have introduced potential bias. Fourth, although the examiner did not have access to the final quantitative results derived from the 3D scanner at the time of app-based measurement, both measurements were performed during the same visit by the same trained examiner in a fixed sequence (3D scanner first, app second) under a partially shared measurement context. This partial nonindependence may have favored agreement, and the observed performance may therefore represent an upper-bound estimate under standardized, trained-examiner conditions. Fifth, the app was not evaluated under its intended unsupervised home-use conditions; performance may differ when measurements are performed by untrained users. Sixth, repeated measurements were not collected, precluding assessment of intra- and interrater reproducibility and repeatability. Finally, ROC-derived cutoffs were sample-based point estimates without CIs, limiting the precision and generalizability of these exploratory findings.

Conclusion

App-based CVAI showed the most favorable agreement and screening performance at 4 months under trained-examiner municipal health-checkup conditions, but performance was lower at 18 and 42 months. App-based Cephalic Index was systematically higher than scanner-based Cephalic Index, potentially increasing false-positive classifications for brachycephaly when identical thresholds are applied. Performance also varied to some extent between devices, although device effects could not be separated from study period and accumulated examiner experience. Overall, positive findings from the app—particularly beyond early infancy and for Cephalic Index-based measures—should be interpreted in light of the child's age and broader clinical findings, with further evaluation or specialist referral considered only when clinically indicated, rather than treated as definitive diagnostic classifications.

Acknowledgments

We sincerely thank all the participants and all individuals involved in this study for their understanding, cooperation, and support. We used ChatGPT (OpenAI) to assist with English-language editing; however, all content was reviewed, revised, and approved by the authors, who take full responsibility for the final manuscript.

Abstract

Background: Idiopathic scoliosis is a common 3D spinal deformity with a global prevalence of 2% to 3% in adolescents. Early detection is crucial for timely intervention and preventing curve progression. Although standing full-spine radiography with Cobb angle measurement remains the diagnostic gold standard, its time-consuming nature limits its utility for large-scale screening. Safe, rapid, and noninvasive screening methods are urgently needed to identify high-risk individuals while reserving x-rays for definitive diagnosis.

Objective: This study aimed to evaluate the diagnostic accuracy of a custom-developed millimeter-wave imaging system in patients with suspected scoliosis, with radiographic Cobb angle measurement serving as the reference standard, and explore its potential as a first-line screening tool.

Methods: This prospective diagnostic accuracy study enrolled consecutive outpatients with suspected scoliosis. All participants underwent rapid millimeter-wave imaging scanning (K_a band, 29-40 GHz with no undressing required) followed by standard standing full-spine radiography. Scoliosis was defined as a Cobb angle of 10° or higher. Millimeter-wave images were evaluated using four morphological indicators: (1) shoulder height asymmetry (≥2 cm), (2) trunk lateral shift (≥2 cm), (3) waistline contour asymmetry (≥5°), and (4) lower-limb height difference (≥1 cm). A multiparameter integration strategy classified screening as positive if more than 2 indicators exceeded threshold values. Cobb angle measurements were performed independently by 2 experienced orthopedic surgeons blinded to millimeter-wave image results and each other's assessments. Diagnostic performance metrics (sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy) were calculated according to the STARD (Standards for Reporting of Diagnostic Accuracy Studies) guidelines. A multivariate logistic regression model incorporating the 4 morphological parameters was constructed for receiver operating characteristic curve analysis.

Results: Ultimately, 132 participants were included. Radiographic evaluation confirmed 98 (74.2%) cases with scoliosis (Cobb angle≥10°) and 34 (25.8%) negative cases. Millimeter-wave imaging achieved an overall accuracy of 86.4% (114/132; 95% CI 76.5%-94.7%), sensitivity of 85.7% (84/98; 95% CI 75.1%-96.5%), specificity of 88.2% (30/34; 95% CI 70.7%-97.6%), positive predictive value of 95.5%, and negative predictive value of 68.2%. Receiver operating characteristic curve analysis of the multivariate logistic regression model exhibited an area under the curve of 0.862 (95% CI 0.802-0.922), with a sensitivity of 92.9% (91/98) and specificity of 38.2% (13/34). Notably, sensitivity was lower for mild curves (Cobb angle=10°-20°) than for moderate or severe curves (≥20°).

Conclusions: Millimeter-wave imaging represents a feasible, rapid, and non-ionizing radiation screening method for scoliosis with good diagnostic accuracy (accuracy=114/132, 86.4%; sensitivity=84/98, 85.7%; specificity=30/34, 88.2%). Its capability to penetrate clothing and rapid scanning time (approximately 2 seconds) make it suitable for large-scale screening applications.

XSL•FO
RenderX

As a first-line screening tool, this method identifies high-risk individuals for targeted referral and definitive radiography. It follows the “as low as reasonably achievable” principle, optimizing scoliosis screening and reducing unnecessary radiation exposure.

(JMIR Pediatr Parent 2026;9:e92125) doi:10.2196/92125

KEYWORDS

idiopathic scoliosis; early detection; millimeter-wave imaging; diagnostic accuracy; nonionizing radiation

Introduction

Idiopathic scoliosis is a common 3D spinal deformity characterized by coronal plane curvature, vertebral rotation, and alterations in the sagittal plane profile [1,2]. Among its various subtypes, adolescent idiopathic scoliosis constitutes the predominant form affecting children and adolescents, with an estimated global prevalence of 2% to 3% [3-6]. Early detection during the adolescent growth spurt is of paramount importance as timely intervention can delay or halt deformity progression, thereby reducing the risk of progression to severe curves requiring surgical correction [7,8].

Currently, standing full-spine radiography with Cobb angle measurement remains the gold standard for diagnosing and monitoring idiopathic scoliosis. According to guidelines from the Scoliosis Research Society and the International Society on Scoliosis Orthopaedic and Rehabilitation Treatment, scoliosis is defined as a coronal curvature of 10° or more as measured using the Cobb method [7]. Although radiography provides high diagnostic accuracy, repeated exposure to ionizing radiation raises concerns regarding cumulative cancer risk, particularly in pediatric patients who may require long-term follow-up [9,10]. Moreover, the procedure is relatively time-consuming, limiting its practicality for large-scale population screening [11].

Accordingly, there is a growing demand for safe, rapid, and noninvasive screening methods capable of identifying individuals at elevated risk of scoliosis while reserving radiography for confirmatory diagnosis [12]. Several radiation-free approaches, including surface topography [13] and optical scanning [14], have been investigated. However, these techniques are frequently constrained by their sensitivity to clothing and ambient lighting, as well as workflow inefficiencies that limit their applicability in high-throughput screening settings [15,16].

Millimeter-wave imaging has been widely adopted in security screening due to its ability to penetrate clothing and generate high-resolution images without ionizing radiation [17,18]. On the basis of frequency-modulated continuous wave radar [19] and synthetic aperture radar processing principles [20], this technology enables reconstruction of surface topography and subsurface contours. When applied to the human back, millimeter-wave imaging has the potential to capture clinically relevant morphological features associated with spinal deformity in a rapid, objective, and privacy-conscious manner (Multimedia Appendices 1 and 2).

Despite the theoretical advantages of millimeter-wave imaging technology, no studies have evaluated its clinical utility for scoliosis detection. The objective of this study was to evaluate the diagnostic accuracy of a custom-developed millimeter-wave imaging system for detecting scoliosis in patients with suspected spinal deformity using radiographic Cobb angle measurement as the reference standard. We hypothesized that millimeter-wave imaging would demonstrate high sensitivity and acceptable specificity, supporting its potential application as a first-line screening tool consistent with the “as low as reasonably achievable” principle.

Methods

Ethical Considerations

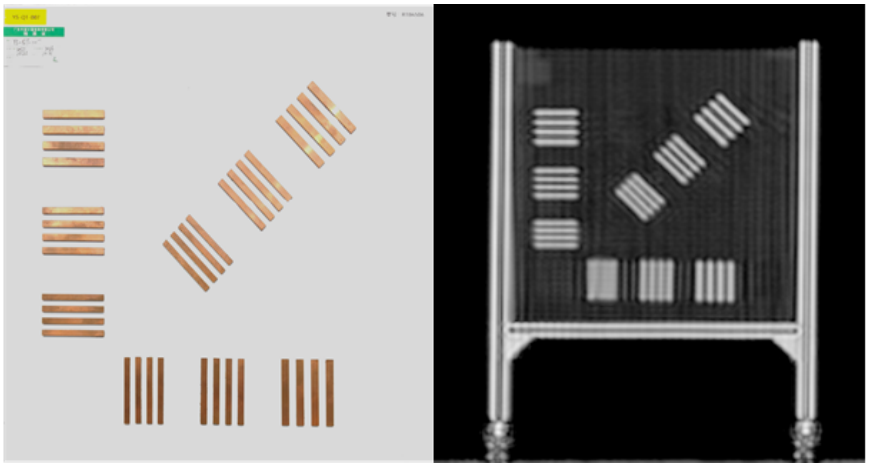
This prospective diagnostic accuracy study was conducted in accordance with the Declaration of Helsinki and approved by the institutional review board of the First Affiliated Hospital of Anhui Medical University (approval PJ 2025-16-05). Written informed consent was obtained from all participants and their legal guardians prior to enrollment.

Study Population

The inclusion criteria were as follows: (1) no prior history of scoliosis diagnosis; (2) suspected scoliosis based on positive physical examination findings, parental concern, or referral from school or community screening programs; and (3) ability to maintain a standing posture during imaging examinations.

The exclusion criteria were as follows: (1) inability to tolerate standing examination due to severe orthostatic intolerance or balance disorders, (2) severe skin conditions or open wounds on the back that might affect imaging quality, or (3) any condition judged by the investigator as potentially compromising patient safety or data integrity.

Millimeter-Wave Imaging System and Acquisition



The scoliosis screening system used a custom-developed millimeter-wave scanner operating in the K_a band (29-40 GHz). This frequency range was selected to balance penetration through common clothing materials with spatial resolution sufficient for detailed surface topography mapping [21]. The system integrated frequency-modulated continuous wave radar for precise range resolution [19] and synthetic aperture radar processing via the range migration algorithm [20,22] to generate high-resolution azimuthal imagery. The fusion of these techniques produced a detailed 3D scattering map of the back’s surface and underlying contours.

The reconstructed volume was characterized by a voxel matrix of 192 (width) × 448 (height) × 128 (depth) with spacings of 4.2 mm (horizontal), 3.6 mm (vertical), and 4.0 mm (depth). A maximum intensity projection algorithm was applied for initial visualization and qualitative analysis. The scanning procedure was completed within approximately 2 seconds, and calibration

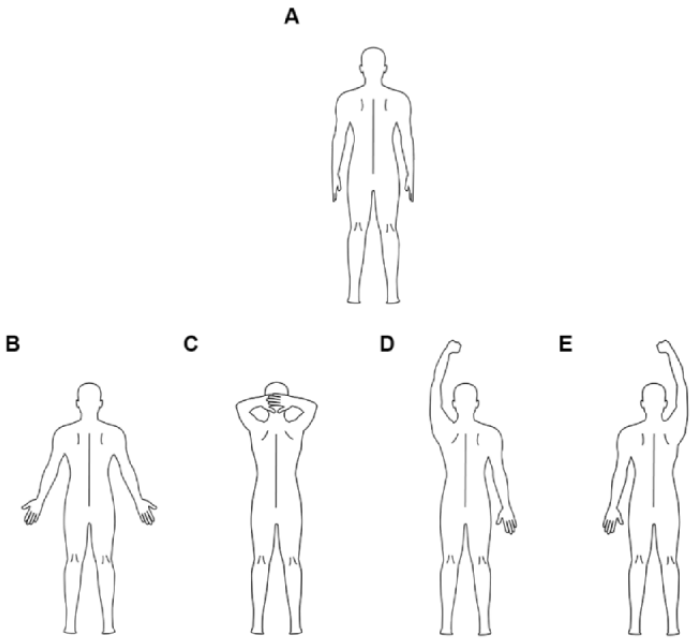
XSL•FO
RenderX

was verified using standardized test boards to ensure imaging accuracy. The image of the calibration test board is shown in Figure 1.

Figure 1. Image of the calibration test board and a scan of the board.

Imaging Protocol

Each participant underwent millimeter-wave scanning in 5 standardized standing positions (as illustrated in Figure 2): natural standing position (posture A), palms externally rotated (posture B), hands behind the head (posture C), and single-arm elevation (postures D and E).



Considering reproducibility and stability, this study used only the natural standing position (posture A) for quantitative analysis, with the remaining 4 postures reserved for qualitative assessment.

Participants were scanned while wearing lightweight clothing (including athletic wear, single-layer garments, or T-shirts) without the need for disrobing, thereby substantially preserving patient privacy and dignity. Metallic items (such as underwire bras) that could potentially interfere with imaging quality were removed when present (Multimedia Appendix 3).

All participants underwent standard standing anteroposterior and lateral full-spine radiography using standardized imaging parameters (85 kV; 20-55 mAs; focus-film distance: 180 cm). Regarding examination sequence, participants first underwent millimeter-wave scanning followed by standard radiographic examination as the definitive diagnostic reference. Both examinations were completed on the same day to minimize potential changes in spinal alignment.

The blinding protocol required millimeter-wave image analysts to be blinded to radiographic results and radiographic assessors to be blinded to millimeter-wave results. Cobb angle measurements were performed independently by 2 experienced orthopedic surgeons, with assessors blinded to each other's results and to millimeter-wave findings. All image identifiers were removed prior to analysis, and an independent data management system was used to prevent unblinding.

Figure 2. Schematic illustration of millimeter-wave image scanning postures.

RenderX

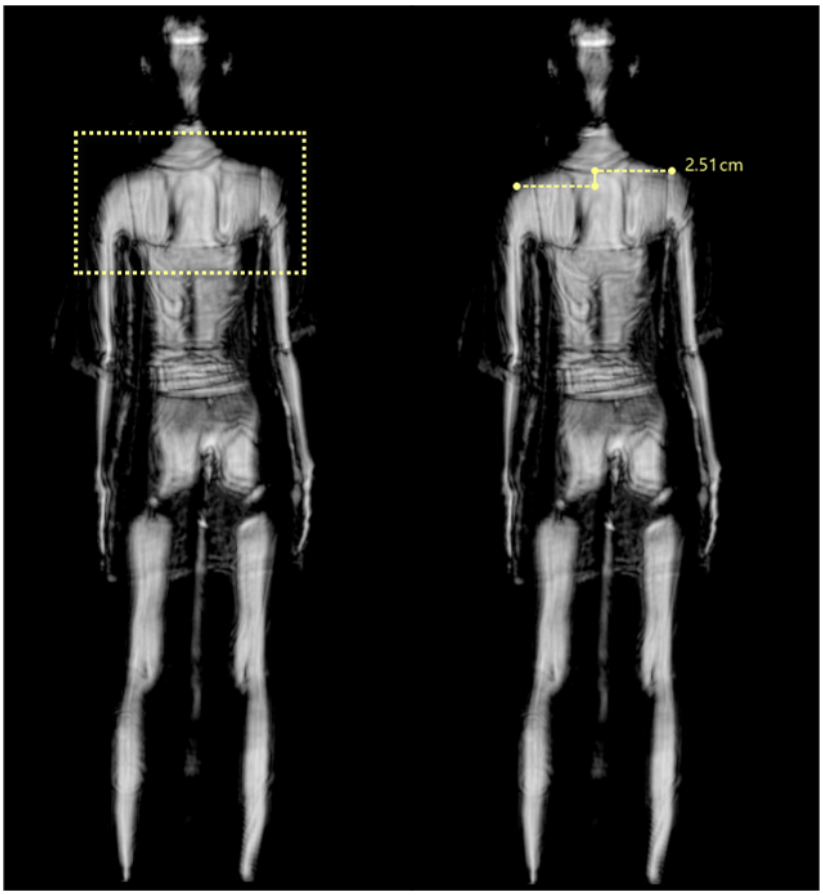

Image Analysis and Screening Criteria

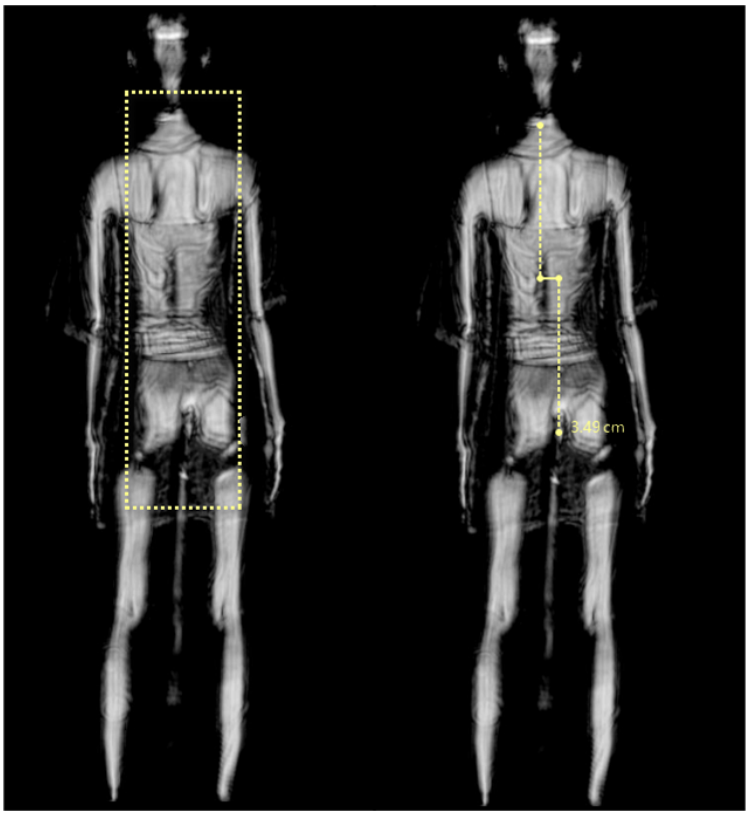
Millimeter-wave images were analyzed using a predefined protocol focusing on 4 clinically relevant morphological indicators [23-29]: shoulder height asymmetry, trunk lateral shift, waistline contour asymmetry, and lower-limb height discrepancy.

Assessment of Shoulder Height Asymmetry

Shoulder balance was evaluated by first interactively selecting the shoulder regions from the millimeter-wave maximum intensity projection image. A least squares fitting algorithm was applied to automatically identify the bilateral acromion points, with submillimeter precision in coordinate extraction. The vertical height difference (ΔH) was calculated as the absolute difference in the z-axis coordinates of the acromion points. The assessment criteria followed those by Lee et al [23] and other clinical standards [24], where ΔH of less than 2 cm was classified as normal and ΔH of 2 cm or more indicated abnormal shoulder imbalance (as illustrated in Figure 3).

Figure 3. Assessment of shoulder balance.



Assessment of Trunk Lateral Shift

Trunk alignment was quantified by measuring the horizontal offset distance (ΔL) between the midpoint of the cervicothoracic junction (C7-T1) and the gluteal cleft. In this study, the assessment of trunk lateral shift was performed by measuring the horizontal distance difference (ΔL) between the medial shoulder midpoint and the gluteal midline point. Following the work by Trobisch et al [25] and related studies on trunk balance [26,27], ΔL of less than 2 cm was classified as normal, and ΔL of 2 cm or more was classified as abnormal (as illustrated in Figure 4).

XSL•FO
RenderX

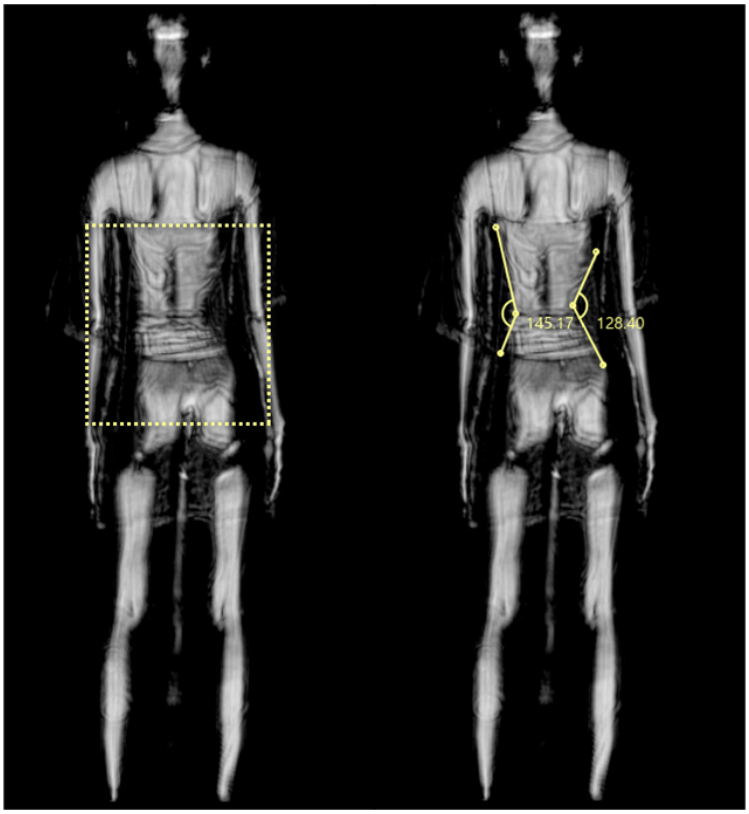


Figure 4. Assessment of trunk lateral shift.

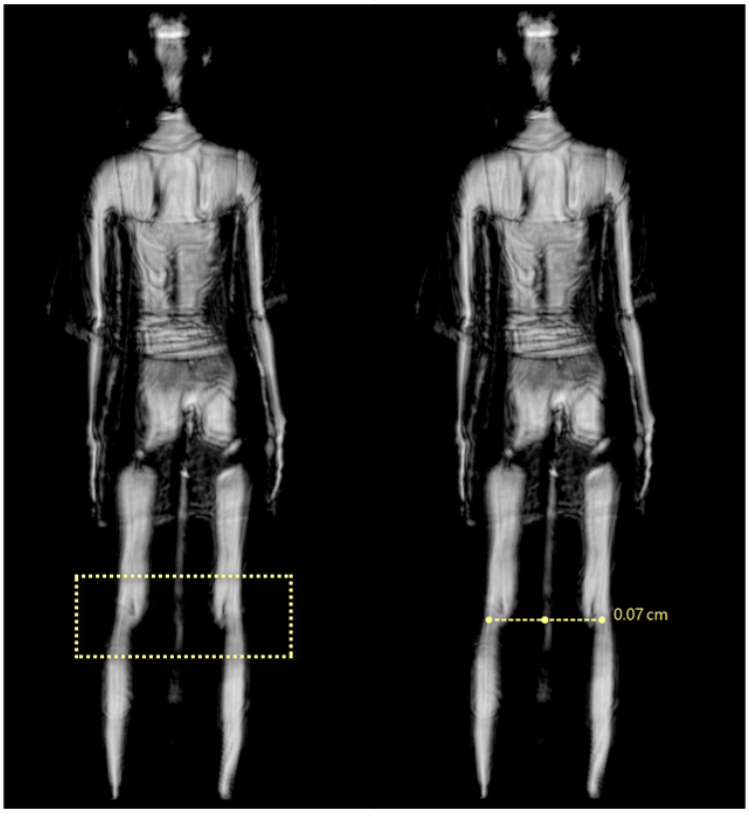
Assessment of Waistline Contour Asymmetry

Waistline symmetry was analyzed by delineating bilateral waistline contours through interactive annotation. Bezier curve fitting technology was used to extract curvature characteristics, and the tangent angle difference (ΔD) at the points of maximum curvature was calculated. Following the work by Qiu et al [28], ΔD of less than 5° was classified as normal, and ΔD of 5° or more indicated abnormal asymmetry (as illustrated in Figure 5).

Figure 5. Assessment of waistline contour asymmetry.



XSL•FO
RenderX

Assessment of Lower-Limb Height Asymmetry

Lower-limb discrepancy was assessed by interactively annotating the popliteal regions in the millimeter-wave images. The system automatically identified the highest points of the bilateral popliteal fossae with knee extension to standardize measurements. The height difference (ΔH) was computed. Following established clinical criteria [29], a threshold of ΔH of less than 1 cm defined the normal range, whereas ΔH of 1 cm or more indicated abnormality (as illustrated in Figure 6).

Figure 6. Assessment of lower-limb asymmetry.

Judgment Criteria

On the basis of a multiparameter integrated strategy, a scan was categorized as positive for scoliosis screening if 2 or more of the 4 morphological indicators met or exceeded their predefined abnormal thresholds; otherwise, it was classified as negative (Multimedia Appendix 4).

Statistical Analysis

Diagnostic performance was assessed using sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy in accordance with the STARD (Standards for Reporting of Diagnostic Accuracy Studies) guidelines [30]. Continuous variables with normal distribution were expressed as means and SDs and compared between groups using the independent-sample *t* test (2-tailed), whereas nonnormally distributed data were analyzed using the Mann-Whitney *U* test. All statistical analyses were performed using SPSS (version 22.0; IBM Corp), with statistical significance defined as a 2-tailed *P* value of less than .05.

Results

Patient Characteristics and Group Distribution

Between July 2024 and December 2025, a total of 165 consecutive patients presenting to the spinal surgery outpatient clinic with suspected scoliosis were screened for eligibility. Of these 165 patients, 19 (11.5%) were excluded for failing to meet the inclusion criteria (eg, not first-time presentation). Of the remaining 146 patients, 14 (9.6%) were subsequently excluded based on the exclusion criteria: 9 (64.3%) for inability to undergo radiographic examination (patient refusal or contraindications) and 5 (35.7%) for excessive perspiration on the back compromising image quality. Ultimately, 132 patients were enrolled and completed the study protocol, constituting the final analysis cohort.

Of the 132 patients enrolled in this study, 98 (74.2%) were confirmed to have scoliosis (Cobb angle≥10°) based on x-ray examination, whereas the remaining 34 (25.8%) had measurements of less than 10° and were classified as the nonscoliotic group. The baseline characteristics of the 2 groups are summarized in Table 1. There were no significant differences in age, height, or weight between the 2 groups (P>.05), ensuring the comparability of the study cohorts.

XSL•FO

Table 1. Baseline characteristics of the study participants.

Characteristic	Scoliosis group (n=98)	Nonscoliosis group (n=34)	*P* value
Age (y), mean (SD; range)	15.9 (9.3; 6-23)	14.7 (8.4; 6-22)	.22
Gender, n (%)			.04
Male	32 (32.7)	18 (52.9)	
Female	66 (67.3)	16 (47.1)	
Height (cm), mean (SD; range)	157.2 (9.3; 122.3-184.4)	155.9 (8.4; 120.2-174.3)	.52
Weight (kg), mean (SD; range)	49.1 (7.2; 26.2-78.9)	47.2 (5.8; 26.1-72.1)	.19
Cobb angle (°), mean (SD; range)	28.5 (12.3; 10.5-87.5)	6.2 (2.1; 1.9-9.7)	<.001

Diagnostic Performance of Millimeter-Wave Imaging

The comparative analysis between millimeter-wave assessments and the x-ray reference standard yielded the results shown in Table 2. The overall diagnostic accuracy of the millimeter-wave imaging protocol was 86.4% (114/132). The technology demonstrated a high sensitivity of 85.7% (84/98) and a specificity of 88.2% (30/34). The positive predictive value was 95.5%, and the negative predictive value was 68.2%.

Table 2. Diagnostic performance of millimeter-wave imaging.

Parameter	Value (%; 95% CI)
Accuracy	86.4 (76.5-94.7)
Sensitivity	85.7 (75.1-96.5)
Specificity	88.2 (70.7-97.6)
PPV[a]	95.5 (94.5-96.7)
NPV[b]	68.2 (66.7-72.7)

[a]PPV: positive predictive value.

[b]NPV: negative predictive value.

Analysis of Millimeter-Wave Morphological Parameters

With the exception of lower-limb length discrepancy, the remaining 3 morphological parameters demonstrated higher abnormality rates in the scoliosis group than in the nonscoliosis group as detailed in Table 3. Notably, shoulder height asymmetry and waistline contour asymmetry also exhibited relatively elevated abnormality rates in the nonscoliosis group (13/34, 38.2% and 11/34, 32.4%, respectively).

Table 3. Millimeter-wave imaging morphological parameter analysis.

Parameter	Abnormalities in the scoliosis group (n=98), n (%)	Abnormalities in the nonscoliosis group (n=34), n (%)
Shoulder height asymmetry	75 (76.5)	13 (38.2)
Trunk lateral shift	38 (38.8)	2 (5.9)
Waistline contour asymmetry	78 (79.6)	11 (32.4)
Lower-limb discrepancy	6 (6.1)	1 (2.9)

Multivariate Model Analysis

To further evaluate the integrated diagnostic capability of millimeter-wave imaging, a multivariate logistic regression model was developed incorporating the 4 morphological parameters. The receiver operating characteristic curve analysis of this composite model demonstrated superior performance compared to the individual parameters. The multivariate model achieved an area under the curve of 0.862 (95% CI 0.802-0.922), indicating excellent discriminatory ability (as illustrated in Figure 7).

The detailed performance metrics of the model are shown in the confusion matrix (Figure 8). The model exhibited a sensitivity of 92.9% (91/98 true positives) and a specificity of 38.2% (13/34 true negatives), with an overall accuracy of 78.8% (104/132). This indicates that the methodology aligns with the primary goal of screening protocols, which is to prioritize sensitivity to avoid missed cases, thereby underscoring its value in clinical practice.

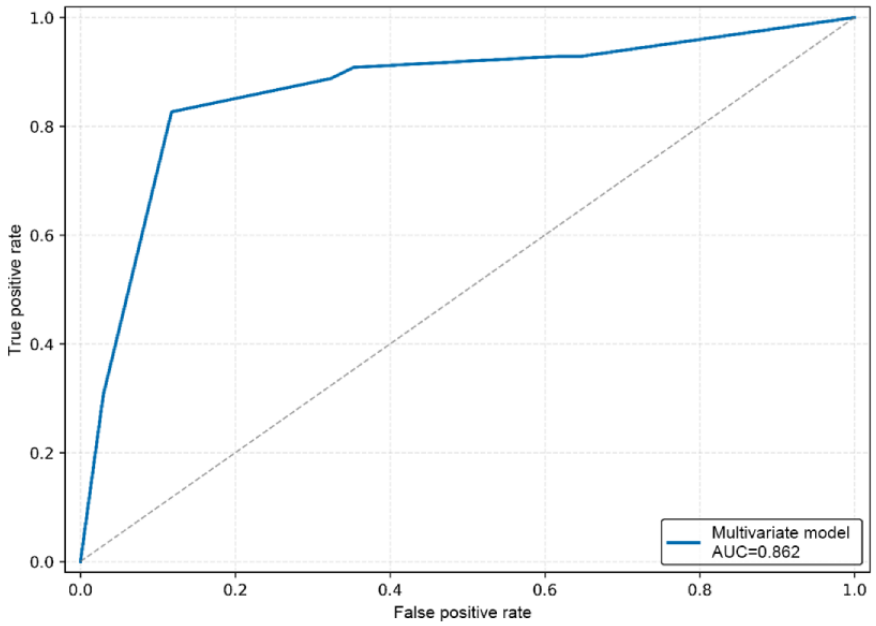
RenderX

Figure 7. Receiver operating characteristic curve of the multivariate logistic regression model. AUC: area under the curve.



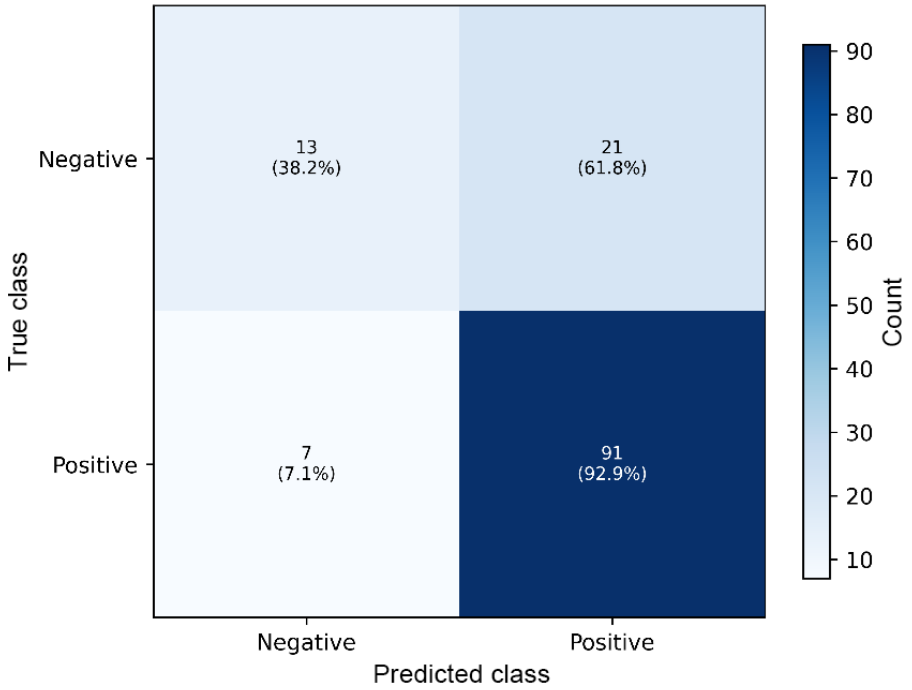


Figure 8. Confusion matrix detailing the performance of the multivariate model.

Subgroup Analysis by Curve Severity

In a subgroup analysis of the 98 patients with scoliosis, the millimeter-wave imaging system demonstrated varying performance across different curve severity groups. The technology demonstrated high diagnostic accuracy in the moderate curve group (Cobb angle=20°-40°) and severe group (≥40°) compared to 75.4% (43/57) in the mild group (10°-20°).

Discussion

Principal Findings

This diagnostic accuracy study evaluated a custom-developed millimeter-wave imaging system in 132 pediatric outpatients with suspected scoliosis. The system demonstrated a sensitivity of 85.7% (84/98), specificity of 88.2% (30/34), and overall accuracy of 86.4% (114/132) for detecting scoliosis (Cobb angle≥10°). Each scan was completed in approximately 2 seconds, effectively minimizing motion artifacts. Notably,

XSL•FO
RenderX

sensitivity was lower for mild curves (Cobb angle=10°-20°) than for moderate or severe curves.

As a non-ionizing modality, millimeter-wave imaging aligns with the "as low as reasonably achievable" principle and may reduce unnecessary radiation exposure in pediatric populations. The rapid acquisition time (approximately 2 seconds) and ability to scan through light clothing balanced efficiency with privacy preservation, supporting application in large-scale, high-throughput settings such as schools or communities. Moreover, the 3D surface data may enable future assessment of parameters such as vertebral rotation, offering morphological information beyond that provided by conventional 2D radiography.

In summary, this technology is suitable for initial scoliosis screening. Key advantages include (1) absence of ionizing radiation, avoiding cumulative cancer risks from repeated radiographic examinations and supporting longitudinal monitoring; (2) ability to image through everyday clothing, preserving patient dignity and addressing privacy concerns relevant to adolescents; (3) rapid scanning, facilitating efficient large-scale screening; and (4) 3D morphological data that complement planar radiographic findings. Current scoliosis screening techniques based on angular measurement primarily include the use of a scoliometer for assessing the angle of trunk rotation (ATR) and optical surface topography systems. Reported sensitivities for these methods typically range from approximately 70% to 86% [31,32]. In comparison, the millimeter-wave imaging system used in this study achieved a sensitivity of 85.7% (84/98), which is comparable to the performance of existing non–radiation-based screening technologies. The device can be positioned as a triage tool to identify high-risk individuals requiring confirmatory radiographic evaluation. It should be emphasized that this system does not replace Cobb angle measurement, and definitive diagnosis still requires standard radiography.

Limitations

This study has several limitations that should be acknowledged. First, diagnostic accuracy was significantly lower in the mild scoliosis group (Cobb angle=10°-20°) than in the moderate (20°-40°) and severe (≥40°) groups. This difference arose because, under the current diagnostic criteria, some imaging-confirmed mild scoliosis cases were classified as negative during initial screening when at least one quantitative parameter did not meet the predefined threshold, resulting in false-negative outcomes (Multimedia Appendix 5). Moreover, although multi-posture analysis often identifies compensatory asymmetries indicative of scoliosis (eg, scapular asymmetry), these features are not fully captured in single-posture or single-parameter assessments. To preserve the objectivity of this blinded diagnostic accuracy study, qualitative findings from multi-posture observations were not incorporated into the formal statistical analysis, nor were they used to retrospectively revise the initial binary (positive or negative) classification based on the predefined quantitative thresholds.

Second, this was a diagnostic accuracy study conducted in patients with suspected scoliosis referred for clinical evaluation, not a screening study in an asymptomatic population. Future multicenter studies with larger and more diverse populations are needed to further validate the clinical applicability of this technology.

Third, we did not include ATR measurements for direct comparison with existing clinical screening tools. In addition, we did not perform direct comparison between clothed and unclothed measurements or between millimeter-wave imaging and optical surface topography systems. Future studies should incorporate direct comparison among ATR measurements, optical surface topography systems, and millimeter-wave imaging.

Finally, diagnostic accuracy was lower for mild scoliosis (10°-20°) as subtle asymmetries may not always meet quantitative threshold criteria. Future integration of machine learning algorithms for automated analysis may improve detection of mild curves [32-35].

Conclusions

Millimeter-wave imaging represents a promising advancement in scoliosis screening. It provides a rapid, safe, and privacy-preserving approach, achieving a diagnostic performance comparable to initial clinical assessments while offering greater objectivity. As an effective preliminary screening step prior to radiographic evaluation, this technology has the potential to optimize health care resource use. Overall, it shows substantial promise for enabling large-scale, routine scoliosis screening in a safe and practical manner, consistent with recommendations from leading clinical organizations.

Abstract

Background: Toilet training is a major challenge for children with autism spectrum disorder. While mobile health offers accessible support, few apps specifically address the complex chaining required for independent toileting routines.

Objective: This pilot study evaluated the feasibility and preliminary effectiveness of a caregiver-mediated mobile app using stepwise animated video modeling with token-based reinforcement support for toilet training in young children with autism spectrum disorder.

Methods: A multiple-baseline design across participants (urination training) and a single-case AB design (defecation training) were used. Ten children (aged 3 - 6 years) were enrolled, and 4 (40%) were included in the final analyses. The tablet-based intervention guided a 16-step toileting routine using animation and token reinforcement. Primary outcomes were caregiver-recorded in-toilet elimination success (percentage) and routine completion (percentage). Secondary outcomes included standardized adaptive behavior scores (Korean Scales of Independent Behavior–Revised) and social validity.

Results: Four children completed the study, whereas 6 were not included in the final analyses for heterogeneous reasons, including child engagement, caregiver implementation burden, and postenrollment ineligibility. Among completers, in-toilet elimination success improved substantially from baseline, reaching 100% for all participants at the limited 3-day follow-up observation window conducted 3 months after the intervention. Notably, one participant showed marked improvement from a stable 0% at baseline to 93.8% (30/32) of elimination events during the intervention. Routine completion also increased across all participants, suggesting improvements in independence. Caregivers reported favorable treatment adherence and social validity.

Conclusions: The app showed preliminary feasibility and was associated with improvements in toileting outcomes among families who maintained engagement. However, the high attrition rate suggests that successful implementation may depend on child engagement readiness and caregiver resources. Future research should prioritize defining readiness criteria to identify families most likely to benefit from digital toileting interventions.

autism spectrum disorder; toilet training; mobile apps; video modeling; token-based reinforcement; activities of daily living; caregivers; pilot projects

Introduction

Autism spectrum disorder (ASD) is often accompanied by challenges in adaptive functioning and daily living routines, including difficulties with sequencing multistep self-care behaviors [1]. Among daily living skills, toileting is a major developmental milestone, yet many children with ASD experience persistent difficulties across the toileting routine—such as communicating need, clothing management, in-toilet elimination, and completing hygiene steps [2-4]. These difficulties can increase caregiver burden and interfere with participation in everyday routines at home and in early childhood

XSL•FO
RenderX

settings (eg, day care or preschool), underscoring the need for feasible, family-centered toileting supports [5].

Behavioral toilet training packages—most notably those derived from rapid toilet training approaches—have been widely used for children with developmental disabilities, including ASD [4,6,7]. Although these approaches can increase in-toilet elimination, most published studies remain small sample sizes and report interventions and outcomes heterogeneously, which limits generalizability across children and settings [5]. In addition, many programs emphasize continence and scheduled routines while paying less attention to the broader toileting sequence required for independence (eg, clothing management, wiping, flushing, and handwashing) and to generalization across settings; some packages may also include aversive components that raise acceptability and ethical concerns [4,7,8].

In recent years, mobile health (mHealth) interventions for children with ASD have proliferated, leveraging the portability and accessibility of tablets and smartphones. However, recent systematic reviews indicate that most ASD-related mHealth apps focus on communication, social skills, or parent-mediated support rather than toileting-specific daily living routines [9,10]. Integrated digital tools that combine structured toileting routines, caregiver-mediated implementation, stepwise video modeling, reinforcement support, and home-based toileting data recording remain limited [11].

Video modeling is an evidence-based instructional strategy in which individuals observe a model performing a target behavior and then practice the same behavior, which can reduce verbal demands and leverage visual learning strengths often reported in ASD [12-14]. Meta-analytic and experimental studies support video modeling for teaching functional skills to children with ASD [14-16]. In toileting, video modeling has shown promise for teaching parts of the toileting routine [17,18]. To address challenges in depicting sensitive behaviors (eg, in-toilet urination or defecation), some studies have incorporated animation to visually represent the full toileting sequence [19,20]. However, for multistep routines, video-based instruction can still be constrained by attention demands and prerequisite learning skills when sequences are long or complex; segmented and stepwise formats have therefore been proposed to support acquisition of response chains [21].

Because toileting requires repeated practice over extended periods, sustaining children's participation and caregiver implementation is a practical challenge. In ASD-focused digital interventions, game-related features (eg, simple token collection, visual rewards, or optional mini games) have been used to support engagement and repeated practice, although evidence remains limited and mixed for daily living skills [22,23]. Technology-assisted delivery may also help standardize modeling, provide in-the-moment prompts, and support caregiver-mediated implementation in naturalistic home settings.

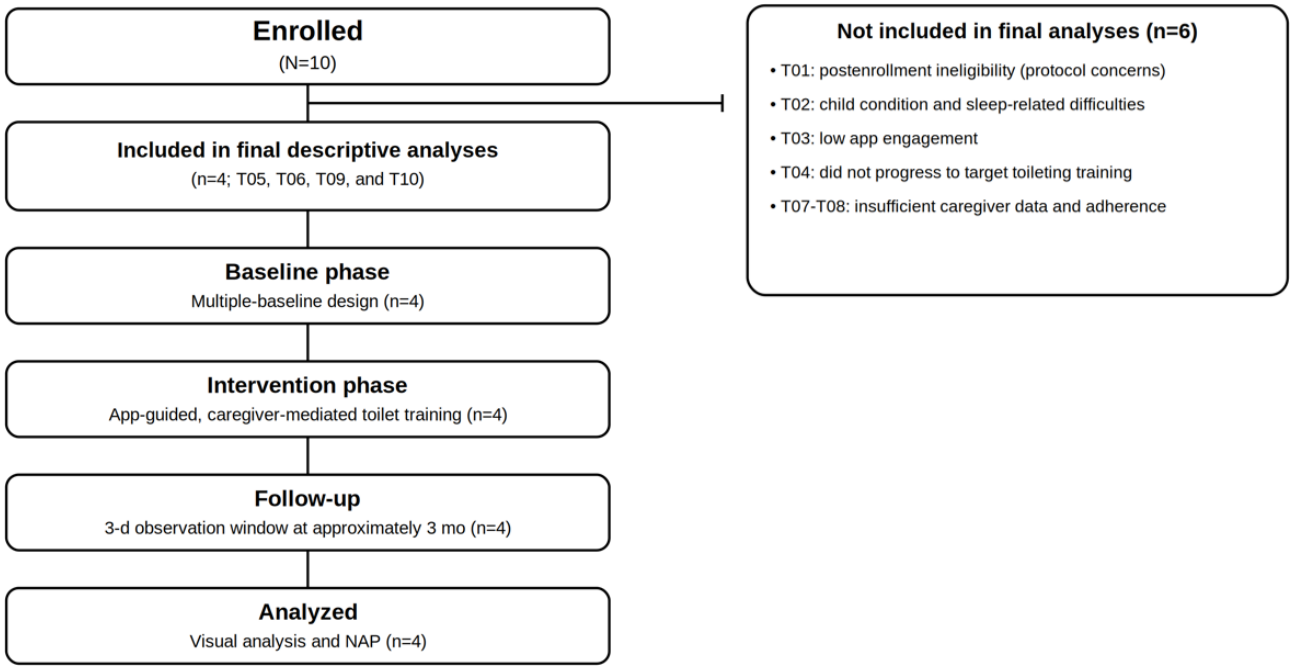
Accordingly, this pilot study describes the development and preliminary evaluation of a tablet-based toileting program that delivers brief, stepwise animated video models with simple interactive prompts, caregiver-entered performance feedback, and a token-based reinforcement system (digital stickers exchanged for preferred reinforcers, with optional mini games). Using single-case experimental designs (a multiple-baseline design across participants for urination training and a single-case AB design for defecation training) with 4 preschool-aged children with ASD, we explored feasibility and preliminary patterns of change in toileting routine completion and independent toileting performance over time.

Methods

Study Design

This pilot study used single-case experimental methods. A multiple-baseline design across participants was applied to evaluate the program for urination (participants T06, T09, and T10), and a single-case design with baseline, intervention, and follow-up phases was used for defecation training (participant T05).

Ethical Considerations



This study was approved by the Public Institutional Review Board designated by the Ministry of Health and Welfare of South Korea (P01-202308-01-056). All procedures were conducted in accordance with the Declaration of Helsinki. Written informed consent was obtained from all parents or legal guardians prior to participation.

Participants and Recruitment

Children were recruited through an online community for caregivers of children with developmental disabilities. Children were eligible if they were aged 3 to 6 years and had either a clinical diagnosis of ASD by a pediatrician or an ongoing diagnostic evaluation for suspected ASD at enrollment. Children were excluded if they were receiving ongoing toilet training outside the study protocol at enrollment. Eligibility additionally required persistent toileting difficulties (eg, elimination outside the toilet, no spontaneous toilet visits, and/or prior attempts with continued problems); no participation in a structured toileting intervention within the 4 weeks prior to enrollment; and the ability to understand simple instructions, with no reported vision or hearing impairments. Formal standardized measures of imitation ability or receptive language were not collected at screening. Withdrawal and discontinuation criteria were defined a priori and applied consistently: participation could be discontinued if (1) unexpected adverse responses or safety concerns arose, (2) repeated refusal or low engagement prevented feasible delivery of the training procedures and/or adequate recording, (3) a new structured toileting intervention was initiated during the study period, or (4) the caregiver withdrew consent. Four children (T05, T06, T09, and T10; n=2 girls) met the prespecified analytic inclusion criterion (≥5 caregiver-reported app-guided training sessions) and were included in the final analyses. Participant flow is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Participant flow. NAP: nonoverlap of all pairs.

Setting and Materials

The intervention was delivered via a mobile app compatible with smartphones and tablets and was implemented by caregivers in naturalistic settings, primarily the children's home bathrooms. To standardize access and screen size across families, caregivers were provided with a 10.4-inch Samsung Galaxy tablet with the app preinstalled. Caregivers were asked not to introduce new toileting interventions during the study and to keep the children's usual toileting routines and concurrent therapies as consistent as feasible across phases.

App Development and Design Rationale

Overview

The app was developed to support toilet training for young children with ASD by integrating video modeling with applied behavior analytic principles to facilitate chaining of a multistep toileting routine [24,25]. The toileting routine was operationalized as a 16-step task analysis (Textbox 1) developed in consultation with a board-certified behavior analyst at Seoul National University Hospital. Segmenting self-care routines into teachable units was intended to support children who commonly experience difficulty with sequencing and adaptive functioning [1].

Textbox 1. The 16-step toileting routine.

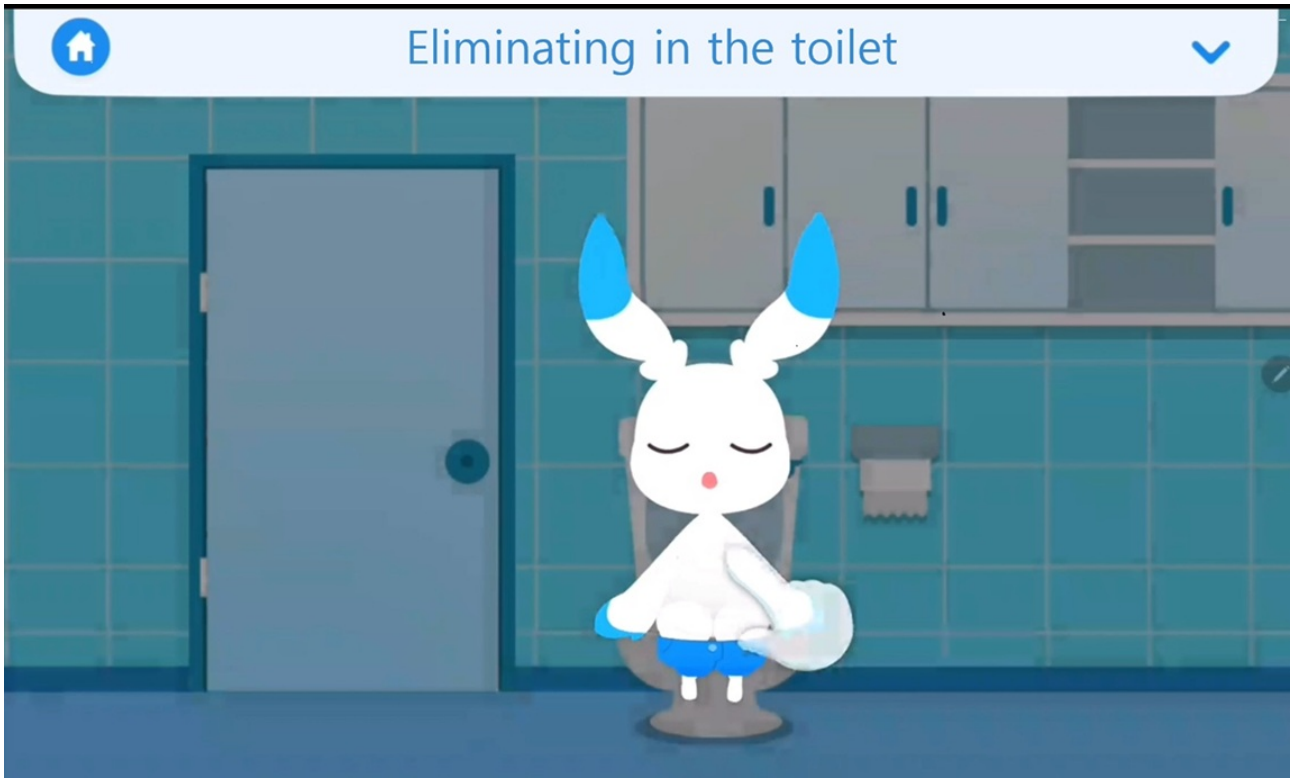
- Step 1: requesting the bathroom
- Step 2: turning on the light
- Step 3: entering the bathroom
- Step 4: checking the toilet lid
- Step 5: pulling down pants
- Step 6: pulling down underwear
- Step 7: sitting on the toilet
- Step 8: eliminating in the toilet (urination and/or defecation)
- Step 9: wiping with toilet paper
- Step 10: putting on underwear
- Step 11: putting on pants
- Step 12: flushing the toilet
- Step 13: washing hands
- Step 14: drying hands with a towel
- Step 15: leaving the bathroom
- Step 16: turning off the light

XSL•FO
RenderX

Rationale for Animation and Character-Based Modeling

The modeling content was implemented as animation rather than live-action video to reduce potential discomfort and privacy concerns associated with depicting sensitive toileting-related behaviors (eg, wiping) using human actors and to present a child-friendly character that may be easier for young children to attend to and imitate. Video modeling aligns with learning characteristics commonly described in ASD by reducing verbal demands and emphasizing visual information [13,14]. Prior toileting-focused interventions have incorporated animation within video modeling to represent sensitive behaviors while preserving a complete routine sequence [19,20].

Reward Features and Reinforcement



The app incorporated a reward structure consistent with token-based reinforcement [24]. Digital sticker tokens were delivered contingent on successful completion of targeted steps. Tokens were accumulated and exchanged using a fixed rule (10 tokens→immediate reward). Reward options could include in-app content (eg, mini games or customization and decoration features) and/or caregiver-selected preferred items or activities available in the bathroom area, allowing for individualized reinforcement while keeping the exchange rule consistent. No punishment or aversive procedures were used.

Intervention: Stepwise Animated Video Modeling App

Overview

The toileting routine was structured as a chained sequence of 16 steps. Caregivers selected target steps for training sessions based on the children's needs. All step-specific animated models featured a single rabbit character (Rudy) to provide consistent visual cues across steps and repeated practice opportunities. The app interface is shown in Figure 2.

Figure 2. User interface of the stepwise animated video modeling.

Session Flow and Feedback

Each training session followed a standardized flow for the selected steps: (1) the child watched the step-specific animated model, (2) the app prompted imitation ("Do what I did!"), (3) a pop-up rating question appeared (eg, "Did your child copy well?") with 2 response options ("Good job" or "Not really"), and (4) feedback was delivered based on the caregiver's response. If "Good job" was selected, the caregiver provided brief praise, and the app displayed a reward animation and delivered a digital sticker token that the child could drag and attach to a collection area. If "Not really" was selected, no reward feedback was provided and the modeling segment was replayed, allowing up to 2 additional attempts for that step.

Token Exchange Rule and Session Schedule

Sticker tokens served as digital tokens. Once the child accumulated 10 tokens, the preselected reward was delivered immediately in the bathroom area. During the intervention phase, caregivers were instructed to conduct at least one app-guided training session per day; training frequency could be individualized (eg, once daily vs 3 times daily) and was kept stable within each child once the intervention began.

Outcomes and Measures

Outcomes were grouped into 4 domains to describe elimination performance, toileting routine performance, caregiver-reported functioning, and implementation.

XSL•FO
RenderX

Caregiver-Recorded Toileting Logs

Caregivers recorded toileting behavior using an online tracking sheet (Google Forms) provided by the research team. Logs were completed whenever the child urinated or defecated or participated in toileting practice and included date and time, location, elimination type (urination or defecation), in-toilet success, and step-level items aligned with the 16-step routine, with optional comments. Because children attended day care, kindergarten, or school, caregivers primarily recorded events occurring when the children were under caregiver supervision; events outside caregiver observation may not have been captured.

Elimination Outcome: In-Toilet Elimination Success

In-toilet elimination was defined as urination or defecation occurring into the toilet bowl. Phase-level success rates were calculated separately for urination and defecation as (number of in-toilet elimination events/total elimination events recorded) × 100. For target-specific elimination outcomes, denominators were based on the elimination type selected in the caregiver log. For urination training participants, events categorized as urination or mixed urination and defecation episodes were included in the urination denominator. Mixed events were coded as in-toilet successes only when the caregiver marked the episode as successful. Records in which urination was mentioned only in free-text comments but not selected as the elimination type were not counted. Practice episodes without elimination, nontarget elimination events, and entries with insufficient information were excluded from the corresponding outcome denominator.

Toileting Routine Performance Outcome: Daily Completion of the 16-Step Routine

Caregivers recorded step-level completion aligned with the 16-step routine for each recorded log entry (including practice episodes regardless of whether elimination occurred). Daily routine completion was calculated as (sum of successfully completed steps recorded that day/total step opportunities recorded that day) × 100. Total step opportunities were defined by the number of recorded log entries for that day multiplied by 16 steps (based on the standardized routine). For example, if 2 log entries were recorded on a given day, the total step opportunities were 32; if 24 steps were completed across those entries, the daily completion for that day was 75%. Given variability in the number of recorded entries per day, day-level percentages were interpreted primarily by patterns over time (eg, trends) rather than isolated single-day values. Because elimination cannot be ethically controlled, routine performance was evaluated separately from elimination outcomes. Step 8 (eliminating in the toilet) was coded as completed only when urination and/or defecation occurred. Practice entries in which elimination did not occur were retained for routine performance analyses, but step 8 was coded as not completed for those entries; elimination outcomes were captured only through the event-based in-toilet success metric.

Toilet Use Method (Initiation and Assistance Categories)

For each log entry, caregivers selected one mutually exclusive category describing how the toileting episode occurred: caregiver prompting, child communication or indication of toileting need, independent toilet use, or accident (elimination outside the toilet). Phase-level percentages were summarized descriptively for each participant.

Caregiver-Reported Outcomes (Standardized Measures)

Caregivers completed standardized questionnaires online at prespecified time points.

The Korean version of the Gilliam Autism Rating Scale–Second Edition (K-GARS-2) is a caregiver, teacher, or clinician–rated autism screening measure for individuals aged 3 to 22 years [26,27]. It includes 42 items across 3 subscales—stereotyped behaviors, communication, and social interaction—yielding standardized scores.

The Korean Scales of Independent Behavior–Revised (K-SIB-R) is a standardized, norm-referenced measure of adaptive functioning [28]. In this study, we summarized (1) toileting age-equivalent scores (years and months) and (2) Personal Self-Care W scores. In addition, to contextualize change relative to age expectations, we expressed Personal Self-Care W scores as deviation from age-based norms in SD units using normative values from the K-SIB-R manual; normative mean and SD values are not reported in this manuscript.

The Behavior Rating Inventory of Executive Function–Preschool Version (BRIEF-P) is a caregiver-rated measure of executive functioning for preschool children [29]. It includes 63 items across 5 clinical scales (inhibit, shift, emotional control, working memory, and plan or organize), with higher scores indicating greater executive function difficulties.

The Korean Parenting Stress Index, Fourth Edition, Short Form (K-PSI-4-SF) assesses parenting stress among parents of children aged 1 to 12 years [30]. It comprises 3 subscales—parental distress, parent-child dysfunctional interaction, and difficult child—and yields a total stress score, with higher scores indicating greater parenting stress.

Treatment Fidelity

Treatment fidelity was evaluated using a 7-item checklist developed for this study based on a prior Korean intervention study using a social validity measure [31]. Caregivers completed the checklist on 5 occasions per participant during the intervention period, rated adherence on a 5-point scale, and reported deviations or modifications. The items assessed were (1) preparation of the training environment, (2) arrangement of materials or reinforcers, (3) caregiver instruction to the child, (4) correct software use, (5) waiting for the child's response, (6) delivery of reinforcement for correct responding, and (7) appropriate responding to incorrect behavior (eg, replay without reinforcement). Fidelity was calculated as (acquired score/total possible score) × 100. The treatment fidelity checklist items can be found in Table S1 in Multimedia Appendix 1.

Social Validity

Social validity was assessed after the intervention using a caregiver questionnaire (9 items, 5-point Likert scale). Items assessed perceived effectiveness, acceptability, safety, feasibility, and overall satisfaction with the toileting program.

XSL•FO
RenderX

The questionnaire was developed and refined based on a prior Korean intervention study reporting treatment fidelity procedures [31].

Procedure and Study Phases

No parallel control group was included in this study; instead, experimental control was supported by the staggered introduction of the intervention across participants.

Caregivers received study information and completed informed consent; the device was distributed; caregivers received 1:1 training on app use and home implementation, including operational definitions for caregiver recording and completion of the Google Forms–based logs; and preintervention questionnaires and recording instructions were completed. During the study, the research team reviewed submitted records weekly and followed up with caregivers via telephone when needed to clarify missing or ambiguous entries.

At baseline, no app-guided training was conducted. Children followed usual toileting routines, and caregivers recorded toileting events and step-level items. Baseline duration was staggered across participants (minimum of 5 days).

During the intervention, caregivers implemented app-guided sessions daily (minimum once per day; the individualized frequency was kept stable within each child) and continued recording. The intervention was introduced sequentially across participants; a participant began the intervention when the preceding participant met an a priori decision rule (mean routine performance across 3 consecutive intervention days exceeding the baseline mean by ≥15 percentage points). The intervention phase ended when the mastery criterion (≥80% for 3 consecutive sessions or days) was met or when the discontinue criterion was met (no meaningful improvement over 15 sessions).

Caregivers completed questionnaires and implementation measures at the end of the intervention period, and a follow-up was conducted 3 months after the intervention and consisted of 3 recording days using the same logs; the app was not used during follow-up.

Data Analysis

Descriptive analyses other than nonoverlap of all pairs (NAP) were conducted using R (version 4.3.1; R Foundation for Statistical Computing). Outcomes were summarized descriptively using visual analysis and phase comparisons. No confirmatory hypothesis testing was performed. To supplement visual analysis of single-case data, NAP [32] was computed using Python (version 3.13.5; Python Software Foundation) for each participant as a descriptive nonoverlap index for daily toileting routine completion. Follow-up days were not included in these calculations. For K-SIB-R Personal Self-Care W scores, SD unit deviation from age norms was computed descriptively as (W − age norm mean)/(age norm SD) using manual-based norms.

Results

Participant Flow and Available Data

A total of 10 children were enrolled. Four children (T05, T06, T09, and T10; n=2 girls) met the prespecified analytic inclusion criterion (≥5 caregiver-reported app-guided training sessions) and were included in the final analyses. Reasons for noncompletion or exclusion from the final analytic sample are summarized in Table S2 in Multimedia Appendix 1. Across phases, the number of caregiver log entries was as follows: n=10 at baseline and n=32 during the intervention for T05, n=42 at baseline and n=90 during the intervention for T06, n=51 at baseline and n=141 during the intervention for T09, and n=32 at baseline and n=144 during the intervention for T10. Follow-up consisted of 3 recording days, during which caregiver log entries were recorded for T05 (n=6), T06 (n=9), T09 (n=14), and T10 (n=14). Participant characteristics and baseline toileting profiles are shown in Table 1.

XSL•FO
RenderX

Table . Baseline characteristics of participants included in the final analyses.

Characteristics	T05	T06	T09	T10
Age	4 years, 3 months	5 years, 3 months	4 years, 6 months	6 years, 11 months
Sex	Female	Male	Male	Female
ASD[a] diagnostic status	Confirmed	Confirmed	Clinical ASD concern; diagnosis pending	Confirmed
Relevant comorbidity	None reported	None reported	None reported	Intellectual disability
K-GARS-2[b]	100	79	94	<69
Language level	Spontaneous 2 - to 3-word phrases	Several spontaneous words (eg, “diaper,” “take off,” “pee,” and “wet wipes”)	Spontaneous 2 - to 3-word phrases for requests	Several spontaneous words (eg, “water,” “cup,” “mom,” and “dad”)
Digital device use	Able to use simple controls	Able to use tablet apps for watching videos at home	Able to select desired items with setup assistance	Able to activate a smart device and open desired apps
Training target	Defecation	Seated urination	Seated urination	Toileting request+seated urination
Baseline toileting profile	Defecated while squatting behind a curtain in the bedroom wearing underwear	Had urine accidents in clothing and walked around undressed afterward	Urinated in the toilet when assisted by the caregiver but had no independent toileting behavior	Self-initiated toilet attempts at home but had accidents outside the home without communication

[a]ASD: autism spectrum disorder.

[b]K-GARS-2: Korean version of the Gilliam Autism Rating Scale–Second Edition.

In-Toilet Elimination Success

Table 2 summarizes the phase-level percentage of elimination events that occurred in the toilet bowl (in-toilet elimination). Because Table 2 reports target-specific elimination outcomes, the denominators in Table 2 differ from the total number of caregiver log entries reported above. Baseline in-toilet elimination success varied across participants (0% - 23/27, 85.2%). During the intervention, all participants showed higher in-toilet elimination success than at baseline, and all participants showed 100% in-toilet elimination based on the available events during the limited 3-day follow-up observation window.

Table . Target-specific in-toilet elimination success across study phases. Percentages were calculated using target-specific elimination events as denominators. Practice episodes, nontarget elimination events, and entries with insufficient information were excluded.

Participant IDs	Target outcome	Baseline, n/N (%)	Intervention, n/N (%)	Follow-up, n/N (%)
T06	Urination	10/35 (28.6)	62/84 (73.8)	8/8 (100)
T10	Urination	23/27 (85.2)	115/123 (93.5)	12/12 (100)
T09	Urination	37/45 (82.2)	131/134 (97.8)	13/13 (100)
T05	Defecation	0 (0)	30/32 (93.8)	6/6 (100)

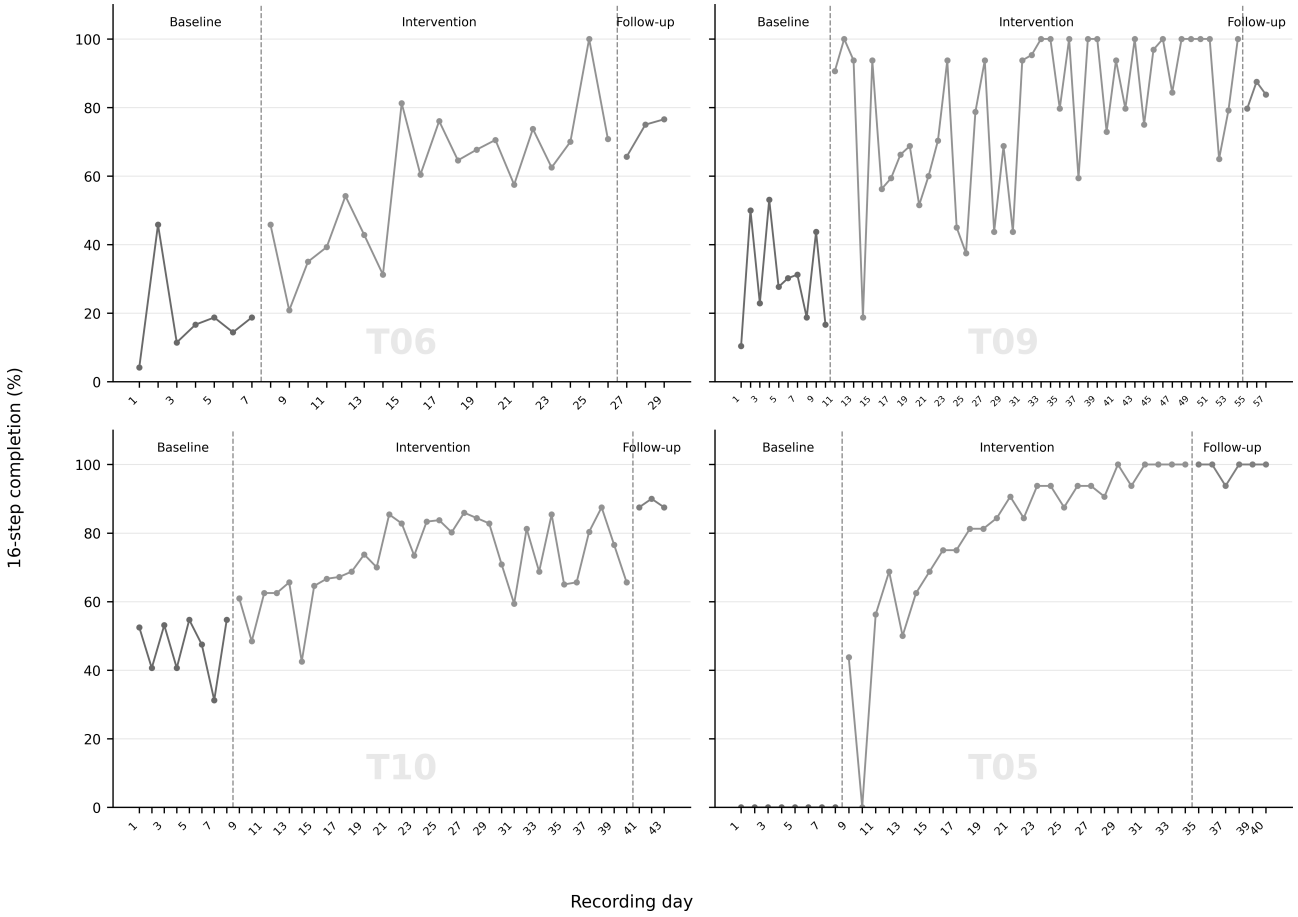
For T06, in-toilet elimination increased from 28.6% (10/35) at baseline to 73.8% (62/84) during the intervention (+45.24 percentage points; Table 2). Follow-up in-toilet elimination success was 100% (8/8) based on the available follow-up events (limited 3-day observation window).

For T10, baseline in-toilet elimination was 85.2% (23/27) and increased to 93.5% (115/123) during the intervention (+8.31 percentage points; Table 2). Follow-up in-toilet elimination success was 100% (12/12) based on the available follow-up events (limited 3-day observation window).

For T09, baseline in-toilet elimination was 82.2% (37/45) and increased to 97.8% (131/134) during the intervention (+15.54 percentage points; Table 2). Follow-up in-toilet elimination success was 100% (13/13) based on the available follow-up events (limited 3-day observation window).

For T05, baseline in-toilet elimination was 0% and increased to 93.8% (30/32) during the intervention (+93.75 percentage points; Table 2). Follow-up in-toilet elimination success was 100% (6/6) based on the available follow-up events (limited 3-day observation window).

It should be noted that percentages were calculated using target-specific elimination events as denominators. Practice episodes, nontarget elimination events, and entries with insufficient information were excluded.



Toileting Routine Performance: Daily Completion of the 16-Step Routine

Daily toileting routine step completion (percentage) for all 4 participants is shown in Figure 3. Because the number of recorded log entries varied by day, day-level percentages were interpreted primarily by patterns over time (eg, level and trend). Visual inspection also indicated differences in the immediacy

XSL•FO
RenderX

of effect: routine completion for T09 exceeded all baseline values from the first intervention days, and T05 increased from a stable 0% at baseline on the first intervention day, indicating relatively immediate changes in level, whereas T06 and T10 showed more gradual improvements across the intervention phase.

Figure 3. Day-level completion of the 16-step toileting routine across baseline, intervention, and follow-up phases. Each data point represents the mean percentage of completed steps across all caregiver-recorded entries within a recording day. The x-axis represents the sequence of recording days with available caregiver-recorded data and does not reflect the actual calendar interval between phases. Vertical dashed lines indicate phase transitions. Follow-up observations were collected approximately 3 months after the intervention phase, although the exact calendar interval varied across participants.

T06 showed a low and stable baseline followed by a clear upward shift and increasing trend after intervention onset, reaching sustained high performance later in the intervention phase and remaining elevated during follow-up.

T10 showed moderate baseline performance with variability; after intervention introduction, routine completion increased overall with intermittent dips, and follow-up values remained within the higher range observed late in the intervention.

T09 showed baseline variability; during the intervention, routine completion continued to fluctuate but with an overall upward pattern and repeated high-performance days later in the intervention. Follow-up values remained higher than baseline.

T05 showed 0% routine completion during baseline and increasing routine completion during the intervention, with high performance later in training and elevated values during follow-up.

Supplementary nonoverlap analyses using day-level 16-step completion percentages indicated substantial phase separation across participants, with NAP values ranging from 0.9580 to 0.9808 (Table 3). This index complemented the visual analysis by quantifying the degree of nonoverlap between the baseline and intervention phases.

XSL•FO
RenderX

Table . Nonoverlap indexes for day-level 16-step toileting routine completion[a].

Participant IDs	Baseline days used, n	Intervention days used, n	Baseline daily 16-step completion (%)	Intervention daily 16-step completion (%)	NAP[b]
T05	8	26	0.00	79.57	0.9808
T06	7	19	18.58	59.18	0.9586
T09	10	44	30.48	79.76	0.9580
T10	8	32	46.88	71.93	0.9648

[a]"Days used" refers to recording days with available step completion data. Follow-up days were not included in nonoverlap analyses. T05 was evaluated in an AB design without staggered replication across participants; indexes for T05 are therefore descriptive only.

[b]NAP: nonoverlap of all pairs.

Toileting Method (Initiation and Assistance Categories)

Phase-level distributions of toileting method categories (independent toilet use, caregiver prompting, child communication or indication, and accident) can be found in Table S3 in Multimedia Appendix 1. Overall, accidents decreased for T05, T06, and T09 during the intervention and were not observed at follow-up for any participant. Independent toilet use increased prominently for T05 and T06. Child communication or indication was observed primarily for T09 and T10 during intervention and follow-up, whereas caregiver prompting remained common, particularly for T09.

Standardized Measures

Baseline characteristics, including K-GARS-2 scores, are shown in Table 1. K-SIB-R outcomes are summarized in Table 4.

Table . Korean Scales of Independent Behavior–Revised toileting age-equivalent (AE) scores and Personal Self-Care W scores (with norm-referenced deviation in SD units, which were computed descriptively using manual-based age norms as [W − age norm mean]/[age norm SD]; normative mean and SD values are not reported).

Participant IDs	Chronological age	Toileting AE		Personal Self-Care W, SD units			Norm-referenced deviation, SD units	
		Before	After	Before	After	ΔW	Before	After
T06	5 y, 3 mo	2 y, 2 mo	3 y, 7 mo	467	482	+15	−3.11	−1.08
T10	6 y, 11 mo	1 y, 11 mo	2 y, 7 mo	465	474	+9	−3.73	−2.65
T09	4 y, 6 mo	1 y, 11 mo	2 y, 7 mo	465	474	+9	−3.53	−1.99
T05	4 y, 3 mo	2 y, 8 mo	4 y, 0 mo	476	484	+8	−1.64	−0.27

On the K-SIB-R Personal Self-Care domain, age-equivalent scores increased from before to after the intervention. To contextualize change relative to age expectations, Personal Self-Care W scores increased for all participants (ΔW=+8 to +15), and deviation from age-based normative means decreased (Table 4). Notably, T06 moved from approximately 3 SDs below the age norm at baseline to approximately 1 SD below after the intervention, and T05 moved to within 1 SD of the age norm after the intervention. Despite improvement, some participants remained at 2 or more SDs below age norms after the intervention (eg, T10).

Exploratory changes in BRIEF-P subscale scores and K-PSI-4-SF percentile ranks can be found in Table S2 in Multimedia Appendix 1.

Implementation Outcomes: Treatment Fidelity and Social Validity

Treatment fidelity scores, calculated from caregiver-completed fidelity checklists (5 administrations per participant), indicated favorable adherence to intervention procedures. Social validity ratings (Table 5) indicated favorable caregiver perceptions of acceptability, safety, and feasibility and overall satisfaction with the program.

XSL•FO
RenderX

Table . Mean scores on the social validity questionnaire from 4 caregivers of participants.

	Mean scores
Total	4.4
Understanding	4.75
Convenience	4.5
Reuse intention	4.25
Recommendation intention	4.75
Children's immersion	4.5
Safety	4.75
Effectiveness	4.25
Expression increase	4.25
Hygiene independence	4

Discussion

Principal Findings

In this pilot study, a caregiver-implemented mobile app that combined stepwise animated video modeling with a structured reward system was associated with improvements in toileting behaviors among young children with ASD. Across participants, the proportion of elimination events occurring into the toilet increased during the intervention and showed 100% in-toilet elimination during the limited 3-day follow-up observation window conducted 3 months after the intervention. In parallel, completion of the 16-step toileting routine improved over time, suggesting gains in broader toileting-related self-care behaviors beyond voiding alone (eg, undressing, flushing, and hygiene steps). Caregivers also reported favorable adherence and favorable perceptions of acceptability and safety, supporting feasibility of home implementation for families who engaged with the app.

A key finding of this pilot study relates to the feasibility boundaries of caregiver-mediated digital interventions. We observed a high attrition rate, with 60% (6/10) of enrolled families discontinuing participation or being excluded from analysis for heterogeneous reasons, including child condition or sleep-related difficulties, low tablet or app engagement, inability to progress beyond toilet sitting readiness, caregiver recording or implementation nonadherence, and postenrollment ineligibility (Table S1 in Multimedia Appendix 1). The high attrition rate represents a major limitation of the present study but also provides useful feasibility information for future research. The pattern of discontinuation suggests that successful implementation of this app requires specific child prerequisites (eg, basic imitation skills and tolerance for tablet interaction) and sufficient parental resources to facilitate the initial sessions. This aligns with broader findings in eHealth research, where open trials often reveal high attrition, highlighting the need to tailor inclusion criteria to the families most likely to benefit [33]. Thus, the findings suggest that the intervention may be beneficial for families able to sustain engagement, but broader applicability requires further study with clearer inclusion criteria. Toileting interventions for children with ASD have historically emphasized in-toilet voiding outcomes using intensive schedules and reinforcement-based packages and may vary widely in components and reporting. Prior reviews indicate that, although many approaches can improve voiding outcomes, the evidence base remains dominated by small-n single-case experimental studies and heterogeneous outcome definitions, which limits comparability and confidence in generalizability [4,5]. Video modeling is often considered well suited for ASD because it reduces verbal demands and leverages visual learning, with evidence supporting its use across functional skill targets [13,14]. Toileting-focused studies have further shown that incorporating animation into video modeling can enable depiction of sensitive behaviors while retaining a complete routine sequence [19,20]. Our findings add to this literature by applying an animated stepwise routine in a mobile format designed for repeated use in naturalistic caregiver-managed settings.

A central conceptual clarification warranted by this study concerns the distinction between the digital platform and the behavioral intervention it delivered. The app served as a structured delivery medium for a multicomponent behavioral intervention that incorporated task analysis, behavior chaining, caregiver-mediated prompting, contingent token-based reinforcement, and stepwise animated video modeling. The study findings therefore reflect the preliminary feasibility and potential benefit of this intervention package as implemented through a caregiver-mediated digital platform rather than evidence on any single technological feature. This distinction is consistent with the broader literature on mHealth interventions, which emphasizes that behavioral mechanisms—not digital packaging—drive therapeutic change. Future work should use dismantling designs or component analyses to clarify the relative contributions of video modeling, token reinforcement, task analytic structure, and caregiver mediation to observed outcomes.

A central design decision was to operationalize toileting as a 16-step task analysis aligned with chaining principles. This allowed caregivers to target discrete steps and reinforce incremental progress rather than focusing exclusively on elimination outcomes [24,25]. Importantly, step completion was tracked even when elimination did not occur (eg, the child sat on the toilet but did not void), reflecting how toileting

XSL•FO
RenderX

practice occurs in real-world routines. This may be relevant for children with ASD who often experience difficulty with sequencing and adaptive self-care skills [1]. The choice of animation (rather than live action) also addressed privacy and potential discomfort associated with human depictions of toileting-related behaviors while providing a consistent, child-friendly model.

Although the app included interactive elements, we interpret the motivational component primarily as reinforcement support. The token exchange rule (10 digital stickers exchanged for an immediate reward) implemented a clear contingency while allowing for individualized reinforcers (eg, in-app activities and/or caregiver-selected preferred items). This characterization avoids overstating "gamification" and makes the hypothesized mechanism explicit: repeated practice of a structured routine paired with contingent reward.

Beyond caregiver-recorded toileting logs, standardized assessment data provided descriptive contextual information that was generally consistent with the behavioral observations. On the K-SIB-R, toileting age-equivalent scores increased for all participants, and Personal Self-Care W scores moved closer to age-based expectations (Table 4). Norm-referenced deviation (SD units) decreased for each participant. These SD unit values represent distance from age norms rather than an effect size from a controlled comparison and should be interpreted cautiously. However, reporting a standardized measure alongside event-based and routine-based outcomes is consistent with the observation that the pattern of change was not limited to a single measurement approach.

This study has limitations consistent with early-stage digital health and single-case experimental research. First, the analytic sample was small (4 children), and 60% (6/10) of enrolled participants were not included due to discontinuation or insufficient exposure, underscoring the central importance of engagement and feasibility in caregiver-mediated digital interventions. Because baseline characteristics were not systematically available for all participants who were not included in the final analyses, formal comparison between completers and noncompleters was not possible; however, available contextual information and reasons for noncompletion or exclusion are summarized in Table S1 in Multimedia Appendix 1. Second, primary outcomes relied on caregiver-reported logs, which may introduce reporting bias and incomplete capture of events occurring outside caregiver supervision. Although caregivers received structured training and the research team reviewed records weekly with telephone follow-up when needed, independent observation and interobserver agreement data were not collected, limiting the reliability of caregiver-reported outcomes. Third, the follow-up phase consisted of 3 recording days at 3 months after the intervention, providing a limited sample of maintenance. Finally, day-level step completion percentages can be influenced by variation in the number of recorded events per day; therefore, trends over time are more interpretable than isolated daily values. In addition, technology-related factors may have affected feasibility. Children with limited interest in or tolerance for tablet-based activities may have difficulty engaging with the intervention, and caregiver time, digital literacy, and home technology environments may influence implementation. Therefore, app-based toileting interventions may not be appropriate for all children with ASD without additional engagement supports or caregiver assistance. Furthermore, because this was an early-stage single-case pilot feasibility study, a formal group-level sample size calculation was not performed. The enrollment target was determined pragmatically based on the intensive caregiver-mediated home implementation protocol, the multiple-baseline design, and anticipated recruitment constraints in young children with ASD requiring toileting support. These limitations indicate that the present findings should be interpreted as preliminary signals of feasibility and potential benefit rather than definitive evidence of effectiveness.

Future work should prioritize more rigorous evaluation, improved measurement, and strategies to sustain engagement while preserving the pragmatic, home-based nature of delivery. We have initiated an exploratory randomized controlled trial (target N=30) to evaluate effectiveness and implementation outcomes more robustly. This next phase can follow established reporting guidance for eHealth interventions and incorporate objective use metrics (in-app logs), a longer follow-up period, and independent outcome verification where feasible. Additional iterative development may also be warranted to support sustained engagement over longer periods given that low engagement was a reason for discontinuation in some families.

Conclusions

A caregiver-implemented mobile app that integrates stepwise animated video modeling, task analysis–based chaining, and reinforcement support was feasible for families who engaged with the software and was associated with improvements in toileting outcomes and adaptive self-care indicators among young children with ASD. Larger controlled studies are needed to determine effectiveness, characterize engagement and attrition, and establish scalable implementation strategies.

Acknowledgments

The authors sincerely thank the participating families, clinicians, and development teams for their commitment to the study and for contributing to the mobile-based animated video modeling app with token-based reinforcement support. The content is solely the responsibility of the authors and does not necessarily represent the official views of the supporting organizations. During manuscript preparation, AI-assisted tools were used to support language editing, translation, and reference formatting. OpenAI's ChatGPT and Google's Gemini were used to support language editing and translation, and OpenAI's ChatGPT was additionally used to support reference formatting. These tools were not used for study design, data generation, data analysis, or interpretation

of the results. All final decisions regarding the content and conclusions of this manuscript were made by the authors, who take full responsibility for its accuracy and integrity.

Funding

This work was supported by the National IT Industry Promotion Agency, an agency under the Ministry of Science and ICT, South Korea, through the Daegu Digital Innovation Promotion Agency, an organization under the Daegu Metropolitan Government. The study was conducted in collaboration with Seoul National University Hospital, where Younglae Kim, JK, and BNK are affiliated. The sponsors had no role in data analysis and interpretation or the decision to submit the manuscript for publication.

Data Availability

The datasets generated and analyzed during the current study contain identifiable participant information and are therefore not publicly available to protect participant privacy. However, deidentified data supporting the findings of this study are available from the corresponding author on reasonable request.

Authors' Contributions

Conceptualization: IS, Yearin Kim
Data curation: IS, Younglae Kim
Formal analysis: IS, Younglae Kim
Funding acquisition: DK, JM
Investigation: Younglae Kim, JK
Methodology: Yearin Kim
Project administration: DK
Resources: Yearin Kim, JK

Abstract

Background: Traditional models of applied behavior analysis (ABA) services for those diagnosed with autism spectrum disorder (ASD) involve time-intensive, labor-intensive, comprehensive, in-person services. The increasing prevalence of ASD in the United States has precipitated a need to identify effective, accessible, and innovative methods to address the needs of those with ASD.

Objective: The present descriptive study examines the feasibility and acceptability of a fully virtual, targeted model of ABA service delivery.

Methods: This retrospective analysis evaluated changes over time in adaptive behavior, maladaptive behavior, and caregiver satisfaction during focused, virtual ABA therapy delivered by a Board Certified Behavior Analyst.

Results: Improvements in standard scores across Vineland-3 domains and improvements in quality of life (Child and Family Quality of Life, Second Edition), in addition to high levels of caregiver satisfaction, were observed over time.

Conclusions: While causality cannot be determined for these improvements, results support the feasibility and acceptability of this novel ABA service delivery model.

Introduction

Behavior analytic services can have profound positive impacts on individuals and their families. Behavior analysts identify behaviors to teach or reduce by working closely with stakeholders and use this information to select approaches for analyzing and changing behavior, and ultimately, to create socially significant and meaningful change for individuals [1]. As social significance varies from person to person, environment to environment, and culture to culture, the specific behaviors targeted by behavior analysts can be as varied as vocational skills and dental care, shoe tying and aggressive behavior, or law enforcement personnel behaviors and kindergarten readiness skills [2].

Due to efforts driven by families, grassroots organizations, service providers, and researchers across several decades, behavior analytic services are widely implemented to support autistic individuals and their families [3] (In an effort to respect the diverse perspectives of those on the autism spectrum, we use both identity-first language [eg, “autistic child”], person-first language [eg, “child with autism”], and neutral language [eg, “person on the autism spectrum”] to describe our participants and the recipients of applied behavior analysis [ABA] therapy [4]). According to a review conducted by Gitimoghaddam et al [5], ABA has been recognized as one of the most empirically validated forms of support for persons diagnosed with autism spectrum disorder (ASD). In recent years, the prevalence of ASD has become a topic of national interest within the United States, particularly following the release in April 2025 of updated prevalence data from 2022. This report indicates an increase in prevalence to 1 in 31 children from 1 in 36 children in 2020 [6].

As of 2019, all 50 states in the United States require “meaningful coverage” for autism treatment, including ABA therapy services [7]. When services are covered by medical insurance, providers must demonstrate medical necessity and clinical progress [8], both of which require the assessment of current functioning over time. Despite the widespread nature of insurance mandates and the common need to evaluate current functioning, there is limited consensus about the best measures to evaluate clinical outcomes or response to treatment [9,10]. Two measures identified to include in the ICHOM’s (International Consortium

XSL•FO
RenderX

for Health Outcomes Measurement) Standard Set of outcomes for ASD are the Vineland Adaptive Behavior Scales-Third Edition (Vineland-3) and the Child and Family Quality of Life, Second Edition (CFQL-2) [9].

The Vineland-3 assessment measures caregiver-reported adaptive and maladaptive behavior [11] and has been used as an outcome measure in a variety of studies evaluating services for autistic individuals [12-15]. One such study evaluated changes in both the adaptive and maladaptive domains from the Vineland-3 as a function of the client's ASD severity level and usage of prescribed therapy hours [14]. The authors stratified participants by age at the first Vineland-3 administration as well as gender and analyzed changes in the adaptive domains and the extent to which participants' maladaptive subdomain scores improved from clinically significant to nonclinically significant following treatment. This approach of including Vineland-3 maladaptive subdomain score changes is not widespread in the ABA therapy outcomes literature, highlighting an important gap in the literature.

Although specific thresholds for minimal clinically important differences (MCID) have not yet been established for the Vineland-3, previous studies, such as Ostrovsky et al [12], have compared their participants' standard score changes over time, with MCID thresholds derived from MCIDs established for the Vineland-II assessment [16]. The MCID thresholds used by Ostrovsky et al [12] were +2.0 for the ABC (Adaptive Behavior Composite) standard score,+2.0 for the communication standard score,+2.6 for the socialization standard score, and +2.6 for the daily living standard score. While these score changes reflect an anchor-based approach to establishing clinical significance, they do not reflect industry data from actual clinical practice. Despite the lack of agreement within the industry about which tools are most appropriate and how to evaluate meaningful change, there is consensus that teaching adaptive behaviors is a primary goal of ABA services [17].

Some research shows a relation between adaptive skills and quality of life (QoL) for individuals with intellectual disability, with stronger adaptive skills being correlated with improved QoL [18]. Among autistic adults, factors associated with QoL may be even more complex than within other adult populations, making the inclusion of this measure critical to understanding how interventions can support improved QoL [19]. Given the interconnected nature of different QoL areas within a family system, one way of evaluating QoL is by assessing the psychosocial aspects at the individual and family level [20]. The CFQL-2 has been established as a reliable measure of psychosocial aspects of QoL, including child, family, caregiver, the financial, external support, partner relationship, coping, and QoL change [21]. Ciobanu et al [22] observed improvement in total QoL and across several subscales for a series of three patients receiving ABA therapy delivered by a parent behavior technician. These results suggest that, for the patients in their study, equipping parents with the knowledge and skills to support their own child's behavior change may have a positive impact on QoL for the whole family system. The extant literature using the CFQL-2 to evaluate QoL among individuals on the spectrum is limited [22,23], but, given the inclusion in the ICHOM ASD standard set [9], this tool may gain traction among ABA service providers interested in evaluating client progress from a variety of angles. A threshold for clinically significant change has not yet been established.

Today, the predominant form of ABA therapy in the United States is center- or home-based services delivered in a 2- or 3-tier model, whereby a Registered Behavior Technician (RBT) is the primary deliverer of care and is directly supervised by a Master's- or Bachelor's-level behavior analyst (often a Board Certified Behavior Analyst [BCBA]). This model is typically considered "comprehensive," which is defined as a scope of treatment that "typically encompasses multiple simultaneous goals within and across multiple domains, such as language, behavior, activities of daily living, social skills, and cognition" in their practice guidelines by the Council for Autism Service Providers [24]. According to these guidelines, comprehensive ABA treatment generally requires 30 - 40 hours of therapy per week to ensure adequate time for teaching and practice opportunities.

Although there is evidence of the efficacy of in-person, comprehensive ABA therapy delivered in a 2- or 3-tier model [25], there are also many challenges related to this service delivery model. The first and most common challenge related to the traditional service delivery model is a lack of access due to geography or a lack of providers within proximity. According to the US Census Bureau census conducted in 2020, a total of 80% of the population of the United States live in urban areas (defined as greater than 2500 people), and 20% live in rural areas (defined as 2500 people or less). Additionally, the availability of services in general tends to be concentrated in larger metropolitan areas [26].

Families who do have access to ABA services within reasonable proximity of their homes may experience other challenges. First, the available services do not always meet the needs of specific autistic individuals. In particular, school-age children with less global functional impairment may not be well-served by a comprehensive treatment program whose time commitment impacts school attendance or participation in enriching extracurricular activities. Recent studies examining the efficacy of lower intensity ABA services have demonstrated support for less time-intensive interventions [13,27].

Next, the comprehensive model relies on lesser-qualified service providers (eg, a provider with a high school diploma and 40 hours of training, supervised by a Master's- or PhD-level provider roughly 5% of the time) to deliver the bulk of client care. Turnover among these providers is high, with the Behavioral Health Center of Excellence reporting annual turnover of 65% in its 2022 ABA Compensation and Turnover Benchmark Report [28]. These high levels of turnover impact caregiver satisfaction [29] and may result in gaps in care or in lower-quality services being provided. According to current literature exploring parent training and caregiver-mediated interventions, increased caregiver participation in intervention can reduce parental stress levels, increase parental self-efficacy, and support positive child outcomes [30]; however, high levels of turnover and other barriers may prevent families from being meaningfully involved in care.

XSL•FO
RenderX

Finally, the costs associated with health care for a child with autism, including traditional ABA services, are significant. A recent report from the Agency for Healthcare Research and Quality indicates that the average total health cost for a child being treated for autism was US $20,122 compared with the average total health cost of US $2201 for a child not being treated for autism [31].

Given the challenges associated with the comprehensive ABA service delivery model, some providers are seeking alternative models that address the concerns detailed above while still producing meaningful change on behalf of the families they serve. One relatively new option is a BCBA-direct, fully virtual, focused ABA therapy model. Services delivered via telehealth are less constrained by the geographic locations of the client or clinician, making it possible for clinicians to reach clients in more rural areas, as well as those residing in areas with a lower ratio of providers to clients. A growing body of literature supports the use of telehealth as an ABA service delivery modality [32-34]. Another benefit of this approach is that individuals who have more targeted clinical needs can receive more tailored interventions, focusing on the area of functional impairment that is most impactful at the time of treatment. These services can be delivered at a lower "dosage" than the recommended 30 - 40 hours per week for comprehensive services, potentially making them more accessible to busy families and more cost-effective for families and their funding sources. This approach is further bolstered by more frequent and consistent contact with a BCBA, who can make treatment decisions throughout each therapy session and evaluate procedures on an ongoing basis, unlike therapy models that rely on RBTs rendering the bulk of service hours. Finally, the telehealth treatment modality can allow for increased caregiver involvement and, therefore, a potential increase in naturalistic learning opportunities by removing many of the barriers families receiving center-based services encounter, such as logistical difficulty with going to the center for caregiver training sessions and a lack of generalization of skills being targeted in an environment very different from their home.

The purpose of this study was threefold: (1) to describe a novel ABA service delivery model that could serve as an alternative for some families; (2) to examine changes in adaptive skills, maladaptive behaviors, and QoL over time for participants who received this novel form of ABA therapy; and (3) to assess the social validity of this novel treatment model through a caregiver satisfaction survey. Evaluation of the fully virtual, BCBA-only, focused treatment model is important because this model represents a structurally different approach to delivering care compared to in-person, RBT-implemented, comprehensive therapy models and has the potential to mitigate many of the challenges associated with prevailing models.

Methods

Service Model

Behavior analytic services were delivered through a fully virtual, BCBA-only, focused treatment model provided by AnswersNow Inc, an ABA service provider. Clinicians delivered services through proprietary, HIPAA (Health Insurance Portability and Accountability Act)-compliant, synchronous audio-video software. All services were rendered by a BCBA, including assessment, direct therapy, therapy protocol modification, and caregiver training. At the outset of care, the assigned BCBA conducted a comprehensive assessment with each participant that included the Vineland-3, the CFQL-2, indirect behavior assessments (eg, FAST [functional assessment screening tool] and QABF [questions about behavior function]), and direct skill assessments based on the participant's clinical presentation (eg, VB-MAPP [Verbal Behavior Milestones Assessment and Placement Program] and AFLS [Assessment of Functional Living Skills]). The BCBA synthesized assessment results to determine the participant's strengths and areas of need, as well as to identify any behaviors that interfered with the participant being able to learn new skills or successfully contact less restrictive environments. The BCBA then developed goals to address the identified behaviors and selected behavior analytic intervention procedures to implement.

Following the initial assessment and throughout the course of treatment, the BCBA updated goals and adjusted therapy procedures in response to the participant's progress. While the specific goals targeted and teaching procedures used varied and were individualized to each participant, all BCBAs prioritized behaviors that were meaningful for families and/or participants and implemented procedures consistent with the principles of behavior analysis. At 6-month intervals, the BCBA conducted a reassessment to evaluate clinical progress and adjust goals accordingly. This reassessment included readministration of the Vineland-3, the CFQL-2, indirect behavior assessments, and direct assessments based on the participant's clinical presentation.

During ongoing treatment, participants received a combination of direct therapy, caregiver-mediated therapy, and caregiver training without the child present. The ratio of these different service types fluctuated throughout the course of treatment based on the participants' and families' needs; all families participated in caregiver training during the course of treatment, whether through caregiver-mediated services or caregiver training without the participant present, with a mean of 2.6 (SD 1.05) hours per week (range 0.25 total h to 6.37 h/wk). Direct therapy sessions consisted of the child interacting directly with the BCBA via synchronous audio-video, with screen-sharing capabilities. Caregiver-mediated sessions consisted of the child, caregivers, and BCBA being present via synchronous audio-video with the BCBA providing coaching and guidance to the caregiver, focusing on strategies for teaching new skills or reducing challenging behaviors, with the caregivers interacting directly with the child. Finally, caregiver training consisted of the BCBA and caregivers meeting via synchronous audio-video. During these sessions, the BCBA provided training to the child's caregivers on specific interventions for teaching their child new skills or reducing challenging behaviors.

Participants

Following IRB review and obtaining an exempt status determination, a sample of deidentified records from individuals who received ABA services through AnswersNow, Inc, between October 2021 and October 2025 was obtained. Participants were

XSL•FO
RenderX

included if they had research consent on file, ASD listed as their primary diagnosis, at least two valid administrations of the Vineland-3 Comprehensive Parent/Caregiver Form (defined as the assessment being completed by the participant's parent or caregiver, not the clinician), at least four months between the first and most recent administration, and at least 15 minutes of ABA therapy (irrespective of service type) per week between the first and most recent administrations. When possible, the same caregiver completed the Vineland-3 at each administration; however, there were instances within the dataset in which 2 different caregivers completed the first and most recent assessments.

Ethical Considerations

AnswersNow, Inc, obtained consent to use deidentified clinical data for research purposes from all participants through a general research consent form signed by families either at the outset of treatment or during services. This research-specific consent was voluntary and revocable at any time, with no relationship to services rendered. Participant data were deidentified before analysis, and no personally identifiable information was shared with the researchers or used in this study. The Clemson University Office of Research Compliance determined the proposed activities involving human participants met the criteria for exempt level review under 45 CFR 46.104(d), and exempt level status was rendered on April 2, 2025 (IRB2025-0021). The data were encrypted and stored in accordance with the Clemson University Minimum Security Standards and analyzed using SPSS (version 31; IBM Corp).

Procedures

The analysis involved evaluating change over time in the results obtained from the comprehensive battery of assessments administered every 6 months, beginning with the first administration until the last administration, regardless of the number of administrations. Any participant with only one administration was not included in the sample. The comprehensive assessment included the administration of the Vineland-3, including all adaptive domain scales (communication, socialization, daily living skills, and ABC), Vineland-3 maladaptive domain scales (ie, internalizing and externalizing) for a subset of participants, the CFQL-2 scales (child, family, caregiver, financial, social network, partner relationship, coping, and overall), indirect behavior assessments (eg, FAST and QABF), and direct assessments based on the participant's clinical needs (eg, VB-MAPP and AFLS).

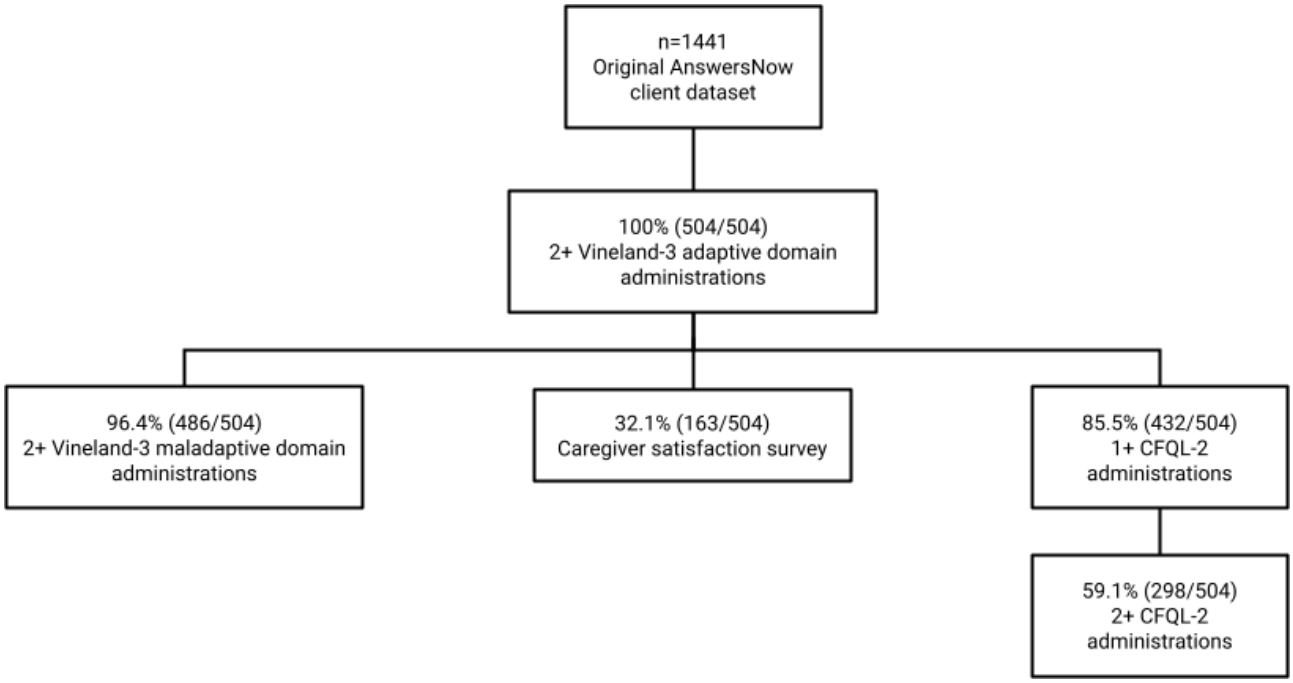
For the purposes of this study, the domain scale scores from the domains in the Vineland-3 assessment tool and the CFQL-2 assessment tool were used to assess participant progress and outcomes while receiving virtual, focused, BCBA-direct ABA therapy. Scale scores from each domain in the Vineland-3 and the CFQL-2 were captured from each administration. MCIDs were calculated for Vineland-3 score changes based on the thresholds used by Ostrovsky et al [12] (ie, +2.0 for ABC standard score, +2.0 for communication standard score, +2.6 for socialization standard score, and +2.6 for daily living standard score). Additionally, comparison analyses similar to those included by Adelson et al [14] were conducted to evaluate maladaptive behavior changes and to determine the potential influence on score change from several variables, including gender, insurer, hours of services, and ASD severity level.

Results

Sample Characteristics

A total of 504 participants from the original dataset of 1441 met the criteria to be included in this study. The total sample of 504 participants included 77% (388/504) males and 23% (116/504) females, and the average age at first Vineland-3 administration was 8.4 (SD 4.3; range 1 - 22) years. Participants were located across five different states: California, Georgia, New York, Texas, and Virginia. Among the 3.8% (19/504) of participants located in California, 18 were Medicaid recipients and 1 participant was not. Participants located in Georgia represented 40.7% (205/504) of the total sample, 153 of whom were Medicaid recipients and 52 of whom were not. The 0.2% (1/504) of participants located in New York consisted of 1 Medicaid recipient. Among the 7.5% (38/504) of participants located in Texas, 25 were Medicaid recipients and 13 were not. Finally, most participants, 47.8% (241/504), were located in Virginia; among these participants, 155 were Medicaid recipients and 86 were not.

ASD severity levels were available for 29.6% (149/504) of participants. This information was not available for all participants because it was not provided by the diagnosing professional. Within the social communication diagnostic domain, 39.6% (59/149) of participants' diagnostic reports indicated diagnostic severity level 1, 34.9% (52/149) indicated level 2, and 25.5% (38/149) indicated level 3. Within the restrictive and repetitive behaviors diagnostic domain, 40.9% (61/149) of participants' diagnostic reports indicated diagnostic severity level 1, 34.9% (52/149) indicated level 2, and 24.2% (36/149) indicated level 3. Across both diagnostic domains, a slight majority of the participants were identified as level 1.



Among the participants included in our dataset, 96.4% (486/504) had at least two administrations of the Vineland-3 that included the internalizing and externalizing subscales of the maladaptive domain. Within the Q-Global assessment administration platform, the maladaptive domain is optional; the clients with missing data for this domain were excluded.

Among the participants in the overall dataset, 85.5% (431/504) had at least one valid CFQL-2 administration on file (administrations were considered invalid if eight or more questions were skipped). To evaluate change in QoL over time, we compared the first and most recent CFQL-2 scores for the 59.1% (298/504) of participants who had at least two valid administrations on file. For this dataset, the CFQL-2 was administered as an interview conducted by the BCBA with the participant's primary caregiver.

The final measure evaluated was caregiver satisfaction. Our dataset contained responses from a sample of 32.1% (162/504) of the total dataset. Figure 1 provides a breakdown of the different measures evaluated, the sample sizes for each, and the percentage of the total sample for which that measure was available.

XSL•FO

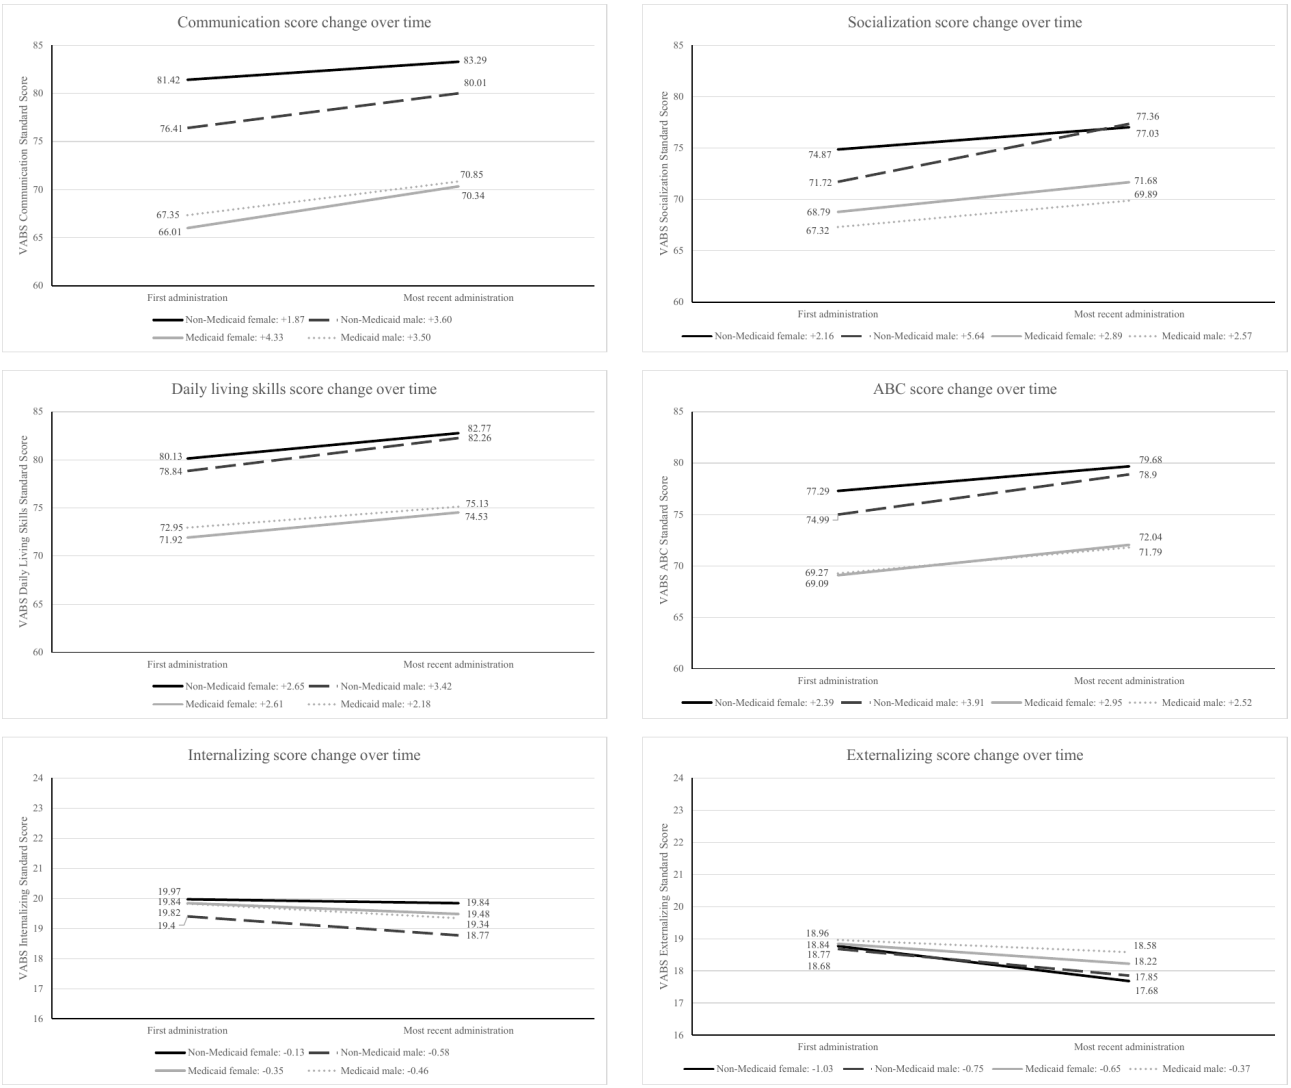
Figure 1. Breakdown of subsamples by measure. CFQL-2: Child and Family Quality of Life, Second Edition.

Service Hours

The average hours of services rendered per week are closely aligned across funding sources, with Medicaid recipients receiving a slightly higher number of hours per week on average 2.66 (SD 1.06) hours compared to non-Medicaid recipients who averaged 2.44 (SD 0.99) hours. That weekly alignment translates to a consistent average of total hours of services rendered, where Medicaid recipients received a slightly higher number of total hours on average (117.14, SD 90.08 h) as compared to non-Medicaid recipients who averaged 116.77 (SD 87.63) hours. The combined averages closely resemble the averages for Medicaid recipients, with an average of 2.6 (SD 1.05) hours per week of services rendered and an average of 117.03 (SD 89.26) total hours rendered. These results are consistent with the total sample size being more heavily comprised of Medicaid recipients.

Vineland-3 Descriptives



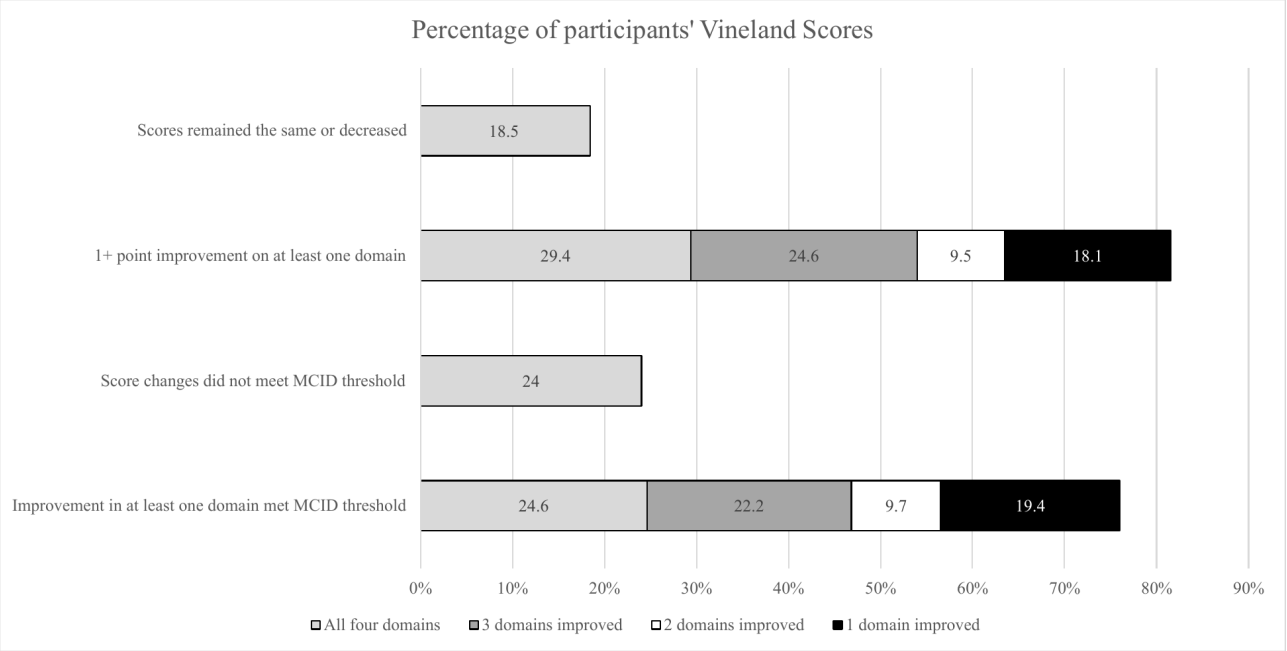
The following section is devoted to providing the descriptive statistics associated with the Vineland-3 administrations. Participants ranged from having 2 to 7 Vineland-3 administrations. Figure 2 displays the various score changes between the first assessment administration and the last assessment (most recent) administration for all participants, broken down by funding source and gender, and includes the adaptive behavior domains, the maladaptive behavior domains, and the ABC. The scoring of the Vineland-3 is based on the following recommended interpretation guidelines: high=130 - 140, moderately high=115 - 129, adequate=86 - 114, moderately low=71 - 85, and low=20 - 70 for scoring the adaptive behavior domains, and average=1 - 17, elevated=18 - 20, and clinically significant=21 - 24 on the maladaptive behavior domains [11].

At the first administration, non-Medicaid funded participants tended to have the highest adaptive behavior domain scores on average, and the averages across both funding groups and genders were consistent in the maladaptive behavior domains. The ideal pattern is for the scores from the adaptive behavior domains to increase across administrations and the scores from the maladaptive behavior domains to decrease. Across both funding groups and genders, there was improvement in all domains over time, suggesting that, on average, participants displayed more adaptive behavior and less maladaptive behavior.

Additionally, further illustrating the change from the first administration to the most recent administration, the average standard score change across domains according to funding source and gender is also included in Figure 2. While there was variability across the domains based on funding source and gender, on average, there were increases in all adaptive behavior domains across gender and funding source, and decreases in the maladaptive behavior domains across gender and funding source, with the least amount of average change being in the maladaptive behavior domains.

XSL•FO
RenderX

Figure 2. Average domain score and domain score change; first assessment to most recent assessment across Non-Medicaid and Medicaid Recipients. ABC: Adaptive Behavior Composite; VABS: Vineland Adaptive Behavior Scales



Across all adaptive and maladaptive behavior domains, average aggregate standard score changes were positive. Participants' (n=504) communication standard scores increased an average of 3.56 (SD 9.77) points, socialization standard scores increased an average of 3.34 (SD 11.62) points, daily living skills' standard scores increased an average of 2.58 (SD 7.89) points, and ABC standard scores increased an average of 2.92 (SD 7.89) points. Within the maladaptive behavior domain, participants' (n=486) v-scale scores decreased by 0.45 (SD 1.81) points on the internalizing subdomain and by 0.55 (SD 2.05) points on the externalizing subdomain. The results indicate improvements in both the adaptive and maladaptive domains; however, it is worth noting that the SDs for the socialization and daily living skills domains were higher, which indicates greater variability in those domains.

To further evaluate changes in domain standard scores, the percentage of participants showing a minimum of a 1-point improvement was calculated for the full sample. Figure 3 displays the pattern of standard score changes for the participants in detail, illustrating that 81.5% (411/504) of participants demonstrated a standard score change of +1 point in at least one domain, and 29.4% (148/504) showed a standard score change of +1 point in all domains. Participants who showed either no standard score change or a –1 or greater point change made up 18.5% (93/504) of the sample.

XSL•FO
RenderX

Figure 3. Bar graph of Vineland scores of participants. MCID: minimal clinically important difference.

Also depicted in Figure 3 are the percentages of participants who met MCID thresholds for improvement from the first to most recent assessment administration, where the MCID scale is change in communication ≥2.0, change in socialization ≥2.6, change in daily living skills ≥2.6, and change in ABC ≥2.0 [12]. A total of 25% (124/504) of participants met MCID thresholds for all the domains, while 24% (121/504) did not meet MCID thresholds in any of the domains. A total of 76% (383/504) of participants met the MCID threshold for at least one domain. A total of 45% (13/31) of non-Medicaid females met MCID thresholds in all internalizing domains, whereas 57.9% (70/121) of non-Medicaid males met MCID thresholds in ABC, 52.9% (64/121) in communication, 48.8% (59/121) in daily living, and 56.2% (68/121) in socialization. A total of 56% (48/85) of Medicaid recipient females met thresholds in ABC and communication, 48.2% (41/85) in daily living, and 57.7% (49/85) in socialization. The data for Medicaid recipient males indicates that 50.9% (136/267) met thresholds for ABC, 56.9% (152/267) in communication, 43.8% (117/267) in daily living, and 44.9% (120/267) in socialization. Overall, the highest MCIDs were observed in the communication and ABC domains across genders and funding sources.

Additionally, changes in internalizing and externalizing scores are often accounted for in terms of the following clinically significant scoring categories: average=1 - 17, elevated=18 - 20, and clinically significant=21 - 24. Due to the nature of how the score ranges differ across the three categories, substantial movement across categories is less likely between the average category and the other categories because the score range for the average category is much larger than the other two categories.

Internalizing Scores

In the context of internalizing scores, in the first assessment administration, 11.9% (32/267) of Medicaid recipient males fell into the average category, 59.9% (160/267) into the elevated category, and 37.1% (99/267) into the clinically significant category. At the most recent administration, there was no substantial change in the percentage of Medicaid recipient males falling into any of the three categories. At the first administration, 17.4% (21/121) of non-Medicaid males fell into the average category, while 61.9% (75/121) fell in the elevated category and 34.7% (42/121) in the clinically significant category. Similarly to Medicaid recipient males, at the most recent administration, there was no substantial change in the percent of non-Medicaid recipient males belonging to all three categories.

While the category composition was slightly different for females compared to males, there was generally a similar trend in the category composition from the first administration to the most recent administration in internalizing scores for females as there was for males. At first administration, 16.5% (14/85) of Medicaid recipient females fell into the average category, 42.4% (36/85) in the elevated category, and 47.1% (40/85) in the clinically significant category. At the most recent administration, 16.5% (14/85) were in the average category, 43.5% (37/85) in elevated, and 40% (34/85) in the clinically significant, indicating a 7.1% decrease in the percentage of Medicaid recipient females who fell into the clinically significant category compared to the first administration. At the first administration, approximately 6.5% (2/31) of non-Medicaid recipient females were in the average category, 58.1% (18/31) in the elevated category, and 35.5% (11/31) in the clinically significant category. At the most recent administration, however, 6.5% (2/31) were in the average category, 61.3% (19/31) in the elevated category, and 32.3% (10/31) in the clinically significant category, indicating a slight decrease in the number of females belonging to the clinically significant category.

Externalizing Scores

The results for externalizing categories generally indicated more pronounced movement as compared to internalizing scores. At the first administration, there were 19.1% (51/267) in the average category, 58.1% (155/267) in the elevated category,

XSL•FO
RenderX

and 22.9% (61/267) in the clinically significant category. At the most recent administration, however, 24% (64/267) of Medicaid males were in the average category, 58.8% (157/267) in the elevated category, and 17.2% (46/267) in the clinically significant category. These results indicate a reduction in the number of males in the clinically significant category and an increase in the number of those in the average category. Non-Medicaid males followed a similar but more pronounced pattern with 24.8% (30/121) in the average category, 51.2% (62/121) in the elevated category, and 24% (29/121) in the clinically significant category at first administration. Whereas, at the most recent administration, 35.5% (43/121) were in the average category, 51.2% (62/121) in the elevated category, and 13.2% (16/121) in the clinically significant category. These results indicate an increase in the number of non-Medicaid males in the average category and a 55% reduction in the number of non-Medicaid males in the clinically significant category.

At the first administration, 23.5% (20/85) of Medicaid recipient females were in the average category, 50.6% (43/85) in the elevated category, and 25.9% (22/85) in the clinically significant category. At the most recent administration, 31.8% (27/85) were in the average category, 51.8% (44/85) in the elevated category, and 16.5% (14/85) in the clinically significant category. These results indicate a clear increase in the number of Medicaid females in the average category, a negligible change in the elevated category, and a substantial decrease in the number belonging to the clinically significant category. Non-Medicaid females, however, showed the most significant change from the first administration to the most recent administration. At the first administration, 19.4% (6/31) of the non-Medicaid females were in the average category, 51.6% (16/31) were in the elevated category, and 29% (9/31) were in the clinically significant category. By contrast, at the most recent administration, 38.7% (12/31) were in the average category, 54.8% (17/31) were in the elevated category, and 6.5% (2/31) were in the clinically significant category indicating a 50% (6/12) increase in the number of non-Medicaid females in the average category and a 77.8% (7/9) decrease in the number of non-Medicaid females in the clinically significant category. These results indicate an overall reduction in external maladaptive behavior for males and females across both funding categories.

Vineland-3 Statistics

Several statistical analyses were conducted to determine the potential relationships between relevant variables and any possible predictive power of outcomes. Those variables included gender, funding source, diagnosis severity levels, treatment modality, and age at first administration. The following section provides a summary of the analyses conducted and the resulting conclusions.

Table 1 illustrates the level of variance associated with each adaptive behavior domain according to funding source type. There is a larger sample size of Medicaid participants vs non-Medicaid participants. Despite that difference, there is a similarity between the two groups outside of the ABC composite score, where there is less variance noted for Medicaid participants. There is, however, a substantial amount of variance for each domain and for each funding source, with the highest levels of variance associated with the socialization domain for both participant groups.

Table . Variance.

Domain	Medicaid count	Medicaid variance	Non-Medicaid count	Non-Medicaid variance
ABC[a]	352	56.37	152	75.58
Communication	352	93.53	152	100.23
Daily living	352	97.02	152	117
Socialization	352	133.86	152	134.6

[a]ABC: Adaptive Behavior Composite.

Table 2 displays a summary of the various statistical tests run: *t* test results and Cohen *d* calculations testing for statistical significance across adaptive behavior domains, CIs for domain standard score change, and the *t* test results testing for statistical significance across domains by gender and funding source. There was slight statistical significance for the socialization domain as compared to the other domains (P=.04). The socialization domain has the largest effect size of the domains (0.197), but it is still relatively small. The Cohen *d* calculations suggest a smaller and therefore minimal difference across the domains. All domains other than socialization cross zero, further emphasizing the lack of statistical significance. There is a demonstrated statistically significant difference (P=.02) between males across funding sources in the socialization domain, however. Males who were supported by non-Medicaid sources showed more significant improvement as compared to males supported by Medicaid. No other gender or funding-related differences were observed.

[a]Stat: statistic.

[b]Sig: significance.

[c]Non-M.: non-Medicaid.

[d]ABC: Adaptive Behavior Composite.

Multiple regression analyses were conducted (Table 3). The first regression analysis assessed the relationship between age at first administration and domain standard score change. The results indicate that older age is associated with smaller improvements in domain standard scores. Additionally, statistically significant relationships were found between age at first administration and the ABC (*P*=.03), communication (*P*=.02), daily living skills (*P*=.02), and socialization (*P*=.02) domains. This further emphasizes how one's age at first administration has some relationship to the extent to which adaptive behavior development occurs in general. It is important to note, however, that ABC is a composite score, so there should be some statistically significant relationship between ABC and the other domains. Finally, the R^2 values are low, which indicates that age at first administration explains only a small portion of the variance in standard score changes.

XSL•FO
RenderX

Next, a regression analysis was conducted to assess whether severity level is a predictor of positive domain standard score change (Table 3). The model explains less than 1% of variance in average standard score change (R^2=0.008). Therefore, the results suggest that severity level is neither statistically significant (P=.61) nor is it a strong predictor of overall improvement across domains.

Lastly, a regression analysis (Table 3) was conducted to determine if age and hours of service were predictors of domain MCID thresholds being met. The results suggest that neither age nor hours of service was a significant predictor of MCID improvement (P<.05).

With regard to the maladaptive behavior domains (internalizing and externalizing), a paired sample t test was conducted for internalizing standard scores and externalizing v-scale scores between first administrations and most recent administrations. The internalizing standard scores from the first Vineland-3 administration were a mean of 9.73 (SD 1.96), and the most recent administration results were a mean of 19.28 (SD 2.07). This yielded an analysis result of t_{485}=5.43, P<.001. The change in internalizing standard scores from the first administration to the most recent administration is statistically significant (P<.001). The decrease in mean indicates a decrease in internalizing standard scores overall, which suggests improvement (reduction) in maladaptive internalizing behaviors between administrations.

With regard to externalizing standard scores, the paired sample t test comparing externalizing scores from the first Vineland-3 administration to scores from the most recent Vineland-3 administration was mean 19.37 (SD 1.79) for the first administration, and mean 18.96 (SD 1.93) for the most recent administration. This yielded an analysis result of t_{485}=6.01, P<.001. The change in externalizing v-scale scores from the first administration to the most recent administration is highly statistically significant (P<.001). The decrease in mean indicates a decrease in externalizing standard scores overall, which suggests improvement (reduction) in maladaptive externalizing behaviors between administrations.

CFQL-2 Descriptives

This section is devoted to providing descriptive statistics for CFQL-2 administrations. Of the total sample of 504 participants, 431 (85.5%) participants received at least one CFQL-2 administration. Some participants received treatment before AnswersNow, Inc, adding the CFQL-2 to its assessment battery, while other participants did not have the CFQL-2 administered for clinical or operational reasons. Most participants (231/431, 53.6%) were males who received support from Medicaid. Medicaid-funded participants also accounted for the majority (304/431, 70.1%) of the total sample (n=431). The process of evaluating CFQL-2 results primarily focused on assessing total QoL and changes in total score.

The scores for each CFQL-2 scale across all participants (n=431) at the most recent administration were child QoL (mean 12.9, SD 2.57; range 0 - 20), family QoL (mean 13.3, SD 4.2; range 0 - 20), caregiver QoL (mean 14.1, SD 3.82; range 0 - 20), financial QoL (mean 11.3, SD 2.86; range 0 - 15), social network QoL (mean 15.1, SD 3.44; range 0 - 20), partner network QoL (mean 11.5, SD 7.64; range 0 - 20), and coping QoL (mean 11.7, SD 2.31; range 4 - 15). Total QoL score mean at most recent administration was 92.4 (SD 16.13; range 51 - 125).

Table 4 represents the percentage of participants' QoL scaled scores where improvement occurred, as well as the type of change that occurred based on the most recent CFQL-2 administration. Improvement was determined based on the following scale thresholds: child QoL, family QoL, caregiver QoL, social network, and partner network QoL (high=16 - 20, adequate=8 - 15, and low=0 - 7); financial QoL (high=12 - 15, adequate=6 - 11, and low=0 - 5), and coping QoL (high=12 - 15, adequate=8 - 11, and low=4 - 7). Overall, 40.9% (122/298) of participants showed an increase in total QoL, 32.9% (98/298) remained the same, and 25.8% (77/298) decreased, with 72.1% (215/298) of the participants experiencing adequate QoL according to the assessment.

Table . Percentage of participants showing improvement and directional change at the most recent administration.

	Improvement scale thresholds			Change direction		
	High	Adequate	Low	Same	Increased	Decreased
Child	15.31	81.67	2.32	43.62	34.11	22.27
Family	35.03	51.04	12.99	42.23	37.12	20.65
Caregiver	38.05	56.38	3.94	42.46	35.96	21.58
Financial	69.61	22.04	7.42	51.74	28.77	19.49

CFQL-2 Statistics

Several statistical analyses were conducted to determine the potential relationships between relevant variables and any possible predictive power of the CFQL-2 outcomes. Those variables included gender, funding source, diagnosis severity levels, and age at the first administration. The following section provides a summary of the analyses conducted and the resulting conclusions.

Table 5 displays the results of a regression analysis testing whether age at first administration, Medicaid status, ASD severity level, initial total QoL, average service hours per week, or gender are significant predictors of change in total QoL standard scores. The results indicate that age at first administration (*P*=.95), Medicaid status (*P*=.58), ASD severity level (*P*=.55), average number of service hours per week (*P*=.41), and gender (*P*=.56) were not significant predictors of change in the average total QoL score. Initial total QoL (ie, the first total QoL score captured), however, was a significant predictor (*P*<.001) of change, indicating that the higher the initial total QoL score, the less likely the participant will be to show improvement in scores over time and the more likely a participant with a lower initial total QoL score would be to show improvement.

Table . Regression analysis of predictors of clinically significant changes in total QoL[a] scores.

Predictor	OR[b] (CI)	*P* value
Intercept	25.15 (1.12 to 565.21)	.04
Age at first administration	1 (0.92 to 1.1)	.95
Medicaid status	1.25 (0.56 to 2.83)	.58
ASD[c] severity level	1.17 (0.71 to 1.92)	.55
Initial total QoL score	0.96 (0.93 to 0.98)	.001
Average hours per week between	1.17 (0.81 to 1.71)	.41
First and most recent administration	1.17 (0.81 to 1.71)	.41
Gender	1.3 (0.54 to 3.11)	.56

[a]QoL: quality of life.

[b]OR: odds ratio.

[c]ASD: autism spectrum disorder.

Additionally, a chi-square test of independence was conducted to examine the relationship between Medicaid status and total QoL score. The results indicated that 127 of 211 (60.2%) Medicaid participants experienced positive changes, and 48 of 87 (55.2%) of non-Medicaid participants experienced positive changes. The difference between the two groups, however, was not statistically significant, χ^2_1=0.5, *P*=.50, indicating that Medicaid status was not associated with a higher likelihood of positive total QoL change.

Caregiver Satisfaction

An optional 4-question Likert scale–based caregiver satisfaction survey was conducted to capture more anecdotal information related to caregiver experience and provide a mechanism for caregivers to give feedback regarding services. Of the 504 participants in the sample, 32% (n=162) completed the satisfaction survey. The survey included the following questions and response options related to satisfaction and experience: (1) how likely are you to recommend services to a family with a child similar to yours (scored on a scale of 1 - 10 where 1=not at all likely and 10=extremely likely), (2) have services been effective for your child (with the answer options of very effective, effective, unsure, ineffective, or very ineffective), (3) what aspect of services is most important to you (with the answer options of accepts my insurance, caregiver training, effective therapies, experienced BCBAs, no waitlist, virtual or video format, all the above, or other), and (4) in the last month, how many times have you considered moving your child to residential services and/or calling emergency services to support your child (with the answer options of never, 1 - 2 times, or 3+ times).

The responses to the questions provide a better understanding of how the caregivers who responded view the services they are receiving. A large portion of the respondents indicated being extremely likely (136/162, 84%) to recommend services, with only 16% (26/162) answering the question with a score of 9 or less. An overwhelmingly large portion of caregivers indicated services were very effective or effective (154/162, 95.1%), with only 2% (3/162) indicating services were ineffective or very ineffective. Just under half the respondents (66/162, 40.7%) indicated effective therapies as the most important aspect of services, followed by the virtual or video format (34/162, 21%) and having experienced BCBAs (32/162, 20%), with only 17.9% (29/162) of respondents indicating caregiver training, accepts my insurance, no waitlist, all the above, and other combined. Lastly, 93.8% (152/162) of respondents indicated they had never considered moving their child to residential services and/or calling emergency services, with 3.7% (6/162) indicating they had considered the options 1 - 2 times, and 1.8% (3/162) indicating they had made those considerations 3 or more times.

A chi-square test of significance (χ^2_3=31.9, *P*=.60; n=162) was conducted to assess the relationship between positive change in Vineland-3 scores across domains and caregiver satisfaction. There was no significance between Vineland-3 domain score change and caregiver satisfaction (*P*=.52). In addition, a

XSL•FO
RenderX

chi-square test of significance (χ^2_{21}=2116.6, *P*=.74; n=162) was conducted to evaluate the association between caregiver satisfaction and which aspect of service was indicated as being most important. There was no statistically significant association between caregiver satisfaction and which aspect of services was indicated as being most important (*P*=.76). Last, a chi-square test of significance (χ^2_6=623.8, *P*<.001; n=162) was conducted to assess the relationship between caregiver satisfaction and frequency of considering residential or emergency services. The results indicate there is a significant statistical association between caregiver satisfaction and the frequency of considering residential or emergency services (*P*<.001). These results suggest that families who considered crisis interventions more frequently are more likely to report lower satisfaction with the services being received, and those who did not consider crisis interventions are more likely to report higher satisfaction with the services being received.

Discussion

Principal Findings

This study was designed to evaluate the acceptability and feasibility of a novel approach to delivering ABA services, specifically a fully virtual, BCBA-delivered, focused ABA service model for individuals diagnosed with ASD. This study explored caregiver perceptions of service effectiveness and satisfaction, which indicate high family satisfaction and positive caregiver perceptions of effectiveness. We also found that participants' adaptive functioning, maladaptive behaviors, and QoL improved between the first assessment battery and the most recent assessment battery according to standard assessments. Given the retrospective design of this study, these changes are being interpreted as changes over time during service delivery and not the direct results of treatment.

Prior research on comprehensive, in-person ABA interventions generally shows that participants demonstrate adaptive behavior improvements, as measured by the Vineland-3, through participation in those programs. For example, Aitken et al [15] found that out of a sample of 1225 children diagnosed with ASD who participated in comprehensive in-person services, 61% demonstrated improvement across multiple adaptive domains of the Vineland-3. Similarly, Adelson et al [14] observed improvements in all Vineland-3 adaptive domains and both maladaptive subdomains. In the present study, the greatest improvements were observed in communication and socialization; however, 81.5% (411/504) of participants exhibited at least a one-point improvement in one or more adaptive behavior domains, and 29.4% (148/504) improved across all adaptive behavior domains. In the maladaptive behavior domains, 38.1% (185/486) of participants showed improvement in the internalizing domain, and 34% (165/486) showed improvement in the externalizing domain. These outcomes translate to significant reductions in either the frequency, intensity, and/or duration of maladaptive behavior observed over time. Furthermore, 76% (383/504) of participants met MCID thresholds in at least one domain. The results indicate the feasibility of this virtual-focused service model as an option for families seeking services to address adaptive behavior deficits and challenging behavior excesses.

QoL changes, as measured by the CFQL-2, were also encouraging. Most participants (175/298, 58.79%) showed improvement in overall QoL scores over time. Previous research has demonstrated the positive impact of caregiver involvement in services on parental self-efficacy and parental stress [30] as well as QoL within the family system [14]. Families in the present study participated in caregiver training, which could be correlated with improvements in QoL observed from the first to the most recent CFQL-2 administration. Regression analyses indicated that initial (baseline) QoL scores were predictive of improvement, with lower baseline scores associated with greater gains. This finding suggests that individuals with less adaptive behavior and lower perceived QoL at the outset of therapy may experience more pronounced benefits from intervention over time as compared to those with a more robust adaptive behavior repertoire and higher perceived QoL at the outset. Recent systematic reviews and meta-analyses examining the role of a child's age, baseline cognitive ability, and the amount of intervention received suggest findings across studies remain inconsistent and advocate the need for further research with controlled designs to better understand how preprogram characteristics are associated with intervention-related outcomes [34,35]. Future studies should further analyze these variables using a comparison group to better evaluate the differential impact of services across groups.

Caregiver satisfaction data revealed overwhelmingly positive opinions of service effectiveness, with 95.1% (154/162) of respondents rating services as effective or very effective and 84% (136/162) reporting they were extremely likely to recommend services. However, exploratory analyses examining associations between satisfaction and other variables yielded mixed results. No significant relationship was found between caregiver satisfaction and Vineland-3 score improvements or between caregiver satisfaction and the aspect of services the caregivers identified as being most important. These findings suggest that caregiver satisfaction may be additionally influenced by factors beyond measurable clinical outcomes, such as communication quality, accessibility, or perceived responsiveness of providers.

Conversely, a significant association between caregiver satisfaction and the frequency of caregivers considering residential or emergency services (χ^2_6=23.82, *P*<.001; Cramér *V*=.27; n=162) did emerge. Families who reported considering crisis interventions more frequently were also more likely to express lower satisfaction with services, whereas those who never considered such interventions reported higher satisfaction with services. This moderate effect size underscores the importance of addressing caregiver stress and crisis risk as part of service delivery, as these factors may substantially impact overall satisfaction and engagement throughout the course of therapy.

Previous studies have found similar results when evaluating the feasibility and acceptability of behavior-analytic virtual services for autistic children. Simcoe et al [36] evaluated a treatment model in which a trained consultant (ie, BCBA, speech and

XSL•FO
RenderX

language pathologist, or early childhood educator) supervised early intervention providers who delivered caregiver coaching in naturalistic developmental behavioral interventions either in-person or virtually. The researchers evaluated three different caregiver- and consultant-completed child outcome measures, as well as acceptability of treatment (caregivers and early intervention providers). They found improvement across all child outcome measures and high acceptability among caregivers and consultants. Similarly, a 2019 review study examined the results of 28 different studies evaluating telehealth as a treatment model for delivering behavior analytic services to individuals on the autism spectrum and found that telehealth can be an acceptable model for these services [32].

This study extends the existing literature by specifically evaluating a fully virtual, BCBA-delivered, focused ABA therapy model for autistic individuals. This study demonstrated the feasibility of implementing this novel treatment model at scale by analyzing data for 504 distinct clients who had at least two Vineland-3 administrations on file. While most ABA therapy programs take a comprehensive approach and require high weekly hours, this study shows that lower dosage focused programs delivering an average of 2.6 hours per week can be acceptable to families seeking support, and that families report positive changes in behavior and QoL over time during service delivery. Finally, this study is aligned with previous research demonstrating that caregiver involvement in therapy is associated with positive behavior change. Taken together with prior research, this study supports the growing body of evidence suggesting the feasibility and acceptability of virtual ABA therapy services. Given the potential challenges associated with in-person, RBT-implemented, comprehensive services some families face, such as lack of access, limited appropriateness of the model for some autistic individuals, lesser qualified providers delivering the majority of services, and high costs, it is important to continue studying and evaluating the impacts of this novel therapy model.

Limitations

This study was descriptive in nature and relied on deidentified archival data, thus limiting our ability to control for potentially confounding variables such as the specific behavior interventions used, socioeconomic status, comorbid conditions, or caregiver stress levels. Given the descriptive nature of this study, we are unable to determine whether the treatment itself produced improvements in adaptive functioning, maladaptive behaviors, or QoL. Demonstrated improvements could be attributed to maturation effects, regression to the mean, or other causes outside the scope of the services delivered. Similarly, the absence of a comparison group limits our ability to draw direct conclusions about the effectiveness of the fully virtual, focused service model compared to that of traditional in-person comprehensive service models.

Some aspects of the current sample also limit the generalizability of the observed changes in adaptive behaviors, maladaptive behaviors, and QoL, in addition to the levels of caregiver satisfaction. One such aspect is the limited geographic representation within our sample. Participants reside across five states, with most participants concentrated in just two states. In addition, diagnostic severity level was only available for a small subset of the total sample, making the composition of the full sample unclear. Taken together, these two features of the current sample suggest cautious interpretation of the generalizability of the findings.

Another important limitation of the analytic sample was that it was derived from a broader clinical population that received services concurrently. The included participants were those who had research consent on file, at least two valid Vineland-3 assessments, a minimum interval between assessments, and ongoing service exposure. Similarly, CFQL-2 and caregiver satisfaction data were available for even smaller subsets of the clinical population. Individuals excluded based on these criteria may have received a qualitatively different experience; it is possible that families who met criteria for inclusion tended to be more engaged, participated longer in services, or had more favorable outcomes than those who were excluded. This further limits the interpretation and generalizability of the data.

An additional limitation of this study is the heterogeneity of the services participants received during treatment. Participants in this study experienced variability in the number of hours received, the ratio of hours by service type, the specific behavior-analytic procedures implemented, and the time between the first and most recent Vineland-3 administrations. We also did not have a direct measure of caregiver engagement or individual goals or goal mastery, both of which were individualized to each participant. Further, there are potential biases associated with the outcome measures evaluated. Specifically, Vineland-3 scores were based on caregiver report; in some cases, a different caregiver completed subsequent Vineland-3 administrations than the caregiver who completed the baseline administration. The CFQL-2 was administered as an interview by the treating BCBA, and satisfaction data were collected voluntarily. These factors introduce a level of variability and potential bias that limit our ability to make direct conclusions about the impact of the services delivered on changes in behavior and QoL. It is possible that some observed differences among participants could be attributed to specific aspects of their treatment that were different from the treatment other participants received. It is also possible that these measurement biases could have resulted in apparent changes in behavior and QoL that were related to momentary caregiver perception rather than true change.

Next, the lack of clear industry benchmarks or MCIDs for the Vineland-3 and CFQL-2 makes evaluation of changes over time difficult. The MCIDs established for the Vineland-II have been used by some existing research, but it is unclear to what extent these MCIDs apply to the Vineland-3. Similarly, there are no established thresholds for clinical significance when evaluating QoL over time using the CFQL-2, making it difficult to determine the extent to which improvements are meaningful.

Finally, there are limitations with the extent to which we evaluated caregiver satisfaction and the specific scores used for evaluating change on the Vineland-3. Specifically, the caregiver satisfaction survey was completed by only a subset of participants who represented less than half the sample of participants (162/504, 32.1%). Representation from the total

XSL•FO
RenderX

dataset was limited by 2 factors: (1) the first caregiver satisfaction survey was sent in November 2023, at which time some families had already exited treatment, and (2) participation in the caregiver satisfaction survey was voluntary. This reality introduces potential response bias depending upon the nature of those who completed the survey and their histories with other services, existing familiarity with ABA methodology, and their familiarity with alternative service delivery options. With regard to the Vineland-3 evaluation, we analyzed standard score changes; however, there are scores that may be more sensitive to change over time and therefore better for longitudinal tracking. For example, the growth scale values monitor a person's progress in the same domain across multiple assessments, vs comparing standard scores from an individual's performance to that of same-age peers within a domain.

Implications for Practice

While this study's design substantially limits causal inference, the findings do highlight the need for further exploration of this novel treatment model in clinical practice. Fully virtual, focused, BCBA-delivered interventions may offer a viable alternative to traditional high-intensity, center-based comprehensive models, particularly for families seeking flexible and/or targeted support or those who have difficulty accessing therapy. The strong caregiver satisfaction ratings suggest that fully virtual focused services can address family needs. Given the strong caregiver satisfaction observed, it is possible that this model could have a multifaceted impact on the socially significant behaviors that affect the independence, well-being, and individual success of those diagnosed with ASD and their families.

The significant association between satisfaction and crisis considerations highlights the need for integrated caregiver support strategies, including proactive crisis planning, coordination of care with a family's other providers, and stress management resources. Families who are facing crises with their children potentially require support beyond what is typically made available by ABA service providers. It is plausible that a more BCBA-directed and implemented model of services could provide that level of necessary proactive crisis planning and stress management by having the luxury of more frequent connections being created in a more targeted manner. By working directly with caregivers to decrease maladaptive behavior as the primary objective of intervention programming, the BCBA's support may more meaningfully improve the family's experience with services as well as the family's general QoL.

Future Directions

A great deal of research addressing the role, experience, and needs of the caregiver in the context of participation in ABA service models is needed. For example, research could look to provide deeper insight into caregiver perceptions and to more specifically identify factors that drive satisfaction beyond a child's progress alone. Future caregiver research might more closely examine the relation between caregiver satisfaction and treatment fidelity, caregiver satisfaction and service duration (eg, do satisfied caregivers stay in treatment longer?), and the level of caregiver involvement and client outcomes. Exploring interventions that specifically target caregiver stress and crisis prevention within remote service frameworks may enhance both satisfaction and overall treatment frequency and efficacy.

Greater emphasis could be placed on examining the combinations of adaptive and maladaptive skills at therapy onset that equate to specific outcomes, rather than more commonly examined variables such as age, gender, diagnostic severity level, and treatment intensity as the primary predictors of outcomes. Additionally, it is feasible to consider the implications of how types of treatment goals, the density of treatment goals, and mastery of goals impact the development of adaptive behavior and the reduction of maladaptive behavior over the course of intervention programming. The relationship among these factors alone could have a direct influence over the Vineland-3 and the CFQL-2 scores, as well as the types of intervention outcomes achieved. Lastly, as noted as a study limitation, growth scale values may be more sensitive to change over time and therefore more effective at longitudinal tracking as opposed to relying on standard scores and/or standard score changes as the primary tracking mechanisms.

Given the difference in treatment plan compositions between comprehensive and focused ABA therapy services, the Vineland-3 ABC standard score may be more appropriate for evaluating improvements in adaptive behavior that result from participation in a comprehensive treatment model. In a focused treatment model, we may expect more targeted gains, with scores in other domains remaining the same or decreasing over time. It would be valuable to assess the extent to which focused services produce improvement in the specific domains directly related to the participant's treatment focus, and whether those gains are maintained over time when treatment shifts to a different focus. This study described a novel model for delivering ABA services, specifically fully virtual, BCBA-delivered, focused treatment, and evaluated changes in behavior and QoL over time, as well as caregiver satisfaction using a real-world clinical dataset. Future research should compare fully virtual ABA services with those of traditional delivery models through an examination of clinical outcomes, caregiver preferences, and BCBA experiences. Longitudinal studies are needed to assess the durability of adaptive skill gains and QoL improvements over time for recipients of both types of service models, and the inclusion of a comparison group would improve experimental control, allowing for a more robust interpretation of results. Fully virtual, BCBA-delivered, focused ABA services appear to be acceptable and feasible for the families in this study. For some families, these services may address a broad range of needs in an ostensibly more economical and accessible fashion than comprehensive in-person services, without potentially sacrificing the quality of services provided or lessening the socially significant impact on the lives of children and families that the practice of ABA has become synonymous with providing.

Abstract

Background: Children and young adults with special health care needs comprise a significant portion of the pediatric population in the United States, where 1 in every 5 children has a complex health care need. These patients are more likely to receive unsafe care and have their needs unmet in part due to lack of accessible information and limited training support. Barriers in communication may contribute to detrimental outcomes for this vulnerable, high-risk population.

Objective: This project aims to identify barriers to communication in children and young adults with special health care needs in the health care setting. These barriers will inform prototype development using human-centered design approaches to create a web-based application. Feedback from patients, caregivers, and health care providers (HCPs) was obtained on the usability and usefulness of the tool within the health care setting.

Methods: A needs assessment was conducted in which participants shared their experiences in providing or receiving health care services via a semistructured interview that was recorded and transcribed. Transcripts were analyzed inductively for themes, coded, and used to categorize the data. On the basis of these themes, iterative development of a web-based application for social stories took place. Focus groups were held to provide relevant feedback on the prototype.

Results: There were 15 participants (n=10, 67% HCPs and n=5, 33% patients and caregivers) interviewed for the needs assessment that informed prototype development. A web-based application for social stories depicting different aspects of health care interactions was created. Focus group feedback from 19 participants (n=12, 63% HCPs and n=7, 37% patients and caregivers) on usability through the System Usability Scale, along with narrative feedback, was obtained. Overall, the usability of the application was supported by caregivers and HCPs.

XSL•FO
RenderX

Conclusions: Children and young adults with special health care needs require medical services that their peers generally do not, thereby compounding potential barriers in communication surrounding health care delivery. Using social stories geared toward health care interactions may help reduce anxiety and difficulty.

KEYWORDS

pediatrics; complex care; human-centered design; qualitative; communication

Introduction

Complex care is defined as "a person-centered approach to address the needs of people whose combinations of medical, behavioral health, and social challenges result in extreme patterns of healthcare utilization and cost" [1]. Approximately 20% of adolescents (aged 12-17 years) in North America live with at least one chronic condition or special health care need, >90% of whom will require ongoing care into adulthood [1-3]. Unfortunately, 67% to 75% of individuals living with special health care needs experience frequent visits to the emergency room, forego recommended care (including lack of annual checkups), and frequently have multiple comorbid health issues [2-4]. As a result, their health care expenditures are estimated to be 5 times greater than those of the general population [5,6]. In addition, patients with complex, special health care needs often require individualized treatment plans to overcome the unique barriers they face in obtaining care [7]. These barriers often result in inequities in patient safety and health care outcomes in this population, particularly in individuals with intellectual disabilities [8]. The complexity of navigating health care systems may be lessened with care coordination in a medical home model; there have been reports of improved family satisfaction with overall care and improved health outcomes with dedicated care coordination [9]. As a result, high-quality and timely access to care services [10] and care coordination is cited as a top priority for individuals with disabilities living with specialized health care needs [11].

Complex care approaches focus on the patient, treating them as an individual embedded within a social context. Complex care programs benefit greatly from strong patient–health care provider (HCP) relationships, excellent communication practices, time, and use of interdisciplinary teams who work with specialized care providers to coordinate and provide patient-centered care [12].

Social stories are personalized narratives used to help teach children and young adults with autism spectrum disorder how to navigate social situations [13]. To do this, social stories use a combination of visual aids and text to teach social skills and increase understanding of social context and cues. The structure and predictability of a social story can decrease anxiety in new or unexpected environments. In addition, they can increase a patient's independence [14] and communication skills, and the skills taught via social stories may then generalize to other social contexts [15].

Patients with complex, special health care needs face several barriers in the health care system when seeking care. These barriers include difficulty communicating with HCPs, a lack of processes to accommodate individual needs, and difficulty accessing recommended care [16]. Specifically for individuals with autism spectrum disorder, patient behavior in combination with deficits in expressive and receptive communication may contribute to challenging medical encounters. A combination of environmental challenges in the setting where medical care is provided, demands placed on the patient (physical examinations or procedure based), and challenges with HCP communication and interaction may invoke challenging behavior in a patient population with reduced communication ability [17].

We sought to address some of these barriers within the health care system for this complex population of patients using the interface between technology and communication. We engaged in a multiphasic study through which we developed an application to address the information and design needs of patients; caregivers; and HCPs who engage in the direct care of patients living with complex, specialized health care needs. The widespread use of technology provides a digital space to create social stories describing health care interactions through visual and narrative means. This intersection of social context in the health care setting may help reduce communication barriers with children and young adults with special health care needs and their caregivers.

We hypothesize that (1) a web-based application can be developed to facilitate communication in the context of health care–specific interactions and flexibility to customize the technology for the patient and (2) a customized web-based application can help close the communication gap that exists for patients with complex, special health care needs, which will lead to fewer poor experiences for patients and caregivers.

Methods

Study Design and Setting

We conducted a human-centered design study in three phases consisting of (1) identifying end user needs using qualitative interviews; (2) conducting rapid, iterative prototyping of a web-based application; and (3) holding focus group sessions with end users for prototype feedback. This study relied on a convenience sample recruited from a large academic-affiliated health system (from both outpatient clinic and inpatient units) located in the Midwest region of the United States. The study population included patients with special health care needs, their caregivers, and HCPs who provide health care to patients with special health care needs.

Ethical Considerations

This project was approved by the University of Illinois College of Medicine Peoria Institutional Review Board under expedited

XSL•FO
RenderX

review (2053251). Assent for pediatric patients aged <18 years or adults without decision-making capacity was obtained along with parent or guardian consent. In addition, adults with decision-making capacity provided consent. Transcripts from interviews and focus groups were deidentified before analysis. Participants in the study were not provided with compensation for taking part.

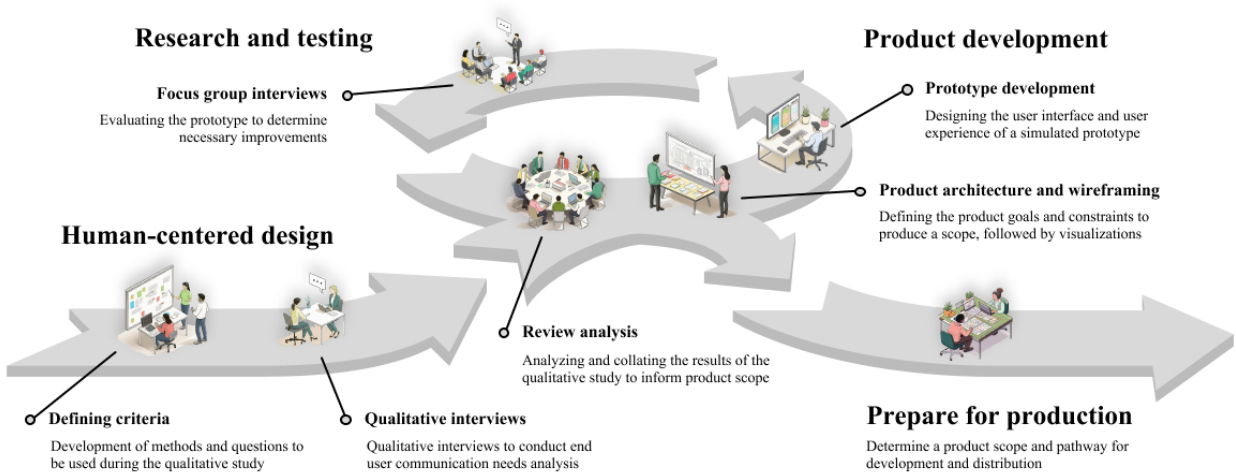
Human-Centered Design Approach

The first phase of this study comprised semistructured interviews. The interviews were designed to elicit participants' perceptions of end user communication needs to inform the development of a prototype of a web-based application to facilitate communication among patients, caregivers, and health care personnel. We conducted qualitative interviews to inform the development of a prototype, which was subsequently tested via focus groups with anticipated end users.

Inclusion Criteria and Participant Eligibility

We gathered a convenience sample from a tertiary care hospital and outpatient care clinic that provides care to patients with special health care needs. To be eligible to take part in all phases of the study, participants needed to meet one of the following criteria: (1) being employed as health care personnel participating in the care of patients with special health care needs in the inpatient or outpatient setting, (2) being a pediatric or adult patient with special health care needs with decision-making capacity who presented for inpatient or outpatient care, or (3) being a caregiver of children or adults with special health care needs who presented for outpatient or inpatient visits.

Recruitment



Recruitment for participation in the interviews to aid in the development of the web-based application and for the focus groups to provide feedback on the prototype took place via informational study fliers that were distributed electronically via email and physically within inpatient and outpatient clinical settings. The flier included a QR code to a participation questionnaire, as well as QR codes to the various types of age-appropriate consent information, giving prospective participants an opportunity to take part in the study. The participants provided their email address to be contacted for the needs assessment interview via phone call or audio-only Zoom videoconference (Zoom Video Communications).

HCPs providing inpatient or outpatient care were identified by their respective departments and emailed the study details and invitation to participate, in addition to the posted fliers.

Caregivers and patients were primarily recruited using fliers posted in clinical settings. To maximize the likelihood of reaching saturation, patients and caregivers were further identified through convenience sampling. They were contacted via phone or email directly for recruitment. For the purposes of saturation in qualitative methods, we targeted a minimum of 5 participants per category (HCPs, caregivers, and patients) [18].

After completing the initial interview, participants were asked whether they would like to take part in future focus groups providing feedback on the web-based application prototype (Figure 1).

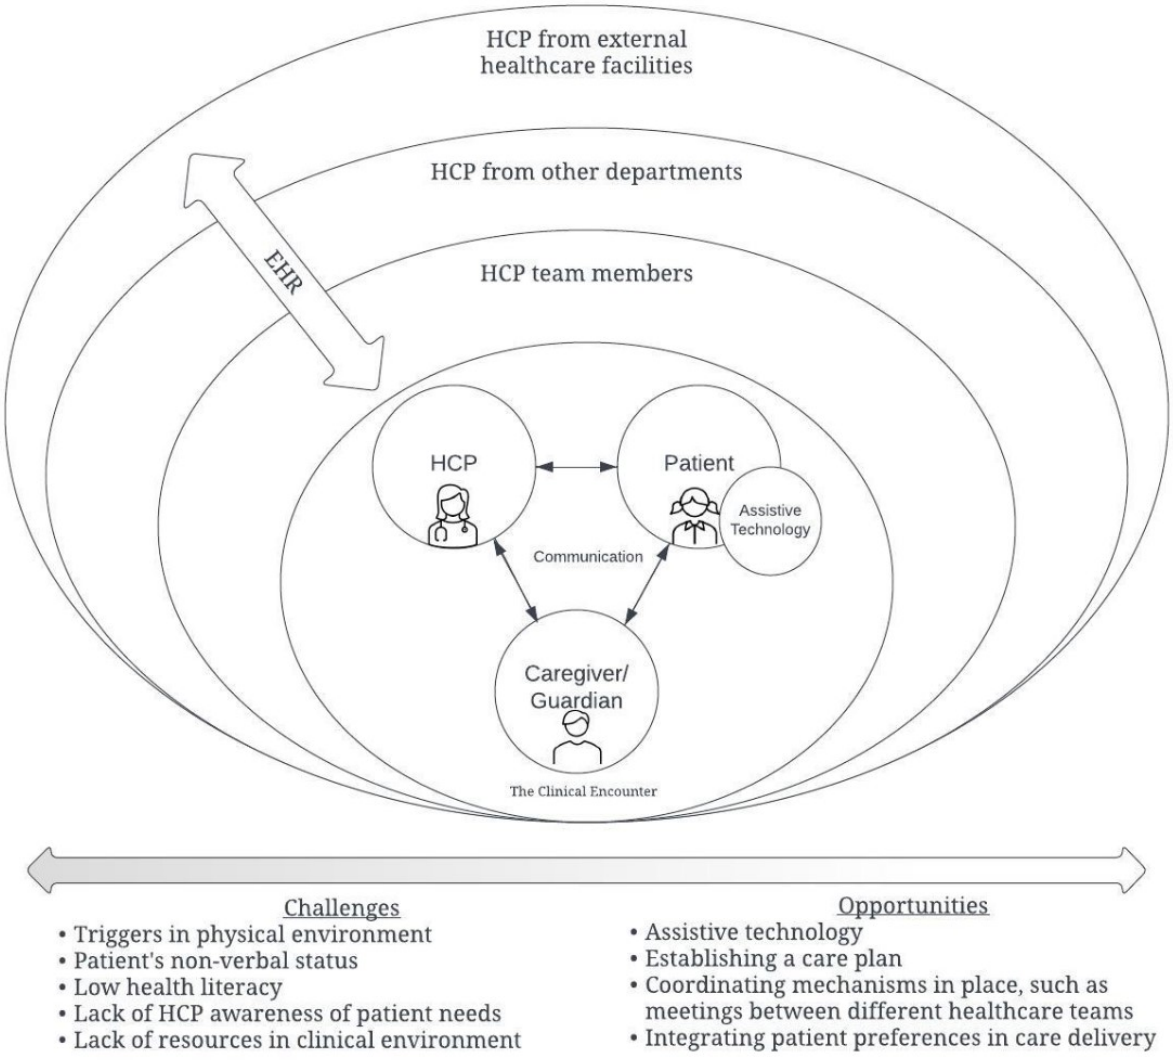
Figure 1. Process map outlining the 3 phases of the study protocol. Phase 1 provided an overview of the human-centered design approach through qualitative interviews, phase 2 incorporated thematic feedback for prototype development, and phase 3 included focus group interviews on the prototype.

Interview Guide Development

The semistructured interview guide underwent several iterations. First, a draft interview guide was developed based on the study aims and clinical context. This was done via discussion among the investigative team; the initial guide was then pilot-tested with 1 caregiver and 1 HCP and subsequently revised. After 4 interviews, transcripts were reviewed in relation to the study's overarching research question. It was determined that the interview questions were too broad in relation to the study's research questions, and the guide underwent subsequent revision. Upon approval of the revised questions, follow-up interviews using the new guide were conducted with 2 of the previous 4 participants.

Before conducting interviews, all interviewers underwent interview training. The training materials were developed based on content made available by the University of Illinois Chicago's

XSL•FO
RenderX



School of Public Health Collaboratory for Health Justice [19]. Training materials were presented, followed by opportunities to practice using the guide. The first 2 to 4 interviews were conducted under the supervision of a faculty member with expertise in qualitative human-centered design methods (AMH). Interviews were recorded and transcribed verbatim using Zoom (audio only). A member of the research team reviewed the auto-generated Zoom transcriptions for accuracy and to strip transcripts of identifiable information before analysis.

Qualitative Analysis

Deidentified transcripts were uploaded to ATLAS.ti (Scientific Software Development GmbH) [20] for subsequent analysis. Approaches to coding were inductive. Coders with backgrounds in medicine (DK), premedicine (MM), and human factors (AMH) reviewed the first 5 transcripts to identify codes and develop a codebook [21]. The remaining transcripts were coded independently by at least 2 trained coders; all discrepancies were identified and resolved for 100% consensus. Emergent themes were identified, sorted into challenges and opportunities, and interpreted for design recommendations. Distributed cognition and communication theories that consider complex interdependencies among multiple individuals, coordinating mechanisms, communication, and information sharing patterns were used for interpretation [22].

The results identified layers of the health system reliant on communication and coordination practices (Figure 2); challenges and opportunities arise within each layer of the complex system. However, at the core of these interactions is communication, which occurs within the clinical encounter. We thereby focused on codes and emergent themes that attested to challenges and opportunities regarding communication as identified in the clinical encounter.

Figure 2. Phase 1 interviews identified opportunities and challenges in communication with health care providers (HCPs) during health care interactions. There are many layers of communication that occur in the coordination of the care of complex patients and their families.

Product Development

Prototyping

In phase 2, qualitative themes from the interviews were provided to the design team responsible for the development of a prototype for a web-based application through a series of meetings with members of the investigative team (AMH, JRH, and MJM) and designer (KF) to develop multiple iterations of the application. Iterative feedback was received from the investigative team and qualitative lead at that point for clinical expertise (JRH and MJM) and participant voices (AMH) and was incorporated. Each iteration of the prototype was shared with the research team to meet the specifications of the prospectively identified communication and end user needs. Approximately 3 iterative cycles were completed to achieve a final prototype.

Clinical Scenario Development

Interviews revealed a common need in both inpatient and outpatient settings: to convey routine tests and procedures in an understandable and nonthreatening manner. To this end, members of the study team developed 2 clinical scenarios through which interaction with the application would guide and convey the steps of a visit or procedure. Our principal investigators, subject matter experts, and internal medicine/pediatric physicians (JRH and MJM) worked closely with content creators to develop a realistic clinical scenario that met the identified areas of need and preference relevant to both inpatient and outpatient care settings. This was developed and refined over several iterations and was ultimately used to inform the flow of the application.

Product Design Integration

A user flow was built to represent high-level user experience. An information flow diagram helped identify how this application might connect to other utilities in the health system. A technical assessment began to explore the feasibility of certain features. On the basis of the feedback received, the user flow and technical assessment were refined to address any identified issues and further focus the scope of the application. In conjunction with clinical scenario development, wireframes were built to visualize the prototype layout and structure and develop a preliminary art style for the content. As a result of project team feedback, the wireframes were revised to represent a final scope for the prototype to be used in focus group user testing. Art styles were explored considering the original research data, market evaluation, and potential full-scale production technical constraints. The final phase involved iterating on the art style and developing all necessary design assets to produce a prototype for user testing.

Research and Prototype Testing

The third phase of our human-centered design study tested the resulting prototype with end user groups. These user groups consisted of patients, caregivers, and HCPs. For participants aged <18 years, caregivers provided verbal consent, and the participating children provided assent. Decisions to participate were audio recorded. Caregivers of adult patients without decision-making capacity provided consent for the patient to participate.

HCPs, patients, and caregivers who consented to participate convened in person and met in separate focus groups (ie, HCPs met separately from patients and caregivers). Focus group participants were welcomed, provided with the project aims and objectives, provided with a tablet and QR code, and briefed on how to access the prototype application from the tablet provided to them. To interact with the prototype, patients and caregivers were given a medical social story to simulate receiving the social story before an upcoming appointment. They then chose whether they wanted to be represented by an animal or person avatar throughout the medical social story.

HCPs were given the same medical social story under the pretense of having to prepare and send the social stories before an upcoming medical encounter with a patient with special health care needs. All participants were presented with the System Usability Scale (SUS) questionnaire upon completion of the scenarios and then took part in a facilitated focus group interview session to provide more granular feedback. Focus group interviews were recorded and transcribed verbatim with participant consent.

Focus Group Data Collection Forms

To evaluate prototype success in the focus group, we adapted survey questions from the SUS [23] and from existing educational immersion scales [24]. Furthermore, we used a semistructured guide to elicit open-ended feedback on the application experience from end users. The SUS is a scale designed to measure participants' perceived usability of a product. Scores range from 0 to 100, with the average score (50th percentile) being 68 [25]. A score above 70 is generally considered acceptable [26-28]. The Learning Immersion Scale in Simulation is a psychometrically validated and reliable survey consisting of 4 factors: cognitive assimilation, emotional buy-in, focused attention, and autotelic experience [24]. We focused on the cognitive assimilation subscale, which measures to what extent an individual differentiates between interaction with the simulated environment and reality [29]. The questionnaire uses a 7-question, 5-point scale adapted from Ko et al [24]. It ranges from "strongly disagree" (1) to "strongly agree" (5). This scale was only administered to caregivers and patients.

Focus Group Data Analysis

SUS surveys were pooled and analyzed descriptively, examining overall usability and usability differences by role (caregivers and patients vs HCPs). The caregiver or parent survey asked 3 additional questions about how they thought their child or the individual under their care would feel about the prototype, which caused the SUS scale score range to change to 0 to 130. Scores are reported as both out of 130 and normalized to fit the original scale from 0 to 100. The resulting focus group transcripts were reviewed iteratively for trends, including areas of feedback (positive and negative) on the prototype interaction experience.

Results

Overview

Results are presented and discussed in the order in which the phase of research took place. There were 15 participants (n=10,

XSL•FO
RenderX

67% HCPs and n=5, 33% patients and caregivers) in the phase 1 individual interviews (Table 1).

Table 1. Participant demographics.

	Patients and caregivers, n (%)	Health care providers, n (%)
Phase 1 interviews (n=15)	5 (33)	10 (67)
Phase 3 focus groups recruited in phase 1 (n=9)	4 (44)	5 (56)
Phase 3 focus groups recruited in phase 3 (n=10)	3 (30)[a]	7 (70)
Phase 3 total (n=19)	7 (37)	12 (63)

[a]One pediatric participant.

Human-Centered Design

Qualitative analysis of the interviews completed in phase 1 identified both challenges and opportunities of care, illustrating design needs for our web-based application. Themes were identified to help prioritize the creation of a web-based application as a potential solution to reduce challenges and facilitate interaction (Multimedia Appendix 1).

Challenges in Communication Based on Cognitive Status

Equating verbal status with cognitive ability emerged as a barrier to effective communication. This challenge was mentioned by HCPs, with 1 patient and 1 caregiver noting this barrier from their perspective. Mainly, HCPs indicated difficulty assessing patient capabilities and capacity to communicate and understand interactions autonomously due to time constraints or unfamiliarity with the patient:

> *Because a lot of times they are so afraid of what's going on, and they're not understanding. And sometimes...providers in the room aren't understanding them. And that can cause a lot of problems.* [HCP]

> *That they're special needs and they don't have the capacity when so many of them have the capacity we [HCPs] just don't have the time to spend with them to understand what they do have.* [HCP]

Meanwhile, patients and caregivers described how this challenge manifested on their end in that HCPs may not provide enough information on what they do with a patient, expressing a desire for more explanation that warranted more communication. One caregiver described their intensive care unit experience as follows:

> *[A] nurse will come in and start something [a routine medical procedure]. You're like, wait a minute, what are you doing? So I don't know if like just a little more communication as to the doctors thought processes of: This is what we're doing. This is what we're thinking and what we're going to try.* [Caregiver]

Several caregivers noted that the barrier was the verbal status (eg, the patient's ability to talk) rather than their cognitive ability or capacity for understanding. One caregiver noted the following:

> *Just because he can't talk doesn't mean he doesn't have feelings and doesn't understand everything.* [Caregiver]

> *Now his mom never left she was able to communicate a lot with us [HCP team].... I didn't know him [the patient] very well. And so if mom worked or couldn't be here, there would have been a lot of gap(s) in communication and understanding what he needed.* [HCP]

Some HCPs corroborated this element of patient understanding despite verbal status:

> *[Patient name] is very, very smart and understands a lot of what we are saying or doing. So even though a child may have special needs and are non-verbal and not able to communicate what they want, how we do, I feel like it's important to know that they still sometimes are aware of their surroundings and are smarter than we really realize.* [HCP]

Opportunities to Improve Communication

The challenge of ascertaining a patient's cognitive status is prevalent, often requiring intervention and the constant presence of a caregiver. Overall, there was a preference for more streamlined and direct communication between HCPs and patients. Ideas for supporting direct communication during an encounter included the use of simplified messaging. For instance, one HCP highlighted the need to use simple language to explain routine procedures in terms readily understood by patients and caregivers:

> *Yes, and it fits people that are aware of medical jargon...[but] our special needs are not. And so we have to be able to. Adjust [using jargon] as according to our patients you know.* [HCPs]

Assistive devices were noted in their ability to promote more direct and patient-centered communication during clinical encounters, potentially bypassing the otherwise constant need for caregiver presence. These devices were often noted to be available through specialty hospital services or otherwise belong to the patient privately for at-home use, and it was noted that they were useful in the health care environment to aid in direct communication between HCPs and their patients. In other cases, involving the caregivers in the health care delivery provides insights into the patient's mannerisms and needs in a way that only those who know them best can decipher. One HCP noted the following:

XSL•FO
RenderX

> *[D]epending on what's going on with them. Absolutely. Yeah, so more individuality in a system, you know. Ability to change it to a specific patient would be helpful.* [HCP]

> *So if they are like not actually having access to smart tablets or for understanding and navigating the My Chart system. So that technology.... To feel comfortable with doing that is one of the barriers.* [HCP]

When describing aspects of an assistive device used for communication, several facilitating device features were noted to enhance communication during the clinical encounter:

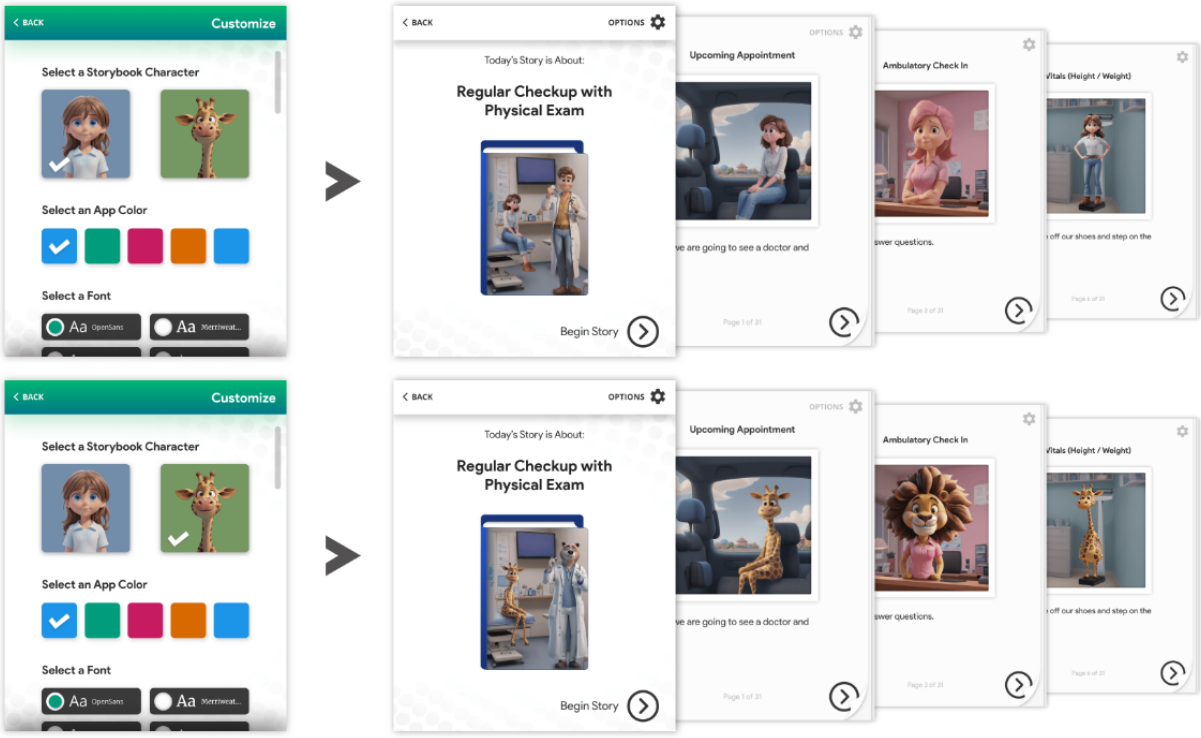
> *So from, provider to patient communication, just having some, a bunch of preset sort of procedures, the very, you know, illustrations that sort of simplify it and make it easy to understand for the patient and then on the opposite, you know, things that allowed them to quickly say and communicate with you without.... That doesn't mean they're the same as everyone else. And so I think a goal with the app is to sort of a breakdown communication barriers so that there's an easier time getting to know them and then also you know those individual preferences as individual traits and things like that can be quickly communicated and just sort of be embedded and quickly understood by providers.* [HCP]

Prototype Development

In the process of prototype development in phase 2, we focused on actionable themes that met the following criteria: (1) opportunities to improve communication in clinical encounters (the reason for this being that broader coordination issues worsened in part because of communication problems, ie, communication is often necessary for coordination) and (2) common or routine tests and procedures experienced in both inpatient and outpatient encounters.

A tappable prototype was built and prepared for testing on tablet devices. Story development and key features targeted emergent qualitative themes, with a focus on routine procedures performed in both inpatient and outpatient visits and on a standardized outpatient visit.

Common procedures patients undergo in both settings are phlebotomy and measurement of vital signs, and a common visit focus in the outpatient setting is a preventative examination or annual physical examination (including obtaining vital signs). An outline of narrative details was created that would help shape the final visual representation of each step within the procedure or visit. A landing page of potential scenarios for social stories was created (Figures S1 and S2 in Multimedia Appendix 2), with the standardized outpatient visit fully developed with 2 different representations, an animal or a person avatar. This allowed the end user to choose the avatar that best reflected their desire to represent themselves in an upcoming encounter.



Research and Prototype Testing

The scope of the themes was then identified by the research team to provide the framework for the iterative prototyping of the web-based application. The web-based application focused on providing a visual and narrative aid to explain treatments or procedures to the patients and caregivers. It also provided the opportunity for the patient to react to the content (Table S1 and Figure S1 in Multimedia Appendix 3).

In the phase 3 focus groups, there were a total of 19 participants (Table 1) who provided feedback on the visual and narrative examples (Figure 3) for the web-based application.

XSL•FO
RenderX

Figure 3. Social story outlining the steps of a routine outpatient preventative examination. The patient or caregiver can select between an animal and a person avatar that represents them throughout the social story.

SUS Results

HCP Results

On the basis of the HCP SUS scores (Table 2), the prototype ranked in the "best imaginable" range with an average score of 93.125 (SD 6.67; 96th-100th percentile). However, due to the small sample size, more participants would be needed to accurately judge the usability and generalizability of the prototype.

Table 2. System Usability Scale scores from health care providers.

Respondent ID	Score (range 0-100)[a]
HCP1	97.5
HCP2	100
HCP3	90
HCP4	92.5
HCP5	100
HCP6	90
HCP7	97.5
HCP8	100
HCP9	97.5
HCP10	87.5
HCP11	80
HCP12	85

[a]Average score: 93.125 (SD 6.67).

XSL•FO
RenderX

Caregiver Results

The caregiver SUS scores (Table 3) also ranked the prototype in the "best imaginable" range, with an average normalized score of 88.08 (96th-100th percentile).

Table 3. System Usability Scale scores from caregivers.

Respondent ID	Original score (0-130)[a]	Normalized score (range 0-100)[b]
CGP1	127.5	98.08
CGP2	112.5	86.54
CGP3	97.5	75
CGP4	125	96.15
CGP5	110	84.62

[a]Average score: 114.5 (SD 12.17).

[b]Average score: 88.08 (SD 9.36).

Patient Results

The 2 patients surveyed rated the prototype just below the average SUS score with an average score of 66.25 (SD19.45; 41st-59th percentile). This would place it in the "OK" range.

Cognitive Assimilation

Caregivers (n=5) consistently provided high scores on the cognitive assimilation scale, with the lowest score being 4.2 for "I was able to see it I was doing it right" and "The situation seemed to flow smoothly" (Table S1 in Multimedia Appendix 4). However, patients (n=2) provided low scores on cognitive assimilation, with an average of 2 for most of the questions (Table S2 in Multimedia Appendix 4).

Focus Group Themes

Common themes from both HCPs and patients and caregivers on the prototype centered on the user-friendly application design, including the avatar choice between an animal and a person. The design was overall appreciated as a general medical social story. However, broad use among patients with special health care needs of all age ranges may be limited by the spectrum of ability. The current narrative explanations and visual aids are most applicable to patients of a certain cognitive ability regardless of chronological age. When used outside of that scope, they may not be as effective for end user interaction. However, both groups generalized applicability to neurotypical children of a similar cognitive level:

> *Yeah, I thought that it was really well laid out. I thought that as a mom and then also as like I'm a pediatric nurse. So from both of those aspects, I feel like this is something that we're currently missing. We're not able to make those connections with our pediatric patients because you know we don't have a lot of child friendly resources to kind of help them prepare for different things that they may go through in their health care process.* [Caregiver]

Both patients and caregivers and HCPs provided feedback on preferences regarding the ability to modify the scope of the medical social story for various end users, including narrative explanations, length, and increased avatar options, which may increase general applicability and end user satisfaction:

> *You know some more of an adult or approaching adults. A tween? Yeah, a tween. I would expect most children would pick the giraffe. Yeah, but I would think more teens and tweens would choose a teenager type avatar. That would kind of bridge the gap between the very childlike and juvenile appearance and the more capturing the ages in between.* [HCP]

Caregivers and patients with specific health care needs identified potential areas of improvement to meet broader patient care accessibility needs. The addition of an audio version with sign language should be considered so that individuals that are hard of hearing or cannot read can still use the application fully.

In the HCP feedback specifically, there was some concern about being able to capture the many different permutations through which an HCP could approach a case to meet the needs of each individual patient or account for variances within a health care system in terms of what information is included. In addition, as the nature of patients with special health care needs may result in frequent encounters with the health care system, the application needs to have the ability to be personalized for repeated similar health care interactions for patients:

> *We use freezy spray so I can speak to that, but you know the hospital will use numbing cream, you know, and it is, you know, you use these words, but they have different things that we can use. Some people use a little light to see your vein. Sometimes you know.* [HCP]

> *Going back to this surgery example, kids have to be under a certain weight to get a mask induction versus the IV induction and so you can't even break it down by 8 years if you have a 7-year-old that weighs the same as in 12-year-old. The seven-year-old will get the IV right? Yeah, it it's very specific.* [HCP]

Discussion

Principal Findings

The initial objective of this project was to create a web-based application that would facilitate communication for patients with complex, special health care needs during interactions with their health care team. Through a 3-phase human-centered design process, we identified communication needs for patients

XSL•FO
RenderX

with complex, special health care needs; their caregivers; and their HCPs. Key themes informed prototype development. The prototype was then reviewed by a group of stakeholders; the results of focus groups with end users support overall usability and utility for certain patient populations.

The results from the phase 1 interviews identified areas of opportunities and challenges in communication for patients with special health care needs in health care encounters. Specifically, HCPs' level of comfort and inclusive communication with the patients and their caregivers during clinical encounters were two areas identified as needing improvement. Patients notably display a broad range of communication abilities, particularly when using alternative and augmentative communication methods. Interestingly, capacity for direct verbal communication may not directly reflect an individual's cognitive ability. This finding highlights how assumptions on patient function and ability and possible ableism may create additional communication barriers during a patient encounter. Additionally, a high reliance on caregivers for verbal communication of the patient status may further complicate the patient's relationship with the health care team, whereas using communication devices available allows for direct communication with the patient. This was consistent with our initial hypothesis and experience within the health care system. Although our data suggest additional multiple areas of opportunity to enhance communication, we focused on the findings most relevant to the interactions among HCPs, patients, and caregivers during an encounter for prototype development. In phase 2, construction of the prototype elements was important to consider for scalability and future digital interfaces. The design of the medical social stories was chosen to depict routine experiences for all patients and their families but potentially significant barriers for patients with complex, special health care needs due to the physical environment and impaired communication and rapport with the health care team. Generated images of an animal or person avatar were incorporated to provide options for individual preferences, but creating avatars using personalized variables was not possible during prototype creation to remain within the scope. Striking an appropriate balance among the development of a web-based application, functionality, and scalability was at the forefront of our decisions when finalizing prototype details. In phase 3, the qualitative feedback from stakeholders highlighted consistencies and potential applicability to a focused patient population with communication barriers and intellectual disabilities. The qualitative feedback from HCPs and caregivers identified that this prototype may be applicable to patients with typical development at the same cognitive level. Overall, caregiver and HCP testing was supportive of the prototype meeting the standards for usability [30]. The combination of the qualitative and quantitative data was positively congruent with HCPs and caregivers, but the small sample size prevents solid conclusions on usability and generalizability to both other institutions and other patient groups with special health care needs.

Limitations of this study include the representativeness of the sample in both size and diversity of disease processes that result in specialized health care needs. Therefore, the full scope of opportunities and challenges faced by patients across the continuum may not be identified. Thus, the broad applicability of a prototype designed for all patients with special health care needs would need further validation across a larger sample size and across multiple areas of care delivery within the health care system. In addition, there was a broad range of levels of ability among patients in the phase 1 interviews, which created variable outcomes in the design of the prototype. Building a prototype that would meet the needs of an innately unique population of patients with varying levels of ability within the same diagnoses exceeded the scope and timeline of the first cycle of this project but is a rich area for further refinement and implementation. Finally, just as the patients are unique, so are the individual approaches that health care team members bring to their patient care. For example, the approach to anesthesia for a surgical procedure may vary depending on the HCP and the patient's unique needs, which, therefore, could limit the generalization of the medical social story.

Conclusions

Our study identified an area of further exploration for increasing successful health care interactions with patients with special health care needs through using social stories in a web-based application. Providing a mechanism to prepare patients and their caregivers for health care interactions by introducing a standardized process allows for structure, visibility, and appropriate anticipation. This also allows for the engagement of HCPs to communicate with patients and families before busy encounters to help set expectations and also potentially reduce anxiety about the unknown. As noted in the stakeholder feedback, these features are also applicable for health care interactions involving neurotypical patients. Future areas of research will be to further the development of the web-based application, including expansion of the medical social stories for increased applicability and evaluating implementation in the workplace for feasibility. In future ambulatory workflow states, distributing the relevant social stories through the electronic medical record before an upcoming health care encounter would mimic the use of social stories in other settings. During inpatient admissions, the social stories may be deployed by caregivers or bedside nursing staff for individualized preparation for the health care process and procedures. Once the workflows are established, an evaluation of patient, caregiver, and HCP satisfaction is warranted to ensure usability and impact. In addition, consideration of a built-in functionality for a caregiver or patient to select an estimated cognitive ability, which may increase applicability to broader neurotypical and neurodivergent patient populations, would require flexibility in terms of social story content and avatar selection. Finally, other common themes that were identified as areas of need were the ability to provide an updated interface with the health care team highlighting important, individualized care elements; patient advocacy; and preferred interfaces with electronic health records.

Abstract

Background: Collaboration between speech-language pathologists (SLPs) and parents is central to pediatric speech sound disorder (SSD) intervention. Prior research has emphasized the relational and home-practice components of collaboration; however, little is known about the enactment, organization, and maintenance of collaborative processes across SLP sessions and home practice in relation to speech sound generalization.

Objective: This study examined the enactment and organization of collaboration between SLPs and parents in pediatric SSD intervention, with attention to children's participation. Using a grounded theory approach, it aimed to develop an empirically grounded conceptual account of how collaboration is organized in relation to speech sound generalization.

Methods: This qualitative study adopted a Strauss and Corbin–oriented grounded theory approach. Semistructured interviews were conducted with 12 SLPs and 10 parents of children aged 4 to 7 years receiving SSD intervention in South Korea. Data collection and analysis proceeded iteratively using open, axial, and selective coding with constant comparison. A paradigm model explicated relationships among categories, and selective coding integrated categories around a core category.

Results: The central phenomenon was conceptualized as striving for triadic collaboration, reflecting SLPs' and parents' efforts to coordinate roles, expectations, and practice while supporting children's participation across SLP sessions and home practice. Three interrelated action/interaction strategies were identified: SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies. These collaborative processes were shaped by background and practice-level constraints. A category integration diagram was developed to represent how the core category, action/interaction strategies, and contextual concerns were organized around triadic collaboration.

Conclusions: The findings suggest that collaboration in pediatric SSD intervention is a contextually embedded process in which SLPs and parents coordinate roles and practices across SLP sessions and home practice while supporting children's participation. The category integration diagram represents how collaborative processes were organized across settings in relation to the gap between structured target sound production and everyday speech use. These findings highlight the relevance of coordinated collaboration for supporting practice across settings in relation to speech sound generalization.

Introduction

Background

Speech sound disorders (SSDs) are among the most common communication disorders in early childhood, affecting approximately 8%-9% of preschool-aged children [1]. SSDs comprise a heterogeneous set of developmental difficulties in speech sound production, including phonological impairment, childhood apraxia of speech (CAS), childhood dysarthria, and articulation impairment, which differ in terms of underlying mechanisms and treatment approaches [2-5]. These challenges are described alongside phonological (linguistic) and motor speech (speech-motor planning, programming, or execution) dimensions [6,7]. Children with SSDs are at increased risk of language and literacy difficulties in later life [8,9]. Persistent speech errors are associated with social–emotional challenges and decreased participation within social and academic contexts [10].

In South Korea, SSDs comprise 44.1% of speech-language service caseloads, and children aged 4 to 7 years comprise approximately half of these cases [11]. Services are delivered in individual one-on-one sessions scheduled on a regular weekly basis, with children typically working with the same speech-language pathologist (SLP) across sessions to support treatment continuity. Parents are involved through brief consultations before or after therapy. These consultations last approximately 10 minutes and focus on reviewing session content and assigning home-based practice. Direct parent participation during therapy sessions is uncommon in many clinical settings, and parental involvement is therefore primarily structured through postsession consultations and home practice guidance. Coordinating therapy implementation within the home environment has become a crucial component of service delivery [12].

Clinical assessments use standardized tools that quantify speech accuracy and severity based on age-referenced norms [13]. Moreover, intervention approaches differ according to diagnostic subtype [5,14]. For example, contrast-based linguistic interventions address phonological impairments [14,15], targeting the reorganization of the phonological system [14,16]; meanwhile, CAS requires motor-based treatment targeting speech planning and sequencing [17,18], focused on accuracy and consistency of motor plans [17,19]. However, standardized assessment tools used in routine clinical settings often provide limited differentiation among SSD subtypes [20,21]. Consequently, in routine service contexts, children are broadly characterized by functional speech sound difficulties, and standardized subtype classification is not documented [22-24]. A key therapeutic objective is to promote generalization from trained stimuli to functional speech use across linguistic units and everyday communication contexts [25-27]. Achieving this generalization requires sufficient practice intensity [26,28].

Evidence suggests that high-intensity interventions—particularly those with increased session frequency and higher practice dose—may facilitate efficient gains associated with generalization [14,28]. However, sustaining high-intensity intervention in routine services is challenging owing to contextual constraints such as limited therapist availability, scheduling demands, and caregiver burden, contributing to the gap between evidence and practice [28-30]. Thus, extending practice opportunities beyond clinic-based intervention is important for supporting generalization [26,28].

SLPs collaborate with parents to extend clinic-based intervention into home-based contexts [31,32]. While relationship-based approaches consider family-specific constraints [31], several barriers hinder consistent home-based practice. Parents frequently face logistical demands, lack of readiness, and experience uncertainty regarding specific roles or activities [33]. Monitoring and supporting home-based practice across contexts are challenging for clinicians [34]. Consequently, clinical practice lacks a structured framework for defining participant roles, facilitating systematic interaction, and providing clear therapeutic guidance [35,36].

Scholars have discussed digital technologies in speech sound intervention as potential tools for alleviating spatiotemporal constraints and extending therapy continuity and practice intensity beyond the clinic into home-based contexts [37,38]. Prior research has mainly focused on their functional utility, including support for child engagement, intervention intensity, and associated outcomes [39-41]. However, research on digitally mediated collaboration among SLPs, parents, and children remains limited [41] and lacks a systematic examination of the organization and maintenance of digitally mediated collaboration under home constraints, including barriers to caregiver participation [42,43]. Studies on telepractice and remote service delivery have reported that digital technologies can enhance flexibility and accessibility and may expand opportunities for collaboration [43,44]. Challenges in rapport building and inequities in technology access may constrain participation [42,45]. These findings highlight the need to investigate the contribution of digitally mediated conditions to collaborative processes in pediatric speech sound intervention [41]. Prior research has highlighted the importance of collaboration between SLPs and parents in pediatric SSD intervention [31,32,46], which facilitates information exchange regarding children's status while enabling the codevelopment of individualized treatment plans [31]. Speech sound objectives relevant to children's daily life can be identified, and intervention strategies can be tailored [31,47]. Scholars have proposed realist-informed frameworks, such as preliminary program theory, for outlining the influence of contextual factors on collaborative practice [46].

Nevertheless, the SSD literature has frequently described collaboration in terms of discrete components, mechanisms, or facilitating and constraining conditions [31,32,46]. Existing studies offer limited guidance on the organization and maintenance of collaboration within clinical and home-based settings [31,46]. Qualitative studies have indicated that parents' understanding of their roles and engagement in home-based practice may change during service engagement in response to family routines, competing demands, and ongoing interactions with services [33,36,48]. Few studies have examined the evolution of collaborative processes among SLPs, parents, and children over time. Moreover, research has paid limited attention to the implementation of collaborative processes and their role

XSL•FO
RenderX

in sustained home-based practice and speech sound generalization [31,33,46]. Thus, a process-oriented examination is required to elucidate how collaboration is sustained across contexts.

Research Objectives

This study aims to examine the enactment and organization of collaboration between SLPs and parents in everyday clinical settings for pediatric SSD intervention involving children with heterogeneous speech sound difficulties. It identifies the roles, interactions, and conditions that influence collaboration across SLP sessions and home practice. It examines children's participation through SLP and parent narratives, focusing on how children are positioned within collaborative processes. Based on interview data on collaborative experiences, the study aims to develop an empirically grounded conceptual account of how collaboration is organized in relation to speech sound generalization.

Methods

Study Design

This qualitative study adopted a Strauss and Corbin–oriented grounded theory (GT) approach to examine real-world interactions among SLPs, parents, and children across clinical and home settings in pediatric speech sound intervention [49]. Analysis focused on interactional processes and contextual constraints through which collaboration was enacted across clinical and home-based contexts [31]. Semistructured interviews were conducted with 10 parents of children with SSDs and 12 SLPs. Children were not directly interviewed because of age and speech-language limitations [50]. The study examined children's participation as described by parents and SLPs during interviews. Data collection and analysis proceeded iteratively using constant comparative methods. Analysis informed subsequent data collection and sampling, enabling the elaboration and refinement of emerging concepts [49]. Consistent with Strauss and Corbin's GT, this study maintained a systematic analytic framework while enabling interpretive flexibility during analysis [49,51]. It used multiple strategies to enhance rigor, including analyst triangulation, member checking, and peer debriefing [51]. The first author, who conducted the interviews and led the analysis, is a PhD candidate in human–computer interaction with training in qualitative research. The research team included members with backgrounds in speech-language pathology and digital health. Analytic memos and team discussions were used to examine emerging interpretations. The reporting of this qualitative study was guided by the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist (Multimedia Appendix 1).

Recruitment

The study used purposive sampling to recruit participants with various clinical experiences, service settings, and levels of involvement in pediatric speech sound intervention. SLPs and parents were independently recruited through social media platforms (eg, Instagram) and online communities. In the initial phase of recruitment, 10 SLPs and 8 parents from Seoul and surrounding metropolitan regions in South Korea were recruited. Eligible parents were primary caregivers of children aged 4 to 7 years receiving speech-language therapy (SLT) for functional speech sound difficulties, including those formally diagnosed with SSD or clinically identified by certified SLPs. These children were currently undergoing or had completed professional SLT within the past 3 months. To focus on functional SSDs, cases involving identifiable organic or neurological conditions—including cleft palate, hearing impairment, intellectual disability, cerebral palsy, autism spectrum disorder, or chromosomal abnormalities—were excluded [2,3,52]. Most children were receiving face-to-face SLT at the time of the interviews, although 1 case involved remote service delivery. Diagnostic information was obtained from available clinical records provided by parents. Available documentation varied across cases; 5 cases included percentage of consonants correct indicators. Additionally, as supplementary information on functional speech intelligibility, Intelligibility in Context Scale scores were collected for all children (range: 2.29-4.29). Standardized subtype classification (eg, phonological vs motor-based subtypes), standard scores for speech production tests, and oral motor assessment results were not routinely documented in clinical records. Information about specific treatment approaches was not documented in the available clinical records. Eligible SLPs were required to have treated at least 5 children with SSDs. All participants were informed of the study objectives and procedures and provided written informed consent electronically via a secure online platform.

Data collection and analysis proceeded concurrently [49]. Guided by emerging analytic categories, the second phase of the recruitment was conducted using theoretical sampling [49,51]. Two SLP–parent dyads (2 SLPs and 2 parents) were recruited through snowball sampling. The members of both dyads were engaged in ongoing therapy with the same child, thus enabling examination of the alignment and negotiation of collaborative expectations within shared therapeutic contexts. The SLPs recommended parents who were eligible to participate.

Data Collection

Data were collected between June and August 2024 using semistructured, in-depth interviews. Interview guides were developed based on the study aims and refined through pilot testing. They were further tailored using prequestionnaire responses and revised in response to ongoing analysis, consistent with the GT methodology [53]. Early interviews broadly explored collaborative practices, while later interviews incorporated focused questions to elaborate and refine emerging themes [49,53]. A brief preonline questionnaire collected contextual information, including parental level of education, session frequency, presence of home practice assignments, and perceived importance of home practice.

Individual interviews with SLPs and parents were conducted by the first author and lasted approximately 60 to 90 minutes. Interviews were conducted in a one-on-one format to support confidentiality and minimize response biases. No prior relationships existed between the interviewer and participants. Interviews were held at locations preferred by the participants, including homes, therapy rooms, and meeting spaces. Participants were informed that the study focused on

XSL•FO
RenderX

collaborative practices in pediatric SLT. They were asked to describe their children's participation and interactions during therapy and home-based practice.

All interviews were audio-recorded and transcribed using an automatic speech recognition tool (Clova Note; NAVER Corporation), followed by manual verification. The first author took field notes to capture contextual details and nonverbal cues. Analytic memos were taken during and after the interviews to document emerging themes and inform subsequent data collection and analysis [49]. Videos and photographs were shown during interviews for contextual illustration only, but were neither collected nor analyzed due to child privacy considerations.

Follow-up interviews were conducted via videoconferencing (Zoom; Zoom Communications Inc) or email when clarification was required during analysis. Data collection continued until theoretical saturation was reached, defined as the point at which additional data no longer contributed to the elaboration of categories and their relationships [51]. Multimedia Appendix 2 outlines the initial interview protocols, originally developed in Korean and translated into English summary tables for reporting.

Data Analysis

Data analysis followed Strauss and Corbin's GT approach using open, axial, and selective coding with constant comparison [49]. Data analysis and collection were conducted simultaneously, enabling emerging concepts to inform analytic focus [49,53].

During open coding, interview transcripts and field notes were examined per line to identify actions, interactions, and conditions [49]. Analytic memos documented emerging concepts and supported comparison across interviews. To calibrate analytic focus and coding boundaries, 3 researchers independently coded 2 interview transcripts (1 with a parent and 1 with an SLP) and engaged in analytic discussions. This process resulted in an initial set of open codes and provisional categories (Multimedia Appendix 3). The analytic coding framework was used as a working tool and iteratively revised as categories were compared, integrated, and elaborated through team discussion.

Axial coding focused on relating categories to subcategories by examining relationships among conditions, action/interaction strategies, and consequences. A paradigm model was used as an analytic tool for organizing these relationships [49,51]. Comparisons across participant groups (SLPs and parents) and contexts (clinical and home-based settings) supported refinement of the properties and dimensions of the categories.

Selective coding included the integration of categories around a core category representing the central collaborative process [49]. Categories were integrated to examine coherence and explanatory adequacy. Data from SLP–parent dyads were used to examine whether these relationships were sustained across shared therapeutic experiences, further refining the core category.

Children's participation was analyzed through SLP and parent narratives, focusing on adults' descriptions of guiding children in participation and the enactment of children's behaviors and expressions during adult–child interactions. Atlas.ti (ATLAS.ti Scientific Software Development GmbH) supported initial coding and management of coded excerpts. Excel (Microsoft Corporation) was used to document the evolving coding framework and track analytic decisions during team discussions.

Ethical Considerations

This study received ethical approval from the Yonsei University Institutional Review Board (number 7001988-202406 -HR-2290-03). Participants provided informed consent and were assured of their right to withdraw at any time without penalty. Data were anonymized and stored securely on an encrypted server. The participants received monetary compensation for their participation.

Results

Participant Characteristics

The study recruited 22 participants (10 parents of children with SSDs and 12 SLPs). Among the parents, 7 (70%) and 3 (30%) were aged in their 30s and 40s, respectively, while 6 (60%) and 4 (40%) resided in Seoul and nearby metropolitan areas, respectively. Regarding education, 1 (10%), 6 (60%), and 3 (30%) completed high school, a bachelor's degree, and a master's degree, respectively.

The children were evenly split by gender (boys: 5/10, 50%; girls: 5/10, 50%) and aged 4 to 6 years, with 5 (50%), 2 (20%), and 3 (30%) aged 4, 5, and 6 years, respectively. Intelligibility in Context Scale scores (5-point parent-rated scale) ranged from 2.29 to 4.29. Among 5 cases with available percentage of consonants correct data, values ranged from 70.83% to 90.69%. Clinical records lacked diagnostic subtype classification; therefore, cases were described as functional speech sound difficulties. Service settings included hospital-based centers, private clinics, and 1 case of home-based therapy. The duration of therapy was less than 1 year for 3 (30%) children, 1-2 years for 4 (40%), and more than 2 years for 3 (30%). Eight children were actively receiving intervention, while 2 had completed intervention within the past 3 months. All children received SLT once or twice per week. Eight parents reported receiving home assignments; 2 reported none. Most parents reported inconsistent home practice because of time constraints; 1 reported consistent implementation. All parents perceived home practice as influencing therapy outcomes, while 3 described it as crucial. Information on specific therapy methods was obtained during parent interviews, as it was unavailable in clinical records.

Among the SLPs, 8 (67%) were aged in their 20s, 2 (17%) were in their 30s, and 2 (17%) were in their 40s. The majority worked in private clinics (7/12, 58%) or hospital-based centers (5/12, 42%), held a master's degree (7/12, 58%) or were enrolled in graduate programs (2/12, 17%) and had clinical experience of less than 4 years (4/12, 33%), 4-8 years (5/12, 42%), and more than 8 years (3/12, 25%). Regarding SSD caseloads, 6 (50%), 4 (33%), and 2 (17%) treated more than 20, 10-20, and fewer than 10 children, respectively. Multimedia Appendix 4 provides detailed participant characteristics.

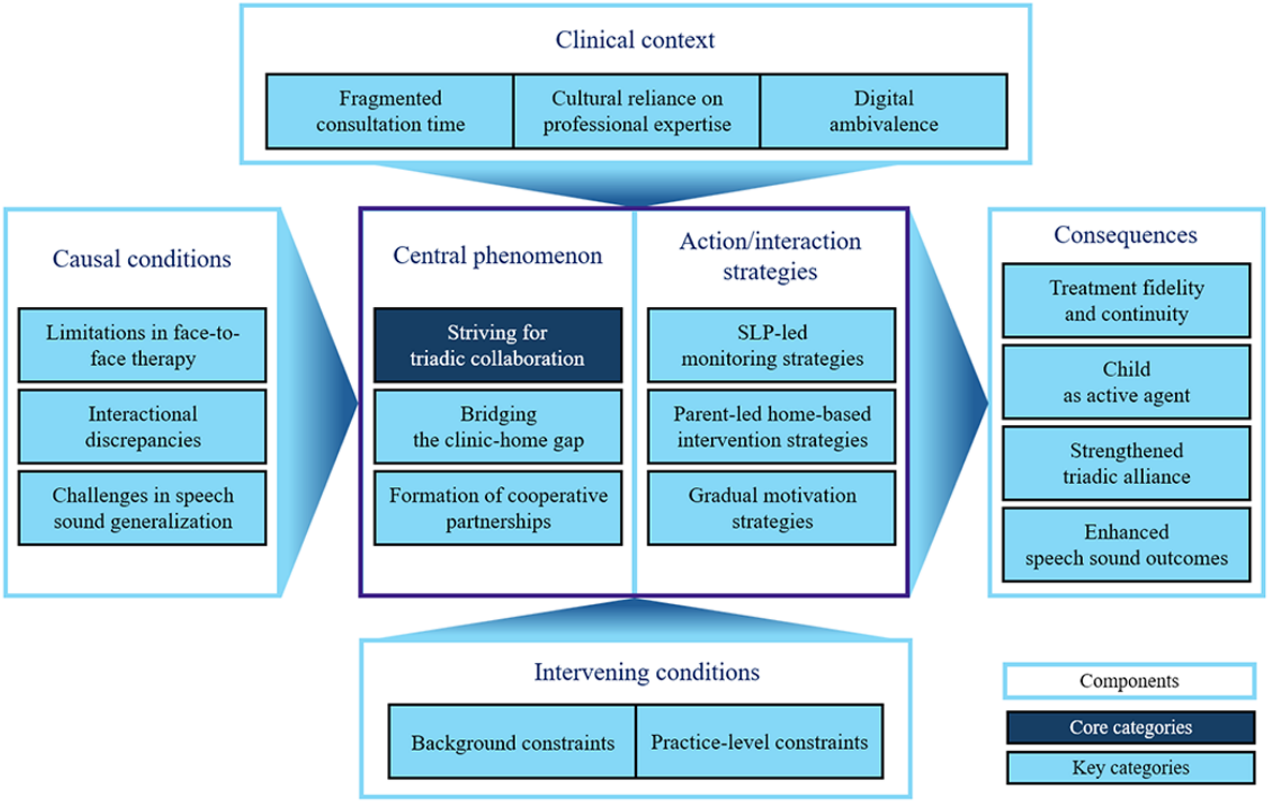
Central Phenomenon: Striving for Triadic Collaboration

Through interviews, collaboration between SLPs and parents was described as an ongoing effort to align roles, expectations, and practices within clinical and home-based settings. Participants emphasized that collaboration required ongoing adjustment rather than agreement: “It’s not that we just follow instructions. We try, and then we adjust depending on how things actually work at home” (P04).

Collaboration was enacted not as passive adherence but as a process of repeated recalibration. Accordingly, the central phenomenon was conceptualized as “striving for triadic collaboration.”



Striving unfolded within a clinical context characterized by fragmented consultation times, cultural reliance on professional expertise, and digital ambivalence. Digitally mediated conditions supported cross-context communication and progress monitoring but raised concerns regarding diminished face-to-face engagement and technological overreliance. Expectations regarding roles and responsibilities centered on the SLP. Several causal conditions intensified this striving. Limitations in face-to-face therapy, interactional discrepancies, and challenges in achieving speech sound generalization were described as influencing efforts to extend practice beyond clinic sessions.

Participants described efforts to bridge the clinic–home gap as the formation of cooperative partnerships. This process involved elucidating roles, negotiating expectations, and extending practice beyond therapy sessions. SLPs adjusted clinical guidance to align with family routines and children’s responses, while parents engaged in repetitive attempts to implement and refine home-based practice: “Even when we agree on the plan, it doesn’t always unfold the way we expected” (SLP05).

Collaboration unfolded not as a fixed agreement but as an ongoing process requiring recalibration in response to contextual constraints, children’s responses, and changes in parental attitudes. Through these adjustments, collaboration evolved over time.

Within the paradigm model, striving for triadic collaboration served as a central phenomenon linking causal conditions, action/interaction strategies, and consequences. Clinical contexts and causal conditions influenced this striving, which was enacted through the action/interaction strategies presented in the following section. These processes were reflected in treatment fidelity and continuity, children’s participation as active agents, a stronger triadic alliance, and changes observed in speech sound performance. Figure 1 presents the paradigm model illustrating these relationships. Multimedia Appendix 5 provides a detailed coding matrix outlining relationships among components, key categories, and subcategories within the paradigm model.

Figure 1. Paradigm model of striving for triadic collaboration. Derived through axial coding, this model illustrates relationships among causal conditions, intervening conditions, the central phenomenon, action/interaction strategies, and consequences. SLP: speech-language pathologist.

Action/Interaction Strategies for Triadic Collaboration

Overview

A total of 3 interrelated action/interaction strategies were identified in response to the central phenomenon of striving for triadic collaboration: SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies. These strategies were enacted in response to clinical and causal conditions and addressed the clinic–home gap. SLP-led monitoring strategies facilitated goal alignment and progress tracking; parent-led home-based intervention strategies extended therapeutic practice into daily contexts; and gradual motivation strategies supported children's engagement in therapeutic tasks. Table 1 summarizes the paradigm-informed coding structure underlying these action/interaction strategies, including key categories and subcategories derived through open and axial coding.

Table 1. Key categories, subcategories, and key codes associated with the action/interaction strategies identified within the paradigm model.

Key categories and subcategories	Key codes
SLP[a]-led monitoring strategies	
Collaborative goal setting	• Explain children's condition objectively to parents • Set therapy goals that reflect children's status and parents' needs • Establish stepwise goals based on difficulty levels
Transparent communication	• SLPs share therapy progress and updates • Parents share observations in daily life • Collaborate with preschool and kindergarten teachers
Progress monitoring	• Visualize progress using graphs and metrics • Compare pretherapy and posttherapy outcomes • Adjust detailed goals according to status changes
Parent-led home-based intervention strategies	
Parent coaching supported by SLP	• Provide home practice guidelines • Encourage and positively reinforce parents' efforts
Parent-led speech practice	• Facilitate consistent child practice • Manage children's stress during home practice
Guided self-monitoring	• Provide visual and auditory discrimination tasks • Offer appropriate cues during practice • Share feedback to promote accurate speech production • Create opportunities for self-correction
Contextualized practice	• Promote generalization through repeated practice in diverse linguistic contexts • Simulate peer interaction scenarios • Encourage generalization in various locations with family support
Gradual motivation strategies	
Choice-supportive interaction	• Incorporate preferred activities into therapy (eg, toys, games, and play) • Apply gamification elements (eg, collection, missions, and challenges) • Offer structured choices during activities (eg, selecting tasks or materials)
Incentive-based participation	• Provide tangible rewards (eg, snacks and drinks) • Use activity-based rewards (eg, playtime and games) • Visualize effort and progress (eg, stickers, stamps, and tracking charts)
Socially mediated reinforcement	• Deliver verbal reinforcement (eg, praise and encouragement) • Use nonverbal reinforcements (eg, high-five and clapping) • Facilitate social recognition (eg, sharing achievements with family members)

[a]SLP: speech-language pathologist.

SLP-Led Monitoring Strategies

Overview

SLPs described monitoring as a strategy for maintaining collaboration with parents and tracking children's progress. Monitoring involved 3 interconnected elements: collaborative goal setting, transparent communication, and progress monitoring.

Collaborative Goal Setting

Collaborative goal setting was described as a process in which SLPs and parents developed a shared understanding of children's status and negotiated therapy goals. SLPs discussed therapy goals with parents based on formal and informal assessment results and positioned this discussion as an initial step in collaborative work.

> *If the mother shares her goals, I try to incorporate them. If they seem appropriate, I include them; if it is too high, I explain why. I set goals together with the mother.* [SLP02]

In clinical settings, parents were often reluctant to express their opinions, citing respect for the expertise of the SLP. This pattern was associated with challenges in collaborative goal setting.

> *The moment a mother says something, she might think she's expressing dissatisfaction with the teacher's curriculum.* [P09]

Parents had limited access to information enabling an objective understanding of their child's status. They reported difficulty in assessing the necessity of therapy and the appropriateness of goals without standardized assessment results.

> *We did an assessment, but I didn't receive a result sheet. They didn't give it to me. So, I had to listen and take notes...because I need to know too.* [P02]

Parents expressed the need for assessment results in an understandable format.

> *It would be good if we could see something like that. Within the children's average range... (so we can know our child's position) similar to pediatric health checkups...* [P01]

Receiving assessment results in a format similar to that used in pediatric health checkups was described as supporting parental understanding.

Transparent Communication

Participants described mutual information exchange about children's progress as part of maintaining collaborative relationships. SLPs sought updates on children's daily lives, while parents expected feedback from therapy sessions. However, time constraints due to back-to-back therapy schedules frequently limited these exchanges.

> *During consultations, I feel extremely rushed. The consultation ends at the same time the next child's class begins...There's so much to talk about, but time is really tight.* [SLP12]

Parents also recognized these constraints and expressed regret about insufficient communication. Consultation time was approximately 5 minutes per session.

> *In 5 minutes, the consultation time is extremely short for asking questions and getting answers.* [P09]

In response to these limitations, SLPs attempted asynchronous communication using digitally mediated communication tools. This approach, however, depended on parental participation.

> *I asked them to record videos of the child practicing. But the mother did it for a while but later asked to stop because it was very demanding.* [SLP06]

These structural and practical barriers limited consistent communication and information exchange between home-based practice and clinic-based intervention.

Progress Monitoring

Progress monitoring was described as a part of maintaining collaboration. SLPs and parents reported that presenting comparative therapy data influenced parental perceptions of therapy.

> *What parents are most curious about is knowing the numbers—how well the child is doing right now.* [SLP05]

SLPs described changes in parental perceptions when objective comparative data were provided. One SLP described playing before-and-after recordings to a parent.

> *The mother didn't really know how unclear her child's pronunciation was. I sent her part of a recording from class...after that she said, "When I listened to just the voice without any context, I could really feel that my child had improved."* [SLP08]

Parents similarly reported that listening to recordings supported clearer recognition of their child's speech difficulty and therapy progress.

> *I told the teacher that I didn't think my child's pronunciation was that bad. But after listening to the recording, I could really hear the difference and realized the improvement.* [P07]

Some parents referenced familiar technology platforms, such as Wink, when discussing potential monitoring formats.

> *Like Wink (a customized learning device for young children), it would be good if teachers could share the child's activities and data that parents can see.* [P09]

Participants described objective digital measurement tools as facilitating shared access to therapy-related information.

Parent-Led Home-Based Intervention Strategies

Overview

SLPs described continued speech practice at home as part of extending therapy beyond clinic sessions. Parent-led home-based intervention involved 4 interconnected elements: parent coaching supported by SLP, parent-led speech practice, guided self-monitoring, and contextualized practice.

XSL•FO
RenderX

Parent Coaching Supported by SLP

SLPs described systematic coaching as part of supporting parent-led home practice, as many parents lacked familiarity with specific guidance methods. Parents demonstrated varying levels of awareness and ability to implement home practice, and many reported difficulty in maintaining it over time. SLPs recognized this gap and provided specific methods to connect therapy-room activities with home-based practice.

> *I let them (parents) feel how my mouth moves, and I also help position theirs, such that they understand the articulation; however, with their daily routines and work, they often forget this technique.* [SLP10]

In response to these limitations, SLPs developed strategies for providing recorded materials with explanations.

> *When I edit and bring recorded materials, we listen to them together and I explain, "This is how I provided stimulation, and at this point the child produced correct articulation.*" [SLP12]

Parents expressed anxiety about providing feedback as nonexperts, which was associated with more passive responses: "If I do this wrong, I might actually create bad habits" (P06).

> *When I really can't understand the pronunciation, I just say "good" and move on. I don't keep asking about it.* [P08]

Three parents enrolled in related academic programs or obtained certifications to provide therapy more formally. This process required considerable time and introduced additional difficulties.

> *I started grad school hoping to help my child more with his therapy but juggling school, practicum hours, and everything at home frequently meant I had to leave him with a sitter, and I ended up being less engaged in his day-to-day therapy.* [P03]

This case reflected challenges in sustaining home practice through individual parental effort and highlighted the need for ongoing professional support.

Parent-Led Speech Practice

Participants described challenges in sustaining speech sound practice at home. Parents reported difficulty in ensuring sufficient practice time due to constraints such as work demands, caring for siblings, and household tasks.

> *I think there are definitely areas that improve if you consistently practice at home too. But it's hard to practice at home. It's difficult to get them to sit down, and I'm tired too.* [P02]

Lack of child cooperation added to challenges in home practice: "They don't want to do homework, and they don't sit for long periods, so sometimes we can't do it" (P04).

Parents limited practice to avoid stressing the children, whereas SLPs emphasized the value of continued home practice.

> *My child said, "Do you think here is a lip teacher's academy?" (during COVID-19, therapists wore clear masks that only showed their mouths). So, I thought I should not stress them anymore, and I don't force them to do this at home.* [P02]

SLPs expressed understanding of the parents' practical difficulties while expressing concern about reduced home practice.

> *I understand being busy, but it's a bit disappointing. It seems like a child could maintain progress if they practiced a little, so it's unfortunate.* [SLP09]

Across interviews, SLPs emphasized the value of home practice, whereas parents described implementation challenges. Divergent perspectives between SLPs and parents emerged consistently.

Guided Self-Monitoring

Guided self-monitoring strategies focused on supporting children's ability to monitor and correct their speech sounds. SLPs described self-monitoring as related to speech sound generalization.

> *The ultimate goal for these children is to monitor themselves without anyone else's help and think "I just made a mistake, I need to do it again"—that's the goal of all therapy.* [SLP07]

Given this purpose, SLPs provided cues that encouraged children to recognize errors before providing correction.

> *Let them think and try as much as possible on their own, and only if that doesn't work, provide the correct sound. The priority is not to give them the answer right away, but to let them figure it out first.* [SLP01]

SLPs described self-evaluation using mobile phone video or recording functions as an effective strategy.

> *If "tiger (Horangi (호랑이))" inconsistently becomes "horanee" or "horiri"...I show children their own appearance and let them hear their own sounds. The process of making them aware is necessary.* [SLP11]

Parents noted that digital recording functions were useful for supporting self-monitoring during home-based practice and mentioned specific tool functionalities.

> *The recording button should be available for repetitive listening...so they can press it many times enough to catch that something is strange by listening to it.* [P09]

SLPs and parents described tools that increased awareness of speech errors and supported children's self-monitoring behaviors (error recognition and self-correction) at home.

Contextualized Practice

Participants described contextualized practice as a way to support children's use of target sounds beyond structured SLP sessions. SLPs emphasized that accurate production during brief clinical sessions did not necessarily extend to everyday speech use without continued home practice.

> *Generalization is practically impossible if we rely only on one 40-minute session a week. The mother needs to guide this at home.* [SLP02]
>
> *Because meeting once or twice a week is too short, generalization does not really happen. If the child*

XSL•FO
RenderX

> *does well only here and then leaves, it goes back to the same.* [SLP06]

SLPs described everyday communication contexts as important because children needed to use target sounds with different people and in comfortable settings, not only during structured interaction with the therapist.

> *To help a child speak well with any person and in any place—not only speaking well because they are tense in front of the therapist—I think support through home practice is needed.* [SLP10]

Parents described successful peer communication as a primary goal of therapy, noting that their children frequently struggled to interact with friends.

> *A frequently asked question was "What?", while many kids commented, "I don't understand what you're saying at all"...They got pointed out a lot by other kids...Occasionally, they didn't interact and couldn't get along with other children.* [P05]

SLPs and parents described peer interaction, story materials, play, and daily routines as contexts for practicing target sounds in varied interactions. SLPs also described gradual increases in practice complexity as relevant to children's use of target sounds in spontaneous speech.

> *If we practice at the word, phrase, and sentence levels first, then when the child says what they really want to say to someone in a longer unit, they can develop control. I don't think that ability suddenly appears when we move to sentences or conversation without practice at the word level.* [SLP12]

> *They don't like it when it feels too formal or like studying, so we end up playing a lot of word chain games—whether we're driving somewhere or just going about our day.* [P01]

These accounts described contextualized practice as connecting structured target sound production in SLP sessions with home routines and everyday speech use.

Gradual Motivation Strategies

Overview

SLPs and parents reported that maintaining children's motivation was important during therapy, as children's willingness to participate shaped therapy activities. SLPs adjusted motivational strategies according to children's developmental level and therapy progression. Three subcategories were identified within gradual motivation strategies: choice-supportive interaction, incentive-based participation, and socially mediated reinforcement.

Choice-Supportive Interaction

SLPs used children's interests and preferences as starting points to foster enjoyment and sustain participation in therapy. They identified these interests during initial consultations and integrated them into sessions by creating customized materials or introducing play-based elements.

> *I try to proceed according to children's interests as much as possible. Characters the child likes or games they enjoy—I blend these in more—I make personalized materials directly.* [SLP12]

SLPs also described offering structured choices, such as allowing children to select materials or activity order, as a way to support participation during repetitive speech practice. These choice-supportive strategies were described as helping children engage with therapy tasks while maintaining a sense of involvement in the activity.

Incentive-Based Participation

SLPs and parents described using external reinforcement strategies to support children's participation during repetitive practice. These strategies included tangible rewards, sticker charts, and activity-based rewards. SLPs described shifting from material rewards to activity-based rewards as therapy progressed.

> *Since we have 40-minute classes, if they concentrate for 30 minutes and finish all these tasks, then they can choose and do activities, board games, toys, or whatever they want for the remaining 10 minutes!* [SLP12]

Parents also used rewards during home practice, but described difficulty adjusting the timing and frequency of reinforcement.

> *At first, I gave them a gift every time they did well, but they started expecting something for even the smallest things. The therapist said the rewards were too frequent, so I switched to giving a gift only after they filled up their grape chart (sticker chart).* [P07]

These accounts described incentive-based participation as a way to support children's cooperation while adjusting reward type and frequency across SLP sessions and home practice.

Socially Mediated Reinforcement

SLPs and parents described socially mediated reinforcement as a way to sustain children's participation through praise, encouragement, and recognition from others. SLPs emphasized process-oriented praise that recognized children's effort during difficult speech tasks rather than simple result-oriented praise.

> *I tell children, "Producing the right sounds is really, really hard—even for older kids—but just trying to practice is already amazing. You're doing such a great job.*" [SLP12]

Parents described learning these specific praise methods from SLPs and applying them at home. They further extended social reinforcement by sharing children's achievements with family members to provide social recognition.

> *I say, "Let's send a video to grandma and grandpa too," then grandma and grandpa call and say "you did so great," and when this continues, the child wants to practice more.* [P05]

These accounts described socially mediated reinforcement as a way to support children's participation through praise, encouragement, and family recognition across SLP sessions and home practice.

XSL•FO
RenderX

Intervening Conditions

Overview

Intervening conditions described by parents and SLPs shaped how the 3 action/interaction strategies were enacted. These conditions were grouped into background constraints and practice-level constraints. Background constraints reflected participants' caregiving responsibilities, work demands, emotional burden, and scheduling constraints, whereas practice-level constraints reflected gaps in feedback continuity, limited visibility of home practice and progress, and burdens associated with material and documentation management across SLP sessions and home practice.

Background Constraints

Parents and SLPs described workload and burnout as limiting sustained engagement in therapy-related activities. Parents reported difficulty maintaining home practice while managing caregiving responsibilities, sibling schedules, and work demands. One parent described being unable to give sufficient attention to the child receiving therapy because she also had to support an older child's schoolwork and was too exhausted after work to complete assigned practice activities (P04). SLPs also described workload constraints in clinical settings. One SLP reported seeing 9 to 10 children consecutively in a day, leaving little time for breaks or extended postsession consultation (SLP12).

Participants also described emotional burden as a background constraint. Parents reported anxiety, guilt, and distress related to their child's developmental trajectory, including concerns about delayed speech, possible disability, and whether they had sought services early enough (P07). SLPs described emotional labor when working with children who resisted therapy tasks or when communicating difficult feedback to parents. One SLP reported that repeated negative feedback and the need to manage children's strong emotional responses sometimes required suppressing her own emotions during sessions (SLP03).

Participants further described scheduling constraints as limiting the regularity and intensity of intervention. Parents coordinated SLT with sibling care, schoolwork, private education, and other rehabilitation services. One parent described moving between an older child's schedule and the younger child's center-based therapy (P09). SLPs similarly noted that some children were managing multiple activities and center visits, making it difficult for families to add or maintain twice-weekly SLT sessions (SLP10). These constraints were described as opportunities for consistent parent-led practice and for intervention at the frequency SLPs sometimes recommended.

Practice-Level Constraints

Parents and SLPs described practice-level constraints involving gaps in feedback continuity, limited visibility of home practice and progress, and burdens associated with material and documentation management across SLP sessions and home practice.

First, participants described gaps in feedback continuity between SLP sessions and home practice. Communication often depended on brief postsession consultations, which limited opportunities for detailed discussion of children's progress, home practice difficulties, or changes in family routines. Some parents described receiving only brief updates when sessions were scheduled back-to-back or when consultation time was embedded within a short therapy slot (P09). One parent explained that, in a hospital-based setting, she had to interrupt the final minutes of the child's session to ask questions, which made consultation difficult because she also wanted the child to use the full therapy time (P03). SLPs similarly described consultation as compressed by clinical schedules, with limited time to explain what had occurred during the session and how practice should continue at home (SLP12). Thus, feedback was present but often brief or fragmented.

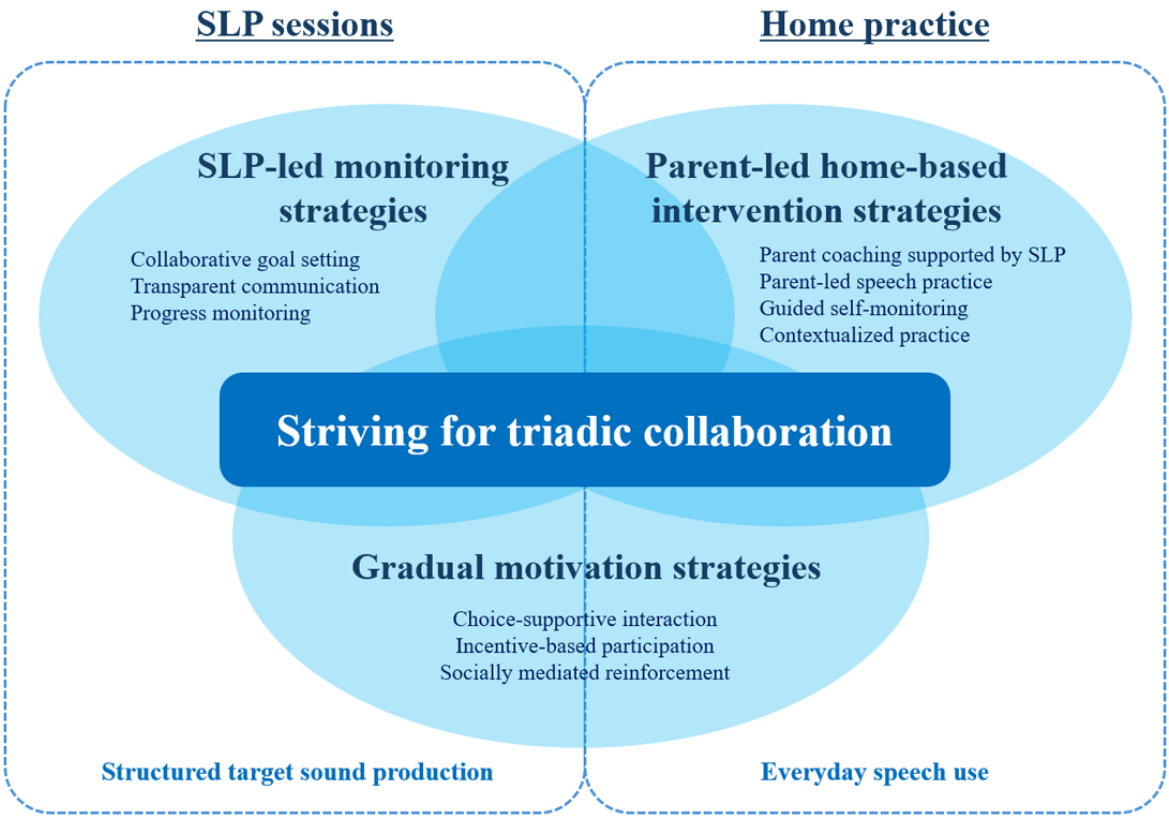
Second, participants described limited visibility of home practice and progress. Parents reported difficulty judging changes in their child's speech because they had become accustomed to the child's pronunciation patterns in daily life. In some cases, parents recognized progress only after comparing recordings or hearing feedback from another person (P07). SLPs also described uncertainty about whether children used target sounds outside the therapy room because they could not directly observe home or everyday communication contexts (SLP01). This constraint was especially relevant when children produced target sounds during structured SLP sessions but did not consistently use them in spontaneous speech or home routines.

Third, participants described material and documentation management as a practice-level burden. SLPs prepared paper-based worksheets, individualized word lists, and activity materials for each child, while parents were expected to store, retrieve, and use these materials during home practice. Parents described difficulties when paper worksheets were misplaced, forgotten, or difficult to organize across repeated sessions (P10). SLPs also described the burden of creating, modifying, and checking practice materials. One SLP described using Google Forms and generative artificial intelligence to prepare vocabulary quizzes, but still needed to manually check and revise materials before use (SLP05). These accounts indicated that material and documentation management were part of the work required to connect SLP sessions with home practice.

Together, these practice-level constraints described limitations in how SLP sessions and home practice were connected. Brief consultation time, limited access to children's performance outside the clinic, and burdens associated with material and documentation management were described even when parents and SLPs were engaged in supporting children's speech practice.

Integration of Categories Around the Core Category

During selective coding, the identified categories were integrated around the core category of striving for triadic collaboration. This core category captured participants' accounts of collaboration as an ongoing effort to coordinate roles, expectations, and practice across SLP sessions and home practice. As described in the contextualized practice category, participants' accounts repeatedly pointed to a gap between structured target sound production in SLP sessions and children's everyday speech use. Structured target sound production and everyday speech use were included in Figure 2



XSL•FO
RenderX

as contextual concerns through which participants described the clinic–home gap.

Within this integration, SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies were organized as overlapping components rather than separate steps. Their overlap reflected participants' accounts that the clinic–home gap required coordination among clinical guidance, home-based practice opportunities, and children's engagement. SLP-led monitoring strategies supported shared understandings of therapy goals, children's progress, and expectations for home practice. Parent-led home-based intervention strategies described how practice guidance was taken up, adapted, or constrained within family routines. Gradual motivation strategies operated across both settings because children's participation had to be supported during structured SLP sessions as well as repeated home practice.

Taken together, these categories represented collaboration as a contextually embedded process of continued adjustment among SLPs, parents, and children. Figure 2 provides a visual representation of category integration derived through selective coding. The dashed areas indicate the 2 settings in which participants described collaborative work: SLP sessions and home practice. The overlapping ovals represent the 3 action/interaction strategies—SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies—and their subcategories as described above. The central bar represents the core category of striving for triadic collaboration, around which these strategies were integrated. Structured target sound production and everyday speech use are shown as contextual concerns that reflected participants' descriptions of the gap between structured SLP sessions and daily speech use.

Figure 2. Category integration diagram of striving for triadic collaboration. The diagram illustrates how speech-language pathologist (SLP)–led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies were organized as overlapping components around the core category of striving for triadic collaboration across SLP sessions and home practice. Structured target sound production and everyday speech use are shown as contextual concerns described by participants.

Discussion

Principal Findings

The findings provide an empirically grounded account of how SLPs and parents organized collaboration across SLP sessions and home practice in relation to the gap between structured target sound production and children's everyday speech use. The core category, striving for triadic collaboration, captured collaboration as an ongoing effort by SLPs and parents to coordinate roles, expectations, and practice while supporting children's participation. This collaboration was enacted through 3 action/interaction strategies: SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies. These strategies were shaped by background and practice-level constraints, including workload and burnout, emotional burden, scheduling constraints, gaps in feedback continuity, limited visibility of home practice and progress, and material and documentation management burden. Together, the findings suggest that collaboration in pediatric SSD intervention was organized as a contextually embedded

XSL•FO
RenderX

process of continued adjustment across SLP sessions and home practice.

Triadic Collaboration as an Organizing Process Across Contexts

Prior research has described collaboration in pediatric SLT as involving relational practices and joint planning between SLPs and parents [31,46,54]. Shared decision-making has also been identified as a key component of pediatric care [55]. Family-centered practice further emphasizes negotiated partnership, mutual understanding, and shared responsibility in service planning [56,57]. Recent work on collaborative relationships between families and SLPs also highlights communication, trust, and shared responsibility within early intervention contexts [58].

The present findings build on this literature by conceptualizing collaboration as a triadic organizing process involving SLPs, parents, and children. This formulation is consistent with research on triadic pediatric consultations, which suggests that children's participation can reshape interactional dynamics rather than positioning children as passive recipients of care [59]. In this study, striving for triadic collaboration captured how participants described the coordination of roles and practices across SLP sessions and home practice.

In interpreting these findings, the 3 action/interaction strategies may be understood as a tentative, nonsequential conceptual lens of alignment, expansion, and internalization. SLP-led monitoring may support alignment by helping SLPs and parents share information about goals, progress, and expectations for home practice. Parent-led home-based intervention may expand practice opportunities into family routines. Gradual motivation strategies may support internalization by helping children move from externally prompted participation toward more self-directed engagement in repeated practice across SLP sessions and home routines.

Collaboration in Relation to Speech Sound Generalization

In relation to speech sound generalization, the findings suggest that collaboration may be relevant because it organizes how practice, feedback, and child participation are coordinated across SLP sessions, home routines, and everyday speech use. Prior SSD research has identified self-monitoring as relevant to generalization [60]. Motivation and engagement have also been discussed in relation to sustained participation in learning and therapeutic contexts [61,62]. Motor learning and speech practice research emphasizes practice conditions, repetition, and feedback in speech intervention [63,64].

Evidence on parent involvement in childhood SSD intervention emphasizes extending practice beyond therapy sessions and supporting home practice [31-33]. Studies of parental roles and coworking further show that home practice is shaped by parents' beliefs, role expectations, and family routines [36,48].

The present findings connect these strands by situating these practices within collaborative work across SLP sessions and home practice. Guided self-monitoring was described as one component of parent-led home-based intervention. Contextualized practice was described as connecting structured target sound production with home routines and everyday communication contexts. These SLP- and parent-supported practices were described as creating opportunities for children to notice and adjust speech production during practice.

Broader work on self-regulation and motivation further supports attention to how children participate in learning and therapeutic activities [65,66]. In this framing, guided self-monitoring is best understood as a participant-described practice within collaborative intervention, with its relation to speech sound generalization requiring further study. Future studies could examine whether and how adult-supported collaborative practices contribute to children's independent self-monitoring and speech sound generalization over time.

The organization of triadic collaboration may also vary according to children's clinical presentation, treatment focus, family resources, and service context. SSD includes heterogeneous clinical presentations, and diagnostic and dimensional accounts emphasize differences across phonological, motor-based, and articulation profiles [2,6,67]. Intervention focus and intensity may also vary by clinical profile and treatment approach [14,15]. Treatment evidence for CAS suggests that some children may require more intensive or specialized clinician-guided intervention [68]. This study identified shared collaborative processes across participants but did not compare these processes by diagnostic subtype or treatment approach.

Family and service constraints also shaped how collaboration was sustained. Studies on parent-mediated interventions have reported challenges related to competing demands on parents' time, children's behavior, and alignment of goals [69]. Recent work on family-centered planning similarly highlights implementation challenges for health professionals and families [30]. In this study, background constraints, including workload and burnout, emotional burden, and scheduling constraints, shaped parents' and SLPs' capacity to sustain therapy-related work. Practice-level constraints, including gaps in feedback continuity, limited visibility of home practice and progress, and material and documentation management burden, shaped how SLPs and parents coordinated practice across settings. These findings suggest that home practice should be introduced with attention to family routines and service constraints to avoid increasing parental burden while extending practice beyond SLP sessions.

Implications for Digital Support

The practice-level constraints identified in this study suggest possible implications for digital support in pediatric SSD intervention. Participants described gaps in feedback continuity, limited visibility of home practice and progress, and burdens associated with material and documentation management. Human–computer interaction research involving pediatric speech-language pathology has highlighted the need to design digital tools that respond to the abilities and contexts of children with disabilities [70]. Related work on parent-clinician communication suggests that visualization tools may support communication when clinical information is difficult to share or interpret across stakeholders [71]. Digital tools could be

XSL•FO
RenderX

explored as supports for feedback continuity, visibility of home practice and progress, and material and documentation management across SLP sessions and home practice. Recent work on automatic speech recognition assessment for children with SSD also suggests the relevance of digital assessment tools for speech-related monitoring and feedback [13]. Design-based research on children's apps emphasizes iterative development and attention to child-centered use contexts [72]. Research on children's digital technologies also suggests that adults' roles in selecting, managing, and implementing tools should be considered during design [73]. These perspectives are relevant because digital support in pediatric SSD intervention would need to consider the practice-level constraints identified in this study, including feedback continuity across settings, visibility of home practice and progress, and material and documentation management. These possibilities should be interpreted as design implications for future research.

Limitations

The findings should be interpreted while accounting for the limitations of the study. First, children's perspectives were examined indirectly through parent and SLP reports due to age and speech-language limitations that constrained direct interviewing. Although this approach provided insights into children's participation within adult–child interactions, it only partially captured children's lived experiences and interpretations of the intervention. Future studies should incorporate developmentally appropriate and creative methods to directly elicit children's perspectives.

Second, this study was conducted within the clinical and cultural context of South Korea; therefore, transferability to other linguistic or health care settings should be considered with caution. Although SSD is a heterogeneous clinical category, formal subtype classification was not routinely conducted within the participants' settings, and subtype-specific differences were not examined. While the study identified common collaborative processes, coordination may vary according to clinical presentation and service context. Information on parents' socioeconomic background was not collected, and variation in these contextual factors may also influence collaborative processes. Future research should examine how socioeconomic variation shapes collaboration across service contexts.

Third, the category integration diagram should be interpreted as a conceptual representation derived from qualitative data. The diagram clarifies relationships among the core category, action/interaction strategies, and contextual concerns identified in this study, but it does not establish feasibility, effectiveness, or implementation requirements across service contexts. Similarly, the digital support implications were inferred from practice-level constraints and participant-described examples. Future research should examine how collaborative processes and potential digital supports operate across SLP sessions and home practice, including their fit with family routines, service delivery constraints, and digital implementation conditions.

Conclusions

This study identified striving for triadic collaboration as the central phenomenon through which SLPs and parents coordinated roles, expectations, and practice while supporting children's participation across SLP sessions and home practice. Three action/interaction strategies—SLP-led monitoring strategies, parent-led home-based intervention strategies, and gradual motivation strategies—were organized around this core category and shaped by background and practice-level constraints. The category integration diagram represents how collaborative processes were organized in relation to the gap between structured target sound production and everyday speech use. These findings provide a process-oriented account of collaboration in pediatric SSD intervention and highlight the relevance of coordinated SLP–parent collaboration and children's participation for supporting practice across settings in relation to speech sound generalization.

Acknowledgments

The authors would like to thank all speech-language pathologists and parents who generously shared their time and experience. Special thanks go to Professor JK for the conceptual guidance and supervision throughout the research process. The authors are also grateful to Professor Minjung Kim for her insightful advice in the field of speech-language pathology.

The authors also acknowledge the use of ChatGPT (OpenAI; GPT-5 series, February 2026 version), which provided assistance with the initial Korean-to-English translation and supported improvement in linguistic clarity and readability throughout the manuscript [74]. All interpretations and analytic decisions were made independently by the authors.

Funding

This research was supported by the Basic Science Research Program through the National Research Foundation of Korea, funded by the Ministry of Education (NRF-2016R1D1A1B02015987).

Data Availability

The qualitative datasets generated and analyzed during this study are not publicly available due to confidentiality protocols approved by the institutional review board and restrictions specified in the participant consent forms, but deidentified data are available from the corresponding author on reasonable request, subject to ethics approval and applicable data-sharing agreements. Deidentified underlying study data may also be provided to the journal for inspection or verification purposes.

Abstract

Background: The Canadian Occupational Performance Measure (COPM) has achieved global implementation across 35 countries in more than 20 language versions. However, its psychometric properties for children with physical disabilities remain unverified.

Objective: This study aimed to evaluate the interrater and test-retest reliability of the Arabic version of the COPM (Arabic-COPM) in this pediatric population.

Methods: A cross-sectional study was conducted using a convenience sample of parents of children with physical disabilities recruited from multi-rehabilitation centers. For the interrater reliability assessment, 100 parents completed the Arabic-COPM through independent interviews with 2 raters. A subsample of 30 (30%) parents repeated the assessment after a 14-day interval for the test-retest reliability analysis, in which they identified their children's 5 most significant daily activity problems and rated the performance and satisfaction levels for each problem using standardized 10-point scales.

Results: Reliability analyses demonstrated excellent psychometric properties. Intraclass correlation coefficients (ICCs) for interrater reliability were 0.84 (performance) and 0.80 (satisfaction), while test-retest reliability coefficients were 0.83 and 0.91, respectively. Interrater agreement analysis revealed 73% concordance in problem prioritization between independent assessors. Bland-Altman plots indicated narrow limits of agreement for both performance (−1.69 to 1.60) and satisfaction scores (−1.03 to 0.98). Cohen κ analysis for problem categorization demonstrated slight-to-fair interrater agreement and slight-to-moderate test-retest agreement across COPM domains. Content analysis identified a predominant concern with daily activities (82%-85% of problems), particularly mobility functions, followed by dressing and eating subcategories.

Conclusions: The Arabic-COPM demonstrated excellent reliability metrics for both interrater consistency and temporal stability when administered to parents of children with physical disabilities. These robust measurement properties support its application as a validated instrument for implementing family-centered rehabilitation approaches in Arabic-speaking clinical contexts.

Introduction

Pediatric physical disability encompasses a spectrum of nonprogressive developmental conditions, including cerebral palsy and spina bifida, which originate from impairments in the developing nervous system [1]. A primary consequence of these disabilities is a significant limitation in the performance of daily activities, adversely affecting fundamental skills such as transferring, standing, and walking, and ultimately compromising functional independence [2,3]. In contemporary rehabilitation, enhancing functional performance and community participation are central objectives. This aligns with a paradigm shift over recent decades toward a family-centered model of care in pediatric rehabilitation [4,5]. This approach necessitates a direct focus on the challenges faced by parents of children with disabilities [6], particularly concerning the breadth and quality of their children's performance in daily activities [7]. Within this model, families are integral partners in all phases of service delivery, from goal-setting and treatment planning to evaluating outcomes. The therapist's role is to be responsive to parental concerns and to equip families with the necessary information for collaborative decision-making [8]. A prominent outcome measure designed to capture this family perspective is the Canadian Occupational Performance Measure (COPM) [9].

The COPM is a semistructured interview developed as a client-centered instrument by Law et al [10]. Its international adoption is evidenced by its availability in over 20 languages across 35 countries [11]. The measure is designed to holistically capture and quantify an individual's functional performance, roles, and environmental needs, facilitating a process in which clients can freely articulate and explore their problems with a therapist [12]. By eliciting clients' perceptions of their own performance and their satisfaction with that performance in self-identified areas of concern, the COPM fosters a collaborative partnership. This cooperation ensures the client's active involvement throughout the evaluation and intervention process [13].

The reliability of the COPM has been investigated in populations with various health conditions [14-16]. Studies have consistently reported excellent interrater reliability, with intraclass correlation coefficients (ICCs) for performance and satisfaction scores ranging from 0.84 to 0.92 in clients with chronic obstructive pulmonary disease [14], psychiatric disorders [15], and stroke [16]. Furthermore, the consistency of problem identification has been demonstrated across different client groups. For instance, 1 study found that 80% of problems prioritized by parents of children with physical disabilities were reidentified in a second interview with a different rater [17]. Similarly, Eyssen et al [18] reported that 66% of problems were consistently prioritized across assessments in patients with neurological disorders.

Despite the expanding use of the COPM in clinical and research settings [8,19-21], the reliability of the Arabic version of the COPM (Arabic-COPM) for parents of children with physical disabilities remains unestablished. Given its importance in family-centered rehabilitation, this study aimed to evaluate the interrater and test-retest reliability of the Arabic-COPM in this population, while also identifying the activity and participation priorities most reported by families.

Methods

Study Design and Participants

This study used a cross-sectional, multicenter design to evaluate the reliability of the Arabic-COPM. A convenience sample of 113 parents or primary caregivers of children with physical disabilities was recruited from various rehabilitation centers and societies in Jordan. The final analysis included 100 participants who completed the study protocol, while 13 were excluded due to scheduling conflicts or failure to attend follow-up appointments.

Inclusion criteria were (1) parents or primary caregivers of children diagnosed with physical disabilities stemming from nonprogressive neurological disorders, as confirmed by neurologists; (2) children demonstrating functional limitations in multiple activities of daily living; and (3) parents possessing sufficient proficiency in Modern Standard Arabic to comprehend and respond to interview questions. Exclusion criteria included parents of children with progressive neurological conditions, parents of children with cognitive or communication impairments that would hinder interview participation, and families unable to commit to the study timeline.

Ethical Considerations

The research protocol received full approval from the institutional review board of King Abdallah University Hospital of Jordan University of Science and Technology (KAUH342020). The study adhered to the principles outlined in the Declaration of Helsinki. Prior to enrollment, all participants engaged in comprehensive briefing sessions detailing the study objectives, procedures, potential risks, and benefits, following which written informed consent was obtained using institution-approved documentation.

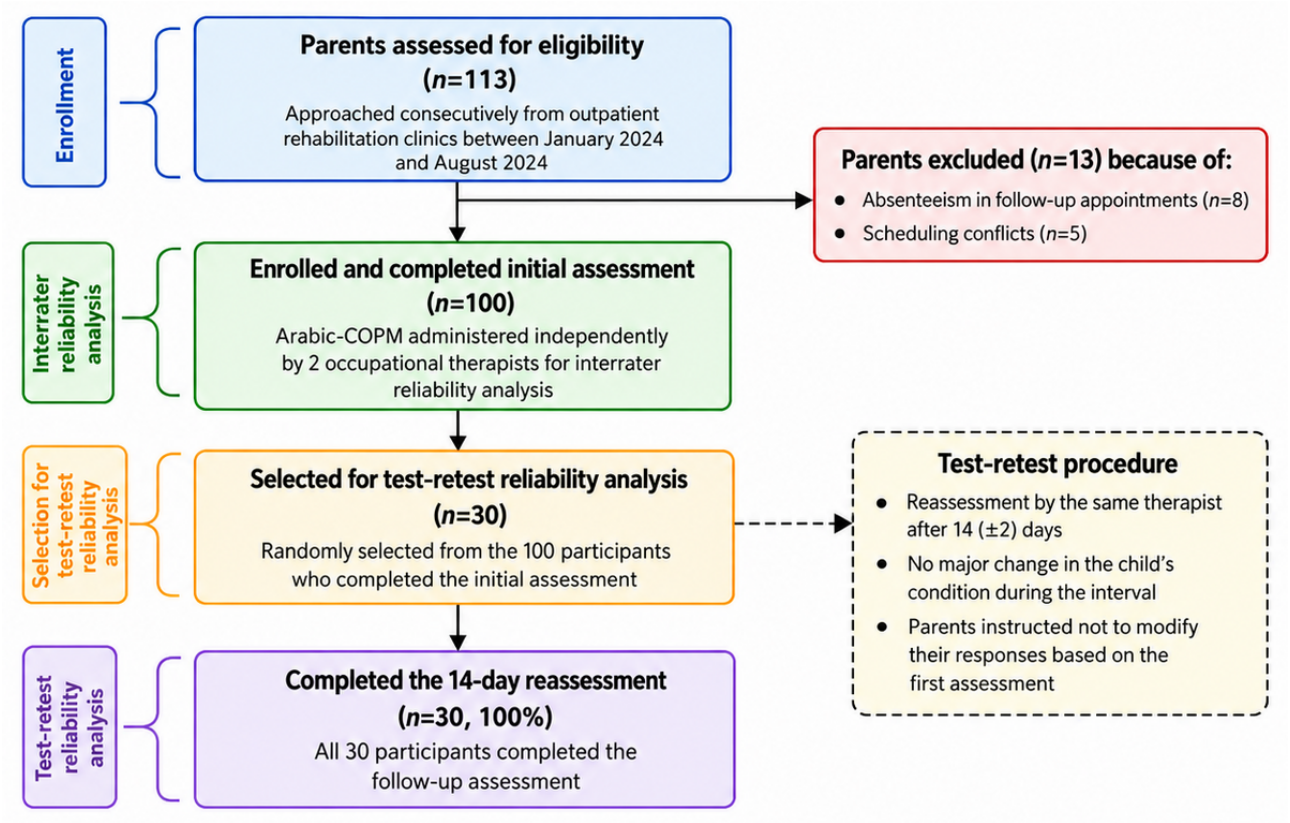
COPM Administration and Assessment Protocol

The COPM was used as the primary client-centered assessment to identify significant challenges in the children's daily functioning. Problem areas identified by families were categorized using a standardized coding system developed by Pollock and Stewart [22], which organizes priorities into 3 main domains: daily activities (with subcategories of self-care, mobility, and communication), productivity (including household management, school participation, and community engagement), and leisure (encompassing socialization, community entertainment, quiet recreation, and physical recreation). The self-care domain was further broken down into 5 specific components: eating, dressing, bathing, toileting, and hygiene.

Standardized Administration Protocol

All assessments were conducted by two independent licensed clinical rehabilitation therapists, each assessing participants independently with experience in pediatric rehabilitation and prior training in the administration of the COPM. Both raters underwent standardized calibration sessions before data

XSL•FO
RenderX



collection to ensure consistency in interview administration, scoring procedures, and problem categorization. The administration followed a structured five-step [22] process using the validated Arabic translation of the COPM. The first step was problem identification: parents enumerated activities and tasks presenting significant challenges in their child's daily routine. The second step was importance scaling: using a 10-point metric (1="minimal importance" to 10="critical importance"), parents rated all identified concerns. The third step was priority selection: through facilitated discussion, parents distilled their concerns to 5 paramount issues. The fourth step was performance evaluation: each prioritized activity received a performance rating (1="complete inability" to 10="optimal performance"). The fifth step was satisfaction evaluation: parents rated their satisfaction with their child's performance or each problem (1="not satisfied" to 10="extremely satisfied"). Mean scores for performance and satisfaction were calculated by averaging the ratings across the 5 prioritized problems.

Reliability Testing Framework

Although the COPM is classified as a patient-reported outcome measure (PROM), it differs from conventional self-administered PROMs because it is conducted through a semistructured clinician-led interview rather than a fixed questionnaire completed independently by respondents. During COPM administration, the clinician actively facilitates problem identification, clarification, prioritization, and scoring of performance and satisfaction. Therefore, the interrater reliability assessment is considered crucial and relevant, as it has also been evaluated in previous COPM validation studies to determine the consistency of identified priorities and scores across independent assessors.

A multiphase protocol was implemented to assess reliability. To evaluate interrater reliability, 100 parents completed the Arabic-COPM twice on the same day, administered by 2 independent raters who were blinded to each other's findings. For test-retest reliability, a random subsample of 30 (30%) parents repeated the assessment with the same rater after a 14-day interval, following an identical administration procedure (Figure 1).

Figure 1. Study flowchart. COPM: Canadian Occupational Performance Measure.

Statistical Analysis

The psychometric evaluation of the Arabic-COPM incorporated comprehensive reliability and agreement analyses. Reliability was assessed using ICCs with a 2-way mixed-effects model, applying absolute agreement for interrater comparisons and consistency for test-retest analyses [23]. Interpretation of reliability coefficients was performed cautiously and in the context of previous COPM and rehabilitation reliability studies, in which the interpretation followed established benchmarks of 0.40 to 0.59 (fair), 0.60 to 0.74 (good), and >0.75 (excellent). However, categorical thresholds for ICC interpretation may vary across methodological frameworks and should not be considered absolute indicators of measurement quality.

Agreement assessment used multiple complementary approaches. For quantitative agreement, Bland-Altman methodology was implemented to evaluate measurement concordance [24]. This involved plotting differences between

XSL•FO
RenderX

paired measurements against their means, with calculation of mean bias ($\bar{d}$) and 95% limits of agreement (LOA; LOA=$\bar{d}$±1.96×SD) [25]. To address visualization challenges in datasets with restricted ranges, traditional scatterplots were enhanced through hexagonal binning techniques that aggregate observations into density-based visualizations, providing better pattern recognition than conventional displays.

For qualitative agreement, problem prioritization consistency was assessed by calculating the proportion of first rater–identified problems that were similarly prioritized by the second rater. Additionally, Cohen κ coefficient was computed to evaluate interrater agreement across COPM domains (daily activity, productivity, and leisure) [26], with interpretation standards: <0.00 (none), 0.00 to 0.20 (slight), 0.21 to 0.40 (fair), 0.41 to 0.60 (moderate), 0.61 to 0.80 (substantial), and 0.81 to 1.00 (almost perfect agreement) [27].

All analyses were conducted using Python (version 3.12; Python Software Foundation; *Matplotlib*) with statistical significance set at $P<.05$, maintaining methodological consistency across comparisons in accordance with contemporary quantitative method evaluation standards.

Results

Sample Characteristics

The final sample consisted of 100 parents of children with physical disabilities. The children had a mean age of 5.4 (SD 2.7) years, with a near-even sex distribution (54 male children and 46 female children). The majority of respondents (n=83, 83%) were the children's mothers. Detailed demographic characteristics are presented in Table 1.

Table 1. Demographic characteristics of the parents and their children with physical disabilities.

Characteristics	Participants
Children's characteristics (n=100)	
Age (years), mean (SD)	5.4 (2.7)
Weight (kg), mean (SD)	17.6 (6.8)
Height (cm), mean (SD)	98.3 (19.5)
Diagnosis, n (%)	
Cerebral palsy	60 (60)
Spina bifida	20 (20)
Other diagnoses	20 (20)
Sex, n (%)	
Male	54 (54)
Female	46 (46)
Parents' characteristics (n=100), n (%)	
Relationship with the child	
Mother	83 (83)
Father	10 (10)
Other	7 (7)
Educational level	
University degree	57 (57)
Nonuniversity degree	43 (43)
Monthly income	
High income (US >$900)	24 (24)
Middle income (US $450-$900)	56 (56)
Low income (US <$450)	20 (20)

Interrater Reliability and Agreement

The Arabic-COPM demonstrated excellent interrater reliability. The ICCs for the mean scores were 0.84 (95% CI 0.77-0.89; $P<.001$) for performance and 0.80 (95% CI 0.70-0.86; $P<.001$) for satisfaction.

Regarding qualitative agreement on problem identification, the first and second raters identified 460 and 450 problems, respectively. A high level of concordance was observed, with 338 (73.5%) of the 460 problems prioritized by the first rater being similarly prioritized by the second rater (Table 2). On the other hand, Cohen κ analysis across the COPM main categories (daily activity, productivity, and leisure) demonstrated slight-to-fair interrater agreement.

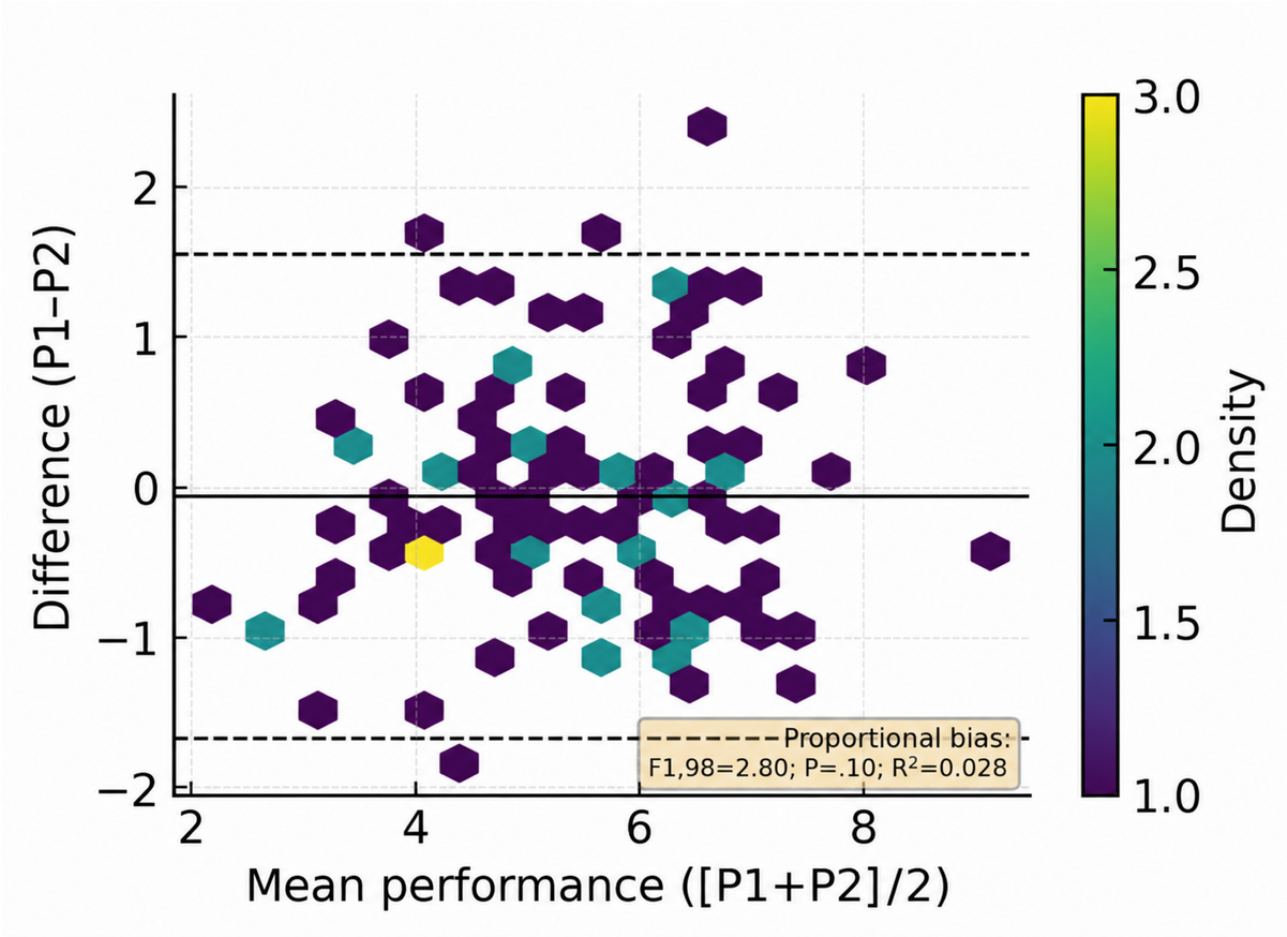
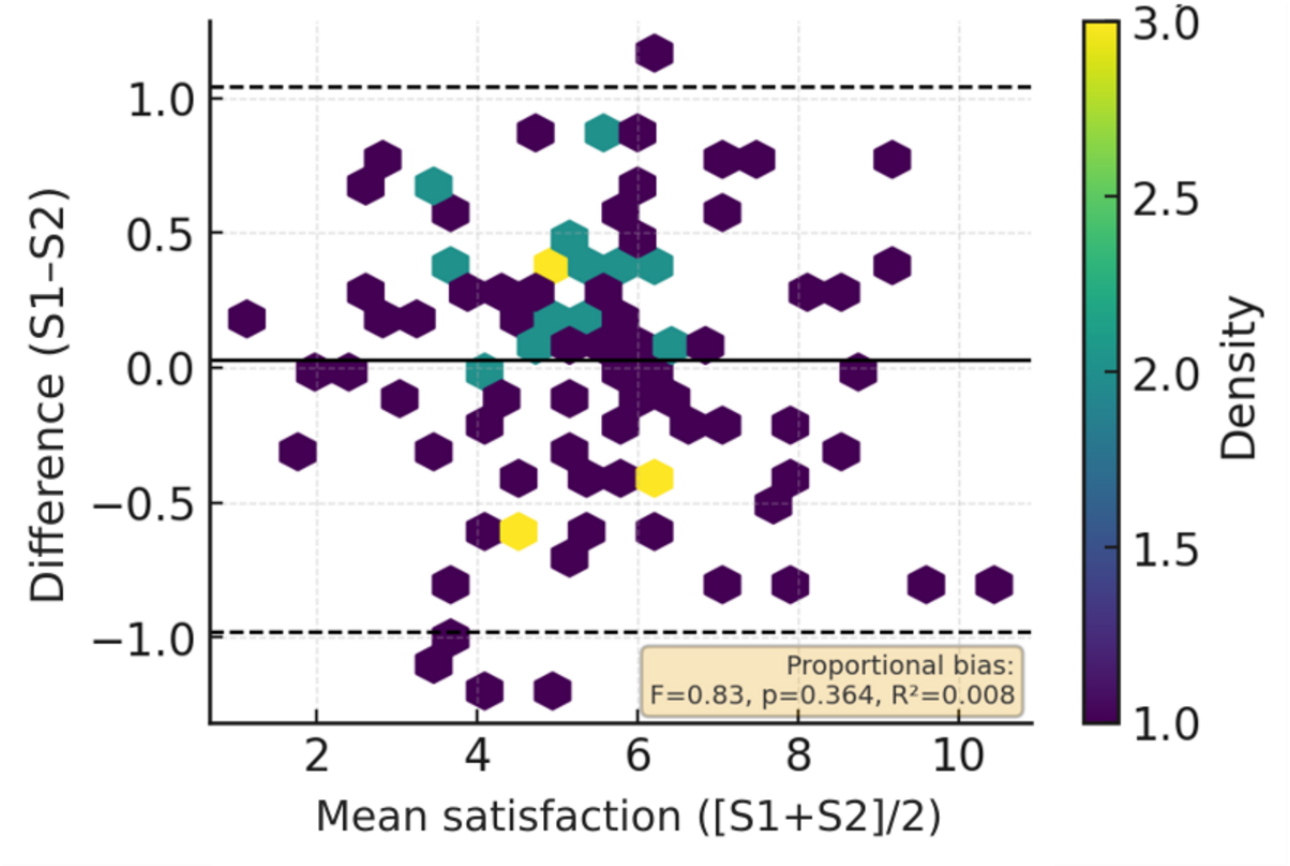
School	30 (7)	24 (5)	−2
Household	0 (0)	0 (0)	0
Community	0 (0)	0 (0)	0
Leisure	50 (11)	43 (10)	−1
Socialization	14 (3)	16 (4)	+1
Community entertainment	13 (3)	10 (2)	−1
Quiet recreation	1 (1)	0 (0)	−1
Physical recreation	22 (5)	17 (4)	−1



[a]This table summarizes all problems identified by parents during the COPM interview and classified using the standardized COPM coding system. The 3 main categories (daily activity, productivity, and leisure) and their corresponding subcategories are presented alongside detailed self-care subcomponents. For each classification level, the table reports the number and percentage of problems identified independently by rater R and rater S. The comparison column (percentage points) reflects the proportional difference between raters for each subcategory, providing an integrated view of agreement patterns across the full activity and participation domain. Rater R and Rater S were 2 independent raters.

Regarding quantitative interrater agreement, Bland-Altman analysis with hexagonal binning visualization demonstrated strong quantitative agreement between raters for both performance and satisfaction scores. The LOA were narrow, ranging from −1.69 to 1.60 (mean bias −0.048, SD 0.84) for performance scores and from −1.03 to 0.98 (mean bias −0.024, SD 0.51) for satisfaction scores. The corresponding Bland-Altman plots (Figures 2 and 3), enhanced through hexagonal binning to visualize data density, show that most observations were clustered around the mean bias line and fell within the 95% LOA.

Supporting these findings, linear regression analysis revealed no evidence of proportional bias. The relationship between score differences and mean scores was nonsignificant for both performance ($F_{1,98}$=2.80; P=.10; R^2=0.028; Figure 2) and satisfaction scores ($F_{1,98}$=0.83; P=.36; R^2=0.008; Figure 3), indicating consistent agreement across the measurement scale.



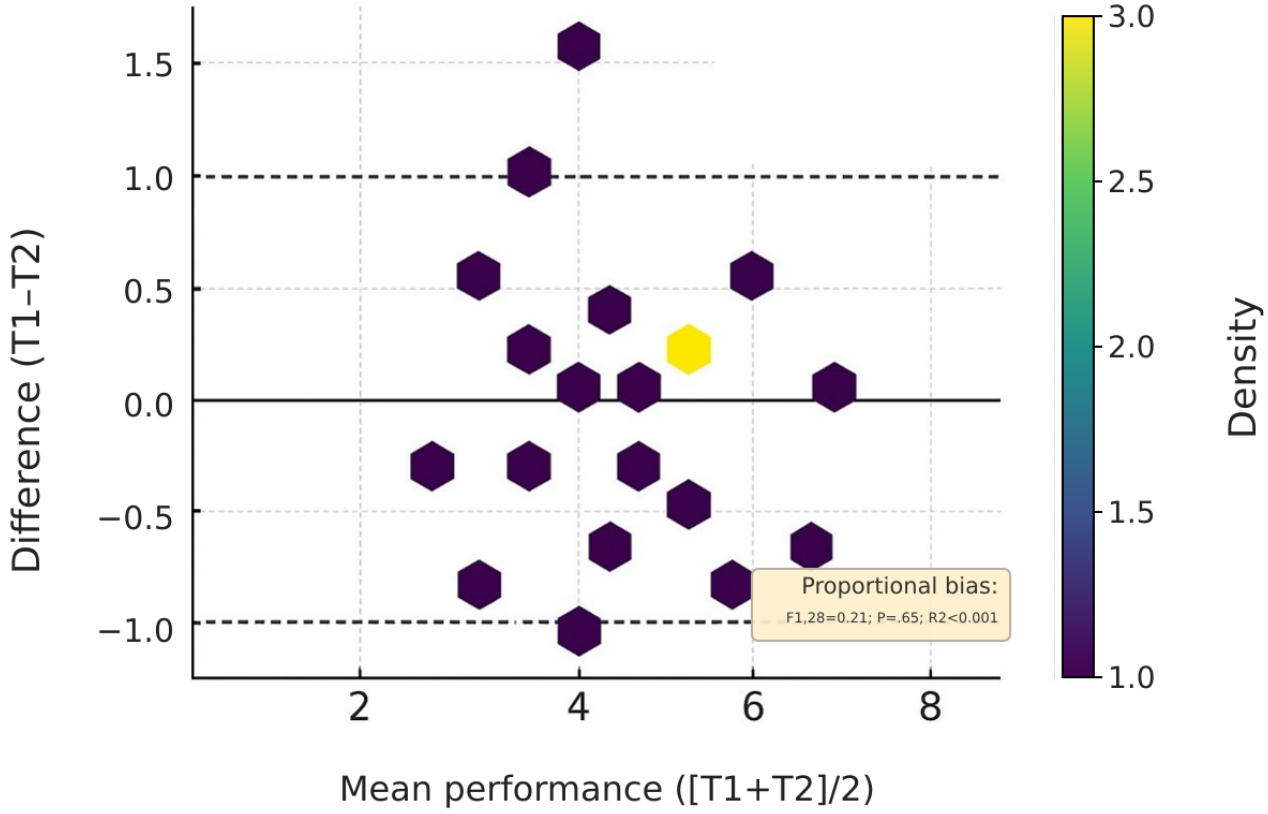
XSL•FO
RenderX

Figure 2. Hexbin Bland-Altman plot of interrater agreement for Canadian Occupational Performance Measure (COPM) performance scores, with proportional bias analysis. This Hexbin Bland-Altman analytical plot illustrates the agreement between 2 independent raters for COPM performance scores. The mean of the 2 raters' scores is plotted on the x-axis, and the score difference (P1−P2) is plotted on the y-axis. Each hexagonal cell represents the local density of overlapping observations, improving clarity in regions of high point concentration. The solid horizontal line represents the mean bias, while the dashed lines indicate the 95% limits of agreement. Proportional bias was examined using linear regression of score differences on their mean values. The association was nonsignificant (F1,98=2.80; *P*=.10; R2=0.028), demonstrating no systematic proportional bias.

XSL•FO
RenderX

Figure 3. Hexbin Bland-Altman plot of interrater agreement for Canadian Occupational Performance Measure (COPM) satisfaction scores, with proportional bias analysis. This Hexbin Bland-Altman plot presents the interrater agreement for COPM satisfaction scores. The x-axis shows the mean satisfaction rating between raters, and the y-axis represents the difference (S1−S2). Hexagonal density shading highlights regions where overlapping values occur. The solid line depicts the mean bias, and the dashed lines represent the 95% limits of agreement. Proportional bias was examined using linear regression of score differences on their mean values. The association was nonsignificant (F1,98=0.83; *P*=.36; R2=0.008), demonstrating no systematic proportional bias.

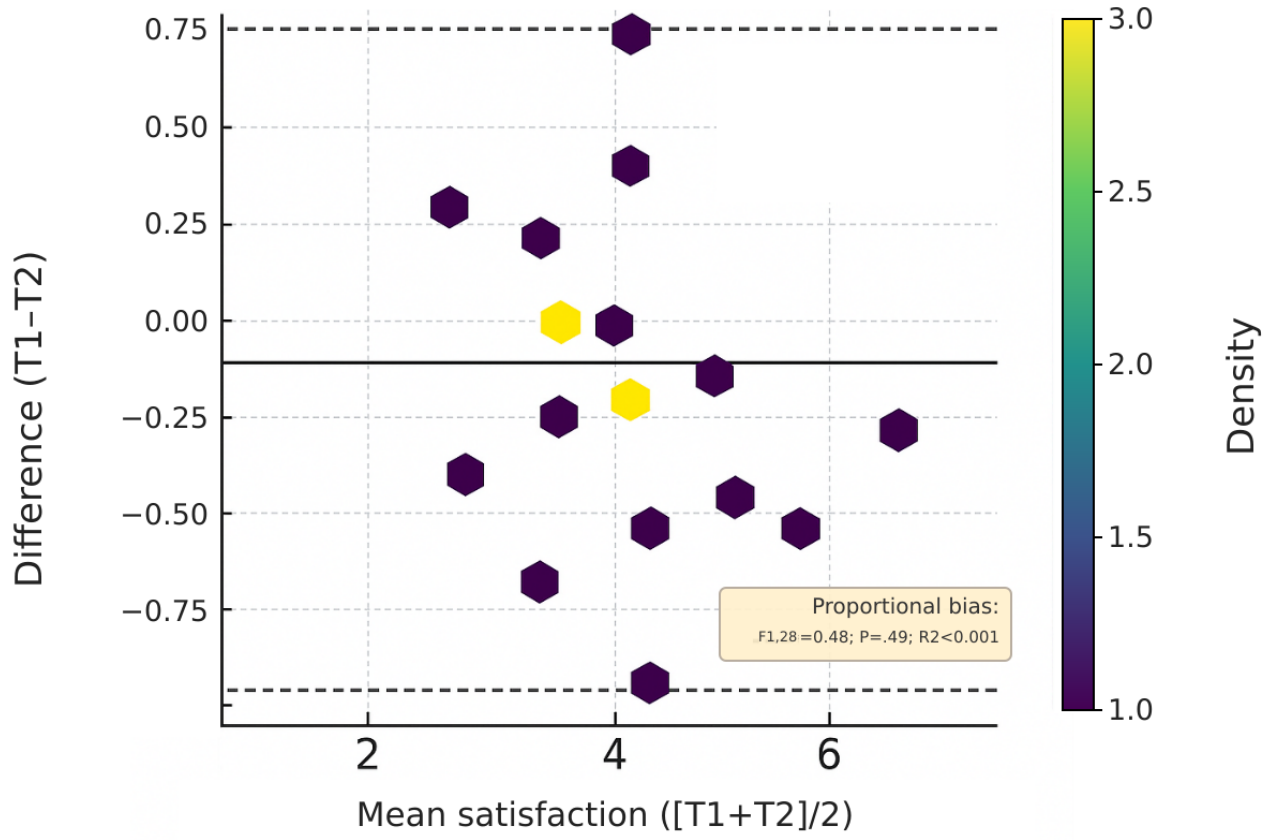
Test-Retest Reliability and Agreement



The Arabic-COPM demonstrated excellent temporal stability, with test-retest reliability ICCs of 0.83 (95% CI 0.64-0.92; *P*<.001) for performance scores and 0.91 (95% CI 0.81-0.95; *P*<.001) for satisfaction scores.

In terms of test-retest quantitative agreement, Bland-Altman analysis, visualized through hexagonal binning plots (Figures 4 and 5), demonstrated strong quantitative agreement across the 2-week interval. The LOA were narrow, spanning from −1.43 to 1.51 (mean bias 0.04, SD 0.75) for performance scores and from −0.56 to 0.78 (mean bias 0.11, SD 0.34) for satisfaction scores. The density-based plots show a tight clustering of data points within the LOA, indicating minimal systematic drift and high measurement repeatability over time.

On the other hand, Cohen κ analysis across the COPM main categories (daily activity, productivity, and leisure) demonstrated slight-to-fair interrater agreement.



XSL•FO
RenderX

Figure 4. Hexbin Bland-Altman plot of test-retest agreement for Canadian Occupational Performance Measure (COPM) performance scores (2-week interval), with proportional bias assessment. This Hexbin Bland-Altman analytical plot illustrates the test-retest agreement of COPM performance scores obtained from the same assessor over a 2-week interval. The mean of the 2 performance scores (T1 and T2) is plotted on the x-axis, and their difference (T1−T2) on the y-axis. Density-based hexagonal binning highlights regions of overlapping values, improving interpretability relative to conventional scatter plots. The mean bias is represented by the solid horizontal line, with the 95% limits of agreement shown as dashed lines. Regression analysis demonstrated that the relationship between score differences and their means was nonsignificant, indicating no proportional bias.

XSL•FO
RenderX

Figure 5. Hexbin Bland-Altman plot of test-retest agreement for Canadian Occupational Performance Measure (COPM) satisfaction scores (2-week interval), with proportional bias assessment. This hexbin Bland-Altman plot displays the test-retest reliability of COPM satisfaction scores across a 2-week interval. The mean satisfaction score is presented on the x-axis, and the difference between sessions (T1−T2) on the y-axis. Density-based hexagonal binning highlights regions of overlapping values, improving interpretability relative to conventional scatter plots. The mean bias is represented by the solid horizontal line, with the 95% limits of agreement shown as dashed lines. Regression analysis demonstrated that the relationship between score differences and their means was nonsignificant, indicating no proportional bias.

Families' Prioritized Concerns

Across both raters, a total of 460 problems were identified by rater R and 450 by rater S (Table 2). The vast majority of parent-prioritized problems fell within the daily activity main category, accounting for 82% to 85% of all reported concerns. Within daily activity, parents expressed the greatest concern for the mobility subcategory, which represented approximately 50% of all identified problems for both raters.

The second most frequently reported main category was leisure (10%-11%), with parents primarily emphasizing difficulties in the physical recreation subcategory (≈5% of all problems). In contrast, productivity concerns were least commonly reported (5%-7%) and were almost exclusively related to the school subcategory, with no meaningful concerns in household or community tasks.

Within the daily activity category, the self-care subcategory represented a substantial proportion of the identified priorities. When examining self-care in more detail, parents reported the highest concern for dressing, followed by eating, with additional—but comparatively fewer—concerns related to toileting, bathing, and hygiene.

Discussion

This study evaluated the interrater and test-retest reliability of the Arabic-COPM in parents of children with physical disabilities. The findings demonstrated strong reliability across both performance and satisfaction scores, supporting the consistency and stability of the Arabic-COPM within pediatric rehabilitation settings.

Psychometric Strength and Cross-Cultural Consistency

The Arabic-COPM exhibited excellent reliability metrics that meet or exceed established standards for outcome measures in rehabilitation. The high ICCs ranging from 0.80 to 0.91 across both interrater and test-retest evaluations indicate remarkable consistency between different clinicians and stability over time. Particularly noteworthy is the exceptional temporal reliability of satisfaction scores (ICC=0.91), suggesting that parental satisfaction with their child's performance represents a particularly stable construct that can be reliably tracked throughout the rehabilitation process.

These reliability findings are generally consistent with several previous COPM studies conducted across different clinical populations and cultural contexts. Similar ICC ranges have been

XSL•FO
RenderX

reported in patients with chronic obstructive pulmonary disease (approximately 0.90) [14], psychiatric disorders (approximately 0.85) [15], and ankylosing spondylitis (approximately 0.92) [13], supporting the stability of the COPM across diverse rehabilitation settings.

However, reliability findings in the broader COPM literature have not been entirely uniform. Some studies and reviews [28,29] have reported lower or more variable agreement levels depending on the assessed population, administration procedures, and methodological approaches. Such variability may reflect the individualized and semistructured nature of the COPM, in which participant priorities, interviewer interaction, contextual influences, and clinical interpretation can affect scoring consistency. Therefore, the findings of the present study should be interpreted within the context of the heterogeneous reliability literature surrounding the COPM.

These reliability findings demonstrate remarkable consistency with previous COPM validation studies across diverse populations and cultural contexts. The similarity of our ICC values to those reported in patients with chronic obstructive pulmonary disease (approximately 0.90) [14], psychotic disorders (approximately 0.85) [15], and ankylosing spondylitis (approximately 0.92) [13] suggests that the core client-centered methodology of the COPM maintains its measurement properties across linguistic and cultural adaptations. This cross-cultural consistency reinforces the fundamental robustness of the COPM framework while simultaneously validating the quality of the Arabic adaptation.

Comprehensive Agreement Analysis

Beyond conventional reliability coefficients, our implementation of multiple agreement methodologies provides a more nuanced understanding of the measure's performance. The Bland-Altman analyses with hexagonal binning visualization revealed narrow LOA with minimal systematic bias, demonstrating precise measurement characteristics at the individual score level. The 73.5% concordance in problem prioritization between independent raters indicates a moderate level of agreement between assessors. Although this finding supports a reasonable degree of consistency in the Arabic-COPM administration process, the remaining variability highlights the influence of interviewer interaction and individualized problem prioritization inherent in semistructured client-centered assessments.

When contextualized within the broader COPM literature, our interrater agreement rate of 73.5% falls between the agreement rates reported in other populations, reflecting the inherent balance between standardization and individualization in client-centered measures. This rate closely approximates the 80% agreement reported in similar pediatric populations [17] while substantially exceeding the 56% and 66% rates reported in stroke and mixed neurological populations [16,18]. This gradient likely reflects differences in cognitive clarity, goal stability, and the nature of therapeutic relationships across these diverse clinical populations.

Therapeutic Dialogue and Clinical Implementation

The variability observed in qualitative agreement measures should not be interpreted as evidence against standardization or measurement consistency. The COPM combines standardized scoring procedures with a semistructured individualized interview format. Although individualized problem identification and interviewer interaction may introduce some variation in prioritized responses across assessors, the strong quantitative reliability findings observed in the present study suggest that the Arabic-COPM maintains acceptable measurement consistency within a structured client-centered assessment framework.

Cultural and Developmental Priorities in Pediatric Rehabilitation

The pattern of problem prioritization revealed important insights into the concerns of Arabic-speaking families of children with physical disabilities. The overwhelming focus on daily activities (82%-85%), particularly mobility and self-care functions such as dressing and eating, provides empirical support for Maslow hierarchy of needs within this specific cultural and clinical context [30]. As Duncan and Blugis [31] articulated in their pediatric adaptation of this framework, families naturally prioritize fundamental needs related to nourishment, personal care, and basic functioning before addressing higher-order productivity or complex leisure pursuits.

This prioritization pattern reflects both practical caregiving realities and developmental aspirations. Parents intuitively recognize that mastery of basic mobility and self-care skills not only reduces caregiver burden but also serves as the essential foundation for peer socialization, educational participation, and eventual transition toward independent living. The predominance of mobility and self-care concerns identified in the present study suggests that families primarily prioritize essential daily functioning needs when identifying rehabilitation goals for children with physical disabilities. In contrast, productivity-related concerns were less frequently reported. These findings may reflect the central importance of functional independence in early pediatric rehabilitation and emphasize the practical relevance of addressing basic daily activities within family-centered rehabilitation planning.

The consistency of these findings with previous research involving children with cerebral palsy [32] suggests that these fundamental concerns may transcend specific diagnostic categories within the broader population of children with physical disabilities.

Limitations and Future Directions

Although this study establishes the fundamental reliability of the Arabic-COPM, several limitations warrant consideration. The scope of this validation study did not permit exploration of how problem prioritization might vary according to disability severity, socioeconomic factors, or cultural subgroups within the Arabic-speaking population. Another limitation is that absolute reliability indices such as the SE of measurement were not evaluated in the present study. Additionally, CIs for descriptive percentage estimates were not calculated and should be considered in future psychometric studies. Future research should investigate these potential moderating variables to provide more nuanced guidance for clinical implementation. Additionally, the focus on reliability represents only the first

XSL•FO
RenderX

step in comprehensive instrument validation. Subsequent studies should establish the responsiveness, minimal clinically important differences, and convergent validity of the Arabic-COPM to fully characterize its measurement properties.

Clinical Implications and Conclusions

Notwithstanding these limitations, our findings provide strong evidence supporting the integration of the Arabic-COPM into clinical practice throughout the Arabic-speaking world. The measure offers rehabilitation professionals a reliable, culturally adapted tool to authentically engage families in the goal-setting process. The consistent prioritization of basic daily activities underscores the importance of addressing these fundamental concerns as the foundation of any comprehensive rehabilitation program.

In conclusion, the Arabic-COPM demonstrates excellent reliability and clinical utility for implementing family-centered care in pediatric rehabilitation. Its successful validation opens new possibilities for standardized outcome measurement and culturally responsive service delivery across Arabic-speaking communities, ultimately supporting improved rehabilitation outcomes for children with physical disabilities and their families.

Abstract

Background: Technology use by children has implications for their physical, mental, and social health and development. There are many challenges in measuring modern screen use by children. To better understand the potential impact of technology on children, it is crucial to have robust methods to measure technology use. Visual recording data may be particularly well suited to capture modern digital technology use (eg, rapid transitions, multitasking, and device switching). It would be valuable to directly compare the 2 commonly used methods (wearable camera images and room video frames) to determine what is captured best by each and how they compare when both are coded by human annotation.

Objective: This study aimed to compare wearable camera images and room video frames to understand what can be captured from each source.

Methods: In a laboratory study, children (aged 3 - 14 years) performed various tasks while wearing a wearable camera and being video recorded by room video cameras. Comparisons between the coding of the wearable camera images and room video frames were performed on a second-by-second basis. Confusion matrices were generated to identify patterns of differences in classifications between wearable camera images and room video frame coding. Percent agreement between the wearable camera image and room video frame coding was calculated based on the confusion matrix.

Results: Across 44 participants, 182,451 contemporaneous wearable camera images and room video frames were coded and merged. There were generally low levels of agreement between the codes. The highest agreement was found for "desktop" and "handheld gaming," and the lowest agreement was found for "smartwatch." The wearable camera and room video methods varied in sampling rate, camera movement, and field of view, leading to differences in what was captured.

Conclusions: Room video might better capture technology that is within a set space and the context of the technology use, while wearable cameras could better capture active technology use, the content of technology, and different locations. Capturing technology use by children is difficult, with no gold standard and no one ideal method.

KEYWORDS

technology use; wearable camera; room video; children; screen use

Introduction

The impact of digital technology use by children is heavily debated, with evidence suggesting that the health effects of digital technology use may be detrimental [1,2], negligible [3], or beneficial [1,4,5]. Similarly, evidence on the educational impact of digital technology use on children is mixed [6].

One important reason for this mixed evidence is that the main measure of technology use by children is through self- or proxy-reported methods, such as questionnaires or diaries [7-9]. These subjective measures may be low cost and generally easy

XSL•FO
RenderX

to administer but are often imprecise due to reporting bias and recall inaccuracy [7,8,10,11]. Another important reason is that the focus has been on just the duration of technology use (ie, screen time), despite compelling evidence that other aspects, such as device type, content, and context of use, are likely to be critical in determining the impact of technology use on child outcomes [6,12,13].

There are many challenges in measuring modern screen use by children, including children commonly using multiple devices (including those of others and sometimes simultaneously), a variety of software with differing content, for various tasks, and in a variety of contexts and locations [7]. However, to better understand the potential impact of digital technology on children, it is crucial to have robust methods to measure digital technology use. Accurately capturing important aspects of modern digital technology use other than time has been identified as a critical issue in the field [6,7].

Visual recordings have been suggested as an alternative to self- or proxy-reported methods, including the use of still photographs [14-20] or video [21] recorded on cameras worn by the child [18-20] or stationary in a room [14-16,21]. Visual recording data may be particularly well suited to capture modern digital technology use (eg, rapid transitions, multitasking, and device switching).

A camera fixed in one location can capture digital technology use within that local context, for example, within a participant's living room. This was used in a pioneering study by Allen [14] in which time-lapsed cameras were installed in 95 families' homes, recording images of the television 4 times per minute. This early study found differences between the recorded results and the parent-reported results in diaries. Home-based fixed room cameras have subsequently been used in several studies to capture television viewing in young children's homes [15,16,21].

A fixed room camera may be useful if the technology use is mainly in one location (eg, a television or computer in the living room) and may create minimal burden and intrusion for participants. Still photographs (typically automatically set to capture a time-lapse sequence) or video recordings can be made from fixed-position cameras. Furthermore, depending on the camera view as well as the image clarity and resolution, it may or may not be possible to capture screen content, facial expressions, along with local context information such as coviewing [16]. However, information is limited to only activities that appear within the fixed field of view of the camera [22]. Fixed room cameras could also be intrusive to the child and family and may have third-party privacy issues [7].

Wearable cameras can be attached to participants (usually on a chest harness, headband, or a lanyard around the neck). Wearable cameras have been used to investigate different health-related behaviors in adolescents and children [18-20,23-25]. Thomas et al [19] used chest-mounted wearable cameras to capture screen use type and context in a study of 10 adolescents, and Everson et al [20] used cameras worn around the neck on a lanyard to capture screen-based activities (as well as dietary behaviors and physical activity behaviors) in a sample of 14 children.

Wearable cameras obviously move with participants; therefore, they are not restricted to one location and can thus provide location context of the digital technology use [26]. Wearing a camera may influence participant behavior, both by reminding them that their behavior is being recorded (an issue also present with fixed room recording devices) and by participant concern about damaging the device (eg, falling over and breaking the camera) or being injured by the camera (eg, if only secured on a lanyard) [20]. Many devices have limited battery life, with 1 study using wearable cameras to assess children's dietary intake in China reporting that cameras needed to be charged twice per day [27]. Wearable cameras can be set to automatically take still images or video stream. Recordings show the field of view of the participant, which is useful. However, the view and mobility of wearable cameras have raised privacy concerns related to capturing inappropriate or unwanted images and images of third parties [28].

In addition to differences in field of view and camera movement, cameras can also vary in whether still photographs or video are recorded. Still image recording is typically done at 1 image per second or slower [17-19] sampling frequencies, whereas video recording is typically at 30 frames per second or greater [21]. Slower sampling frequencies may miss brief activities performed by children, but they also create less data to be processed. Recorded images or frames are typically coded image or frame by image or frame by humans, which is very labor intensive [7,17-19]. Slower sampling rates may also enable lower storage and battery usage. Cameras also vary in image quality, which is influenced by both resolution (pixels per image) and shutter speed. Higher pixel counts enable more detailed images, although they create larger data files. A slow shutter speed enables more light collection per image but also increases the risk of blurred images from movement of either the camera or an object in the field of view while the shutter is open.

The different aspects of visual recording options for measuring children's use of technology appear to influence the likely information available from each method, with each method potentially being robust and valuable in its own right. Given these differences and the high processing burden in human coding of visual recordings, knowing which method would best suit a particular research project is important. It would therefore be valuable to directly compare the 2 commonly used methods (wearable camera images and room video frames) to determine what is captured best by each and how they compare when both are coded by human annotation. Furthermore, as digital technology engagement has been shown to differ between age groups [29,30] and genders [31], it would be valuable to compare whether there are any age or gender differences in what the 2 methods capture.

To our knowledge, no study has directly compared wearable camera images with room video frames within the same participants. Therefore, the aim of this study was to compare human annotation of wearable camera images and room video frames to understand what can be captured from each data source and to provide examples of issues relating to each, to help health, education, and general child development researchers decide which to use for a particular study. The

XSL•FO
RenderX

secondary aim was to compare results based on children's gender and age.

Methods

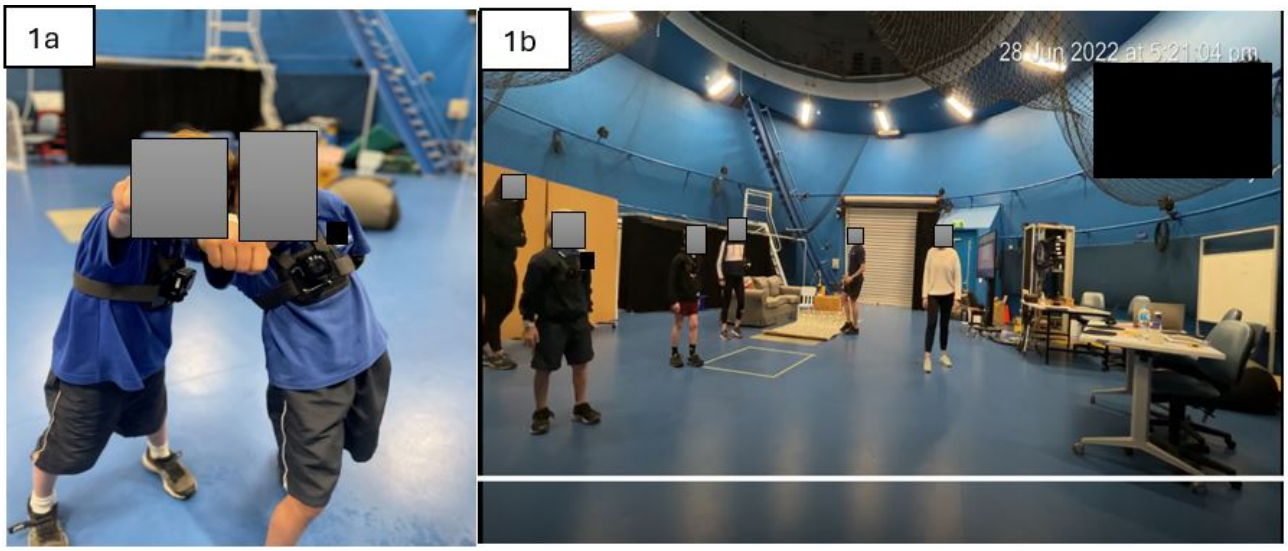
Study Design

An experimental laboratory study was conducted in which children performed a variety of digital technology–related and non–digital technology–related tasks while wearing a wearable camera and being video recorded by 2 room video cameras within a 10-m-diameter laboratory space.

Participants

Typically developing children aged between 3 and 14 years were recruited among university networks and in the community via word of mouth, flyers, and social media advertisements. Recruitment was stratified based on gender and age of the participants, with the aim of recruiting approximately equal numbers of boys and girls and children in 3 age brackets according to Australian school ages (3 - 5 y to represent a preschool-aged population, 6 - 10 y to represent a primary school–aged population, and 11 - 14 y to represent secondary school–aged and early adolescence population). Children were excluded from the study if they had any psychological or physical clinical diagnosis, as reported by their caregiver, which may have influenced their ability to understand and follow instructions or perform requested tasks.

Ethical Considerations



Ethical approval was obtained from the Curtin University Human Ethics Committee (HRE2022-0157). Caregivers provided written informed consent, and children gave verbal or written assent, as appropriate to their age.

Measures

Wearable Camera

One Brinno TLC120 automatic wearable camera operating at a 1-second frequency was fitted to the child's chest (using an adjustable chest-mounted harness to minimize the previously noted issues with lanyards; Figure 1A). The rapid transitions in digital technology use mean longer epochs risk missing brief but meaningful activities. The wearable camera weighed 101 g, was 60×60×35 mm in size, captured a 112° field of view, and did not record audio or video. Images were date- and time-stamped. The wearable camera was used to capture digital technology use during each activity directly from the field of view of the child.

Figure 1. Laboratory space with cameras. (A) Children with wearable cameras. (B) Laboratory space with room video camera on tripod.

Room Video

Room video recording was captured by 2 iPhone 12s (Apple Inc) using a super-wide lens at 30 frames per second. The iPhones were positioned on either side of the laboratory on 1-m-tall tripods approximately 4 m from the center of the room (Figure 1B). One iPhone was classified as the primary video (the most ideal location in the laboratory, providing the best view), and the second iPhone was the secondary video and was only used as a backup (eg, if the primary video battery ran out or the view was blocked by a person). The room videos were used to capture digital technology exposure during each activity by capturing the whole room.

Study Protocol

Children attended a single approximately 1-hour data collection session at a Curtin University laboratory with their caregivers between July and October 2022. Children either participated in the data collection session alone (n=10) or with a friend or sibling (n=38), with a maximum of 2 children participating simultaneously. Two to three researchers, experienced in working with children, were present at each data collection session. After providing informed consent, caregivers completed a brief sociodemographic questionnaire. Subsequently, children were asked for their verbal or written assent, as appropriate to their age, and were then fitted with the wearable camera.

The laboratory was set up to capture different tasks, both with and without digital technology, and involving a range of postures and movements. Following laboratory and equipment

XSL•FO
RenderX

familiarization, children then completed each task for at least 2 to 3 minutes, allowing for 120 to 180 images to be captured by the wearable camera (based on a 1-s epoch frequency). Tasks were performed in a standardized order where possible. However, flexibility was given in the protocol to ensure the participant's enjoyment. Some tasks were completed with a research assistant, the child's caregiver, or the second child in the session to replicate coviewing tasks (eg, when a child watches a television program with a caregiver or sibling) and to support children in completing the tasks. Tasks included watching programs on a television or laptop, playing on a gaming device (Nintendo Switch), reading a book, drawing on paper, playing with magnetic tiles or Jenga, using a desktop computer, drawing on a tablet, taking photographs with a smartphone, throwing and catching a ball, watching a video on a smartphone, and checking step counts via a smartwatch. Children were instructed on the position or movement to complete the task to allow the capture of images and video from a range of ecologically valid postures and movements. Table 1 provides a full list of tasks completed by the child, with devices used for each task. In total, 9 technologies were included: television, desktop, laptop, tablet, smartphone, smartwatch, handheld gaming console, combined gaming controller, and single gaming controller.

Table . Tasks completed by child.

Device	Position or movement	Details of task
Television	Sitting on bean bag	Watching a program of child's choice on television via laptop (HDMI cable connected to television)
Television	Lying (prone)	Watching a program of child's choice on television via laptop (HDMI cable connected to television)
Laptop	Lying (side lying)	Watching a program of child's choice via laptop
Laptop	Sitting (chair)	Watching a program of child's choice via laptop
Handheld gaming console	Sitting (couch)	Playing Mario Kart via Nintendo Switch using just Switch screen
Handheld gaming console	Standing	Playing Mario Kart via Nintendo Switch using just Switch screen
Book[a]	Lying (prone)	Reading a book
Stationary game (using a controller)	Sitting (couch)	Playing Mario Kart via Nintendo Switch connected to television
Magnetic tiles[a] or Jenga	Sitting (floor)	Playing with magnetic tiles on floor
Active game	Standing while moving or jumping	Playing Just Dance or NS Sports via Nintendo Switch connected to television
Desktop	Sitting (chair)	Drawing or reading on desktop computer
Tablet	Standing	Drawing app
Pencils and crayons[a]	Standing	Drawing and coloring in with paper and colored pencils or crayons
Tablet	Standing while moving	Participating in Cosmic Kids Yoga video or similar age-appropriate movement-based YouTube video
Smartphone	Walking, jumping, running, and skipping	Taking selfies or pictures of posters while walking, jumping, running, or skipping
Ball[a]	Standing while throwing and catching	Throwing and catching a netball or basketball
Smartphone	Lying supine or crook lie (floor)	Watching "Smiling Minds" Sea Creatures video or video of choice
Smartwatch	Jumping, handstands	Jumping and handstands then checking heart rate or steps via smartwatch
Smartwatch	Running, cartwheels	Running and then checking heart rate or steps via smartwatch screen
Smartwatch	Climbing stairs	Climbing stairs and then checking heart rate or steps via smartwatch screen

Analysis

Wearable Camera Coding

The wearable camera automatically processed images into a time-lapse video file (.avi), which was later downloaded and converted into single images (.jpg) using the open-source software FFmpeg (version 4.3 FFmpeg Team), which labeled each image with a participant code and image number. Images for each participant were viewed by a member of the research team, who recorded the corresponding technology code (Table 2) for each image recorded in a spreadsheet with image numbers and time stamps. Each image was coded in chronological order as indicated by the image number. The coder first determined if the image was codable or not. Uncodable images were images that could not be confidently annotated due to poor image quality, such as if the image was blurry, had poor lighting, or was obscured. If codable, each image was then coded to determine if any digital technology was visible. If not, then the image was coded as "no digital technology." If a digital technology was visible and active (ie, screen turned on), then the digital technology in the image was coded first for the primary technology device (the technology related to the primary task the child was doing). If there was more than one technology device visible in the image, any other technology was also coded, allowing for up to 3 technologies to be coded for the same image.

Table . Technology code definitions.

Coding options	Definition
Uncodable: blurry	Any image or set of images where the image quality is so poor due to being blurred that the coder is unable to confidently determine what is occurring in all aspects of the image.
Uncodable: obscured images	Any image or set of images where the image quality is so poor due to lighting that the coder is unable to confidently determine what is occurring in all aspects of the image. Poor lighting can include images that are too dark or too overexposed to accurately determine anything.
Uncodable: poor lighting	Images that are completely black or fully blocked by something and cannot be coded as having an active screen-based media device according to the coding rules. Includes completely blacked images.
Unsure	Coder is uncertain what is in the image.
No digital technology	No digital technology is visible (or active for room video).
Television	A device shaped like a box or rectangle with a screen that receives electrical signals and changes them into moving images. Can stand-alone or be mounted to a wall. Can be a smart television (ie, internet connected).
Desktop computer	A computer that fits on a desk but is not easily moved from place to place. Has a monitor, keyboard, mouse, and tower.
Laptop computer	A computer that is small enough to be carried around easily and is flat when closed. Indicated by an inbuilt keyboard.
Smartphone	A handheld device that can be used as a small computer, connect to the internet, and run apps.
Tablet	A small, flat computer that is controlled by touching the screen with one's finger or a special pen. Does not require a keyboard or mouse. Includes e-readers.
Handheld gaming console	Portable, self-contained devices that have a built-in screen, game controls, and speakers.
Combined gaming controller	When the child has the Nintendo Switch controller, which is controlled by 2 hands (ie, it has both the red and the blue parts together or the black controller in their hand).
Single gaming controller	When the child has the controller separated and/or in separate hands.
Smartwatch	A watch that has an electronic screen with features of a smartphone or a computer. Includes fitness trackers, such as a FitBit.

Room Video Coding

Video files were downloaded from the iPhones, with separate files for each participant. The secondary video was used for 4 participants (due to the primary video battery running out). The video frames for each participant were viewed by a member of the research team using QuickTime software (Apple Inc), with the technology code (Table 2) for each frame recorded in a spreadsheet. Video frames were coded in chronological order. To gain an understanding of the context, coders were encouraged to watch several video frames prior to coding. The coder would first determine if a frame was codable using the same codes as those used for the wearable camera images. Next, the coder would determine if any technology was visible and active. The definition of "active" varied from that used for wearable camera images, given the broader field of view of the room video, which

XSL•FO
RenderX

always included screens not always in use, such as the television screen. To be an active screen, it needed to be (1) within the child's field of view as determined by the child's head position, (2) facing the child, and (3) turned on or the child had active engagement with the screen. For smartwatches or gaming controllers to be coded, the child had to be actively engaging with the device. As with the wearable camera images coding, the primary technology was the technology related to the primary task the child was doing, and up to 2 additional technologies could be coded if they met the abovementioned criteria and were within the video frame. A custom-made Python program was used to generate second-by-second datasets of the video code spreadsheets to enable synchronization with the wearable camera code spreadsheets using a lookup table approach, whereby each time stamp in one dataset was matched to its corresponding time stamp in the other.

Interrater Reliability of Wearable Camera and Fixed Room Video Coding

The wearable camera images and room video frames from 3 participants (one from each age group) were independently coded by a second researcher to determine interrater reliability by assessing percentage agreement and Cohen κ [32]. For the wearable camera images, a very good interrater reliability was observed for all age groups, with an average percentage agreement of 92.5% (range 90.3% - 94.7%) and an average κ of 0.88 (range 0.86 - 0.92). For the room video frames, a good level of interrater reliability was found, with an average percentage agreement of 84.8% (range 72.7% - 98.8%) and an average κ (range 0.66 - 0.98), with the lowest level of agreement found for the youngest participant.

Statistical Analysis

As up to 3 technologies could be coded for each wearable camera image and room video frame, a variable was created to describe all possible combinations of the 9 technologies (television, desktop, laptop, tablet, smartphone, smartwatch, handheld gaming console, combined gaming controller, and single gaming controller), resulting in a total of 50 technology combinations (eg, television and combined gaming controller being used simultaneously when playing a video game). Including "no digital technology," "unsure," and "uncodable" created 53 categories (Table S1 in Multimedia Appendix 1).

An additional "any technology combination" variable was created to describe when each of the technologies was coded either alone or in combination with another technology (eg, "any television" when television was coded either alone or in combination with other technologies). This resulted in a variable with a total of 9 categories: any television, any desktop, any laptop, any tablet, any smartphone, any smartwatch, any handheld gaming console, any combined gaming controller, and any single gaming controller. As the technology types could be used together simultaneously, the 9 "any technology combination" categories were not distinct categories, as each individual image or frame could be coded for a number of these categories.

Comparisons between the coding of the wearable camera images and room video frames were made on a second-by-second basis. Confusion matrices were generated for the 53 categories to identify patterns of differences in classifications between wearable camera image and room video frame coding. Percent agreement between the wearable camera image and room video frame coding was calculated based on the confusion matrix with the 53-category variable.

The 9 "any technology combination" categories were used to determine if a particular technology was coded at the same second by both the wearable camera and room video regardless of whether the technology was coded by itself or with other technologies. Percent agreement between the wearable camera image and the room video frame coding was calculated based on whether either source coded the technology. As percent agreement does not take into account chance agreement, and given the different prevalence of some technologies, prevalence-adjusted bias-adjusted κ (PABAK) was also calculated [32,33]. We interpreted PABAK values using the Landis and Koch [34] classification scale where below-chance agreement <0.00, slight agreement 0.00 to 0.20, fair agreement 0.21 to 0.40, moderate agreement 0.41 to 0.60, substantial agreement 0.61 to 0.80, and almost perfect agreement 0.81 to 1.00. Agreement between the wearable camera and room video was compared between gender and age groups using separate two-way *t* tests or Wilcoxon tests (depending on distribution of data) comparing PABAK between genders and one-way ANOVA or Kruskal-Wallis (depending on distribution of data) comparing PABAK between age groups.

Results

Overview

A total of 48 children completed the study; however, a technical error resulted in some missing wearable camera image time stamps. Therefore, 4 participants were excluded, leaving a sample of 44 participants (girls: n=25, 55%) with a mean age of 8.3 (SD 3.3) years (Multimedia Appendix 2). Eleven children were aged between 3 and 6 years, 22 children were aged between 7 and 10 years, and 11 children were aged between 11 and 14 years. Across the 44 participants, a total of 182,451 contemporaneous wearable camera images and room video frames were coded, which equated to 50.7 hours of observed recording. At an individual participant level, the mean recording duration was 72.5 (SD 11.2, range 39.7-103.0) minutes.

Frequency of Technology Codes for Wearable Camera Images and Room Video Frames

Table 3 presents the frequency distribution of categories with at least 100 images or frames using the 53 categories of possible technology codes based on the wearable camera images and room video frames. Table S2 in Multimedia Appendix 1 contains the distribution of all 53 categories. "No digital technology" was coded for 46% (n=84,178) and 29% (n=52,504) of the wearable camera images and room video frames, respectively. The most frequently coded technologies based on the wearable camera images were "television" (n=21,900, 12%), "laptop" (n=11,596, 6%), and "desktop" (n=9426, 5%). For the room video frames, the most frequently coded technologies were "laptop" (n=19,150, 11%), "television" (n=18,266, 10%), and

XSL•FO
RenderX

"television & single gaming controller" (n=16,005, 9%). Ten percent (n=17,802) of the wearable camera images were coded as "uncodable" compared to only 3 (0%) room video frames.

Table . Frequency and agreement of 53 category technology coding based on wearable camera and room video recordings.

Technology coded	Wearable camera images (N=182,451), n (%)	Room video frames (N=182,451), n (%)	Agreement, n (%)
Uncodable	17,802 (9.8)	3 (0)	0 (0)
Unsure	234 (0.1)	39 (0.02)	0 (0)
No digital technology	84,178 (46.1)	52,504 (28.8)	41,113 (48.9)
Television	21,900 (12)	18,266 (10)	3825 (17.5)
Desktop	9426 (5.2)	11,893 (6.5)	8759 (73.6)
Laptop	11,596 (6.4)	19,150 (10.5)	10,510 (54.9)
Tablet	7327 (4)	14,565 (8)	5299 (36.4)
Smartphone	4866 (2.7)	9120 (5)	3063 (33.5)
Smartwatch	182 (0.1)	1822 (1)	57 (3.1)
Handheld gaming console	6812 (3.7)	10,758 (5.9)	5988 (55.7)
Combined gaming controller	1922 (1.1)	486 (0.3)	182 (9.4)
Single gaming controller	176 (0.1)	30 (0.02)	0 (0)
Laptop and combined gaming controller	76 (0.04)	0 (0)	0 (0)
Laptop and handheld gaming console	310 (0.2)	113 (0.1)	75 (24.2)
Tablet and smartphone	6 (0)	262 (0.1)	1 (0.4)
Tablet and tablet	1111 (0.6)	0 (0)	0 (0)
Television and combined gaming controller	4142 (2.3)	9346 (5.1)	3028 (32.4)
Television and laptop	6608 (3.6)	9970 (5.5)	4068 (40.8)
Television and single gaming controller	2034 (1.1)	16,005 (8.8)	1559 (9.7)
Television and smartphone	460 (0.3)	4117 (2.3)	150 (3.6)
Television and smartwatch	64 (0.04)	432 (0.2)	8 (1.8)
Television and tablet	389 (0.2)	3147 (1.7)	155 (5)
Television and laptop and smartwatch	0 (0)	171 (0.09)	0 (0)
Television and single gaming controller and single gaming controller	286 (0.2)	0 (0)	0 (0)

Table 4 presents the frequency distribution of categories using the 9 "any technology combination" category codes for both the wearable camera images and room video frames. The most frequently coded technologies based on the wearable camera images were "any television" (36,198/182,451, 19.8%), "any laptop" (n=18,816, 10.3%), and "any desktop" (n=9479, 5.2%). For the room video frames, the most frequently coded technologies were "any television" (n=61,477, 33.7%), "any laptop" (n=29,461, 16.1%), and "any tablet" (n=18,075, 9.9%).

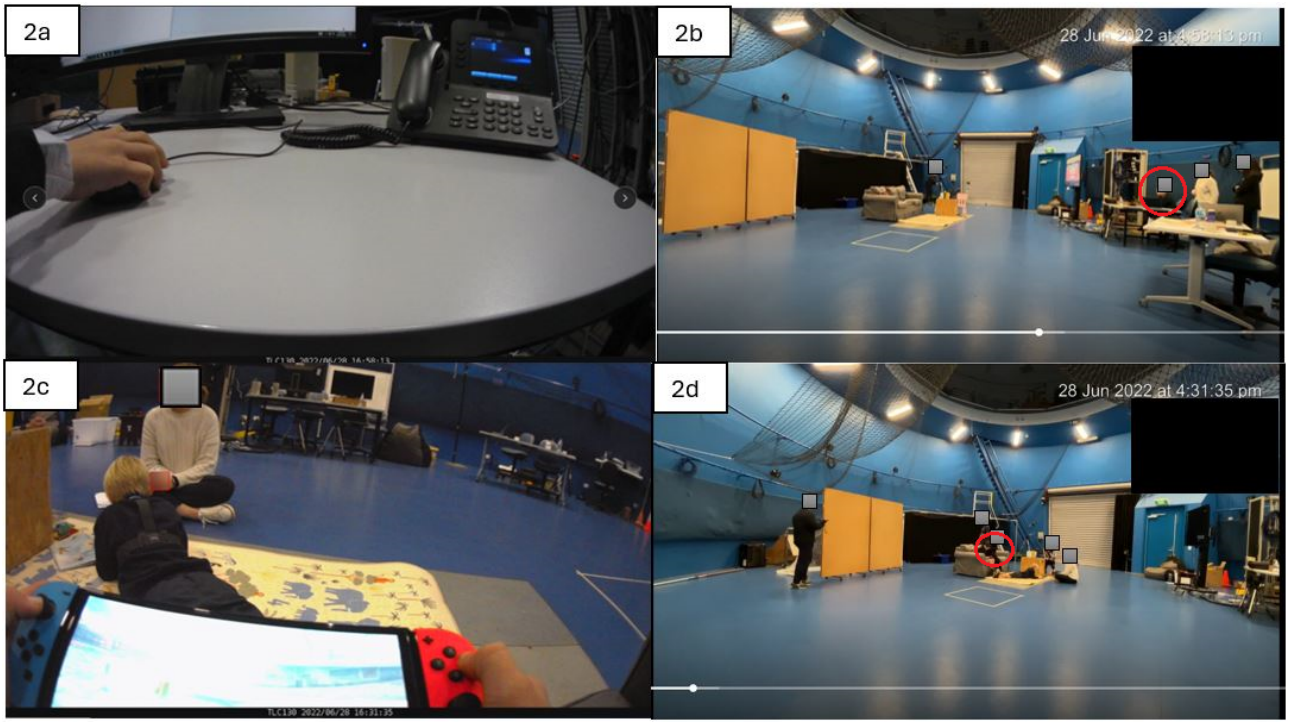
Comparison of Technology Codes From Wearable Camera Images and Room Video Frames

Overview

Table 3 presents the agreement of the 53-category codes from the wearable camera images and room video frames. Table 4 presents the agreement of all possible classifications for each general technology type combined (ie, the 9 "any technology combination") codes from the wearable camera images and room video frames. Regardless of whether technology was coded uniquely (53 codes) or in any combination (9 codes), there was generally below-chance agreement between the wearable camera image–based and room video frame–based codes. Specifically, for the 9 "any technology combination," the average percent agreement was 38.6% (range 3% - 69.6%), with PABAK scores ranging from −0.939 to 0.391.

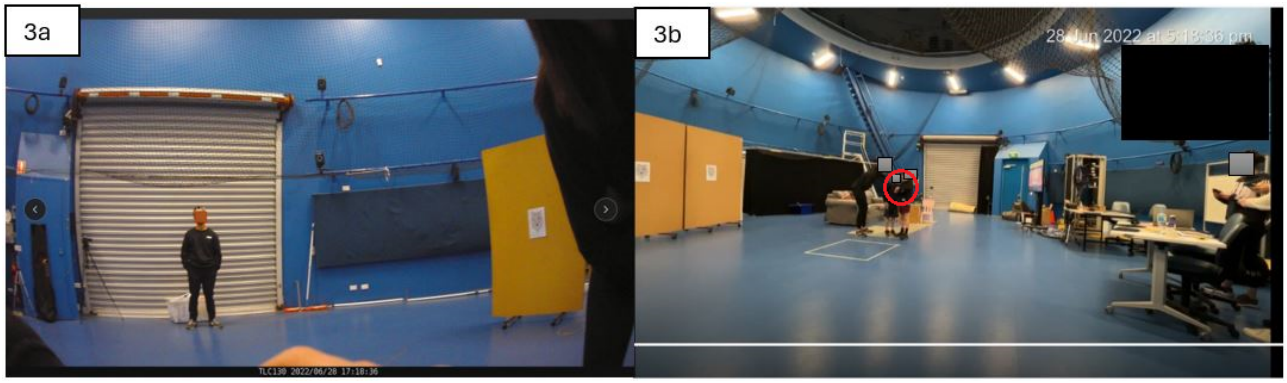
While the study did not have an independent reference standard to assess accuracy, it appeared that the wearable camera images provided better information for differentiating background screens from screens being actively engaged with, as well as providing a closer and more detailed image that could enable assessment of content. In contrast, the room video images appeared to provide better information when the child was moving or prone or lying, when the interaction with technology was brief or involved hand controls, the context of use that could include course, and the use of multiple devices.



Coding issues were identified related to wearable camera and room video differences, including sampling rate, camera movement, and field of view.

Examples of Coding Issues Related to Differing Sampling Rates

The highest agreement when considering whether a technology was coded was found for more stationary technology use or technology held closer to the child for a longer duration of time; for example, "any desktop" (8784/12,628, 69.6%) had fair agreement (PABAK: 0.391), and "any handheld gaming console" (6314/11,705, 53.9%) had slight agreement (PABAK: 0.079). Figure 2 shows instances where a desktop and a handheld gaming console were coded in agreement based on both the wearable camera image and room video frame.

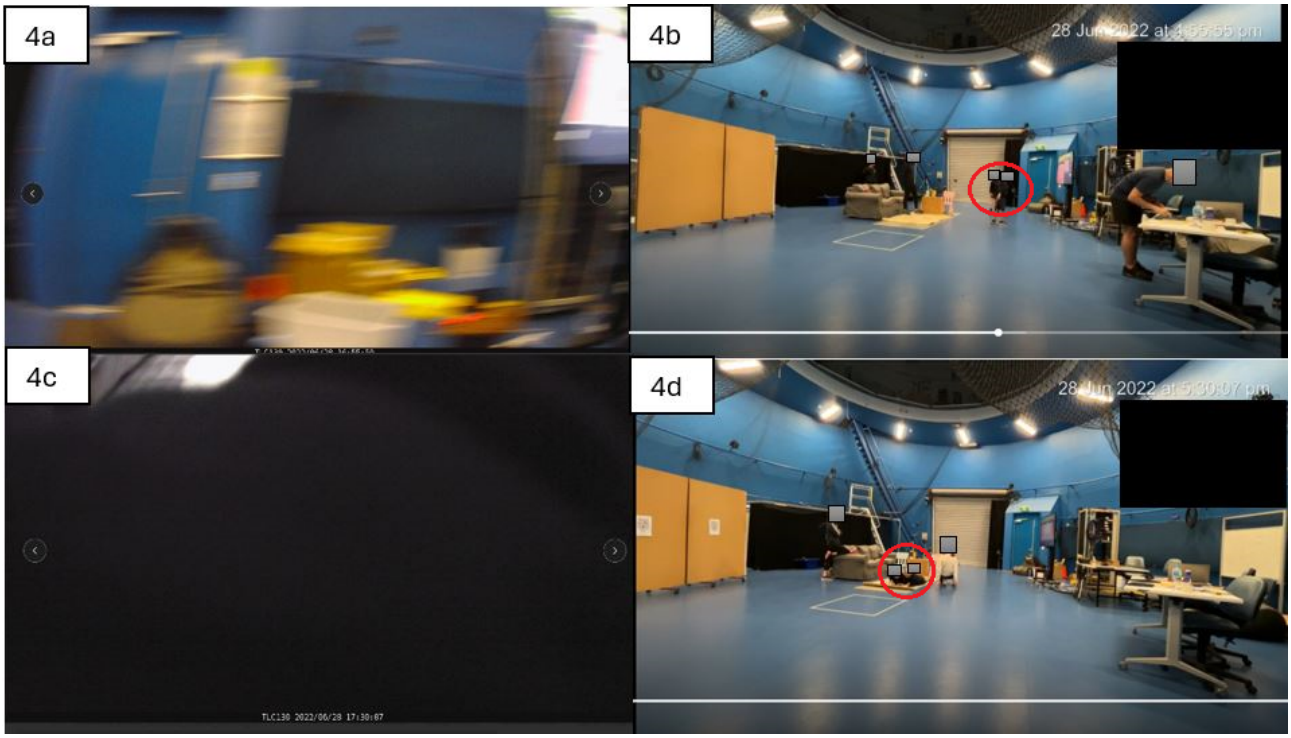


XSL•FO
RenderX

Figure 2. Impact of sampling rate on coding of longer duration activities. (A) Wearable camera coded desktop, (B) room video coded desktop, (c) wearable camera coded handheld gaming, and (D) room video coded handheld gaming. The red circles indicate the child with the wearable camera.

All other technologies were rated as having below-chance agreement, with the lowest agreement for coding of "any smartwatch" (86/2821, 3%, PABAK: −0.939), which was typically a very brief activity. Smartwatch was coded over an order of magnitude more frequently based on the room video (2661/182,451, 1.5%) compared to the wearable camera image (246/182,451, 0.1%; Table 4). Figure 3 shows an instance when "smartwatch" was coded based on the room video, but "no digital technology" was coded based on the wearable camera.

Figure 3. Impact of sampling rate on coding of brief activity. (A) Wearable camera coded no digital technology. (B) Room video coded smartwatch. Red circle indicates the child with the wearable camera.



Examples of Coding Issues Related to Camera Movement

"Uncodable" was coded more frequently based on wearable camera images (17,802/182,451, 9.8%) than on room video frames (n=3, 0%). Likewise, more wearable camera images (n=234, 0.1%) than room video frames (n=39, 0.02%) were coded as "unsure." The reason for wearable camera images to be coded as "uncodable" was likely often due to camera movement or a slower shutter speed causing images to be too blurry to code or due to the camera being obscured (eg, child lying on their stomach). Figure 4 shows instances when the wearable camera image was coded as "uncodable" due to being blurry or obscured, but technology was coded based on the room video frame.

XSL•FO
RenderX

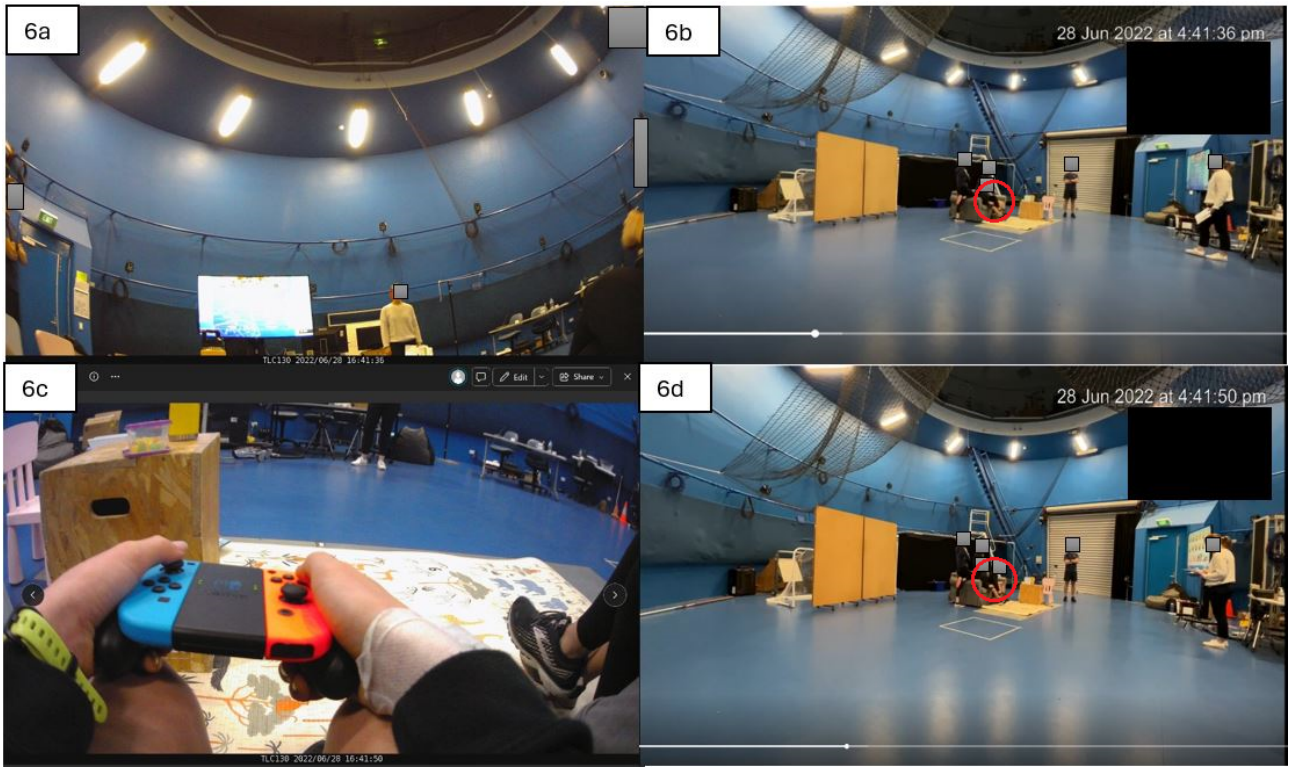
Figure 4. Effect of camera movement or position. (A) Wearable camera uncodable: blurry, (B) room video coded single controller and television, (C) wearable camera uncodable: obscured image, and (D) room video coded smartphone. Red circles indicate the child with the wearable camera.

Examples of Coding Issues Related to Differing Fields of View

Overall, a higher number of frames were coded as "no digital technology" based on the wearable camera images (84,178/182,451, 46.1%) compared to room video frames (52,504/182,451, 28.8%). Accordingly, percent agreement between wearable camera images and room video frames coded as "no digital technology" was only 48.9% (n=41,113). If a wearable camera image was coded as "no digital technology," it was frequently coded as containing a technology based on the room video frame, particularly "television" (8783/84,178, 10.4%), "laptop" (7866/84,178, 9.3%), or "tablet" (6387/84,178, 7.6%). However, if a room video image was coded as "no digital technology," it was only infrequently coded as a technology based on wearable camera images. Figure 5 shows instances when "no digital technology" was coded based on the wearable camera but "television" was coded based on the room video.

Figure 5. Impact of differing fields of view. (A) Wearable camera coded no digital technology and (B) room video coded television. Red circles indicate the child with the wearable camera.

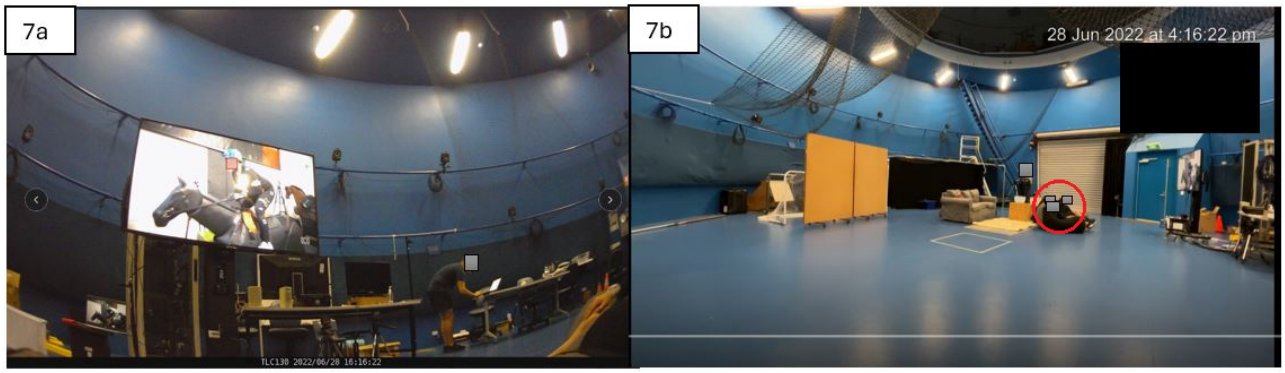
Examples of Coding Issues Related to Technology Device Differences



To identify patterns of differences in classifications between wearable camera image and room video frame coding and to determine if a technology (ie, television) was coded as different between the wearable camera and room video or in combination with other technology types, the 53-category confusion matrix can be considered. Multimedia Appendix 3 contains a link to an interactive version of the 53-category confusion matrix, along with an explanation of how to use the interactive figure and clarification of where the link will take the reader.

On the basis of the 53-category confusion matrix, 3825 image and frame were coded as "television" by both the wearable camera and room video (percent agreement: 17.5%). When considering images coded as "television" based on the wearable camera (21,900/182,451, 12%), 8161 (37%) frames were coded as "television & single gaming controller" based on the room video, and 3579 (16%) frames were coded as "television &

XSL•FO
RenderX



combined gaming controller" based on the room video. When considering frames coded as "television" based on the room video recording (18,266/182,451, 10%), there were low numbers of images coded as "television & single gaming controller" (219/18,266, 1.2%) or "television & combined gaming controller" (206/18,266, 1.1%) based on the wearable camera. A total of 3028 images per frame were coded based on both the wearable camera and room video as "television & combined gaming controller" (percent agreement: 32.4%), and a total of 1559 images per frame were coded based on both the wearable camera and room video as "television & single gaming controller" (percent agreement: 9.7%). Figure 6 shows instances when only "television" or "combined gaming controller" were coded based on the wearable camera image, but "television & combined gaming controller" was coded based on the room video frame.

Figure 6. Impact of field of view and thus ability to code from gaming involving hand controllers and television screen. (A) Wearable camera coded television, (B) room video coded combined controller and television, (C) wearable camera coded combined controller, and (D) room video coded combined controller and television. Red circles indicate the child with the wearable camera.

"Television" as coded based on the room video (18,266/182,451, 10%) was often coded as "television & laptop" (1955/18,266, 10.7%) based on wearable camera. Similarly, "television" as coded based on the wearable camera (21,900/182,451, 12.0%) was also often coded "television & laptop" (1064/21,900, 4.9%) based on the room video. A total of 4068 images per frame were coded based on both the wearable camera and room video as "television & laptop," with a percent agreement of 40.8%. Figure 7 shows an instance when both "television & laptop" were coded based on both the wearable camera image and the room video frames, highlighting the level of detail visible.

Figure 7. Impact of field of view on capturing television and laptop technology. (A) Wearable camera coded television and laptop and (B) room video coded television and laptop. Red circle indicates the child with the wearable camera.

XSL•FO
RenderX

Gender and Age Group Stratification

There were similar frequencies of codes between genders and age groups for the 9 "any technology combination" coded based on the wearable camera and room video (Table S3 in Multimedia Appendix 1). Overall, there were no significant differences in the PABAK results between either gender or age groups (Table S3 in Multimedia Appendix 1).

Discussion

Summary of Results

Overall, there were generally very low levels of agreement between the codes based on wearable camera images and room video frames for all technology types, as well as for coding whether or not technology was being used. Across all the categories, the highest agreement was found for "desktop" and "handheld gaming console" codes, and the lowest agreement was found for "smartwatch." Differences mostly occurred when multiple technologies were being used or coded or not, as combinations of technology were often captured with the room video but not necessarily with the wearable camera. Similar patterns to those observed in the whole sample were seen when comparing genders and age groups.

Previous literature has compared self-reported and objective measurements of technology use [35,36], with a previous systematic review finding discrepancies between device-logged and self-reported digital media use and reporting that self-reported measures were rarely accurate reflections of device-logged media use [37]. While there are now many studies that have used visual images to measure human behavior, no previous studies that have directly compared wearable camera images and room video frames to understand what can be captured from each of these data sources were identified. The wearable camera and room video varied in aspects such as sampling rate, the ability of the camera to move, and field of view, leading to differences in what was captured by each source. Prior studies have compared different types of cameras and camera views for other outcomes, for example, comparing a head-worn camera with a laptop camera to assess eye tracking [38] and a head-worn camera with an overhead drone camera to assess park quality [39]. The closest identified comparison to this study compared measures of parent-infant behavior using the same head-worn video cameras on the infant, parent, and observing researcher [40]. This study found that both the direction of the field of view (eg, infant's perspective and mother's perspective) and the viewing distance (ie, researcher perspective vs infant and mother) influenced what could be measured. Their findings thus concur with this study that while there was concordance on some outcomes, different camera views provided better options for different outcomes. For example, infant facial expressions were best measured from the mother-worn camera; however, due to the differing visual field, whole-body movements were often missed by the first-person cameras (mother- and infant-worn camera) compared to the third-person cameras (researcher perspective) [40].

The highest agreement for technology types was observed for technology devices that were used when the child was more stationary or when the device was closer to the child (ie, desktop and handheld gaming consoles; Figure 2). Brief technology activities (eg, smartwatch use) were captured better with the room video due to higher sampling rate, resulting in the lowest agreement (Figure 3). Child engagement with a smartwatch tended to occur quickly and was therefore easily missed with the 1-second sampling frequency of camera images and may also have been missed in camera images because of blurring due to the quick movement. Smartwatches are becoming increasingly available to children; therefore, it would be important to capture use effectively [41]. In addition, when a child looked at their wrist, it may not be in view of the wearable camera (eg, the child's arm blocking the camera). Due to these multiple issues, the use of the smartwatch may not have been captured in the wearable camera, which could perhaps be better captured in a room video recording at 30 frames per second.

Activities involving child movement (eg, jumping, running, skipping, and cartwheels) were not captured as well by the wearable camera compared to the room video. A higher percentage of images were coded as *"uncodable"* for the wearable camera images compared to the room video frames. This was often due to movement of the child or camera and a slow shutter speed, leading to blurred images. Furthermore, activities involving prone postures were not captured well by the wearable camera, as the child blocked the wearable camera view (ie, child lying on their stomach; Figure 4).

Owing to the differing fields of view, the wearable camera could miss technology but was more likely to detect active use of technology. It is likely that background use of certain technologies (ie, television and laptop) was coded based on the room video recording but not by the wearable camera images. More frames were coded as "no digital technology" based on the wearable camera images compared to the room video recording. Either the wearable camera missed capturing the technology or the room video "overcaptured" technology use. As captured by the room video, technology devices could still have been used, but due to the field of view of the wearable camera, the technology was missed. However, when determining active technology use based on the room video recording, it was sometimes hard to determine if the child was actively using or engaged with the technology or not, for example, if a technology was in the peripheral vision of the child (Figure 5). Wearable cameras primarily capture first-person, action-proximal engagement, whereas room video captures environmental availability and background exposure.

Technology use involving simultaneous use of hand gaming controllers and a television screen was not captured as well by the wearable cameras due to the field of view missing either the controller or television screen. Single and combined gaming controllers were often coded simultaneously with television for the room video frames but often only coded as "television" based on the wearable camera images (Figure 6). If single and combined gaming controllers were simultaneously coded with television in the wearable camera, then they were likely also simultaneously coded in the room video. The single and combined gaming controllers were often held outside the field of view of the wearable camera and, when within the field of view, could appear blurry in the wearable camera images due to movement of the child and controllers and a slow shutter

XSL•FO
RenderX

speed. On the basis of the wearable camera, it was sometimes difficult to determine whether the child was simply watching television or gaming using the television, whereas this could be captured within the room video given the different point of view.

Pros and Cons of Each Data Source

Room video data had a wider field of view; therefore, it was able to better capture technology that was in the room and had the ability to capture the context of the technology use. With the ability to capture the whole room, it was clear when the child was passively watching a program on the television compared to actively playing a video game. Additionally, although not an aim of this study, room video would have the ability to capture coviewing and co-use of technology (as seen in Figures 2-7). Borzekowski and Robinson [16] previously used a fixed room camera to capture coviewing of television and behaviors while watching television, such as eating, reading, or doing homework, and playing. On the other hand, the wider field of view of the video recording sometimes limited the quality of the video frames, and therefore, on occasion, it was hard to determine if there was technology present (eg, a laptop in the background). In addition, although not an aim of this study, it would be difficult to determine the content of the technology. For example, on occasion, it was difficult to determine if the television was actively on with a program or just a standby screen; therefore, it would be difficult to determine if the content was a violent movie compared to educational children's content. Furthermore, when determining active technology use based on the room video, it was sometimes difficult to determine if the child was actively using or engaged with the technology or not, for example, capturing technology in the peripheral vision of the child (as seen in Figure 5). Vadathya et al [21] previously attempted to combat this issue by developing a method to determine whether the target child was looking at the television using a home-based fixed room camera. There are also privacy concerns with recording room images.

The wearable camera had a smaller field of view but was closer in proximity and more focused (as seen in Figures 2 and 7). The wearable camera was able to capture active engagement with the technology and, due to the proximity to the technology, would have a greater ability to capture the content on the screen (as seen in Figure 7). Previous studies using wearable cameras to measure device use by adolescents have shown that it is feasible to code multiple screens with details of the screen content (eg, gaming, television viewing, social media, communication, creative content, and internet) as well as the location (eg, bedroom and living room) [18,19]. However, a wearable camera also has limitations. The children were often moving, which led to blurry images (as seen in Figure 4). With the camera mounted on the chest, sometimes some technologies were not visible either due to the position of the child or the placement of the technology (as seen in Figure 6). Particularly for gaming, the controller was frequently not visible in the wearable camera frame due to the child holding the controller out of view or due to movement of the child (such as using the single controller during active play). Therefore, the task may have been missed, with both gaming and television watching activities being coded as "television." Sometimes only a very small part of the screen was visible (eg, the corner of a tablet), therefore potentially missing technology that was out of frame. Moreover, if the engagement with the technology occurred quickly (eg, using a smartwatch), it was easily missed with images only captured every second (as seen in Figure 3). Furthermore, if the child was in certain positions (eg, lying on their stomach), the camera could be blocked, leading to "uncodable" images (as seen in Figure 4). Previous studies have also found that wearable cameras have the ability to capture screen use when the participant is upright or partially upright but capture a high percentage of images of the ceiling or obscure images due to the participants being positioned on their backs or in other positions [18,42,43]. Despite an ethical framework being established for privacy concerns with wearable cameras [28], parents remained concerned, especially with the varied locations of use creating greater potential for capture of nonconsenting third parties. The advantages and challenges of each data source are summarized in Table 5.

Table . Advantages and challenges of fixed room video and wearable cameras.

Method	Advantages	Challenges
Fixed room video	• Can capture technology within the whole space • Can capture the context of the technology, such as passively watching television or actively playing a video game • Can capture coviewing and co-use of technology	• Difficult to determine content on technology device • Difficult to determine active engagement with technology compared to background use • Privacy concerns with recording room images
Wearable camera	• Can capture active engagement with the technology • Has the ability to capture the content on the screen • Has the ability to capture technology use in various locations	• Movement can result in blurry images • Technology may not be visible within field of view • Privacy concerns with the ability to capture content in varied locations

Strengths and Limitations

A strength of this study was the simultaneous use of both a wearable camera and 2 fixed room video cameras to capture technology use. Another strength was that there was the broad age range from 3 to 14 years and the wide variety of technology devices included in the study. However, there were several limitations. First, the video camera placement at approximately 6 m from the center of the laboratory led to reduced video frame quality. There was also a potential that the time stamp synchronization of the wearable camera images and room video frames was not perfect and that small discrepancies in the time stamp synchronization could result in mismatches, which would affect the agreement of brief activities, such as checking the smartwatch. Finally, as the data were collected in a laboratory setting, the results should be generalized with caution to free-living conditions. We encourage further research in free-living conditions, despite the challenges of such studies.

Implications for Further Research

If future research is continued in free-living conditions, a few considerations should be made. Similar to previous literature [28], caregivers expressed concerns about privacy if the devices were used in a home setting and were worried about other children being captured if the devices were used in a school setting. Caregivers were more comfortable if the recording devices could be turned on and off and if the devices could be smaller. There were also concerns from caregivers about wearing the camera during certain activities, such as contact sports and swimming.

The coding of the wearable camera and fixed video frames was based on decisions made by the coders. In practice, researchers are likely to be able to interpolate coding for some blurred or obscured images, for example, when a screen temporarily moves out of view. This approach was not used in this study to enable clear comparisons of issues, such as movement blurring. Coding of both sources had the potential for human error and was extremely time-consuming (taking ~6 h per hour of recorded data), which suggests that it may be unsuitable for large-scale studies. Machine learning software could potentially be used to reduce the high researcher burden for the analysis of technology use via camera images or video frames [7], and advances in AI should be examined for accuracy in coding child behaviors from images [44].

Given the complexity of modern technology use, future research could usefully evaluate the simultaneous use of several data collection methods to use the relative advantages of different methods [7]. This could include questionnaires to provide some complementary information for image data, such as context or purpose. Images from both the wearable camera and the stationary video camera can capture useful and complementary information and thus could be used together. Similarly, multiple objective measures could be used simultaneously, for example, combining on-device recording of apps used or websites visited to triangulate the classification of content coded from image data.

Conclusions

Overall, there was poor agreement for children's technology use between the wearable camera images and room video frames. The results did not differ based on gender or age of the participants. The wearable camera and room video varied in sampling rate, the ability to move, and perspective, leading to differences in what was captured by each method. Both the room video and wearable camera methods have strengths and limitations due to these differences. Overall, fixed room video might better capture that technology is within a single set space and the context of the technology use, and the view and higher sampling rate of video may be better when child movement or prone lying is involved, handheld devices are used, interactions with technology are brief, or multiple devices are used within a set location. Wearable cameras could better differentiate the active use of technology versus background television, the content of the technology (due to the closer view of screen detail), and different locations of use. Future use of wearable cameras and room video to capture digital technology use should carefully consider the purpose of the study along with the potential limitations of each data source. Capturing digital technology use by children is difficult, with no gold standard and no one ideal method.

Acknowledgments

The authors would like to thank the participating children and their caregivers for their time to participate in this study and acknowledge the valuable contributions the Healthy Digital Child Parent Advisory Group and Expert Advisory Group made to the study design and interpretation. No generatve AI was used in the preparation of this manuscript.

Funding

This study was partly funded by the Australian Research Council through the ARC Centre of Excellence for the Digital Child (grant CE200100022) and the Curtin School of Allied Health 2022 Teaching and Research Grant.

Abstract

Background: Adolescent nicotine use initiation remains a significant public health concern. While screen-based behaviors have been linked to substance use, few prospective studies have examined specific forms of interactive screen engagement or tested potential psychological mechanisms underlying this association.

Objective: This study aimed to examine whether weekend texting screen time was prospectively associated with subsequent nicotine use initiation among early adolescents and evaluate whether negative urgency statistically accounted for part of this association.

Methods: We analyzed longitudinal data from a large cohort of adolescents who were nicotine naive at baseline. Weekend texting screen time (hours) was assessed via self-report. Negative urgency, reflecting impulsive action during negative affect, was measured using the UPPS (Urgency, Premeditation, Perseverance, and Sensation Seeking) impulsivity scale. Incident nicotine use initiation was modeled using Cox proportional hazards regression, adjusting for sex, age, race, ethnicity, and household income. We evaluated whether adjustment for negative urgency attenuated the texting-initiation association and conducted a sensitivity analysis restricted to participants for whom texting assessment, negative urgency assessment, and nicotine use initiation were temporally ordered.

Results: Among 5,965 nicotine-naïve adolescents followed prospectively, 239 (4%) initiated nicotine use. Greater weekend texting was associated with increased hazard of nicotine use initiation (per hour: hazard ratio [HR]=1.07, 95% CI 1.04 - 1.11). A 5-hour increase corresponded to an approximately 30% to 40% higher hazard of initiation. Weekend texting was positively associated with negative urgency (β=0.079; *P*<.001), and negative urgency independently predicted nicotine use initiation (per point: HR=1.19, 95% CI 1.13 - 1.25). Inclusion of negative urgency slightly attenuated the texting association (per hour: HR=1.06, 95% CI 1.02 - 1.09), although attenuation was modest. In standardized models, a 1-SD increase in weekend texting was associated with a 21% higher hazard of initiation (HR=1.21, 95% CI 1.10 - 1.31). In a sensitivity analysis restricted to participants with temporally ordered assessments and nicotine use initiation, weekend texting remained associated with nicotine use initiation (HR=1.11, 95% CI 1.06 - 1.16), and negative urgency remained independently associated with use initiation (HR=1.11, 95% CI 1.02 - 1.21). Adjustment for negative urgency attenuated the texting log-hazard coefficient by 6.8%.

Conclusions: Greater weekend texting screen time was prospectively associated with subsequent nicotine use initiation among early adolescents. Negative urgency was independently associated with nicotine use initiation and modestly attenuated the texting-initiation association. These findings are consistent with overlapping contributions of digital engagement and affect-driven impulsivity to early nicotine risk but do not establish a causal mediating pathway.

adolescent nicotine initiation; screen time; SMS text messaging; negative urgency; impulsivity; longitudinal study

Introduction

Adolescent nicotine use initiation remains a major public health concern as early onset of use is associated with increased risk of nicotine dependence, polysubstance use, and long-term adverse health outcomes. Although traditional combustible cigarette use has declined in recent years, the proliferation of electronic nicotine delivery systems and related products has sustained elevated rates of experimentation and initiation during adolescence [1,2]. Longitudinal studies indicate that early e-cigarette use is associated with increased likelihood of subsequent combustible cigarette use initiation [3,4]. Identifying

XSL•FO
RenderX

modifiable behavioral risk factors that precede nicotine use onset is therefore critical for prevention efforts, particularly given that adolescence is a sensitive developmental period characterized by increased susceptibility to social influence and risk behavior [5].

Screen-based technology use has increased dramatically among youth over the past decade. Adolescents now spend substantial time engaging in texting, messaging, and other forms of digital social interaction [6,7], particularly during weekends, when structured activities are reduced. Prior research has linked greater overall screen time with substance use, including alcohol and nicotine [8,9], but findings have been inconsistent and often limited by cross-sectional designs, aggregation of heterogeneous screen behaviors, or lack of temporal ordering [10]. Importantly, different forms and contexts of screen engagement may not carry equivalent information regarding substance use vulnerability. Texting and messaging are socially interactive behaviors that may capture peer communication and interpersonal engagement more directly than passive screen activities such as television viewing. We focused specifically on weekend texting because weekends are periods with fewer school-related constraints and, therefore, weekend use may more closely reflect discretionary patterns of peer-oriented digital engagement. This distinction does not imply that weekday texting or other interactive screen behaviors are unimportant; rather, weekend texting was examined as a specific, socially interactive exposure that may be particularly informative during periods of relatively unstructured time.

Impulsivity-related traits may represent one individual-level factor associated with both digital engagement and substance use risk. Negative urgency—the tendency to act impulsively during states of negative affect—is a well-established predictor of adolescent substance use initiation and escalation [11,12]. Although negative urgency is conceptualized as an impulsivity-related personality disposition, longitudinal research indicates that negative urgency itself shows meaningful developmental change across adolescence, increasing during early adolescence before leveling off [13]. Thus, negative urgency is not developmentally invariant during this period. Youth with elevated negative urgency are more likely to engage in maladaptive coping behaviors, including nicotine use, particularly in emotionally charged contexts [14]. Interactive digital environments may also involve emotionally salient social feedback, peer reinforcement, and interpersonal stressors [15,16]. Accordingly, greater engagement in these environments and negative urgency may jointly characterize adolescents at elevated risk of substance use initiation. However, whether negative urgency statistically accounts for part of the longitudinal association between digital engagement and subsequent nicotine use initiation remains unclear.

Despite this conceptual overlap, the extent to which impulsivity traits help explain the relationship between screen engagement and nicotine use initiation remains unclear. A key gap in the literature is the lack of longitudinal, prospective investigations testing whether specific forms of screen time are prospectively associated with incident nicotine use initiation among nicotine-naive adolescents and whether negative urgency statistically accounts for part of this longitudinal association. We conceptualized negative urgency as an affect-related impulsivity characteristic associated with vulnerability to risky behavior rather than as evidence that nicotine use initiation occurs during or immediately following texting episodes. Most prior studies have relied on cross-sectional designs, limiting causal inference, or have not examined mediation mechanisms grounded in personality and affect regulation frameworks [17,18]. Clarifying whether impulsivity partially explains this association has implications for both digital health guidance and targeted prevention strategies.

The present study addresses this gap using prospective data from a large cohort followed from early adolescence. We examined whether weekend texting screen time was associated with subsequent nicotine use initiation among youth who were nicotine naive at baseline. We further evaluated whether negative urgency was associated with both texting behavior and nicotine use initiation and whether adjustment for negative urgency attenuated the texting-initiation association.

We tested three primary hypotheses. First, greater weekend texting screen time would be associated with increased risk of incident nicotine use initiation. Second, higher texting screen time would be associated with greater negative urgency. Third, higher negative urgency would be independently associated with nicotine use initiation, and adjustment for negative urgency would partially attenuate the association between texting screen time and use initiation.

By focusing on a specific, socially interactive form of screen engagement and using prospective time-to-event analyses, this study aimed to clarify behavioral and personality mechanisms that may contribute to early nicotine use risk in contemporary digital environments.

Methods

Study Design and Participants

Data were drawn from a large longitudinal cohort of adolescents, the Adolescent Brain Cognitive Development (ABCD) study, assessed at multiple time points [19]. The assessments used in the present analyses took place between 2019 and 2024. Baseline Screen Time Questionnaire (STQ) assessments in the analytic sample were completed between March 2019 and October 2023, with subsequent UPPS (Urgency, Premeditation, Perseverance, and Sensation Seeking) and substance use follow-up assessments extending up to March 2024. The present analyses were restricted to participants with available STQ data [20] and UPPS impulsivity data [21], as well as information regarding nicotine use initiation [22]. To establish temporal ordering, participants who reported nicotine use initiation on or before the STQ assessment were excluded, yielding a nicotine-naive baseline cohort. Participants were further restricted to those with complete covariate data required for multivariable modeling. The final analytic sample consisted of adolescents followed prospectively for incident nicotine use initiation.

RenderX

Measures

Weekend Texting Screen Time

Weekend texting screen time at baseline was assessed using a self-report item from the STQ [20] that asked participants to report the number of hours spent texting or messaging on a cell phone, tablet, computer, or similar electronic device during weekends. Responses were recorded in hours. The distribution of texting time was right skewed, with many participants reporting low levels of exposure and a smaller subset reporting higher durations.

Negative Urgency

Impulsivity was assessed using the negative urgency subscale of the UPPS impulsive behavior measure [21]. Negative urgency reflects the tendency to act impulsively during states of negative affect. A summed score was used for analysis, with higher scores indicating greater urgency. The negative urgency score was treated as a continuous variable in all models. For each participant, negative urgency was obtained from the earliest available UPPS assessment taking place on or after the baseline STQ assessment. Eligible assessments were restricted to those taking place within 2500 days after the STQ assessment. In the primary analytic sample, 52.2% of selected UPPS assessments took place within 1 day of the STQ assessment; the median interval was less than 1 day (IQR <1 - 321; range <1 - 590 days).

Nicotine Use Initiation

Incident nicotine use initiation was defined as first reported use of nicotine products occurring after the baseline STQ assessment. Time to event was calculated from the date of the STQ assessment to the reported onset date of nicotine use. Participants who did not initiate nicotine use during follow-up were censored at their last available assessment.

Covariates

All models were adjusted for demographic covariates, including sex, age at baseline assessment, race, ethnicity, and household income. Income was included as a continuous variable. Analyses were conducted using a complete-case approach, with participants missing covariate data excluded from adjusted models.

Statistical Analysis

Descriptive statistics were calculated for weekend texting screen time and negative urgency. Weekend texting screen time was assessed at the baseline STQ assessment. For each participant, negative urgency was obtained from the earliest available UPPS assessment taking place on or after the STQ assessment within the specified 2500-day eligibility window. Because the timing of the selected UPPS assessment varied across participants, including assessments taking place on the same day as the STQ, negative urgency was not treated as a uniformly subsequent assessment. Associations between baseline texting screen time and follow-up negative urgency were evaluated using linear regression models adjusted for demographic covariates.

Prospective associations between baseline texting screen time and incident nicotine use initiation were examined using Cox proportional hazards regression models [23]. The primary model estimated the total association between baseline texting screen time and time to nicotine use initiation, adjusting for demographic covariates. Participants were restricted to those who were nicotine naive at baseline. Time to event was defined as the number of days from the baseline texting assessment to the first recorded nicotine use onset date derived from longitudinal substance use data. Participants without nicotine use initiation were censored at their last available follow-up assessment. Because Cox proportional hazards models explicitly incorporated each participant's observed time-to-event or censoring time, follow-up duration was not included as an additional covariate. We nevertheless examined the association between weekend texting screen time and follow-up duration to assess potential differential observation by exposure. To enhance interpretability, hazard ratios (HRs) were reported per 1-hour increase in weekend texting screen time and were additionally expressed for increases corresponding to 1 SD, 1 IQR, and 5 hours.

To examine whether negative urgency statistically accounted for part of the association between texting screen time and nicotine use initiation, a second Cox model included both texting screen time and negative urgency. Change in the texting coefficient following inclusion of negative urgency was used to quantify attenuation of the association. Because negative urgency was not uniformly assessed after STQ and before nicotine use initiation, these analyses were interpreted as associational rather than as establishing causal mediation.

As a sensitivity analysis addressing temporal ordering, we repeated the Cox analyses after excluding participants whose recorded nicotine use initiation occurred before or on the date of their selected UPPS assessment. This restriction ensured the sequence STQ assessment→UPPS negative urgency assessment→nicotine use initiation among participants experiencing the outcome. The time origin remained the baseline STQ assessment to preserve comparability with the primary survival analysis. Models used the same demographic covariates and family-level clustering as the primary analyses.

An exploratory product-of-coefficients analysis was additionally conducted on the log-hazard scale with nonparametric bootstrap CIs. Because the temporal ordering required for causal mediation was not consistently present in the primary sample, this analysis was interpreted only as a statistical breakdown of associations and not as an estimate of a causal indirect effect or causal proportion mediated.

Cox models incorporated clustering at the family level to account for nonindependence of observations. Proportional hazards assumptions were evaluated using Schoenfeld residual tests [24]. No violations of the proportional hazards assumption were detected. All analyses were conducted in R (R Foundation for Statistical Computing) [25] using the *data.table* and *survival* packages [26,27], along with custom code for bootstrap-based mediation analyses. Statistical significance was evaluated at a 2-sided α level of .05.

Ethical Considerations

The ABCD study protocol was approved by the centralized Institutional Review Board (IRB) at the University of California, San Diego (160091), with participating study sites obtaining or relying on appropriate local IRB approval. Parents or legal guardians provided written informed consent, and participating youth provided assent. The present study involved secondary analysis of deidentified ABCD study data obtained through the National Institute of Mental Health Data Archive and was determined to be exempt from review by the University of California, San Diego IRB (815599). All study procedures were conducted in accordance with applicable ethical guidelines and the principles of the Declaration of Helsinki.

Results

Sample Characteristics

Of 8048 participants with available STQ and UPPS data, 771 individuals who reported nicotine use initiation on or before the STQ assessment were excluded to ensure a nicotine-naive baseline cohort. This yielded 7277 eligible participants. After restricting to individuals with complete exposure and mediator data and valid follow-up time, 5965 participants were included in the primary Cox proportional hazards analyses, during which 239 incident nicotine use initiation events were observed (Table 1).

Table . Baseline characteristics of participants who did and did not initiate nicotine use during follow-up. *P* values reflect unadjusted comparisons between groups using *t* tests for continuous variables, chi-square tests for categorical variables, and Wilcoxon rank-sum tests for household income.

Characteristics	No nicotine use onset (n=5726)	Nicotine use onset (n=239)	*P* value

[a]STQ: Screen Time Questionnaire.

[b]Not applicable.

[c]UPPS: Urgency, Premeditation, Perseverance, and Sensation Seeking.

In the primary analytic sample, participants had a median follow-up of 311 (IQR 232-366) days, with a maximum follow-up of 1407 days. A total of 28.7% (2827/9858) of participants had no follow-up Substance Use Interview assessment after the STQ, and 10.9% (1074/9858) had near-immediate follow-up (≤30 days). Follow-up duration was weakly inversely associated with weekend texting screen time (r=−0.044), indicating minimal differential follow-up by exposure (Table 2).

XSL•FO

Correlation: exposure and follow-up, *r*	−0.044
Slope (days per 1 hour of screen time)	−2.23

Weekend texting screen time and UPPS negative urgency scores were approximately normally distributed after cleaning. The negative urgency score had a mean of 8.36 (SD 2.43).

Association Between Weekend Texting Screen Time and Negative Urgency

In linear regression models, greater weekend texting screen time was significantly associated with higher negative urgency scores (β=0.079; *P*<.001; Tables 3 and 4). Each additional hour of weekend texting screen time was associated with a modest but statistically robust increase in negative urgency, although the overall variance explained was small (R^2=0.008).

Table . Cox proportional hazards models estimating hazard ratios (HRs) for incident nicotine use[a].

Predictor	Model 1 HR (95% CI)	*P* value	Model 2 HR (95% CI)	*P* value
Weekend texting screen time (exposure)	1.07 (1.04 - 1.11)	<.001	1.06 (1.02 - 1.09)	<.001
Negative urgency (mediator)	—[b]	—	1.19 (1.13 - 1.25)	<.001

[a]Model 1 includes weekend texting screen time only; model 2 includes both weekend texting screen time and UPPS negative urgency. HRs represent the change in risk per 1-hour increase in weekend texting screen time and per 1-unit increase in negative urgency score.

[b]The predictor was not included in the model.

Table . Standardized effects per 1-SD increase in exposure and mediator variables, including standardized estimates from models before and after adjustment for negative urgency; the exploratory product-of-coefficients estimate is also shown.

Predictor	Standardized HR[a] (95% CI)
Weekend texting screen time (primary model)	1.21 (1.10 - 1.31)
Weekend texting screen time (adjusted for negative urgency)	1.17 (1.06 - 1.28)
Negative urgency	1.49 (1.29 - 1.73)
Exploratory product-of-coefficients estimate	1.04 (1.02 - 1.06)

[a]HR: hazard ratio.

Models were adjusted for demographic covariates (sex, age, race, ethnicity, and household income); full parameter estimates are provided in Table S1 in Multimedia Appendix 1.

Weekend Texting and Nicotine Use Initiation

In Cox proportional hazards models, greater weekend texting screen time was significantly associated with increased risk of incident nicotine use initiation. Each additional hour of weekend texting screen time was associated with a 7% higher hazard of

XSL•FO
RenderX

initiation, corresponding to an HR of 1.07 with a 95% CI of 1.04 to 1.11. Model discrimination was modest, with a concordance of 0.617. There was no evidence of violation of the proportional hazards assumption.

The magnitude of this association was clinically meaningful when scaled to larger differences in exposure. A 5-hour increase in weekend texting screen time corresponded to approximately a 40% higher hazard of nicotine use initiation. When standardized, a 1-SD increase in weekend texting screen time was associated with a 21% higher hazard of nicotine use initiation (HR=1.21, 95% CI 1.10 - 1.31).

Association After Adjustment for Negative Urgency

When UPPS negative urgency was included in the model, it independently predicted nicotine use initiation, with each 1-point increase associated with a 19% higher hazard. The association between weekend texting screen time and nicotine use initiation was modestly reduced after adjustment for negative urgency (HR=1.06 per hour), although the magnitude of this attenuation was small. The persistence of the texting association after adjustment indicates that negative urgency statistically accounted for only a portion of the observed association. Because negative urgency was not uniformly assessed before nicotine use initiation, this attenuation should not be interpreted as evidence of a causal indirect effect. In standardized models, the adjusted for negative urgency effect of weekend texting screen time remained statistically significant (HR=1.17, 95% CI 1.06 - 1.28), whereas a 1-SD increase in negative urgency was associated with a 49% higher hazard of nicotine use initiation (HR=1.49, 95% CI 1.29 - 1.73).

Exploratory Bootstrap Statistical Decomposition

Exploratory bootstrap analyses yielded a statistically significant product-of-coefficients estimate for the association involving weekend texting, negative urgency, and nicotine use initiation (Table 5). On the log-hazard scale, the product estimate was 0.014 (95% CI 0.008 - 0.022). The standardized product estimate was 0.0365 (95% CI 0.0201 - 0.0561). Because negative urgency did not uniformly precede nicotine initiation in the primary analytic sample, these estimates are presented as statistical decompositions rather than causal indirect effects, and the corresponding proportion should not be interpreted as the proportion of the total effect causally mediated through negative urgency.

Table . Bootstrap mediation results estimating indirect effects of weekend texting screen time on nicotine use initiation through UPPS negative urgency[a].

Effect	Estimate (95% CI)
Indirect effect—log-hazard	0.014 (0.008-0.022)
Indirect effect—standardized log-hazard	0.0365 (0.0201-0.0561)
Standardized indirect HR[b]	1.04 (1.02-1.06)

[a]Effects are presented on both the log-hazard scale and as hazard ratios. Standardized estimates reflect effects per 1 SD increase in exposure. CIs are derived from bootstrap resampling.

[b]HR: hazard ratio.

Sensitivity Analysis Restricting to Temporally Ordered Assessments

Because negative urgency did not uniformly precede nicotine use initiation in the primary analytic sample, we conducted a sensitivity analysis restricted to participants for whom the temporal sequence of baseline STQ assessment, UPPS negative urgency assessment, and nicotine use initiation was preserved. Of the 239 nicotine use initiators in the primary sample, 109 had their selected UPPS assessment before nicotine use onset, whereas 130 had recorded nicotine use onset before the selected UPPS assessment. Exclusion of the latter participants yielded 5835 participants and 109 events; after restriction to complete covariate data, the adjusted sensitivity models included 5345 participants and 96 events.

Weekend texting remained associated with subsequent nicotine use initiation in the temporally ordered sample (HR=1.11, 95% CI 1.06 - 1.16; P<.001). After adjustment for negative urgency, the association remained significant (HR=1.10, 95% CI 1.05 - 1.16; P<.001), and negative urgency was independently associated with nicotine use initiation (HR=1.11, 95% CI 1.02 - 1.21; P=.01). Inclusion of negative urgency attenuated the weekend texting log-hazard coefficient by 6.8%. There was no evidence of violation of the proportional hazards assumption (global P=.83 for both models).

Sensitivity Analysis Using Visit-Based Nicotine Use

Sensitivity analyses using a fallback definition of nicotine use initiation based on the first observed nicotine use at follow-up visits yielded consistent results with slightly larger effect sizes. In these models, both weekend texting screen time and negative urgency remained strongly associated with nicotine use initiation, and model discrimination was higher, reflecting increased event capture in this framework.

Overall, the association between weekend texting and nicotine use initiation was robust across alternative outcome definitions.

Discussion

Principal Findings

In this longitudinal analysis of nicotine-naive early adolescents, greater weekend texting screen time was associated with increased risk of subsequent nicotine use initiation. This association persisted after adjustment for demographic covariates and remained statistically significant after adjustment for negative urgency. Weekend texting was also positively associated with negative urgency, and negative urgency was independently associated with nicotine use initiation. Adjustment for negative urgency produced modest attenuation of the texting-initiation association, suggesting that the two measures

XSL•FO
RenderX

capture partially overlapping information relevant to early nicotine use risk.

Importantly, negative urgency was not uniformly measured before nicotine use initiation in the primary analytic sample, precluding a strong temporal or causal mediation interpretation. However, in a sensitivity analysis restricted to participants with temporally ordered STQ, UPPS, and nicotine use onset assessments, both weekend texting and negative urgency remained associated with subsequent nicotine use initiation. These findings support the robustness of the observed associations while indicating that negative urgency accounts for only a modest portion of the texting-initiation relationship.

Interpretation of Effect Sizes

Although the per-hour association was modest, larger exposure differences were associated with clinically meaningful increases in nicotine use initiation risk. A 5-hour increase in weekend texting corresponded to an approximately 30% to 40% higher hazard of initiation, with modest attenuation after accounting for negative urgency. Consistent with this, standardized models indicated that a 1-SD increase in weekend texting screen time was associated with a 21% higher hazard of initiation. Given the highly skewed distribution of texting behavior, such increments represent meaningful shifts in exposure and suggest that high-intensity digital engagement may carry substantive risk.

Negative urgency demonstrated a robust association with use initiation. A 1-SD increase in negative urgency corresponded to approximately 50% higher hazard of nicotine use onset, consistent with extensive literature linking urgency-related impulsivity to early substance use and escalation. These findings reinforce the central role of affect-driven impulsive behavior in adolescent nicotine vulnerability.

Comparison With Existing Literature

Prior research has demonstrated associations between overall screen time and adolescent substance use, including smoking and vaping [8,9]. However, much of this literature has relied on cross-sectional designs, aggregated heterogeneous forms of screen behavior, or failed to establish temporal ordering between exposure and initiation [10,17]. By restricting analyses to nicotine-naive adolescents and using prospective time-to-event modeling, the present study strengthens inference regarding temporal sequencing.

Our focus on weekend texting should not be interpreted as evidence that weekend exposure is uniquely associated with nicotine use initiation or that weekday texting and other interactive digital behaviors are unimportant. Rather, weekend texting represents the specific measure of discretionary, socially interactive digital engagement examined in the present study. Future studies directly comparing weekday and weekend texting and other screen modalities will be necessary to determine whether the observed association is specific to weekend messaging or reflects broader patterns of digital social engagement.

Few studies have examined specific interactive forms of screen engagement such as texting and messaging. Text-based communication may differ from passive screen behaviors (eg, television viewing) in that it involves real-time social interaction, emotional salience, and peer reinforcement [15,28]. Consistent with this distinction, prior literature has suggested that screen time requiring interaction with others, such as texting, may be more strongly associated with vaping than more passive forms of screen use, such as watching videos [29]. Such environments may amplify social contagion effects or increase exposure to peer norms related to substance use [30,31].

The observed role of negative urgency aligns with theoretical models emphasizing affect regulation and impulsivity as key drivers of adolescent risk behavior. Youth high in negative urgency may be more likely to engage in maladaptive coping strategies, including substance use, particularly in emotionally charged contexts [11,12,14]. Digital communication environments may heighten emotional reactivity, social comparison, or interpersonal stress, thereby interacting with urgency-related traits [16,28]. Our findings provide empirical support for this conceptual framework.

Negative Urgency and Potential Mechanisms

The attenuation of the texting coefficient after inclusion of negative urgency suggests that negative urgency statistically accounts for a modest portion of the association between weekend texting and nicotine use initiation. This interpretation was supported by the temporally ordered sensitivity analysis, in which both weekend texting and negative urgency remained associated with subsequent nicotine use initiation. However, these findings should not be interpreted as establishing negative urgency as a causal mediator or as indicating that texting episodes directly provoke nicotine use through acute negative affect. Rather, greater digital social engagement and negative urgency may represent correlated behavioral and individual-level characteristics associated with vulnerability to early nicotine use initiation [32,33].

This pattern suggests that additional mechanisms, as well as sources of residual confounding, likely contribute. These may include peer network exposure and social influence processes [30], digital advertising and product marketing [34,35], sensation-seeking tendencies not fully captured through negative urgency [36], and sleep disruption associated with high digital engagement [37]. Future work should examine these pathways directly, potentially incorporating peer network analyses, ecological momentary assessment, or digital trace data.

Generalizability

The large and diverse ABCD cohort provides an important opportunity to examine risk factors for nicotine use initiation beginning in early adolescence. However, participants were approximately 10 years old at the baseline texting assessment, and nicotine use initiation during the observed follow-up therefore represents relatively early onset. The findings should consequently not be generalized to nicotine use initiation across the full adolescent age range, particularly initiation occurring during mid- or late adolescence, when prevalence is substantially higher. Instead, the present results identify behavioral and individual difference correlates of comparatively early nicotine use initiation. Replication across later developmental periods

XSL•FO
RenderX

will be important. Because assessments used in the present analyses spanned 2019 to 2024, the observed associations reflect the nicotine product and digital media environments during that period; both environments have continued to evolve.

Limitations

Several limitations warrant consideration. First, texting screen time was self-reported and may be subject to recall bias or social desirability effects. Objective digital use metrics would strengthen future studies. Second, although the prospective design improves temporal inference, residual confounding cannot be excluded. Unmeasured variables such as peer substance use, parental monitoring, or mental health symptoms may partially account for observed associations. Additionally, other screen modalities, particularly social media use, may confound this association as adolescents who text heavily on weekends may also have greater exposure to peer modeling or nicotine-related content online.

Third, the timing of the negative urgency assessment varied across participants. For approximately half of the analytic sample, the UPPS assessment took place within 1 day of the STQ assessment, whereas for others, the selected UPPS assessment took place substantially later. Moreover, among some participants who initiated nicotine use, the selected UPPS assessment took place after the recorded nicotine use onset date. This timing precludes interpretation of the primary negative urgency analyses as demonstrating causal mediation. We therefore interpret negative urgency as statistically accounting for part of the observed association rather than as an established causal intermediary. Reassuringly, sensitivity analyses restricted to participants for whom STQ assessment preceded UPPS assessment and UPPS assessment preceded nicotine use initiation yielded consistent associations for both weekend texting and negative urgency. Nevertheless, studies with prospectively scheduled and clearly separated exposure, mediator, and outcome assessments are needed to establish mediation.

Future Directions

Future research should extend this work in several ways. First, incorporating objective digital use data would allow for more precise quantification of exposure patterns and timing. Second, examining additional impulsivity facets and affect regulation constructs may clarify which personality dimensions most strongly link digital engagement to substance use risk. Third, integrating peer network measures could test whether social contagion mediates part of the association. Fourth, longitudinal models that evaluate reciprocal influences among digital engagement, impulsivity development, and substance experimentation would deepen mechanistic understanding.

From a prevention standpoint, these findings suggest that adolescents with high digital engagement and elevated negative urgency may benefit from interventions targeting emotion regulation and coping skills. Digital literacy efforts may also help reduce exposure to substance-related content in online social environments.

Conclusions

In a longitudinal cohort of nicotine-naive early adolescents, greater weekend texting screen time was associated with a higher hazard of subsequent nicotine use initiation. Negative urgency was independently associated with initiation and modestly attenuated the texting-initiation association. These associations persisted in a sensitivity analysis requiring temporal ordering of texting assessment, negative urgency assessment, and nicotine use initiation. Although these findings do not establish negative urgency as a causal mediator, they suggest that digital engagement and affect-driven impulsivity represent partially overlapping correlates of early nicotine use risk. Future longitudinal studies with clearly separated assessment of exposure, potential mediators, and nicotine use onset are needed to clarify the mechanisms underlying these associations.

Acknowledgments

The authors extend their heartfelt appreciation to the participants and their families, whose involvement made the Adolescent Brain Cognitive Development study possible. Their commitment, time, and openness in sharing their experiences are critical to advancing research in this area. Their contributions form the cornerstone of this work, enabling a deeper understanding of adolescent development and supporting efforts to enhance health and well-being for future generations. The authors are deeply thankful for their participation—this research would not be possible without them.

Funding

This study was funded by the National Institute on Alcohol Abuse and Alcoholism through grant K23 AA026869 awarded to ADM. The Adolescent Brain Cognitive Development study is supported by the following grants: U01DA041022, U01DA041028, U01DA041048, U01DA041089, U01DA041106, U01DA041117, U01DA041120, U01DA041134, U01DA041148, U01DA041156, U01DA041174, U24DA041123, and U24DA041147.

Data Availability

This study used data from the Adolescent Brain Cognitive Development study [38], a longitudinal research initiative funded by the National Institutes of Health. Abstract

Background: Screen time (ST) is the time spent using screen-based devices and has become a global health concern. Excessive ST negatively impacts children's health and development; however, it has been increasing dramatically among young children. Parents are the primary caregivers responsible for monitoring children's ST. Therefore, identifying potential barriers and their attributes is fundamental to taking early action.

Objective: The study aimed to assess barriers to reducing excessive ST and the factors associated with these barriers among mothers of under-five children in Woliso City Administration, Central Ethiopia.

Methods: A community-based cross-sectional study was conducted from January 10, 2024, through February 29, 2024. A systematic random sampling technique was used to select 423 mothers of under-five children. EpiData (version 3.1) was used for data entry, and SPSS (version 20) was used for analysis. Linear regression analysis was used to identify factors associated with barriers to reducing ST. The multiple linear regression assumptions were checked, and statistical significance was declared at $P<.05$ with 95% CIs.

Results: A total of 423 participants were involved in this study (a 100% response rate). The mean score of barriers among mothers was 4.28 (SD 1.04). Educational status of the mother (β=−0.130, 95% CI −0.255 to −0.004), child's ST (β=0.369, 95% CI 0.328-0.409), parental attitude (β=−0.382, 95% CI 0.264-0.499), parental perceptions of the effect of ST on cognitive well-being (β=0.021, 95% CI 0.009-0.034), parental restrictive practices regarding ST (β=−0.011, 95% CI −0.004 to −0.018), and availability of public facilities (β=0.849, 95% CI 0.759-0.940) were shown to have a significant association with parental barriers.

Conclusions: Most mothers of under-five children experienced 4 barriers to reducing ST. The study also identified 6 factors associated with barriers to reducing ST, including level of education, attitudes toward ST, restrictive practices, perceptions of cognitive effects, children's ST, and lack of public facilities. Enhancing access to public spaces, implementing educational programs, and developing community initiatives are recommended to overcome these barriers and support healthy screen habits.

Introduction

Screen time (ST) refers to a person's time spent using screens or digital devices such as smartphones, tablets, televisions, video games, computers, or wearable technology [1-3]. According to the World Health Organization (WHO), children under the age of 2 years should not have any ST, whereas those aged 2 to 5 years are recommended to limit their ST to a maximum of 1 hour per day. Individuals exceeding these guidelines are classified as having excessive ST [2].

Recently, ST has emerged as a global health concern [4]. The duration of exposure to screen-based devices has been progressively increasing over time [1]. Notably, a substantial proportion of young children are currently exceeding the WHO's recommendations for ST [5]. For instance, in Singapore, children aged 2 years have an average ST of 2.4 (SD 2.2) hours per day [6]. In Canada, the mean ST for children is 1.4 hours per day at age 5 and 1.5 hours per day at age 3 [7], while in Ontario, 13.6% and 43.5% of children exceed 2 hours per day and 1 hour per day, respectively [8]. Furthermore, in the United Kingdom, 75% of children aged 12 months exceed zero ST [9]. In addition,

XSL•FO
RenderX

excessive ST is observed in Latin America (47%), Brazil (66.05%), and Malaysia (91.4%), where children spend significant amounts of time on screens [10-12]. Specifically, in Australia, children at 6 months of age are exposed to screens for an average of 1 hour and 16 minutes per day, which increases to 2 hours and 28 minutes by 24 months, with some children exceeding 3 hours per day [13]. Moreover, in Japan, 29.4% of children aged 18 months and 24.5% of children aged 30 months watch television for 4 or more hours per day [14]. In Portugal, about 85% of children under 2 years and 80% of infants aged 6 to 12 months are exposed to screens daily, with 79% spending up to 1 hour per day [15]. Similarly, a recent study in Ethiopia reported that 75.9% of under-five children had excessive ST, underscoring that this global concern is also highly prevalent in local Ethiopian settings [16].

Excessive ST causes various problems in children. It compromises both physical and cognitive development in young children and is positively associated with obesity, sleep problems, depression, and anxiety [17]. It generally leads to delays in all developmental domains, including physical, cognitive, mental, social, and scholastic [18,19]. Physically, it contributes to obesity [3,20,21], a sedentary lifestyle [3], disturbed sleep [22-24], headaches [3], eye strain [3,25], and musculoskeletal pain, such as in the neck, back, and wrists [3]. Mentally, it is linked to communication delays, including expressive speech delay [3,19,26,27], repression or delay in cognitive and motor development [19,27,28], hyperactivity-inattention [3,14], autism spectrum disorder [29], aggressive behavior [3], antisocial behavior [14], a desire for instant gratification [3], and poor concentration [3,7]. Additionally, it leads to fear of missing out, fear of being left out, media addiction, self-harm, anxiety, and depression [3]. Socially, excessive ST causes delays in socioemotional development [19], reduced socialization, and increased social anxiety [3]. Scholastically, it is associated with decreased academic performance [3]. These adverse effects underscore the necessity for parents to limit their children's ST to recommended levels [1-3,23].

Parents play a crucial role in shaping their child's screen usage, as they are their child's first teachers [4,30,31]. They have significant control over their child's health behaviors during the younger years [32], and children tend to adopt habits established in early childhood throughout their lives [22]. Parents should act as role models for healthy screen use, limit their own media use, and model online etiquette. Attentive parenting requires face time away from screens [3,23]. While both parents influence children's screen use, this study focused exclusively on mothers because they are the primary caregivers in most Ethiopian households, particularly during the early years of child development. Mothers typically spend more time with under-five children than fathers. Therefore, examining maternal perspectives provides the most relevant insights into parental barriers to reducing ST in this context.

Parents face multifaceted challenges in monitoring their children's ST. Common barriers include societal pressure to use screens, children's enjoyment of ST, busy family schedules, poor weather limiting outdoor play, and the perceived need for ST for educational purposes [33]. Additionally, parents often face a lack of time, parental fatigue [34], and safety issues [35]. A Reddit content analysis during the COVID-19 pandemic highlighted various barriers, including competing work and in-home obligations, using screens to occupy children during travel, children's screen use with other caregivers, offering ST while parents needed rest, pandemic-related changes in routine, and using screens to encourage necessary behaviors [36]. A study from Selangor, Malaysia, reported an overall mean score of 3.51 (SD 0.83) for parental barriers [37].

Despite rapid urbanization and increasing access to digital devices, there has been limited information about the concept of ST and parental barriers in supervising their children's screen use. Yet there are no national guidelines or structured interventions to help parents manage screen exposure in early childhood. Moreover, caregiving practices, including reliance on screen devices to calm a baby or to complete household chores, may complicate efforts to reduce screen use. Socioeconomic disparities and limited access to public facilities further exacerbate barriers to reducing ST.

Identifying and understanding barriers to reducing ST is crucial for developing effective interventions to promote healthy screen usage among children under-five. However, there has been limited information available about parental barriers to reducing children's ST and associated factors. As this was the first study of its type in Ethiopia, it may shed light on the parental obstacles to monitoring their children's ST, and the information obtained from this study may be used as a foundation for future studies in the field.

Accordingly, this study aimed to answer the following research questions:

1. What is the mean level of barriers to reducing children's ST among mothers of under-five children in Woliso City Administration?
2. What factors are associated with barriers to reducing children's ST?

Methods

Study Design and Setting

A community-based cross-sectional study was conducted from January 10, 2024, through February 29, 2024, in Woliso City Administration. The city is in Oromia Regional State, about 114 km southwest of Addis Ababa, the capital city of Ethiopia. Ethiopia is rapidly shifting from an agrarian lifestyle to urbanization [38]. The country is also undergoing a digital revolution as a result of the national initiative "Digital Ethiopia," which is playing a crucial role in access to digital devices and increased usage [39]. As a result, about 85.4 million and 28.6 million people are actively using mobile phones and the internet, respectively [40]. In particular, about 94.8% of parents in Woliso City had screen devices, of which 99.4% were mobile phones [16].

Regarding ST and the physical environment, about 54.5% of Ethiopian children and adolescents adhere to the sedentary recreational ST guidelines, whereas only 43% of children and adolescents have access to physical activity settings [41,42]. In

XSL•FO
RenderX

Woliso City, only 26.7% of parents reported having available playgrounds, and about 56.8% of children had outdoor playtime of more than 1 hour [16].

Generally, the study setting (Woliso City) has 4 administrative kebeles (lower administrative units)—namely Ayetu, Egersa, Burka Gudina, and Hora—with an estimated 15,476 households. As of 2014, the estimated total population of the city was 118,000, including 19,389 children under the age of 5 years.

Study Participants and Eligibility Criteria

All mothers of under-five children living in the Woliso City Administration were the source population. All mothers of under-five children who were permanent residents of the city and willing to participate were included in the study. However, mothers who did not have a screen device or whose children were blind were excluded from the study.

Sample Size Determination and Sampling Method

The sample size needed for this study was determined using the single-population proportion formula, considering a 95% CI level, a 5% margin of error, and a 50% proportion of occurrence. After adding a 10% nonresponse rate, a sample size of 423 was obtained and allocated proportionally across kebeles. A systematic random sampling technique was used, targeting every 36th household. The first household was selected by lottery method. In each selected household, mothers or guardians of under-five children were approached and invited to participate. Data collectors explained the study objectives, obtained informed consent, and administered the questionnaire to eligible respondents.

Data Collection Instruments and Techniques

Four data collectors and 1 supervisor conducted the data collection using a validated, structured, and pretested interviewer-administered questionnaire adapted from a previous study [37], after translating it into the local languages (Afan Oromo and Amharic). The questionnaire contained sociodemographic information, child-related factors, parental factors, parental barriers to reducing ST, home environment–related questions, and neighborhood environment–related questions.

Sociodemographic factors include information related to family size, age of the mother, age of the father, marital status, educational status of both parents, occupation of both parents, religion, ethnicity, number of rooms in the house, and monthly income.

Regarding child-related factors, the questionnaire included age, sex, number of children, ST in minutes, and childcare facility. A child's average daily ST, reported by parents, was calculated by multiplying weekday ST by 5 and weekend ST by 2, then dividing the sum by 7 [6].

For parent-related factors, the questionnaire assessed both parents' average daily ST. Parental self-efficacy in reducing their child's ST was evaluated using a single question rated on a 5-point scale, ranging from "not at all confident" to "very confident." Then the scores were divided into 3 categories based on percentiles [8,37]. Parents' attitudes toward ST were evaluated by an 8-item questionnaire on a 5-point Likert scale, ranging from 1 ("strongly disagree") to 5 ("strongly agree"), where scores above 32 indicated a positive attitude [8,10,37]. Additionally, parental perceptions were assessed using 11 questions that examined the effects of ST on their child's physical, cognitive, and social well-being [43]. They rated the influence as 1 ("negative impact"), 2 ("no impact"), or 3 ("positive impact"), with higher scores indicating a more positive effect on their child's specific well-being [37]. Parenting style was assessed using an adapted version of the Steinberg instrument, a widely used tool for measuring parenting style [44]. Two dimensions were measured: involvement (9 items) and strictness (6 items) on a 5-point scale from 1 ("strongly disagree") to 5 ("strongly agree"). Based on the Baumrind classification, parents were categorized into 4 groups according to the median split of involvement and strictness [45]. Furthermore, parental restrictive practices on ST were assessed by 6 sedentary-related restrictive practice questions on a 5-point Likert scale, in which higher scores reflected more restrictive practices [46].

Home environment–related factors include information on the number of screen devices, the presence of screen devices in the child's eating, playing, or sleeping rooms, and the presence of outdoor playthings. The neighborhood environment–related factors include questions about the availability of public facilities or a garden, perceived safety from crime, and perceived pedestrian safety.

Lastly, the outcome variable of this study, parental barriers to reducing a child's excessive ST, was assessed using 6 items adapted from validated instruments [8,37]. Each item was rated on a 5-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree"). Item scores were averaged to produce a continuous barrier score ranging from 1 to 6, with higher values indicating stronger perceived barriers [8,37]. Internal consistency was confirmed with Cronbach α of 0.82, demonstrating good reliability.

Data Quality Control

The data quality was meticulously ensured from the collection to the analysis stages. The standardized questionnaire was translated into Afan Oromo and Amharic, and then back into English. The researchers and the supervisor conducted regular checks for inconsistencies or missing data, and the data were coded and cleaned before analysis. Moreover, comprehensive training was provided to data collectors and supervisors on data collection tools, procedures, ethics, study aims, and participants' rights.

Data Processing and Analysis

EpiData (version 3.1; EpiData Association) was used for data entry and SPSS (version 20.0; IBM Corp) was used for analysis. All normality assumptions were tested and met for the continuous variables. Descriptive statistics were presented as frequency tables and in-text narratives. Dummy tables were created for all categorical variables, and bivariate linear regression analysis was conducted. All independent variables with $P<.25$ in the bivariate analysis were entered into the multiple linear regression model. Key assumptions were

XSL•FO
RenderX

assessed and met: linearity was checked using scatterplots, homoscedasticity by examining residual plots, normality of residuals with histograms and the Shapiro-Wilk test, and multicollinearity using variance inflation factors (all <2). Statistical significance was set at $P<.05$, and unstandardized β coefficients with 95% CIs were reported.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki. Accordingly, an ethical approval letter (reference number: IRB/23117/2023) was first obtained from the Arba Minch University Institutional Research Ethics Review Board Office. Then, a letter of support was submitted to the Woliso Town Administration to facilitate cooperation during data collection. After explicitly explaining the study's aim, benefits, and risks, written informed consent was obtained from each participant. To maintain the confidentiality of participants' information, personal identifiers, including names and house numbers, were anonymized.

Results

Sociodemographic Characteristics of Participants

A total of 423 parents took part in this study, resulting in a 100% response rate. The majority of participants were married (n=412, 97.4%), and three-quarters had a moderate (4-6) number of total family members (n=321, 75.9%). The mean ages of mothers and fathers were 31.29 (SD 5.511) and 37.32 (SD 5.939) years, respectively. Approximately half of the mothers (n=223, 52.7%) and the majority of fathers (n=343, 81.1%) completed college or higher education. In terms of employment, 188 (44.4%) mothers were unemployed, while most fathers, 415 (98.1%), were employed. Most participants were identified as Oromo, totaling 374 (88.4%) and 236 (55.8%) of participants reported following the Protestant religion. Around one-third (n=144, 34.0%) of participants earned less than 11,000 Ethiopian Birr (ETB 1=US $0.02 as of February 29, 2024), and one-quarter of participants lived in homes with 2 or fewer rooms (Table 1).

Child-Related Factors

In this study, the mean age of under-five children was 29.1 (SD 14.818) months. More than half of the children were male (n=233, 55.1%), and approximately one-fifth were an only child (n=97, 22.9%). Nearly half, 223 (52.7%), of the children received home care from their parents (Table 2). Additionally, the mean ST of under-five children in this study was 2.268 (SD 1.425) hours per day.

Parental-Related Factors

The mean ST of mothers and fathers was 2.39 (SD 1.27) and 3.16 (SD 1.72) hours per day, respectively. In this study, approximately 190 (44.9%) of mothers had low self-efficacy to say no to their child's ST. In addition, about one-third (n=129, 30.5%) of participants held a positive attitude toward their child's ST. Regarding parenting style, approximately 165 (39.0%) participants were identified as neglectful (Table 3). The mean scores for parental perceptions of the effects of ST on children's physical, cognitive, and social well-being were 6.95 (SD 2.31), 8.09 (SD 2.65), and 5.73 (SD 1.92), respectively. Moreover, the mean score of parental restrictive practice concerning ST was 19.74 (SD 6.45).

Home Environment–Related and Neighborhood Environment–Related Factors

A significant majority of participants (n=401, 94.8%) had at least 3 screen devices in their homes, and approximately 197 (46.6%) parents placed a TV in the room where their child plays, eats, or sleeps. Additionally, 345 (81.6%) parents provided outdoor play equipment for their children, while only 122 (28.8%) parents reported the availability of public facilities, gardens, or playgrounds in their neighborhood (Table 4). Moreover, the mean scores for perceived safety concerning crime and pedestrian issues were 17.50 (SD 6.76) and 17.37 (SD 4.94), respectively.

Barrier to Reducing Children's ST

The overall mean score of barriers toward reducing their child's ST was 4.28 (SD 1.04), with the most common challenges including the need for time to complete household chores, poor weather conditions, and the fact that their child enjoys screen-based activities (Table 5).

[a]ETB: Ethiopian Birr.

[b]ETB 1=US $0.02 as of February 29, 2024.

[c]ST: screen time.

In the bivariate analysis, educational status of mothers and the availability of screen devices in the child's bedroom were identified as having a negative association with parental barriers to reducing ST. Accordingly, mothers of under-five children who had primary education (β=−0.416, 95% CI −0.772 to −0.060; *P*=.02), mothers of under-five children with college education or above (β=−0.243, 95% CI −0.457 to −0.030; *P*=.03), and not having screen devices in the bedroom (β=−0.325, 95% CI −0.523 to −0.127; *P*=.001) were associated with fewer barriers.

On the other hand, factors found to be positively associated with parental barriers to reducing ST included marital separation (β=1.184, 95% CI 0.565 to 1.802; *P*<.001), child's ST (β=0.650, 95% CI 0.618-0.683; *P*=.02), mother's ST (β=0.097, 95% CI 0.019-0.174; *P*=.02), moderate maternal self-efficacy to say no to ST (β=0.361, 95% CI 0.050-0.671; *P*=.02), low maternal self-efficacy to say no to ST (β=0.381, 95% CI 0.169-0.593; *P*<.001), positive maternal attitude (β=0.451, 95% CI 0.232-0.670; *P*<.001), perception of the influence of ST on the child's cognitive well-being (β=0.046, 95% CI 0.009-0.084; *P*=.02), restrictive practices regarding ST (β=0.087, 95% CI 0.074-0.101; *P*<.001), providing outdoor playthings (β=1.523, 95% CI 1.256-1.791; *P*<.001), presence of public facilities such as gardens and playgrounds (β=1.739, 95% CI 1.594-1.884; *P*<.001), perceived crime safety (β=0.035, 95% CI 0.021-0.049; *P*<.001), and perceived pedestrian safety (β=0.032, 95% CI 0.012-0.052; *P*=.002).

Factors Associated With Barriers to Reducing a Child's ST

In the simple linear regression analysis, 22 variables with a *P*<.25 were identified and included in the multiple linear regression models. All assumptions for multiple linear regression were met, and the explanatory variables in the final models explained about 89.4% of the variation in barriers to reducing ST (R^2=0.894 and adjusted R^2=0.892). The multiple linear regression analysis revealed that educational status of the

XSL•FO
RenderX

mother, the child's ST, attitude, perceptions of the effect of ST on cognitive well-being, restrictive practices regarding ST, and the availability of public facilities were significantly associated with barriers to reducing their under-five children's ST.

In this study, mothers of under-five children with only a primary school education faced fewer barriers compared to those with a secondary school education (adjusted β=−0.130, 95% CI −0.255 to −0.004; *P*=.04). Additionally, participants with a positive attitude toward child ST were more likely to encounter higher barriers in reducing ST than those with a negative attitude (adjusted β=0.382, 95% CI 0.264-0.499; *P*<.001). For each unit increase in perceptions of the effect of ST on a child's cognitive well-being, the mean score of barriers was increased by 0.021 (adjusted β=0.021, 95% CI 0.009-0.034; *P*=.001). Moreover, for a 1-unit increase in restrictive practices regarding ST, the mean score of barriers decreased by 0.011 (adjusted β=−0.011, 95% CI −0.004 to −0.018; *P*=.001). The only child-related factor that was significantly associated with parental barriers was the child's ST. Accordingly, parents whose children spent more hours on screens faced greater barriers to reducing ST (adjusted β=0.369, 95% CI 0.328-0.409; *P*<.001). Lastly, parents who indicated a lack of public facilities, gardens, or playgrounds in their area were more likely to experience higher barriers to reducing ST than their counterparts (adjusted β=0.849, 95% CI 0.759-0.940; *P*<.001) (Table 7).

Table . Factors associated with barriers to reducing children's screen time among mothers of under-five children in Woliso City Administration, Oromia, Ethiopia, 2024 (N=423).

[a]ST: screen time.

Discussion

Principal Findings

This study assessed barriers to reducing ST and its associated factors among mothers of under-five children in the Woliso City Administration. Accordingly, the study found that the mean barrier score was 4.28 (SD 1.04). Factors significantly associated with barriers to reducing ST included mother's educational status, child's ST, attitudes, perceptions of the effect of ST on cognitive well-being, restrictive practices regarding ST, and the availability of public facilities.

In this study, the mean score for barriers was found to be 4.28 (SD 1.04), which is notably higher than the mean score 3.51 (SD 0.83) reported in a previous Malaysian study [37]. The variation in scores could be attributed to differences in study populations, as this study focused solely on mothers, while the Malaysian study included both parents [37]. Research indicates that mothers often bear a larger share of managing children's routines and ST [47], and a recent systematic review also confirms that maternal caregiving roles remain central in moderating child ST [48]. Additionally, the difference in study settings may account for this variation. The nature of community-based studies, which reach a diverse population, often allows them to capture a broader range of everyday challenges and barriers experienced by parents. Socioeconomic status [37], cultural norms, and parenting practices [49] also likely contribute to these differences.

According to this study, mothers of under-five children with only a primary school education faced fewer parental barriers to reducing their children's ST compared with those with a secondary school education. This finding may be because mothers with higher education levels may have greater access to resources, support systems, and outdoor employment status, which can influence their ability to manage their children's ST effectively. This finding is congruent with research indicating that higher educational attainment often correlates with increased awareness of the potential negative impacts of ST, leading to more restrictive practices and fewer perceived barriers [50].

Additionally, mothers with a positive attitude toward ST were more likely to encounter higher barriers in reducing ST. This finding is supported by a study from Australia [49] and Malaysia [37]. Research indicates that parents' positive attitudes toward ST can lead to more permissive practices and a lower perceived need to restrict ST, thereby increasing the barriers they face in attempting to reduce it [49]. Conversely, parents with negative attitudes are more likely to implement stricter controls and face fewer barriers. Recent reviews also highlight similar findings, noting that parental attitudes and self-efficacy strongly influence barriers to ST reduction [49].

XSL•FO
RenderX

Furthermore, our study reported that there was a positive association between parental perceptions of the effects of ST on their child's cognitive well-being and barriers. This finding is supported by research indicating that parents who perceive ST as having a positive impact on cognitive development may face greater barriers [49]. When parents perceived ST to be beneficial to their child or themselves, it became a barrier for them to place necessary restrictions on ST activity [50,51]. This aligns with updated evidence showing that parental confusion and mixed perceptions about ST benefits remain a major barrier [48].

Apart from that, parental restrictive practices regarding ST were negatively associated with barriers to reducing ST. Parents who monitor and employ greater restrictions on ST may face fewer challenges in managing their child's ST due to the consistent enforcement of ST rules [49,52]. This finding is congruent with recent intervention studies that report that restrictive practices are effective strategies for reducing barriers [53].

Furthermore, our study reported that mothers whose children spent more time on screens faced greater barriers to reducing ST. This was supported by previous studies [8,37,54]. Increased ST can lead to more ingrained habits and screen addiction [3], making it extremely hard for parents to enforce restrictions, which can increase parental barriers [55].

Finally, our study reported that parents who indicated a lack of public facilities, gardens, or playgrounds in their area faced greater barriers to reducing ST. The absence of accessible outdoor spaces limits children's opportunity for physical activity, making it more challenging for parents to encourage alternatives to ST, thereby increasing barriers to reducing ST [56]. The UNESCO MGIEP (United Nations Educational, Scientific, and Cultural Organization—Mahatma Gandhi Institute of Education for Peace and Sustainable Development) highlighted that equitable access to green spaces is crucial for promoting healthy behaviors and reducing ST among children [57]. Additionally, community programs aimed at reducing ST were less successful in neighborhoods with limited green spaces, as children had fewer options for outdoor play [56].

These findings should be understood within Ethiopia's social environment, where childcare facilities such as kindergartens and nursery schools are limited, and playgrounds and safe outdoor spaces are scarce. Such contextual realities restrict opportunities for alternative activities and create barriers to reducing screen use. The broader social environment, including limited facilities and cultural caregiving practices, remains crucial for interpreting and designing locally tailored interventions.

Strengths and Limitations of the Study

To the best of our knowledge, this is a pioneering study in Ethiopia that identified barriers to reducing ST. Thus, it can be used as a baseline for future studies. Its community-based design ensured that diverse real-life challenges were captured. Comprehensive data collection through a validated questionnaire and a multilingual approach (Afan Oromo and Amharic) facilitated accurate responses. However, several limitations should be noted. First, the cross-sectional design limits causal inference. Second, reliance on self-reported ST may introduce recall bias, as parents may not accurately remember or estimate their child's daily screen use. Third, social desirability bias may have influenced responses, with some parents underreporting ST or overstating restrictive practices to align with perceived norms. The reliance on maternal reports of their partner's ST is also a limitation. Fourth, although we adjusted for multiple covariates, residual confounding cannot be ruled out, as unmeasured factors (eg, parental mental health) may also influence barriers. These limitations should be considered when interpreting the findings, and future longitudinal studies using objective measures of ST are recommended.

Implications for Practice

The findings from this study underscore the need for targeted interventions to reduce ST among young children. Health care providers, educators, and policymakers should prioritize enhancing access to public facilities, gardens, and playgrounds as alternatives to ST. Additionally, implementing educational programs for parents can raise awareness of the negative impacts of excessive ST and provide strategies for effective management. Community-based initiatives that create screen-free zones and organize family-friendly events can foster environments that support healthy screen habits. Health care professionals should integrate ST management guidelines into routine pediatric care, offering parents consistent support and personalized recommendations. Providing parents with practical tools and resources for monitoring and restricting ST can help to overcome identified barriers and promote healthier screen habits among children.

For the scientific community, this study highlights the importance of further research on the barriers and predictors of parental efforts to reduce ST in various cultural and socioeconomic settings. It encourages the development and testing of community-based initiatives and interventions that create supportive environments for reducing children's ST. Additionally, it advocates for policies that enhance access to public facilities, gardens, and playgrounds to promote healthy child development. By addressing a significant research gap, this pioneering study in Ethiopia provides valuable insights and potential solutions for both clinical practice and the scientific community, ultimately contributing to the global effort to manage and reduce children's ST.

Conclusions

Most mothers with a child aged younger than 5 years experienced 4 barriers in their efforts to reduce ST. In addition, this study identified several associated factors with barriers to reducing ST, including maternal education, parental attitudes, restrictive practices, perceptions of ST's cognitive effects, the child's ST, and lack of public facilities such as gardens and playgrounds. Based on these findings, we recommend that relevant bodies enhance access to public facilities and playgrounds to provide alternatives to screen use, implement educational programs for parents to raise awareness about the negative impacts of excessive ST, and develop community-based initiatives that support screen-free activities. Interventions should also address parental attitudes and misconceptions, promote balanced and evidence-based perspectives, and support

XSL•FO
RenderX

consistent restrictive practices such as monitoring and removing screens from children's bedrooms. Furthermore, community-based initiatives that encourage screen-free activities can complement household efforts, and integrating ST management guidelines into routine pediatric care will ensure that parents receive culturally appropriate support. Together, these measures can reduce barriers and foster healthier screen habits among young children.

Acknowledgments

The authors are pleased to express our heartfelt gratitude to the School of Nursing, College of Medicine and Health Sciences, Arba Minch University, for providing us with the opportunity to undertake this study. The authors also appreciate the study participants, data collectors, and supervisors who generously gave their invaluable time during data collection. Moreover, the authors thank the administrative staff of the town of Woliso for their hospitable and cooperative approach during data collection. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article. No generative AI tools were used in the preparation of this manuscript.

Funding

The authors declared no financial support was received for this work.

Data Availability

The data used in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

AD contributed to conceptualization, methodology, analysis, and preparing the manuscript. WG contributed to supervision, methodology, analysis, and editing the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The internet is highly convenient and has become an indispensable part of daily life. However, its widespread use also has notable disadvantages, such as the risk of internet addiction. Still, increased internet use may enhance eHealth literacy, and online health information seeking may contribute to health promotion. In Hong Kong, internet addiction and low physical activity among adolescents are growing concerns, underscoring the need to address internet use to better support the health and well-being of youth.

Objective: This study aimed to investigate the effects of internet use, eHealth literacy, and internet addiction on adolescents' physical activity in Hong Kong.

Methods: An online cross-sectional study was conducted in Hong Kong between June 2023 and August 2023. Secondary school students aged 12 to 18 years were recruited. Data were collected using the eHealth Literacy Scale, the International Physical Activity Questionnaire, the Chen Internet Addiction Scale, and a questionnaire assessing demographic characteristics and the use of eHealth technologies. Spearman ρ correlation and mediation analyses were performed to examine the relationships among variables.

Results: A total of 117 participants were included. Participants reported an average internet use of 5.28 (SD 3.50) hours per day, and the mean eHealth literacy score was 31.15 (SD 4.04). Correlation analyses revealed that internet use was positively correlated with internet addiction (r=0.33; P<.001) but negatively correlated with physical activity (r=−0.21; P=.02), and internet addiction was negatively correlated with physical activity (r=−0.26; P=.005). In addition, the mediation analysis demonstrated that both internet use and eHealth literacy had a direct effect on internet addiction (B=1.53, P<.001 and B=−0.91, P=.002, respectively). Internet addiction had a direct effect on physical activity (B=−43.94, P=.02). In contrast, eHealth literacy had no significant direct effect on physical activity and did not mediate the relationship between internet use and physical activity.

Conclusions: The findings highlight the importance of eHealth literacy in reducing internet addiction. However, future research should further examine factors that mediate the relationship between eHealth literacy and physical activity or other health-related behaviors. This study sheds light on the benefits of promoting eHealth literacy among adolescents to prevent internet addiction and offers practical insights for teachers and parents.

eHealth literacy; internet use; internet addiction; physical activity; adolescents

Introduction

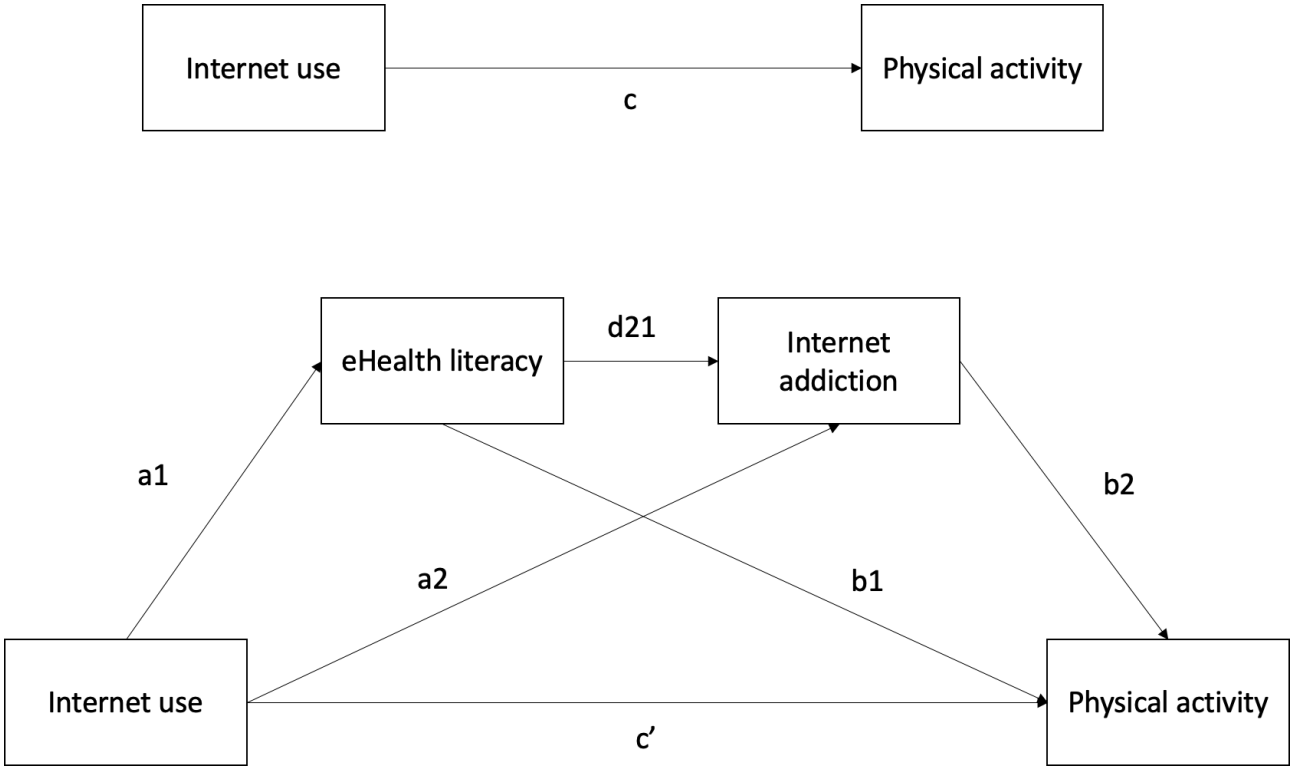
The internet has transformed modern life and has become an integral part of our daily activities by providing widespread access to information and connectivity [1]. However, these benefits are accompanied by potential drawbacks, including the risk of addiction. Internet addiction is a growing global concern, and a substantial body of research suggests that excessive internet use can lead to various adverse health outcomes, including distress and impairment in daily functioning [2].

In Hong Kong, the prevalence of internet addiction among adolescents ranged from 17% to 26.8% over the 6-year longitudinal study from the 2009 to 2010 to 2015 to 2016 school years [3]. A review by Chung et al [4] found an increasing prevalence, consistent with the upward trend in internet use

XSL•FO
RenderX

among adolescents over the past decade. Moreover, internet-related behaviors, including excessive smartphone use, have intensified since the COVID-19 pandemic disrupted daily routines [5]. Adolescents who spend more time using the internet have an increased risk of adverse outcomes, such as decreased physical activity and poor physical development [2]. Overall, these findings highlight the importance of addressing internet and smartphone use among adolescents to support their health and well-being.

The potential impact of internet addiction on physical activity and cardiovascular health has elicited concern [6-9]. Problematic internet use has been associated with physical inactivity among high school students [10,11]. Physical inactivity and sedentary behavior can lead to adverse health problems, such as obesity and cardiovascular disease [12]. For instance, children who engage in sedentary behaviors, such as screen viewing, were found to be approximately 5.68 times more likely to become overweight [13]. Furthermore, adolescents with low physical activity levels were reported to be 7.69 times more likely to have high blood pressure [14]. These findings indicate the need to identify potential protective factors that might reduce internet addiction and promote physical activity.



Longer time spent using the internet may facilitate health information seeking online [15]. eHealth literacy is defined as the ability to seek, find, understand, and appraise health information from electronic sources and to apply the knowledge gained to address or solve health problems [16]. This concept has become increasingly important because the internet has become a major source of health information, and digital health interventions have become more common [17]. Studies have reported that eHealth literacy is a significant predictor of health-promoting behaviors, including physical activity, nutritional behaviors, life appreciation, social support, stress management, and health responsibility, among adolescents [18,19]. These findings highlight the benefits of promoting eHealth literacy among young individuals. Evidence suggests that a poor health status and unhealthy lifestyle during adolescence are associated with poor health in adulthood [20,21]. Thus, eHealth literacy appears to be a protective factor worthy of further investigation. Furthermore, a study reported a negative association between health literacy and internet addiction [22]. To further explain the potential relationships among internet use, eHealth literacy, internet addiction, and physical activity, social cognitive theory provides a useful theoretical framework [23]. This theory emphasizes the dynamic interactions among personal, environmental, and behavioral factors [23]. Within this framework, internet use may function as an environmental factor by providing access to public information and shaping attitudes and norms related to physical activity. Personal factors may be represented by eHealth literacy, which can influence personal beliefs and foster self-efficacy related to adopting physical activity, and by internet addiction, which may reflect low self-efficacy in regulating online behavior and serve as a maladaptive coping strategy that undermines physical activity. Physical activity, in turn, is the behavioral outcome.

Internet addiction and low physical activity levels among adolescents in Hong Kong have become growing concerns [3,24,25]. For instance, the Student Health Service Annual Health Report for the 2023 to 2024 school year reported that 96.1% of secondary school students did not meet the recommended physical activity levels [26]. Furthermore, the proportion of secondary school students engaging in recreational screen time for 2 or more hours per day increased from 78% in the 2022 to 2023 school year to 80.9% in the 2023 to 2024 school year [26]. Enhancing eHealth literacy can help address internet addiction and insufficient physical activity among adolescents. However, although studies on eHealth literacy have been conducted in Hong Kong, they have mainly focused on adults [27,28]. Thus, little is known about eHealth literacy among Hong Kong adolescents. Furthermore, to the best of our knowledge, no study has examined the relationships among eHealth literacy, internet addiction, and physical activity in this population. This gap in the literature warrants further investigation. Evidence indicates that eHealth can positively affect health behaviors, and this potential should be specifically examined in relation to internet addiction and physical activity.

This study investigated the effects of internet use, eHealth literacy, and internet addiction on physical activity levels among adolescents in Hong Kong. In addition, this study examined the mediating role of eHealth literacy in mitigating the negative effects of internet use and internet addiction on physical activity (Figure 1). Specifically, we hypothesized that (1) internet use is positively associated with eHealth literacy, (2) eHealth literacy is negatively associated with internet addiction, (3) eHealth literacy is positively associated with physical activity, and (4) eHealth literacy and internet addiction mediate the relationship between internet use and physical activity.

Methods

Participants

A total of 7 secondary school students who participated in a research internship program at The Hong Kong Polytechnic University assisted with participant recruitment for this study after receiving approval from their respective schools. As the participating secondary schools did not have their own ethics review bodies, ethics approval for the study was obtained from the study institution. Participants were recruited through convenience sampling from the secondary schools attended by the student interns. After the study details were explained to students and their parents, students were invited to complete a set of questionnaires administered through Google Forms. Upon selecting "agree" on the Google Form, participants were directed to the questionnaire section. To minimize duplicate responses, participants were instructed to complete the questionnaire only once using their Google account. Data were collected between June 2023 and August 2023, which coincided with the summer school holiday period in Hong Kong. As students generally have more free time to use digital devices during the holiday, this period was selected for data collection.

The eligibility criteria for participation were as follows: (1) an age of 12 to 18 years, (2) status as a full-time secondary school student in Hong Kong, (3) ability to understand traditional Chinese, and (4) ability to use electronic devices to access the online survey. Individuals who self-reported neurological illnesses (eg, stroke and autism), functional disabilities (eg, blindness), or any form of psychosis or intellectual disability that could hinder completion of the online survey were excluded from participation.

A total of 123 responses were received. Of these, 5 respondents did not provide informed consent, and one did not meet the inclusion criteria. Therefore, 117 responses were included in the analysis. For sample size estimation, a confidence level of 95% was applied, with the margin of error set at 10% because of the relatively short data collection period and the estimated proportion was set to 0.5. On the basis of these parameters, the estimated required sample size was 96.

Outcome Measures

Demographic Information and eHealth Technology Use

Demographic information was collected, including participants' age, sex, grade, height, and weight. Furthermore, a set of questions was used to evaluate participants' use of technology and health-related applications, including (1) the amount of time spent on the internet per day and (2) whether technologies were used for health monitoring. The measured domains and the validity and localization testing of the instruments used are summarized in Table 1.

XSL•FO
RenderX

Table . Summary of instruments used in the test: domains measured and reference on validity testing or translation.

Instruments	Domains measured	Validity test and translation studies
eHealth Literacy Scale	Consumer's integrative knowledge, comfort, and perceived skills at searching, and evaluation and application of electronic information to address health-related problems	Koo et al [29]
International Physical Activity Questionnaire	Monitor activity habits over the previous 7 days, with focus on leisure, domestic, work, and transport	Macfarlane et al [30]
Chen Internet Addiction Scale	Compulsive use, withdrawal, tolerance, problems in interpersonal relationships, as well as health and time management	Chen et al [31]

eHealth Literacy Scale

The eHealth Literacy Scale (eHEALS) is a questionnaire designed to evaluate individuals' eHealth literacy. It includes items that measure self-perceived competence and confidence in finding, evaluating, and applying health information obtained from electronic sources [16]. This scale comprises 8 items, which are rated on a 5-point Likert scale. This study used the Chinese version of the eHEALS (C-eHEALS) [29]. Koo et al [29] examined the psychometric properties of the C-eHEALS. Additionally, the C-eHEALS was used in a study of adolescents in Hong Kong and demonstrated excellent internal consistency (Cronbach α=0.95) [32]. In this study, the C-eHEALS similarly exhibited high internal consistency (Cronbach α=0.92).

International Physical Activity Questionnaire

The Chinese version of the International Physical Activity Questionnaire (IPAQ)–Short Form (IPAQ-C) was used in this study [30]. This self-reported questionnaire assesses the amount of physical activity individuals engaged in during the past week [30]. An example item is as follows: "During the last seven days, on how many days did you participate in vigorous physical activities?" [30]. Responses are converted into metabolic equivalent of task (MET) values based on the duration and intensity of physical activity (MET=3.3 for walking, 4 for moderate physical activity, and 8 for vigorous physical activity) [30]. For example, if an individual walks for 60 minutes per day over 7 days, their MET score is calculated by multiplying 3.3 by 60 minutes and 7 days, yielding a total of 1386 METs. A higher MET score indicates a higher level of physical activity. The IPAQ-C demonstrated satisfactory psychometric properties and was validated among adolescents in Hong Kong [30].

Chen Internet Addiction Scale

The Chen Internet Addiction Scale (CIAS) is a self-reported instrument consisting of 26 items designed to assess various symptoms and problems related to internet use [31]. The scale covers 4 main dimensions: compulsive use, withdrawal, tolerance, and problems related to interpersonal relationships, health, and time management. The total CIAS score ranges from 26 to 104. Established cutoff points for screening (57/58) and diagnosis (63/64) are available to classify the severity of internet addiction. In addition, the total score can be used to assess the tendency toward internet addiction, with higher scores indicating greater severity [33]. In this study, only the total CIAS score was used for analysis. The Cronbach α for the CIAS was 0.95 in a previous study conducted in Hong Kong [34] and 0.95 in this study.

Data Analysis

Data are presented as mean (SD), unless otherwise indicated. After examining the distributional assumption, the normality assumption was found to be violated. Therefore, Spearman ρ correlation was used to examine the relationships between internet addiction, physical activity, eHealth literacy, and internet use among adolescents. A mediation model was then used to examine the role of eHealth literacy as a mediator in the relationships between internet use, internet addiction, and physical activity. The mediation analysis was conducted using model 6 of Hayes PROCESS macro in SPSS (IBM Corp). Specifically, internet use served as the independent variable, physical activity level (ie, the MET score derived from the IPAQ) served as the dependent variable, and eHealth literacy and internet addiction were specified as mediators of the relationship between internet use and physical activity (Figure 1). In addition, age, sex, and BMI were included as control variables. Bootstrapping with 5000 resamples was performed [35]. The 95% CI was defined by the lower limit CI and upper limit CI. Mediation effects were considered statistically significant if the CI did not include zero. All statistical analyses were conducted using SPSS (version 29.0.2), and a *P* value of<.05 was considered statistically significant.

Ethical Considerations

Ethics approval was obtained from the Institutional Review Board of The Hong Kong Polytechnic University (HSEARS20230701001). Before participation, parents were asked to provide electronic informed consent, and both students and their parents had to indicate agreement to participate. No compensation was provided to participants. All data collected were anonymized and stored in a password-encrypted database.

Results

A total of 117 participants completed the survey. Of these, 61.5% (72/117) were girls. The mean age of the participants was 15.9 (SD 1.29) years. The majority (n=50, 42.7%) of the participants were secondary school year 5 students. On average, the participants reported spending 5.28 (SD 3.50) hours per day using the internet, and the mean eHealth literacy score was 31.15 (SD 4.04). Table 2 presents the characteristics and scores of the participants.

XSL•FO

Table . Participant characteristics and scores of questionnaires (N=117).

	Values
Sex, n (%)	
Female	72 (61.5)
Male	45 (38.5)
Age (y), mean (SD)	15.9 (1.29)
BMI (kg/m^2), mean (SD)	20.2 (3.05)
Form, n (%)	
1	7 (6)
2	2 (1.7)
3	11 (9.4)
4	35 (29.9)
5	50 (42.7)
6	11 (9.4)
Missing	1 (0.9)
Internet use per day (h), mean (SD)	5.28 (3.50)
Use technology to monitor health, n (%)	
Yes	36 (30.8)
No	81 (69.2)
Physical activity, mean (SD)	2667.65 (2657.73)
Internet addiction (possible range 26 - 104), mean (SD)	63.00 (13.83)
eHealth literacy (possible range 8 - 40), mean (SD)	31.15 (4.04)

Correlations between internet use, internet addiction, eHealth literacy, and physical activity are presented in Table 3. Internet use was significantly and positively correlated with internet addiction (r=0.33; P<.001) and negatively correlated with physical activity (r=−0.22; P=.02). eHealth literacy was negatively correlated with internet addiction (r=−0.26; P=.005) but was not correlated with internet use or physical activity. Internet addiction was negatively correlated with physical activity (r=−0.25; P=.006).

Table . Spearman ρ correlation between internet use, internet addiction, eHealth literacy, and physical activity.

	1	2	3	4
Internet use	—[a]	—	—	—
Internet addiction	0.33[b]	—	—	—
eHealth literacy	0.06	−0.12	—	—
Physical activity	−0.21[c]	−0.26[d]	−0.05	—

[c]P<.05.
[d]P<.01.

The results of the mediation analysis are presented in Table 4 and Figure 2. Internet use had a direct effect on internet addiction (B=1.53; P<.001). eHealth literacy also had a direct effect on internet addiction (B=−0.91; P=.002). Internet addiction had a direct effect on physical activity (B=−43.94; P=.02). The findings revealed neither a direct effect of internet use on physical activity or eHealth literacy nor a direct effect of eHealth literacy on physical activity. Only one significant indirect effect was observed: internet use was indirectly associated with physical activity through internet addiction (B=−67.19, 95% CI −148.17 to −9.45).

Discussion

Principal Findings

This study examined the relationships between internet use, eHealth literacy, internet addiction, and physical activity. In particular, we hypothesized that eHealth literacy and internet addiction mediate the relationship between internet use and physical activity. The results indicated that internet addiction was the only significant mediator in this relationship. Although our findings revealed that eHealth literacy was not associated with internet use and physical activity, it had a direct effect in reducing internet addiction.

Our results revealed no significant association between time spent on the internet and eHealth literacy. This finding suggests that spending more time online does not necessarily improve individuals' ability to understand and use health-related information available online. This result contrasts with the findings of some previous studies. For instance, one study reported that more frequent use of information and communication technology was associated with a higher level of eHealth literacy [36]. Various factors may explain this discrepancy, including a lower level of trust in online health information than in information provided by clinicians [37] and the nature of online activities, which may be primarily entertainment oriented rather than health related [38]. In addition, experiences during the COVID-19 pandemic may have contributed to increased health awareness and, consequently, increased eHealth literacy [39]. Thus, the effect of recent internet use on eHealth literacy might be less pronounced than before. Overall, these findings indicate that although internet use is widespread, it does not automatically translate into improved eHealth literacy.

A significant negative relationship was observed between eHealth literacy and internet addiction, which supports one of our hypotheses. This finding indicates that a higher level of eHealth literacy is associated with a lower level of internet addiction. Individuals who are more familiar with searching for and understanding online health information might be more aware of the potential drawbacks of excessive internet use and thus may be better able to avoid behaviors that contribute to addiction [40]. This finding underscores the importance of enhancing eHealth literacy as a potential strategy for mitigating internet addiction and identifies a critical target for future intervention programs.

This study also examined the relationship between eHealth literacy and physical activity and found no significant relationship in either the correlation or the mediation analysis. Although previous studies have reported a positive relationship between eHealth literacy and physical activity [18,40], our results suggest that being literate in eHealth does not necessarily translate into increased engagement in healthy behaviors, such as physical activity. The lack of a significant relationship might be due to various external factors such as personal motivation, social influence, limited resources, academic demands, or other daily life commitments, which may play a more prominent role in affecting adolescents' willingness and opportunities to engage in physical activity [41,42]. Therefore, although eHealth literacy is an important ability in terms of accessing and understanding health information, it does not appear to affect physical activity behaviors directly; it may thus reflect a gap between health-related intentions and actual behavior [43]. Moreover, the perceived need to engage in health-promoting behaviors

XSL•FO
RenderX

might be another variable contributing to the nonsignificant results [44,45]. For instance, a study on the use of mobile health applications reported that individuals with severe obesity were more likely to use health applications to engage in health behaviors than individuals who were underweight [44]. In addition, a study by Weaver et al [45] examining the types of health information searching (wellness, illness, or mixed information) found that individuals who searched only for wellness-related information reported a better health status and a higher level of physical activity than those in other groups [45]. These findings indicate that although individuals may be confident in their ability to search for and use online health resources, not all individuals are motivated to change their lifestyle in favor of wellness. Some may consider themselves as healthy or may not prioritize health behavior changes at their current life stage. Individuals may possess eHealth literacy but engage with health information only when they perceive a need, such as searching for illness-related information when experiencing symptoms. The nonsignificant relationship between eHealth literacy and physical activity observed in this study might indicate that adolescents with eHealth literacy place less emphasis on promoting their wellness.

This study provides preliminary results regarding the use of health information from electronic sources among adolescents in Hong Kong. The level of eHealth literacy observed in our sample (mean 31.15, SD 4.04) was comparable to that reported in other countries, such as the mean score of 28.4 (SD 7.6) reported by Koo et al [29]. Although no official cutoff score exists for the eHEALS to define adequate eHealth literacy, a recent study on adults in China suggested a cutoff of 29.5 [46]. On the basis of this reference value, only 19.7% (23/117) of adolescents in this study scored below the suggested cutoff value, indicating that 80.3% (94/117) of our participants had adequate eHealth literacy. Furthermore, our results suggest that internet addiction could be reduced by increasing eHealth literacy. In addition to seeking health information online, adolescents also obtain health advice from school [47]. Thus, educators should consider incorporating electronic health information sources into classroom instruction or extracurricular activities. However, eHealth literacy was not associated with physical activity in this study. Future studies should examine the factors mediating the relationship between eHealth literacy and health-promoting behaviors. In particular, further investigation is needed to understand how eHealth literacy can be translated into actual health-related behaviors among adolescents.

This study has several limitations. First, all the measures were self-reported; therefore, the participants' responses may have been influenced by social desirability bias or inaccurate due to recall bias regarding, for example, the time spent on the internet and physical activity. Second, this study included a relatively small sample from a few secondary schools in Hong Kong. Thus, its generalizability is limited. Future studies with larger and more diverse samples are recommended to increase representativeness among Hong Kong adolescents.

Conclusions

This study investigated the relationships among internet use, eHealth literacy, internet addiction, and physical activity. The results provided preliminary evidence regarding the level of eHealth literacy among adolescents in Hong Kong. Furthermore, the results highlight the significant role of eHealth literacy in reducing internet addiction; however, eHealth literacy was not found to be associated with physical activity. Teachers and parents should promote adolescents' eHealth literacy as a strategy to support health and prevent internet addiction.

Abstract

Background: Screen-based media use among children has been increasing, particularly in lower socioeconomic groups. As this behavior is linked to obesogenic habits, it is crucial to examine the associations between screen-based media use and adiposity in primary schoolchildren, particularly those from socially vulnerable contexts, such as children from the Educational Territories of Priority Intervention program.

Objective: This study aimed to examine the associations between screen-based media use and adiposity in primary schoolchildren from socially vulnerable contexts.

Methods: This study, part of the BeE-school Project, included 735 children (mean age 7.7, SD 1.2 years; n=380, 51.7% boys and n=355, 48.3% girls) from 10 primary schools located in vulnerable contexts in northern Portugal. Researchers recorded weight, height, and waist circumference and calculated BMI *z* scores and the waist-to-height ratio (WHtR). Screen-based media use was reported by parents using the ScreenQ tool, which includes 4 domains (screen access, frequency of use, media content, and caregiver-child coviewing). Sociodemographic and anthropometric data of parents were obtained via a questionnaire. Generalized linear models were applied.

Results: A higher screen-based media use score was associated with higher BMI *z* scores and WHtR (b=0.064, 95% CI 0.034-0.094 and b=0.002, 95% CI 0.001-0.003, respectively) even after adjusting for children's sex and age and parents' education and BMI. Significant associations (P<.05) were also observed for the domains of screen access, frequency of use, and media content.

Conclusions: Screen-based media use is linked to higher BMI and WHtR in vulnerable children. Reducing screen access, limiting use frequency, and curating media content could improve health outcomes. Interventions for obesity prevention should consider these factors.

Trial Registration: ClinicalTrials.gov NCT05395364; https://clinicaltrials.gov/study/NCT05395364

KEYWORDS

screen-based media use; screen time; children; adiposity; obesity

Introduction

Children are now growing up in a technological society, with the use of electronic devices being an essential part of their lives [1]. This has led to an increase in personal screen media device use among children and adolescents, providing numerous entertainment options, such as watching videos, gaming, using social media, and communicating with family and friends [2]. This use encompasses both active and passive engagement with various devices and content [1,3].

From a very early age, screen-based media use is a reality, with children spending many more hours per day in screen time than the international recommendation of no more than 2 hours per day for children and adolescents aged 5 to 17 years [4,5].

XSL•FO
RenderX

According to the American Academy of Pediatrics (AAP), for children aged 6 years and older, healthy habits should be encouraged, and screen-based activities should be limited [6]. It is also recommended to turn off all screens during family meals and outings and to turn off and remove screens from bedrooms 30 to 60 minutes before bedtime [6].

In Portugal, the percentage of children aged 6 to 9 years who spend more than 2 hours per day engaging in screen time on weekdays is around 35%, increasing significantly on weekends to approximately 78% [7]. Also, this prevalence tends to decrease in families with higher levels of parental education, in contrast to an increase in families with lower levels of parental education. In the latter group, children spend around 45% of weekdays and 77% of weekend days exceeding 2 hours of screen time per day [7].

On the other hand, the prevalence of overweight and obesity among school-aged children is 25.7% and 12.5%, respectively, with higher rates observed in families with lower levels of education [7]. This highlights the need to understand the associations between screen-based media use and adiposity in socioeconomically vulnerable contexts.

The associations between excessive screen time and behaviors that promote obesity are well-established [1,8]. For example, obesogenic behaviors (including physical inactivity, increased sedentary behavior, poor dietary habits, and disrupted sleep patterns) [5] have been associated with excessive screen time and childhood obesity [4,5,9]. Additionally, excessive screen time can lead to depression, anxiety, and poor school performance in children [4]. Despite this, there remains controversy over studies' findings that balance the benefits and harms of screen-based media use, taking into account the type of media and how it is used [4,10]. In addition, although the association between screen use and adiposity has already been studied [8], this relationship remains unclear in the context of primary schoolchildren from socially vulnerable backgrounds.

In Portugal, a school is considered vulnerable if it belongs to the Educational Territories of Priority Intervention. These schools are located in areas characterized by socioeconomic vulnerability, where poverty and social exclusion are prevalent [11,12].

Previous studies examining the relationship between screen-based media use and adiposity in children have shown mixed results. While some report positive associations [1,5,8], others find weaker or inconsistent links depending on factors such as the type of media used and children's daily contexts [4]. Furthermore, most research focuses on general population samples, leaving limited evidence on how these associations operate among socially vulnerable groups. As a result, important gaps remain in understanding how screen use relates to adiposity in children living in disadvantaged settings.

To address this, the objective of this study was to analyze the associations between screen-based media use and adiposity in primary schoolchildren from socially vulnerable contexts.

Methods

Study Design and Participants

This study is part of the broader BeE-school Project, a trial conducted in primary schools that are part of the Educational Territories of Priority Intervention project, which covers territories characterized by social vulnerabilities. For this cross-sectional study, a total of 735 children from 10 primary schools participated with parental consent. The inclusion criteria required that children be from 10 primary schools located in economically and socially disadvantaged areas marked by poverty and social exclusion. Children with cognitive or physical impairments that could compromise data collection were excluded from the study.

Anthropometrics

Children's weight and height were measured at school by trained researchers using standardized procedures. Measurements were taken with a pediatric scale and stadiometer (SECA 799; SECA GmbH & Co KG), with weight rounded to the nearest 100 g. Height was measured with the head positioned in the Frankfort plane and recorded to the nearest 0.1 cm. Waist circumference was measured directly on the skin, 1 cm above the uppermost lateral border of the right ilium, at the end of normal expiration, and recorded to the nearest 0.1 cm [13]. Children were measured while at school, lightly dressed and without shoes. If there was any doubt about the measurement, the procedure was repeated.

The BMI was calculated as the ratio of body weight to height squared (kg/m^2) and converted into SD scores (BMI *z* score [BMIz]) adjusted for specific age and sex categories using the World Health Organization (WHO) growth reference [14]. The waist-to-height ratio (WHtR) was calculated by dividing waist circumference by height.

Weight status was defined according to WHO cutoff points of BMI and categorized into 3 groups: normal and underweight (SD ≤1), overweight (1< SD ≤2), and obesity (SD >2). Normal and underweight were grouped together due to the low number of underweight cases in our sample.

Parents self-reported their height and weight, from which BMI was calculated. Parental BMI was categorized according to WHO guidelines into 3 categories: normal and underweight (BMI ≤24.9 kg/m^2), overweight (BMI 25-29.9 kg/m^2), and obesity (BMI ≥30 kg/m^2). Due to the small number of underweight parents (8 mothers and 2 fathers), they were grouped with normal weight cases.

BMI and WHtR were used as indirect anthropometric indicators commonly used to estimate general and central adiposity, acknowledging that they do not represent direct measures of body fat.

Sociodemographic Information

Parents' education levels were collected through a questionnaire and categorized into 3 groups: "less than secondary level," "secondary educational level," and "university studies." These variables (mothers' and fathers' education levels) were

XSL•FO
RenderX

considered as covariates in the fully adjusted model of the analysis.

Screen-Based Media Use

Children's screen-based media use was assessed through the ScreenQ questionnaire, filled out by parents. This 16-item questionnaire included 4 domains derived from aspects of media use cited in AAP recommendations: access to screens, frequency of use, media content, and caregiver-child coviewing [15,16].

The evaluation of screen media access includes questions about screen use during meals, in the bedroom, while waiting, ownership of media devices, and screen use at night during the school period (questions 1 to 5). Frequency of use is assessed not only by the number of screen-time hours per day but also by factors such as the age at which children first had contact with screens, whether they use screens to fall asleep, and whether they frequently use screens to calm down (questions 6 to 9). Media content is evaluated through items that assess exposure to violent content, content pacing, and whether children independently choose what to view (questions 10 to 12). Finally, caregiver-child coviewing considers not only the presence of an adult but also the nature of interaction between the adult and the child during screen use (questions 13 to 15) [16].

The 16 items of ScreenQ are summed for a total score ranging from 0 (perfect adherence with AAP recommendations) to 27 points (extreme nonadherence—a major risk for adverse effects). The score for each dimension was calculated by summing the scores of the corresponding questions.

Internal consistency of the scale for children aged >5 years is 0.64 (Cronbach α), which indicates a good internal consistency [15]. In our sample, Cronbach α was also calculated, and a value of 0.61 was obtained, indicating good internal consistency. The total score and the scores for each domain were analyzed as predictors of adiposity in the statistical analysis.

Statistical Analysis

Descriptive analysis encompassed measures of central tendency and dispersion tailored to each variable type. Quantitative variables were summarized using mean and SD, while categorical variables were described using counts (n) and percentages (%). Proportions of categorical variables were compared using chi-square tests for contingency tables, and a 2-tailed Student *t* test was applied for quantitative variables.

Generalized linear models were used to assess the associations between children's screen-based media use (predictor) and children's adiposity (BMI and WHtR) as dependent variables, with a significance level set at .05.

Three models were used. Model 1 was the unadjusted model, model 2 incorporated children's sex and age as covariates, and model 3 represented the fully adjusted model, including children's sex and age, as well as mothers' and fathers' education levels, and mothers' and fathers' BMI as covariates. Data analysis was conducted using SPSS (version 29.0.1; IBM Corp).

Ethical Considerations

This study was approved by the Ethics Committee for Life and Health Sciences (CEICVS 009/2022) of the University of Minho and registered on the ClinicalTrials database (NCT05395364). The research adhered to the Code of Ethics of the World Medical Association (Declaration of Helsinki). All participants, including parents or caregivers, signed informed consent forms, and children were asked for their assent to participate before any procedures were conducted.

Results

Descriptive data for the participants are presented in Table 1. In a sample of 735 school-aged children, 380 (51.7%) were boys and 355 (48.3%) were girls, with a mean age of 7.7 (SD 1.2) years. Most of the children had normal weight (448/728, 61.5%), 22.7% (165/728) were overweight, and 15.8% (115/728) had obesity. Around half of the mothers (305/552, 55.3%) had normal weight, whereas 37.8% (191/505) of fathers fell into this category. Nearly half of fathers were overweight (237/505, 46.9%).

[b]Model 1: unadjusted model.

[c]Model 2: adjusted model for children's sex and age.

[d]Model 3: adjusted model for children's sex and age, mothers' and fathers' education level, and mothers' and fathers' BMI.

[e]*P* value<.05.

A higher screen-based media use score was significantly associated with higher BMIz (b=0.053, 95% CI 0.023-0.083) and WHtR (b=0.002, 95% CI 0.001-0.003) in the fully adjusted model. Similar associations were observed for the domains of screen access, frequency of use, and media content. Caregiver-child coviewing was not significantly associated with BMIz (b=0.008, 95% CI –0.075 to 0.092) or WHtR (b=–0.0004, 95% CI –0.004 to 0.003).

Discussion

Principal Results

We found that children with higher ScreenQ scores—reflecting screen media use that does not align with AAP recommendations—tended to have higher BMIz and WHtR values. We also found that specific characteristics of screen media use—such as screen access, frequency of use, and media content—were significantly associated with both measures.

Comparison With Prior Work

Our findings indicate that children with nonadherence to AAP recommendations had a higher risk of adverse effects concerning surrogates of obesity. This is in accordance with existing evidence that identifies overweight and obesity as one of the first health consequences of excessive screen time in children [1,4,17,18]. Since 1985, when the first paper about the effects of media use on children's adiposity was published by Dietz and Gortmaker [19], the scientific community has observed the negative consequences of excessive media use by children. Additionally, the frequency of media use has been increasing in recent years, particularly during successive lockdowns when screen use significantly surged in many regions worldwide [20]. The long-term effects of the COVID-19 pandemic lockdowns remain unclear [21], and it is possible they have influenced the frequency of postpandemic screen viewing.

According to Hutton et al [16], screen media use could pose potential neurobiological risks. Furthermore, the AAP has cited language delay, poor sleep, impaired executive function and general cognition, and decreased parent-child engagement as some of the other consequences of screen-based media use by children [16,22].

Screen time is typically associated with sedentary behavior and linked to a higher consumption of energy-dense foods, promoting an energy imbalance [23-25]. Children who increased or consistently maintained high screen time from preschool to school age were more likely to adopt unhealthier dietary patterns, such as frequent snacking or consuming energy-dense foods [26]. Media can act as a trigger or prompt for eating, extend the duration of eating, or distract from feelings of satiety [8]. Another growing concern is the presence of food marketing in digital media, especially targeted at children, which can explain the link between screen-based media use and higher energy consumption [8]. Marketing and the commercial determinants of health have the power to shape children's food preferences, purchasing behaviors, and consumption patterns. Because the most commonly promoted food products to children are sugary breakfast cereals, soft drinks, savory snacks, confectionery, and fast food, accounting for about 60% to 90% of all food marketing [27], it is possible that their consumption might increase. Screen-based media use is also linked to poorer sleep, which can cause changes in appetite-regulating hormones such as ghrelin and leptin, leading to increased hunger and decreased satiety [8].

Concerning screen access, children now have a wide variety of screen media devices available to them, such as smartphones, tablets, laptops, desktops, gaming consoles, and televisions. According to Dy et al [28], the devices that children have the most access to are televisions, followed by smartphones and tablets. With all these access opportunities, screen time during important periods such as mealtimes and bedtimes has emerged, with screen use during meals becoming increasingly common among children and adolescents [29]. This has a significant impact on child health, as screen use during meals has been linked to increased consumption of snacks, including high-calorie and low-nutrient products [29].

The type of content is another important aspect to discuss. Screen media content available to children varies widely, differing in aspects such as target audience, educational value, and language used [30]. These factors have been linked to cognitive and learning outcomes [28,30,31]. Content can also influence diet, particularly through the promotion of unhealthy eating behaviors via junk food marketing [17]. Children are

XSL•FO
RenderX

exposed to marketing of unhealthy foods and are considered a vulnerable group for this type of digital content [17,30]. However, depending on the content, media use can also have a significantly positive impact on children's health, and interventions that use media to promote the adoption of healthy lifestyles should be considered [1,31].

Despite some studies identifying coviewing screen media as having a positive impact on health outcomes [28], in our study, this dimension did not appear to be significantly associated with adiposity. According to Dy et al [28], children are nearly 9 times more likely to have excessive screen time when watching alone compared to watching with an adult, and excessive screen use has been linked to worse health outcomes, as mentioned earlier. However, our findings regarding this specific domain could be related to the type of coviewing, such as interactive or passive coviewing. Alroqi et al [30], who investigated the influence of the quantity, content, and context of screen media use on the language development of 85 Saudi children aged 1 to 3 years, reported that passive coviewing of television was more common than interactive coviewing, with the latter appearing to have a positive effect on children's development and health. It is noteworthy that despite the nonsignificant result, the association between coviewing and BMIz is positive, and a higher screen use without adult supervision is associated with a higher BMIz.

Apart from health consequences, media use by children was also identified by Priftis and Panagiotakos [4], in a review documenting the health effects of excessive screen viewing on children and adolescents, as potentially having a socioeconomic impact as well. Moreover, lower maternal education levels and lower household income were linked to higher odds of increased screen time [26]. Moreover, some parents seem to believe that screen time increases children's creativity and imagination [28], while others reported having strict rules concerning screen-based media use in their homes [10].

This study was conducted with a specific group of children from primary schools located in socially vulnerable territories. However, not all families had a very low socioeconomic status, which may explain the relatively higher rates of mothers (268/607, 44.2%) and fathers (186/577, 32.2%) with a university education level. Nevertheless, as educational level is considered an important surrogate variable for socioeconomic status [32], we accounted for it as a potential confounder in our analysis.

This study has several strengths that should be emphasized. First, we used trained researchers to collect the anthropometric measures, and we included both BMIz and WHtR as measures of adiposity, thereby enhancing the validity of our findings. To assess adiposity, BMI has been widely used as a surrogate measure; however, WHtR has recently been identified as a potentially better surrogate measure for adiposity. It predicts total and trunk fat mass more accurately and can discriminate lean mass in the pediatric population, unaffected by children's age and sex [33]. Second, we used the ScreenQ as a measure of screen-based media use, an instrument that has already been validated for Portuguese children. ScreenQ evaluates not only the screen time but also other dimensions of screen-based media use: access to screens, frequency of use, media content, and caregiver-child coviewing [15,16], allowing a more comprehensive analysis. Third, the analysis considered potential confounders such as children's characteristics and parents' sociodemographic and weight status. Finally, this study was conducted in a specific context of vulnerability, which has not yet been extensively studied in Portugal.

Limitations

We recognize that this study has some limitations. First, the cross-sectional design did not allow us to identify a causal relationship. Second, the data on ScreenQ, sociodemographic factors, and parents' anthropometrics were self-reported by parents, potentially introducing social desirability bias. To minimize the impact of these limitations on the credibility of the findings, we used validated instruments (such as the ScreenQ) and ensured anonymity in participation to reduce potential response bias. We also interpreted the results cautiously, clearly acknowledging the direction of the associations without implying causality. These measures help safeguard the trustworthiness and robustness of the study's conclusions.

Finally, the use of BMI and WHtR as surrogate indicators of adiposity represents a limitation, as these measures may not fully capture body fat distribution and can be influenced by factors such as muscle mass. Although BMI and WHtR likely capture relevant population-level variation in body shape [34], future studies should consider incorporating objective measures of adiposity to provide more precise assessments.

Conclusions

Screen-based media use was significantly associated with higher BMI and WHtR among primary schoolchildren from socially vulnerable contexts. Future school-based interventions should emphasize the substantial impact of screen use on children's adiposity, particularly in light of their socioeconomic circumstances.

Abstract

Background: Adolescents' exposure to electronic cigarette (e-cigarette) content through social media platforms influences their perceptions and behaviors, although cross-country analyses in different regulatory environments are scarce.

Objective: This study evaluated the association between e-cigarette exposure on social media platforms and e-cigarette susceptibility and use in Jalisco (Mexico) and Southern California (United States).

Methods: In 2022-2023, students from 23 high schools in Jalisco (n=1418) and 11 in Southern California (n=2953) were surveyed with harmonized measures on past-month frequency of social media platform use (ie, YouTube [Google], Instagram [Meta], TikTok [ByteDance], Snapchat [Snap Inc], WhatsApp [Meta], Facebook [Meta], Twitter (now "X"), and Twitch [Twitch Interactive]) and seeing e-cigarette posts on each social media platform used; which were recoded to 5-point scores (range 0-4) for social media platforms use and e-cigarette post exposure. Country-stratified logistic models regressed e-cigarette susceptibility (among noncurrent users) and past-month use on social media platform scores, adjusting for age, sex, family affluence, and friends' e-cigarette use.

Results: Past-month e-cigarette use was higher in Jalisco (248/1418, 17.5%) than Southern California (139/2953, 4.7%; *P*<.001). Social media use and e-cigarette exposure on each social media platform differed across samples (*P* values<.001). In Southern California, more frequent social media use was positively associated with e-cigarette susceptibility (adjusted odds ratio [AOR] 1.83, 95% CI 1.48-2.25), whereas in Jalisco, higher frequency of exposure to e-cigarette content was associated with susceptibility (AOR 1.21, 95% CI 1.02-1.43). Higher frequency of social media use and exposure to e-cigarette content were both positively associated with past-month e-cigarette use in Southern California; in Jalisco, greater exposure to social media platforms and e-cigarette content was associated with past-month use.

XSL•FO
RenderX

Conclusions: Frequent social media platform use and e-cigarette exposure through social media platforms appear to be associated with e-cigarette susceptibility and use across contexts. Stronger policies to limit and enforce online exposures are needed.

Introduction

Over the last decade, adolescent cigarette use has significantly decreased in many countries around the world that have adopted strong tobacco control policies, including bans on cigarette advertising through traditional media channels [1,2]. In contrast, adolescents' use of electronic cigarettes (e-cigarettes) has increased as countries have been slower to adopt and enforce strong e-cigarette regulations. Moreover, increases in e-cigarette use have coincided with and appear to be partly explained by the growing and widespread use of social media platforms, which is often the primary means of adolescent exposure to e-cigarette marketing [3].

e-Cigarettes were first marketed as a harm reduction product to help adult smokers quit [4], yet they have become increasingly popular among adolescents in both high and middle-income countries with different regulatory frameworks. In the United States, for example, adolescent e-cigarette use rapidly increased in 2017-2018, which prompted policy actions, including federal prohibition of e-cigarette sales to anyone younger than 21 years in December 2019 [5]. Furthermore, in 2020, the US Food and Drug Administration (FDA) banned cartridge-based e-cigarettes with any flavors except tobacco or menthol, and the FDA has also denied marketing requests for most e-cigarette products [6]. Despite enforcement issues and loopholes for some e-cigarette types (eg, disposables), these measures have been accompanied by decreased current e-cigarette use among high schoolers from 20.8% in 2018 to 10% in 2023 [7,8]. However, e-cigarettes remain the most commonly used tobacco product among US adolescents [7]. These trends generally characterize adolescents in California (United States), although the prevalence of e-cigarette use is lower there than in other states [9].

In Mexico, the 2008 General Tobacco Control Law stipulated that no new tobacco products or any products that resemble tobacco products could be introduced or sold in the country [10]. Regulators interpreted this legislation as a de facto ban on e-cigarette marketing and sales, with a 2020 Presidential Decree specifically banning their importation and clarifying that the General Tobacco Control Law banned e-cigarette marketing and sales [11]. However, the national prevalence of past-month e-cigarette use among 15- to 18-year-olds increased from 2% in 2021 to 3.3% in 2022 [12]. Even though the prevalence is relatively low compared with the United States, the increase from 2021 to 2022 represents a 65% growth in use. Furthermore, representative data from urban public schools in large Mexican cities suggest that e-cigarette use is substantially higher than these estimates [13], perhaps due to reduced bias from adolescents' self-administering surveys in schools compared with the national surveys that involve survey administration in households. Importantly, despite Mexico's e-cigarette ban, e-cigarettes are accessible through a variety of venues in both the formal and informal economy due to a lack of enforcement [14,15]. Illegal marketing through social media platforms—which is particularly challenging to enforce—may also contribute to Mexican adolescents' e-cigarette use.

The growth in internet access has been accompanied by increasing use of social media platforms worldwide [16]. In Mexico, 96% of adolescents and young adults reported using social media platforms in 2021 [17], and in 2022, 97% of US adolescents aged between 13 and 17 years reported using them [18]. Furthermore, in 2023, it was estimated that 77% of US high-school students used social media platforms several times a day [19]. Among youth in Canada, England, and the United States, those in the United States reported the greatest increase in noticing e-cigarette marketing from 2017 to 2019, with "websites or social media" being the second most reported channel of marketing exposure [20]. Additionally, a 2021 survey among middle- and high-school students in the United States found that 73.5% of social media users reported having ever seen e-cigarette–related content on social media platforms [21]. To our knowledge, there are no studies in Mexico or other Latin American countries where e-cigarettes are banned that have assessed exposure to e-cigarette content across social media platforms and its associations with susceptibility or use of these products.

e-Cigarette advertisements on social media platforms usually portray the devices and their use as desirable, trendy, and fashionable, which likely appeals to adolescents [22]. Indeed, exposure to e-cigarette advertisements has been associated with more positive perceptions of vaping, lower harm perception, change in perceived acceptability among peers [23], as well as with greater susceptibility to and current use of e-cigarettes among both adolescents and young adults [24,25]. To maximize attention and engagement, many e-cigarette brands use social media *influencers* or celebrities to promote their products [22]. Even though advertisements on social media platforms can be targeted to specific population groups (ie, >18 y), 1 study found that more than 60% of the e-cigarette brands and *influencers* on Instagram [Meta] had no age-gating restrictions for followers, although their posts were intended only for adult users [26]. A key feature of social media concerns its transnational reach across jurisdictional borders, making it possible for adolescents in one country to access content from other countries, even if the content contains marketing that is illegal in their home countries.

This study examined similarities and differences in the use of social media platforms, exposure to e-cigarette posts on social media platforms, and their associations with e-cigarette susceptibility and use among high schoolers from the southern

XSL•FO
RenderX

part of Jalisco in Mexico and Southern California in the United States. As described above, tobacco regulations and adolescent e-cigarette use prevalence differ between Mexico and the United States, with potential consequences for adolescents' exposure to e-cigarette content via social media platforms. Furthermore, a higher proportion of the Mexican American population live in Southern California [27], which may help reduce differences in the study populations due to cultural background. We expected lower exposure and use among Mexican adolescents due to the national e-cigarette ban. Nevertheless, in both countries, we expected that greater exposure to e-cigarette posts on social media platforms would be positively associated with susceptibility and use, even after adjusting for overall social media platform use. To our knowledge, this is the first study of adolescent exposure to e-cigarette content across specific social media platforms and the association with susceptibility and use across countries.

Methods

Population

Data for Mexico come from the 2022-2023 Mental Health, Addiction, and Violence Survey in the state of Jalisco. A convenience sample of high schools (n=23) in 16 municipalities of the Southern part of Jalisco answered an online, self-administered survey from November 2022 to February 2023. A total of 1557 students were invited to participate, 131 (8.4% approximately) refused, yielding a sample of n=1426. US data come from the Assessing Developmental Patterns of Vaping, Alcohol, Nicotine, and Cannabis Use and Emotional Wellbeing (ADVANCE) cohort [27] in Southern California; participants were recruited as ninth-grade students in either 2020 (class of 2024) or 2021 (class of 2025) from 11 high schools. To harmonize survey timing with Mexico, we analyzed data only from the February to June 2023 survey, when the Southern California students were in 10th or 11th grade. A total of 4206 students were invited to participate, 631 (15% approximately) refused, yielding a sample of 3575. Participants with missing data were dropped from analyses (Jalisco final sample, n=1418, vs Southern California final sample, n=2953).

Ethical Considerations

Before survey administration, both studies obtained students' assent, and ADVANCE also obtained parental consent. For the Mental Health, Addiction, and Violence Survey in the state of Jalisco, active parental consent was not required from the ethics committee; parents were informed about the study and could request that their child be excluded. Protocols were approved by the Institutional Review Board and Ethics Committee of the Ministry of Health of Ciudad Guzmán, Jalisco, Mexico (103/RVI/2021), and for Southern California, by the Institutional Review Board of University of Southern California (HS-19-00682). Participants in ADVANCE received a small token of appreciation (eg, stickers or a pen). Absentee and transfer students were offered a US $10 gift card to complete the survey independently. No incentives were provided for participants in Jalisco. Projects are hosted on secure servers. To protect participants' privacy, data were deidentified before sharing. When data transfer was required, a 2-step secure procedure was used. First, a password-protected link to the REDCap (Research Electronic Data Capture; Vanderbilt University) server was sent to the authorized recipient. The password was then transmitted separately in a second email. The download link was single-use and remained active for a limited time to further enhance security.

Measurements

Social Media Platforms–Related Variables

To assess general social media engagement, students were asked, "How often do you visit the following social media sites?" for each of the following social media platforms—Facebook [Meta], Instagram, WhatsApp [Meta; Jalisco only], Snapchat [Snap Inc; Southern California only], Twitter (now "X" [X Corp] as of July 24, 2023), YouTube [Google], TikTok [ByteDance], and Twitch [Twitch Interactive]. Response options in both surveys were (1) 0="I don't use this social media," (2) 1="once a month or less," (3) 2="weekly," (4) 3="daily," (5) 4="several times a day," and (6) 5="I don't know."

Next, to assess exposure to e-cigarette content on social media, students were asked, "How often do you see posts about e-cigarettes and nicotine vaping products on the following social media sites (same as above)?" In Jalisco responses were "I don't use this social media," "never," "once a month or less," "weekly," "daily," and "several times a day" while in Southern California responses were "never," "monthly or less," "weekly," "daily," "several times a day," and " I don't know". To harmonize responses across samples, first we recoded "I don't use this social media" (Jalisco) and "don't know" (Southern California) along with "never" as 0, indicating no exposure; then we rescaled all remaining responses to a 0-4 scale for comparability (0="I don't use this social media, never, or I don't know," 1="once a month or less," 2="weekly," 3="once a day," and 4="several times a day"). Finally, we calculated 2 continuous scores, that is, social media use score and e-cigarette postexposure score by averaging responses across platforms (range=0-4) to reflect students' average frequency of social media use and exposure to e-cigarette–related content, respectively.

e-Cigarette Use and Susceptibility

Students reported their frequency of using e-cigarettes in the previous 30 days ("In the last 30 days, how many total days have you used any electronic cigarette with nicotine?"). Responses were recoded into a dichotomous variable (0="No use in the past 30 days" [noncurrent users], and 1="any use in the past 30 days"). Susceptibility to use e-cigarettes was assessed with the question "Do you think that at some point during the next 12 months, you will use an e-cigarette?" with responses recoded as a dichotomous variable based on previous research on susceptibility among youth [28] (0="definitely not, 1="probably not," "probably yes," or "definitely yes").

Covariates

Sociodemographic variables included age (12 y, 13 y, 14 y, 15 y, 16 y, 17 y, 18 y, 19 y or older), sex (female and male), and household wealth, using the Family Affluence Scale (FAS). The FAS includes the following questions, (1) how many cars

XSL•FO
RenderX

or trucks does your family own (0, 1, 2 or more); (2) do you have a room for yourself? (0 or 1); (3) during the last 12 months, how many times did you go on vacation with your family? (0, 1, 2, 3 or more); (4) how many computers does your family have? (0, 1, 2, 3 or more). The FAS has shown reliability and validity as a measure of socioeconomic status [29], in both the United States [30] and Mexico [31]. As is standard practice, the FAS items were summed (range=0-9), with higher scores indicating higher family affluence. Use of e-cigarettes by friends was also assessed (Jalisco: "Of your five best friends, how many use electronic cigarettes?" and Southern California: "How many of your five (5) closest friends use electronic cigarettes for vaping nicotine?") with responses dichotomized to indicate having any friends who use (0=none, and 1=1-5).

Analyses

For descriptive analyses, datasets were combined to allow comparison of sample characteristics using Pearson chi-square tests for categorical variables and independent sample *t* tests for the continuous variables. We used Pearson chi-square tests to assess if there were any differences in the frequency of social media platform use and frequency of exposure to e-cigarette content through social media platforms across countries. Then, for each country, we conducted crude and adjusted logistic regression models with Standard Errors (SEs) clustered by school to account for intragroup correlation among students within schools were estimated for each of two outcomes, (1) susceptibility to use e-cigarettes (analytic sample=noncurrent users [n=1170 for Jalisco, and n=2695 for Southern California]) and (2) current e-cigarette use (analytic sample=entire sample [n=1418 for Jalisco, and n=2953 for Southern California]). Independent variables included the index of frequency of exposure to e-cigarette posts on social media, as well as the frequency of social media use index and other covariates. Due to potential different effects per social media platform [28], sensitivity analyses were conducted by analyzing one social media platform at a time, adjusted by the frequency of social media use (Multimedia Appendix 1). To further assess the robustness of findings to alternative methods for handling within-school correlation, additional sensitivity analyses were conducted using multilevel logistic regression models with school specified as a random effect. Results from multilevel models were consistent in direction, magnitude, and statistical significance with those from the clustered SE approach; therefore, clustered models were retained as the primary analyses (Multimedia Appendix 2). Finally, pooled analyses across countries were conducted using adjusted models for susceptibility and use that included an interaction between country and exposure to e-cigarette content via social media. These pooled models were treated as supplementary to country-stratified analyses due to differences in the measurement of key variables across countries (Multimedia Appendix 3). All analyses were conducted using Stata (v.19; StataCorp LLC).

Results

Compared with the Southern California sample, the Jalisco sample was younger, more likely to be male, and had lower family affluence (Table 1). Susceptibility and past-month e-cigarette use were higher in Jalisco (vs Southern California), as were the number of friends using e-cigarettes, frequency of social media exposure, and frequency of e-cigarette exposure on social media platforms.

Table 1. Sample characteristics of high-school students in Jalisco (Mexico) and Southern California (United States).

Characteristics	Jalisco (N=1418[a])	Southern California (N=2953[a])	*P* value
Age (y), mean (SD)	15.9 (0.97)	16.7 (0.58)	<.001
Sex, n (%)			<.001
Female	887 (62.5)	1656 (56.1)	
Male	531 (37.5)	1297 (43.9)

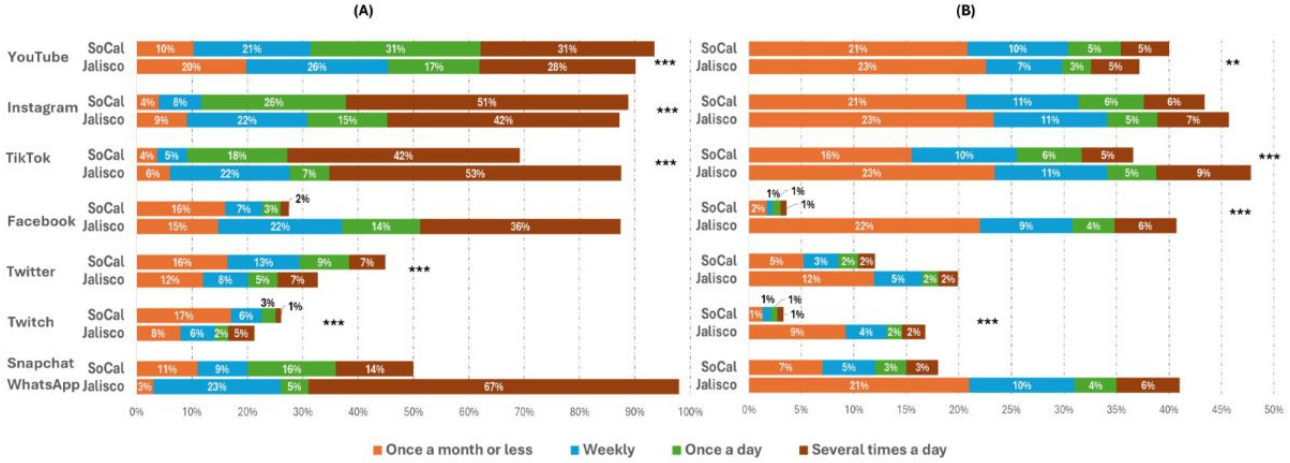
e-Cigarettte use, n (%)			<.001
Not current, not susceptible	830 (58.5)	2469 (83.6)	
Not current, susceptible	340 (24)	340 (11.5)	
Past-month use	248 (17.5)	139 (4.7)	
Best friends' use of e-cigarettes, n (%)	785 (55.4)	730 (24.7)	<.001
Frequency of using social media (range=0-4), mean (SD)	2.1 (0.77)	1.6 (0.66)	<.001
Frequency of e-cigarette exposure on social media (range=0-4), mean (SD)	0.66 (0.83)	0.36 (0.56)	<.001



[a]Sample for Jalisco included 23 high schools; Southern California included 11 high schools.

WhatsApp was the most frequently used platform among those assessed in Jalisco, with 67% (n=950) of students reporting its use several times a day (not asked in Southern California). In Jalisco, among the social media platforms queried in both countries (Figure 1A), the frequency of use reported was significantly different between countries for YouTube, Instagram, TikTok, Facebook, Twitter, and Twitch (*P*<.001 for all). YouTube was the most frequently used in both sites; however, most Southern California students reported using it once a day (907/2953, 31%) or several times a day (918/2953,

XSL•FO
RenderX

31%) while fewer Jalisco students reported the same (235/1418, 17% once per day; 399/1418, 28% several times per day). Facebook was frequently used in Jalisco (710/1418, 50% at least once a day), while fewer than 30% (799/2953) of students reported any use of that platform in Southern California. Twitch was the least used platform in both samples.

Figure 1. (A) Frequency of using social media, high school students in Jalisco and Southern California, and (B) frequency of e-cigarette exposure on social media, high school students in Jalisco and Southern California. Snapchat and WhatsApp were not compared since they were not included in both samples. Significance of *P* values: **.05, ***<.001. SoCal: Southern California.

The frequency of e-cigarette exposure on each social media platform differed across samples, except for Instagram (Figure 1B). TikTok was the platform through which Jalisco students reported the greatest exposure, with 25% (333/1418) reporting seeing e-cigarette content at least weekly (153/1418, 11% weekly; 66/1418, 5% once per day; and 127/1418, 9% several times per day). Instagram had the highest self-reported exposure to e-cigarette posts in Southern California, with at least 21% (620/2953) reporting weekly exposure (313/2953, 11% weekly; 185/2953, 6% once per day; and 169/2953, 6% several times per day). The lowest frequency of e-cigarette exposure for Southern California was through Twitch and Facebook, and exposure was lowest through Twitch and Twitter in Jalisco.

For each sample, separate bivariate and multivariate adjusted logistic regression models were estimated for e-cigarette susceptibility among high schoolers who did not use e-cigarettes in the last month (Table 2). In unadjusted and adjusted models for both Jalisco and Southern California, females had lower odds of being susceptible than males (adjusted odds ratio [AOR] 0.62, 95% CI 0.47-0.83; AOR 0.60, 95% CI 0.52-0.71, respectively), and those whose best friends used e-cigarettes had higher odds of susceptibility (AOR 3.80, 95% CI 2.87-5.03; AOR 3.35, 95% CI 2.48-4.52, respectively). In bivariate models for both samples, higher frequency of social media use and of exposure to e-cigarette content via social media were positively associated with susceptibility; however, in adjusted models, more frequent social media use was positively associated with susceptibility in Southern California (AOR 1.83, 95% CI 1.48-2.25) but not in Jalisco. In adjusted models, greater frequency of exposure to e-cigarette content on social media was independently associated with susceptibility only in Jalisco (AOR 1.21, 95% CI 1.02-1.43).

[a]OR: odds ratio.

[b]AOR: adjusted odds ratio from model that includes all variables shown in table.

[c]Frequency of using social media index represents the average of the reported frequency of using each social media platform, it ranges from (0-4).

[d]Frequency of seeing e-cigarette posts on social media index represents the average of the reported frequency of seeing e-cigarettes posts in each social media platform, ranges (0-4).

[e]*Ref*: reference value.

In unadjusted and adjusted models for past-month e-cigarette use in both samples (Table 3), a higher frequency of exposure to e-cigarette content on social media (Jalisco: AOR 1.49, 95% CI 1.27-1.74; and Southern California: AOR 1.51, 95% CI 1.15-1.73) was positively associated. Elevated odds were also observed for higher frequency of social media use (Jalisco: AOR 1.21, 95% CI 0.99-1.47; and Southern California: AOR 1.41, 95% CI 1.15-1.97), although results for Jalisco were borderline statistically significant. Having best friends who used e-cigarettes (Jalisco: AOR 6.46, 95% CI 4.38-9.54; and Southern California: AOR 11.24, 95% CI 6.94-18.22) was associated with a higher likelihood of using e-cigarettes, and in Southern California only, females (AOR 0.50, 95% CI 0.34-0.72) had a lower likelihood of using e-cigarettes.

Models by each specific social media platform showed that only Instagram and TikTok were significantly associated with susceptibility in Jalisco, whereas TikTok was the only platform significantly associated with susceptibility in Southern California. In Jalisco, exposure to e-cigarette posts across all social media platforms was independently associated with past-month use, while for Southern California, exposure to e-cigarette posts on Instagram, TikTok, Snapchat, or Twitter was associated with susceptibility (Multimedia Appendix 1). In models pooling data from both countries, interactions between country and exposure to e-cigarette content were not significant for susceptibility (χ^2_1=1.13, *P*=.30) or e-cigarette use (χ^2_1= 0.26, *P*=.60; results not shown).

Discussion

Aligned with our first hypothesis, we found high levels of self-reported use of and exposure to e-cigarette content through social media platforms in samples of high schoolers in Jalisco (Mexico) and Southern California (United States), particularly for YouTube, Instagram, and TikTok. However, these findings were surprising and contrary to our second hypothesis, given that Mexico bans commercial advertising for e-cigarettes across all channels, including social media platforms [32]. California has no prohibitions regarding online marketing; however, marketing and sales of all flavored tobacco products, except menthol, are prohibited, and starting in 2025, this ban is planned to be extended to online sales and include fines to ensure age verification [33,34]. In addition, e-cigarette products authorized by the FDA will not be able to market to the youth [35], although enforcement of marketing restrictions, particularly on social media platforms, remains challenging. We also found that past-month use of e-cigarettes was significantly lower in Southern California (139/2953, 4.7%) than in Jalisco (248/1418, 17.5%). Prevalence in Jalisco was substantially higher than in national surveys [36], although consistent with previous research in urban areas of Mexico [13], while the lower prevalence observed in Southern California aligns with data indicating lower e-cigarette use in California compared with other states [9]. More research is needed to understand the factors driving the difference in e-cigarette use prevalence between samples; better law enforcement, paired with media campaigns and prevention programs in schools, could play an important part in Southern California.

As illustrated in Figure 1, adolescents' frequency of using specific social media platforms differed across the 2 samples, with more sizable differences for Facebook, which was higher in Jalisco. However, in both samples, the frequency of exposure to e-cigarette content through Facebook, as well as through Snapchat (only asked in Southern California) and WhatsApp (only asked in Jalisco), was low compared with TikTok, Instagram, and YouTube. A meta-analysis that examined associations between social media use and risky behaviors found that social media platforms that were introduced relatively early, like Facebook, had weaker associations than contemporary social media platforms when it comes to substance use [37]. In the past, Facebook has faced scrutiny for its impact on promoting unhealthy behaviors and targeting youth with advertisements, and in 2021, the platform limited the targeting options to 18-year-olds and older and banned all tobacco and nicotine products advertising [38]. That policy, along with Facebook use declining among the US youth [18] and other measures taken by California, could help explain the relatively low exposure reported in the Southern California sample. Additionally, the user guidelines across social media platforms prohibit any marketing and sales of any tobacco products in both countries; however, posts alluding to e-cigarettes and other substances can still be found. Studies are needed to characterize the content of e-cigarette–related posts across social media platforms, as such content may both promote and discourage e-cigarette use. Understanding the balance and nature of these

XSL•FO
RenderX

messages is important not only for preventing dissemination of pro–e-cigarette content, but also for identifying content that may support prevention and cessation of e-cigarettes. For example, predominant topics in e-cigarette posts on Snapchat, one of the less popular social media platforms we studied, included messages about "health consequences" and "quitting" [39].

Higher exposure to e-cigarette posts was associated with higher use in both samples, as observed in previous studies. A meta-analysis that reviewed cross-sectional cohort studies and longitudinal studies found that those exposed to e-cigarette posts during the last 30-days are more likely to report current use [40]. Also consistent with other studies [41,42], we found that higher exposure to e-cigarette posts was associated with susceptibility to use e-cigarettes among students in both samples; however, the adjusted association remained statistically significant only for Jalisco. There are several possible explanations for the lack of association in Southern California. There was heterogeneity in effects across social media platforms (Multimedia Appendix 1); when examined individually, only TikTok had a significant association with susceptibility. Additionally, Southern California had a higher percentage of nonsusceptible students (Southern California: 2469/2953, 83.6% vs Jalisco: 830/1418, 58.5%), and possibly stronger social norms and/or higher levels of peer influence against e-cigarette use exist there. Indeed, fewer students reported having best friends who used e-cigarettes in Southern California compared with Mexico (785/2953, 24.7% vs 785/1418, 55.4%, respectively), which may have resulted in lower exposure to e-cigarette posts from their best friends that may have a greater impact on susceptibility than posts from people whom they do not know. In fact, high-school students in Southern California who had more friends who posted pictures of themselves partying or drinking alcohol online (via Facebook or MySpace [Viant Technology LLC]) were more likely to report that they smoked and used alcohol [43]. Although site-specific analyses suggested differences across sites, pooled analyses including a site-by-exposure interaction term did not indicate statistically significant effect modification by site (models not shown). In combination with minor measurement differences across sites, these results warrant cautious interpretation of between-site differences. Future research should try to understand whether sources of exposure to posts vary across different groups, cities, or countries, as this may help identify strategies to prevent such posts.

Although our data cannot ascertain the nature of the e-cigarette–related posts adolescents viewed on social media platforms, explicit and implicit promotion of e-cigarettes abounds. e-Cigarette marketing through social media platforms presents challenges for regulation. The World Health Organization recommends a comprehensive ban on Tobacco Advertising, Promotion, and Sponsorship, including efforts to limit digital content created in one country being broadcast in others [44-46]. However, for this to be effective, countries and platforms must be actively engaged and willing to collaborate. Differences in regulatory frameworks across and within countries pose a significant challenge. Additionally, only some content posted on social media platforms comes directly from the tobacco and vaping industry, and *influencer*- and user-generated content [47] will likely be harder to regulate, although requiring content moderation and age gates for specific types of content may help. Knowing that exposure to e-cigarette posts on social media platforms is associated with higher e-cigarette use among adolescents, countries should collaborate to protect their youth.

Peer influence is one of the most common drivers for substance use among adolescents, including for e-cigarettes [48-50]. Similar to other studies, having friends who use e-cigarettes was associated with a higher likelihood of susceptibility to and use of e-cigarettes in both samples, with stronger associations for students in Southern California. Longitudinal measures on (online) interactions among adolescents are much needed to better understand diffusion processes of tobacco products in adolescent peer networks [51]. The lack of association we found between family affluence and either susceptibility or use has been observed in other middle-income countries [52,53]. One possible explanation comes from diffusion of innovations theory [54], where, when a product is first introduced, those in higher socioeconomic status groups are more likely to know about and afford it; however, as the product becomes more popular, costs come down, and adoption extends across socioeconomic status groups. Indeed, as e-cigarettes became more popular, the global market transitioned from refillable devices to relatively cheaper pod systems to disposable devices, the last of which is now the most commonly used e-cigarette device among youth [55]. Additionally, in Mexico, these devices can be found on sale for $100 Mexican pesos (approximately US $5) on street markets or *tianguis*, which makes them affordable even to adolescents in lower socioeconomic status groups.

This first study to compare social media platforms use, exposures to e-cigarette content, and their associations with e-cigarette susceptibility and use among adolescents in Mexico and the United States has limitations. First, although measures used in each country were harmonized and have similar face validity, some measures were not identical across sites (eg, differences in question wording or response options; Multimedia Appendix 3). As a result, findings from cross-site comparisons should be interpreted with caution. Second, the temporal relationship between these social media platforms use, exposure to e-cigarette content, and susceptibility and use could not be determined. Selective attention to e-cigarette content is less likely to explain results around susceptibility than current use, as youth who have not initiated e-cigarette use might be less likely to actively seek content lowering their exposure. Additionally, our results align with previous cross-sectional and longitudinal studies, as well as with a large body of research showing tobacco marketing effects on youth [56]. Furthermore, our subsequent cognitive interviews with adolescents in Jalisco confirmed their confidence in distinguishing e-cigarette exposures by social media platforms. Third, our assessment of social media platforms was limited to those for which data were available on their popularity, with 2 social media platforms (WhatsApp in Southern California and Snapchat in Jalisco) not evaluated in both sites. Exclusion of social media platforms may have underestimated exposure and, potentially, attenuated observed associations. However, relative to the social media

platforms assessed, WhatsApp and Snapchat are less popular in the sites where they were not assessed [18,57], suggesting that their omission is unlikely to have substantially altered the associations observed. Nevertheless, future studies may cast a broader net across social media platforms to more comprehensively characterize adolescents' social media environments. Fourth, unmeasured confounders, such as mental health or other substance use, including among parents, were not included in the analyses due to a lack of harmonization. Finally, participation rates differed across study sites, in part due to differences in parental consent procedures. Active parental consent was required in Southern California, whereas passive (opt-out) consent was used in Jalisco, likely resulting in higher participation rates in the latter. The slightly lower participation rates in Southern California may have introduced differential selection bias based on parental engagement and potential confounders (eg, risk behaviors); however, we believe such biases would be minimal due to the relatively high participation rates in both sites. In addition, we surveyed students from convenience samples from public schools in both countries; therefore, the results may not generalize to broader populations of high schoolers, whether for the state or country. However, our findings are consistent with the prevalence of e-cigarette use found in previous studies that also involved self-administered questionnaires [13]. Additionally, these findings offer valuable preliminary insights into potential cross-country patterns of susceptibility and use of e-cigarettes across distinct regulatory and social contexts that warrant further investigation using population-representative data.

Exposure to social media and social media posts about e-cigarettes was high in both samples of high-school students and associated with susceptibility to and use of e-cigarettes. Despite Mexico having banned the sales and importation of e-cigarettes, susceptibility and current use were higher among adolescents in Jalisco than in Southern California, demonstrating that the ban alone is insufficient without proper enforcement. This cross-country comparison contributes to the literature highlighting how differences in regulatory environments and enforcement can influence youth exposure and behavior, reinforcing the need for coordinated, cross-border tobacco control strategies. Cross-national collaboration may be needed to limit adolescents' exposure to pro–e-cigarette content and reduce use in both countries. Future research should prioritize population-based studies to monitor trends in youth exposure and use across diverse social media platforms and settings, while also evaluating how enforcement strategies, digital marketing regulations, and broader cultural and social contexts interact to shape adolescents' susceptibility and use, to inform more effective public health policies.
